About the same time the waters of Loch Ness in the north of Scotland exhibited also a very unusual agitation. About ten o'clock the river Oich, which falls into the head of the loch, swelled very much, and ran upwards from the loch with a high wave two or three feet above its usual level. The motion of the wave was in a direction contrary to that of the wind, and it proceeded with great rapidity up the river for the space of 200 yards, broke on a shallow, and overflowed the banks. It then returned gently to the loch. This ebbing and flowing continued for about an hour, the height of the waves gradually diminishing, till, about 11 o'clock, a wave higher than any of the former broke with such violence on the bank on the side of the river, that it ran upwards of 30 feet from the bank.

218 In Ireland.

Between two and three o'clock in the afternoon, at Kinsale in Ireland, when the weather was perfectly calm and the tide nearly full, a great body of water suddenly burst into the harbour, and with such violence,

Earthquakes and Volcanoes.

lence, that it broke the cables of two vessels, each moored with two anchors, and of several boats which lay near the town. The vessels were whirled round several times by an eddy formed in the water, and then hurried back again with the same rapidity as before. These motions were repeated different times; and while the current rushed up along one side of the harbour, it ran down with the same violence along the other. The muddy bottom of the harbour was greatly altered; the mud was removed from some places and deposited in others. At one place the height of the water, where it was measured, was found to be five feet and a half; in other places it is said to have been much higher, particularly where it flowed into the market-place with such rapidity, that many persons had not time to escape, but were immersed, knee deep, in the water. These commotions extended several miles up the river, and were most perceptible in shallow places. The alternate elevation and depression of the water continued about ten minutes, when the tide returned to its usual level. In the evening, between six and seven, the water rose again, but with less violence than before, and continued to ebb and flow till three next morning. The rise of the waters was not at first gradual, but, accompanied with a hollow noise, rose six or seven feet in a minute, and rushed in like a deluge, after which it as suddenly subsided. The waters, too, became thick and muddy, emitting at the same time a most offensive smell. Similar agitations of the waters were observed all along the coast to the westward of Kinsale.

219 Effects at sea.

Such were the phenomena of this earthquake, as they were observed on land in the different places which have been mentioned. Its effects were also severely felt at sea. A frigate off St Lucar received so violent a shock, that it was supposed she had struck the ground. Another vessel in N. Lat. 36. 24. between nine and ten in the morning, was so much shaken and strained as if she had struck upon a rock. The seams of the deck opened, and the compass was overturned. The sensation experienced by some persons on board of another vessel, which was then in N. Lat. 25°. W. Long. 40°. were such as if she had been suddenly raised up and suspended by a rope. One person looking out at the cabin window, thought he saw land about a mile distant; but when he reached the deck, no land was to be seen. A strong current was observed crossing the ship's way to leeward. The current returned in about a minute with great violence; and, at the distance of about a league, three craggy pointed rocks were seen throwing up water of various colours, and seemingly resembling fire. This appearance terminated in a thick black cloud, which arose heavily in the atmosphere. Between nine and ten in the morning another ship, 40 leagues off St Vincent, received so violent a shock, that the men on deck were thrown a foot and a half above its surface, and the anchors, although they were lashed down, bounced up. Immediately after the ship sunk in the water so low as the main chains. On heaving the lead a great depth of water was found, and the line was of a yellow colour, and gave out the smell of sulphur. The first shock was the most violent; but smaller ones were repeated for 24 hours.

220 On springs.

The effects of this earthquake on springs were very remarkable. On the afternoon of the 31st of October, the water of a fountain at Colares was observed to be greatly diminished. On the morning of the 1st of November, the day on which the earthquake happened, it became thick and muddy, but afterwards recovered its usual quantity and limpidity. In some places springs appeared where there had been formerly no water, and continued afterwards to flow. At Varge, on the river Macaas, many springs of water burst forth at the time of the earthquake, and some threw up their waters mixed with sand of various colours, to the height of 18 or 20 feet. In Barbary, a stream of water, which was as red as blood, burst forth from a mountain, which was split in two. At Tangier all the fountains were dried up during the whole of the day on which the earthquake happened. The mineral waters of Toplitz, a village in Bohemia, which have been celebrated since the year 1672, experienced a very remarkable change. The principal hot spring had continued to flow from the time it was discovered, of the same temperature and the same in quantity. On the morning of the earthquake, between 11 and 12 o'clock, the waters of this spring increased so much in quantity, that all the baths ran over in the space of half an hour. A short time before the water increased, it flowed from the spring thick and muddy; and then having entirely stopped for about a minute, it burst out with great violence, carrying before it a great quantity of reddish ochre. It afterwards became limpid, and flowed as formerly; but in larger quantity, and of a higher temperature. At Angouleme in France the earth opened in one place, and discharged a great body of water, which was mixed with reddish sand. Most of the springs in the neighbourhood sunk so low, that for some time it was supposed they had become quite dry.

Such were the extraordinary effects of this terrible earthquake, which extended over a space not less than four millions of square miles. Other earthquakes, although of more limited extent, have produced effects not less destructive, and particularly some of the earthquakes which have visited Italy and Sicily in modern times; accounts of which have been drawn up with accuracy and attention. Some of these we shall now detail.

221 Earthquake in Calabria in 1783.

One of the most calamitous earthquakes was that which befel Calabria in the year 1783. Of this earthquake Sir William Hamilton, who, soon after the earthquake happened, visited the scenes of desolation which it left behind, has drawn up a particular account. He observes, that "if on a map of Italy, and with your compass on the scale of Italian miles, you were to measure off 22, and then fixing the central point on the city of Oppido, which seemed to be the spot where the earthquake had exerted its greatest force, form a circle, the radius of which will be 22 miles, you will then include all the towns, villages, &c. that have been utterly ruined, and the spots where the greatest mortality happened, and where there have been the most visible alterations on the face of the earth. Then extend your compass in the same scale to 72 miles, preserving the same centre, and form another circle, you will include the whole country that has any mark of having been affected by the earthquake. A gradation was plainly observed in the damage done to the

Earthquakes and Volcanoes. the buildings, as also in the degree of mortality, in proportion as the countries were more or less distant from this supposed centre of the evil."

This earthquake, it has been remarked, differed very considerably from others in one circumstance, which was this. Where it happened that two towns were situated at the same distance from the centre, one of which was placed on a hill, and the other on a plain, it was found that the town on the lowest situation always sustained the greatest damage from the shocks of the earthquakes which are alluded to above.

That part of Calabria which most severely felt this dreadful calamity, lies between the 38th and 39th degrees of latitude, and the force of the earthquakes extended from the foot of the Appenines called Monte Dijo, Monte Sacro, and Monte Caulene, as far to the westward as the Tyrrhene sea. By the shock of the 5th of February, every town, village, and farm-house nearest to the mountains, whether situated on some part of the elevated ground or on the plain, was left a heap of ruins. In proportion to the distance from the centre, as has been already hinted, the damage sustained was more or less considerable. But even the more distant towns and villages suffered greatly from the shocks which happened on the 7th, 26th, and 28th of February, and on the 1st of March. From the time the first shock came on, the earth continued in a constant tremor; the shocks were felt with different degrees of force in different parts of the provinces which were the scene of this terrible calamity; and the motion was either in a whirling direction, as in a vortex, or horizontal, or pulsatory, the beatings proceeding from the bottom upwards. The apprehensions and alarms of the miserable inhabitants were terribly increased by this variety of changing motions, dreading that every moment the earth would open under their feet and swallow them up. That part of Calabria which suffered from this earthquake, was also drenched with long continued and heavy rains, accompanied with frequent and furious squalls of wind. These rains prevailed particularly on the western side, where many fissures had appeared in the mountains. Some mountains had been lowered greatly, and others had been entirely swallowed up. The roads were rendered impassable by the deep chasms which were left by the shock; valleys were filled up by the parts of mountains which were split asunder; the course of rivers was changed; springs were dried up, and new springs burst out where none existed before.

At Laureana in Farther Calabria, two houses, surrounded with extensive plantations of olive and mulberry trees, situated in a valley, were removed by the force of the earthquake, with all their trees, and carried to the distance of a mile; and on the spot where they formerly stood, hot water burst from the earth, and was projected to a considerable height into the air. The water was mixed with sand of a reddish colour. Some countrymen and shepherds, who were employed in rural affairs near this spot, were swallowed up, with their teams of oxen, and their whole flocks of goats and sheep. The number of inhabitants who lost their lives in this calamity, exceeded, according to some calculations, 32,000; but it is supposed by others, that, including strangers, the number was not less than 40,000.

Earthquakes and Volcanoes. The inhabitants of the town of Scilla, on the first shock of the earthquake on the 5th of February, had fled along with their prince to the sea shore for safety, and remained either on the strand or in boats near the shore. In the night time a tremendous wave overflowed the land to the distance of three miles from the shore, and, in its return, swept off near 3000 of the inhabitants, among whom was the prince. This water was said by some to have been boiling hot, so that many of the people were supposed to have been scalded with it. A mountain, it is asserted, of 500 palms in height, and 1300 palms in circumference at its base, was detached from the place where it stood, and carried to the distance of four miles. It was about the same time that the hill on which the town of Oppido stood, and which extended three miles in length, was split in two, and filled up on each side the bed of a river. Two great lakes were formed by the current of the rivers being stopped; and, as they increased in extent, infected the air with their putrid and noisome exhalations.

Sir William Hamilton, who was then resident at Naples as ambassador from Britain, was indefatigable in obtaining every kind of information with regard to the effects of this earthquake. With this view he made an extensive tour over those parts of the country which had been visited by this calamity. Some of the accounts which were first published seem to have been somewhat exaggerated, either from the love of the marvellous in those who framed them, or from the excessive alarms of the surviving sufferers. On the 2d of May following Sir William landed on the coast of Hither Calabria. The effects of the earthquake were first perceived at Cedraro. The inhabitants had quitted their houses, but it did not appear that the town had sustained any material damage. Most of the inhabitants of St Lucido were then living in barracks, and the baron's palace, as well as the church steeple, had suffered greatly. He afterwards landed at the town of Pizzo in Farther Calabria. This town stood on volcanic tufa. It sustained great injury from the shock of the 5th February, but was completely destroyed by that of the 28th. Here he was informed, that Stromboli, a volcanic mountain which is nearly opposite, and in full view, but 50 miles distant, had ejected much less matter, and had thrown up less smoke, during the time of the earthquakes, than it had done for many years before. Even at this time slight shocks of earthquakes were occasionally felt. One indeed happened the same night. The boat in which he slept received a smart shock, and seemed to be lifted out of the water; but this shock was unaccompanied with noise.

The town of Monteleone is situated on a hill which overlooks some fine rich plains and the sea below. These plains, formerly covered with numerous towns and villages, now exhibited a gloomy scene of utter desolation. The town of Monteleone itself had not suffered materially from the first shock on the 5th of February; but it was considerably damaged by some of those which took place afterwards. It was generally observed, that the shocks of the earthquake came on with a rattling noise, which seemed to proceed from the westward. They usually began with a horizontal motion, and terminated with a whirling motion, during which most of the buildings in the province were thrown down. It was generally observed too, that previous to a shock the clouds

Earthquakes and Volcanoes.

clouds seemed to be unusually still and motionless, and that a shock quickly succeeded a heavy shower of rain.

Approaching the plain, it was observed, according to the general remark made above, that the towns and villages were more or less desolated in proportion to their vicinity to the plain. Of the town of Mileto, which stood in a bottom, not a house remained. Soriano and the noble Dominican convent presented a heap of ruins. According to the same general remark, all the buildings which stood upon the high grounds, the soil of which is a gritty sandstone, sustained less damage than those situated in the plain, for the latter were universally thrown down. The soil of the plain is a sandy clay of various colours, and full of sea shells. It is frequently intersected by rivers and torrents which have formed wide and deep ravines. Passing through St Pietro, a town in ruins, Sicily was seen and the summit of Mount Ætna, which at this time threw out a considerable quantity of smoke. In a swampy plain through which he passed, Sir William examined a number of small holes in the earth, of the shape of an inverted cone. These holes were covered with sand as well as the surrounding soil. During the earthquake of the 5th of February, water mixed with sand spouted up to a considerable height from each of these openings. The river, it was observed, before these fountains burst out, was dried up; but soon after the waters returned, and overflowed their banks. It appeared from more extensive observation, that the same thing had uniformly happened to all the other rivers in the plain during the shock of the 5th of February. This has been ascribed to the first impulse of the earthquake proceeding from the bottom upwards, and this seemed to be the general opinion. The surface of the plain then rising suddenly, the rivers which are shallow naturally disappeared; and the plain returning with violence to its former level, the rivers returned and overflowed from the sudden depression of the boggy grounds, which would naturally force out the water under their surface.

The town of Rosarno, and the duke of Monteleone's palace, was a heap of ruins; six feet high of the walls only remained. It was somewhat singular, that the only building which escaped uninjured was the public jail. At Laureana Sir William ascertained the truth of the circumstance of the two tenements which were said to have been removed from their situations. These stood in a valley surrounded with high grounds. In the same valley were observed hollows in the form of inverted cones similar to those which he had formerly examined. Between this place and the town of Polistene he did not see a single house, after travelling four days through a rich and beautiful country. Every thing presented the most indescribable misery: the violence of the earthquake was so great that all the inhabitants were buried in an instant alive or dead in the ruins of their houses. This town was situated between two rivers that were occasionally subject to overflow their banks. Of six thousand inhabitants, more than two thousand lost their lives by the shock on the 5th of February.

The princess Gerace Grimaldi, with four thousand of her subjects, perished at Casal Nuova on the same day; some persons who were dug alive out of the ruins observed, that they felt their houses fairly lifted up without any previous warning. An inhabitant of this town, being at that moment on a hill which overlooked the plain, when he felt the shock turned round towards the town, but he could see nothing excepting a thick white cloud of dust. So completely was this town destroyed, that no vestige of house or street remained; all lay in the same confused heap of ruins. Other towns had suffered in the same manner, and now exhibited the same scene of desolation.

Terra Nuova suffered severely from the same earthquake. It is situated between two rivers which had formed deep and wide ravines in their course; one of these was not less than 500 feet deep, and three quarters of a mile broad. In consequence of the great depth of this ravine, and the violent motion of the earth, two large masses of the soil on which a great part of the town, consisting of some hundred houses, had been thrown into the ravine at the distance of half a mile from the place where they formerly stood. Many of the inhabitants who had been carried along with their houses, were dug out of the ruins alive, and even some of them escaped unhurt. Of 1600 inhabitants, 400 only remained alive. In other places in the same neighbourhood, great tracts of land had been removed and carried to a considerable distance, with all their plantations and crops, which continued to grow and thrive in their new situation as well as formerly. The river here disappeared at the moment of the earthquake; but soon after returned, and covered the bottom of the ravine to the depth of three feet. This water was observed to be salt like that of the sea.

The whole town of Molochi di Sotto had been thrown into the ravine, and a vineyard of many acres lay near it in an inclined situation, but had not suffered any other injury. In several parts of the plain, the soil, with all its trees and crops of corn, to the extent of many acres, had sunk eight and ten feet below the level of the plain; and in other places it had risen the same height. The soil of this plain, it is to be observed, is composed of clay mixed with sand, which readily assumes any form.

22[illegible] Destruction of Oppido.

Sir William next proceeded to Oppido, which, it will be recollected, was considered as the central point on which the greatest force of the earthquake was exerted. This city stands on a mountain of gritstone of a reddish colour. It is surrounded by two rivers, which run in a deep ravine. It had been reported, that the mountain on which the city stands, had been split in two, and stopped up the course of the rivers; but it appeared on examination, that huge masses of the plain on the edge of the ravine, had been detached into it, and had so far filled it up, as to stop the course of the rivers, the waters of which were collecting, and forming lakes to a great extent. Part of the rock, it was found, on which the city stood, was separated, and with several houses upon it, was thrown into the ravine. Great tracts of land, with plantations of vines and olives, were transported from one side of the ravine to the other, to a distance exceeding half a mile.

"Having walked, (says Sir William), over the ruins of Oppido, I descended into the ravine, and examined carefully the whole of it. Here I saw, indeed, the wonderful force of the earthquake, which has produced exactly the same effects as those described in the ravine at Terra Nuova, but on a scale infinitely greater. The enormous masses of the plain detached from each side of

Earthquakes and Volcanoes.

of the ravine, lie sometimes in confused heaps, forming real mountains, and having stopped the course of two rivers (one of which is very considerable), great lakes are already formed; and if not assisted by nature or art so as to give the rivers their due course, must infallibly be the cause of a general infection in the neighbourhood. Sometimes I met with a detached piece of the surface of the plain (of many acres in extent) with the large oaks and olive trees, with corn or lupins under them, growing as well and in as good order at the bottom of the ravine, as their companions from whence they were separated do on their native soil, at least 500 feet higher, and at the distance of about three quarters of a mile. I met with whole vineyards in the same order in the bottom, that had likewise taken the same journey. As the banks of the ravine from whence these pieces came are now bare and perpendicular, I perceived that the upper soil was a reddish earth, and the under one a sandy white clay, very compact, and like a soft stone. The impulse these huge masses received, either from the violent motion of the earth alone, or that assisted with the additional one of the volcanic exhalations set at liberty, seems to have acted with greater force on the lower and more compact stratum than on the upper cultivated crust: for I constantly observed, where these cultivated lands lay, the under stratum of compact clay had been driven some hundred yards farther, and lay in confused blocks; and, as I observed, many of these blocks were in a cubical form. The under soil, having had a greater impulse, and leaving the upper in its flight, naturally accounts for the order in which the trees, vineyards, and vegetation fell, and remain at present in the bottom of the ravine.

"In another part of the bottom of the ravine there is a mountain composed of the same clay soil, and which was probably a piece of the plain detached by an earthquake at some former period: it is about 250 feet high, and 400 feet diameter at its basis. This mountain, as is well attested, has travelled down the ravine near four miles; having been put in motion by the earthquake of the 5th of February. The abundance of rain which fell at that time, the great weight of the fresh detached pieces of the plain which I saw heaped up at the back of it, the nature of the soil of which it is composed, and particularly its situation on a declivity, account well for this phenomenon; whereas the reports which came to Naples of a mountain having leaped four miles, had rather the appearance of a miracle. I found some single timber trees also with a lump of their native soil at their roots, standing upright in the bottom of the ravine, and which had been detached from the bottom of the plain above mentioned. I observed also, that many confused heaps of the loose soil, detached by the earthquake from the plains on each side of the ravine, had actually run like a volcanic lava (having probably been assisted by the heavy rain, and produced many effects much resembling those of lava during their course down a great part of the ravine. At Santa Christina, near Oppido, the like phenomena have been exhibited, and the great force of the earthquake of the 5th of February seems to have been exerted on these parts, and at Casal Nuova, and Terra Nuova.

The next places which were visited were the towns of Seminara and Palmi. Palmi is nearer the sea, and had suffered most; not fewer than 1400 of the inhabitants having been destroyed. In the course of his tour in this part of the country, he was informed that the sea was observed to be hot, and fire was seen issuing from the earth.

At Reggio, although the shock had been much less violent than in other places, no house was yet habitable. During the earthquakes which visited this place in 1770 and 1780, near 17,000 inhabitants lived for several months encamped in the fields, or in barracks.

Having examined the different places on the Calabrian coast, which had suffered from this terrible earthquake, Sir William Hamilton sailed for Messina in Sicily, to be informed of its effects there. He found that the shock had been very violent, but far less so than on the opposite shores. Many of the houses, even in the lower part of the town, were standing, and some of them had sustained little damage; but in the more elevated situations the shocks seemed to have had scarcely any effect. This still corresponds with the general remark, which was already made. A striking instance of this appeared in two convents, which are situated on elevated places, and had suffered nothing from the earthquakes which had afflicted the country for four months. It was said that fire had been seen issuing from fissures of the earth near the shore. The shock of the earthquake on the 5th of February, seemed to proceed from the bottom upwards; but the succeeding shocks came on with a horizontal or whirling motion.

A remarkable circumstance with regard to fish, was taken notice of at Messina, and indeed the same thing was observed along the coast of Calabria, where the effects of the earthquake had been most severe. A small fish, somewhat larger than the English white bait, but resembling it, and which usually lies at the bottom of the sea, buried in sand, had remained for several months after the commencement of the earthquakes, near the surface, and was taken in great abundance to be the common food of poor people. Before the earthquake, this fish was extremely rare, and was considered as a great delicacy. After the earthquake, indeed, it was observed, that fish of all kinds were found in greater abundance.

These earthquakes, of which we have now given so detailed an account, continued for many months afterwards; tremulous motions of the earth continued to be felt, and they were not perfectly settled even in the year 1784.

223 Earthquakes in Peru.

The southern continent of America is often visited by earthquakes. In the year 1797, Peru was afflicted with this dreadful calamity, which perhaps in the extent of surface which experienced the dreadful shock, exceeds that of any earthquake, the history of which is on record. The following is a short account of this earthquake by M. Cavanilles. "In the midst, (says he), of the most profound calm, there is frequently heard a dreadful bellowing noise, the forerunner of earthquakes, to which this part of the world is often exposed. After the year 1791, this noise was frequently heard in the neighbourhood of the mountain of Tunguragua. Antonio Pineda and Née, the two naturalists employed in the expedition round the world, when examining the declivity of this volcano, the lava of which had been hardened more by the internal fire than

Earthquakes and Volcanoes.

than by the ardour of the sun, were struck with terror by the horrible sound which they heard, and the heat which they experienced. Pineda, that valuable member of society, whose premature death is still deplored by the friends of science, foretold that a terrible eruption was preparing in the mountain of Tunguragua; and his conjectures were confirmed by the event. On the 4th of February 1797, at three quarters past seven in the morning, the summit of the volcano was more free from vapours than usual; the interior part of the mountain was agitated by frequent shocks, and the adjacent chains burst in such a manner, that in the space of four minutes an immense tract of country was convulsed by an undulating movement. Never did history relate the effects of an earthquake so extraordinary, and never did any phenomenon of nature produce more misfortunes, or destroy a greater number of human beings. A number of towns and villages were destroyed in a moment: some of them, such as Riobamba, Quero, Pelileo, Patate, Pillaro, were buried under the ruins of the neighbouring mountains; and others in the jurisdictions of Harnbata, Latacunga, Guaranda, Riobamba, and Alausi, were entirely overthrown. Some sustained prodigious loss by the gulfs which were formed, and by the reflux of rivers intercepted in their course by mounds of earth; and others, though in part saved, were in such a shattered state as to threaten their total ruin. The number of persons who perished during the first and succeeding shocks is estimated at 16,000. At ten o'clock in the morning, and four in the afternoon, the same day, (February 4.) after a dreadful noise, the earth was again agitated with great violence, and it did not cease to shake, though faintly, for the whole months of February and March; but, at three quarters past two in the morning of the 5th of April, the villages already ruined were again exposed to such violent shocks as would have been sufficient to destroy them. This extraordinary phenomenon was felt throughout the extent of 140 leagues from east to west, from the sea as far as the river Napo; and without doubt farther, for we are little acquainted with these districts which are inhabited by the savages. The distance north-east and south-west between Popayan and Piura, is reckoned to be 170 leagues; but in the centre of that district, 1 degree 16.6 from these places, is situated the part totally destroyed, and which comprehends 40 leagues from north to south between Guarandam and Machache, and twenty leagues from east to west. But, as if an earthquake alone had not been sufficient to ruin this fertile and populous country, another misfortune, hitherto unknown, was added. The earth opened, and formed immense gulfs; the summits of the mountains tumbled down into the valleys, and from the fissures in their sides there issued an immense quantity of fetid matter, which in a little time filled up valleys a thousand feet in depth and six hundred in breadth. It covered the villages, buildings, and inhabitants; choked up the sources of the purest springs, and being condensed by desiccation, in the course of a few days into an earthy and hard paste, it intercepted the course of rivers, made them flow backwards for the space of 87 days, and converted whole districts of dry land into lakes. Very extraordinary phenomena, which will doubtless be one day mentioned in history, occurred during these earthquakes; I shall, however, content myself with mentioning only two of them. At the same moment that the earth shook, the lake of Quirotoa, near the village of Insiloc, in the jurisdiction of Latacunga, took fire, and the vapour which rose from it suffocated the cattle and flocks that were feeding in the neighbourhood. Near the village of Pelileo, a large mountain named Moya, which was overturned in an instant, threw out a prodigious stream of the before-mentioned thick fetid matter, which destroyed and covered the miserable remains of that city. Naturalists will one day find, in these ravaged countries, objects worthy of their researches. Fragments of the minerals and earths of Tunguragua are about to be transported to Spain: but it is not in such fragments that we ought to search for the cause of these surprising phenomena; we must visit the country itself, where this conflict of the elements took place, and where the ruins it occasioned are still to be seen (G)."

224 In Scotland.

To the history of earthquakes now given, we shall only add the following account of the earthquakes which have taken place at Comrie in Perthshire, in Scotland, which was communicated to the Royal Society of Edinburgh, by Dr Finlayson, in a letter from Mr Taylor.

"The earthquakes which have lately (January 1790) taken place at Comrie (H) and its neighbourhood, are certainly very deserving of attention. I shall therefore cheerfully comply with your request, and give you as particular a description as I can of such of them as have been most remarkable. To give a particular account of all the noises or concussions which, during the last half year, have been heard or felt at Comrie, and within a short distance to the north, east, and west of that village, is beyond my power, and would indeed be of little use. With regard to these small concussions, it will be sufficient to say, that many of them have sometimes been observed to succeed one another in the space of a few hours; that they take place in all kinds of weather; that they are thought by some people to proceed from north-west to south-east, and by others, from north-east to south-west; that they have not been observed to affect the barometer; that they do not extend in any direction above three or four miles from Comrie; and that towards the south they are bounded by the Earn, which is in the immediate vicinity of the village. The same person, though bestowing the minutest attention, is often uncertain whether they proceed from the earth

(G) The volcano of Tunguragua occasioned an earthquake in 1557.

(H) Comrie is a village about 22 miles west of Perth, situated in the valley of Strathearn, and on the north side of the river Earn, about four miles below the place where it issues from the lake. The remains of a Roman camp on the opposite side of the river, have made the name of this village very well known to Scottish antiquaries.

Earthquakes and Volcanoes.

earth or from the air, sometimes believing them to come from the one, and sometimes from the other; neither do all agree with respect to the seat of any one of them.

"After the strictest inquiry, I find it impossible to determine with accuracy the date of any of the concussions which took place before the 2d of September last. Some people in the neighbourhood of Killin assert positively, that they heard unusual rumbling noises in the month of May; but the impression which these noises made was so faint, that they would probably have been soon forgotten altogether, had they not been succeeded by concussions of a less equivocal nature. Towards the end of August, two or three shocks are said to have been felt at Dundurn, Dunira Lodge and Comrie; but I have not been able to learn the precise day or hour on which any of them happened. The truth is, the concussions hitherto observed were feeble, and the minds of the people seem not to have been roused to particular attention till the 2d of September. About eleven o'clock that evening, a smart shock was felt at Comrie. I myself heard here, for the first time, a rumbling noise, which I took for that of a large table, dragged along the floor above stairs, and which I probably would never have thought of again, unless my attention had been turned to it by the alarm which it had excited in the neighbourhood. Many other feeble noises or concussions are said to have been observed in Glen Leadnach and about Comrie during the months of September and October. At this time, however, I confess I was disposed to doubt the numerous reports of earthquakes with which the country was filled, and to ascribe them to the workings of an imagination, on which the alarm of the 2d of September still continued to be impressed.

"On the 5th of November, a concussion took place two or three minutes before six o'clock P. M. which was too violent to be mistaken. Some compared the noise which accompanied it to that of heavy loaded waggons, dragged with great velocity along a hard road or pavement, and thought that it passed under their feet. To me it seemed as if an enormous weight had fallen from the roof of the house, and rolled with impetuosity along the floor of the rooms above; and it must have made a similar impression on the servants, for some of them instantly ran up stairs to discover what had happened. Others were sensible of a tremulous motion in the earth, perceived the flames of the candles to vibrate, and observed the mirrors and kitchen utensils placed along the walls to shake and clatter. There is also reason to believe that the waters in the loch of Monivaird, in the near neighbourhood of Ochtertyre, suffered unusual agitation, as the wild fowl then upon the loch were heard to scream and flutter. The noise on this occasion, as far as I can judge, did not last above ten or twelve seconds. During the course of the day, the mercury in the barometer rose and fell several times, and at six o'clock it stood at $28\frac{1}{2}$ inches. The sky was then perfectly serene, and hardly a breath of wind was to be felt; but next morning, about six o'clock, a violent tempest rose, which raged without intermission for 24 hours.

"At Glen Leadnach, Comrie and Lawers, this concussion was much more violent, and the noise that accompanied it much more alarming. The inhabitants of these places, and of Aberuchill and Dunira, declare, that they perceived distinctly the earth heaving under them, and the motion communicated to their chairs, and other furniture. They imagined that the slates and stones were tumbling from their houses, and many of them ran out in the greatest trepidation, from the notion, that the roofs were falling in. Even the domestic animals were alarmed, and contributed, by their howls and screams, to increase the terrors of the people. Though I have not been able to discover whether Loch Earn was ever agitated by these concussions, there is little doubt, that the river near Comrie was affected on this occasion, as two men then on its banks heard the dashing of its waters. This great shock was succeeded by a number of those slighter rumbling noises which have been already mentioned. Not less than 30 of them were counted in the space of two hours after it happened; but they did not extend above two miles to the east, north, and west of Comrie.

"On the 10th of November, at three o'clock P. M. we had here another shock of much the same length, violence, and extent, as that on the 5th. The mercury in the barometer on this day was more stationary than on the former, and at the time of the earthquake was 29 inches high. The weather was calm and hazy. It was a market-day at Comrie; and the people, who were assembled from all parts of the country, felt as if the mountains were to tumble instantly upon their heads. The hard-ware exposed for sale in the shops and booths shook and clattered, and the horses crowded together with signs of unusual terror.

"About one o'clock P. M. of the 29th December, we had another pretty smart shock, during a violent storm of wind and rain, which continued the whole day, and which was at its height during the time of the earthquake. Indeed, as has been remarked already, these concussions seem to have no dependence on the weather. According to the accounts of those who live nearest to the centre of the phenomena, rumbling noises, like those above described, may be heard in all states of the atmosphere.

"Though I mention no more of these earthquakes, you are not to conclude, that many more have not taken place, and some of them perhaps equally violent with those of the 5th and 10th of November. Several shocks have happened during the stillness of the night, which, even at this distance from Comrie, where their centre seems to be, have been abundantly terrifying. But the great resemblance, or rather the perfect similarity of their effects, and of the impression they make on our minds, renders it unnecessary for me to trouble you with a particular description of each of them.

"The direction of all the noises or concussions I have observed, great as well as small, appeared to be in the same line from N. W. to S. E. Others describe them as sometimes proceeding in that direction, and sometimes as coming from N. E. to S. W. I have not heard any other line of direction ascribed to them.

"Upon the fullest enquiry, I find, that these earthquakes have been very limited in point of extent. The greater shocks have been feebly felt at Loch Earn head, about Killin, and at Ardonich, on the southern bank of Loch Tay. They do not appear to have extended farther eastward on that lake; and, what is more remarkable, they had not been felt in Glen Almond,

Earthquakes and Volcanoes.

mond, or the small glen through which the military road from Crieff to Tay-bridge passes. The farmer at Auchnafree, (which lies at the head of Glen Almond, and is separated from Glen Leadnach only by the mountain Benechoni, over the northern side of which his shepherds daily travel), has assured me, that neither he, nor any of his people, have been at any time sensible of the least extraordinary noise or concussion. Towards the east, the two first great shocks extended to Monzie, Cultoquhey and Dollary, about seven miles distant from Comrie. The shock of the 5th of November reached still farther, and was felt, though but faintly, at Ardoch and Drummond Castle towards the S. E. In the direction of the south, however, the banks of the Earn seem to be its general boundary, as the noise of the most violent concussion was heard but faintly at the manse of Comrie, and along the strath on the south side of the river. The limits of the lesser concussions, I am confident, do not extend above three miles in any direction from their centre. They are commonly observed at Lawers on the east; throughout the whole of Glen Leadnach, at Dunira, Dalchonzie and Aberuchill, on the north and west; and do not reach so far as the manse, which is about three quarters of a mile on the south of Comrie (1)."

In another communication, dated in 1793, from the same gentleman, he observes, that " there is no reason to believe that these phenomena are yet come to an end. After temporary intermissions, sometimes of several months, they have returned, ever since their first appearance in 1789, without any apparent difference in their extent or force. The rumbling noises or slighter concussions, as usual, are observed at Comrie, in Glen Leadnach, and the places in their near neighbourhood; the more violent extend to much the same distance as formerly described. Having been only occasionally in that country since February 1791, I have not been able to ascertain dates. On the 2d of September 1791, at five minutes past five in the afternoon, a slight shock was felt at Ochtertyre. The barometer was not in order, on which account the weight of the atmosphere could not be ascertained. Its electrical state was tried by Saussure's electrometer, but no indication of any thing uncommon was perceived. Since that period, shocks have been observed at different times till within these few weeks past.

" From this account, it will be observed, that all the greater shocks have taken place in the season of autumn or the beginning of winter; that this has been now repeated for more than four years; and that those greater shocks have been succeeded at short intervals by rumbling noises or more feeble concussions. It has also been remarked, that they have in general been preceded or followed by great rains or boisterous weather; but variations in the weather take place so frequently in our climate at that season of the year, that the connection between them and the phenomena above described, is probably altogether accidental."

21 Causes of earthquakes

After the view which we have given of the phenomena and history of earthquakes, we now proceed to the consideration of the causes, by the operation of which, according to the speculations of philosophers, these terrible convulsions of nature, which spread ruin and desolation in some of the fairest portions of the earth, are to be accounted for. Various opinions have been formed, and various hypotheses have been proposed, for the explanation of these dreaded phenomena. According to some of the ancient philosophers, subterraneous clouds existed in the internal cavities of the earth, and these bursting into lightning, shook and demolished the vaults which contained them. This was the opinion of Anaxagoras. It was supposed by others, that earthquakes were owing to the falling in of immense arched roofs, which confined subterraneous fires; the vaults or arches being weakened by the constant burning of these fires. Some ascribed earthquakes to the vapour of water which was produced, and greatly rarefied, by means of internal fires; while others, among whom was Epicurus and some of the peripatetic philosophers, sought for the explanation of the phenomena of earthquakes, in the explosion of certain inflammable substances, which were exhaled from the internal cavities of the earth.

22 according to the ancients

23 the moderns

Some of the modern philosophers, as Gassendi, Kircher, Varenius, Des Cartes, and others, have adopted the last hypothesis, according to which it is supposed, that there are immense cavities in the earth, communicating with each other. Some of these cavities contain water, and others contain vapours and exhalations, arising from bituminous, sulphureous, and other inflammable substances. These combustible materials being kindled by some subterraneous spark, or by some actual flame, proceeding through narrow fissures from without, or by the heat evolved during the mixture of different substances, and the formation of new ones, produce commotions on the surface of the earth, according to the extent of the cavities, and the quantity and active nature of the inflamed matter. Those who support

(1) " The tract within which the concussions described in this letter appear to have been confined, is a space of a rectangular form, which extends from east to west along the north side of the Earn about 22 miles in length, by a little more than five in breadth; reckoning the utmost length from about Monzie to the head of Loch Tay, and the breadth from a little south of the Earn northward to the ridge which separates the branches of that river from those of the Almond. The whole of this tract is mountainous, except toward the eastern extremity, where it joins the low country, and on the banks of the river Earn on the south. It is intersected by narrow glens or valleys, the most considerable of which is Glen Leadnach, where the centre of the concussions seems to be placed. The mineralogy of this part of the country has not hitherto been accurately examined; but it is known in general, that the stone is the primary schistus, and in some places granite; that no mineral veins, nor any hot springs, have been found in it, and that no volcanic appearances have been observed. In the valleys, among the mountains, iron ore, of the kind that is called bog ore, is said to abound. Dr Hutton has remarked, that the line which terminates this tract on the south-east, seems to be nearly the same with that where the primary strata sink under the surface, and are covered by the secondary or horizontal strata. *Note by Mr Playfair.*"

Earthquakes and Volcanoes.

support this hypothesis think, that it receives illustration from a common experiment of mixing together iron filings and sulphur, and burying them in the earth; and in consequence of the chemical action of these substances on each other, and the elastic vapours thus produced, the shaking of the earth is effected.

13 Hypothesis of Woodward.

A different hypothesis has been proposed by Dr Woodward. According to this hypothesis, water is continually raised by means of subterraneous heat, from the abyss which he supposes to occupy the centre of the earth, to furnish rain and dew. Obstructions may take place in this process of nature, and whenever this happens a swelling and commotion are occasioned by the heat in the waters of the abyss. This force is at the same time exerted against the incumbent strata, and thus the agitation and concussion, with the other phenomena which accompany earthquakes, are produced.

9 Of Amontons.

Another hypothesis, different from any of these, has been proposed by M. Amontons, of which the following explanation is given. The atmosphere being taken at 45 miles high, and the density of the air increasing in proportion to the absolute height of the superincumbent column of fluid, it is shewn that at the depth of 43,528 fathoms below the surface of the earth, the air is but one-fourth lighter than mercury. But this depth is only about one seventy-fourth of the semidiameter of the earth. The immense sphere beyond this depth, the diameter of which is 6,451,538 fathoms, may perhaps be only filled with air: this air must be here greatly condensed, and heavier than the heaviest bodies with which we are at present acquainted. It is found by experiment, that the more air is compressed, the more do equal degrees of heat increase its elastic force, and the more capable it becomes of producing violent effects. As, for instance, the temperature of boiling water increases the elasticity of the air beyond its natural force in temperate climates, by a quantity equal to one-third of the weight with which it is pressed. Hence it is concluded, that a degree of heat which on the surface of the earth produces only a moderate effect, may occasion violent convulsions by the rarefaction of the denser air at great depths; but if it be considered that this condensed air may be exposed to much higher degrees of heat than that of boiling water, the elastic force of the air thus produced, and assisted by the great weight of a high column, may be more than sufficient to convulse and break up the solid orb of 43,528 fathoms, the weight of which, comparing it with that of the included air, would be trifling.

These hypotheses, however insufficient they may appear for explaining in a satisfactory manner the phenomena of earthquakes, were generally adopted till about the middle of the 18th century, when the knowledge of electricity began to be cultivated and extended. This principle was applied successively in the explanation of many natural phenomena, and, among others, the phenomena of earthquakes were ascribed to the same principle. An earthquake which was felt at London in the month of March 1749, directed the attention of philosophers to this explanation.

23 Of Stukeley.

The first who made this attempt, we believe, was Dr Stukeley, who had been much occupied about that time with electrical experiments. The consideration of the phenomena which accompanied this earthquake, led him to suppose that it could not be occasioned by vapours generated in the cavities of the earth, or by any process like fermentation, in which elastic fluids are formed and disengaged, to which such effects could be ascribed. He is of opinion, that no evidence has yet been brought to establish the probability of the existence of extensive cavities within the earth. On the contrary, he thinks there is good reason to presume, that it is in a great measure solid, so that there is little space for those changes which are supposed to be effected within the cavities, to take place. Coal pits, he adds, which have been frequently known to be on fire, and for a great length of time, never exhibited any of the phenomena which accompany an earthquake on the surface of the ground above.

The earthquake which visited London and other places of Britain, in March 1749, was felt in a circuit of 30 miles diameter; but there was no eruption of fire or vapour, and it was unattended with smoke or smell. From this consideration alone, of the extent of surface which felt the effects of the earthquake, he supposes that it could not be ascribed to the expansive force of subterraneous vapours; for, he observes, small fire-balls which are exploded in the air, emit a sulphureous smell to the distance of several miles. Now, it cannot be imagined, that so prodigious a force, acting instantaneously, on so great an extent of ground, should neither break the surface, nor indicate its presence either by the sight or smell. But if this effect is to be ascribed to fermentation, this process is not instantaneous; it continues many days, and the evaporation of such a quantity of inflammable matter would require a long space of time. Such an effect, therefore, can only be accounted for on electrical principles, the operation of which is always instantaneous.

If earthquakes were occasioned by vapours and subterraneous fermentations, explosions and eruptions, such processes would entirely destroy springs and fountains, wherever they had once existed. This, however, is contrary to what happens, for although springs are stopped, or otherwise changed, previous to an earthquake, or about the time it happens, they very often recover their former state. In the great earthquake which happened A. D. 17, in Asia Minor, and which shook a mass of earth 300 miles in diameter, and destroyed 13 great cities, neither the springs nor the face of the country received any injury.

If it be considered, that a subterraneous power capable of moving 30 miles in diameter, as in the earthquake mentioned above, which happened at London, must exist and operate at least 15 or 20 miles under the surface, the hypothesis of earthquakes being occasioned by the force of vapours will be found totally inapplicable, because this force must move an inverted cone of solid earth, the base of which is 30 miles in diameter, and the axis 15 or 20. This is an effect which is impossible to any known natural power, excepting that of electricity.

But besides, no subterraneous explosion can account for the singular effects of an earthquake on ships that are far out in the ocean. It has been already observed, that they seem as if they struck on a rock, or as if some solid body struck against their bottom. Even fishes, it is found, are particularly affected by the shock of an earthquake; but a subterraneous explosion could only produce on the water a gradual swell. It could not communicate

Earthquakes and Volcanoes.

communicate to it that impulse by which it produces effects, as if it were a stone projected with great force against solid bodies.

From the consideration of all these circumstances, Dr Stukeley is of opinion, that the phenomena of earthquakes can only be satisfactorily explained on electrical principles. He was particularly led to this opinion by directing his attention to the phenomena which accompanied the earthquakes which took place in England in 1749 and 1750. For five or six months previous to this time, the weather had been unusually warm; the wind was from the south and south-west, and there had been no rain, so that the earth was particularly prepared to receive an electrical shock. The flat country of Lincolnshire had suffered greatly from extreme drought, and hence, as dry weather is favourable to electricity, earthquakes and other similar phenomena are more frequent in southern regions of the world. Before the earthquake at London, all vegetables had been unusually premature, and it is well known how much electricity quickens vegetation. About the same time the aurora borealis had been very frequent. A very short time before the earthquake, it had exhibited unusual colours, and its motions were to the south, contrary to the ordinary direction. From these circumstances an earthquake was predicted by Italians and others who had been accustomed to the appearances which precede them. During this year, too, meteors of different kinds, as fire-balls, lightnings, and coruscations, had been common; and particularly it was observed in the night preceding the earthquake, and early in the morning on the day on which it happened, that coruscations were very frequent. In these circumstances nothing was wanting to produce an earthquake, according to this hypothesis, but the touch of a non-electric body. This body must be derived from the air or atmosphere; hence it is inferred, that if a non-electric could discharge its contents upon any part of the earth, in this prepared and highly electrical state, a violent commotion or earthquake must be produced; and as the discharge from an excited tube produces a shock on the human body, so the discharge of electric matter from an extent of many miles of solid earth, must produce an earthquake. The rattling, uncouth noise which attends it, is to be ascribed to the snap which is occasioned by the contact.

Before the earthquake alluded to came on, a black cloud suddenly covered the atmosphere to a great extent; the discharge of a shower, according to this hypothesis, probably occasioned the shock; and as the electrical snap precedes the shock, a sound was observed to roll from the Thames towards Temple-bar, before the motion of the houses ceased. This noise, which is generally the forerunner of earthquakes, it is supposed can only be accounted for on the principles of electricity. The contrary to this would take place, were these phenomena owing to subterraneous eruptions. The flames and sulphureous smells which accompany earthquakes, might, it is thought, be more easily accounted for on the same principles, than by eruptions from the bowels of the earth. The sudden concussion, too, seems to be produced by a motion which could only be excited by electricity, not proceeding from any convulsion in the interior parts of the earth, but from a uniform vibration along its surface, like that of a musical string, or like the vibratory motion of a glass, when the edge is rubbed with the finger. From the circumstance that earthquakes are chiefly fatal to places near the sea coasts, along the course of rivers, and elevated situations, a farther proof is derived, that they depend on the operation of electricity. The course or direction which the earthquake above alluded to took, affords an illustration of this point. Another argument in favour of the electrical hypothesis is drawn from the effects of the earthquake, or the state of the weather at the time, on persons of weak or nervous constitutions. To some these disorders proved at that time fatal; and its effects, in general, were similar to those of artificial electricity.

Of Beccaria.

A similar hypothesis was proposed by Beccaria, to account for the phenomena of earthquakes. He supposes that the electric matter to which these phenomena are owing, is lodged deep in the earth, and that it is this matter discharged from the earth, to restore the equilibrium or deficiency which the clouds in the atmosphere have sustained during thunder storms, by giving out their electrical matter to another part of the earth. This, he supposes, is confirmed by the noise resembling thunder, and the flashes of lightning which are perceived during earthquakes.

Of Priestley.

Dr Priestley proposes to construct, on the principles of Stukeley and Beccaria, an hypothesis which he thinks will explain the phenomena in a more satisfactory manner. For this purpose he supposes the electric matter to be some way or other accumulated on one part of the surface of the earth, and on account of the dryness of the season, not easily to diffuse itself. It may, as Beccaria supposes, force its way into the higher regions of the air, forming clouds in its passage out of the vapours which float in the atmosphere, and occasion a sudden shower, which may farther promote the passage of the fluid. The whole surface thus unloaded will receive a concussion like any other conducting substance, on parting with or receiving a quantity of the electric fluid. The rushing noise will likewise sweep over the whole extent of the country; and upon this supposition also, the fluid, in its discharge from the country, will naturally follow the course of the rivers, and also take the advantage of any eminences, to facilitate its ascent into the higher regions of the air. In making some experiments on the passage of the electrical fluid over water, he observed that it produced a tremulous motion, and therefore he concludes that it must receive a concussion resembling that which is given to the waves of the sea by an earthquake. To try this still farther, he immersed his hands in water, while an electrical flash passed over its surface, and he felt a sudden concussion, like that which is supposed to affect ships at sea during an earthquake. The impulse, which was felt in different parts of the water, was strongest near the place where the explosion was made.

"Pleased with this resemblance of the earthquake, he observes, I endeavoured to imitate that great natural phenomenon in other respects; and it being frosty weather, I took a plate of ice, and placed two sticks about three inches high on their ends, so that they would just stand with ease; and upon another part of the ice I placed a bottle, from the cork of which was suspended a brass ball with a fine thread. Then making the electrical flash pass over the surface of the ice, which it did

did with a very loud report, the nearer pillar fell down, while the more remote stood, and the ball which had hung nearly still, immediately began to make vibrations, about an inch in length, and nearly in a right line from the place of the flash.

"I afterwards diversified this apparatus, erecting more pillars, and suspending more pendulums, sometimes upon bladders stretched on the mouth of open vessels, and at other times on wet boards swimming in a vessel of water. This last method seemed to answer the best of any; for the board representing the earth, and the water the sea, the phenomena of them both during an earthquake may be imitated at the same time; pillars, &c. being erected on the board, and the electric flash being made to pass, either over the board, over the water, or over them both *."

The ingenious Dolomieu proposes to account for these phenomena on different principles. On this subject he makes the following observations with regard to the earthquakes which desolated Calabria in 1783, and the causes by which they were produced. "The sea, says he, during the earthquakes of 1783, had little share in the shocks on the main land. The mass of water experienced no general movement, or fluctuation, or oscillation; the waves did not rise above their ordinary limits. Those which on the night of the 5th February beat against the coast of Sicily, and which afterwards covered the point of the Faro of Messina, were only the effects of a particular cause. The fall of a mountain into the sea raised the waters, which received an undulating motion, as happens always in similar cases. The undulation reached from the point of Sicily beyond the cape of Rosacolmo, extending in length along the coast which runs to the south; but always with a decrease in elevation as it was more remote from Sicily. Whatever inquiries the author has made, he has not been able to discover, in all the details which have been given him, any proofs of the existence of electrical phenomena; no spark, no disengagement of the electrical fluid, which the Neapolitan naturalists wish to assign as the cause of earthquakes.

"The state of the atmosphere was not the same in the whole range of earthquakes. While the tempests and the rain seemed to have conspired with them for the destruction of Messina, the interior part of Calabria enjoyed very fine weather. A little rain fell in the plain in the morning of the 5th of February; but the sky was clear during the rest of the day. This month and that of March were not only pretty serene, but likewise warm. There were some storms and rain; but they were the natural attendants of the season.

"The moving force seems to have resided under Calabria itself, since the sea which surrounds it had no share in the oscillations or vibrations of the continent. This force seems also to have advanced along the ridge of the Apennines in ascending from the south to the north. But what power in nature is capable of producing such effects? I exclude electricity, which cannot accumulate continually during the course of a year, in a country surrounded with water, where every thing conspires to place this fluid in equilibrio. Fire remains to be considered. The element, by acting directly upon the solids, can only dilate them; then their expansion is progressive, and cannot produce violent and instantaneous movements. When fire acts upon fluids, such as air and water, it gives them an astonishing expansion; and we know that then their elastic force is capable of overcoming the greatest resistances. These appear the only means which nature could employ to operate the effects we speak of: but in all Calabria there is no vestige of a volcano; nothing to point out any interior combustion; no fire concealed in the centre of mountains, or under their base; a fire which could not exist without some external signs. The vapours dilated, the air rarefied by a heat constantly active, must have escaped through some of the crevices or clefts formed in the soil; they must have formed currents. Both flame and smoke must have issued by some one or other of these passages. These once opened, the pressure would have ceased; the force not meeting with any more resistance, would have lost its effect; and the earthquake could have no longer continued. None of these phenomena took place: we must then renounce the supposition of a combustion acting directly under Calabria. Let us see whether, having recourse to a fire at some distance from this province, and acting upon it only as an occasional cause, we shall be able to explain all the phenomena which have accompanied the shocks. Let us take for example Ætna in Sicily, and suppose large cavities under the mountains of Calabria; a supposition which *cannot be refused.* It is certain that immense subterraneous cavities do exist, since Ætna, in elevating itself by the accumulation of its explosions, must leave in the heart of the earth cavities proportioned to the greatness of the mass.

"The autumn of 1782 and the winter of 1783 were very rainy. The interior waters, augmented by those of the surface, may have run into those caverns which form the focus of Ætna: there they must have been converted into vapour capable of the highest degree of expansion, and must have pressed forcibly against every thing which opposed their dilatation. If they found canals to conduct them into the cavities of Calabria, they could not fail to occasion there all the calamities of which I have given the description.

"If the first cavity is separated from the second by a wall (so to speak) or some slight division, and this separation is broken down by the force of the elastic vapour, the whole force will act against the bottom and sides of the second. The focus of the shocks will appear to have changed place, and become weaker in the space which was agitated most violently by the first earthquake.

"The plain, which was undoubtedly the most slender part of the vault, yielded most easily. The city of Messina, placed upon low ground, experienced a shock which the buildings on higher grounds did not. The moving force ceased at once as suddenly as it acted violently. When, at the periods of the 7th of February and the 28th of March, the focus appeared changed, the plain scarce suffered any thing. The subterraneous noise, which preceded and accompanied the shocks, appeared always to come from the south-west, in the direction of Messina. It seemed like thunder under ground, which resounded beneath vaults.

"If Ætna, then, has been the occasional cause of the earthquakes, it has also prepared, for some time, the misfortunes of Calabria, by gradually opening a passage along the coast of Sicily to the foot of the Neptunian

Earthquakes and Volcanoes.

Earthquakes and Volcanoes.

nian mountains: for during the earthquakes of 1780, which disturbed Messina the whole summer, they felt, for the whole length of that coast, from Taormina even to the Faro, considerable shocks; but near the villages of Alli and Fiume de Nisi, which are situated about the middle of that line, shocks so violent were experienced, that they dreaded lest the mouth of a volcano should open. Each shock resembled the effort of a mine that had not strength to make an explosion. It appears, that then the volcano opened a free passage for the expansion of its vapours, and that they have since circulated without restraint; since in the year 1783 the earthquake was almost nothing upon that part of Sicily, at the time that Messina buried under its ruins the half of its inhabitants."

234 Ascribed to the force of steam.

By others the phenomena of earthquakes have been ascribed to the force of vapour or steam, which, no doubt, is an agent sufficiently powerful, if it is confined so, that its prodigious elastic force may be exerted; but it is denied by those who oppose this hypothesis, that earthquakes, though very frequent in regions where subterranean fires are really known to exist, as in volcanic countries, always happen in such places, and therefore water cannot be converted into vapour. But, besides, it is well known, that this vapour, even admitting the possibility of its production in subterranean cavities would be re-converted into water, the moment it came in contact with a cold body, which would deprive it of the principle of heat, in combination with which water assumes the form of vapour.

Many objections might have been made to the hypotheses which have been proposed to account for earthquakes. Many of these will probably occur to the attentive reader, who is a little acquainted with the nature and properties of the agents by which they are supposed to be produced; but whatever may be the cause of these extraordinary phenomena, it appears that it is very far from being clearly ascertained. Perhaps all the agents which have been stated as the cause of earthquakes, may have some influence in contributing to the effect, and many operate at different times, and in different circumstances.

Sect. II. *Of Volcanoes.*

235 Volcanoes in every part of the world.

Volcanoes exist in almost every part of the world, from the north to the south pole. Hecla in Iceland, and a volcano which has been observed in Terra del Fuego, at the termination of the southern continent of America, nearly comprehend the extremities of the globe; and having mentioned these boundaries, it is unnecessary to observe, that they exist in all climates.

236 Number of them.

The number of volcanoes at present known, is not less than 100. The volcanoes of Europe are well known: these are Vesuvius in Italy, Ætna in Sicily, and Hecla in Iceland. To these may be added the volcanoes in the Æolian or Lipari islands on the coast of Italy, of which Stromboli is remarkable for having thrown out flames, without the eruption of other volcanic matter, for more than 2000 years. In Asia there is a volcano on Mount Taurus; five in Kamtschatka, 10 in the islands of Japan; one in the peak of Adam in the island of Ceylon; four which have been observed in Sumatra; and some others in different parts of the Asiatic continent or islands. There are also some volcanoes on the African continent, as well as in some of the islands. Volcanoes exist also in the American continent, and in many of the islands which have been discovered in the South seas.

23[illegible] Are a[illegible] near [illegible] sea,

Almost all volcanoes are in the immediate vicinity of the sea. Mount Taurus, in the interior of Asia, and some of the volcanoes in the Andes, are the only exceptions to this.

23[illegible] and in [illegible] tops [illegible] moun[illegible]

Another general remark which may be made with regard to volcanoes is, that they always occupy the tops of mountains. No volcano was ever found bursting out in plains. The existence of volcanoes at the bottom of the ocean seems to be an exception; but it is to be observed, that these are also in the peaks of mountains, which have been raised up from great depths at the bottom of the ocean.

23[illegible] Symp[illegible] of an [illegible]tion.

The first symptom of an approaching eruption is an increase of the smoke, if smoke has been emitted, in fair weather. This smoke is of a whitish colour; but, after some time, black smoke is observed to shoot up in the midst of the column of white smoke. These appearances are usually accompanied with explosions. The black smoke is then followed, at a shorter or longer distance of time, by a reddish-coloured flame. Showers of stones are afterwards thrown out, and some of them are projected to great heights in the air, which shews that the force by which they are impelled is very great. Along with these, ashes are likewise ejected. These phenomena, which daily increase in frequency and violence, are also usually preceded and accompanied by earthquakes, and hollow noises from the bowels of the earth, something like those that precede earthquakes unaccompanied with volcanic eruptions. The smoke, flame, and the quantity of stones and ashes, increase, and the stones are at last thrown out red hot.

The smoke which issues from the crater has been observed to be sometimes in a highly electrified state. The ashes are strongly attracted, and carried up along with the smoke to great heights in the atmosphere, forming a dense black column of vast height and size. Flashes of lightning are seen darting in a zig-zag direction, through the column of smoke and ashes; and this lightning is sometimes attended with thunder. But from some observations which have been made, this thunder and lightning are seemingly less intense than atmospheric electricity. When these terrible appearances have continued for four or five months, or for a longer or shorter time, according to the nature of the eruption, the lava begins to flow. This is a current of melted matter, which sometimes boils over the top, and sometimes, when the mountain is high, as is the case with Ætna, bursts out at the side, and makes a passage for itself. The period of the duration of the eruption is very different. Sometimes it continues to flow, at intervals, for the space of several weeks.

24[illegible] Matt[illegible] thrown [illegible] of vo[illegible] noes.

The matters ejected from volcanoes are lavas, which are either more or less consolidated; ashes, slags of different kinds, and stones which have undergone little or no fusion. For an account of the nature and properties of volcanic productions, see Mineralogy. Stones have been projected into the air from Mount Ætna, to the height of 7000 feet. A stone which was ejected from Vesuvius, measured 12 feet long, and 45 feet in circumference; and even larger masses have been thrown out from Ætna.

Water has been frequently ejected from volcanoes. This

Earth-quakes and Volcanoes.

This water is sometimes cold, and sometimes hot. Eruptions of water have taken place, both from Vesuvius and Ætna. At one time salt water was ejected from Mount Vesuvius. Different opinions have been held concerning the origin of this water, or its connexion with the volcano. This is founded on the circumstance already taken notice of in the general remark which was made, that almost all volcanoes are in the vicinity of the sea.

It seems to be a singular circumstance in the history of volcanoes, that when once eruptions have commenced, they follow each other in rapid succession; and at other times that they cease for a long period. From the year 1447, Ætna ceased to throw out any fire till the year 1536, when a terrible eruption took place, accompanied with smoke, flame, ashes, and burning stones. This conflagration continued to rage with great violence for many weeks. The following year a river swelled and overflowed its banks to a great distance; furious squalls of wind succeeded, after which there was a terrible eruption from Ætna. The torrents of flaming and fused matter which flowed out, destroyed towns, villages, and vineyards, to a great extent. After the conflagration, the summit of the mountain fell in with a dreadful crash. For 100 years after this period, the eruptions seemed to observe some kind of regularity, returning periodically every 25 and 30 years. From the year 1686 to 1755, the same year on which the earthquake at Lisbon happened, for more than half a century, Ætna enjoyed profound repose.

The first considerable eruption of Vesuvius, the account of which is recorded in history, happened in the year 79 of the Christian era. It was this eruption which destroyed Herculaneum and Pompeii; but this was not the first eruption of this mountain, for the streets of these cities have been since discovered to be paved with lava. Since that time, 30 different eruptions have taken place. There was a very remarkable one in 1538.

Volcanoes become extinct and are rekindled.

It would appear that volcanoes seem to become quite extinct, and are rekindled. Some of the Roman writers, as Diodorus Siculus, Vitruvius, and others, speak of Vesuvius only as having been a volcano. After this period it burnt for 1000 years, and again became extinct, from 1136 to 1506. Pools of water had collected in the crater, and woods were growing on its sides, and even in the crater itself. Vesuvius has now burnt for three centuries past, as furiously as ever; but particularly, during the 18th century. Of 29 eruptions which have taken place from Vesuvius, since the reign of Titus, half of the number have happened in the 18th century.

Submarine volcanoes.

Beside the volcanoes, the history of which we have now briefly detailed, volcanoes are known to exist at the bottom of the ocean. These are distinguished by the name of *submarine volcanoes*. Excepting in situation, so far as the history of submarine volcanoes is known, they resemble the volcanoes on land. It would appear that they exist in the tops of mountains at the bottom of the ocean, and eject immense burning masses of matter in whirlwinds of ashes and pumice, with prodigious torrents of lava. Submarine volcanoes are either very few in number, or the places where they exist have not been ascertained. Those that are certainly known are at Santorin, the Azores, and Iceland. The island of Santorin, formerly called Thera and St Irene, was denominated by the Greeks, in allusion to its origin, Καμμενι, or "burnt." According to Pliny, there is a tradition, that it arose out of the sea, at a very remote but unknown period.

Without going far back into history, to inquire concerning the early eruptions of this volcano, we shall mention some of a later date, the existence of which is better ascertained. In 1457, an eruption took place, at which time ashes and red-hot rocks were ejected, with a great quantity of lava. This event, with the date of it, is recorded on a marble stone, erected near the gate of Fort Scarus, in Santorin. An eruption also took place in 1570. This produced a new island, called the *Little Kaminoi*. In 1650, the agitations of the volcanoes continued for the greater part of a year. Smyrna and Constantinople were incommoded with the ashes, which rushed from the ocean in whirlwinds of flame. The same volcano opened again in 1707. The Little Kaminoi, mentioned, was increased, and it is now more than three leagues in circumference. A violent eruption took place in 1767, which shook the earth greatly for some days, and raised the sea in such a manner, as to excite apprehensions of the destruction of the islands in the neighbourhood. A thick black smoke darkened the air, which was so infected with a strong smell of sulphur, that many persons and animals were suffocated by it. Black ashes resembling gunpowder were dispersed around, and torrents of flame issuing from the sea, and waving above it, to the height of several feet, lighted, at intervals, the horrid scene. At the end of 10 or 12 days the eruption began to be more moderate; and a new island which had been thrown up was discovered. When it was examined, many parts of it were still burning; but the next day, those whom curiosity had drawn to the spot, were compelled to betake themselves to flight. They felt the new soil moving; in some parts it rose, and sunk in others. The earth, sea, and sky, soon resumed their formidable appearance; the boiling sea changed colour; flames in rapid succession issued as from a furnace, but accompanied with ashes and pumice. The frightful noise of subterranean thunders was heard; it seemed as if enormous rocks, darting from the bottom of the abyss, beat against the vaults above it, and were alternately repelled and thrown up again. The repetition of their blows seemed to be distinctly heard. Some of them finding a passage, were seen flying up red hot into the air, and again falling into the sea from which they had been ejected. Masses were produced, held together for some days, and then disappeared. In this general disorder, large portions of the Little-Kaminoi were swallowed up. Meanwhile the labour of the volcano took a larger surface. Its ejections became prodigiously abundant, and a new island was seen forming. By successive additions continued for near four months, it made a junction with that produced in June. From the colour of its soil it was named the *Black Island*. It is larger than the Little Kaminoi, and is separated from it by a narrow strait. After frequent alarms for several months, the volcano opened again on the 15th of April in the following year; but the eruption was only for a moment, when it threw out a multitude of burning rocks, which fell at the distance of two miles.

Similar

Earthquakes and Volcanoes.

Similar submarine volcanoes have been observed near the island of St Michael, one of the Azores or Western islands in the Atlantic ocean. In the year 1638, near the island of St Michael, where the sea was known to be 120 feet deep, there arose, after an agitation of several weeks, an island about six miles round. It was again swallowed up in about the same space of time that had elapsed during its formation. In the year 1691, this volcano was in great agitation for a month. It convulsed the whole island of St Michael, and by the heat and violent commotion of the sea, as well as by the eruption of flames, ashes, and pumice, occasioned great damage; but in this case no island appeared. Similar eruptions were known in 1720, and in 1757. During the latter eruption, some of the islands were shaken to their foundations.

After this account of submarine volcanoes, of their effects, and of the islands formed by them, it would be unnecessary to enter into any detail of the submarine volcano which threw up an island off the coast of Iceland, in the year 1783. This island, the existence of which seemed to be fully ascertained, was again swallowed up in the ocean, and was seen no more.

243 Mud volcanoes.

Volcanoes of a very different kind have been described. The volcanoes to which we allude, have received the name of *mud volcanoes*, from ejecting a great quantity of mud. These, however, are similar to those which have been already described, in having volcanic motions and convulsive eruptions. The first volcano of this kind which was discovered is in the island of Sicily, near a place called Maccalouba, between Arragona and Girgenti. It is in a hill of a conical shape, truncated at the top, and 150 feet high. The summit is a plain, half a mile round, and the whole surface is covered with thick mud. The depth of the mud, which is supposed to be immense, is unknown. There is not the slightest appearance of vegetation upon it. In the rainy season the mud is much softened; the surface is even, and there is a general ebullition over it, which is accompanied with a very sensible rumbling noise. In the dry season, the mud acquires greater consistency, but without ceasing its motion. The plain assumes a form somewhat convex; a number of little cones are thrown up, which rarely rise to the height of two feet. Each of them has a crater, where a black mud is seen in constant agitation, and incessantly emitting bubbles of air. With these the latter insensibly rises, and as soon as the crater is full of it, it disgorges. The residue sinks, and the cone has a free crater until a new emission.

This hill is sometimes subject to alarming convulsions. Earthquakes are felt at the distance of two or three miles, accompanied with internal noises, resembling thunder. These increase for several days, and terminate in an eruption of a prodigious spout of mud, earth, and stones, which rises two or three hundred feet into the air. This explosion is repeated twice or thrice in the course of 24 hours. Some years pass over without any eruption, but it generally happens that the eruptions continue yearly for five years successively. An eruption from this mud volcano took place in 1777.

Phenomena somewhat similar have been described by Pallas, which he observed partly in the peninsula of the Kercha, the boundary of Europe to the south-east of Little Tartary, now Taurida, and partly in the island of Taman, which is separated from Kercha only by one of the mouths of the river Cuban. The island of Taman is situated in Asia. These places, he observes, are in flat countries where there are few hills, and those very little raised above the level of the sea. The whole is covered with beds of slime, mixed with sand, with some beds of marl and sea-shells. From this he concludes that no real volcanic pit can exist here. Copious springs of petroleum are found in several places, and also pools or syphons of various dimensions, through most of which a briny mud is disgorged in bubbles. Pallas observed several of these pools, both in the peninsula and in Taman. The last eruption which took place, he observes, was in 1794. This was the greatest and most copious that had been known. It proceeded from the top of a hill at the north point of Taman. The place where the new gulf opened was a pool, where the snow and rain water usually remained for a long time. The explosion came on with a noise like that of thunder, and with the appearance of a mass of fire in the form of a sheaf. This lasted only for about half an hour, and it was accompanied with a thick smoke; but the ebullition which threw up part of the liquid mud, continued till the next day, after which the mud ran slowly in streams down the hill. The mud discharged was of a soft clay, of a bluish ash colour, every where of the same nature, and mixed with brilliant sparks of mica, with a small quantity of marl, calcareous and sandy fragments of schistus, which seemed to have been torn from their beds.

Pallas supposes that a very deep coal mine had been for ages on fire, under Kercha and Taman, and that the sea having accidentally broken into the burning cavities of the mine, the expansion produced by the water converted into steam, and the struggle of the different aeriform substances to get free, forced the upper beds, broke them in pieces, and formed a passage to themselves. The vapours, as they escaped, carried the mud along with them. But others have supposed that these phenomena are not produced by fire; that the appearance of the sheaf of fire must have been extraneous, or, that it was only a quantity of inflammable air, which exploded when it came to the surface; or, perhaps it was altogether an illusion, from the appearances of the vapours which were emitted.

An account is given of a singular phenomenon, somewhat similar to the above, which was observed in 1711, at Bosely, near Wenlock, in Shropshire. After a great hurricane, the inhabitants were awakened in the middle of the night by commotions of the earth, which were accompanied with noise. Some persons went to an eminence from which the noise proceeded, and they saw water oozing through the turf, while at the same time inflammable air was emitted. The water was not hot. This continued for some time, but at last it ceased to throw out any inflammable air for some years, previous to the year 1746, when a second eruption took place, attended with similar circumstances.

We shall not dwell longer on the history of volcanoes. For a particular account of the most remarkable eruptions of the principal volcanoes in the world, the reader is referred to the history given under Ætna, Hecla, and Vesuvius. We shall now proceed to state some of the opinions and conjectures of philosophers,

phers with regard to the cause of these extraordinary phenomena.

Earthquakes and Volcanoes.

Volcanic eruptions have been ascribed to the action of the waters of the sea, bursting in upon an immense quantity of fused or burning matter; to the action of central fires, and to the decomposition of different substances, by which a great quantity of heat and inflammable substances is produced.

Causes of Volcanoes.

Water, according to some philosophers, is absolutely necessary for the formation of volcanoes. This opinion is supported by the circumstance of almost all volcanoes being near the sea. According to this opinion, they were all formed under the surface of the waters of the ocean. The first explosion at the formation of a volcano, it is supposed, was preceded by an earthquake. The first eruptions would be extremely violent, and immense quantities of matter would be ejected. Torrents of lava would continue to be discharged for a long series of ages, and thus the foundations of the burning mountain are laid in the bottom of the ocean. But it becomes a question, in what way the internal fire was preserved from extinction by the incumbent waters of the ocean? To this M. Houel replies, that the fire having disposed the substances in fusion to make an eruption, next laid open the earth, and emitted as much matter as it could discharge, with a force sufficient to overcome the resistance of the column of water, which would oppose its ascent; but as the strength of the fire diminished, the matter discharged was no longer expelled beyond the mouth; but, by accumulating there, soon closed up the orifice. Thus, only small orifices would be left sufficient for giving vent to the vapours of the volcano, and from which only small bubbles of air could ascend to the surface of the water, until new circumstances, such as originally gave occasion to the eruption of the volcano, again took place in the bowels of the earth, and produced new eruptions, either through the same or other mouths. The appearance of the sea over the new formed volcano, in its state of tranquillity, would then be similar to what it is betwixt the islands of Basilizzo and Pariaria. Columns of air bubbles are there ascending at the depth of more than 30 feet, and burst on their arriving at the surface. This air would continue to disengage itself with little disturbance as long as it issues forth only in small quantity, until, at the very instant of explosion, when prodigious quantities, generated in the burning focus, would make their way at once, and the same phenomena which originally took place would again make their appearance."

A volcano, while under water, cannot act precisely as it does in the open air. Its eruptions, though equally strong, cannot extend to so great a distance. The lava accumulates in greater quantity round the crater; the sand, ashes, and pozzolana are not carried away by the winds, but are deposited around its edges, and prevent the marine substances which are driven that way by the waters from entering. Thus they agglomerate with these bodies, and thus a pyramidal mount is formed of all the materials together.

In this manner M. Houel supposes that the mountain was gradually raised out of the sea by the accumulation of lava, &c. at every eruption, and that the cavern of the volcano was gradually enlarged, the lava being driven down into the bottom of the cavern by the continued action of the stones which the volcano is constantly throwing up; that it was there fused, and at last thrown out at the top of the mountain to accumulate on its sides. M. Houel's opinion about the volcanic fire we shall give in his own words.

"We cannot form any idea of fire subsisting alone, without any pabulum, and unconnected with any other principle. We never behold it but in conjunction with some other body, which nourishes and is consumed by it. The matter in fusion, which issues from the focus, is but the incombustible part of that which nourishes the fire, and into the bosom of which that active principle penetrates in search of pabulum. But as the fire acts only in proportion to the facility with which it can dissolve and evaporate, I am of opinion, that it is only the bottom of the volcano on which it acts; and that its action extends no farther than to keep these substances which it has melted in a constant state of ebullition. That fusible matter being discharged from the mouth of the volcano, and hardening as it is gradually cooled by the action of the air, produces that species of stones which are distinguished by the name of *lavas*. This lava, even when in the focus, and in a state of fluidity, must also possess a certain degree of solidity, on account of the gravity and density of its particles. It therefore opposes the fire with a degree of resistance which irritates it, and requires, to put it into a state of ebullition, a power proportioned to the bulk of the mass.

"That quantity of matter, when dissolved by the action of the fire, must constantly resemble any other thick substance in a state of ebullition. Small explosions are produced in various parts over the surface of every such substance while in a state of ebullition; and, by the bursting of these bubbles, a great number of small particles are scattered around. This is the very process carried on in the focus of a volcano, though on a scale immensely more large; and the vast explosions there produced expel every body which lies in their way with the utmost violence; nor is there any piece of lava which falls down from the upper part of the arch, of weight sufficient to resist this violent centrifugal force.

"The pabulum by which the internal fire is supported, M. Houel thinks to be substances contained in the mountain itself, together with bitumen, sulphur, and other inflammable materials, which may from time to time flow into the focus of the volcano in a melted state though the subterraneous ducts, and the explosions he ascribes to water making its way in the same manner. The water is converted into steam, which fills the cavern and pushes the melted lava out at the crater; this opinion is corroborated by the copious smoke which always precedes an irruption. But, combined with the water, there is always a quantity of other substances, whose effects precede, accompany, or follow the eruptions, and produce all the various phenomena which they display. The eruption of water from Ætna in the year 1775 proceeded undoubtedly from this cause. The sea, or some of the reservoirs in Ætna or the adjacent mountains, by some means discharged a vast quantity of water into the focus of the volcano. That water was instantly resolved into vapour, which filled the whole crater, and issued from the mouth of the crater. As soon as it made its way into the open atmosphere, it was condensed again into water, which streamed down the

Earthquakes and Volcanoes.

the sides of the mountain in a dreadful and destructive torrent."

Others have attempted to account for the existence of volcanic fire, on the supposition that it is derived from central fires, and to these it is supposed that volcanoes act the part of chimneys; while others are of opinion that they are owing to the chemical decomposition of different substances, by which inflammable matters are evolved, with a great deal of heat, and by means of the latter the combustible materials are kindled, and exhibit the phenomena which are thus proposed to be accounted for.

M. Patrin is one of the latest naturalists who, with the assistance of modern chemistry, has attempted to account for the phenomena of volcanoes on the principles of this science. For a full view of his theory, or rather of his fanciful conjectures on this subject, we must refer the reader to the work itself†. But the following is a recapitulation of the principles on which he gives this explanation. All volcanoes, he observes, in a state of activity, are in the vicinity of the sea, and are never found but in those places where sea salt is abundant. The volcanoes of the Mediterranean abstract the salt which the waters of the ocean hold in solution, and are constantly pouring in by the straits of Gibraltar. The strata of primitive schistus are the great laboratories in which volcanic matters are prepared, by a constant circulation of different fluids; but, according to this theory, these strata contribute no part of their own substance. They suffer no waste in the process.

† *Hist. Nat. de Minéral.* tom. v.

The sphere of the activity of volcanoes may be far extended in these strata, but they have no other outlet beside spiracles, by which the gaseous substances escape, of which one part is dissipated in the atmosphere, and the other becomes concrete by its combination with oxygen. The concretion of these fluids is supposed to be analogous to the concretion of the primitive matters of the globe, according to the theory of La Place; and the elective attractions determine, in the same way, the formation of stony crystals.

Volcanic eruptions are proportioned, in regard to their violence and duration, to the extent of the strata of schistus in which the volcanic fluids are accumulated. These fluids are,

1. *Muriatic acid*, which carries off the oxygen from the metallic oxides of the schistus.

2. *The oxygen of the atmosphere*, which constantly replaces in the metals that which was carried off by the muriatic acid.

3. *Carbonic acid gas*, which the water absorbs from the atmosphere, and conveys to the schistus, which always abounds in carbone.

4. *Hydrogen*, which proceeds from the decomposition of water. A part of this hydrogen is inflamed by electric explosions; the other united to carbonic acid forms oil, which becomes petroleum by its combination with sulphuric acid; and it is to this petroleum that the bitterness of sea water is owing.

5. *The electric fluid*, which is attracted from the atmosphere by the metals contained in the schistus. Sulphur seems to be the most homogeneous portion of this fluid, which has become concrete. Phosphorus is a modification of it, and it contributes to the fixation of oxygen. The sulphur formed in the schistus by means of the electric fluid, combines with the oxygen, and forms sulphuric acid, which decomposes the sea salt.

6. *The metalliferous fluid.* This forms the iron in lavas. It is the origin of metallic veins, and the colouring principle of organized bodies. This substance in its undecomposed state affords iron, but by decomposition it produces other metals. It is conjectured to be one of the principles of muriatic acid, and it contributes, along with phosphorus, to fix oxygen under an earthy form.

7. The last of the volcanic fluids is *azotic gas*. To this gas is owing the formation of the masses of carbonate of lime which are ejected by Vesuvius, and of the calcareous earth contained in lavas.

Such are the materials with which the author proposes to form the different substances which are produced in volcanoes, and by the operation of which he proposes to explain the phenomena of volcanic eruptions. Our readers will probably agree with us in thinking, that the present state of chemical science, even with the assistance of such hypothetical substances as the metalliferous fluids, is yet inadequate to give any degree of support to such opinions, even in the form of conjecture. We shall therefore dismiss it without farther remark.

24 Observations on the nature of the strata.

We shall now conclude this subject with some interesting observations by M. de Luc, on the nature of the strata in which volcanic fires exist.

"Volcanoes, he observes, have been more numerous on the surface of our continents, when they were under the waters of the ancient sea; and as this class of mountains, raised by subterranean fires, manifest themselves still on the shores of the present sea, and in the middle of its waters, it is of importance to geology and the philosophy of the earth to obtain as just ideas of them as possible.

"I have attended a great deal to this subject from my own observations; and I have shown, at different times, the errors into which several geologists and naturalists, in treating of it, have fallen.

"This class of mountains, in particular, requires that we should see them, that we should behold them during their eruptions, that we should have traced the progress of their lava, and have observed closely their explosions; that we should have made a numerous collection of the matters which they throw up under their different circumstances, that we might afterwards be able to study them in the cabinet, and to judge of their composition according to the phenomena which have been observed on the spot.

"This study is highly necessary when we apply it to geology and the philosophy of the earth, in order that we may avoid falling into those mistakes which make us ascribe to subterranean fires what does not belong to them, or which leads us to refuse them what really belongs to them.

"We read in the *Journal de Physique* for January 1804, under the title, *On the Cause of Volcanoes*, the following assertions:

'What is the nature of the matters which maintain these subterranean fires? We have seen that Chimboraço, all these enormous volcanoes of Peru, and the Peak of Teneriffe, are composed of porphyry.

'The Puy-de-Dôme is also composed of porphyry, as well as the Mont d'Or and the Cantal.

'Ætna,

'Ætna, Solfatara, and Vesuvius, are also of the porphyry kind.

Earthquakes and Volcanoes.

'These facts prove that the most considerable volcanoes with which we are acquainted are of porphyry.'

"This opinion, that the fires of volcanoes have their centres in such or such a rock, and that their lavas are produced from these rocks, has always appeared to me not to be founded on any certain data. Opinions also on this subject have varied; some having placed the origin of lava in horn rock, others in granite or schist, and at present it is assigned to porphyry.

"I have always been of opinion that nothing certain could be determined in regard to this point. It ever remains uncertain whether the seat of the matters of which lava is formed be in compact rocks, or in strata in the state of softness, pulverulent, and muddy.

"Those who see lava issue from a volcano in its state of fusion and incandescence, and in its cooling, are convinced that the nature of every thing is changed, that it exhibits a paste in which nothing can be known, except the substances which the volcanic fires have not reduced to fusion.

"But these substances contained in the paste of lava, and those which are the most numerous, show us, that the strata from which they proceed cannot be similar to those exposed to the view, nor even to the most profound strata to which we can penetrate.

"Admitting the hypothesis, that the strata from which the lavas proceed are in a pulverulent and muddy state, containing elements of all these small crystals, one may conceive how they are formed there, insulated, grouped, or solitary, and are found then in the lava in that state of insolution.

"The fragments of natural rocks thrown up by Vesuvius are not of the same kind as the matters of which the lava is composed. Most of these fragments are micaceous rocks with laminæ of greater or less size, and of a kind of granite called *syenite*. I have found some composed of white quartzy rock; it is found sometimes of calcareous rock.

"The most probable idea that can be formed in regard to the origin of these fragments is, that they have been carried from the borders of the strata through which the lava, that comes from great depths, has opened for itself a passage. These fragments are carried to the surface of the lava as far as the bottom of the chimney of the crater, whence they have been thrown out by explosions, mixed with fragments separated, or rather torn, from the lava; for it is not by the lava that they have been brought forth to view, but by explosions.

"Some of these fragments of natural rocks have not been attacked by the fire; others have more or less; which depends, no doubt, on the place which they occupied in the volcano, and on the time which they remained in it. The most of the latter have retained at their surface a crust of lava, and this crust contains substances which are not the same as that of the fragment it covers.

"On Vesuvius the strata pierced by eruptions are lower than the surface of the soil; in Auvergne and several places of Germany they are above; for this reason there are seen there in their place schists or granites, which the eruptions have broken to form for themselves a passage.

"No volcano rests on natural strata: they sometimes show themselves on the exterior; but they have been opened by eruptions, and their edges have remained in their place.

"The focus of no volcano exists or has existed in the cone which appears above the surface of the ground. They have been raised by eruptions, which, proceeding from great depths, have thrown them up through the upper strata. When it is said, therefore, that the volcanic mountains of Auvergne rest on granite, this is a mistake, and an incorrect expression has been used by those who have not formed a just idea of the phenomenon. Lava may have flowed upon granite or any other rock, and rested upon it; but this is never the case with the volcano itself: its bases are below all the rocks visible.

"It is from the bosom even of the lava, when in a state of fusion in the interior of the volcano, that all the explosions proceed. In that state of fusion they contain all the matters which produce fermentations, and the disengagement of expansible fluids.

"I have been enabled to ascertain this on Vesuvius as far as was possible. The continual noise which was heard through the two interior mouths of the crater which I had before my eyes, was that of an ebullition, accompanied with inflammable vapours, and the gerbes of burning matters which they threw up at intervals were separated pieces of the lava in its state of fusion. I saw several of them in the air change their form, and sometimes become flat on the bodies which they struck or embraced in falling. And among the most apparent of these fragments there are always a multitude of small ones of the size of peas and nuts, and still smaller ones, which show at their surface, by their asperities, all the characters of laceration.

"The name of *scoriæ* has been given to these fragments, to distinguish them from compact lava, though their composition be the same as that of the hardest lava; and it is for want of reflecting properly on this point that it has been said that it is the compact part only that we must observe, in order to judge of their nature. The pieces which I took from the flowing lava with an iron hook, have at their surface the same lacerations and the same asperities as the fragments thrown up by explosions, and both contain the same substances.

"This separation, by tearing off the parcels of the lava, effected by fermentations and explosions which proceed from their bosom, serves to explain those columns, sometimes prodigious, of volcanic sand, which rise from the principal crater. When seen with a magnifying glass, this sand exhibits nothing but lava reduced very small, the particles of which, rough with inequalities, have the bright black colour and the varnish of recent lava.

"Parcels of substances which exist in our strata, such as fragments of quartz, scales of mica, and crystals of feldspar, are found sometimes in lava. Similar matters must no doubt be disseminated in the composition of our globe, without there being reason to conclude that the strata from which they proceed are the same as the exterior strata. It is neither in the granites, the porphyries,

Earth-quakes and Volcanoes.

ries, nor the horn rock, and still less in the schists and calcareous rocks, that the schorls of volcanoes, the leucites, and perhaps olivins, will be found. These small crystals are brought to view by the lava, otherwise they would be unknown to us.

"These lavas contain a great deal of iron, which they acquire neither from the granite nor porphyries. Might not one see in the ferruginous sand which is found in abundance on the borders of the sea near Naples, and in the environs of Rome, specimens of that kind of pulverulent strata from which lava proceeds?

"I have here offered enough to prove that it cannot be determined that lava proceeds from strata similar to those with which we are acquainted. The operations of volcanoes, those vast laboratories of nature, will always remain unknown to us, and on this subject our conjectures will always be very uncertain.

"What is the nature of that mixture which gives birth to these eruptions, that produce lava and throw up mountains? What we observe as certain is, that the introduction of the water of the sea is necessary to excite these fermentations, as containing marine acid, and other salts, which, united to the sulphuric acid, the bases of which are contained in abundance in the subterranean strata, determine these fermentations, which produce the disengagement of fire and other fluids, and all the grand effects that are the consequence.

Several naturalists have believed, and still believe, that fresh or rain water is sufficient for this purpose; but they are mistaken: this opinion is contradicted by every fact known. To be convinced of this, nothing is necessary but to take a short view of them. I have done it several times, as it is necessary to consider them often. I shall here enumerate the principal ones:—No burning mountain exists in the interior part of the earth; and all those which still burn are, without exception, in the neighbourhood of the sea, or surrounded by its waters. Among the deliquescent salts deposited by the smoke of volcanoes, we distinguish chiefly the marine salt, united to different bases. Several of the volcanoes of Iceland, and Hecla itself, sometimes throw up eruptions of water, which deposit marine salt in abundance. No extent of fresh water, however vast, gives birth to a volcano. These facts are sufficient to prove that the concurrence of sea-water is absolutely necessary to excite those fermentations which produce volcanoes.

"I shall here repeat the distinction I have already made between burnt-out volcanoes and the ancient volcanoes, that I may range them in two separate classes.

"When we simply give the name of *burnt-out* or *extinguished* volcanoes to volcanic mountains which are in the middle of the continents, it is to represent them as having burnt while the land was dry, and inhabited as it is at present; which is not a just idea. These volcanoes have burnt when the land on which they are raised was under the waters of the ancient sea, and none of them have burnt since our continents became dry. It is even very apparent that most of them were extinct before the retreat of the sea, as we find by numerous examples in the present sea.

"Those which I denominate extinct volcanoes are such as no longer burn, though surrounded by the sea, or placed on the borders of it. They would still burn, were not the inflammable matters by which they were raised really exhausted and consumed. Of this kind is the volcano of Agde, in Languedoc. Of this kind also are many of the volcanic islands which have not thrown up fire since time immemorial.

"M. Humboldt, in his letters written from Peru, speaks of the volcanoes which he visited, but what he says is not sufficiently precise to enable us to form a just idea of them. He represents Chimboraço as being composed of porphyry from its bottom to its summit, and adds, that the porphyry is 1900 toises in thickness; afterwards, he remarks, that it is almost improbable that Chimboraço, as well as Pichincha and Antisana, should be of a volcanic nature: 'The place by which we ascended, (says he), is composed of burnt and scorified rock, mixed with pumicestone, which resembles all the currents of lava in this country.'

"Here are two characters very different. If Chimboraço be porphyry from the top to the bottom, it is not composed of burnt and scorified rocks, mixed with pumicestone; and if it be composed of burnt rocks, it cannot be porphyry. This expression, *burnt and scorified rocks*, is not even exact, because it excites the idea of natural rocks, altered in their place by fire, and they are certainly lava which has been thrown up by the volcano. But the truth must be, that Chimboraço, and all the other volcanoes of Peru, are composed of volcanic matters, from their base at the level of the sea to the summit.

"I have just read in the *Annales du Muséum d'Histoire Naturelle**, a letter of the same traveller, written from Mexico, on his return from Peru, where, speaking of the volcanoes of Popayan, Pasto, Quito, and the other parts of the Andes, he says, 'Great masses of this fossil (*obsidian*) have issued from the craters; and the sides of these gulfs, which we closely examined, consist of porphyry, the base of which holds a mean between obsidian and pitchstone (*pechstein*).' M. Humboldt therefore considers obsidian, or black compact glass, as a natural fossil or rock, and not a volcanic glass†."

GEOMAN[...]

GEOMANCY, Geomantia, a kind of divination, performed by means of a number of little points, or dots, made on paper at random: and considering the various lines and figures which those points present; and thence forming a pretended judgment of futurity, and deciding any question proposed.

The word is formed of the Greek γη, *terra*, "earth;" and μαντεια, "divination;" it being the ancient custom to cast little pebbles on the ground, and thence to form their conjectures: instead of the points afterwards made use of.

Polydore Virgil defines geomancy a kind of divination performed by means of clefts or chinks made in the ground; and takes the Persian Magi to have been the inventors thereof.

GEOMETRY.

INTRODUCTION.

THERE is reason to believe that geometry, as well as most of the other sciences, was first cultivated in Egypt; and, according to some authors, it had its origin in the necessity there was of assigning to the inhabitants every year their particular shares of land: for as the country was annually overflowed by the Nile, it has been taken for granted (perhaps without good reason), that the land-marks would be obliterated, and the possessions rendered undistinguishable from one another. Such is said to have been the origin of land-measuring, the form under which geometry was first known, and from which it has taken its name; for geometry literally signifies *the measuring of the earth.*

The historian *Herodotus* refers the origin of geometry to the time when *Sesostris* intersected Egypt by numerous canals, and divided the country among the inhabitants; and this account of the beginning of the science has been considered by some as very probable.

From Egypt geometry was carried into Greece by *Thales* of Miletus about 600 years before the Christian æra. This celebrated philosopher is said to have made numerous discoveries in geometry; and in particular to have first observed that any angle in a semicircle is a right angle; a discovery which gave him great joy, and for which he thanked the muses by a sacrifice.

Among the disciples of *Thales* were *Anaximander* and *Anaxagoras:* the first of these wrote an elementary treatise or introduction to geometry, the earliest of which there is any mention in history; and the last is said to have attempted the quadrature of the circle, a problem which has baffled the skill of mathematicians of every age.

Pythagoras followed *Thales*, and had the merit of discovering one of the most beautiful and important propositions of the whole science, namely, that the square of the hypothenuse of a right-angled triangle is equal to the squares of the two other sides. He is said to have been so transported with joy at this discovery, that he sacrificed a hundred oxen to the gods as a testimony of his gratitude. The truth of this anecdote has however been doubted, on account of the philosopher's moderate fortune and religious opinions concerning the transmigration of souls.

Zenodorus is the earliest of the geometers whose writings have reached modern times, a part of them having been preserved by Theon, in his commentary on Ptolemy.

Hippocrates of Chios cultivated geometry, and distinguished himself by the quadrature of the curvilineal space contained between half the circumference of one circle, and the fourth part of the circumference of another circle, their concavities being both turned the same way, and the radius of the former to that of the latter as 1 to $\sqrt{2}$. He also wrote elements of geometry which are now lost.

The founding of the school of Plato forms one of the earliest and most important epochs in the history of geometry; for to that philosopher we are said to be indebted for the discovery of the *Geometrical Analysis*, by which the science has been greatly extended, and which is indeed absolutely necessary for the resolution of problems of a certain degree of difficulty.

The Conic Sections, and the theory of *Geometrical Loci*, are commonly reckoned among the improvements which geometry received from his disciples; and there is reason to suppose that these, as well as many other important discoveries which we have not room here to enumerate, were first suggested by the attempts of the geometers of the Platonic school to resolve two celebrated problems, namely, to trisect, or divide into three equal parts, a given angle; and to construct a cube which should be the double of another cube; which last problem *Hippocrates* had shewn to be equivalent to the finding of two mean proportionals between two given lines. The esteem in which *Plato* held the science of geometry is fully evinced by the following inscription over the door of his school: *Let no one enter here that is ignorant of geometry.*

The science of geometry was likewise cultivated in all its branches by the philosophers of the Alexandrian school, among whom *Euclid* claims, in a particular manner, our attention. This celebrated mathematician lived about 300 years before the Christian æra, and probably studied geometry at Athens under the disciples of *Plato*. From Greece he went to Alexandria, allured thither no doubt by the fame of the celebrated school of that city, and by the favours conferred by the first *Ptolemy* upon learned men. He composed elements of geometry in a systematic form, comprehending in them such propositions belonging to the first principles of the science as had been discovered by mathematicians previous to his time. This work has had the singular good fortune to preserve the highest reputation in all ages and in all countries where science has been cultivated, and it has served as the groundwork of innumerable other treatises, few of which, if any, have excelled it. Many commentaries have been written on it, and it has been translated into almost all

the

the European and Oriental languages. *Euclid* is likewise known to have written other works on geometry: of these we have his *Data*, which may be regarded as a continuation of his elements; and an account of a work of his on *porisms* (see PORISMS) preserved in the writings of *Pappus*, but which has suffered so much from time as to be almost unintelligible.

After *Euclid*, lived *Archimedes*, who cultivated and improved all the branches of the mathematics known at that period, and in a particular manner geometry. He was the first that found nearly the ratio of the diameter of a circle to its circumference, and he squared the parabola. He likewise wrote treatises on the Sphere and Cylinder, on Spirals, on Conoids and Spheroids, besides others on mixt Mathematics. He also extended and improved the Geometrical Analysis, the principles of which had been established in the school of *Plato*. Many of the writings of *Archimedes* have been lost; but such as remain prove him to have been one of the greatest geometers that ever lived, and indeed the NEWTON of antiquity.

Apollonius of Perga was nearly contemporary with *Archimedes*, that is, he flourished about the end of the second century before the Christian æra. He studied geometry in the Alexandrian school under the successors of *Euclid*, and he greatly extended the theory of the conic sections (see introduction to CONIC SECTIONS). He also composed treatises on different parts of Geometrical Analysis, but of these only one has come down to us entire; it is entitled *de sectione rationis*, and was discovered in the Arabic tongue, from which it has been translated into Latin by *Dr Halley*. Such accounts however are preserved in the *mathematical collections of Pappus* of his other treatises, that several of them have been restored by modern mathematicians. We may mention in particular his treatises *de Locis Planis*, *de Sectione Spatii*, *de Sectione Determinata*, *de Tactionibus*, each of which is divided into two books.

Having mentioned *Archimedes* and *Apollonius*, by far the most illustrious mathematicians of the period in which they lived, we shall pass over several others who contributed nothing to the improvement of the science, and therefore are but little known to us. We shall however briefly notice *Theodosius*, who lived about 50 years A. C. and who is the author of a work on Spherics, which is considered as one of the most valuable of the books on the ancient geometry.

Pappus and *Theon* of Alexandria deserve to be mentioned as among the most celebrated of the commentators and annotators on the ancient geometry. We are particularly indebted to Pappus (who lived about the middle of the fourth century) for our knowledge of various discoveries and treatises of the ancient geometers, which, but for the account he has given of them in his *mathematical collections*, would have been for ever lost to mathematicians of modern times.

Proclus, the head of the Platonic school at Athens, cultivated mathematics about the middle of the fifth century; and although it does not appear that he made any discoveries in the science, yet he rendered it some service by his example and instruction. He wrote a commentary on the first book of Euclid, which contains many curious observations respecting the history and metaphysics of mathematics.

We have now briefly noticed the principal epochs in the history of geometry, and the most celebrated men who have contributed to its improvement from the earliest periods of history to the end of the fifth century; but long before this time the æra of discovery seems to have been past, and the science on the decline. Still however the Alexandrian school existed, and it was possible that a *Euclid* or an *Apollonius* might again arise in that seminary. But the taking of Alexandria by the Arabs in the year 641 gave a death-blow to the sciences, not only in that capital, but throughout the whole Greek empire. The library, a treasure of infinite value, was burnt, and the stores of learning which had been accumulating for ages were annihilated for ever.

Although by this unfortunate event the sciences suffered an irreparable loss, it must be attributed to the fanaticism of the new religion which the conquerors had adopted, rather than to national ignorance or barbarity; for before that period, the sciences, when on the decline in Greece, had found an asylum among them, and about 120 years after the death of Mohammed they again took them under their protection.

The Arabs translated the greater part of the works of the Greek geometers, and chiefly those introductory to astronomy. They even began to study the more sublime geometry of the ancients; for *Apollonius's* Conic Sections became familiar to them, and some of the books of that work have only reached us in an Arabic version. They gave to Trigonometry its present simple and commodious form, and greatly simplified its operations by the introduction of sines instead of the chords of double arcs, which had been formerly used.

After geometry, as well as its kindred mathematical sciences, had remained for several centuries under the protection of the Arabs, it was again received into Spain, Italy, and the rest of Europe, about the year 1400. Among the earliest writers on the subject after this period, were *Leonardus Pisanus*, and *Lucas Paciolus* or *de Burgo*.

The limits within which we must necessarily confine this sketch of the history of the science, will not, however, allow us to enumerate all the improvements which it has received since the restoration of letters in Europe; for a list of the names of those who have contributed more or less to its extension, would include almost every mathematician of note from the time of Leonardus Pisanus to the present day.

The writings of the ancient geometers have been assiduously sought after, and held in great repute; for it appears that as far as they carried some of their theories, they left but little room for improvement, and of this remark we think the writings of Euclid, of Archimedes, and of Apollonius, afford remarkable instances. Euclid's elements of geometry have been considered, at least in this country, as one of the best books that could be put into the hands of the mathematical student, particularly that edition of its first six and eleventh and twelfth books which was given to the world by the late *Dr Simson*. An excellent system of geometry, comprehending the first six books of the illustrious ancient, together with three supplementary books, has of late years been published by *Mr Professor Playfair*, of the University of Edinburgh. We believe no modern system has excelled that of *Euclid* (as

First Principles.

(as restored to its original purity by Dr Simson) in respect of logical accuracy and systematic arrangement. There is one, however, which we must particularly mention on account of its great excellence, and the use we have made of it in the system we are now to present to our readers. It is that of Mr Legendre, which we consider as the most complete and extensive that has yet appeared.

SECT. I. THE FIRST PRINCIPLES.

Definitions.

I. Geometry is a science which treats of the properties and relations of quantities having extension, and which are called magnitudes. Extension is distinguished into length, breadth, and thickness.

II. A *Point* is that which has position, but not magnitude.

III. A *Line* is that which has only length. Hence the extremities of a line are points, and the intersections of one line with another are also points.

IV. A *Straight* or *Right Line* is the shortest way from one point to another.

Plate CCXX. Fig. 1.

V. Every line which is neither straight, nor composed of straight lines, is a *Curve Line*. Thus AB is a straight line, ACDB is a line made up of straight lines, and AEB is a curve line.

VI. A *Superficies*, or *Surface*, is that which has only length and breadth. Hence the extremities of a superficies are lines, and the intersections of one superficies with another are also lines.

VII. A *Plane Superficies* is that in which any two points being taken, the straight line between them lies wholly in that superficies.

VIII. Every superficies which is neither plane nor composed of plane superficies, is a *Curve Superficies*.

IX. A *Solid* is that which has length, breadth, and thickness. Hence the boundaries of a solid are superficies; and the boundary which is common to two solids, which are contiguous, is a superficies.

X. A *Plane Rectilineal Angle* is the inclination of two straight lines to one another, which meet together, but are not in the same straight line. The point in which the lines meet one another is called the *Vertex* of the angle.

Fig. 2.

When there is only one angle at a point, it may be expressed by the letter placed at that point; thus the angle contained by the lines EF and EG may be called the angle E: if, however, there be several angles, as at B, then each is expressed by three letters, one of which is the letter that stands at the vertex of the angle, and the others are the letters that stand somewhere upon the lines containing the angle, the letter at the vertex being placed between the other two. Thus the angle contained by the lines BA and BD is called the angle ABD or DAB.

Angles in common with other quantities admit of addition, subtraction, multiplication, and division. Thus the sum of the angles ABC and DBC is the angle ABC; the difference of the angles ABC and ABD is the angle DBC.

Fig. 3.

XI. When a straight line standing on another straight line makes the adjacent angles equal to one another, each of them is called a *Right Angle*, and the straight line which stands on the other is called a *Perpendicular* to it. Thus, if DC meet AB, and make the angles ACD, DCB equal to one another; each of them is a right angle, and DC is a perpendicular to AB.

XII. An *Obtuse Angle* is that which is greater than a right angle, and an *Acute Angle* is that which is less than a right angle. Thus ABC being supposed a right angle, DBC is an obtuse angle, and EBC an acute angle. Fig. 4.

XIII. *Parallel Straight Lines* are such as are in the same plane, and which being produced ever so far both ways, do not meet. Fig. 5.

XIV. A *Plane Figure* is a plane terminated every where by lines.

If the lines be straight, the space which they enclose is called a *Rectilineal* figure, or a *Polygon*, and the lines themselves constitute the *Perimeter* of the polygon. Fig. 6.

XV. When a polygon has three sides (which is the smallest number it can have) it is called a *Triangle*; when it has four, it is called a *Quadrilateral*; when it has five, a *Pentagon*; when six, a *Hexagon*, &c.

XVI. An *Equilateral* triangle is that which has three equal sides (fig. 7.); an *Isosceles* triangle is that which has only two equal sides (fig. 8.); and a *Scalene* triangle is that which has all its sides unequal (fig. 9.). Fig. 7. 8. 9.

XVII. A *Right-angled* triangle is that which has a right angle; the side opposite to the right angle is called the *Hypothenuse*. Thus in the triangle ABC, having the angle at B a right angle, the side AC is the hypothenuse. Fig. 10.

XVIII. An *Obtuse-angled* triangle is that which has an obtuse angle, (fig. 9.); and an *acute-angled* triangle is that which has three acute angles (fig. 11.). Fig. 9. 11.

XIX. Of quadrilateral figures, a *square* is that which has all its sides equal, and all its angles right angles (fig. 12.). A *Rectangle* is that which has all its angles right angles, but not all its sides equal, (fig. 13.). A *Rhombus* is that which has all its sides equal, but its angles are not right angles, (fig. 14.). A *Parallelogram*, or *Rhomboid*, is that which has its opposite sides parallel (fig. 15.). A *Trapezoid* is that which has only two of its opposite sides parallel, (fig. 16.). Fig. 12. 13. 14. 15. 16.

XX. A *Diagonal* is a straight line which joins the vertices of two angles, which are not adjacent to each other; such is AC. Fig. 89.

XXI. An *Equilateral Polygon* is that which has all its sides equal; and an *Equiangular Polygon* is that which has all its angles equal. If a polygon be both equilateral and equiangular, it is called a *Regular Polygon*.

XXII. Two polygons are *equilateral* between themselves, when the sides of the one are equal to the sides of the other, each to each, and in the same order; that is, when in going about each of the figures in the same direction, the first side of the one is equal to the first side of the other; the second side of the one is equal to the

First Principles.

the second side of the other; the third to the third, and so on. The same is to be understood of two polygons which are *equiangular* between themselves.

Explanation of Terms.

An *Axiom* is a proposition, the truth of which is evident at first sight.

A *Theorem* is a truth which becomes evident by a process of reasoning called *Demonstration.*

A *Problem* is a question proposed, which requires a solution.

A *Lemma* is a subsidiary truth employed in the demonstration of a theorem, or the solution of a problem.

The common name of *Proposition* is given indifferently to theorems, problems, and lemmas.

A *Corollary* is a consequence which follows from one or several propositions.

A *Scholium* is a remark upon one or more propositions that have gone before, tending to show their connection, their restriction, their extension, or the manner of their application.

A *Hypothesis* is a supposition made either in the enunciation of a proposition, or in the course of a demonstration.

Explanation of Signs.

That the demonstrations may be more concise, we shall make use of the following signs borrowed from Algebra; and in employing them we shall take for granted that the reader is acquainted with at least the manner of notation and first principles of that branch of mathematics.

To express that two quantities are equal the sign $=$ is put between them; thus $A = B$, signifies that the quantity denoted by A is equal to the quantity denoted by B.

To express that A is less than B, they are written thus; $A < B$.

To express that A is greater than B, they are written thus; $A > B$.

The sign $+$ (read *plus*) written between the letters which denote two quantities, indicates that the quantities are to be added together; thus $A+B$ means the sum of the quantities A and B.

The sign $-$ (read *minus*) written between two letters, means the excess of the one quantity above the other; thus $A-B$ means the excess of the quantity denoted by A above the quantity denoted by B. The signs $+$ and $-$ will sometimes occur in the same expression; thus $A+C-D$ means that D is to be subtracted from the sum of A and C, also $A-D+C$ means the same thing.

The sign $\times$ put between two quantities means their product, if they be considered as numbers; but if they be considered as lines, it signifies a rectangle having these lines for its length and breadth; thus $A\times B$ means the product of two numbers A and B; or else a rectangle having A and B for the sides about one of its right angles. We shall likewise indicate the product of two quantities, in some cases, by writing the letters close together; thus m A will be used to express the product of m and A, and so on with other expressions, agreeable to the common notation in algebra.

2

The expression A^2 means the square of the quantity A, and A^3 means the cube of A; also PQ^2, and PQ^3 mean, the one the square, and the other the cube, of a line whose extremities are the points P and Q.

On the other hand the sign $\surd$ indicates a root to be extracted; thus $\sqrt{A\times B}$ means the square root of the product of A and B.

AXIOMS.

1. Two quantities, each of which is equal to a third, are equal to one another.
2. The whole is greater than its part.
3. The whole is equal to the sum of all its parts.
4. Only one straight line can be drawn between two points.
5. Two magnitudes, whether they be lines, surfaces, or solids, are equal, when, being applied the one to the other, they coincide with one another entirely, that is, when they exactly fill the same space.
6. All right angles are equal to one another.

Note.—The references are to be understood thus: (7.) refers to the 7th proposition of the section in which it occurs; (4. 2.) means the 4th proposition of the 2d section; (2. cor. 28. 4.) means the 2d corollary to the 28th proposition of the 4th section.

THEOREM I.

Fig. 17.

A straight line CD, which meets with another AB, makes with it two adjacent angles, which, taken together, are equal to two right angles.

At the point C let CE be perpendicular to AB. The angle ACD is the sum of the angles ACE, ECD; therefore, $ACD+BCD$ is the sum of the three angles ACE, ECD, BCD. The first of these is a right angle, and the two others are together equal to a right angle; therefore, the sum of the two angles ACD, BCD, is equal to two right angles.

Cor. 1. If one of the angles is a right angle, the other is also a right angle.

Fig. 18.

Cor. 2. All the angles ACE, ECD, DCF, FCB, at the same point C, on the same side of the line AB, are taken together, equal to two right angles. For their sum is equal to the two angles ACD, DCB.

THEOREM II.

Two straight lines which coincide with each other in two points, also coincide in all their extent, and form but one and the same straight line.

Fig. 19.

Let the points which are common to the two lines be A and B; in the first place it is evident that they must coincide entirely between A and B; otherwise, two straight lines could be drawn from A to B, which is impossible (axiom 4.). Now let us suppose, if possible, that the lines when produced separate from each other at a point C, the one becoming ACD, and the other ACE. At the point C let CF be drawn, so as to make the angle ACF a right angle; then, ACE being a straight line, the angle FCE is a right angle (1. cor. 1.); and because ACD is a straight line, the angle

angle FCD is also a right angle, therefore the angle FCE is equal to FCD, a part to the whole, which is impossible; therefore the straight lines which have the common points A, B cannot separate when produced, therefore they must form one and the same straight line.

Theorem III.

Fig. 19. If two adjacent angles ACD, DCB make together two right angles, the two exterior lines AC, CB, which form these angles, are in the same straight line.

For if CB is not the line AC produced, let CE be that line produced, then, ACE being a straight line, the angles ACD, DCE are together equal to two right angles (1.); but, by hypothesis, the angles ACD, DCB are together equal to two right angles, therefore ACD+DCB=ACD+DCE. From these equals take away the common angle ACD, and the remaining angles DCB, DCE are equal, that is, a part equal to the whole, which is impossible, therefore CB is the line AC produced.

Theorem IV.

Fig. 20. If two straight lines AB, DE cut each other, the vertical or opposite angles are equal.

For since DE is a straight line, the sum of the angles ACD, ACE is equal to two right angles (1.), and since AB is a straight line, the sum of the angles ACE, BCE is equal to two right angles, therefore the sum ACD+ACE is equal to the sum ACE+BCE; from each of these take away the same angle ACE, and there remains the angle ACD equal to its opposite angle BCE.

In like manner, it may be demonstrated, that the angle ACE is equal to its opposite angle BCD.

Cor. 1. From this it appears, that if two straight lines cut one another, the angles they make at the point of their intersection are, together, equal to four right angles.

Cor. 2. And hence all the angles made by any number of lines meeting in one point are, together, equal to four right angles.

Theorem V.

Fig. 21. Two triangles are equal, when they have an angle, and the two sides containing it of the one equal to an angle, and the two sides containing it of the other, each to each.

Let the triangles ABC, DEF have the angle A equal to the angle D, the side AB equal to DE, and the side AC equal to DF; the triangles shall be equal. For if the triangle ABC be applied to the triangle DEF, so that the point A may be on D, and the line AB upon DE, then the point B shall coincide with E, because AB=DE; and the line AC shall coincide with DF, because the angle BAC is equal to EDF; and the point C shall coincide with F, because AC=DF; and since B coincides with E, and C with F, the line BC shall coincide with EF, and the two triangles shall coincide exactly, the one with the other; therefore they are equal (ax. 5.).

Cor. Hence it follows, that the bases, or third sides BC, EF of the triangles are equal, and the remaining angles B, C of the one are equal to the remaining angles E, F of the other, each to each, namely, those to which the equal sides are opposite.

Theorem VI.

Two triangles are equal, when they have a side, and the two adjacent angles of the one equal to a side, and the two adjacent angles of the other, each to each. Fig. 22.

Let the side BC be equal to the side EF, the angle B to the angle E, and the angle C to the angle F, the triangle ABC shall be equal to the triangle DEF. For if the triangle ABC be applied to the triangle DEF, so that the equal sides BC, EF may coincide; then because the angle B is equal to E, the side BA shall coincide with ED, and therefore the point A shall be somewhere in ED; and because the angle C is equal to F, the side CA shall coincide with FD, and therefore the point A shall be somewhere in FD; now the point A being somewhere in the lines ED, and FD, it can only be at D their intersection; therefore the two triangles ABC, DEF must entirely coincide, and be equal to one another.

Cor. Hence it appears that the remaining angles A, D of the triangles are equal, and the remaining sides AB, AC of the one are equal to the remaining sides DE, DF of the other, each to each, viz. those to which the equal angles are opposite.

Theorem VII.

Any two sides of a triangle are together greater than the third. Fig. 22.

For the side BC, for example, being the shortest way between the points B, C, (def. 4.) must be less than BA+AC.

Theorem VIII.

If from a point O, within a triangle ABC, there be drawn straight lines OB, OC to the extremities of BC one of its sides, the sum of these lines shall be less than that of AB, AC the two other sides. Fig. 23.

Let BO be produced to meet CA in D; because the straight line OC is less than OD+DC, to each of these add BO, and BO+OC$\angle$BO+OD+DC; that is BO+OC$\angle$BD+DC.

Again, since BD$\angle$BA+AD, to each of these add DC and we have BD+DC$\angle$BA+AC, but it has been shewn that BO+OC$\angle$BD+DC, much more then is BO+OC$\angle$BA+AC.

Theorem IX.

If two sides AB, AC of a triangle ABC are equal to two sides DE, DF of another triangle DEF, each to each; but if the angle BAC contained by Fig. 24. Fig. 25. Fig. 26.

First Principles.

by the former is greater than the angle EDF contained by the latter; the third side BC of the first triangle shall be greater than the third side EF of the second.

Suppose AG drawn so that the angle $CAG=D$, take $AG=DE$ and join CG; then the triangle GAC is equal to the triangle EDF, (6.) and therefore $GC=EF$. Now there may be three cases, according as the point G falls without the triangle BAC, or on the side BC, or within the same triangle.

Fig. 24. Case I. Because $GC<GI+IC$, and $AB<AI+IB$, (7.) therefore $GC+AB<GI+AI+IC+IB$, that is $GC+AB<AG+BC$, from each of these unequal quantities take away the equal quantities AB, AG, and there remains $GC<BC$, therefore $EF<BC$.

Fig. 25. Case II. If the point G fall upon the side BC, then it is evident that GC, or its equal EF, is less than BC.

Fig. 26. Case III. Lastly, if the point G fall within the triangle BAC, then $AG+GC<AB+BC$, (8.) therefore, taking away the equal quantities AG, AB, there remains $GC<BC$ or $EF<BC$.

Cor. Hence, conversely, if EF be less than BC, the angle EDF is less than BAC; for the angle EDF cannot be equal to BAC, because then (5.) EF would be equal to BC; neither can the angle EDF be greater than BAC, for then (by the theor.) EF would be greater than BC.

Theorem X.

Fig. 22. Two triangles are equal, when the three sides of the one are equal to the three sides of the other, each to each.

Let the side $AB=DE$, $AC=DF$, and $BC=EF$; then shall the angle $A=D$, $B=E$, $C=F$.

For if the angle A were greater than D, as the sides AB, AC, are equal to DE, DF, each to each, it would follow, (9.) that BC would be greater than EF, and if the angle A were less than the angle D, then BC would be less than EF; but BC is equal to EF, therefore the angle A can neither be greater nor less than the angle D, therefore it must be equal to it. In the same manner it may be proved, that the angle $B=E$, and that the angle $C=F$.

Scholium.

It may be remarked, as in Theorem V. and Theorem VI. that the equal angles are opposite to the equal sides.

Theorem XI.

Fig. 27. In an isosceles triangle the angles opposite to the equal sides are equal to one another.

Let the side $AB=AC$, then shall the angle $C=B$. Suppose a straight line drawn from A the *vertex* of the triangle to D the middle of its base; the two triangles ABD, ACD have the three sides of the one equal to the three sides of the other, each to each, namely AD common to both, $AB=AC$, by hypothesis, and $BD=DC$, by construction, therefore (preced. theor.) the angle B is equal to the angle C.

Cor. Hence every equilateral triangle is also equiangular.

Scholium.

From the equality of the triangles ABD, ACD, it follows, that the angle $BAD=DAC$, and that the angle $BDA=ADC$; therefore these two last are right angles. Hence it appears, that a straight line drawn from the vertex of an isosceles triangle to the middle of its base is perpendicular to that base, and divides the vertical angle into two equal parts.

In a triangle that is not isosceles, any one of its three sides may be taken indifferently for a *base*; and then its *vertex* is that of the opposite angle. In an isosceles triangle, the base is that side which is not equal to the others.

Theorem XII.

If two angles of a triangle are equal, the opposite sides are equal, and the triangle is isosceles. Fig. 28

Let the angle $ABC=ACB$, the side AC shall be equal to the side AB. For if the sides are not equal, let AB be the greater of the two; take $BD=AC$, and join CD; the angle DBC is by hypothesis equal to ACB, and the two sides DB, BC are equal to the two sides AC, BC, each to each; therefore the triangle DBC is equal to the triangle ACB; (5.) but a part cannot be equal to the whole; therefore the sides AB, AC cannot be unequal, that is, they are equal, and the triangle is isosceles.

Theorem XIII.

Of the two sides of a triangle, that is the greater which is opposite to the greater angle; and conversely, of the two angles of a triangle, that is the greater which is opposite to the greater side. Fig. 29

First, let the angle $C>B$, then shall the side AB opposite to C be greater than the side AC opposite to B. Suppose CD drawn, so that the angle $BCD=B$; in the triangle BDC, BD is equal to DC, (12.) but $AD+DC>AC$, and $AD+DC=AD+DB=AB$, therefore $AB>AC$.

Next, let the side $AB>AC$, then shall the angle C opposite to AB, be greater than the angle B, opposite to AC. For if C were less than B, then, by what has been demonstrated, $AB<AC$, which is contrary to the hypothesis of the proposition, therefore C is not less than B: and if C were equal to B, then it would follow that $AC=AB$, (12.) which is also contrary to the hypothesis; therefore C is not equal to B, therefore it is greater.

Theorem XIV.

From a given point A without a straight line DE, no more than one perpendicular can be drawn to that line. Fig. 30

For suppose it possible to draw two, AB and AC; produce

produce one of them AB, so that BF=AB, and join CF. The triangle CBF is equal to the triangle ABC, for the angle CBF is a right angle, as well as CBA, and the side BF=BA; therefore the triangles are equal, (5.) and hence the angle BCF=BCA; but the angle BCA is by hypothesis a right angle; therefore the angle BCF is also a right angle; hence AC and CF lie in a straight line, (3.) and consequently two straight lines ACF, ABF may be drawn between two points, A,F, which is impossible, (ax. 4.) therefore it is equally impossible that two perpendiculars can be drawn from the same point to the same straight line.

Theorem XV.

Fig. 30. If from a point A, without a straight line, DE, a perpendicular AB be drawn upon that line, and also different oblique lines AE, AC, AD, &c. to different points of the same line.

First, The perpendicular AB shall be shorter than any one of the oblique lines.

Secondly, The two oblique lines AC, AE, which meet the line DE on opposite sides of the perpendicular, and at equal distances BC, BE from it, are equal to one another.

Lastly, Of any two oblique lines AC, AD, or AE, AD, that which is more remote from the perpendicular is the greater.

Produce the perpendicular AB, so that BF=BA, and join FC, FD.

1. The triangle BCF is equal to the triangle BCA; for the right angle CBF=CBA, the side CB is common, and the side BF=BA, therefore the third side CF=AC, (5.) but AF$\angle$AC+CF, (7.) that is 2 AB$\angle$2 AC; therefore AB$\angle$AC, that is, the perpendicular is shorter than any one of the oblique lines.

2. If BE=BC, then, as AB is common to the two triangles ABE, ABC, and the right angle ABE=ABC, the triangles ABE, ABC shall be equal, (5.) and AE=AC.

3. In the triangle DFA, the sum of the lines AD, DF is greater than the sum of AC, CF, (8.) that is, 2 AD$>$2 AC; therefore AD$>$AC, that is, the oblique line, which is more remote from the perpendicular, is greater than that which is nearer.

Cor. 1. The perpendicular measures the distance of any point from a straight line.

Cor. 2. From the same point, three equal straight lines cannot be drawn to terminate in a given straight line; for if they could be drawn, then, two of them would be on the same side of the perpendicular, and equal to each other, which is impossible.

Theorem XVI.

Fig. 31. If from C, the middle of a straight line AB, a perpendicular CD be drawn to that line. First, Every point in the perpendicular is equally distant from the extremities of the line AB. Secondly, Every point without the perpendicular is at unequal distances from the same extremities, A B.

1. Let D be any point in CD, then, because the two oblique lines DA, DB are equally distant from the perpendicular, they are equal to one another (15.), therefore every point in CD is equally distant from the extremities of AB.

2. Let E be a point out of the perpendicular; join EA, EB, one of these lines must cut the perpendicular in F; join BF, then AF=BF, and AE=BF+FE; but BF+FE$>$BE, (7.) therefore AE$>$BE, that is, E any point out of the perpendicular is at unequal distances from the extremities of AB.

Theorem XVII.

Plate CCXLI. Fig. 32. Two right-angled triangles are equal, when the hypothenuse and a side of the one are equal to the hypothenuse and a side of the other, each to each.

Let the hypothenuse AC=DF, and the side AB=DE; the triangle ABC shall be equal to DEF. The proposition will evidently be true (10.) if the remaining sides BC, EF are equal. Now, if it be possible to suppose that they are unequal, let BC be the greater, take BG=EF, and join AG; then the triangles ABG, DEF, having the side AB=DE, BG=EF, and the angle B=E, will be equal to one another (5.), and will have the remaining side AG=DF; but by hypothesis DF=AC; therefore AG=AC; but AG cannot be equal to AC (15.), therefore it is impossible that BC can be unequal to EF, and therefore the triangles ABC, DEF are equal to one another.

Theorem XVIII.

Two straight lines AC, ED, which are perpendicular to a third straight line AE, are parallel to each other. Fig. 33.

For if they could meet at a point O, then two perpendiculars OA, OE, might be drawn from the same point O, to the straight line AE, which is impossible (14.).

In the next theorem, it is necessary to assume another axiom, in addition to those already laid down in the beginning of this section.

Axiom.

7. If two points E, G in a straight line AB are situated at unequal distances EF, GH from another straight line CD in the same plane, these two lines, when indefinitely produced, on the side of the least distance GH, will meet each other. Fig. 34.

Theorem XIX.

If two straight lines AB, CD be parallel, the perpendiculars EF, GH to one of the lines, which are terminated by the other line, are equal, and are perpendicular to both the parallels. Fig. 35.

For if EF and GH, which are perpendicular to CD, were unequal, the lines AB, CD would meet each other (by the above axiom) which is contrary to the supposition that they are parallel. And if EF, GH be

not

First Principles.

not perpendicular to AB, let EK be perpendicular to EF, meeting GH in K; then because EK and FH are perpendicular to EF, they are parallel (18.), and therefore, by what has been just shewn, the perpendiculars EF, KH, must be equal; but by hypothesis EF=GH, therefore KH=GH, which is impossible; therefore EF is perpendicular to AB; and in the same way it may be shewn that GH is perpendicular to AB.

Cor. Hence it appears, that through the same point E, no more than one parallel can be drawn to the same straight line CD.

Theorem XX.

Fig. 36. Straight lines AB, EF, which are parallel to the same straight line CD, are parallel to each other.

For let HKG be perpendicular to CD, it will also be perpendicular to both AB and EF (19.), therefore these last lines are parallel to each other.

Theorem XXI.

Fig. 37. If a straight line EF meet two parallel straight lines AB, CD, it makes the alternate angles AEF, EFD equal.

Let EH and GF be perpendicular to CD, then these lines will be parallel (18.), and also at right angles to AB (19.), and therefore FH and GE are equal to one another (19.), therefore the triangles FGE, FHE, having the side FG=HE, and GE=FH, and FE common to both, will be equal; and hence the angle FEG will be equal to EFH, that is, FEA will be equal to EFD.

Cor. 1. Hence if a straight line KL intersect two parallel straight lines AB, CD, it makes the exterior angle KEB equal to the interior and opposite angle EFD on the same side of the line. For the angle AEF=KEB, and it has been shewn that AEF=EFD; therefore KEB=EFD.

Cor. 2. Hence also, if a straight line EF meet two parallel straight lines AB, CD, it makes the two interior angles BEF, EFD on the same side together, equal to two right angles. For the angle AEF has been shewn to be equal to EFD, therefore, adding the angle FEB to both, AEF + FEB=EFD+FEB; but AEF+FEB is equal to two right angles, therefore the sum EFD+FEB is also equal to two right angles.

Theorem XXII.

Fig. 38. If a straight line EF, meeting two other straight lines AB, CD, makes the alternate angles AEF, EFD equal, those lines shall be parallel.

For if AE is not parallel to CD, suppose, if possible, that some other line KE can be drawn through E, parallel to CD; then the angle KEF must be equal to EFD (21.), that is (by hypothesis), to AEF, which is impossible; therefore, neither KE, nor any other line drawn through E, except AB, can be parallel to CD.

Cor. If a straight line EF intersecting two other straight lines AB, CD, makes the exterior angle GEB equal to the interior and opposite angle EFD on the same side; or the two interior angles BEF, EFD on the same side equal to two right angles; in either case the lines are parallel. For, if the angle GEB=EFD, then also AEF=EFD, (4.). And if BEF+EFD= two right angles, then, because BEF+AEF=two right angles (1.), BEF+EFD=BEF+AEF, and taking BEF from both, EFD=AEF, therefore (by the theorem) in each case the lines are parallel.

Theorem XXIII.

Fig. 39. If a side AC of a triangle ABC be produced towards D, the exterior angle BCD is equal to both the interior and opposite angles BAC, ABC.

Let CE be parallel to AB, then the angle B=BCE, (21.) and the angle A=ECD, (1 cor. 21.) therefore B+A=BCE+ECD=BCD.

Cor. The exterior angle of a triangle is greater than either of the interior opposite angles.

Theorem XXIV.

Fig. 40. The three interior angles of a triangle ABC taken together are equal to two right angles.

For if AC be produced to D, then A+B=BCD, (23.); to each of these equal quantities add ACB, then shall A+B+ACB=BCD+BCA; but BCD+BCA =two right angles, (1.) therefore A+B+ACB=two right angles.

Cor. 1. If two angles of one triangle be equal to two angles of another triangle, each to each; the third angle of the one shall be equal to the third angle of the other, and the triangles shall be equiangular.

Cor. 2. If two angles of a triangle, or their sum, be given, the third angle may be found, by subtracting their sum from two right angles.

Cor. 3. In a right-angled triangle, the sum of the two acute angles is equal to a right angle.

Cor. 4. In an equilateral triangle, each of the angles is equal to the third part of two right angles, or to two thirds of one right angle.

Theorem XXV.

Fig. 41. The sum of all the interior angles of a polygon is equal to twice as many right angles wanting four as the figure has sides.

Let ABCDE be a polygon; from a point F within it draw straight lines to all its angles, then the polygon shall be divided into as many triangles as it has sides; but the sum of the angles of each triangle is equal to two right angles, (24.) therefore the sum of all the angles of the triangles is equal to twice as many right angles as there are triangles, that is, as the figure has sides; but the sum of all the angles of the triangles is equal

equal to the sum of all the angles of the polygon, together with the sum of the angles at the point F, which last sum is equal to four right angles, (2 Cor. 4.) therefore the sum of all the angles of the polygon, together with four right angles, is equal to twice as many right angles as the figure has sides, and consequently the sum of the angles of the polygon is equal to twice as many right angles, wanting four, as the figure has sides.

Cor. The four interior angles of a quadrilateral are taken together equal to four right angles.

Theorem XXVI.

Fig. 42. The opposite sides of a parallelogram are equal, and the opposite angles are also equal.

Draw the diagonal BD; the two triangles ADB, DBC have the side BD common to both, and AB, DC being parallel, the angle ABD=BDC (21.) also AD, BC being parallel, the angle ADB=DBC, therefore the two triangles are equal (6.), and the side AB, opposite to the angle ADB, is equal to DC, opposite to the equal angle DBC. In like manner the third side AD is equal to the third side BC, therefore the opposite sides of a parallelogram are equal.

In the next place, because of the equality of the same triangles, the angle A is equal to the angle C, and also the angle ADC composed of the two angles ADB, BDC is equal to the angle ABC composed of the angles CBD, DBA; therefore the opposite angles of a parallelogram are also equal.

Theorem XXVII.

If the opposite sides of a quadrilateral ABCD are equal, so that AB=DC, and AD=BC; then the equal sides are parallel, and the figure is a parallelogram. Fig. 42.

Draw the diagonal BD. The two triangles ABD, CDB have the three sides of the one equal to the three sides of the other, each to each, therefore the triangles are equal (10.); and the angle ADB, opposite to AB, is equal to DBC opposite to DC, therefore the side AD is parallel to BC (22.). For a similar reason AB is parallel to DC; therefore the quadrilateral ABCD is a parallelogram.

Theorem XXVIII.

If two opposite sides AB, DC, of a quadrilateral are equal and parallel, the two other sides are in like manner equal and parallel; and the figure is a parallelogram. Fig. 42.

Draw the diagonal BD. Because AB is parallel to CD, the alternate angles ABD, BDC are equal, (21.); now the side AB=DC, and DB is common to the triangles ABD, BDC, therefore these triangles are equal, (5.) and hence the side AD=BC, and the angle ADB=DBC, consequently AD is parallel to BC, (22.) therefore the figure ABCD is a parallelogram.

SECT. II. OF THE CIRCLE.

Definitions.

Fig. I. A *Circle* is a plane figure contained by one line which is called the *circumference*, and is such, that all straight lines drawn from a certain point within the figure to the circumference, are equal to one another.

And this point is called the *centre* of the circle.

II. Every straight line CA, CE, CD, &c. drawn from the centre to the circumference, is called a *radius* or *semidiameter;* and every straight line, such as AB, which passes through the centre, and is terminated both ways by the circumference, is called a *diameter*.

Hence it follows that all the radii of a circle are equal, and all the diameters are also equal, each being the double of the radius.

III. An *Arch* of a circle is any portion of its circumference, as FHG.

The *chord* or *subtense* of an arch is the straight line FG which joins its extremities.

IV. A *Segment* of a circle is the figure contained by an arch, and its chord. If the figure be the half of the circle it is called a *Semicircle*.

Note. Every chord corresponds to two arches, and consequently to two segments; but in speaking of these, it is always the smallest that is meant, unless the contrary be expressed.

V. A *Sector* of a circle is the figure contained by an arch DE and the two radii CD, CE, drawn to the extremities of the arch. If the radii be at right angles to each other it is called a *Quadrant*.

VI. A straight line is said to be *placed* or *applied* in a circle, when its extremities are in the circumference of the circle as FG. Plate CCXLIII. fig. 115.

VII. A rectilineal figure is said to be *inscribed* in a circle when the vertices of all its angles are upon the circumference of the circle; in this case the circle is said to be *circumscribed* about the figure.

VIII. A straight line is said to *touch* a circle, or to be a *tangent* to a circle, when it meets the circumference in one point only; such, for example, is BD, fig. 49. The point A which is common to the straight line and circle, is called *the Point of Contact*.

IX. A polygon is said to be *described* or *circumscribed* about a circle when all its sides are tangents to the circle; and in this case the circle is said to be *inscribed* in the polygon. Fig. 118.

Theorem I.

Plate CCXLI. fig. 43.

Any diameter AB, divides the circle and its circumference into two equal parts.

For if the figure AEB be applied to AFB, so that the base AB may be common to both, the curve line AEB must fall exactly upon the curve line AFB; otherwise there would be points in the one or the other unequally distant from the centre, which is contrary to the definition of a circle.

Theorem

Of the Circle.

Theorem II.

Fig. 44. Every chord is less than the diameter.

Let the radii CA, CD be drawn from the centre to the extremities of the chord AD; then the straight line AD is less than AC+CD, that is AD<AB.

Theorem III.

A straight line cannot meet the circumference of a circle in more than two points.

For if it could meet it in three, these three points would be equally distant from the centre, and therefore three equal straight lines might be drawn from the same point to the same straight line, which is impossible (2 cor. 15. 1.).

Theorem IV.

Fig. 45. In the same circle, or in equal circles, equal arches are subtended by equal chords, and, conversely, equal chords subtend equal arches.

If the radius AC be equal to the radius EO, and the arch AMD equal to the arch ENG; the chord AD shall be equal to the chord EG.

For the diameter AB being equal to the diameter EF, the semicircle AMDB may be applied exactly upon the semicircle ENGF, and then the curve line AMBD shall coincide entirely with the curve line ENGF, but the arch AMD being supposed equal to ENG, the point D must fall upon G, therefore the chord AD is equal to the chord EG.

Conversely, if the chord AD=EG, the arch AMD is equal to the arch ENG.

For if the radii CD, OG be drawn, the two triangles ACD, EOG have three sides of the one equal to three sides of the other, each to each, viz. AC=EO, CD=OG and AD=EG, therefore these triangles are equal, (10. 1.) and hence the angle ACD=EOG. Now if the semicircle ADB be placed upon EFG, because the angle ACD=EOG, it is evident that the radius CD will fall upon the radius OG, and the point D upon G, therefore the arch AMD is equal to the arch ENG.

Theorem V.

Fig. 45. In the same circle, or in equal circles, the greater arch is subtended by the greater chord, and, conversely, (if the arch be less than half the circumference) the greater chord subtends the greater arch.

For let the arch AH be greater than AD, and let the chords AD, AH, and the radii CD, CH be drawn. The two sides AC, CH, of the triangle ACH, are equal to the two sides AC, CD, of the triangle ACD; and the angle ACH is greater than ACD; therefore the third side AH is greater than the third side AD, (9. 1.) therefore the chord which subtends the greater arch is the greater. Conversely, if the chord AH be greater than AD, it may be inferred (cor. 9. 1.) from the same triangles that the angle ACH is greater than ACD, and that thus the arch AH is greater than AD.

Note. Each of the arches is here supposed less than half the circumference; if they were greater, the contrary property would have place, the arch increasing as the chord diminishes.

Theorem VI.

The radius CG, perpendicular to a chord AB, bisects the chord (or divides it into two equal parts), it also bisects the arch AGB subtended by the chord. Fig. 46.

Draw the radii CA, CB; these radii are two equal oblique lines in respect of the perpendicular CD, therefore they are equally distant from the perpendicular (15. 1.) that is AD=DB.

In the next place, because CG is perpendicular to the middle of AB, every point in CG is at equal distances from A and B, (16. 1.) therefore, if GA, GB be drawn, these lines are equal, and as they are the chords of the arches AG, BG, the arches are also equal. (4.).

Scholium.

Since the centre C, the middle D of the chord AB, and the middle G of the arch subtended by that chord, are three points situated in the same straight line perpendicular to that chord; and that two points in a straight line are sufficient to determine its position; it follows, that a straight line which passes through any two of these points must necessarily pass through the third; and must be perpendicular to the chord. It also follows, that a perpendicular to the middle of a chord passes through the centre, and the middle of the arch subtended by that chord.

Theorem VII.

If three points A, B, C, be taken in the circumference of a circle, no other circumference which does not coincide with the former, can be made to pass through the same three points. Fig. 47.

Let the chords AB, BC be drawn, and let OD, OF be drawn from the centre, perpendicular to, and consequently bisecting those chords. The centre of every circle passing through A and B must necessarily be somewhere in the perpendicular DO, (last theor.) and in like manner the centre of every circle passing through B and C, must be somewhere in the perpendicular OF, therefore the centre of a circle passing through A, B, and C, must be in the intersection of the perpendiculars DO, FO; and consequently can only be at one and the same point O; therefore, only one circle can be made to pass through the same three points A, B, C.

Cor. One circumference of a circle cannot intersect another in more than two points, for if they could have three common points they would have the same centre, and consequently would coincide with each other.

Theorem VIII.

Two equal chords are equally distant from the centre; Fig. 48.

centre; and of unequal chords, that which is nearer the centre is greater than that which is more remote.

Let the chord AB=DE, suppose the chords bisected by the perpendiculars CF, CG, from the centre, and draw the radii CA, CD. The right-angled triangles CAF, CDG have equal hypothenuses CA, CD; the side AF (=½AB) of the one is also equal to the side DG (=½DE) of the other, therefore, their remaining sides CF, CG (which are the distances of the chords from the centre) are equal (17. 1.).

Next let the chord AH be greater than DE; the arch AKH shall be greater than DME. Upon the arch AKH take ANB equal to DME; draw the chord AB, and suppose COF drawn from the centre perpendicular to AB, and CI perpendicular to AH. It is evident that CF>CO, and (15. 1.) CO>CI; much more then is CF>CI; but CF=CG, because the chords AB, DE are equal; therefore CG>CI; that is, the chord nearer the centre is greater than that which is farther from it.

Theorem IX.

Fig. 9. The perpendicular BD, drawn at the extremity of a radius CA, is a tangent to the circle.

For any oblique line CE is greater than the perpendicular CA, (15. 1.) therefore the point E is without the circle; therefore the line BD has but one point A common with the circumference, and consequently it is a tangent to the circle. (Def. 8.).

Scholium.

Through the same point A, only one tangent, AD, can be drawn to the circle. For if it be possible to draw another, let AG be that other tangent; draw CF perpendicular to AG; then CF shall be less than CA, (15. 1.) therefore F must be within the circle; and consequently AF when produced must necessarily meet the circle in another point besides A; therefore it cannot be a tangent.

Theorem X.

Fig. 5[illegible] and 5[illegible] If BC, the distance of the centres of two circles, be less than the sum of their radii; and also the greater radius less than the sum of the distance of their centres and the lesser radius; the two circles intersect each other.

For that the circles may intersect each other in a point A, it is necessary that the triangle ABC be possible; therefore, not only must CB be less than CA +AB, but also the greater radius AB must be less than AC+CB; (7. 1.) and it is evident, that as often as the triangle ABC can be constructed, the circumferences described on the centres B, C, shall intersect each other in two points A, D.

Theorem XI.

Fig. 52. If the distance CB of the centres of two circles be equal to the sum of the radii CA, BA, the circles shall touch each other externally.

It is evident that they have a common point A; but they cannot have more; for if they had two, then the distance of the centres must necessarily be less than the sum of the radii.

Theorem XII.

If the distance CB of the centres of two circles be equal to the difference of the radii, the two circles shall touch each other internally. Fig. 53.

In the first place, it is evident that the point A is common to them both; they cannot, however, have another; for that this may happen, it is necessary that the greater radius AB be smaller than the sum of the radius AC and the distance CB of the centre, (10.) which is not the case.

Cor. Therefore, if two circles touch each other, either internally or externally, their centres and the point of contact are in the same straight line.

Theorem XIII.

In the same circle, or in equal circles, equal angles ACB, DCE, at the centres, intercept upon the circumference equal arches AB, DE. And, conversely, if the arches AB, DE are equal, the angles ACB, DCE are equal. Fig. 54.

First, if the angle ACB be equal to DCE, the one angle may be applied upon the other; and as the lines containing them are equal, it is manifest that the point A will fall upon D, and the point B upon E; thus the arch AB will coincide with, and be equal to the arch DE.

Next, if the arch AB be equal to DE, the angle ACB is equal to DCE; for if the angles are not equal; let ACB be the greater; and let ACI be taken equal to DCE; then, by what has been already demonstrated, the arch AI=DE; but by hypothesis AB=DE; therefore, AI=AB which is impossible; therefore the angle ACB=DCE.

Theorem XIV.

The angle BCD at the centre of a circle is double the angle BAD at the circumference, when both stand on the same arch BD. Fig. 55. Fig. 56.

First let the centre of the circle be within the angle BAD; draw the diameter AE. The exterior angle BCE of the triangle BCA is equal to both the inward and opposite angles BAC, CBA; (23. 1.) but the triangle BCA being isosceles, the angle BAC=CBA; therefore the angle BCE is double of the angle BAC. For the same reason, the angle DCE is double of the angle DAE, therefore the whole angle BCD is double of the whole angle BAD. Fig. 55.

Suppose in the next place that the centre is without the angle BAD; then, drawing the diameter AE, it may be demonstrated, as in the first case, that the angle ECD is double of the angle EAD, and that the angle Fig. 56.

angle ECB, a part of the first, is double the angle EAB a part of the other; therefore the remaining angle BCD is double the remaining angle BAD.

Theorem XV.

Fig. 57. Fig. 58. All angles BAD, BFD in the same segment BAFD of a circle are equal to one another.

Fig. 57. If the segment be greater than a semicircle, from the centre C draw CB and CD; then the angles BAD and BFD being (by last theorem) each equal to half BCD, they must be equal to one another.

Fig. 58. But if the segment BAFD be less than a semicircle, let H be the intersection of BF and AD; then, the triangles ABH and FDH having the angle AHB of the one equal to FHD of the other, (4. 1.) and ABH =FDH, (by case 1.) will have the remaining angles of the one equal to the remaining angles of the other; that is the angle BAH=HFD, or BAD=BFD.

Theorem XVI.

Fig. 59. The opposite angles of any quadrilateral figure ABCD described in a circle are together equal to two right angles.

Draw the diagonals AC, BD; because the angle ABC=ACD, and CBD=CAD, (last theor.) the sum ABD+CBD=ACD+CAD; or ABC=ACD+CAD; to each of these equals add ADC, and ABC+ADC= ACD+CAD+ADC; but the last three angles being the angles of the triangle ADC, are taken together equal to two right angles, (24. 1.) therefore ABC+ADC= two right angles. In the same manner, the angles BAD, BCD may be shewn to be together equal to two right angles.

Theorem XVII.

Fig. 60. In a circle, the angle BAD in a semicircle is a right angle, but the angle ABD in a segment greater than a semicircle is less than a right angle; and the angle AED in a segment less than a semicircle is greater than a right angle.

Let C be the centre, join CA, and produce BA to F. Because CB=CA, the angle CAB=CBA; (11. 1.) and because CD=CA, the angle CAD =CDA, therefore the whole angle BAD=CBA +CDA; but these two last angles are together equal to DAF, (23. 1.) therefore the angle BAD=DAF; and hence each of them is a right angle.

And because ABD+ADB is a right angle, therefore ABD, an angle in a segment greater than a semicircle, is less than a right angle.

And because ABDE is a quadrilateral in a circle, the opposite angles B and E are equal to two right angles (last theor.), but B is less than a right angle; therefore the angle E, which is in a segment less than a semicircle, is greater than a right angle.

Theorem XVIII.

The angle BAC contained by AC, a tangent, and AB, a chord drawn from the point of contact, is equal to any angle ADB in the alternate segment of the circle. Fig. 61.

Draw the diameter AE, and join DE. The angles EAC, EDA, being right angles, (last theor.) are equal to one another; and of these, EAB, a part of the one, is equal to EDB, a part of the other (15.) therefore the remainder, BAC, of the former is equal to the remainder, BDA, of the latter.

SECT. III. OF PROPORTION.

Definitions.

I. When one magnitude contains another a certain number of times exactly, the former is said to be a *multiple* of the latter, and the latter a *part* of the former.

II. When several magnitudes are multiples of as many others, and each contains its parts the same number of times, the former are said to be *equimultiples* of the latter, and the latter *like parts* of the former.

III. Betwixt any two finite magnitudes of the same kind there subsists a certain relation in respect to quantity, which is called their *ratio*. The two magnitudes compared are called the *terms* of the ratio, the first the *antecedent*, and the second the *consequent*.

IV. If there be four magnitudes, or quantities, A, B, C, D, and if A contain some part of B just as often as C contains a like part of D, then, the ratio of A to B is said to be the same with (or equal to) the ratio of C to D.

It follows immediately from this definition, that if A contain B just as often as C contains D, then the ratio of A to B is equal to the ratio of C to D; for in that case it is evident that A will contain any part of B just as often as C contains a like part of D.

V. When two ratios are equal, their terms are called *proportionals*.

To denote that the ratio of A to B is equal to the ratio of C to D, they are usually written thus, A : B :: C : D, or thus, A : B=C : D, which is read thus; A is to B as C to D; such an expression is called an *analogy* or a *proportion*.

VI. Of four proportional quantities, the last term is called a *fourth proportional* to the other three taken in order.

VII. Three quantities A, B, C, are said to be proportionals, when the ratio of the first A to the second B is equal to the ratio of the second B to the third C.

VIII. Of three porportional quantities, the middle term is said to be a *mean proportional* between the other two, and the last a *third proportional* to the first and second.

IX. Quantities are said to be *continual proportionals*, when the first is to the second, as the second to the third, and as the third to the fourth, and so on.

X. When there is any number of magnitudes A, B, C, D, of the same kind, the ratio of the first A to the last D is said to be compounded of the ratio of A

Of Proportion.

A to B, and of the ratio of B to C, and of the ratio of C to D.

XI. If three magnitudes A, B, C, be continual proportionals; that is, if the ratio of A to B be equal to the ratio of B to C; then the ratio of the first A to the third C is said to be *duplicate* of the ratio of the first A to the second B. Hence, since by the last definition the ratio of A to C is compounded of the ratio of A to B and of B to C, a ratio which is compounded of two equal ratios is *duplicate* of either of them.

XII. If four magnitudes A, B, C, D be continual proportionals, the ratio of the first A to the fourth D is said to be *triplicate* the ratio of the first A to the second B. Hence a ratio compounded of three equal ratios is triplicate of any one of them.

XIII. *Ratio of Equality* is that which equal magnitudes bear to each other.

The next four definitions explain the names given by geometers to certain ways of changing either the order or magnitude of proportionals, so that they still continue to be proportional.

XIV. *Inverse Ratio* is when the antecedent is made the consequent, and the consequent the antecedent. See Theor. 3.

XV. *Alternate* proportion is when antecedent is compared with antecedent, and consequent with consequent. See Theor 2.

XVI. *Compounded* ratio is when the sum of the antecedent and consequent is compared either with the antecedent, or with the consequent. See Theor. 4.

XVII. *Divided* ratio is when the difference of the antecedent and consequent is compared either with the antecedent or with the consequent. See Theor. 4.

Axioms.

1. Equal quantities have each the same ratio to the same quantity; and the same quantity has the same ratio to each of any number of equal quantities.

2. Quantities having the same ratio to one and the same quantity, or to equal quantities, are equal among themselves; and those quantities, to which one and the same quantity has the same ratio, are equal.

3. Ratios equal to one and the same ratio are also equal, one to the other.

4. If two quantities be divided into, or composed of parts that are equal among themselves, or all of the same magnitude, then will the whole of the one have the same ratio to the whole of the other, as the number of parts in the one has to the number of equal parts in the other.

Theorem I.

Equimultiples of any two quantities have to each other the same ratio as the quantities themselves.

Let A and B be any two quantities, and, m being put to denote any number, let m A, m B be equimultiples of those quantities, m A shall have to m B the same ratio that A has to B.

Let the ratio of A to B be equal to the ratio of one number p to another number q, that is, let A contain p such equal parts as B contains q, (Ax. 4.) then, if x be put for one of those equal parts, we have

$$A=p\,x,\ B=q\,x,$$

and consequently, multiplying both by the same number m,

$$m\,A=m\,p\,x,\ m\,B=m\,q\,x,$$

or, which is evidently the same,

$$m\,A=p\times m\,x,\ m\,B=q\times m\,x.$$

Hence it appears that m A contains the quantity $m\,x$ as a part p times; and that m B contains the same quantity q times; therefore the ratio of m A to m B is the same as the ratio of the number p to the number q (Ax. 4.); but the ratio of A to B is also equal to the ratio of p to q, (by hypothesis), therefore the ratio of m A to m B is equal to the ratio of A to B (Ax. 3.).

Cor. Hence like parts of quantities have to each other the same ratio as the wholes: that is, $\frac{A}{m} : \frac{B}{m} :: A : B$; for A and B are equimultiples of $\frac{A}{m}$ and $\frac{B}{m}$.

Theorem II.

If four quantities of the same kind be proportionals, they shall also be proportionals by alternation.

Let A, B, C, D be four quantities, of the same kind, and let A : B :: C : D; then shall A : C :: B : D.

Let the equal ratios of A to B, and of C to D, be the same as the ratio of the number p to the number q; then A will contain p such equal parts as B contains q, (Ax. 4.) and C will, in like manner, contain p such equal parts as D contains q; let each of the equal parts thus contained in A and B be x, and let each of those contained in C and D be y, then

$$A=p\,x,\ B=q\,x,\ C=p\,y,\ D=q\,y.$$

Now as $A=p\,x$, and $C=p\,y$; it is manifest that A and C are equimultiples of x and y, therefore the ratio of A to C is equal to the ratio of x to y, (1.) and as $B=q\,x$, and $D=q\,y$, B and D are in like manner equimultiples of x and y; therefore the ratio of B to D is equal to the ratio of x to y; therefore the ratio of A to C is equal to the ratio of B to D.

Cor. If the first of four proportionals be greater than the third, the second is greater than the fourth; and if the first be less than the third, the second is less than the fourth.

Theorem III.

If four quantities be proportionals, they are also proportionals by inversion.

Let A : B :: C : D; then shall B : A :: D : C.

For let the equal ratios of A to B, and of C to D, be the same as the ratio of the number p to the number q, then as B will contain q such equal parts as A contains

Of Proportion.

tains p (Ax. 4.), B will be to A as q is to p, and as D will contain q such equal parts as C contains p, D will be to C also as q to p, therefore the ratio of B to A is equal to the ratio of D to C (Ax. 3.).

Theorem IV.

If four quantities be proportionals, they are also proportionals by composition, and by division.

Let A : B :: C : D, then will
A+B : A :: C+D : C, and A+B : B :: C+D : D;
also A—B : A :: C—D : D, and A—B : B :: C—D : D.

Let us suppose, as in the two preceding theorems, that the ratios of A to B, and of C to D, are each equal to the ratio of the number p to the number q, so that A contains p such equal parts as B contains q, and C contains p such equal parts as D contains q; and let x as before denote each of the equal parts contained in A and B, and y each of the equal parts contained in C and D; then, since

$$A=px, \quad B=qx, \quad C=py. \quad D=qy,$$

therefore $A+B=px+qx=(p+q)x$;
$C+D=py+qy=(p+q)y$.

Now as A+B contains x $p+q$ times, and A contains the same quantity p times, and B contains it q times, (by the 4th axiom),

$$A+B : A :: p+q : p, \text{ and } A+B : B :: p+q : q,$$

and as C+D contains y $p+q$ times, and C contains it p times, and D contains it q times,

$$C+D : C :: p+q : p, \text{ and } C+D : D :: p+q : q.$$

Thus it appears that the ratios of A+B to A, and of C+D to C, are equal to the same ratio, namely, that of $p+q$ to p; therefore (Ax. 3.) A+B : A :: C+D : C. It also appears that the ratios of A+B to B, and C+D to D are each equal to the ratio of $p+q$ to q; therefore (Ax. 3.) A+B : B :: C+D : D.

In the same manner the second part of the theorem may be proved, namely, that
A—B : A :: C—D : C and A—B : B :: C—D : D.

Theorem V.

If four quantities be proportionals, and there be taken any equimultiples of the antecedents, and also any equimultiples of the consequents; the resulting quantities will still be proportionals.

Let A : B :: C : D, and m A, m C be any equimultiples of the antecedents, and n B, n D any equimultiples of the consequents; then m A : n B :: m C : n D.

The quantities p, q, x and y being supposed to express the same things as in the foregoing theorems; because

$$A=px, \quad B=qx, \quad C=py, \quad D=qy,$$

therefore, multiplying the antecedents by the number m, and the consequents by n,

$$mA=mpx, \quad nB=nqx,$$
$$mC=mpy, \quad nD=nqy,$$

and hence the ratio of m A to n B is equal to the ratio of the number mp to the number nq, (Ax. 4.) and the ratio of m C to n D, is equal to the same ratio of mp to nq, therefore (Ax. 3.) m A : n B :: m C : n D.

Theorem VI.

If there be any number of quantities, and as many others, which, taken two and two, have the same ratio; the first shall have to the last of the first series the same ratio which the first of the other series has to the last.

First, let there be three quantities A, B, C, and other three H, K, L, and let A : B :: H : K, and B : C :: K : L, then will A : C :: H : L.

A,	B,	C,
H,	K,	L

For let the equal ratios of A to B, and of H to K, be the same with the ratio of a number p to another number q, so that x and y being like parts of A and H, and also like parts of B and K, as in the former theorems,

$$A=px, B=qx, H=py, K=qy.$$

Also let C contain q equal parts, each equal to v, and let L contain q equal parts, each equal to z, so that

$$C=qv, \quad L=qz,$$

then because B : C :: K : L, that is, $qx : qv :: qy : qz$, and qx and qv are equimultiples of x and v, also qy and qz are equimultiples of y and z, therefore (1. & Ax. 3.) $x : v :: y : z$, hence (by last theorem) $px : qv :: py : qz$, that is, (because $A=px$, $C=qv$, $H=py$, $L=qz$) A : C :: H : L.

Next, let these four quantities, A, B, C, D, and other four H, K, L, M, such, that A : B :: H : K, and B : C :: K : L, and C : D :: L : M, then will A : D :: H : M.

A,	B,	C,	D,
H,	K,	L,	M.

For, because A : B :: H : K, and B : C :: K : L; therefore, by the first case, A : C :: H : L; and because C : D :: L : M, therefore by the same case, A : D :: H : M. The demonstration applies in the same manner to any number of quantities.

Cor. Hence it appears, that ratios compounded of the same number of like or equal ratios are equal to one another.

Note.—When four quantities are proportionals in the manner explained in this theorem, they are said to be so from *equality of distance*; and it is usual for mathematical writers to say that they are so, *ex æquali* or *ex æquo*.

Theorem VII.

If there be any number of quantities, and as many others, which taken two and two in a crofs order have the same ratio; the first shall have to the last of the first series the same ratio which the first has to the last of the other series.

First, let there be three quantities A, B, C, and other three H, K, L, such that A : B :: K : L, and B : C :: H : K; then will A : C :: H : L.

A, B, C,
H, K, L.

For let the equal ratios of A to B, and of K to L be equal to the ratio of the number p to the number q, so that as before.

$$A=p\,x,\ B=q\,x,\ K=p\,y,\ L=q\,y.$$

Also, let C be supposed to contain q equal parts, each equal to z, and let H contain p equal parts, each equal to v, so that

$$C=q\,z,\ H=p\,v;$$

Then, because B : C :: H : K, that is, $q\,x : q\,z :: p\,v : p\,y$; therefore (1. & Ax. 3.) $x : z :: v : y$, and consequently (5.) $p\,x : q\,z :: p\,v : q\,y$, that is (because $p\,x$ =A, $q\,z$=C, $p\,v$=H, $q\,y$=L) A : C :: H : L.

Next, let there be four quantities A, B, C, D, and other four H, K, L, M such, that A : B :: L : M, and B : C :: K : L, and C : D :: H : K, then will A : D :: H : M; for because A : B :: L : M, and B : C :: K : L; by the foregoing case A : C :: K : M; and again because C : D :: H : K; therefore, by same case, A : D :: H : M. The demonstration applies in the same manner to any number of quantities.

A, B, C, D,
H, K, L, M.

Note.—In this theorem, as in the last, the four quantities A, D, H, M, are said to be proportionals from *equality of distance;* but because in this case the proportions are taken in a cross order, it is common to say, that they are so, *ex æquali, in proportione perturbata*, or *ex æquo inversely.*

Theorem VIII.

If to the two consequents of four proportionals there be added any two quantities that have the same ratio to the respective antecedents, these sums and the antecedents will still be proportionals.

Let A : B :: C : D
and A : B′ :: C : D′

(where B′ and D′ denote two quantities distinct from those denoted by B and D); then will

$$A : B+B' :: C : D+D'.$$

For since A : B :: C : D, by inversion, (3.) B : A :: D : C, but A : B′ :: C : D′, therefore (6.) B : B′ :: D : D′, and by composition, (4.) and inversion B : B+B′ :: D : D+D′, and since A : B :: C : D; therefore (6.) A : B+B′ :: C : D+D′.

Cor. 1. If instead of two quantities B′, D′, there be any number B′, B″, &c. and D′, D″, &c. which taken two and two have the same ratio to the antecedents A, C, that is, if

$$A : B :: C : D,$$
$$A : B' :: C : D',$$
$$A : B'' :: C : D'';$$

then will A : B+B′+B″ :: C : C+D′+D″.

For since A : B+B′ :: C : D+D′ (by the theor.)
and A : B″ :: C : D″,

therefore, by the proposition,

$$A : B+B'+B'' :: C : D+D'+D''.$$

Cor. 2. If any number of quantities of the same kind be proportionals, as one of the antecedents is to its consequent, so is the sum of all the antecedents to the sum of all the consequents.

Let A : B :: C : D :: E : F,

then because A : A :: B : B,
and A : C :: B : D,
and A : E :: B : F;

therefore, A : A+C+E :: B : B+D+F; and by alternation,

$$A : B :: A+C+E : B+D+F.$$

In treating of proportion we have supposed that the antecedent contains some part of the consequent a certain number of times exactly, which part is therefore a common measure of the antecedent and consequent. But there are quantities which cannot have a common measure, and which are therefore said to be *incommensurable;* such, for example, are the sides of two squares, one of which has its surface double that of the other.

Although the ratio of two incommensurable quantities cannot be expressed in numbers, yet we can always assign a ratio in numbers which shall be as near to that ratio as we please. For let A and B be any two quantities whatever, and suppose that x is such a part of A that A=$p\,x$; then if q denote the number of times that x can be taken from B, and d the remainder, we have B=$q\,x+d$, and $q\,x$=B—d; and because $p : q :: p\,x : q\,x$, therefore $p : q$ :: A : B—d. Now as d is less than x, by taking x sufficiently small d may be less than any proposed quantity, so that B—d may differ from B by less than any given quantity; therefore two numbers p and q may always be assigned, such, that the ratio of p to q shall the same as the ratio of A to a quantity that differs less from B than by any given quantity, however small that quantity may be.

Hence we may conclude, that whatever has been delivered in this section relating to commensurable quantities, may be considered as applying equally to such as are incommensurable.

SECT. IV. THE PROPORTIONS OF FIGURES.

Definitions.

I. *Equivalent Figures* are such as have equal surfaces.

Two figures may be equivalent, although very dissimilar; thus a circle may be equivalent to a square, a triangle to a rectangle, and so of other figures.

We shall give the denomination of *equal* figures to those

Proportions of Figures. those which, being applied the one upon the other, coincide entirely; thus, two circles having the same radius are equal; and two triangles having three sides of the one equal to three sides of the other, each to each, are all equal.

II. Two figures are *similar*, when the angles of the one are equal to the angles of the other, each to each; and the *homologous* sides proportionals. The homologous sides are those which have the same position in the two figures; or which are adjacent to the equal angles. The angles themselves are called *homologous angles*.

Two equal figures are always similar, but similar figures may be very unequal.

III. In two different circles, *similar sectors*, *similar arches*, *similar segments*, are such as correspond to equal angles at the centre. Thus the angle A being equal to the angle O, the arch BC is similar to the arch DE, and the sector ABC to the sector ODE, &c. Fig. 62.

IV. The *Altitude of a parallelogram* is the perpendicular which measures the distance between the opposite sides or bases AB, CD. Fig. 63. Plate CCXLII.

V. The *Altitude of a triangle* is the perpendicular AD drawn from the vertical angle A upon the base BC. Fig. 64.

VI. The *Altitude of a trapezoid* is the perpendicular EF drawn between its two parallel bases AB, CD. Fig. 65.

VII. The *Area* and the surface of a figure are terms of nearly the same signification. The term *area*, however, is more particularly used to denote the superficial quantity of the figure in respect of its being measured, or compared with other surfaces.

Theorem I.

Fig. 66. Parallelograms which have equal bases and equal altitudes are equivalent.

Let AB be the common base of the parallelograms ABCD, EBAF, which being supposed to have the same altitude, the sides DC, FE opposite to the bases will lie in DE a line parallel to AB. Now, from the nature of a parallelogram, AD=BC, and AF=BE; for the same reason DC=AB, and FE=AB; therefore, DC=FE, and taking away DC and FE from the same line DE, the remainders CE and DF are equal; hence the triangles DAF, CBE have three sides of the one equal to three sides of the other, each to each; and consequently are equal (10. 1.). Now if from the quadrilateral ABED, the triangle ADF be taken away, there will remain the parallelogram ABEF; and if from the same quadrilateral ABED, the triangle CBE, equal to the former, be taken away, there will remain the parallelogram ABCD; therefore the two parallelograms ABCD, ABEF, which have the same base, and the same altitude, are equivalent.

Cor. Every parallelogram is equivalent to a rectangle of the same base and altitude.

Theorem II.

Fig. 67. Every triangle ABC is the half of a parallelogram ABCD, having the same base and altitude.

For the triangles ABC, ACD are equal (28. 1.).

Cor. 1. Therefore a triangle ABC is the half of a rectangle BCEF of the same base and altitude.

Cor. 2. All triangles having equal bases, and equal altitudes, are equivalent.

Theorem III.

Fig. 69. Two rectangles of the same altitude are to each other as their bases.

Let ABCD, AEFD be two rectangles, which have a common altitude AD; the rectangle ABCD shall have to the rectangle AEFD the same ratio that the base AB has to the base AE.

Let the base AB have to the base AE the ratio of the number p (which we shall suppose 7.) to the number q (which may be 4.) that is, let AB contain p (7.) such equal parts as AE contains q (4.), then, if perpendiculars be drawn to AB and AE at the points of division, the rectangles ABCD and AEFD will be divided, the former into p, and the latter into q rectangles, which will be all equal (1.) for they have equal bases, and the same altitude; thus the rectangle ABCD will also contain p such equal parts as the rectangle AEFD contains q; therefore the rectangle ABCD is to AEFD as the number p to the number q (Ax. 4. 3.), that is, as the base AB to AE.

Theorem IV.

Fig. 71. Any two rectangles are to each other as the products of any numbers proportional to their sides.

Let the numbers m, n, p, q, have among themselves the same ratios that the sides of the rectangles ABCD, AEFG have to each other; that is, let AB contain m such equal parts, whereof AD contains n, and AE contains p, and AF contains q; then shall ABCD : AEFG :: $m\,n : p\,q$.

Let the rectangles be so placed that the sides AB, AE may be in a straight line, then AD and AG will also lie in a straight line (3. 1.). Now (3.)

ABCD : AEHD :: AB : AE :: $m : p$,

but $m : p :: nm : np$, (1. 3.)

therefore ABCD : AEHD :: $nm : np$.

Again, AEHD : AEFG :: AD : AG :: $n : q$;

but $n : q :: pn : pq$;

therefore, AEHD : AEFG :: $pn : pq$;

and it was shewn that

ABCD : AEHD :: $nm : np$ or pn,

therefore, (6. 3.) ABCD : AEFG :: $mn : pq$.

Scholium.

Hence it appears, that the product of the base by the altitude of a rectangle may be taken for its measure, observing that by such product is meant that of the number of linear units in the base by the number of linear units in the altitude. This measure is however not absolute, but relative, for it must be supposed, that in comparing one rectangle with another, the sides of both are measured by the same linear unit. For example, if the base of a rectangle A be three units, and its altitude 10, the rectangle is represented by 3×10 or 30; this number considered by itself has no meaning,

Proportions of Figures.

meaning, but if we have a second rectangle B, the base of which is twelve units, and altitude seven, this second rectangle shall be represented by the number 12×7 or 84; and hence it may be concluded that the two rectangles are to each other as 30 to 84; therefore, if in estimating any superficies the rectangle A be taken for the measuring unit, the rectangle B shall have for its absolute measure $\frac{84}{30}$, that is, it shall be $\frac{84}{30}$ superficial units.

It is more common, as well as more simple, to take for a superficial unit a square, the side of which is an unit in length; and then the measure which we have regarded only as relative becomes absolute; for example the number 30, which is the measure of the rectangle A, represents 30 superficial units or 30 squares, each having its side equal to an unit. To illustrate this, see fig. 72.

Theorem V.

Fig.

The area of any parallelogram is equal to the product of its base by its altitude.

For the parallelogram ABCD is equivalent to the rectangle FBCE, which has the same base BC, and the same altitude AO (Cor. 1.); but the measure of the rectangle is $BC \times AO$, (4.) therefore the area of the parallelogram is $BC \times AO$.

Cor. Parallelograms having the same base, or equal bases, are to each other as their altitudes; and parallelograms having the same altitude are to each other as their bases; for in the former case put B for the common base and A and A′ for the altitudes, then the areas of the figures are $B \times A$ and $B \times A'$; and it is manifest that $B \times A : B \times A' :: A : A'$; and in the latter case, putting A for the common altitude, and B and B′ for the bases, it is evident that $B \times A : B' \times A :: B : B'$.

Theorem VI.

Fig. 6

The area of a triangle is equal to the product of its base by the half of its altitude.

For the triangle ABC is half of the parallelogram ABCD, which has the same base BC, and the same altitude AO (2.), but the area of the parallelogram is $BC \times AO$ (5.), therefore that of the triangle is $\frac{1}{2}$ BC $\times$AO, or $BC \times \frac{1}{2}$ AO.

Cor. Two triangles of the same altitude are to each other as their bases; and two triangles having the same base are to each other as their altitudes.

Theorem VII.

Fig. 7

The area of a trapezoid ABCD is equal to the product of its altitude EF by half the sum of its parallel sides AB, CD.

Through the point I, the middle of BC, draw KL parallel to the opposite side AD, and produce DC to meet KL. In the triangles IBL, ICK, IB is equal to IC by construction, and the angle CIK=BIL, and the angle ICK=IBL (21. 1.) therefore these triangles are equal; and hence the trapezoid ABCD is equivalent to the parallelogram ALKD, and has for its measure $AL \times EF$. But AL=DK, and because the triangle IBL is equal to the triangle KCI, the side BL=CK, therefore AB+CD=AL+DK=2AL; hence AL is half the sum of the parallel sides AB, CD; and as the area of the trapezoid is equal to $FE \times AL$, it is also equal to $FE \times \left(\frac{AB+CD}{2}\right)$.

Theorem VIII.

Fig. 69.

If four straight lines AB, AC, AD, AE, be proportionals; the rectangle ABFE, contained by the two extremes, is equivalent to the rectangle ACGD contained by the means. And conversely, if the rectangle contained by AB, AE, the extremes, be equivalent to the rectangle contained by AC, AD the means, the four lines are proportionals.

Let the rectangles be so placed as to have the common angle A, and let BF, DG intersect each other in H. Because the rectangles ABHD, ACGD have the same altitude AD,

ABHD : ACGD :: AB : AC; (3.),

and because the rectangles ABHD, ABFF have the same altitude AB, for the same reason

ABHD : ABFE :: AD : AE;

but by hypothesis AB : AC :: AD : AE, therefore (Ax. 3. 3.) ABHD : ACGD :: ABHD : ABFE, therefore (Ax. 2. 3.) the rectangle ACGD=ABFE.

Next suppose that the rectangle ACGD=ABFE; then ABHD : ACGD :: ABHD : ABFE, (Ax, 1. 3.) but ABHD : ACGD :: AB : AC, (3.) and ABHD : ABFE :: AD : AE, therefore AB : AC :: AD : AE.

Cor. If three straight lines be proportionals, the rectangle contained by the extremities is equal to the square of the mean; and if the rectangle contained by the extremes be equal to the square of the mean, the three straight lines are proportionals.

Theorem IX.

Fig. 70.

If four straight lines be proportionals, and also other four, the rectangles contained by the corresponding terms shall be proportionals; that is, if AB : BC :: CD : DE, and BF : BG :: DH : DI, then shall *rectangle* AF : *rect.* BM :: *rect.* CH : *rect.* DQ.

For in BG and DI, produced if necessary, take BF=BF, and DH=DH, and let FP be parallel to BC, and HN to DE; then (3.)

rect. AF : *rect.* BP :: AB : BC,
and *rect.* CH : *rect.* DN :: CD : DE;

but AB : BC :: CD : DE, (by hypothesis) therefore,

rect. AF : *rect.* BP :: *rect.* CH : *rect.* DN;

now (3.) *rect.* BP : *rect.* BM :: BF : BG, and *rect.* DN : *rect.* DQ :: DH : DI; but BF : BG :: DH : DI, (by hypoth.) therefore,

rect. BP : *rect.* BM :: *rect.* DN : *rect.* DQ;

but

Proportions of Figures. but it has been shewn that

rect. AF : rect. BP :: rect. CH : rect. DN,

therefore (6. 3.)

rect. AF : rect. BM :: rect. GH : rect. DQ.

Cor. Hence the squares of four proportional straight lines are themselves proportionals.

Theorem X.

Fig. 74. If a straight line AC be divided into any two parts at B, the square made upon the whole line AC shall be equal to the squares made upon the two parts AB, BC, together with twice the rectangle contained by those two parts: which may be expressed thus, $AC^2=AB^2+BC^2+2AB\times BC$.

Suppose the square ACDE to be constructed; take AF=AB, draw FG parallel to AC, and BH parallel to CD.

The square ACDE is made up of four parts; the first ABIF is the square upon AB, because AF=AB; the second IDGH is the square upon BC, for AC=AE, and AB=AF, therefore AC—AB=AE—AF, that is BC=EF; but BC=IG, and EF=DG, (26. 1.) therefore IGDH is the square upon BC, and the remaining two parts are the two rectangles BCGI, FEHI, which have each for their measure $AB\times BC$, therefore the square upon AC is equal to the squares upon AB and BC, and twice the rectangle $AB\times BC$.

Theorem XI.

Fig. 75. If a straight line AC be the difference of two straight lines AB, BC; the square made upon AC shall be equal to the excess of the two squares upon AB and BC above twice the rectangle contained by AB and BC; that is,

$$AC^2=AB^2+BC^2-2AB\times BC.$$

Construct the square ABIF, take AE=AC, and draw CG parallel to BI, and HK parallel to AB; and complete the square EFLK. The two rectangles CBIG, GLKD have each $AB\times BC$ for their measure; and if these be taken from the whole figure ABILKEA, that is from AB^2+BC^2, there will remain the square ACDE, that is, the square upon AC.

Theorem XII.

Fig. 76. The rectangle contained by the sum and the difference of two straight lines is equal to the difference of the squares upon those lines; that is,

$$(AB+BC)\times(AB-BC)=AB^2-BC^2.$$

Construct upon AB and AC the squares ABIF, ACDE; produce AB, so that BK=BC, and complete the rectangle AKLE. The base AK of the rectangle is the sum of the two lines AB, BC; and its altitude AE is the difference of the same lines; therefore, the rectangle AKLE=(AB+BC) (AB—BC); but the same rectangle is composed of two parts ABHE+BHLK, of which, BHLK is equal to the rectangle EDGF, for BH=DE, and BK=FE; therefore, AKLE=ABHE+EDGF; but these two parts constitute the excess of the square ABIF above the square DHIG, the former of which is the square upon AB, and the latter the square upon BC, therefore $(AB+BC)\times(AB-BC)=AB^2-BC^2$.

Theorem XIII.

Fig. The square upon the hypothenuse of a right-angled triangle is equal to the sum of the squares upon the two other sides.

Let ABC be a right-angled triangle; having formed the squares upon its three sides, draw a perpendicular AD from the right angle upon the hypothenuse, and produce it to E, and draw the diagonals AF, CH. The angle ABF is evidently the sum of ABC and a right angle, and the angle HBC is also the sum of ABC and a right angle; therefore the angle ABF=HBC; now AB=BH, for they are sides of the same square, and BC=BF for the same reason, therefore the triangles ABF, HBC have two sides, and the included angle of the one equal to two sides and the included angle of the other, each to each, therefore the triangles are equal (5. 1.) but the triangle ABF is the half of the rectangle BDEF (which for brevity's sake we shall call BE) because it has the same base BF, and the same altitude BD, (2.) and the triangle HBC is in like manner half of the square AH, for the angles BAC, BAL being both right angles, CA and AL constitute a straight line parallel to BH, (3. 1.) and thus the triangle HBC, and the square AH have the same base HB, and the same altitude AB; from which it follows that the triangle is half of the square (2). It has now been proved that the triangle ABF is equal to the triangle HBC; and that the rectangle BE is double of the former, and the square AH double of the latter; therefore the rectangle BE is equal to the square AH. It may be demonstrated in like manner that the rectangle CDEG, or CE, is equal to the square AI; but the rectangles BE, CE make up the square BCGF, therefore the square BCGF upon the hypothenuse is equal to the squares ALHB, AKIC upon the other two sides.

Theorem XIV.

Fig. In a triangle ABC, if the angle C is acute, the square of the opposite side AB is less than the squares of the sides which contain the angle C; and if AD a perpendicular be drawn to BC from the opposite angle, the difference shall be equal to twice the rectangle $BC\times CD$; that is,

$$AB^2=AC^2+CB^2-2BC\times CD.$$

First. Suppose AD to fall within the triangle, then BD=BC—CD, and consequently (11.) $BD^2=BC^2+CD^2-2BC\times CD$; to each of these equals add AD^2; then, observing that $BD^2+DA^2=BA^2$, and $CD^2+DA^2=CA^2$,

$$AB^2=BC^2+CA^2-2BC\times CD.$$

Next, suppose AD to fall without the triangle, so that BD=CD—BC, and therefore $BD^2=CD^2+BC^2-2BC\times CD$, (11.) to each of these add AD^2 as before,

before, and we get

$$AB^2 = BC^2 + CA^2 - 2BC \times CD.$$

Theorem XV.

In a triangle ABC, if the angle C is obtuse, the square of the opposite side AB is greater than the sum of the squares of the sides which contain the angle C; and if AD a perpendicular be drawn to BC from the opposite angle, the difference shall be equal to twice the rectangle $BC \times CD$, that is,

$$AB^2 = AC^2 + BC^2 + 2BC \times CD$$

For $BD = BC + CD$, and therefore (10.) $BD^2 = BC^2 + CD^2 + 2BC \times CD$; to each of these equals add AD^2, then, observing that $AD^2 + DB^2 = AB^2$, and $AD^2 + DC^2 = AC^2$,

$$AB^2 = BC^2 + CA^2 + 2BC \times CD.$$

Scholium.

It is only when a triangle has one of its angles a right angle, that the sum of the squares of two of its sides can be equal to the squares of the third side; for if the angle contained by those sides be acute, the sum of their squares is greater than the square of the opposite side, and if the angle be obtuse, that sum is less than the square of the opposite side.

Theorem XVI.

Fig.

If a straight line AE be drawn from the vertex of any triangle ABC to the middle of its base BC; the sum of the squares of the sides is equal to twice the square of half the base, and twice the square of the line drawn from the vertex to the middle of the base; that is, $AB^2 + AC^2 = 2BE^2 + 2AE^2$;

Draw AD perpendicular to BC, then

$$AB^2 = BE^2 + EA^2 - 2BE \times ED, \ (14.)$$
$$\text{and } AC^2 = CE^2 + EA^2 + 2CE \times ED, \ (15.)$$

therefore, by adding equals to equals, and observing that $BE = CE$, and therefore $BE^2 = CE^2$, and $2BE \times ED = 2CE \times ED$,

$$AB^2 + AC^2 = 2BE^2 + 2AE^2.$$

Theorem XVII.

Fig.

A straight line DE drawn parallel to one of the sides of a triangle ABC divides the other two sides AB, AC proportionally, so that AD : DB :: AE : EC.

Join BE and CD. The triangles BDE, CDE, having the same base DE, and the same altitude, are equivalent, (2) and the triangles ADE, BDE, having the same altitude, are to one another as their bases, (6.) that is, ADE : BDE :: AD : DB; the triangles ADE, CDE, having also the same altitude, are to one another as their bases; that is, ADE : CDE :: AE : EC, but the triangle BDE has been proved equal to CDE; therefore, because of the common ratio in the two proportions, we have (Ax. 3.)

AD : DB :: AE : EC.

Cor. Hence by composition AB : AD :: AC : AE; and AB : BD :: AC : CE.

Theorem XVIII.

Conversely, if two of the sides AB, AC of a triangle are divided proportionally by the straight line DE, so that AD : DB :: AE : EC, then shall the line DE be parallel to the remaining side BC. Fig. 81.

For if DE is not parallel to BC, suppose some other line DO to be parallel to BC; then, AB : BD :: AC : CO (17.); and since by hypothesis AD : DB :: AE : EC, and consequently, by composition, AE : BD :: AC : CE, therefore, AC : CO :: AC : CE; therefore, CO=CE (2 Ax. 3.) which is impossible; therefore DO is not parallel to BC.

Cor. If it be supposed that BA : AD :: CA : AE, still DE will be parallel to BC; for by division BD : AD :: CE : AE, this proportion being the same as in the Theorem, the conclusion must be the same.

Theorem XIX.

A straight line AD, which bisects the angle BAC of a triangle, divides the base BC into two segments proportional to the adjacent sides BA, AC; that is, BD : DC :: BA : AC. Fig. 82.

Through the point C draw CE parallel to AD, so as to meet BA produced. In the triangle BCE, the line AD is parallel to one of its sides CE, therefore BD : DC :: BA : AE; now the triangle CAE is isosceles, for, because of the parallels AD, CE, the angle ACE=DAC, and the angle AEC=BAD, (21. 1.) but by hypothesis DAC=BAD; therefore ACE=AEC; and consequently AE=AC, (12. 1.) therefore, substituting AC instead of AE in the above proportion, it becomes BD : DC :: BA : AC.

Theorem XX.

If two triangles be equiangular, their homologous sides are proportional, and the triangles are similar. Fig. 84.

Let ABC, CDE be two equiangular triangles, which have the angle BAC=CDE, ABC=DCE, and ACB=DEC; the homologous sides, or the sides adjacent to the equal angles, shall be proportional; that is, BC : CE :: AB : CD :: AC : DE.

Place the homologous sides BC, CE in the same direction, and produce the sides BA, ED, till they meet in F. Because BCE is a straight line, and the angle BCA is equal to CED, the lines CA, EF are parallel, (22. 1.) and in like manner, because the angle ABC=DCE, the lines BF, CD are parallel; therefore the figure ACDF is a parallelogram, and hence AF=CD, and CA=DF (26. 1.). In the triangle BFE the line AC is parallel to the side FE, therefore BC :

Proportions of Figures.

BC : CE :: BA : AF; or since AF=CD, BC : CE :: BA : CD. Again, in the same triangle, because CD is parallel to the side BF, BC : CE :: FD : DE, or, since FD=AC, BC : CE :: AC : DE; having now shewn that BC : CE :: BA : CD, and that BC : CE :: AC : DE, it follows that BA : CD :: AC : DE; therefore the equiangular triangles BAC, CDE have their homologous sides proportional, and hence (def. 2.) the triangles are similar.

Scholium.

It is manifest, that the homologous sides are opposite to the equal angles.

Theorem XXI.

Fig. 83. If two triangles have their homologous sides proportional, they are equiangular and similar.

Suppose that BC : EF :: AB : DE :: AC :: DF; then shall A=D, B=E, C=F. At the point E make the angle FEG=B, and at the point F make EFG=C; then the third angle G shall be equal to the third angle A, and the two triangles ABC, GEF shall be equiangular; therefore, by the last theorem BC : EF :: AB : GE; but by hypothesis BC : EF :: AB : DE, therefore GE=DE (Ax. 2. 3.). In like manner, because by the same theorem BC : EF :: CA : FG; and by hypothesis BC : EF :: CA : FD; therefore FG=FD; but it was shewn that EG=ED, therefore, the triangles GEF, DEF, having the sides of the one equal to those of the other, each to each, are equal, but, by construction, the triangle GEF is equiangular to ABC therefore also the triangles DEF, ABC are equiangular and similar.

Theorem XXII.

Fig. 85. Two triangles which have an angle of the one equal to an angle of the other, and the sides about these angles proportional, are similar.

Let the angle A=D, and let AB : DE :: AC : DF, the triangle ABC is similar to DEF. Take AG=DE, and draw GH parallel to BC, then the angle AGH=ABC, (21. 1.) therefore the triangle AGH is equiangular to ABC, and consequently (20.) AB : AG :: AC : AH; but by hypothesis AB : DE :: AC : DF, and by construction AG=DE, therefore AH=DF; the two triangles AGH, DEF are therefore equal, (5. 1.) but the triangle AGH is similar to ABC, therefore DEF is similar to ABC.

Theorem XXIII.

Fig. 86. In a right-angled triangle, if a perpendicular AD be drawn from the right angle upon the hypothenuse, then,

1. The triangles ABD, CAD on each side of the perpendicular are similar to the whole triangle BAC, and to one another.
2. Each side AB or AC is a mean proportional between the hypothenuse BC, and the adjacent segment BD or DC.
3. The perpendicular AD is a mean proportional between the two segments BD, DC.

1. The triangles BAD, BAC have the common angle B; besides, the right angle BAC is equal to the right angle BDA, therefore the third angle BAD of the one, is equal to the third angle BCA of the other; therefore, these triangles are equiangular and similar; and in the same manner it may be shewn, that the triangle DAC is equiangular and similar to BAC; therefore the three triangles are equiangular and similar to each other.

2. Because the triangle BAD is similar to the triangle BAC, their homologous sides are proportional. Now the side BD of the lesser triangle is homologous to the side BA of the greater, because they are opposite to the equal angles BAD, BCA; in like manner BA, considered as a side of the lesser triangle, is homologous to the side BC of the greater, each being opposite to a right angle; therefore, BD : BA :: BA : BC. In the same manner it may be shewn that CD : CA :: CA : CB, therefore each side is a mean proportional between the hypothenuse and the segment adjacent to that side.

3. By comparing the homologous sides of the two similar triangles ABD, ACD, it appears that BD : DA :: DA : DC; therefore the perpendicular is a mean proportional between the segments of the hypothenuse.

Theorem XXIV.

Fig. 8[illegible] Two triangles, which have an angle of the one equal to an angle of the other, are to each other as the rectangles of the sides which contain the equal angles; that is, the triangle ABC is to the triangle ADE, as the rectangle $AB \times AC$ to the rectangle $AD \times AE$.

Join BE; because the triangles ABE, ADE have a common vertex E, they have the same altitude, therefore ABE : ADE :: AB : AD, (Cor. to 6.); but AB : AD :: $AB \times AE$: $AD \times AE$, (3.) therefore,

$$ABE : ADE :: AB \times AE : AD \times AE.$$

In the same manner it may be demonstrated that

$$ABC : ABE :: AB \times AC : AB \times AE;$$

Therefore (6. 3.) $ABC : ADE :: AB \times AC : AD \times AE$.

Cor. Therefore the two triangles are equivalent, if the rectangle $AB \times AC = AD \times AE$, or (8.) if AB : AD :: AE : AC, in which case, the sides about the equal angles are said to be *reciprocally* proportional.

Scholium.

What has been proved of triangles is also true of parallelograms, they being the doubles of such triangles.

Theorem XXV.

Fig 85 Two similar triangles are to each other as the squares of their homologous sides.

Let

Proportions of Figures.

Let the angle A=D, the angle B=E, and therefore the angle C=F,

then (20.) AB : DE :: AC : DF;

now AB : DE :: AB : DE,

for the two ratios are identical, therefore (9.)

$AB^2 : DE^2 :: AB \times AC : DE \times DF$;

but ABC : DEF :: $AB \times AC : DE \times DF$, (24.)

therefore ABC : DEF :: $AB^2 : DE^2$, (Ax. 3. 3.)

therefore the two similar triangles ABC, DEF, are to each other as the squares of the homologous sides AB, DE, or as the squares of any of the other homologous sides.

Theorem XXVI.

Fig. 89. Similar polygons are composed of the same number of triangles which are similar and similarly situated.

In the polygon ABCDE, drawn from one of the angles A the diagonals AC, AD to all the other angles. In the polygon FGHIK, draw in like manner from the angle F, homologous to A, the diagonals FH, FI to the other angles.

Because the polygons are similar, the angle ABC is equal to its homologous angle FGH (Def. 2.) also the sides AB, BC are proportional to FG, GH, so that AB : FG :: BC : GH, therefore the triangles ABC, FGH are similar (22.); therefore the angle BCA=GHF, and these being taken from the equal angles BCD, GHI, the remainders ACD, FHI are equal; but the triangles ABC, FGH being similar, AC : FH :: BC : GH, besides, because of the similarity of the polygons, BC : GH :: CD :: HI; therefore AC : FH :: CD : HI; now it has been already shewn that the angle ACD=FHI, therefore the triangles ACD, FHI are similar (22.). It may be demonstrated in the same manner that the remaining triangles are similar, whatever be the number of sides of the polygon; therefore two similar polygons are composed of the same number of triangles, similar to each other, and similarly situated.

Theorem XXVII.

Fig. [illegible] The perimeters of similar polygons are as the homologous sides, and the polygons themselves, are as the squares of the homologous sides.

For, since by the nature of similar figures AB : FG :: BC : GH :: CD : HI, &c. therefore, (2. cor. 8. 3.) AB+BC+CD, &c. the perimeter of the first figure, is to FG+GH+HI, &c. the perimeter of the second, as the side AB to its homologous side FG.

Again, because the triangles ABC, FGH are similar, ABC : FGH :: $AC^2 : FH^2$ (25.), in like manner ACD : FHI :: $AC^2 : FH^2$, therefore,

ABC : FGH :: ACD : FHI.

By the same manner of reasoning,

ACD : FHI :: ADE : FIK,

and so on if there be more triangles; hence, from this series of equal ratios, it follows (2. cor. 8. 3.) that ABC+ACD+ADE, or the polygon ABCDE, is to FGH+FHI+FIK, or the polygon FGHIK, as one of the antecedents ABC is to its consequent FGH, or as AB^2 to FG^2; therefore, similar polygons are to each other as the squares of their homologous sides.

Cor. 1. If three similar figures have their homologous sides equal to the three sides of a right-angled triangle, the figure having the greatest side shall be equal to the two others; for these three figures are proportional to the squares of their homologous sides, and the square of the hypothenuse is equal to the squares of the other two sides.

Cor. 2. Similar polygons have to each other the duplicate ratio of their homologous sides. For let L be a third proportional to the homologous sides AB, FG, then (def. 11. 3.) AB has to L the duplicate ratio of AB to FG; but AB : L :: $AB^2 : AB \times L$ (3.), or, since $AB \times L = FG^2$, (cor. to 8.) AB : L :: $AB^2 : FG^2$ :: ABCDE : FGHIK, therefore the figure ABCDE has to the figure FGHIK, the duplicate ratio of AB to FG.

Theorem XXVIII.

The segments of two chords AB, CD, which cut each other within a circle, are reciprocally proportional, that is AO : DO :: CO : OB. Fig. 88.

Join AC and BD; and because the triangle AOC, BOD have the angles at O equal (4. 1.), and the angle A=D and the angle C=B (15. 2.) the triangles are similar; therefore the homologous sides are proportional, (20.) that is, AO : DO :: CO : BO.

Cor. Hence $AO \times BO = CO \times DO$, (8.) that is, the rectangle contained by the segments of the one chord is equal to the rectangle contained by the segments of the other.

Theorem XXIX.

If from a point O without a circle, two straight lines be drawn, terminating in the concave arch BC; the whole lines shall be reciprocally proportional to the parts of them without the circle, that is OB : OC :: OD : OA. Fig. 90.

Join AC, BD; then the triangles OAC, OBD have the common angle O, also the angle B=C (15. 2.), therefore the triangles are similar, and the homologous sides are proportional, that is, OB : OC :: OD : OA.

Cor. Therefore (8.) $OA \times OB = OC \times OD$, that is, the rectangles contained by the whole lines, and the parts of them without the circle, are equal to one another.

Theorem XXX.

If from a point O without a circle a straight line OA be drawn touching the circle, and also a straight line OC cutting it, the tangent shall be a mean proportional between the whole line which Fig. 91.

Problems.

which cuts the circle, and the part of it without the circle, that is, OC : OA :: OA : OD.

For if AC, AD be joined, the triangles OAD, OCA, have the angle at O common to both, also the angle ACD or ACO is equal to DAO (18. 2.), therefore the triangles are similar (20.), and consequently CO : OA :: OA : OD.

Cor. Therefore (cor. to 8.) $CO \times OD = OA^2$, that is, the square of the tangent is equal to the rectangle contained by the whole line which cuts the circle, and the part of it without the circle.

Theorem XXXI.

Fig. 92. In the same circle, or in equal circles, any angles ACB, DEF are to each other as the arches AB, DF of the circles intercepted between the lines which contain the angles.

Suppose the arch AB to have to the arch DF the ratio of the number p to the number q; then the arch AB being supposed divided into equal parts A g, g h, h B, the number of which is p, the arch DF shall contain q equal parts D k, kl, lm, mn, n F, each of which is equal to any one of the equal parts into which AB is divided. Draw straight lines from the centres of the circles to the points of division, these lines will divide ACB into p angles and DEF into q angles, which are all equal (13. 2.) therefore, the angle ACB has to the angle DEF the ratio of the number p to the number q, which ratio is the same as that of the arch AB to the arch DF.

Cor. Hence it appears that angles may be measured and compared with each other by means of arches of circles described on the vertices of the angles as centres, observing, however, that the radii of the circles must be equal.

SECT. V. PROBLEMS.

Problem I.

Plate CCXLIII. fig. 93. To bisect a given straight line AB; that is, to divide it into two equal parts.

From the points A and C as centres, with any radius greater than the half of AB, describe arches, cutting each other in D and D on each side of the line AB. Draw a straight line through the points D, D, cutting AB in C; the line AB is bisected in C.

For the points D, D, being equally distant from the extremities of the line AB, are each in a straight line perpendicular to the middle of AB, (16. 1.), therefore the line DCD is that perpendicular, and consequently C is the middle of AB.

Problem II.

Fig. 94. To draw a perpendicular to a given straight line BC, from a given point A in that line.

Take the points B and C at equal distances from A; and on B and C as centres, with any radius greater than BA, describe arches, cutting each other in D; draw a straight line from A through D, which will be the perpendicular required. For the point D, being at equal distances from the extremities of the line BC, must be in a perpendicular to the middle of BC (16. 1.), therefore AD is the perpendicular required.

Problem III.

Fig. 95. To draw a perpendicular to a given line, BD, from a given point A without that line.

On A as a centre, with a radius sufficiently great, describe an arch, cutting the given line in two points B, D; and on B and D as centres, with a radius greater than the half of BD, describe two arches, cutting each other in E; draw a straight line through the points A and E, meeting BD in C; the line AC is the perpendicular required.

For the two points A and E are each at equal distances from B and D; therefore, a line passing through A and E is perpendicular to the middle of BD, (16. 1.).

Problem IV.

At a given point A, in a given line AB, to make an angle equal to a given angle K. Fig. 96.

On K as a centre, with any radius, describe an arch to meet the lines containing the angle K, in L and I; and on A as a centre, with the same radius, describe an indefinite arch BO; on B as a centre, with a radius equal to the chord LI, describe an arch, cutting the arch BO in D; draw AD, and the angle DAB shall be equal to K.

For the arches BD, LI having equal radii and equal chords, the arches themselves are equal (4. 2.), therefore the angles A and K are also equal (13. 2.).

Problem V.

To bisect a given arch AB, or a given angle C. Fig. 97.

First. To bisect the arch AB, on A and B as centres, with one and the same radius, describe arches to intersect in D; join CD, cutting the arch in E, and the arch AE shall be equal to EB.

For, since the points C and D are at equal distances from A, and also from B, the line which joins them is perpendicular to the middle of the chord AB (16. 1.), therefore, the arch AB is bisected at E, (6. 2.).

Secondly. To bisect the angle C; on C as a centre, with any distance, describe an arch, meeting the lines containing the angle in A and B; then find the point D

Problems. D as before, and the line CD will manifestly bisect the angle C, as required.

Scholium.

By the same construction we may bisect each of the arches AE, EB; and again we may bisect each of the halves of these arches, and so on; thus by successive subsivisions, an arch may be divided into four, eight, sixteen parts, &c.

Problem VI.

Fig. 98. Through a given point A, to draw a straight line parallel to a given straight line BC.

On A as a centre, with a radius sufficiently large, describe the indefinite arch EO; on E for a centre, with the same radius, describe the arch AF; in EO take ED equal to AF, draw a line from A through D, and AD will be parallel to BC.

For if AE be joined, the angle EAD is equal to AEB (13. 2.), and they are alternate angles, therefore AD is parallel to BC, (22. 1.).

Problem VII.

Fig. 99. To construct a triangle, the sides of which may be equal to three given lines A, B, C.

Take a straight line, DE, equal to one of the given lines A; on D as a centre, with a radius equal to another of the lines B, describe an arch; on E as a centre, with a radius equal to the remaining line C, describe another arch, cutting the former in F; join DF and EF, and DEF will be the triangle required, as is sufficiently evident.

Scholium.

It is necessary that the sum of any two of the lines be greater than the third line (7. 1.).

Problem VIII.

Fig. 100. To construct a parallelogram, the adjacent sides of which may be equal to two given lines A, B, and the angle they contain equal to a given angle C.

Draw the straight line DE=A; make the angle GDE=C, and take DG=B; describe two arches, one on G as a centre, with a radius GF=DE, and the other on E, with a radius EF=DG, then DEFG shall be the parallelogram required.

For by construction the opposite sides are equal, therefore, the figure is a parallelogram, (27. 1.) and it is so constructed, that the adjacent sides and the angle they contain have the magnitudes given in the problem.

Cor. If the given angle be a right angle, the figure will be a rectangle; and if the adjacent sides be also equal, the figure will be a square.

Problem IX.

To find the centre of a given circle, or of a circle of which an arch is given. Fig. 101.

Take any three points A, B, D, in the circumference of the circle, or in the given arch, and having drawn the straight lines AB, BD, bisect them by the perpendiculars EG, FH; the point C where the perpendiculars intersect each other is the centre of the circle, as is evident from Theorem VI. sect. 2.

Scholium.

By the very same construction a circle may be found that shall pass through three given points A, B, C; or that shall be described about a given triangle ABC.

Problem X.

To draw a tangent to a given circle through a given point A. Fig. 102. 103.

If the given point A be in the circumference (fig. 102), draw the radius AC; and through A, draw AD perpendicular to AC, and AD will be a tangent to the circle, (9. 2.). But if the given point A be without the circle, (fig. 103.) draw AC to the centre, and bisect AC in O, and on O as a centre, with OA or OC as a radius, describe a circle which will cut the given circle in two points D and D′; join AD and AD′, and each of the lines AD, AD′, will be a tangent to the circle.

For, draw the radii CD, CD′, then each of the angles ADC, AD′C is a right angle, (17. 2.); therefore AD and AD′ are both tangents to the circle, (9. 2.).

Cor. The tangents AD, AD′ are equal to one another, (17. 1.)

Problem XI.

To inscribe a circle in a given triangle ABC. Fig. 104.

Bisect A and B any two angles of the triangle by the straight lines AO, BO, which meet each other in O; from O draw OD, OE, OF, perpendiculars to its sides; these lines shall be equal to one another.

For in the triangles ODB, OEB, the angles ODB =OEB, and the angle OBD=OBE; therefore the remaining angles BOD, BOE, are equal; and as the side DB is common to both triangles, they are equal to one another, (6. 1.), therefore the side OD=OE; in the same manner it may be demonstrated, that OD =OF; therefore the lines OD, OE, OF, are equal to one another, and consequently a circle described on O as a centre, with OD as a radius, will pass through E and F; and as the sides of the triangle are tangents to the circle, (9. 2.) it will be inscribed in the triangle.

Problem XII.

Upon a given straight line AB, to describe a seg- Fig. 105.

ment

Problems.

ment of a circle that may contain an angle equal to a given angle C.

PRODUCE AB towards D, and at the point B make the angle DBE equal to the given angle C; draw BO perpendicular to BE, and GO perpendicular to the middle of AB, meeting BO in O; on O as a centre, with OB as a radius, describe a circle, which will pass through A, and AMB shall be the segment required.

For since FE is perpendicular to BO, FE is a tangent to the circle, therefore the angle EBD (which is equal to C by construction) is equal to any angle AMB in the alternate segment, (18. 2.).

PROBLEM XIII.

Fig. 106. Fig. 107. To divide a straight line, AB, into any propofed number of equal parts; or into parts having to each other the same ratios that given lines have.

FIRST, Let it be proposed to divide the line AB, (fig. 106.) into five equal parts. Through the extremity A draw an indefinite line AG, take AC of any magnitude, and take CD, DE, EF, and FG, each equal to AC, that is, take AG equal to five times AC; join GB, and draw CI parallel to GB, the line AI shall be one-fifth part of AB, and AI being taken five times in AB, the line AB shall be divided into five equal parts.

For since CI is parallel to GB, the sides AG and AB are cut proportionally in C and I; but AC is the fifth part of AG; therefore AI is the fifth part of AB.

Next, let it be proposed to divide AB (fig. 107.) into parts, having to each other the ratios that the lines P, Q, R, have. Through A draw AG, and in AG take AC=P, CD=Q, DE=R; join EB, and draw CI and DK parallel to EB; the line AB shall be divided as required.

For, because of the parallels CI, DK, EB, the parts AI, IK, KB, have to each other the same ratios that the parts AC, CD, DE have, (17. 4.) which parts are by construction equal to the given lines P, Q, R.

PROBLEM XIV.

Fig. 108. To find a fourth proportional to three given lines, A, B, C.

DRAW two straight lines DE, DF, containing any angle; on DE take DA=A, and DB=B, and on DF take DC=C; join AC, and draw BX parallel to AC; then, BX shall be the fourth proportional required.

For, because BX is parallel to AC, DA : DB :: DC : DX (17. 4.) that is, A : B :: C : DX, therefore DX is a fourth proportional to A, B, and C.

COR. The same construction serves to find a third proportional to two lines A and B; for it is the same as a fourth proportional to the lines A, B, and C.

PROBLEM XV.

Fig. 109. To find a mean proportional between two straight lines, A, B.

UPON any straight line DF take DE=A, and EF =B; and on DF as a diameter describe a semicircle DGF; draw EG perpendicular to DF, meeting the circle in G; the line EG shall be the mean proportional required.

For, if DG, FG, be joined, the angle DGF is a right angle, (17. 2.) therefore, in the right-angled triangle DGF, GE is a mean proportional between DE and EF, (23. 4.).

PROBLEM XVI.

To divide a given straight line AB into two parts, so that the greater may be a mean proportional between the whole line and the other part. Fig. 11[0].

AT B, one of the extremities of the line, draw BC perpendicular to AB, and equal to the half of AB; on C as a centre, with CB as a radius, describe a circle; join AC, meeting the circle in D; make AF= AD, and AB shall be divided at F in the manner required.

For since AB is perpendicular to the radius, it is a tangent to the circle (9. 2.), and if AC be produced to meet the circle in E, AB : AF :: AE : AB, (30. 4.) and by division, AB—AF : AF :: AE—AB : AB; but AB—AF=BF, and since DE=2BC=AB, therefore AE—AB=AD=AF, therefore BF : AF :: AF : AB.

SCHOLIUM.

When a line is divided in this manner it is said to be divided in *extreme and mean ratio*.

PROBLEM XVII.

To make a square equivalent to a given parallelogram or to a given triangle. Fig. 112. Fig. 113.

FIRST, Let ABCD be a given parallelogram, (fig. 112.) the base of which is AB, and altitude DE; find XY a mean proportional between AB and DE, (by problem 15.) and XY shall be the side of the square required.

For since by construction AB : XY :: XY : DE, therefore, $XY^2=AB\times DE$ (8. 4.) = parallelogram ABCD (5. 4.).

Next, let ABC be a given triangle (fig. 113.) BC its base, and AD its altitude; find XY a mean proportional between half the base and the altitude, and XY shall be the side of the square required.

For since $\frac{1}{2}$BC : XY :: XY : AD; therefore (8. 4.) $XY^2=\frac{1}{2}BC\times AD$=triangle ABC (6. 4.).

PROBLEM XVIII.

Upon a given line EF, to construct a rectangle EFGX equivalent to a given rectangle ABCD. Fig. 11[4].

FIND a fourth proportional to the three lines EF, AB and AD; (by problem 14.) draw EX, perpendicular to EF, and equal to that fourth proportional, and complete the rectangle EFGX, which will have the magnitude required.

For since EF : AB :: AD : EX, therefore (8. 4.) $EF\times EX=AB\times AD$, that is, the rectangle EFGX is equal to the rectangle ABCD.

PROBLEM

Problems.

Problem XIX.

Fig. 1.

To make a triangle equivalent to a given polygon ABCDE.

First, draw the diagonal CE, so as to cut off the triangle CDE; draw DG parallel to CE, to meet AE produced in G; join CG, and the given polygon ABCDE shall be equivalent to another polygon ABCG which has one side fewer.

For since DG is parallel to CE, the triangle CGE is equivalent to the triangle CDE, (2. cor. 2. 4.) to each add the polygon ABCE, and the polygon ABCDE shall be equivalent to the polygon ABCG.

In like manner, if the diagonal CA be drawn into BF parallel to CA, meeting EA produced, and CF be joined, the triangle CFA is equivalent to the triangle CBA, and thus the polygon ABCDE is transformed to the triangle CFG.

In this way a triangle may be found equivalent to any other polygon, for by transforming the figure into another equivalent figure that has one side fewer, and repeating the operation, a figure will at last be found which has only three sides.

Scholium.

As a square may be found equivalent to a triangle, by combining this problem with Prob. XVII. a square may be found equivalent to any rectilineal figure whatever.

Problem XX.

Plate CCXLI. Fig. 8.

Upon a given line FC to construct a polygon similar to a given polygon ABCDE.

Draw the diagonals AC, AD; at the point F, make the angle GFH=BAC, and at the point G, make the angle FGH=ABC; thus a triangle FGH will be constructed similar to ABC. Again, on FH construct in like manner a triangle FIH, similar to ADC and similarly situated; and on FI construct a triangle FKI similar to AED and similarly situated; and these triangles FGH, FHI, FIK, shall form a polygon FGHIK similar to ABCDE (26. 4.).

Problem XXI.

Plate CCXLII. Fig. 11.

To inscribe a square in a given circle.

Draw two diameters AC, BD, so as to intersect each other at right angles; join the extremities of the diameters A, B, C, D, and the figure ABCD shall be a square inscribed in the circle.

For the angles AOB, BOC, &c. being all equal, the chords AB, BC, CD, DA are equal; and as each of the angles of the figure ABCD is in a semicircle, it is a right angle, (17. 2.) therefore the figure is a square.

Problem XXII.

Fig. 116.

To inscribe a regular hexagon and also an equilateral triangle in a given circle.

From any point A in the circumference, apply AB and BC each equal to AO the radius; draw the three diameters AD, BE, CF, and join their adjacent extremities by the lines AB, BC, &c. and the figure ABCDEF thus formed is the hexagon required.

For the triangles AOB, BOC being by construction equilateral, each of the angles AOB, BOC is one-third of two right angles, (4. cor. 24. 1.) and since AOB+BOC+COD=two right angles, therefore COD=one third of two right angles, therefore the three angles AOB, BOC, COD, are equal, and as these are equal to the angles AOF, FOE, EOD, the six angles at the centre are all equal; therefore, the chords AB, BC, CD, DE, EF, FA are all equal; thus the figure is equilateral. It is also equiangular, for the angles FAB, ABC, &c. are in equal segments, each having for its base the chord of two-sixths of the circumference, therefore, the angles, A, B, &c. are equal (15. 2.).

If straight lines be drawn joining A, C, E, the vertices of the alternate angles of the hexagon, there will be formed an equilateral triangle inscribed in a circle; as is sufficiently evident.

Scholium.

As the form of reasoning by which it has been shewn that an equilateral hexagon inscribed in a circle is also equiangular, will apply alike to any equilateral polygon: it may be inferred that every equilateral polygon inscribed in a circle is also equiangular.

Problem XXIII.

To inscribe a regular pentagon in a given circle. Fig. 117.

Draw any radius AO, and divide it into two parts AF, FO, such, that AO : OF :: OF : AF; (16.) from A place AG in the circumference equal to OF; join OG, and draw the chord AHB perpendicular to OG, the chord AB shall be a side of the pentagon required.

Join GF, and because AO : OF :: OF : AF, and that AG=OF, therefore, AO : AG :: AG : AF; now the angle A is common to the two triangles OAG, GAF, and it has been shewn that the sides about the angle in the two triangles are proportionals; therefore (22. 4.) the triangles are similar, and the triangle AOG being isosceles, the triangle AGF is also isosceles, so that AG=GF; but AG=FO, (by construction) therefore, GF=FO, and the angle FOG=FGO, and FOG + FGO = 2FOG; but AFG = FOG + FGO, (23. 1.) and AFG = FAG, therefore FAG = 2 FOG; hence in the isosceles triangle AOG, each of the angles at the base is double the vertical angle AOG, therefore the sum of all the angles is equal to five times the vertical angle AOG; but the sum of all the angles is equal to two right angles, (24. 1.) therefore the angle AOG is one fifth of two right angles, and consequently AOB=2AOG=two-fifths of two right angles equal one-fifth of four right angles, therefore the arch AB is one-fifth of the whole circumference. If we now suppose straight lines BC, CD, DE, to be applied in the circle each equal to AB, the chord of one-fifth of the circumference, and AE to be joined, the figure thus formed will be an equilateral pentagon, and it is also equiangular (Schol. 22.).

Problem

Of the Quadrature of the Circle.

PROBLEM XXIV.

Having given ABCD, &c. a regular polygon inscribed in a circle, to describe a regular polygon of the same number of sides about the circle.

DRAW GH a tangent to the circle at T the middle of the arch AB; do the same at the middle of each of the other arches BC, CD, &c. these tangents shall form a regular polygon GHIK, &c. described about the circle.

Join OG, OH, &c. also OT and ON. In the triangles OTH, ONH, the side OT=ON, and OH is common to both, and OTH, ONH, are right angles, therefore the triangles are equal (17. 1.) and the angles TOH=NOH; now B is the middle of the arch TN, therefore OH passes through B; and in the same manner it appears that I is in the line OC produced, &c. Now because OT bisects the arch AB it is perpendicular to the chord AB (6. 2.), therefore GH is parallel to AB (9. 2. and 18. 1.), and HI to BC, therefore the angle GHO=ABO, and IHO=CBO, and hence GHI=ABC; and in like manner it appears, that HIK=BCD, &c, therefore the angles of the circumscribed polygon are equal to those of the inscribed polygon. And because of the parallels, GH : AB :: OH : OB, and HI : BC :: OH : OB, therefore, GH : AB :: HI : BC; but AB=BC; therefore GH=HI. For the same reason HI=IK, &c. therefore, the polygon is regular, and similar to the inscribed polygon.

SECT. VI. OF THE QUADRATURE OF THE CIRCLE.

AXIOM.

Fig. 120. IF ABC be an arch of a circle, and AD, CD be two tangents at its extremities, intersecting each other in D; the sum of the tangents AD, DC is greater than the arch ABC.

Fig. 118. COR. Hence the perimeter of any polygon described about a circle, is greater than the circumference of the circle.

PROPOSITION I. THEOREM.

Fig. 119. Equilateral polygons, ABCDEF, GHIKLM, of the same number of sides inscribed in circles are similar, and are to one another as the squares of the radii of the circles.

As each of the polygons is by hypothesis equilateral, it will also be equiangular (Schol. 22. 5.). Let us suppose, for example, that the polygons are hexagons; then, as the sum of the angles is the same in both, viz. eight right angles (25. 1.), the angle A will be one-sixth part of eight right angles, and the angle G will be the same; therefore A=G; in like manner B=H, C=K, &c. and as the figures are equilateral, AB : GH :: BC : HI :: CD : IK, &c. therefore (2. def. 4.) the figures are similar. Draw AO, BO, GP, HP to the centres of the circles; then, because the angle AOB is the same part of four right angles that the arch AB is of the whole circumference; and the angle GHP the same part of four right angles that GH is of the whole circumference (13. 2.) the angles AOB, GPH are each the same part of four right angles; therefore they are equal; the isosceles triangles AOB, GPH are therefore similar, (22. 4.) and consequently AB : GH :: AO : GP, therefore (9. and 27. 4.) polygon ABCDEF : polygon GHIKLM :: $AO^2 : GP^2$.

PROP. II. THEOREM.

Fig. 121. A circle being given, two similar polygons may be found, the one inscribed in the circle, and the other described about it, which shall differ from each other by a space less than any given space.

LET AG be the side of a square equal to the given space; and let ABG be such an arch of the given circle, that AG is its chord. Bisect the fourth part of the circumference, (5. 5.) then bisect one of its halves, and proceed in this manner, till, by repeated bisections, there will at length be found an arch AB less than AG. As the arch thus found will be contained in the circumference a certain number of times exactly, its chord AB is the side of a regular figure inscribed in the circle; apply lines in the circle, each equal to AB, thus forming the regular figure ABC, &c. and describe a regular figure DEF, &c. of the same number of sides about the circle. Then, the excess of the circumscribed figure above the inscribed figure shall be less than the square upon AG. For draw lines from D and E to O the centre; these lines will pass through A and B (24. 5.); also, a line drawn from O, to H the point of contact of the line DE, will bisect AB, and be perpendicular to it; and AB will be parallel to DE. Draw the diameter AL, and join BL, which will be parallel to HO (18. 4.). Put P for the circumscribed polygon, and p for the inscribed polygon; then, because the triangles ODH, OAK are evidently like parts of P and p, P : p :: ODH : OAK (1. 3.); but the triangles ODH, OAK being similar, ODH : OAK :: $OH^2 : OK^2$ (25. 4.), and on account of the similar triangles OAK, LAB, OA^2 or OH^2 : $OK^2 :: LA^2 : LB^2$ (20. and 9. 4.); therefore, $P : p :: LA^2 : LB^2$, and by division and inversion, $P : P-p :: LA^2 : LA^2-LB^2$, or AB^2; but LA^2, that is, the square described about the circle, is greater than the equilateral polygon of eight sides described about the circle, because it contains that polygon, and for the same reason the polygon of eight sides is greater than the polygon of sixteen sides, and so on; therefore $LA^2 > P$, and as it has been proved that $P : P-p :: LA^2 : AB^2$, of which proportion, the first term P is less than the third LA^2; therefore (2. 3.) the second $P-p$ is less than the fourth AB^2, but $AB^2 < AG^2$, therefore $P-p < AG^2$.

COR. 1. Because the polygons P and p differ from one another more than either of them differs from the circle, the difference between each of them, and the circle, is less than the given space, viz. the square of AG. And therefore, however small any space may be, be, a polygon may be inscribed in the circle, and another described about it, each of which shall differ from the circle by less than the given space.

Cor. 2. A space which is greater than any polygon that can be inscribed in a circle, but which is less than any polygon that can be described about it, is equal to the circle itself.

Prop. III. Theorem.

Fig. 1.. The area of any circle is equal to a rectangle contained by the radius, and a straight line equal to half the circumference.

Let ABC, &c. be any equilateral polygon inscribed in the circle, and DEF, &c. a similar polygon described about it; draw lines from the extremities of AB and DE a side of each polygon to O the centre; and let OKH be perpendicular to these sides. Put P for the perimeter of the polygon DEF, &c. and p for the perimeter of the polygon ABC, &c. and n for the number of the sides of each. Then, because $n \times \frac{1}{2}\text{DE} = \frac{1}{2}\text{P}$, $n \times \frac{1}{2}\text{DE} \times \text{OH} = \frac{1}{2}\text{P} \times \text{OH}$, but $n \times \frac{1}{2}\text{DE} \times \text{OH} = n \times$ triangle DOE $=$ polygon DEF, &c. therefore, $\frac{1}{2}\text{P} \times \text{OH} =$ polygon DEF, &c.; and in like manner it appears, that $\frac{1}{2}p \times \text{OK} =$ polygon ABC, &c. Now let Q denote the circumference of the circle, then, because $\frac{1}{2}\text{Q} > \frac{1}{2}p$, and $\text{OH} > \text{OK}$, therefore $\frac{1}{2}\text{Q} \times \text{OH} > \frac{1}{2}p \times \text{OK}$, that is $\frac{1}{2}\text{Q} \times \text{OH}$ is greater than the inscribed polygon. Again, because $\frac{1}{2}\text{Q} < \frac{1}{2}\text{P}$ (axiom), therefore $\frac{1}{2}\text{Q} \times \text{OH} < \frac{1}{2}\text{P} \times \text{OH}$, that is, $\frac{1}{2}\text{Q} \times \text{OH}$ is less than the circumscribed polygon: Thus it appears that $\frac{1}{2}\text{Q} \times \text{OH}$ is greater than any polygon inscribed in the circle, but less than any polygon described about it; therefore, $\frac{1}{2}\text{Q} \times \text{OH}$ is equal to the circle (2.).

Prop. IV. Theorem.

Fig. 11.. The areas of circles are to one another as the squares of their radii.

Let ABCDEF and GHIKLM be equilateral polygons of the same number of sides inscribed in the circles, and OA, PG their radii; and let Q be such a space, that $\text{AO}^2 : \text{GP}^2 ::$ circle ABD : Q; then, because $\text{AO}^2 : \text{GP}^2 ::$ polygon ABCDEF : polygon GHIKLM, and $\text{AO}^2 : \text{GP}^2 ::$ circle ABE : Q, therefore polygon ABCDEF : polygon GHIKLM :: circle ABE : Q; but circle ABE $>$ polygon ABCDEF, therefore Q $>$ polygon GHIKLM; that is, Q is greater than any polygon inscribed in the circle GHL. In the same manner, it is demonstrated that Q is less than any polygon described about the circle GHL; therefore Q is equal to the circle GHL (2.). And because $\text{AO}^2 : \text{GP}^2 ::$ circle ABD : Q, therefore $\text{AO}^2 : \text{GP}^2 ::$ circle ABE : circle GHL.

Cor. 1. The circumferences of circles are to one another as their radii. Put M for half the circumference of the circle ABE, and N for half the circumference of GKL; then, circle ABE : circle GHL :: $\text{AO}^2 : \text{GP}^2$; but $\frac{1}{2}\text{M} \times \text{AO} =$ circle ABE, also $\frac{1}{2}\text{N} \times \text{GP} =$ circle GHL, (3.) therefore $\frac{1}{2}\text{M} \times \text{AO} : \frac{1}{2}\text{N} \times \text{GP} :: \text{AO}^2 : \text{GP}^2$, and by alternation $\frac{1}{2}\text{M} \times \text{AO} : \text{AO}^2 :: \frac{1}{2}\text{N} \times \text{GP} : \text{GP}^2$, therefore (3. 4.) $\frac{1}{2}\text{M} : \text{AO} :: \frac{1}{2}\text{N} : \text{GP}$, and again by alternation $\frac{1}{2}\text{M} : \frac{1}{2}\text{N} :: \text{AO} : \text{GP}$, therefore M : N :: AO : GP.

Cor. 2. A circle described with the hypothenuse of a right-angled triangle as a radius, is equal to two circles described with the other two sides as radii. Let the sides of the triangle be a, b and the hypothenuse h, and let the circles described with these lines as radii be A, B and H.

$$\begin{aligned} &\text{because A} : \text{H} :: a^2 : h^2 \\ &\text{and B} : \text{H} :: b^2 : h^2, \\ &\text{therefore A} + \text{B} : \text{H} :: a^2 + b^2 : h^2 \ (8.\ 3.) \\ &\text{but } a^2 + b^2 = h^2 \ (13.\ 4.), \text{ therefore A} + \text{B} = \text{H}. \end{aligned}$$

Prop. V. Problem.

Having given the area of a regular polygon inscribed in a circle, and also the area of a similar polygon described about it; to find the areas of regular inscribed and circumscribed polygons, each of double the number of sides. Fig. 122.

Let AB be the side of the given inscribed polygon, and EF parallel to AB that of the similar circumscribed polygon, and C the centre of the circle; if the chord AM, and the tangents AP, BQ be drawn, the chord AM shall be the side of the inscribed polygon of double the number of sides; and PQ or 2 PM that of the similar circumscribed polygon. Put A for the area of the polygon, of which AB is a side, and B for the area of the circumscribed polygon; also a for the area of the polygon of which AM is a side, and b for the area of the similar circumscribed polygon; then A and B are by hypothesis known, and it is required to find a and b.

I. The triangles ACD, ACM, which have a common vertex A, are to one another as their bases CD, CM; besides, these triangles are to one another as the polygons, of which they form like parts, therefore A : a :: CD : CM. The triangles, CAM, CME, which have a common vertex M, are to each other as their bases CA, CE; they are also to one another as the polygons a and B, of which they are like parts; therefore, a : B :: CA : CE; but because of the parallels DA, ME, CD : CM :: CA : CE; therefore, A : a :: a : B; therefore, the polygon a, which is one of the two required, is a mean proportional between the two known polygons A and B, so that $a = \sqrt{\text{A} \times \text{B}}$.

II. The triangles CPM, CPE, having the same altitude CM, are to one another as PM to PE. But as CP bisects the angle MCE, PM : PE :: CM : CE (19. 4.) :: CD : CA :: A : a; therefore, CPM : CPE :: A : a; and consequently CPM+CPE, or CME : CPM :: A+a : A, and CME : 2 CPM :: A+a : 2 A; but CME and 2 CPM, or CMPA, are to one another as the polygons B and b, of which they are like parts; therefore, A+a : 2 A :: B : b. Now the polygon a has been already found, therefore by this last proportion the polygon b is determined; that is, $b = \dfrac{2\text{A} \times \text{B}}{\text{A} + a}$.

Prop. VI. Problem.

To find nearly the ratio of the circumference of a circle to its diameter.

Let the radius of the circle $=1$, then, the sides of the inscribed square being the hypothenuse of a right-angled triangle of which the radii are the sides, (see fig.

fig. 115.) the area of the inscribed square will be 2; (13. 4.) and the circumscribed square, being the square of the diameter, will be 4. Now, retaining the notation of last problem, if we make $A=2$ and $B=4$, the formulæ $a=\sqrt{A\times B}, b=\frac{2A\times B}{A+a}$ gives us $a=2.8284271$, &c. the area of the inscribed octagon, and $b=3.3137085$, &c. the area of the circumscribed octagon. By substituting these numbers in the formulæ, instead of A and B, we shall obtain the areas of the inscribed and circumscribing polygons of 16 sides; and thence we may find those of 32 sides, and so on as in the following table:

N° *of sides.*	*Ins. Polygons.*	*Cir. Polygons.*
4	2.0000000	4.0000000
8	2.8284271	3.3137085
16	3.0614674	3.1825979
32	3.1214451	3.1517249
64	3.1365485	3.1441184
128	3.1403311	3.1432236
256	3.1412772	3.1417504
512	3.1415138	3.1416321
1024	3.1415729	3.1416025
2048	3.1415877	3.1415951
4096	3.1415914	3.1415933
8192	3.1415923	3.1415928
16384	3.1415925	3.1415927
32768	3.1415926	3.1415926

Hence it appears that the areas of a regular polygon of 32768 sides inscribed in the circle, and of a similar polygon described about it, differ so little from each other, that the numbers which express them are the same as far as the eighth decimal place. And as the circle is greater than the one polygon, and less than the other, its area will be nearly 3.1415926. But the area is the product of the radius and the half of the circumference; therefore, the radius being unity, half the circumference is 3.1415926 nearly; and the radius is to half the circumference, or the diameter is to the circumference, nearly as 1 to 3.1415926.

Scholium.

In this way the ratio of the diameter to the circumference may be found to any degree of accuracy; but neither by this, nor any other method yet known, can the ratio be exactly determined.

Archimedes, by means of inscribed and circumscribed polygons of 96 sides, found that the diameter is to the circumference as 7 to 22, nearly, which ratio is nearer to the truth than can be expressed by any smaller numbers; and Metius found it to be more nearly as 113 to 355. Both of these expressions are convenient on account of the smallness of the numbers, but later mathematicians have carried the approximation to a much greater degree of accuracy. Thus, it has been found that the diameter being 1, the circumference is greater than 3.1415926535897932, but less than the same number having its last figure increased by unity; and some have even had the patience to carry the approximation as far as the 150th place of decimals.

SECT. VII.

Definitions.

I. A straight line is *perpendicular*, or at right angles, to a plane, when it is perpendicular to every straight line meeting it in that plane. The plane is also perpendicular to the line.

II. A line is *parallel* to a plane, when they cannot meet each other, although both be produced. The plane is also parallel to the line.

III. Parallel planes are such as cannot meet each other, though produced.

IV. It will be demonstrated (Theor. 3.) that the common section of two planes is a straight line; this being premised, the *inclination* of two planes is the angle contained by two straight lines drawn perpendicular to the line, which is their common section, from any point in it, the one perpendicular being drawn in the one plane, and the other in the other plane.

This angle may be either acute or obtuse.

V. If it be a right angle the two planes are perpendicular to each other.

VI. A *solid angle* is that which is made by the meeting of more than two plane angles, which are not in the same plane, in one point. Thus the solid angle S is formed by the plane angles ASB, BSC, CSD, DSA.

Theorem I.

One part of a straight line cannot be in a plane and another part above it.

For from the definition of a plane (7. def. 1.) it is manifest that if a straight line coincide with a plane in two points it must be wholly in the plane.

Theorem II.

Two straight lines which cut each other in a plane determine its position; that is, the plane can coincide with these lines only in one position. Plat CCXI. fig. 1

Let the straight lines AB, AC cut each other in A; conceive a plane to pass through AB, and to be turned about that line, till it pass through the point C; and this it can manifestly do only in one position; then, as the points A and C are in the plane, the whole line AC must be in the plane; therefore there is only one position in which the plane can coincide with the same two lines AB, AC.

Cor. Therefore a triangle ABC, or three points A, B, C not in a straight line, determine the position of a plane.

Theorem III.

If two planes AB, CD intersect each other, their intersection is a straight line. Fig. 1

Let E and F be two points in the line of common section, and let a straight line EF be drawn between them; then the line EF must be in the plane AB, (7.

(7. def. 1.) and the same line must also be in the same plane CD, therefore it must be the common section of them both.

Theorem IV.

Fig. If a straight line AP is perpendicular to two straight lines PB, PC at P the point of their intersection; it will also be perpendicular to the plane MN, in which these lines are.

Draw any other line PQ in the plane MN, and from Q any point in that line draw QD parallel to PB; make DC=DP; join CQ, meeting PB in B; and join AB, AQ, AC. Because DQ is parallel to PB, and PD=DC; therefore BQ=QC, and BC is bisected in Q: Hence in the triangle BAC,

$$AB^2+AC^2=2\,AQ^2+2\,BQ^2, \ (16.\ 4.)$$

and in the like manner, in the triangle PBC,

$$PB^2+PC^2=2\,PQ^2+2\,CQ^2;$$

therefore, taking equal quantities from equal quantities, that is, subtracting the two last quantities, which are put equal to each other, from the two first, and observing that as APB, APC are by hypothesis right-angled triangles, $AB^2-BP^2=AP^2$, and $AC^2-CP^2=AP^2$, we have

$$AP^2+AP^2=2\,AQ^2-2\,PQ^2,$$

and therefore $AP^2=AQ^2-PQ^2$, or $AP^2+PQ^2=AQ^2$; therefore the triangle APQ is right-angled at P, (schol. 15. 4.) and consequently AP is perpendicular to the plane MN (Def. 1.).

Cor. 1. The perpendicular AP is shorter than any oblique line AQ, therefore t measures the distance of the point A from the plane.

Cor. 2. From the same point P in a plane no more than one perpendicular can be drawn. For if it be possible that there can be two perpendiculars, conceive a plane to pass through them, and to intersect the plane MN in the straight line PQ; then these perpendiculars will be in the same plane, and both perpendicular to the same line PQ, at the same point P in that line, which is impossible.

It is also impossible that from a point without a plane two perpendiculars can be drawn to the plane; for if the straight lines AP, AQ could be two such perpendiculars, then the triangle APQ would have two right angles, which is impossible.

Theorem V.

Fig. 126. If a straight line AP be perpendicular to a plane MN, every straight line DE parallel to AP is perpendicular to the same plane.

Let a plane pass through the parallel lines AP, DE, and intersect the plane MN in the line PD; through D draw BC at right angles to PD; take DC=DB, and join PB, PC, AB, AC, AD. Because DB=DC, therefore PB=PC; (cor. 4. 1.) and because AP is perpendicular to the plane MN, so that APB, APC are right angles, AB=AC, (cor. 5. 1.) therefore ABC is an isosceles triangle; and since its base BC is bisected at D, BC is perpendicular to AD; (schol. 11. 1.) but by construction BC is perpendicular to PD; therefore (4.) BC or BD is perpendicular to the plane passing through the lines AD and PD, or AP and DE; hence BD is perpendicular to DE, but PD is also perpendicular to DE, (19. 1.) therefore DE is perpendicular to the two lines DP, DB; and therefore it is perpendicular to the plane MN passing through them.

Cor. 1. Conversely, if the straight lines AP, DE are perpendicular to the same plane MN, they are parallel; for if not, through D draw a parallel to AP; this parallel will be perpendicular to the plane MN, (by the theorem) therefore, from the same point D two perpendiculars may be drawn to a plane, which is impossible (4.).

Cor. 2. Two straight lines A and B which are parallel to a third line C, though not in the same plane, are parallel to each other. For suppose a plane to be perpendicular to the line C, the lines A and B parallel to this perpendicular are perpendicular to the same plane; therefore, by the preceding corollary, they are parallel between themselves.

Theorem VI.

Two planes MN, PQ, perpendicular to the same straight line AB, are parallel to each other. Fig. 127.

For, if they can meet each other, let O be a point common to both, and join OA, OB; then the line AB, which is perpendicular to the plane MN, must be perpendicular to AO, a line drawn in the plane MN from the point in which AB meets that plane. For the same reason AB is perpendicular to BO; therefore OA, OB are two perpendiculars drawn from the same point O, to the same straight line AB, which is impossible.

Theorem VII.

The intersections EF, GH of two parallel planes MN, PQ with a third plane FG, are parallel. Fig. 128.

For if the lines EF, GH, situated in the same plane, are not parallel, they must meet if produced; therefore, the planes MN, PQ, in which they are, must also meet, which is contrary to the hypothesis of their being parallel.

Theorem VIII.

Any straight line AB, perpendicular to MN, one of two parallel planes MN, PQ, is also perpendicular to PQ the other plane. Fig. 127.

From B draw any straight line BC in the plane PQ, and let a plane pass through the lines AB, BC, and meet the plane MN in the line AD, then AD will be parallel to BC, (7.), and since AB is perpendicular to the plane MN, it must be perpendicular to the line AD, therefore it is also perpendicular to BC; (19. 1.) hence (Def. 1.) the line AB is perpendicular to the plane PQ.

Theorem IX.

Parallel straight lines EG, FH, comprehended between two parallel planes MN, PQ, are equal. Fig. 128.

Let a plane pass through the lines EG, FH, and meet

meet the parallel planes in EF and GH; then EF and GH are parallel (7.) as well as EG and FH; therefore, EGHF is a parallelogram, and EF=GH.

Cor. Hence two parallel planes are everywhere at the same distance from each other. For, if EF and GH are perpendicular to the two planes, they are parallel, (1. cor. 5.) therefore they are equal.

Theorem X.

Fig. 129. If two straight lines CA, EA, meeting one another, be parallel to two other lines DB, FB, that meet one another, though not in the same plane with the first two; the first two and the other two shall contain equal angles, and the plane passing through the first two shall be parallel to the plane passing through the other two.

Take AC=BD, AE=BF, and join CE, DF, AB, CD, EF. Because AC is equal and parallel to BD, the figure ABDC is a parallelogram; therefore, CD is equal and parallel to AB. For a similar reason EF is equal and parallel to AB; therefore also CE is equal and parallel to DF (2 cor. 5. and 28. 1.); therefore the triangles CAE, DBF are equal, (10. 1.) hence the angle CAE=DBF.

In the second place, the plane ACE is parallel to the plane BDF: For suppose that the plane parallel to BDF, passing through the point A, meets the lines CD, EF in any other points than C and E, (for example in G and H), then (9.) the three lines AB, GD, FH are equal; but the three lines AB, CD, EF have been shewn to be equal; therefore, CD=GD, and FH=EF, which is absurd, therefore the plane ACE is parallel to BDF.

Theorem XI.

Fig. 130. If a straight line AP be perpendicular to a plane MN, any plane APB, passing through AP, shall be perpendicular to the plane MN.

Let BC be the intersection of the planes AB, MN; if in the plane MN the line DE be drawn perpendicular to BP, the line AP, being perpendicular to the plane MN, shall be perpendicular to each of the straight lines BC, DE; therefore the angle APD is a right angle; now PA and PD are drawn in the planes AB, MN perpendicular to their common section, therefore (5. Def.) the planes AB, MN are perpendicular to each other.

Scholium.

When three straight lines, such as AP, BP, DP, are perpendicular to each other, each is perpendicular to the plane of the two other lines.

Theorem XII.

Fig. 130. If the plane AB is perpendicular to the plane MN; and in the plane AB a straight line PA be drawn perpendicular to BP, the common intersection of the planes, then shall PA be perpendicular to the plane MN.

For, if in the plane MN, a line PD be drawn perpendicular to PB, the angle APD shall be a right angle, because the planes are perpendicular to each other, therefore, the line AP is perpendicular to the two lines PB, PD, therefore it is perpendicular to their plane MN.

Cor. If the plane AB be perpendicular to the plane MN, and from any point P, in their common intersection, a perpendicular be drawn to the plane MN; this perpendicular shall be in the plane AB; for if it is not, a perpendicular AP may be drawn in the plane AB to the common intersection BP, which will be at the same time perpendicular to the plane MN; therefore, at the same point P, there may be two perpendiculars to a plane NM, which is impossible (4.).

Theorem XIII.

If two planes AB, AD are perpendicular to a third, their common intersection AP is perpendicular to the third plane. Fig.

For, if through the point P, a perpendicular be drawn to the plane MN, this perpendicular shall be in the plane AB, and also in the plane AD, (cor. 12.) therefore it is at their common intersection AP.

Theorem XIV.

If two straight lines be cut by parallel planes, they shall be cut in the same ratio. Fig.

Let the line AB meet the planes MN, PQ, RS in A, E, B; and let CD meet them in C, F, D, then shall AE : EB :: CF : FD. For draw AD meeting the plane PQ in G, and join AC, EG, GF, BD; the lines EG, BD, being the common sections of the plane of the triangle ABD and the parallel planes PQ, RS, are parallel (7.), and in like manner it appears, that AC, GF are parallel; therefore AE : EB (:: AG : GD) :: CF : FD.

Theorem XV.

If a solid angle be contained by three plane angles, the sum of any two of these is greater than the third. Fig.

It is evidently only necessary to demonstrate the theorem, when the plane angle which is compared with the sum of the other two is greater than either of them; for, if it were equal to or less than one of them, the theorem would be manifest: therefore let S be a solid angle formed by three plane angles ASB, ASC, BSC, of which ASB is the greatest. In the plane ASB make the angle BSD=BSC; draw any straight line ADB, and having taken SC=SD, join AC, BC; the triangles BSC, BSD having two sides, and the included angle of the one equal to two sides, and the included angle of the other, each to each, are equal (5. 1.), therefore BE=BC; now AB $\angle$ AC+BC, therefore, taking BD from the first of these unequal quantities, and BC from the second, we get AD $\angle$ AC; and as the triangles ASD, ASC have SD=SC, and SA common to both, and AD $\angle$ AC, therefore (9. 1.) the angle ASD $\angle$ ASC; and, adding DSB to the one, and CSB to the other, ASB $\angle$ ASC+BSC.

Theorem XVI.

If each of two solid angles be contained by three plane Fig.

Of Solids bounded by Planes.

plane angles equal to one another, each to each, the planes in which the equal angles are, have the same inclination to one another.

Let the angle ASB=DTE, the angle ASC =DTF, and the angle BSC=ETF; the two planes ASB, ASC, shall have to each other the same inclination as the two planes DTE, DTF.

Take A any point in SA, and in the two planes ASB, ASC, draw AB and AC perpendiculars to AS, then (def. 4.) the angle BAC is the inclination of these planes; again, take TD=SA, and in the planes TDE, TDF draw DE and DF perpendiculars to TD, and the angle EDF shall be the inclination of these other planes; join BC, EF. The triangles ASB, DTE have the side AS=DT, the angle SAB=TDE and ASB=DTE, therefore the triangles are equal, and thus AB=DE, and SB=TE: In like manner it appears that the triangles ASC, DTF are equal, and therefore, that AC=DF, and SC=TF. Now the triangles BSC, ETF, having BS=TE, SC=TF, and the angle BSC=ETF, are also equal, and therefore BC=EF; but it has been shewn that AB=DE, and that AC=DF; therefore the triangles BAC, EDF are equal, and consequently the angle BAC=EDF; that is, the inclination of the planes ASB and ASC is equal to the inclination of the planes DTE and DTF. In the same manner it may be proved that the other planes have the same inclination to one another.

Scholium.

If the three plane angles which contain the solid angles, are equal each to each, and if besides the angles are also *disposed in the same order* in the two solid angles, then these angles when applied to one another will coincide, and be equal. But if the plane angles be *disposed in a contrary order*, the solid angles will not coincide, although the theorem is equally true in both cases. In this last case the solid angles are called *Symmetrical angles.*

SECT. VIII. OF SOLIDS BOUNDED BY PLANES.

Definitions.

I. A *Solid* is that which has length, breadth, and thickness.

II. A *Prism* is a solid contained by plane figures, of which two that are opposite are equal, similar, and parallel; and the others are parallelograms.

Fig. 4. To construct this solid, let ABCDE be any polygon: if in a plane parallel to ABC there be drawn straight lines FG, GH, HI, &c. equal and parallel to the sides AB, BC, CD, &c. so as to form a polygon FGHIK equal to ABCDE, and straight lines AF, BG, CH, &c. be drawn, joining the vertices of the homologous angles in the two planes; the planes or faces ABGF, BCHG, &c. thus formed will be parallelograms; and the solid ABCDEFGHIK contained by these parallelograms and the two polygons, is the prism itself.

III. The equal and parallel polygons ABCDE, FGHIK are called the *Bases* of the prism, and the distance between the bases is its *Altitude.*

Fig. 5. IV. When the base of a prism is a parallelogram, and consequently the figure has all its faces parallelograms, it is called a *parallelopiped.* A parallelopiped is *rectangular* when all its face are rectangles.

V. A *Cube* is a rectangular parallelopiped contained by six equal squares.

Pl. CCXV. Fig. 1. VI. A *Pyramid* is a solid contained by several planes, which meet in the same point A, and terminate in a polygonal plane BCD.

VII. The polygon ABCDE is called the *Base* of the pyramid; the point S is its *Vertex;* and a perpendicular let fall from the vertex upon the base is called its *Altitude.*

VIII. Two solids are *similar,* when they are contained by the same number of similar planes, similarly situated, and having like inclinations to one another.

Theorem I.

Two prisms are equal when the three planes which contain a solid angle of the one are equal to the three planes which contain a solid angle of the other, each to each, and are similarly situated. Plate CCXLIV. Fig. 134.

Let the base ABCDE be equal to the base *a b c d e*, the parallelogram ABGF equal to the parallelogram *a b g f*, and the parallelogram BCHG equal to the parallogram *b c h g;* the prism ABCI shall be equal to the prism *a b c i.*

For let the base ABCDE be applied to its equal the base *a b c d e*, so that they may coincide with each other; then, as the three plane angles which form the solid angle B are equal to the three plane angles which form the angle *b*, each to each, viz. ABC=*a b c* ABG=*a b g*, and GBC=*g b c*, and as these angles are similarly situated, the solid angles B and *b* are equal (15. 7.) therefore the side BG shall fall upon the side *b g;* and because the parallelograms ABGF, *a b g f* are equal, the side FG shall fall upon its equal *f g;* in like manner it may be shewn, that GH falls upon *g h*, therefore the upper base FGHIK coincides entirely with its equal *f g h i k*, and the two solids coincide with each other, or occupy the same space, therefore the prisms are equal.

Scholium.

A prism is entirely determined, when its base ABCDE is known, and its edge BG is given in magnitude and position; for if through the point G, GF be drawn equal and parallel to AB, and GH equal and parallel to BC, and the polygon FGHIK be described equal to ABCDE (20. 5.), it is evident that the

 points

Of Solids bounded by Planes.

points FKI will have determinate positions; therefore any two prisms constructed with the same *data* cannot be unequal.

Theorem II.

Fig. 135. In any parallelopiped the opposite planes are equal and parallel.

From the nature of the solid (4. def.) the bases ABCD, EFGH are equal parallelograms, and their sides are parallel, therefore the planes AC, EG are parallel; and because AD is equal and parallel to BC, and AE is equal and parallel to BF, the angle DAE =CBF, and the plane DAE is parallel to the plane CBF, (10. 7.) therefore also the parallelogram DAEH is equal to the parallelogram CBFG. It may in like manner be demonstrated, that the opposite parallelograms ABFE, DCGH are equal and parallel.

Cor. Hence, in a parallelopiped, any one of the six planes which contain it may be taken for its base.

Theorem III.

Fig. 136. The plane BDHF, which passes through two parallel opposite edges BF, DH, of a parallelopiped AG, divides it into two triangular prisms ABDHEF, GHFBCD, equal to one another.

For the triangles ABD, EFH, having their sides equal and parallel, are equal, and the lateral faces ABFE, ADHE, BDHF are parallelograms; therefore the solid ABDHEF is a prism; for like reasons the solid GHFBCD is a prism. Again, because the plane angles which contain the solid angle at G are equal to those which contain the solid angle at A, viz. the angle FGH=DAB, FGC=DAE, and HGC =BAE, the planes in which these angles are have the same inclination to one another, (16. 7.); as, however, these angles are not disposed in the same order, but in a contrary order, the solid angles cannot be made to coincide with one another, and consequently the prisms cannot be proved equal by superposition, as in Theorem I. Their equality may however be established by reasoning thus:

The inclination of each of any two adjacent faces of a prism to the base, and the length of an edge being given, the prism is evidently restricted to one determinate magnitude; and it will evidently have the same magnitude whichsoever of the two sides of the base it may stand upon; that is, whether it be constructed above or below the base. Now if the upper base FGH of the one prism be applied to the lower base DAB of the other, so that the sides FG, GH, FH may be upon the sides DA, AB, DB equal to them, then the prism GHFBCD will have the position ABDHEF′; and the two faces ABF′E′ of ADH′E′ of the prism below the base will have each the same inclination to it, as the equivalent faces ABFE, ADHE of the prism above the base; and the edge AE′ is equal to the edge AE; therefore the conditions which determine the magnitude of both prisms are identical, and consequently the prisms are equal.

Theorem IV.

Of Solids bounded by Planes.

If two parallelopipeds AG, AL have a common base ABCD, and have their upper bases in the same plane, and between the same parallel straight lines EK, HL, the two parallelopipeds are equivalent to each other. Fig. 137. Fig. 138.

Because AE is parallel to BF, and HE to GF, the angle AEI=BFK, HEI=GFK, and HEA =GFB; of these six angles the three first form the solid angle E, and the three others form the solid angle F; therefore since the plane angles are equal each to each, and similarly situated, the solid angles E and F are equal. Now if the prism AEIDHM be applied to the prism BFKCGL, so that their bases AEI, BFK, which are equal, may coincide with each other, then, because the solid angle E is equal to the solid angle F, the side EH shall fall upon FG, and this is all that is necessary to prove that the two prisms coincide entirely, for the base AEI and the edge EH determine the prism AEM, and the base BFK and the edge FG determine the prism BFL; therefore the prisms are equal. But if from the solid AEL, the prism AEM be taken away, there will remain the parallelopiped AIL; and if from the same solid AEL, the prism BFL be taken away, there will remain the parallelopiped AEG; therefore the parallelopipeds AIL, AEG are equivalent to each other.

Theorem V.

Parallelopipeds upon the same base, and having the same altitude, are equivalent to one another. Fig. 139.

Let ABCD be the common base of the two parallelopipeds AG, AL, which, because they have the same altitude, will have their upper bases in the same plane; then, because EF and AB are equal and parallel, as also IK and AB; EF is parallel to IK, (cor. 2. 5. 7.) for a similar reason GF is parallel to LK. Let the sides EF, HG, as also the sides LK, IM, be produced, so as to form by their intersections the parallelogram NOPQ; it is manifest that this parallelogram is equal to each of the bases EFGH, IKLM. Now, if we suppose a third parallelopiped, which, with the same lower base ABCD, has for its upper base NOPQ, this third parallelopiped will be equivalent to the parallelopiped AG, (4.) for the same reason the third parallelopiped will be equivalent to the parallelopipeds AL; therefore the two parallelopipeds AG, AL, which have the same base and the same altitude, are equivalent to one another.

Theorem VI.

Any parallelopiped AG is equivalent to a rectangular parallelopiped, having the same altitude, and an equivalent base. Fig. 139, 140.

At the points A, B, C, D, let AI, BK, CL, DM, be drawn perpendicular to the plane ABCD, and terminating in the plane of the upper base; then, IK, KL, KL, LM, MI, being joined, a parallelopiped AL will thus be formed, which will manifestly have its lateral faces AK, BL, CM, DI rectangles; and if the base AC is also a rectangle, the solid AL will be a rectangular parallelopiped equivalent to the parallelopiped AG. But if ABCD is not a rectangle, (fig. 140.) draw AO and BN perpendicular to CD, and OQ and NP perpendicular to DC, meeting ML in Q and P; the solid ABNOIKPQ will manifestly be a rectangular parallelopiped, which will be equal to the parallelopiped AL, for they have the same base ABKI, and the same altitude, viz. AO; therefore the rectangular parallelopiped AP is equivalent to the parallelopiped AG, (fig. 139.) and they have the same altitude, and the base ABNO of the former is equivalent to the base ABCD of the latter.

Theorem VII.

Fig. 144. Any section NOPQR of a prism, made by a plane parallel to its base ABCDE, is equal to the base.

For the parallels AN, BO, CP contained between the parallel planes ABC, NOP are equal (9. 7.); and thus all the figures ABON, BCPO, &c. are parallelograms; hence the side ON=AB, OP=BC, PQ=CD, &c. also, the equal sides are parallel, therefore, the angle ABC = NOP, the angle BCD = OPQ, &c. therefore the two polygons ABCDE, NOPQR, have their sides and angles equal, each to each; therefore, they are equal.

Theorem VIII.

Plate CCLV. fig. 1. Two rectangular parallelopipeds AG, AL, which have the same base ABCD, are to each other as their altitudes AE, AI.

Suppose that the altitudes AE, AI are to each other as the numbers p and q, so that AE will contain p such equal parts as AI contains q. Let AE and AI be divided into p and q equal parts respectively, and let planes pass through the points of division parallel to the base ABCD; thus the parallelopiped AG will be divided into p solids, which will also be parallelopipeds having equal bases (7.) and equal altitudes, therefore they will be equal among themselves; and in like manner the parallelopiped AL will be divided into q equal solids; and as each of the solids in AG is equal to each of the solids in AL, the parallelopiped AG will contain p such equal parts as the parallelopiped AL contains q; therefore the parallelopiped AG will be to the parallelopiped AL as the number p to the number q, that is, as AE the altitude of the former to AI the altitude of the latter.

Theorem IX.

Fig. 140. Two rectangular parallelopipeds AG, AK, which have the same altitude AE, are to each other as their bases ABCB, AMNO.

Let the two solids be placed, the one by the side of the other, as represented in the figure, and let the plane ONKL be produced, so as to meet the plane DCGH in PQ, thus forming a third parallelopiped AQ, which may be compared with each of the parallelopipeds AG, AK. The two solids AG, AQ, having the same base ADHE, are to each other as their altitudes AB, AO, (8.) and, in like manner, the two solids AQ, AK, having the same base AOLE, are to each other as their altitudes AD, AM; that is,

solid AG : *sol.* AQ :: AB : AO
sol. AQ : *sol.* AK :: AD : AM;

but AB : AO :: *base* AC : *base* AP (3. 4.)
and AD : AM :: *base* AP : *base* AN,

therefore,

sol. AG : *sol.* AQ :: *base* AC : *base* AP,
sol. AQ : *sol.* AK :: *base* AP : *base* AN,

therefore (7. 3.)

sol. AG. *sol.* AK :: *base* AC : *base* AN.

Theorem X.

Rectangular parallelopipeds are to each other as the products of the numbers proportional to their bases and altitudes, or as the products of the numbers proportional to their three dimensions. Fig. 142.

Let AG be a parallelopiped, the three dimensions of which are expressed by the lines AB, AD, AE, and AZ another parallelopiped the dimensions of which are expressed by the lines AO, AM, AX. Let the two solids AG, AZ be so placed that their surfaces may have a common angle BAE; produce such of the planes as are necessary so as to form a third parallelopiped AK, having the same altitude as the parallelopiped AG. By the last proposition

sol. AG : *sol.* AK :: *base* AC : *base* AN,

and by the last theorem but one,

sol. AK : *sol.* AZ :: AE : AX,

but, considering the bases AC, AN as measured by numbers, as also the altitudes AE, AX,

base AC : *base* AN :: AE × *base* AC : AE × *base* AN
and AE : AX :: AE × *base* AN : AX × *base* AN

therefore,

sol. AG : *sol.* AK :: AE × *base* AC : AE × *base* AN,
sol. AK : *sol.* AZ :: AE × *base* AN : AX × *base* AN,

therefore, (7. 3.)

sol. AG : *sol.* AZ :: AE × *base* AC : AX × *base* AN;

which proportion, by substituting for the bases AC, AN their numerical values AB × AD aud AO × AM becomes

sol. AG : *sol.* AZ :: AB × AD × AE : AO × AM × AX.

Scholium.

Hence it appears that the product of the base of a rectangular parallelopiped by its altitude or the product of its three dimensions, may be taken for its numerical measure;

Of Solids bounded by Planes.

measure; and it is upon this principle that all other solids are estimated. When two parallelopipeds are compared together by means of their bases and altitudes, their bases must be considered as measured by the same superficial unit, and their altitudes by the same linear unit; thus if P and Q denote two parallelopipeds, and the base of P contains three such equal spaces as that of Q contains four; and the altitude of P contains two such equal lines, as that of Q contains five, then, $P : Q :: 3\times2 : 4\times5 :: 6 : 20$.

If all the dimensions of each solid are used in comparing them together, then the same linear unit must be employed in estimating all the dimensions of both solids; thus, if the length, breadth, and height of the solid P be four, three, and six linear units, respectively; and those of Q, seven, two, and five of the same unit; then $P : Q :: 4\times3\times6 : 7\times2\times5 :: 72 : 70$.

As lines are compared together by considering how often each contains some other line taken as a measuring unit, and surfaces by considering how often each contains a square whose side is that unit; so solids may be compared, by considering how often each contains a cube, the side or edge of which is the same linear unit. Accordingly, the dimensions of the parallelopipeds P and Q being as we have just now supposed, the proportion $P : Q :: 72 : 70$ may be considered as indicating that P contains 72 such equal cubes as Q contains 70.

The magnitude of a solid, its bulk, or its extension, constitutes its *solidity*, or its *content*; thus we say, that the solidity or the content of a rectangular parallelopiped is equal to the product of its base by its altitude; or to the product of its three dimensions.

Theorem XI.

The solidity of any parallelopiped, or in general of any prism, is equal to the product of its base by its altitude.

1. Any parallelopiped is equivalent to a rectangular parallelopiped of the same altitude, and an equivalent base (6.); and it has been shewn, that the solidity of such a parallelopiped is equal to the product of its base and altitude.

2. Every triangular prism is the half of a parallelopiped of the same altitude, but having its base double that of the prism (3.); therefore, the solidity of the prism is half that of the parallelopiped, or it is half the product of the base of the parallelopiped by its altitude, that is, it is equal to the product of the base of the prism by its altitude.

3. Any other prism may be divided into as many triangular prisms as the polygon which forms its base can be divided into triangles, but the solidity of each of these is equal to the product of its base by their common altitude; therefore, the solidity of the whole prism is equal to the product of the sum of all their bases by the common altitude, or it is equal to the product of the base of the prism, which is the sum of them all, by its altitude.

Cor. Two prisms having the same altitude are to each other as their bases; and two prisms having the same base are to each other as their altitudes.

3

Theorem XII.

Fig. 14

Similar prisms are to one another as the cubes of their homologous sides.

Let AG, IP be two similar prisms, of which AB, IK are two homologous sides, the prism AG is to the prism IP as the cube of AB to the cube of IK. Let E and N be two homologous angles of the prisms, and ES, NV perpendiculars to the planes of their bases; join IV; take IR=AE, and in the plane INV draw RT perpendicular to IV; then RT shall be perpendicular to the plane IL (11. and 12. of 7.), also RT shall be equal to ES; for if the solid angles A and I were applied the one to the other, the planes which contain them would coincide (schol. 16. 7.), and the point E would fall upon the point R, and therefore the perpendicular ES would coincide with the perpendicular RT (2. cor. 4. 7.). Now the content of a prism being the product of its base by its altitude (11.), it follows that *prism* AG : *prism* IP :: ES$\times$*base* AC :: NV$\times$ *base* IL; but *base* AC : *base* IL :: $AB^2 : IK^2$ (27. 4.) and therefore considering the lines expressed by numbers, ES $\times$ *base* AC or RT $\times$ *base* AC : NV $\times$ *base* IL :: $RT\times AB^2 : NV \times IK^2$ (5. 3.) therefore *prism* AG : *prism* IP :: $RT\times AB^2 : NV\times IK^2$; but RT : NV :: RI or AE : NI (20. 4.) :: AB : IK (def. of sim. figs.), and consequently $RT\times AB^2 : NV\times IK^2 :: AB^3 : IK^3$ (5. 3.); therefore *prism* AG : *prism* IP :: $AB^3 : IK^3$.

Cor. Similar prisms are to one another in the triplicate ratio of the homologous sides. For let Y and Z be two such lines that AB : IK :: IK : Y :: Y : Z, then the ratio of AB to Z is triplicate the ratio of AB to IK (12. def. 3.). Now, since AB : IK :: IK : Y, therefore $AB^2 : IK^2 :: IK^2 : Y^2$, (9. 4.) and, multiplying the antecedents by AB, and consequents by IK, $AB^3 : IK^3 :: AB\times IK^2 : IK\times Y^2 :: AB\times IK : Y^2$, but $Y^2=IK\times Z$ (8. 4.); therefore $AB^3 : IK^3 :: AB\times IK : IK\times Z$ :: AB : Z, but *prism* AG : *prism* IP :: $AB^3 : IK^3$, therefore *prism* AG : *prism* IP :: AB : Z, which last ratio is triplicate the ratio of AB to IK.

Theorem XIII.

Fig. 14

If a triangular pyramid ABCD be cut by a plane $b\,c\,d$ parallel to its base, the section $b\,c\,d$ is similar to the base BCD.

For because the planes $b\,c\,d$, BCD are parallel, their intersections $b\,c$, BC with a third plane BAC are parallel (7. 7.); and, for a like reason, $c\,d$ is parallel to CD, and $d\,b$ to DB; therefore the angle $b\,c\,d$=BCD, $c\,d\,b$=CDB, and $d\,b\,c$=DBC (10. 7.); hence the triangles $b\,c\,d$, BCD are equiangular, and consequently similar.

Cor. 1. If two triangular pyramids ABCD, EFGH, which have equal bases, and equal altitudes, be cut by planes $b\,c\,d, f\,g\,h$ that are parallel to the bases, and at equal distances from them, the sections are equal. For conceive the bases of the pyramids to be in the same plane, then their vertices will be in a plane parallel to their bases, and the sections, $b\,c\,d, f\,g\,h$ will also be in a plane parallel to their bases, therefore, AB : Ab ::

EF :

EF : Ef (14. 7.), but because the the triangles ABC, Abc are similar, AB : Ab :: BC : bc, and, in like manner EF : Ef :: FG : fg, therefore, BC : bc :: FG : fg, and $BC^2 : bc^2 :: FG^2 : fg^2$ (9. 4.); but $BC^2 : bc^2$ :: *triangle* BCD : *trian.* bcd, and $FG^2 : fg^2$ :: *trian.* FGH : *trian.* fgh (25. 4.); therefore, *trian.* BCD : *trian.* bcd :: *trian.* FGH : *trian.* fgh, but *trian.* BCD=*trian.* FGH (by hyp.) therefore *trian.* bcd=*trian.* fgh.

Scholium.

It is easy to see that what is here demonstrated of triangular pyramids, is equally true of polygonal pyramids having equal bases and altitudes.

Theorem XIV.

Fig. 145. A series of prisms of the same altitude may be circumscribed about any pyramid ABCD, such that the sum of the prisms shall exceed the pyramid by a solid less than any given solid Z.

Let Z be equal to a prism standing on the same base with the pyramid, viz. the triangle BCD, and having for its altitude the perpendicular drawn from a certain point E in the line AC upon the place BCD. It is evident that CE multiplied by a certain number m will be greater than AC; divide CA into as many equal parts as there are units in m, and let these be CF, FG, GH, HA, each of which will be less than CE. Through each of the points F, G, H, let planes be made to pass parallel to the plane BCD, making with the sides of the pyramid the sections FPQ, GRS, HTU, which will be all similar to one another, and to the base BCD (13.). From the point B draw in the plane of the triangle ABC the straight line BK parallel to CF, meeting FP produced in K. In like manner, from D draw DL parallel to CF, meeting FQ in L; join KL, and it is plain that the solid KBCDLF is a prism. By the same construction let the prisms PM, RO, TV be described. Also let the straight line IP, which is in the plane of the triangle ABC be produced till it meet BC in h; and let the line MQ be produced till it meet DC in g. Join hg, then hCg QFP is a prism; and is equal to the prism PM (cor. 11.). In the same manner is described the prism mS equal to the prism RO, and the prism qU equal to the prism TV. The sum, therefore, of all the inscribed prisms hQ, mS and qU is equal to the sum of the prisms PM, RO and TV, that is, to the sum of all the circumscribed prisms except the prism BL; wherefore, BL is the excess of the prisms circumscribed about the pyramid above the prisms inscribed within it. But the prism BL is less than the prism which has the triangle BCD for its base, and for its altitude the perpendicular from E upon the plane BCD, which prism is, by hypothesis, equal to the given solid Z; therefore the excess of the circumscribed above the inscribed prisms is less than the solid Z. But the excess of the circumscribed prisms above the inscribed is greater than their excess above the pyramid ABCD, because ABCD is greater than the sum of the inscribed prisms; much more therefore is the excess of the circumscribed prisms above the pyramid less than the solid Z. A series of prisms of the same altitude has therefore been circumscribed about the pyramid ABCD exceeding it by a solid less than the given solid Z.

Theorem XV.

Pyramids that have equal bases and altitudes are equal to one another. Fig. 146.

Let ABCD, EFGH be two pyramids that have equal bases BCD, FGH, and also equal altitudes; the pyramid ABCD is equal to the pyramid EFGH.

If they are unequal, let the pyramid EFGH exceed the pyramid ABCD by the solid Z. Let a series of prisms of the same altitude be circumscribed about the pyramid ABCD that shall exceed it by a solid less than Z, (14.) and let another series equal in number to the former, and having all the same altitude, be described about the pyramid EFGH; then, because the pyramids have equal altitudes, the altitude of each of the prisms described about the one pyramid is equal to the altitude of each of the prisms described about the other pyramid; therefore the sections of the pyramids which are the bases of the corresponding prisms will be at equal distances from the bases of the pyramids, and hence these sections will be equal; (1. cor. 13.) and because the prisms have all the same altitude, the corresponding prisms will be equal, and the sum of the prisms described about the pyramid ABCD will be equal to the sum of the prisms described about the pyramid EFGH. Let the pyramid EFGH be denoted by P, and the pyramid ABCD by p, and put Q for the sum of the prisms described about P, and q for the prisms described about p: Then by hypothesis $Z=P-p$, and by construction $Z>q-p$, therefore $P-p>q-p$, and consequently $P>q$; but it has been shewn that $q=Q$, therefore $P>Q$, that is, the pyramid EFGH is greater than the sum of the prism described about it, which is impossible, therefore the pyramids ABCD, EFGH are not unequal, that is, they are equal.

Theorem XVI.

Every prism having a triangular base may be divided into three pyramids that have triangular bases, and that are equal to one another. Fig. 147.

Let ABC, DEF be the opposite bases of a triangular prism. Join AE, EC, CD; and because ABED is a parallelogram, of which AE is the diameter, the triangle ADE is equal to the triangle ABE; therefore the pyramid of which the base is the triangle ADE and vertex the point C, is equal to the pyramid of which the base is the triangle ABE, and vertex the point C. But the pyramid of which the base is the triangle ABE and vertex the point C, that is the pyramid ABCE, is equal to the pyramid DEFC, (15.) for they have equal bases, viz. the triangles ABC, DFE, and the same altitude, viz. the altitude of the prism ABCDEF. Therefore, the three pyramids ADEC, ABEC, DFEC are equal to one another; but these pyramids make up the whole prism ABCDEF; therefore, the prism ABCDEF is divided into three equal pyramids.

Cor. 1. From this it is manifest that every pyramid

Of Cylinders, Cones, and the Sphere.

mid is the third part of a prism which has the same base and the same altitude with it; for if the base of the prism be any other figure than a triangle, it may be divided into prisms having triangular bases.

Cor. 2. Pyramids having equal altitudes are to one another as their bases; because the prisms upon the same bases, and of the same altitude, are to one another as their bases.

Of Cylinders, Cones, and the Sphere.

SECT. IX. OF CYLINDERS, CONES, AND THE SPHERE.

Definitions.

I. A *Cylinder* is a solid figure described by the revolution of a right-angled parallelogram about one of its sides, which remains fixed.

The *Axis* of the cylinder is the fixed straight line about which the parallelogram revolves.

The *Bases* of the cylinder are the circles described by the two revolving opposite sides of the parallelogram.

II. A *Cone* is a solid figure described by the revolution of a right-angled triangle about one of the sides containing the right angle, which side remains fixed.

The *Axis* of the cone is the fixed line about which the triangle revolves.

The *Base* of the cone is the circle described by that side containing the right angle which revolves.

III. A *Sphere* is a solid figure described by the revolution of a semicircle about a diameter.

The *Axis* of a sphere is the fixed line about which the semicircle revolves.

The *Centre* of a sphere is the same with that of the semicircle.

The *Diameter* of a sphere is any straight line which passes through the centre, and is terminated both ways by the superficies of the sphere.

IV. *Similar* cones and cylinders are those which have their axes and diameters of their bases proportional.

Theorem I.

Fig. 148. If from any point E in the circumference of the base of a cylinder ABCD, a perpendicular EF be drawn to the plane of the base AEB, the straight line EF is wholly in the cylindric superficies.

Let HG be the axis, and AGHD the rectangle, which by its revolution describes the cylinder. Because HG is perpendicular to AG in every position of the revolving rectangle, it is perpendicular to the plane of the circle described by AG; and because AD, the line which describes the cylindric superficies, is parallel to GH, it is also perpendicular to the plane of that circle. (5. 7.). Now when by the revolution of the rectangle AGHD the point A coincides with the point E, the line EF will coincide with AD, and thus will be wholly in the cylindric superficies; for otherwise two perpendiculars might be drawn to the same plane, from the same point, which is impossible (2 cor. 4. 7.).

Theorem II.

Fig. 149. A cylinder and a parallelopiped having equivalent bases and the same altitude are equal to one another.

Let ABCD be a cylinder, and EF a parallelopiped having equivalent bases, viz. the circle AGB and the parallelogram EH, and having also equal altitudes; the cylinder ABCD is equal to the parallelopiped EF. If not, let them be unequal; and first let the cylinder be less than the parallelopiped EF; and from the parallelopiped EF let there be cut off a part EQ by a plane PQ parallel to NF, equal to the cylinder ABCD. In the circle AGB inscribe the polygon AGKBLM that shall differ from the circle by a space less than the parallelogram PH, (1 cor. 2. 6.) and cut off from the parallelogram EH a part OR equal to the polygon AGKBLM, then it is manifest that the parallelogram OR is greater than the parallelogram OP, therefore the point R will fall between P and N. On the polygon AGKBLM let an upright prism be constituted of the same altitude with the cylinder, which will therefore be less than the cylinder, because it is within it; (1.) and if through the point R a plane RS parallel to NF be made to pass, it will cut off the parallelopiped ES equal to the prism AGBC, because its base is equal to that of the prism, and its altitude is the same. But the prism AGBC is less than the cylinder ABCD, and the cylinder ABCD is equal to the parallelopiped EQ, by hypothesis; therefore, ES is less than EQ, and it is also greater, which is impossible. The cylinder ABCD therefore is not less than the parallelopiped EF; and in the same manner it may be shewn not to be greater than EF, therefore they are equal.

Theorem III.

If a cone and cylinder have the same base and the same altitude, the cone is the third part of the cylinder. Fig. 150.

Let the cone ABCD, and the cylinder BFKG have the same base, viz. the circle BCD, and the same altitude, viz. the perpendicular from the point A upon the plane BCD; the cone ABCD is the third part of the cylinder BFKG. If not, let the cone ABCD be the third part of another cylinder LMNO having the same altitude with the cylinder BFKG; but let the bases BCD, LIM be unequal, and first let BCD be greater than LIM. Then, because the circle BCD is greater than the circle LIM, a polygon may be inscribed in BCD that shall differ from it less than LIM does, (1. cor. 2. 6.) and which therefore will be greater than LIM. Let this be the polygon BECFD; and upon BECFD let there be constituted the pyramid ABECFD, and the prism BCFKHG. Because the polygon BECFD is greater than the circle LIM, the prism BCFKHG is greater than the cylinder LMNO, for they have the same altitude, but the prism has the greater base. But the pyramid ABECFD is the third part of the prism BCFHG (16. 8.); therefore it is greater

Of Cylinders, Cones, and the Sphere.

greater than the third part of the cylinder LMNO. Now the cone ABECFD is by hypothesis the third part of the cylinder LMNO, therefore, the pyramid ABECFD is greater than the cone ABCD, and it is also less, because it is inscribed in the cone, which is impossible. Therefore the cone ABCD is not less than the third part of the cylinder BFKG. And in the same manner, by circumscribing a polygon about the circle BCD, it may be shewn, that the cone ABCD is not greater than the third part of the cylinder BFKG; therefore, it is equal to the third part of the cylinder.

Theorem IV.

Fig. 151.

If a hemisphere and cone have equal bases and altitudes, a series of cylinders may be inscribed in the hemisphere, and another series may be circumscribed about the cone, having all the same altitudes with one another, and such that their sum shall differ from the sum of the hemisphere and the cone by a solid, less than any given solid.

Let ADB be a semicircle, of which the centre is C, and let CD be at right angles to AB; let DB and DA be squares described on DC, draw CE, and let the figure thus constructed revolve about DC: then the quadrant BCD will describe a hemisphere having C for its centre, and the triangle CDE will describe a cone having its vertex at C, and having for its base the circle described by DE, equal to that described by BC, which is the base of the hemisphere. Let W be a given solid, a series of cylinders may be described in the hemisphere ADB, and another described about the cone ECI, so that their sum shall differ from the sum of the hemisphere and cone, by a solid less than the solid W.

Upon the base of the hemisphere let a cylinder be constituted equal to W, and let its altitude be CX. Divide CD into such a number of equal parts, that each of them shall be less than CX; let these be CH, HG, GF and FD. Draw FN, GO, HP parallel to CB, meeting the circle in K, L, and M, and the straight line BE in Q, R, and S. Draw K*f*, L*g*, M*h*, perpendicular to GO, HP, and CB; and draw Q*q*, R*r*, S*s*, perpendicular to the same lines. It is evident that the figure being thus constructed, if the whole revolve about CD, the rectangles F*f*, G*g*, H*h*, will describe cylinders that will be circumscribed by the hemisphere BDA; and that the rectangles DN, F*q*, G*r*, H*s* will also describe cylinders that will circumscribe the cone ICE. Now it may be demonstrated, as was done of the prisms inscribed in a pyramid (14. 8.), that the hemisphere exceeds the sum of all the cylinders described within it, by a solid less than the cylinder generated by the rectangle HB, that is, by a solid less than W. In the same manner it may be demonstrated, that the sum of the cylinders circumscribing the cone ICE is greater than the cone by a solid less than the cylinder generated by the rectangle DN, that is, by a solid less than W. Therefore, since the sum of the cylinders inscribed in the hemisphere together with a solid less than W, is equal to the hemisphere; and since the sum of the cylinders described about the cone is equal to the cone together with a solid less than W; adding equals to equals, the sum of all the cylinders together with a solid less than W is equal to the hemisphere and cone together with a solid less than W; therefore, the difference between the whole of the cylinders, and the sum of the hemisphere and the cone, is equal to the difference of two solids, each of which is less than W; but this difference must also be less than W; therefore the difference between the two series of cylinders, and the sum of the hemisphere and cone is less than the given solid W.

Theorem V.

The same things being supposed as in last theorem, the sum of all the cylinders inscribed in the hemisphere, and described about the cone, is equal to a cylinder having the same base and altitude with the hemisphere. Fig. 151.

For, the same construction being supposed as in last theorem, let L be the point in which GO meets the circle ADB, then because CGL is a right angle, if CL be joined, the circles described with the radii CG and GL are equal to the circle described with the radius CL or GO (2. cor. 4. 6.). Now CG=GR, because CD=DE, therefore, the circles described by the revolution of the radii GR and GL about the point G are together equal to the circle described by the revolution of the radius GO about the same point G; therefore also the cylinders that stand upon the two first of these circles having the common altitude GH are equal to the cylinder which stands upon the remaining circle, and which has the same altitude GH. The cylinders described by the revolution of the rectangles G*g* and G*r* are therefore equal to the cylinder described by the rectangle GP. And as the same may be shewn of all the rest, the cylinders described by the rectangles H*h*, G*g*, F*f*, and by the rectangles H*s*, G*r*, F*q*, DN, are together equal to the cylinder described by DB, that is, to the cylinder having the same base and altitude with the hemisphere.

Theorem VI.

Every sphere is two-thirds of the circumscribing cylinder. Fig. 151.

Let the figure be constructed as in the two last theorems, and if the hemisphere described by the quadrant BDC be not equal to two-thirds of the cylinder described by the rectangle BD, let it be greater by the solid W. Then as the cone described by CDE is one-third of the cylinder described by BD, the cone and the hemisphere together will exceed the cylinder by W. But that cylinder is equal to the sum of all the cylinders described by the rectangle H*h*, G*g*, F*f*, H*s*, G*r*, F*q*, DN; therefore, the hemisphere and the cone added together exceed the sum of all these cylinders by the solid W, which is absurd; for it has been shewn (4.) that the hemisphere and the cone together differ from the sum of these cylinders by a solid less than W. The hemisphere is therefore equal to two-thirds of the cylinder described

Of Cylinders, Cones, and the Sphere.

scribed by the rectangle BD; and therefore the whole sphere is two thirds of the cylinder described by twice the rectangle BD, that is, to two-thirds of the circumscribing cylinder.

We here conclude the *Elements of Geometry*. Their application, constituting what is sometimes called *Practical Geometry*, will be given under the article Mensuration.

George.

GEORGE I. II. and III. kings of Great Britain.—George I. the son of Ernest Augustus, duke of Brunswick Lunenburgh, and elector of Hanover, succeeded to the throne of Great Britain in 1714, in virtue of an act of parliament, passed in the latter part of the reign of King William III. limiting the succession of the crown, after the demise of that monarch, and Queen Anne (without issue), to the princess Sophia of Hanover, and the heirs of her body, being Protestants.—George II. the only son of the former, succeeded him in 1727, and enjoyed a long reign of glory; dying amidst the most rapid and extensive conquests in the 77th year of his age. He was succeeded by his grandson George III. our late sovereign. For particulars, see Britain, N° 374—701.

G E O

George, or *Knights of St George*, has been the denomination of several military orders, whereof that of the Garter is one of the most illustrious. See Garter, and *St George*, below.

King George's Islands, are two islands in the South sea, lying in W. Long. 144. 56. S. Lat. 14. 28. They were first discovered by Commodore Byron in 1765, and were since visited by Captain Cook in 1774. Commodore Byron's people had an encounter with the inhabitants, which proved fatal to some of the natives; but Captain Cook was more fortunate. A lieutenant and two boats well-armed were sent on shore by Captain Cook; and landed without opposition. As soon as the gentlemen landed, the islanders embraced them by touching noses, a mode of civility used in New Zealand,

George. land, which is 900 leagues distant, and the only place besides this where the custom has been observed to prevail. Notwithstanding this ceremony, however, very little real friendship seemed to take place on the part of the islanders. They crowded about the boats as the people were stepping into them, and seemed in doubt whether they should detain them or let them go; at last, however, not thinking themselves sufficiently strong, they seemed contented with their departure, and assisted them in pushing off their boats; but some of the most turbulent threw stones into the water, which fell very near them, and all seemed to glory that they had as it were driven them off. The British brought off five dogs of a white colour with fine long hair, with which the island seemed to be plentifully supplied. These they purchased with small nails, and some ripe bananas which had been brought from the Marquesas. On this island Mr Forster found a kind of scurvy-grass, which the natives informed him they were wont to bruise and mix with shell fish; after which, they threw it into the sea whenever they perceived a shoal of fish. This preparation intoxicates them for some time; and thus they are caught on the surface of the water without any other trouble than that of taking them out. The name of this plant among the natives is *enow*. The largest island, which they call *Tiookea*, is something of an oval shape, and about 10 leagues in circuit; the other island, which lies two leagues to the westward of Tiookea, is four leagues long from north-east to south-west, and from three to five miles broad. The soil of both is extremely scanty; the foundation consists of coral, very little elevated above the surface of the water.

George, St, or *George of Cappadocia;* a name whereby several orders, both military and religious, are denominated. It took its rise from a saint or hero famous throughout all the East, called by the Greeks *Μεγαλομαρτυς*, q. d. *great martyr*.

On some medals of the emperors John and Manuel Comneni, we have the figure of St George armed, holding a sword or javelin in one hand, and in the other a buckler, with this inscription; an O, and therein a little

P

A, and ΓΕ—ΓΙΟC, making Ο ΑΓΙΟΣ ΓΕΟΡΓΙΟΣ, *O*

O

holy George. He is generally represented on horseback, as being supposed to have frequently engaged in combats in that manner. He is highly venerated throughout Armenia, Muscovy, and all the countries which adhere to the Greek rite: from the Greek, his worship has long ago been received into the Latin church; and England and Portugal have both chosen him for their patron saint.

Great difficulties have been raised about this saint or hero. His very existence has been called in question. Dr Heylin, who wrote first and most about him, concluded with giving him entirely up, and supposing him only a symbolical device; and Dr Pettingal has turned him into a mere Basilidian symbol of victory. Mr Pegg, in a paper in the Archæologia *, has attempted to restore him. And, finally, Mr Gibbon † has sunk him into an Arian bishop in the reigns of Constantius and Julian.—The bishop alluded to,

* Vol. i.

† [...]. Hist. [...] ii. [...]04.

George the Cappadocian, was so surnamed, according to our author, from his parents or education; and was born at Epiphania in Cilicia, in a fuller's shop. "From this obscure and servile origin he raised himself by the talents of a parasite: and the patrons, whom he assiduously flattered, procured for their worthless dependent a lucrative commission or contract, to supply the army with bacon. His employment was mean: he rendered it infamous. He accumulated wealth by the basest arts of fraud and corruption; but his malversations were so notorious, that George was compelled to escape from the pursuits of justice. After this disgrace, in which he appears to have saved his fortune at the expence of his honour, he embraced, with real or affected zeal, the profession of Arianism. From the love, or the ostentation, of learning, he collected a valuable library of history, rhetoric, philosophy, and theology; and the choice of the prevailing faction promoted George of Cappadocia to the throne of Athanasius." His conduct in this station is represented by our historian as polluted by cruelty and avarice, and his death considered as a just punishment for the enormities of his life, among which Mr Gibbon seems to rank his "enmity to the gods."

The immediate occasion of his death, however, as narrated by ecclesiastical writers, will not probably appear calculated to add any stain to his memory. "There was in the city of Alexandria a place in which the heathen priests had been used to offer human sacrifices. This place, as being of no use, Constantius gave to the church of Alexandria, and George the bishop gave orders for it to be cleared, in order to build a Christian church on the spot. In doing this they discovered an immense subterraneous cavern, in which the heathen mysteries had been performed, and in it were many human skulls. These, and other things which they found in the place, the Christians brought out and exposed to public ridicule. The heathens, provoked at this exhibition, suddenly took arms and rushing upon the Christians, killed many of them with swords, clubs and stones: some also they strangled, and several they crucified. On this the Christians proceeded no farther in clearing the temple; but the heathens, pursuing their advantage, seized the bishop as he was in the church, and put him in prison. The next day they despatched him; and then fastening the body to a camel, he was dragged about the streets all day, and in the evening they burnt him and the camel together. This fate, Sozomen says, the bishop owed in part to his haughtiness while he was in favour with Constantius, and some say the friends of Athanasius were concerned in this massacre; but he ascribes it chiefly to the inveteracy of the heathens, whose superstitions he had been very active in abolishing.

This George, the Arian bishop of Alexandria, was a man of letters, and had a very valuable library, which Julian ordered to be seized for his own use; and in his orders concerning it, he says that many of the books were on philosophical and rhetorical subjects, though many of them related to the doctrine of the impious Galileans (as in his sneering contemptuous way he always affected to call the Christians). 'These books (says he) I could wish to have utterly destroyed; but lest books of value should be destroyed along with them, let those also be carefully sought for.'

But Mr Gibbon gives a different turn to the affair of of George's murder, as well as relates it with different circumstances. "The Pagans (says he) excited his devout avarice; and the rich temples of Alexandria were either pillaged or insulted by the haughty prelate, who exclaimed, in a loud and threatening tone, 'How long will these sepulchres be permitted to stand?' Under the reign of Constantius, he was expelled by the fury, or rather by the justice of the people: and it was not without a violent struggle, that the civil and military powers of the state could restore his authority, and gratify his revenge. The messenger who proclaimed at Alexandria the accession of Julian, announced the downfal of the archbishop. George, with two of his obsequious ministers, Count Diodorus and Darcontius master of the mint, was ignominiously dragged in chains to the public prison. At the end of 24 days, the prison was forced open by the rage of a superstitious multitude, impatient of the tedious forms of judicial proceedings. The *enemies of gods* and men expired under their cruel insults; the lifeless bodies of the archbishop and his associates were carried in triumph through the streets on the back of a camel; and the inactivity of the Athanasian party was esteemed a shining example of evangelical patience. The remains of these guilty wretches were thrown into the sea; and the popular leaders of the tumult declared their resolution to disappoint the devotion of the Christians, and to intercept the future honours of these martyrs, who had been punished like their predecessors, by the enemies of their religion. The fears of the Pagans were just, and their precautions ineffectual. The meritorious death of the archbishop obliterated the memory of his life. The rival of Athanasius was dear and sacred to the Arians, and the seeming conversion of those sectaries introduced his worship into the bosom of the Catholic church. The odious stranger, disguising every circumstance of time and place, assumed the mask of a martyr, a saint, and a Christian hero; and the infamous George of Cappadocia has been transformed into the renowned St George of England, the patron of arms, of chivalry, and of the Garter."

Knights of St George. See GARTER. There have been various other orders under this denomination, most of which are now extinct; particularly one founded by the emperor Frederic III. in the year 1470, to guard the frontiers of Bohemia and Hungary against the Turks; another, called *St George of Alfama*, founded by the kings of Arragon; another in Austria and Carinthia; and another in the republic of Genoa, still subsisting, &c.

Religious of St George. Of these there are divers orders and congregations; particularly canons regular of St George in Alga, at Venice, established by authority of Pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached in 1396, at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence of all other religious. Another congregation of the same institute in Sicily, &c.

St George del Mina, the capital of the Dutch settlements on the Gold coast of Guinea, situated seven or eight miles west of Cape-coast castle the capital of the British settlements there. W. Long. 5'. and N. Lat. 5°.

St George, a fort and town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel, belonging to the British; it is otherwise called *Madras*, and by the natives *Chilipatam*. It fronts the sea, and has a salt water river on its back side, which hinders the fresh water springs from coming near the town, so that they have no good water within a mile of them. In the rainy seasons it is incommoded by inundations; and from April to September, it is so scorching hot, that if the sea breezes did not cool the air, there would be no living there. There are two towns, one of which is called the *White Town*, which is walled round, and has several bulwarks and bastions to defend it: it is 400 paces long and 150 broad, and is divided into regular streets. Here are two churches, one for the Protestants, and the other for the Papists; as also a good hospital, a town hall, and a prison for debtors. They are a corporation, and have a mayor and aldermen, with other proper officers. The *Black Town* is inhabited by Gentoos, Mahometans, and Portuguese and Armenian Christians, and each religion has its temples and churches. This, as well as the White Town, is ruled by the English governor and his council. The diamond mines are but a week's journey from this place, which renders them pretty plentiful, but there are no large ones since that great diamond was procured by Governor Pitt. This colony produces very little of its own growth or manufacture for foreign markets, and the trade is in the hands of the Armenians and Gentoos. The chief things the British deal in, besides diamonds, are calicoes, chintz, muslins, and the like. In 1794 the population of the town was estimated at 300,000. Their rice is brought by sea from Gangam and Orixa, their wheat from Surat and Bengal, and their fire wood from the islands of Diu; so that an enemy, with a superior force at sea, may easily distress them. The houses of the White Town are built with brick, and have lofty rooms and flat roofs. The houses in the *White Town* have all green Venetian windows, and are surrounded by gardens. The Black Town consists chiefly of thatched cottages. The military power is lodged in the governor and council, who are also the last resort in civil causes. The company have two chaplains, who officiate by turns. They never attempt to make proselytes, but leave that to the Popish missionaries. The salaries of the Company's writers are very small: but if they have any fortune of their own, they may make it up by trade; which must generally be the case, for they commonly grow rich. It was taken by the French in 1764, who restored it at the peace of Aix-la-Chapelle.

St George's, the largest of the Bermuda or Summer islands. W. Long. 65. 10. N. Lat. 32. 30.

Cross of St George, a red one in a field argent, which makes part of the British standard.

GEORGE, a lake in America in the state of New York, about 35 miles long, and from one to seven broad. There are some beautiful islands in it, the largest of which is about two miles broad, commanding a delightful and very extensive prospect. There are manifest traces of a large town of the aborigines, and the-

the island itself appears to have been the favourite residence of an Indian prince. It lies to the south of Lake Champlain, and its waters lie about 100 feet higher. It abounds with fishes of a superior quality, such as the Oswego bass, and speckled trouts of considerable magnitude. The French at one period called it Lake Sacrament, as they were at the trouble to bring from it their water for sacramental purposes, to the churches they had planted in Canada.

GEORGETOWN, the name of several towns in America, such, for instance, as Georgetown in Maryland, about 65 miles S. W. of Philadelphia; Georgetown in the county of Lincoln, and district of Maine, lying on both sides of Kennebeck river, 148 miles S. W. of Philadelphia, where the Roman Catholics have a very flourishing college: it is the name of a village in Fayette county, Pennsylvania, where a number of boats are annually built; and of a post town in the district of the same name, where the Episcopalians, Baptists, and Methodists, have each a place of worship. It is also the name of a port of entry in South Carolina, situated on the Sampit river, 12 miles from the sea. It has a flourishing academy, where orphans and poor children are educated gratis.

GEORGIA, a country of Asia, bounded on the north by Circassia, on the east by Daghestan and Shirvan, on the south by Armenia, and on the west by the Euxine or Black sea; comprehending the greatest part of the ancient Colchis, Iberia, and Albania. About the etymon of the name of this country, authors are not agreed. The most probable opinion is, that it is a corruption by softening of *Kurgia*, from the river Kur; whence also it is supposed that the inhabitants are called by the Persians indifferently *Gurgi* and *Kurgi*; and the country *Kurgistan* and *Gurgistan*: It is divided by a ridge of mountains into eastern and western; the former of which is again subdivided into the kingdoms of Caket, Carduel or Carthuel, and Goguetia; and the latter into the provincess of Abcassia, Mireta or Imeretia, and Guriel. Another division is into Georgia Proper, Abcassia, and Mingrelia. A third division will be afterwards mentioned.

"Georgia, (says Sir George Chardin) is as fertile a country as can be seen; the bread is as good here as in any part of the world; the fruit of an exquisite flavour and of different sorts: no place in Europe yields better pears and apples, and no place in Asia better pomegranates. The country abounds with cattle, venison, and wild fowl of all sorts: the river Kur is well stocked with fish; and the wine is so rich, that the king of Persia has always some of it for his own table. The inhabitants are robust, valiant, and of a jovial temper; great lovers of wine, and esteemed very trusty and faithful; endowed with good natural parts, but, for want of education, very vicious. The women are generally so fair and comely, that the wives and concubines of the king of Persia and his court are for the most part Georgian women. Nature has adorned them with graces nowhere else to be met with: it is impossible to see them without loving them; they are of a good size, clean limbed, and well shaped. Another traveller, however, of no mean character, thus expresses himself with respect to the women: "As to the Georgian women, they did not at all surprise us; for we expected to find them perfect beauties. They are, indeed no way disagreeable; and may be counted beauties, if compared with the Curdes. They have an air of health that is pleasing enough; but, after all, they are neither so handsome nor so well shaped as is reported. Those who live in the towns have nothing extraordinary more than the others; so that I may, I think, venture to contradict the accounts that have been given of them by most travellers."

This country formerly abounded with great cities, as appears not only from its history, but from the ruins of many of them still visible, which show that they must have been very large, opulent, and magnificently built. These were all destroyed by the inundations of northern barbarians from Mount Caucasus, as the Alans, Huns, Suevi, and some others, so much noted in history for their strength, courage, and conquests.

The latest division of this country is into nine provinces; five of which were subject to the famous prince Heraclius, forming what is commonly called the kingdom of Georgia; and four were under the dominion of David, composing the kingdom or principality of Imeretia. See IMERETIA.

This whole country is so extremely beautiful, that some fanciful travellers have imagined they had here found the situation of the original garden of Eden. The hills are covered with forests of oak, ash, beech, chesnuts, walnuts, and elms, encircled with vines, growing perfectly wild, but producing vast quantities of grapes. From these is annually made as much wine as is necessary for the yearly consumption; the remainder is left to rot on the vines. Cotton grows spontaneously, as well as the finest European fruit trees. Rice, wheat, millet, hemp, and flax, are raised on the plains, almost without culture. The valleys afford the finest pasturage in the world; the rivers are full of fish; the mountains abound in minerals, and the climate is delicious; so that nature appears to have lavished on this favourite country every production that can contribute to the happiness of its inhabitants.

On the other hand, the rivers of Georgia being fed by mountain torrents, are at all seasons either too rapid or too shallow for the purposes of navigation: the Black sea, by which commerce and civilization might be introduced from Europe, has been till very lately in the exclusive possession of the Turks: the trade of Georgia by land is greatly obstructed by the high mountains of Caucasus; and this obstacle is still increased by the swarms of predatory nations, by which those mountains are inhabited.

It is said, that in the 15th century, a king of Georgia divided among his five sons the provinces of Carduel and Caket, Imeretia, Mingrelia, Guriel, and Abcassia. These petty princes were too jealous to unite for their common defence, and too weak singly to resist a foreign enemy, or even to check the encroachments of their great vassals, who soon became independent. By forming a party among these nobles, the Turks gradually gained possession of all the western provinces, while the Persians occupied the governments of Carduel and Caket. Since that period the many unsuccessful attempts of the Georgians to recover their liberty have repeatedly produced the devastation of their country. Abbas the Great is said to have carried off in one expedition from the provinces of

Georgia. of Carduel and Caket no less than 80,000 families; a number which, probably, exceeds the whole actual population of those provinces. The most horrible cruelties were again exercised on the unhappy people, at the beginning of the present century, by the merciless Nadir; but these were trifling evils, compared with those arising from the internal dissensions of the great barons. This numerous body of men, idle, arrogant, and ferocious, possessed of an unlimited power over the lives and properties of their vassals, having no employment but that of arms, and no hopes of aggrandizing themselves but by the plunder of their rivals, were constantly in a state of warfare; and as their success was various, and the peasants of the vanquished were constantly carried off and sold to the Turks or Persians, every expedition increased the depopulation of the country. At length they invited the neighbouring mountaineers, by the hopes of plunder, to take part in their quarrels; and these dangerous allies, becoming acquainted with the country, and being spectators of the weakness of its inhabitants, soon completed its desolation. A few squalid wretches, half naked, half starved, and driven to despair by the merciless exactions of their landlords, are thinly dispersed over the most beautiful provinces of Georgia. The revolutions of Persia, and the weakness of the Turks, indeed enabled the princes of the country to recover their independence; but they did not long enjoy this advantage, as they have recently been subdued by the Russians, and the country now forms a province of that unwieldy empire.

The capital of Georgia is Teflis, where Prince Heraclius resided (See Teflis). Of this prince, so celebrated for his exploits and success in shaking off the Ottoman yoke, we have the following account by the late Professor Guldenstaedt when he travelled into these parts in 1770. "Heraclius, or, as he is called, the Tzar Iracli, is above 60 years old, of a middle size, with a long countenance, a dark complexion, large eyes, and a small beard. He passed his youth at the court and in the army of the celebrated Nadir Shah, where he contracted a fondness for Persian customs and manners, which he has introduced into his kingdom. He has seven sons and six daughters. He is much revered and dreaded by the Persian khans his neighbours; and is usually chosen to mediate between them in their disputes with each other. When they are at war, he supports one of the parties with a few troops, who diffuse a spirit and courage among the rest, because the Georgian soldiers are esteemed the bravest of those parts; and Prince Heraclius himself is renowned for his courage and military skill. When on horseback he has always a pair of loaded pistols at his girdle, and, if the enemy is near, a musket slung over his shoulder. In all engagements he is the foremost to give examples of personal bravery; and frequently charges the enemy at the head of his troops with the sabre in his hand. He loves pomp and expence; he has adopted the dress of Persia; and regulates his court after the manner of that country. From the example of the Russian troops, who were quartered in Georgia during the last Turkish war, he has learnt the use of plates, knives, and forks, dishes and household furniture, &c."

The subjects of Heraclius were estimated at about 60,000 families; but this, notwithstanding the present desolated state of the country, is probably an under valuation. The peasants belonging to the queen, and those of the patriarch, pay no tax to the prince, and therefore do not appear on the books of the revenue officers. Many similar exemptions have likewise been granted by the prince to his sons-in-law, and his favourites. Besides, as the impost on the peasants is not a poll-tax, but a tax on hearths, the inhabitants of a village, on the approach of the collectors, frequently carry the furniture of several huts into one, and destroy the remainder, which are afterwards very easily replaced. It is probable, therefore, that the population of Georgia does not fall short of 350,000 souls. The revenues may be estimated at about 150,000 rubles, or 26,250l. They consist of, 1. The customs, farmed at 1750l.—2. Rent paid by the farmers of the mint, at Teflis, 1750l.—3. The tribute paid by the khans of Erivan and Gansha, 7000l.—and, 4. The hearth money levied on the peasants, amounting to 15,750l. The common coins here are the abasses, of about 15d. value, and a small copper coin, stamped at the mint at Teflis. Besides these, a large quantity of gold and silver money is brought into the country from Persia and Turkey, in exchange for honey, butter, cattle, and blue linens.

The government of Georgia was despotic; and though now subject to Russia, it is still in a great measure governed by its own laws. The punishments in criminal cases are shockingly cruel; fortunately they are not frequent, because it is seldom difficult to escape into some of the neighbouring countries, and because the prince is more enriched by confiscating the property of the criminal, than by putting him to torture. Judicial combats are considered as the privilege of nobility, and take place when the cause is extremely intricate, or when the power and interest of two claimants are so equal, that neither can force a decision of the court in his favour. This mode of trial is called an appeal to the judgment of God.

The dress of the Georgians nearly resembles that of the Cossacks; but men of rank frequently wear the habit of Persia. They usually dye their hair, beard, and nails with red. The Georgian women employ the same colour to stain the palms of their hands. On their heads they wear a cap or fillet, under which their black hair falls on their forehead: behind it is braided into several tresses. Their eyebrows are painted with black, in such a manner as to form one entire line, and their faces are perfectly coated with white and red. Their robe is open to the girdle, so that they are reduced to conceal their breasts with their hands. Their air and manner are extremely voluptuous. Being generally educated in convents, they can all read and write; a qualification which is very unusual among the men, even of the highest rank. Girls are betrothed as soon as possible, often at three or four years of age. In the streets the women of rank are always veiled, and then it is indecent in any man to accost them. It is likewise uncivil in conversation to inquire after the wives of any of the company. These, however, are not ancient customs, but are a consequence of the violences committed by the Persians, under Shah Nadir.

Travellers

Travellers accuse the Georgians of drunkenness, superstition, cruelty, sloth, avarice, and cowardice; vices which are everywhere common to slaves and tyrants, and are by no means peculiar to the natives of this country. The descendants of the colonists, carried off by Shah Abbas, and settled at Peria, near Ispahan, and in Masanderan, have changed their character with their government; and the Georgian troops, employed in Persia against the Affghans, were advantageously distinguished by their docility, their discipline, and their courage.

The other inhabitants of Georgia are Tartars, Ossi, and Armenians, called in the Georgian language Somakhi. These last are found all over Georgia, sometimes mixed with the natives, and sometimes in villages of their own. They speak among themselves their own language, but all understand and can talk the Georgian. Their religion is partly the Armenian, and partly the Roman Catholic. They are the most oppressed of the inhabitants, but are still distinguished by that instinctive industry which everywhere characterizes the nation.

Besides these, there are in Georgia considerable numbers of Jews, called, in the language of the country, Uria. Some have villages of their own; and others are mixed with the Georgian, Armenian, and Tartar inhabitants, but never with the Ossi. They pay a small tribute above that of the natives.

Georgia, one of the United States of America, lying between South Carolina and Florida. It is about 290 miles long from north to south, 250 broad, and its area is about 62,000 square miles. It is bounded by Florida on south, the Atlantic on the east, Alabama on the west, and South Carolina on the north. The whole coast is bordered with islands; the principal of which are Skidaway, Wassaw, Sapelo, Frederica, Jekyl, Cumberland, and Amelia.

The settlement of a colony between the rivers Savannah and Alatamaha was meditated in England in 1732, for the accommodation of poor people in Great Britain and Ireland, and for the further security of Carolina. Private compassion and public spirit conspired to promote the benevolent design. Humane and opulent men suggested a plan of transporting a number of indigent families to this part of America free of expence. For this purpose they applied to the king, George II. and obtained from him letters patent, bearing date June 9, 1732, for legally carrying into execution what they had generously projected. They called the new province *Georgia*, in honour of the king, who encouraged the plan. A corporation, consisting of 21 persons, was constituted by the name of, The Trustees for settling and establishing the colony of Georgia.

In November 1732, 116 settlers embarked for Georgia to be conveyed thither free of expence, furnished with every thing requisite for building and for cultivating the soil. Mr James Oglethorpe, one of the trustees, and an active promoter of the settlement, embarked as the head and director of these settlers. They arrived at Charlestown early in the next year. Mr Oglethorpe, accompanied by William Bull, shortly after his arrival, visited Georgia; and after surveying the country, marked the spot on which Savannah now stands, as the fittest to begin their settlement. Here they accordingly began and built a small fort, and a number of small huts for their defence and accommodation. Such of the settlers as were able to bear arms were embodied, and well appointed with officers, arms, and ammunition. A treaty of friendship was concluded between the settlers and their neighbours the Creek Indians, and every thing wore the aspect of peace and future prosperity. But the fundamental regulations established by the trustees of Georgia were ill adapted to the circumstances and situation of the poor settlers, and of pernicious consequences to the prosperity of the province. Yet although the trustees were greatly mistaken with respect to their plan of settlement, it must be acknowledged their views were generous. Like other distant legislators, who framed their regulations upon principles of speculation, they were liable to many errors and mistakes; and however good their design, their rules were found improper and impracticable. These injudicious regulations and restrictions, the wars in which they were involved with the Spaniards and Indians, and the frequent insurrections among themselves, threw the colony into a state of confusion and wretchedness too great for human nature long to endure. Their oppressed situation was represented to the trustees by repeated complaints; till at length finding that the province languished under their care, and weary with the complaints of the people, they in the year 1752 surrendered their charter to the king, and it was made a royal government. —In the year 1740, the Rev. George Whitefield founded an orphan house academy in Georgia about 12 miles from Savannah. Mr Whitefield died at Newbury port, in New England, in October 1770, in the 56th year of his age, and was buried under the Presbyterian church in that place. From the time Georgia became a royal government in 1752 till the peace of Paris in 1763, she struggled under many difficulties, arising from the want of credit and friends, and the frequent molestations of enemies. The good effects of the peace were sensibly felt in the province of Georgia. From this time it began to flourish under the fatherly care of Governor Wright. To form a judgment of the rapid growth of the colony, we need only attend to its exports. In the year 1763, they consisted of 7500 barrels of rice, 9633 pounds of indigo, 1250 bushels of Indian corn, which, together with deer and beaver skins, naval stores, provisions, timber, &c. amounted to no more than 27,021l. sterling. Ten years afterwards, in 1773, they amounted to 121,677l. sterling. The chief articles of export from this state are, rice, tobacco, indigo, sago, lumber of various kinds, naval stores, leather, deer skins, snake-root, myrtle, bees wax, corn, live stock, &c.

During the American war, Georgia was overrun by the British troops, and the inhabitants were obliged to flee to the neighbouring states for safety. Since the peace the progress of the population of this state is said to have been astonishingly rapid; but it was for a time a good deal checked by the hostile irruptions of the Creek Indians, who continually harassed the frontiers of the state. This evil is now little known, and the recent

Georgia. recent annexation of Florida to the territories of the United States, is likely to secure Georgia from Indian warfare in future.

From the sea coast to the distance of more than 100 miles, the country is a level plain; the soil a sandy loam, and covered with pine, except in the morasses, and places occasionally inundated by the rivers, where it is rich, and favourable to the growth of most agricultural productions. Beyond this plain the surface rises into pleasant waving hills, which stretch backwards till they unite with the chain of Apalachian mountains. This undulating country is extremely rich and fertile.

The climate in general is somewhat warmer than that of South Carolina. The range of the thermometer in winter is from 40 to 60 Fahrenheit. From 1st June to 1st September it fluctuates from 76 to 90; but has been observed as high as 102°. The flat country is moist and unhealthy; but the upper parts are pleasant and salubrious.

The wild animals are still pretty numerous round the swamps, and on the high ridges, especially bears and deer. Alligators abound in the Alatamaha river, yet they are not dreaded, and have rarely attacked men, though they occasionally destroy animals. The magophex or gouffre, which inhabits a shell 15 inches long, burrows in the pine lands. It is able to move with a man on its back. Honey bees abound in the swamps, and musquitos are numerous during the heats of summer.

The population of Georgia in 1810 was 252,433, including 107,019 slaves, and 1801 free blacks. Savannah, the largest town, contained 7624 inhabitants in 1817. The population of the state in 1800 was 162,686, including 59,699 slaves, and 1919 free blacks; so that the slaves increased rather faster than the white inhabitants in the interval between these periods. The militia of Georgia in 1815 amounted to 27,480. The shipping of the state in the same year amounted to 15,287 tons; and the exports in 1817 amounted to 8,790,714 dollars. The chief articles of export are live stock, maize, rice, tobacco, cotton, indigo, flour, tar, naval stores, &c.

Cotton is more extensively cultivated in this than in any other state; and the species which grows along the coast, and is known by the name of *sea island*, is in high estimation. An acre yields about 600 pounds in the seed. Tobacco is also cultivated to a great extent; and within the last ten or fifteen years, sugar has been raised in considerable quantities. It grows along the coast, and about 120 miles inwards. An acre is said to yield from 2000 to 4000 pounds.

Savannah river forms a part of the divisional line which separates this state from South Carolina. It is formed principally of two branches, by the names of *Tugulo* and *Keowee*, which spring from the mountains. It is navigable for boats 140 miles. Ogeechee river, about 18 miles south of the Savannah, is a small river, and nearly parallel with it in its course. Alatamaha, about 90 miles south of Savannah river, is navigable as far as Darien. It is a noble river, but of difficult entrance. Like the Nile, it discharges itself by several mouths into the sea. Besides these, there is Turtle river, Crooked river, and St Mary's, which form a part of the southern boundary of the United States. The principal river in the middle and western parts of this state is the Apalachicola, which is formed by the Catahouchee and Flint rivers. It forms the western boundary of the state for 120 miles, and after a long southern course falls into the gulf of Mexico.

No general character will apply to the inhabitants at large. Collected from different parts of the world, as interest, necessity, or inclination led them, their character and manners must of course partake of all the varieties which distinguish the several states and kingdoms from whence they came. There is so little uniformity, that it is difficult to trace any governing principles among them. An aversion to labour is too predominant, owing in part to the relaxing heat of the climate, and partly to the want of necessity to excite industry. An open and friendly hospitality, particularly to strangers, is an ornamental characteristic of a great part of this people.

In regard to religion, politics, and literature, this state is yet in its infancy. In Savannah is an Episcopal church, a Presbyterian church, a synagogue, and a German Lutheran church, supplied occasionally by a German minister from Ebenezer, where there is a large convenient stone church, and a settlement of sober and industrious Germans of the Lutheran religion. In Augusta they have an Episcopal church. In Midway is a society of Christians established on the congregational plan. Their ancestors emigrated in a colony from Dorchester, near Boston, about the year 1700, and settled at a place named Dorchester, about 20 miles south-west of Charlestown, South Carolina. In 1752, for the sake of a better climate and more land, almost the whole society removed and settled at Midway.—They, as a people, retain in a great measure that simplicity of manners, that unaffected piety and brotherly love, which characterized their ancestors, the first settlers of New England. The upper countries are supplied pretty generally by Baptist and Methodist ministers; but the greater part of the state is without ministers of any denomination.

The numerous defects in the late constitution of this state, induced the citizens pretty universally to petition for a revision of it. It was accordingly revised, or rather a new one was formed, in the course of the year 1789, nearly upon the plan of the constitution of the United States, which has lately been adopted by the state.

The charter containing the present system of education in this state was passed in the year 1785. A college, with ample and liberal endowments, is instituted in Louisville, a high and healthy part of the country, near the centre of the state. There is also provision made for the institution of an academy in each county in the state, to be supported from the same funds, and considered as parts and members of the same institution, under the general superintendence and direction of a president and board of trustees, appointed for their literary accomplishments from the different parts of the state, and invested with the customary powers of corporations. The institution thus composed is denominated *the university of Georgia*.—The funds for the support of this institution are principally in lands, amounting in the whole to about 50,000 acres, a great part of which is of the best quality,

lity, and at present very valuable. There are also nearly 6000l. sterling in bonds, houses, and town lots in the town of Augusta. Other public property to the amount of 1000l. in each county has been set apart for the purposes of building and furnishing their respective academies. The funds originally designed for the support of the orphan house are chiefly in rice plantations and negroes.

GEORGIA, a township in the county of Franklin, containing about 400 inhabitants. It is situated on Lake Champlain, opposite to the north end of South Hero island.

GEORGIA, a cluster of barren islands in the South sea, to the eastward of the coast of Terra del Fuego, in lat. 54° 30′ S. and long. 37° W. One of these islands is 90 miles in length, and 30 in breadth.

GEORGIC, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry. The word is borrowed from the Latin *georgicus*, and that of the Greek γεωργικος, of γη, *terra*, "earth," and εργαζομαι, *opero*, "I work, or labour," of εργον, *opus*, "work." Hesiod and Virgil are the two greatest masters in this kind of poetry.—The moderns have produced nothing in this kind, except Rapin's book of Gardening; and the celebrated poem entitled Cyder, by Mr Philips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

GEORGIUM Sidus. See ASTRONOMY *Index*.

GEPIDÆ, GEPIDES, or GEPIDI, in *Ancient Geography*, according to Procopius, were a Gothic people, or a canton or branch of them; some of whom, in the migration of the Goths, settled in an island at the mouth of the Vistula, which they called *Gepidos* after their own name, which denotes lazy or slothful; others in Dacia, calling their settlement there *Gepidia*.

GERANIUM, CRANE'S BILL, in *Botany*, a genus of plants belonging to the monadelphia class; and in the natural method ranking under the 14th order, *Gruinales*. See BOTANY *Index*.

GERAR, or GERARA, in *Ancient Geography*, the south boundary of Canaan near Berseba; situated between Cades and Sur; two deserts well known, the former facing Egypt, the latter Arabia Petræa.

GERARDE, JOHN, a surgeon in London, and the greatest botanist of his time, was many years chief gardener to Lord Burleigh; who was himself a great lover of plants, and had the best collection of any nobleman in the kingdom, among which were a great number of exotics introduced by Gerarde. In 1597 he published his *Herbal*, which was printed at the expence of J. Norton, who procured from Francfort the same blocks in wood as were used in the herbal of Tabernæmontanus, In 1663, Thomas Johnson, an apothecary, published an improved edition of Gerarde's book; which met with such approbation by the university of Oxford, that they conferred on him the degree of doctor of physic. The descriptions in the herbal are plain and familiar; and both these authors have laboured more to make their readers understand the characters of the plants, than to inform them that they themselves understood Greek and Latin. The herbal of Gerarde is now to be considered only as a literary

curiosity. The figures in general express very accurately the characters of the plants they are intended to represent.

GERARDIA, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 40th order, *Personatæ*. See BOTANY *Index*.

GERFALCON. See FALCO, ORNITHOLOGY *Index*.

GERGESA, in *Ancient Geography*, a Transjordan town, no otherwise known than by the *Gergeseni* of St Matthew, and *Gergesæi* of Moses; supposed to have stood in the neighbourhood of Gadara and near the sea of Tiberias. The *Gergesæi*, one of the seven ancient people of Canaan, less frequently mentioned than the rest, appear to have been less considerable and more obscure: their name is from *Girgasi*, one of Canaan's sons. See GIRGASHITES.

GERIZIM. See GARIZIM.

GERM, in vegetation. See GERMEN.

GERMAN, in matters of genealogy, signifies whole, entire, or own. *Germani, quasi eadem stirpe geniti*; (Fest.). Hence,

Brother GERMAN, denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, &c. who are only so by the mother's side.

Cousins GERMAN, are those in the first or nearest degree, being the children of brothers or sisters.

Among the Romans we have no instance of marriage between cousins german before the time of the emperor Claudius, when they were very frequent.

Theodosius prohibited them under very severe penalties, even fine and proscription. See CONSANGUINITY.

GERMAN, or *Germanic*, also denotes any thing belonging to Germany; as the German empire, German flute, &c.

GERMANDER. See TEUCRIUM, BOTANY *Index*.

GERMANICUS CÆSAR, the son of Drusus, and paternal nephew to the emperor Tiberius, who adopted him; a renowned general, but still more illustrious for his virtues. He took the title of *Germanicus* from his conquests in that country; and though he had the moderation to refuse the empire offered to him by his army, Tiberius, jealous of his success, and of the universal esteem he acquired, caused him to be poisoned, A. D. 29, aged 34. He was a protector of learning; and composed some Greek comedies and Latin poems, some of which are still extant.

GERMANTOWN, in the county of Philadelphia, Pennsylvania, in North America, about seven miles from the city of Philadelphia. It was once esteemed the second town in the country, till many inland towns in a short time rose superior to it, both for the extent of their establishments and number of inhabitants. The knitting of cotton, thread, and worsted stockings, is carried on in it to a considerable extent. The principal congregation of the people called Mennonists is in Germantown, who derive their name from one Menno Simon, a learned man of Witmars in Germany. Although inimical to the doctrine of general salvation, they will not swear, fight, bear any civil office, go to law, or take interest for money. Germantown is also memorable for a bloody battle which was fought in it on the 4th of October, 1777.

GERMANY.

GERMANY, a very extensive empire of Europe, but which, in different ages of the world, has had very different limits. Its name, according to the most probable conjecture, is derived from the Celtic words *Ghar man*, signifying a warlike man, to which their other name, *Allman*, or *Aleman*, likewise alludes.

The ancient history of the Germans is altogether wrapped up in obscurity. The first time we find them mentioned by the Roman historians, is about the year 211 B. C. at which time Marcellus subdued Insubria and Liguria, and defeated the Gæsatæ, a German nation situated on the banks of the Rhine. From this time history is silent with regard to any of these northern nations, till the irruption of the Cimbri and Teutones, who inhabited the most northerly parts of Germany.

1 Limits of ancient Germany.

It is very difficult to fix the limits of the country called *Germany* by the Romans. The southern Germans were intermixed with the Gauls, and the northern ones with the Scythians; and thus the ancient history of the Germans includes that of the Dacians, Huns, Goths, &c. till the destruction of the western Roman empire by them. Ancient Germany, therefore, we may reckon to have included the northern part of France, the Netherlands, Holland, *Germany* so called at present, Denmark, Prussia, Poland, Hungary, part of Turkey in Europe, and Muscovy.

The Romans divided Germany into two regions; Belgic or Lower Germany, which lay to the southward of the Rhine; and Germany Proper, or High Germany.

2 Nations inhabiting Lower Germany.

The first lay between the rivers Seine and the Rhine; and in this we find a number of different nations, the most remarkable of which were the following.

1. The Ubii, whose territory lay between the Rhine and the Mosa or Maese, and whose capital was the city of Cologne. 2. Next to them were the Tungri, supposed to be the same whom Cæsar calls *Eburones* and *Condrusi;* and whose metropolis, then called *Attuatica*, has since been named *Tongres*. 3. Higher up from them, and on the other side of the Moselle, were the Treviri, whose capital was Augusta Trevirorum, now *Triers*. 4. Next to them were the Tribocci, Nemetes, and Vangiones. The former dwelt in Alsace, and had Argentoratum, now *Strasburg*, for their capital; the others inhabited the cities of Worms, Spire, and Mentz. 5. The Mediomatrici were situated along the Moselle, about the city of Metz in Lorrain: and above them were situated another German nation, named *Raurici*, *Rauraci*, or *Rauriaci*, and who inhabited that part of Helvetia, or Switzerland, about Basil. To the westward and southward of these were the Nervii, Suessiones, Silvanectes, Leuci, Rhemi, Lingones, &c. who inhabited Belgic Gaul.

Between the heads of the Rhine and Danube was seated the ancient kingdom of Vindelicia, whose capital was called *Augusta Vindelicorum*, now *Augsburg*. Below it on the banks of the Danube were the kingdoms of Noricum and Pannonia. The first of these was divided into Noricum *Ripense* and *Mediterraneum*. It contained a great part of the provinces of Austria, Stiria, Carinthia, Tyrol, Bavaria, and some others of less note. The latter contained the kingdom of Hungary, divided into Upper and Lower; and extended from Illyricum to the Danube, and the mountains Cætii in the neighbourhood of *Vindebona*, now *Vienna*.

Upper or High Germany lay beyond the Rhine and the Danube. 3 Nations inhabiting High Germany.

Between the Rhine and the Elbe were the following nations. 1. The Chauci, Upper and Lower; who were divided from each other by the river Visurges, now the *Weser*. Their country contained what is now called *Bremen*, *Lunenburg*, *Friezland*, and *Groninghen*. The Upper Chauci had the Cherusci, and the lower the Chamavi on the south-east, and the German ocean on the north-west. 2. The Frisii, Upper and Lower, were divided from the Lower Chauci by the river Amisia, now the Ems; and from one another by an arm of the Rhine. Their country still retains the name of *Friesland*, and is divided into east and west; but the latter is now dismembered from Germany, and become one of the Seven United Provinces. 3. Beyond the Isela, now the *Isel*, which bounded the country of the Frisi, were situated the Bructeri, who inhabited the tract now called *Broecmorland;* and the Marsi, about the river Luppe. On the other side of that river were the *Usipii* or *Usipetes;* but these were famed for often changing their territories, and therefore found in other places. 4. Next to these were the Juones, or inhabitants of Juliers, between the Maese and the Rhine. 5. The Catti, another ancient and warlike nation, inhabited Hesse and Thuringia, from the Hartzian mountains to the Rhine and Weser: among whom were comprehended the Mattiaci, whose capital is by some thought to be *Marpurg*, by others *Baden*. 6. Next to these were the Sedusii bordering upon Suabia; the Norisci, or the ancient inhabitants of Northgow, whose capital was Nuremberg; and the Marcomanni, whose country anciently reached from the Rhine to the head of the Danube, and to the Neckar. The Marcomanni afterwards went and settled in Bohemia and Moravia, under their general or king Maroboduus: and some of them in Gaul, whence they drove the Boii, who had seated themselves there. 7. On the other side of the Danube, and between the Rhine and it, were the Hermunduri, who possessed the country now called *Misnia* in Upper Saxony; though some make their territories to have extended much farther, and to have reached quite to, or even beyond, the kingdom of Bohemia, once the seat of the Boii, whence its name. 8. Beyond them, on the north of the Danube, was another seat of the Marcomanni along the river Albis, or Elbe. 9. Next to Bohemia were situated the Quadi, whose territories extended from the Danube to Moravia, and the northern part of Austria. These are comprehended under the ancient name of *Suevi;* part of whom at length forced their way into Spain, and settled a kingdom there. 10. Eastward of the Quadi were situated the Bastarnæ, and parted from them by the Granna, now *Gran;* a river that falls into the Danube, and by the Carpathian mountains, from them called *Alpes Bastarnicæ*. The country of the Bastarnæ indeed

indeed made part of the European Sarmatia, and so was without the limits of Germany properly so called; but we find these people so often in league with the German nations, and joining them for the destruction of the Romans, that we cannot but account them as one people.

Between those nations already taken notice of, seated also on the other side of the Danube and the Hercynian forest, were several others whose exact situation is uncertain, viz. the Martingi, Burii, Borades, Lygii or Logiones, and some others, who are placed by our geographers along the forest above mentioned, between the Danube and the Vistula.

On this side the Hercynian forest, were the famed Rhætii, now *Grisons*, seated among the Alps. Their country, which was also called *Western Illyricum*, was divided into Rhætia *Prima* or *Propria* and *Secunda*; and was then of much larger extent, spreading itself towards Suabia, Bavaria, and Austria.

On the other side of the Hercynian forest were, 1. The Suevi, who spread themselves from the Vistula to the river Elbe. 2. The Longobardi, so called according to some on account of their wearing long beards, but, according to others, on account of their consisting of two nations, viz. the Bardi and Lingones. These dwelt along the river Elbe, and bordered southward on the Chauci above mentioned. 3. The Burgundi, of whose original seat we are uncertain. 4. The Semnones; who, about the time of Tiberius, were seated on the river Elbe. 5. The Angles, Saxons, and Goths, were probably the descendants of the Cimbri; and inhabited the countries of Denmark, along the Baltic sea, and the peninsula of Scandinavia, containing Norway, Sweden, Lapland, and Finmark. 6. The Vandals were a Gothic nation, who, proceeding from Scandinavia, settled in the countries now called *Mecklenburgh* and *Brandenburgh*. 7. Of the same race were the Dacians, who settled themselves in the neighbourhood of the Palus Mæotis, and extended their territories along the banks of the Danube.

4
W[illegible] of the Scordisci with the Romans.

These were the names of the German nations who performed the most remarkable exploits in their wars with the Romans. Besides these, however, we find mention made of the Scordisci, a Thracian nation, who afterwards settled on the banks of the Danube. About the year 113 B. C. they ravaged Macedon, and cut off a whole Roman army sent against them; the general, M. Porcius Cato, grandson to Cato the censor, being the only person who had the good fortune to make his escape. After this, they ravaged all Thessaly; and advanced to the coasts of the Adriatic, into which, because it stopped their farther progress, they discharged a shower of darts. By another Roman general, however, they were driven back into their own country with great slaughter; and soon after, Metellus so weakened them by repeated defeats, that they were incapable, for some time, of making any more attempts on the Roman provinces. At last, in the consulship of M. Livius Drusus and L. Calpurnius Piso, the former prevailed on them to pass the Danube, which thenceforth became the boundary between the Romans and them. Notwithstanding this, in the time of the Jugurthine war, the Scordisci repassed the Danube on the ice every winter, and being joined by the Triballi a people of Lower Mæsia, and the Daci of Upper Mæsia, penetrated as far as Macedon, committing everywhere dreadful ravages. So early did these northern nations begin to be formidable to the Romans, even when they were most renowned for warlike exploits.

5
Expedition of Julius Cæsar into Germany.

Till the time of Julius Cæsar, however, we hear nothing more concerning the Germans. About 58 years B. C. he undertook his expedition into Gaul; during which, his assistance was implored by the Ædui, against Ariovistus, a German prince who oppressed them. Cæsar, pleased with this opportunity of increasing his power, invited Ariovistus to an interview; but this being declined, he next sent deputies, desiring him to restore the hostages he had taken from the Ædui, and to bring no more troops over the Rhine into Gaul. To this a haughty answer was returned; and a battle soon after ensued, in which Ariovistus was entirely defeated, and with great difficulty made his escape.

In 55 B. C. Cæsar having subdued the Suessiones, Bellovaci, Ambiani, Nervii, and other nations of Belgic Gaul, hastened to oppose the Usipetes and Tenchtheri. These nations having been driven out of their own country by the Suevi, had crossed the Rhine with a design to settle in Gaul. As soon as he appeared, the Germans sent him a deputation, offering to join him, provided he would assign them lands. Cæsar replied, that there was no room in Gaul for them; but he would desire the Ubii to give them leave to settle among them. Upon this, they desired him to retreat with the Ubii; but in the mean time fell upon some Roman squadrons: which so provoked Cæsar, that he immediately marched against them, and coming unexpectedly upon them, defeated them, with great slaughter. They fled in the utmost confusion; but the Romans pursued them to the conflux of the Rhine and the Maese, where the slaughter was renewed with such fury, that almost 400,000 of the Germans perished. After this, Cæsar being resolved to spread the terror of the Roman name through Germany, built a bridge over the Rhine, and entered that country. In this expedition, however, which was his last in Germany, he performed no remarkable exploit. A little before his death, indeed, he had projected the conquest of that, as well as of a great many other countries; but his assassination prevented the execution of his designs. Nor is there any thing recorded of the Germans till about 17 B. C. when the Tenchtheri made an irruption into Gaul, and defeated M. Lollius, proconsul of that province. At last, however, they were repulsed, and forced to retire with great loss beyond the Rhine.

6
Rhætii invade Italy.

Soon after this the Rhætii invaded Italy, where they committed the greatest devastations, putting all the males they met to the sword, without distinction of age: nay, we are told, that when they happened to take women with child, they consulted their augurs to know whether the child was a male or female; and if they pronounced it a male, the mother was immediately massacred. Against these barbarians was sent Drusus, the second son of Livia, a youth of extraordinary valour and great accomplishments. He found means to bring them to a battle; in which the Romans proved victorious, and cut in pieces great numbers of their enemies, with very little loss on their own

own side. Those who escaped the general slaughter, being joined by the Vindelici, took their route towards Gaul, with a design to invade that province. But Augustus, upon the first notice of their march, despatched against them Tiberius with several chosen legions. He was no less successful than Drusus had been; for having transported his troops over the lake Brigantium, now Constance, he fell unexpectedly on the enemy, gave them a total overthrow, took most of their strong holds, and obliged the whole nation to submit to such terms as he chose to impose upon them.

7 They are subdued, together with the Vindelici and Norici.

Thus were the Vindelici, the Rhætii, and Norici, three of the most barbarous nations in Germany subdued. Tiberius, to keep the conquered countries in awe, planted two colonies in Vindelicia, and opened from thence a road into Rhætia and Noricum. One of the cities which he built for the defence of his colonies, he called, from his father Drusus, *Drusomagus*; the other by the name of Augustus, *Augusta Vindelicorum*; which cities are now known by the names of *Mimminghen* and *Augsburg*. He next encountered the Pannonians, who had been subdued by Agrippa, but revolted on hearing the news of that great commander's death, which happened 11 years B. C. Tiberius, however, with the assistance of their neighbours the Scordisci, soon forced them to submit. They delivered up their arms, gave hostages, and put the Romans in possession of all their towns and strong holds. Tiberius spared their lives; but laid waste their fields, plundered their cities, and sent the best part of their youth into other conntries.

8 and the Pannonians.

In the mean time, Drusus having prevented the Gauls from revolting, which they were ready to do, prepared to oppose the Germans who dwelt beyond the Rhine. They had collected the most numerous and formidable army that had ever been seen in those parts; with which they were advancing towards the Rhine, in order to invade Gaul. Drusus defeated them as they attempted to cross that river; and, pursuing the advantage he had gained, entered the country of the Usipetes, now *Relinchusen*, and from thence advanced against the Sicambri in the neighbourhood of the Lyppe and Yssel. Them he overthrew in a great battle, laid waste their country, burnt most of their cities, and following the course of the Rhine, approached the German ocean, reducing the Frisii and the Chauci between the Ems and the Elbe. In these marches the troops suffered extremely for want of provisions; and Drusus himself was often in great danger of being drowned, as the Romans who attended him were at that time quite unacquainted with the flux and reflux of the ocean.

9 Exploits of Drusus in Germany.

The Roman forces went into East Friesland for their winter quarters; and next year (10 B. C.) Drusus marched against the Tenchtheri, whom he easily subdued. Afterwards, passing the Lupias, now the Lyppe, he reduced the Catti and Cherusci, extending his conquests to the banks of the Visurgis or Weser; which he would have passed, had he not been in want of provisions, the enemy having laid waste the country to a considerable distance. As he was retiring, the Germans unexpectedly fell upon him in a narrow passage; and having surrounded the Roman army, cut a great many of them in pieces. But Drusus having animated his men by his example, after a bloody conflict, which lasted the whole day, the Germans were defeated with such slaughter, that the ground was strewed for several miles with dead bodies. Drusus found in their camp a great quantity of iron chains which they had brought for the Romans; and so great was their confidence, that they had agreed beforehand about the division of the booty. The Tenchtheri were to have the horses, the Cherusci and Sicambri the baggage, and the Usipetes and Catti the captives. After this victory, Drusus built two forts to keep the conquered countries in awe; the one at the confluence of the Lyppe and the Alme, the other in the country of the Catti on the Rhine. On this occasion also he made a famous canal, long after called in honour of him *Fossa Drusiana*, to convey the waters of the Rhine into the Sala or Sale. It extended eight miles; and was very convenient for conveying the Roman troops by water to the countries of the Frisii and Chauci, which was the design of the undertaking.

The following year (9 B. C.) Augustus, bent on subduing the whole of Germany, advanced to the banks of the Rhine, attended by his two sons-in-law Tiberius and Drusus. The former he sent against the Daci, who lived up to the south of the Danube; and the latter to complete the conquest he had so successfully begun in the western parts of Germany. The former easily overcame the Daci, and transplanted 40,000 of them into Gaul. The latter, having passed the Rhine, subdued all the nations from that river to the Elbe; but having attempted in vain to cross this last, he set out for Rome: an end, however, was put to his conquests and his life by a violent fever, with which he was seized on his return.

After the death of Drusus, Tiberius again overran all those countries in which Drusus had spent the preceding summer; and struck some of the northern nations with such terror, that they sent deputies to sue for peace. This, however, they could not obtain upon any terms; the emperor declaring that he would not conclude a peace with one, unless they all desired it. But the Catti, or according to some the Sicambri, could not by any means be prevailed upon to submit; so that the war was still carried on, though in a languid manner, for about 18 years. During this period, some of the German nations had quitted their forests, and begun to live in a civilized manner under the protection of the Romans; but one Quinctilius Varus being sent to command the Roman forces in that country, so provoked the inhabitants by his extortions, that not only those who still held out refused to submit, but even the nations that had submitted were seized with an eager desire of throwing off the yoke. Among them was a young nobleman of extraordinary parts and valour, named *Arminius*. He was the son of Sigimer, one of the most powerful lords among the Catti, had served with great reputation in the Roman armies, and been honoured by Augustus with the privileges of a Roman citizen and the title of knight. But the love of his country prevailing over his gratitude, he resolved to improve the general discontent which reigned among his countrymen, to deliver them from the bondage of a foreign dominion. With this view he engaged, underhand, the leading men of all the nations between the Rhine and the Elbe, in a conspiracy against the Romans. In order to put Varus off

10 Arminius heads the Germans against the Romans.

off his guard, he at the same time advised him to show himself to the inhabitants of the more distant provinces, administer justice among them, and accustom them, by his example, to live after the Roman manner, which he said would more effectually subdue them than the Roman sword. As Varus was a man of a peaceable temper, and averse from military toils, he readily consented to this insidious proposal, and, leaving the neighbourhood of the Rhine, marched into the country of the Cherusci. Having there spent some time in hearing causes and deciding civil controversies, Arminius persuaded him to weaken his army, by sending out detachments to clear the country of robbers. When this was done, some distant nations of Germany rose up in arms by Arminius's directions; while those through which Varus was to pass in marching against them, pretended to be in a state of profound tranquillity, and ready to join the Romans against their enemies.

11
...s off ...rus with army.

On the first news of the revolt, Varus marched against the enemy with three legions and six cohorts; but being attacked by the Germans as he passed through a wood, his army was almost totally cut off, while he himself and most of his officers fell by their own hands. Such a terrible overthrow, though it raised a general consternation in Rome, did not, however, dishearten Augustus, or cause him to abandon his enterprise. About two years after (A. D. 12.), Tiberius and Germanicus were appointed to command in Germany. The death of Augustus, however, which happened soon after, prevented Tiberius from going on his expedition; and Germanicus was for some time hindered from proceeding in his, by a revolt of the legions, first in Pannonia, and then in Germany. About the year 15, Germanicus having brought over the soldiers to their duty, laid a bridge across the Rhine, over which he marched 12,000 legionaries, 26 cohorts of the allies, and eight alæ (squadrons of 300 each) of horse. With these he first traversed the Cœsian forest (part of the Hercynian, and thought to lie partly in the duchy of Cleves, and partly in Westphalia), and some other woods. On his march he was informed that the Marsi were celebrating a festival with great mirth and jollity. Upon this he advanced with such expedition, that he surprised them in the midst of their debauch; and giving his army full liberty to make what havock they pleased, a terrible massacre ensued, and the country was destroyed with fire and sword for 50 miles round, without the loss of a single man on the part of the Romans.—This general massacre roused the Bructeri, the Tubantes, and the Usipetes; who, besetting the passes through which the Roman army was to return, fell upon their rear, and put them into some disorder; but the Romans soon recovered themselves, and defeated the Germans with considerable loss.

12
...loits of ...mani...

The following year (A. D. 16), Germanicus taking advantage of some intestine broils which happened among the Catti, entered their country, where he put great numbers to the sword. Most of their youth, however, escaped by swimming over the Adrana, now the Oder, and attempted to prevent the Romans from laying a bridge over that river: but being disappointed in this, some of them submitted to Germanicus, while the greater part, abandoning their villages, took refuge in the woods; so that the Romans, without opposition, set fire to all their villages, towns, &c. and having laid their capital in ashes, began their march back to the Rhine.

Germanicus had scarce reached his camp, when he received a message from Segestes, a German prince, in the interest of the Romans, acquainting him that he was besieged in his camp by Arminius. On this advice, he instantly marched against the besiegers; entirely defeated them; and took a great number of prisoners, among whom was Thusneldis, the wife of Arminius, and daughter of Segestes, whom the former had carried off, and married against her father's will. Arminius then, more enraged than ever, for the loss of his wife, whom he tenderly loved, stirred up all the neighbouring nations against the Romans. Germanicus, however, without being dismayed by such a formidable confederacy, prepared himself to oppose the enemy with vigour: but, that he might not be obliged to engage such numerous forces at once, detached his lieutenant Cæcina, at the head of 40 cohorts, into the territories of the Bructeri; while his cavalry, under the command of Pedo, entered the country of the Frisii. As for Germanicus himself, he embarked the remainder of his army, consisting of four legions, on a neighbouring lake; and transported them by rivers and canals to the place appointed on the river Ems, where the three bodies met. In their march they found the sad remains of the legions conducted by Varus, which they buried with all the ceremony their circumstances could admit. After this they advanced against Arminius, who retired and posted himself advantageously close to a wood. The Roman general followed him; and coming up with him, ordered his cavalry to advance and attack the enemy. Arminius, at their first approach, pretended to fly but suddenly wheeled about, and giving the signal to a body of troops, whom he had concealed in the wood, to rush out, obliged the cavalry to give ground. The cohorts then advanced to their relief; but they too were put into disorder, and would have been pushed into a morass, had not Germanicus himself advanced with the rest of the cavalry to their relief. Arminius did not think it prudent to engage these fresh troops, but retired in good order; upon which Germanicus also retired towards the Ems. Here he embarked with four legions, ordered Cæcina to reconduct the other four by land, and sent the cavalry to the sea side, with orders to march along the shore to the Rhine. Though Cæcina was to return by roads well known, yet Germanicus advised him to pass, with all possible speed, a causeway, called the *long bridges*, which led across vast marshes, surrounded on all sides with woods and hills that gently rose from the plain.

Arminius, however, having got notice of Cæcina's march, arrived at the long bridges before Cæcina, and filled the woods with his men, who, on the approach of the Romans, rushed out, and attacked them with great fury. The legions, not able to manage their arms in the deep waters and slippery ground, were obliged to yield: and would in all probability have been entirely defeated, had not night put an end to the combat. The Germans, encouraged by their successes, instead of refreshing themselves with sleep, spent the whole night in diverting the courses of the springs which

Germany. which rose in the neighbouring mountains; so that, before day, the camp which the Romans had begun was laid under water, and their works were overturned. Cæcina was for some time at a loss what to do; but at last resolved to attack the enemy by daybreak, and, having driven them to their woods, to keep them there in a manner besieged, till the baggage and wounded men should pass the causeway, and get out of the enemy's reach. But when his army was drawn up, the legions posted on the wings, seized with a sudden panic, deserted their stations, and occupied a field beyond the marshes. Cæcina thought it advisable to follow them; but the baggage stuck in the mire, as he attempted to cross the marshes, which greatly embarrassed the soldiers. Arminius perceiving this, laid hold of the opportunity to begin the attack; and crying out, "This is a second Varus, the same fate attends him and his legions," fell on the Romans with inexpressible fury. As he had ordered his men to aim chiefly at the horses, great numbers of them were killed; and the ground becoming slippery with their blood and the slime of the marsh, the rest either fell or threw their riders, and, galloping through the ranks, put them in disorder. Cæcina distinguished himself in a very eminent manner; but his horse being killed, he would have been taken prisoner, had not the first legion rescued him. The greediness of the enemy, however, saved the Romans from utter destruction; for just as the legions were quite spent, and on the point of yielding, the barbarians on a sudden abandoned them in order to seize their baggage. During this respite, the Romans struggled out of the marsh, and having gained the dry fields, formed a camp with all possible speed, and fortified it in the best manner they could.

The Germans having lost the opportunity of destroying the Romans, contrary to the advice of Arminius, attacked their camp next morning, but were repulsed with great slaughter; after which they gave Cæcina no more molestation till he reached the banks of the Rhine. Germanicus, in the mean time, having conveyed the legions he had with him down the river Ems into the ocean, in order to return by sea to the river Rhine, and finding that his vessels were overloaded, delivered the second and 14th legions to Publius Vitellius, desiring him to conduct them by land. But this march proved fatal to great numbers of them; who were either buried in the quicksands, or swallowed up by the overflowing of the tide, to which they were as yet utter strangers. Those who escaped, lost their arms, utensils, and provisions; and passed a melancholy night upon an eminence, which they had gained by wading up to the chin. The next morning the land returned with the tide of ebb; when Vitellius, by a hasty march, reached the river Usingis, by some thought to be the Hoerenster, on which the city of Groningen stands. There Germanicus, who had reached that river with his fleet, took the legions again on board, and conveyed them to the mouth of the Rhine, whence they all returned to Cologne, at a time when it was reported they were totally lost.

This expedition, however, cost the Romans very dear, and procured very few advantages. Great numbers of men had perished; and by far the greatest part of those who had escaped so many dangers returned without arms, utensils, horses, &c. half naked, lamed, and unfit for service. The next year, however, Germanicus, bent on the entire reduction of Germany, made vast preparations for another expedition. Having considered the various accidents, that had befallen him during the war, he found that the Germans were chiefly indebted for their safety to their woods and marshes, their short summers and long winters; and that his troops suffered more from their long and tedious marches than from the enemy. For this reason he resolved to enter the country by sea, hoping by that means to begin the campaign earlier, and surprise the enemy. Having therefore built with great despatch, during the winter, 1000 vessels of different sorts, he ordered them early in the spring (A. D. 16.) to fall down the Rhine, and appointed the island of the Batavians for the general rendezvous of his forces. When the fleet was sailing, he detached Silius, one of his lieutenants, with orders to make a sudden irruption into the country of the Catti; and, in the mean time, he himself, upon receiving intelligence that a Roman fort on the Luppias was besieged, hastened with six legions to its relief. Silius was prevented, by sudden rains, from doing more than taking some small booty, with the wife and daughter of Arpen, king of the Catti; neither did those who besieged the fort wait the arrival of Germanicus. In the mean time, the fleet arriving at the island of the Batavians, the provisions and warlike engines were put on board and sent forward; ships were assigned to the legions and allies; and the whole army being embarked, the fleet entered the canal formerly cut by Drusus, and from his name called *Fossa Drusiana*. Hence he sailed prosperously to the mouth of the Ems; where, having landed his troops, he marched directly to the Weser, where he found Arminius encamped on the opposite bank, and determined to dispute his passage. The next day Arminius drew out his troops in order of battle; but Germanicus, not thinking it advisable to attack them, ordered the horse to ford over under the command of his lieutenants Stertinius and Emilius; who, to divide the enemy's forces, crossed the river in two different places. At the same time Cariovalda, the leader of the Batavian auxiliaries, crossed the river where it is most rapid; but being drawn into an ambuscade, he was killed, together with most of the Batavian nobility; and the rest would have been totally cut off, had not Stertinius and Emilius hastened to their assistance. Germanicus in the mean time passed the river without molestation. A battle soon after ensued, in which the Germans were defeated with so great a slaughter, that the ground was covered with arms and dead bodies for more than 10 miles round; and among the spoils taken on this ocasion, were found, as formerly, the chains with which the Germans had hoped to bind their captives.

13 His second expedition.

In memory of this signal victory Germanicus raised a mount, upon which he placed as trophies the arms of the enemy, and inscribed underneath the names of the conquered nations. This so provoked the Germans, though already vanquished and determined to abandon their country, that they attacked the Roman army unexpectedly on its march, and put them into some disorder. Being repulsed, they encamped between a river and a large forest surrounded by a marsh except on on one side, where it was enclosed by a broad rampart formerly raised by the Angrivarii as a barrier between them and the Cherusci. Here another battle ensued; in which the Germans behaved with great bravery, but in the end were defeated with great slaughter.

After this second defeat, the Angrivarii submitted, and were taken under the protection of the Romans, and Germanicus put an end to the campaign. Some of the legions he sent to their winter quarters by land, while he himself embarked with the rest on the river Ems, in order to return by sea. The ocean proved at first very calm, and the wind favourable; but all of a sudden a storm arising, the fleet consisting of 1000 vessels, was dispersed: some of them were swallowed up by the waves; others were dashed in pieces against the rocks, or driven upon remote and inhospitable islands, where the men either perished by famine, or lived upon the flesh of the dead horses with which the shores soon appeared strewed; for, in order to lighten their vessels, and disengage them from the shoals, they had been obliged to throw overboard their horses and beasts of burden, nay, even their arms and baggage. Most of the men, however, were saved, and even great part of the fleet recovered. Some of them were driven upon the coast of Britain; but the petty kings who reigned there generously sent them back.

14 His fleet dispersed by a storm.

On the news of this misfortune, the Catti, taking new courage, ran to arms; but Caius Silius being detached against them with 30,000 foot and 3000 horse, kept them in awe. Germanicus himself, at the head of a numerous body, made a sudden irruption into the territories of the Marsi, where he recovered one of Varus's eagles, and having laid waste the country, he returned to the frontiers of Germany, and put his troops into winter quarters: whence he was soon recalled by Tiberius, and never suffered to return into Germany again.

After the departure of Germanicus, the more northern nations of Germany were no more molested by the Romans. Arminius carried on a long and successful war with Maroboduus king of the Marcomanni, whom he at last expelled, and forced to apply to the Romans for assistance; but, excepting Germanicus, it seems they had at this time no other general capable of opposing Arminius, so that Maroboduus was never restored. After the final departure of the Romans, however, Arminius having attempted to enslave his country, fell by the treachery of his own kindred. The Germans held his memory in great veneration; and Tacitus informs us, that in his time they still celebrated him in their songs.

15 Death of Arminius.

Nothing remarkable occurs in the history of Germany from this time till the reign of the emperor Claudius. A war indeed is said to have been carried on by Lucius Domitius, father to the emperor Nero. But of his exploits we know nothing more than that he penetrated beyond the river Elbe, and led his army farther into the country than any of the Romans had ever done. In the reign of Claudius, however, the German territories were invaded by Cn. Domitius Corbulo, one of the greatest generals of his age. But when he was on the point of forcing them to submit to the Roman yoke, he was recalled by Claudius, who was jealous of the reputation he had acquired.

In the reign of Vespasian, a terrible revolt happened among the Batavians and those German nations who had submitted to the Romans; a particular account of which is given under the article ROME. The revolters were with difficulty subdued; but, in the reign of Domitian, the Dacians invaded the empire, and proved a more terrible enemy than any of the other German nations had been. After several defeats, the emperor was at last obliged to consent to pay an annual tribute to Decebalus king of the Dacians; which continued to the time of Trajan. But that warlike prince refused to pay tribute; alleging, when it was demanded of him, that "he had never been conquered by Decebalus." Upon this the Dacians passed the Danube, and began to commit hostilities in the Roman territories. Trajan, glad of this opportunity to humble an enemy whom he began to fear, drew together a mighty army, and marched with the utmost expedition to the banks of the Danube. As Decebalus was not apprised of his arrival, the emperor passed the river without opposition, and entering Dacia, laid waste the country with fire and sword. At last he was met by Decebalus with a numerous army. A bloody engagement ensued, in which the Dacians were defeated; though the victory cost the Romans dear: the wounded were so numerous, that they wanted linen to bind up their wounds; and to supply the defect, the emperor generously devoted his own wardrobe. After the victory, he pursued Decebalus from place to place, and at last obliged him to consent to a peace on the following terms: 1. That he should surrender the territories which he had unjustly taken from the neighbouring nations. 2. That he should deliver up his arms, his warlike engines, with the artificers who made them, and all the Roman deserters. 3. That for the future he should entertain no deserters, nor take into his service the natives of any country subject to Rome. 4. That he should dismantle all his fortresses, castles, and strong holds. And, lastly, That he should have the same friends and foes with the people of Rome.

16 The Dacians invade the Roman empire.

With these hard terms Decebalus was obliged to comply, though sore against his will; and being introduced to Trajan, threw himself on the ground before him, acknowledging himself his vassal; after which the latter, having commanded him to send deputies to the senate for the ratification of the peace, returned to Rome.

This peace was of no long duration. Four years after (A. D. 105.), Decebalus, unable to live in servitude as he called it, began, contrary to the late treaty, to raise men, provide arms, entertain deserters, fortify his castles, and invite the neighbouring nations to join him against the Romans as a common enemy. The Scythians hearkened to his solicitations; but the Jazyges, a neighbouring nation, refusing to bear arms against Rome, Decebalus invaded their country. Hereupon Trajan marched against him; but the Dacian, finding himself unable to withstand him by open force, had recourse to treachery, and attempted to get the emperor murdered. His design, however, proved abortive, and Trajan pursued his march into Dacia. That his troops might the more readily pass and repass the Danube, he built a bridge over that river; which by the ancients is styled the most magnificent and wonderful of all his works*. To guard the bridge, he

* See *Architecture*, N° 133.

he ordered two castles to be built; one on this side the Danube, and the other on the opposite side; and all this was accomplished in the space of one summer. Trajan, however, as the season was now far advanced, did not think it adviseable to enter Dacia this year, but contented himself with making the necessary preparations.

17
They are subdued by Trajan.

In the year 106, early in the spring, Trajan set out for Dacia; and having passed the Danube on the bridge he had built, reduced the whole country, and would have taken Decebalus himself, had he not put an end to his own life, in order to avoid falling into the hands of his enemies. After his death the kingdom of Dacia was reduced to a Roman province; and several castles were built in it, and garrisons placed in them, to keep the country in awe.

18
Marcomanni and Quadi formidable to the empire.

After the death of Trajan, the Roman empire began to decline, and the northern nations to be daily more and more formidable. The province of Dacia indeed was held by the Romans till the reign of Gallienus; but Adrian, who succeeded Trajan, caused the arches of the bridge over the Danube to be broken down, lest the barbarians should make themselves masters of it, and invade the Roman territories. In the time of Marcus Aurelius, the Marcomanni and Quadi invaded the empire, and gave the emperor a terrible overthrow. He continued the war, however, with better success afterwards, and invaded their country in his turn. It was during the course of this war that the Roman army is said to have been saved from destruction by that miraculous event related under the article CHRISTIANS, p. 70. col. 2.

In the end, the Marcomanni and Quadi were, by repeated defeats, brought to the verge of destruction, insomuch that their country would probably have been reduced to a Roman province, had not Marcus Aurelius been diverted from pursuing his conquests by the revolt of one of his generals. After the death of Marcus Aurelius, the Germanic nations became every day more and more formidable to the Romans. Far from being able to invade and attempt the conquest of these northern countries, the Romans had the greatest difficulty to repress the incursions of their inhabitants. But for a particular account of their various invasions of the Roman empire, and its total destruction by them at last, see the article ROME.

19
Roman empire destroyed by the Heruli.

The immediate destroyers of the Roman empire were the Heruli; who, under their leader Odoacer, dethroned Augustulus the last Roman emperor, and proclaimed Odoacer king of Italy. The Heruli were soon expelled by the Ostrogoths; and these in their turn were subdued by Justinian, who annexed Italy to the eastern empire. But the popes found means to obtain the temporal as well as spiritual jurisdiction over a considerable part of the country, while the Lombards subdued the rest. These last proved very troublesome to the popes, and at length besieged Adrian I. in his capital. In this distress he applied to Charles the Great, king of France; who conquered both Italy and Germany, and was crowned emperor of the west in 800.

20
History of Germany since the time of Charlemagne.

The posterity of Charlemagne inherited the empire of Germany until the year 880; at which time the different princes assumed their original independence, rejected the Carlovingian line, and placed Arnulph king of Bohemia on the throne. Since this time Germany has ever been considered as an elective monarchy. Princes of different families, according to the prevalence of their interest and arms, have mounted the throne. Of these the most considerable, until the Austrian line acquired the imperial power were the houses of Saxony, Franconia, and Suabia. The reigns of these emperors contain nothing more remarkable than the contests between them and the popes; for an account of which see the article ITALY. From hence, in the beginning of the 13th century, arose the factions of the Guelphs and Gibellines, of which the former was attached to the popes, and the latter to the emperor; and both, by their virulence and inveteracy, tended to disquiet the empire for several ages. The emperors too were often at war with the infidels; and sometimes, as happens in all elective kingdoms, with one another, about the succession.

But what more deserves our attention is the progress of government in Germany, which was in some measure opposite to that of the other kingdoms of Europe. When the empire raised by Charlemagne fell asunder, all the different independent princes assumed the right of election; and those now distinguished by the name of *electors* had no peculiar or legal influence in appointing a successor to the imperial throne; they were only the officers of the king's household, his secretary, his steward, chaplain, marshal, or master of his horse, &c. By degrees, however, as they lived near the king's person, and had, like all other princes, independent territories belonging to them, they increased their influence and authority; and in the reign of Otho III. 984, acquired the sole right of electing the emperor. Thus, while in the other kingdoms of Europe, the dignity of the great lords, who were all originally allodial or independent barons, was diminished by the power of the king, as in France, and by the influence of the people as in Great Britain; in Germany, on the other hand, the power of the electors was raised upon the ruins of the emperor's supremacy, and of the people's jurisdiction. In 1440, Frederic III. duke of Austria was elected emperor, and the imperial dignity continued in the male line of that family for 300 years. His successor Maximilian married the heiress of Charles duke of Burgundy; whereby Burgundy and the 17 provinces of the Netherlands were annexed to the house of Austria. Charles V. grandson of Maximilian, and heir to the kingdom of Spain, was elected emperor in the year 1519. Under him MEXICO and PERU were conquered by the Spaniards; and in his reign happened the REFORMATION in several parts of Germany; which, however, was not confirmed by public authority till the year 1648, by the treaty of Westphalia, and in the reign of Ferdinand III. The reign of Charles V. was continually disturbed by his wars with the German princes and the French king Francis I. Though successful in the beginning of his reign, his good fortune towards the conclusion of it began to forsake him; which, with other reasons, occasioned his abdication of the crown. See CHARLES V.

His brother Ferdinand I. who in 1558 succeeded to the throne, proved a moderate prince with regard to religion. He had the address to get his son Maximilian declared king of the Romans in his own lifetime,

time, and died in 1564. By his last will he ordered, that if either his own male issue, or that of his brother Charles, should fail, his Austrian estates should revert to his second daughter Anne, wife to the elector of Bavaria, and her issue. We mention this destination, as it gave rise to the late opposition made by the house of Bavaria to the pragmatic sanction, in favour of the empress queen of Hungary, on the death of her father Charles VI. The reign of Maximilian II. was disturbed with internal commotions, and an invasion from the Turks: but he died in peace in 1576. He was succeeded by his son Rodolph; who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom he ceded Hungary and Austria in his lifetime. He was succeeded in the empire by Matthias; under whom the reformers, who went under the names of *Lutherans* and *Calvinists*, were so much divided among themselves, as to threaten the empire with a civil war. The ambition of Matthias at last tended to reconcile them; but the Bohemians revolted, and threw the imperial commissaries out of a window at Prague. This gave rise to a ruinous war, which lasted 30 years. Matthias thought to have exterminated both parties; but they formed a confederacy, called the *Evangelic League*, which was counterbalanced by a Catholic league.

Matthias dying in 1618, was succeeded by his cousin Ferdinand II.; but the Bohemians offered their crown to Frederic the elector Palatine, the most powerful Protestant prince in Germany, and son-in-law to his Britannic majesty James I. That prince was incautious enough to accept of the crown: but he lost it, by being entirely defeated by the duke of Bavaria and the imperial generals at the battle of Prague; and he was even deprived of his electorate, the best part of which was given to the duke of Bavaria. The Protestant princes of Germany, however, had among them at this time many able commanders, who were at the head of armies, and continued the war with wonderful obstinacy: among them were the margrave of Baden Durlach, Christian duke of Brunswick, and Count Mansfeld; the last was one of the best generals of the age. Christiern IV. king of Denmark declared for them; and Richelieu, the French minister, was not fond of seeing the house of Austria aggrandized. The emperor, on the other hand, had excellent generals; and Christiern, having put himself at the head of the evangelic league, was defeated by Tilly, an Imperialist of great reputation in war. Ferdinand made so moderate a use of his advantages obtained over the Protestants, that they formed a fresh conspiracy at Leipsic, of which the celebrated Gustavus Adolphus king of Sweden was the head. An account of his glorious victories is given under the article SWEDEN. At last he was killed at the battle of Lutzen in 1632. But the Protestant cause did not die with him. He had brought up a set of heroes, such as the duke of Saxe Weimer, Torstenson, Banier, and others, who shook the Austrian power; till under the mediation of Sweden, a general peace was concluded among all the belligerent powers, at Munster, in the year 1648: which forms the basis of the present political system of Europe.

Ferdinand II. was succeeded by his son Ferdinand III. This prince died in 1657; and was succeeded by the emperor Leopold, a severe, unamiable, and not very fortunate prince. He had two great powers to contend with, France on the one side, and the Turks on the other; and was a loser in his war with both. Louis XIV. at that time king of France, was happy in having the two celebrated generals Condé and Turenne in his service. The latter had already distinguished himself by great exploits against the Spaniards; and, on the accession of Leopold, the court of France had taken the opportunity of confirming the treaty of Munster, and attaching to her interest several of the independent princes of Germany. The tranquillity which now took place, however, was not established upon any permanent basis. War with Spain was resumed in the year 1668; and the great successes of Turenne in the Netherlands stimulated the ambition of the prince of Condé, to attempt the conquest of Franche Compté, at that time under the protection of the house of Austria. This was accomplished in three weeks: but the rapid success of Louis had awakened the jealousy of his neighbours to such a degree, that a league was formed against him by England, Holland, and Sweden; and the French monarch, dreading to enter the lists with such formidable enemies, consented to the treaty of Aix-la-Chapelle, by which, among other articles, Franche Compté was restored. The flames of war, however, were renewed by the insatiable ambition of the French monarch; who, having entered into an alliance with Charles II. of England, aimed at nothing less than the total overthrow of the Dutch republic. The events of that war are related under the article UNITED PROVINCES; here it is sufficient to observe, that the misfortunes of the Dutch excited the compassion of the emperor and court of Spain, who now openly declared themselves their allies. Turenne was opposed by the prince of Orange in conjunction with the celebrated Imperial general Montecuculi, whose artful conduct eluded even the penetration of Turenne, and he sat down suddenly before the city of Bonne. Here he was joined by the prince of Orange, who had likewise found means to elude the vigilance of the French generals. Bonne surrendered in a short time, and several other places in Cologne fell into the hands of the allies; who likewise cut off the communication betwixt France and the United Provinces; so that Louis was soon obliged to recal his armies, and abandon all his conquests with greater rapidity than they had been made. In 1674 he was abandoned by his ally Charles II. of England, and the bishop of Munster and elector of Cologne were compelled to renounce their allegiance to him; but notwithstanding these misfortunes, he continued everywhere to make head against his enemies, and even meditated new conquests. With a powerful army he again invaded Franche Compté in person, and in six weeks reduced the whole province to his obedience. In Alsace, Turenne defeated the Imperial general at Sintzheim, and ravaged the palatinate. Seventy thousand Germans were surprised; a considerable detachment was cut in pieces at Mulhausen; the elector of Brandenburg, who had been intrusted with the chief command, was routed by Turenne near Colmar; a third body met with a similar fate at Turkheim; and the whole German forces were obliged at last to evacuate the province and repass the Rhine.

Germany.

In consequence of these disasters the imperial general Montecuculi was recalled to act against Turenne. The military skill of the two commanders seemed to be nearly equal; but before the superiority could be adjudged to either, Turenne was killed by a cannon ball as he was reconnoitring a situation for erecting a battery. By his death the Imperialists obtained a decided superiority. Montecuculi penetrated into Alsace; and the French, under De Lorges nephew to the deceased general, were happy in being able to escape a defeat.

Part of the German army now sat down before Treves, where they were opposed by Mareschal Crequi; but the negligence of that general exposed him to such a dreadful defeat, that he was obliged to fly into the city with only four attendants. Here he endeavoured in vain to animate the people to a vigorous defence. The garrison mutinied against his authority; and, when he refused to sign the capitulation they made, delivered him up prisoner to the enemy. Louis in the mean time had taken the field in person against the prince of Orange; but the disastrous state of affairs in Germany induced him to recal the prince of Condé to make head against Montecuculi. In this campaign the prince seemed to have the advantage. He compelled the Germans to raise the sieges of Hagenau and Saverne; and at last to repass the Rhine without having been able to force him to a battle.

This was the last campaign made by these celebrated commanders; both of them now, contented with the fame they had acquired, retiring from the field to spend the remainder of their days in peace. The excellent discipline, however, which the two great French generals had introduced into their armies, still continued to make them very formidable, though it did not always ensure them of victory. In Germany, the duke of Lorrain, who had recovered Philipsburg, was repeatedly defeated by Mareschal Crequi, who had been ransomed from his captivity, and become more prudent by his defeat. In Flanders, the prince of Orange was overmatched by the duke of Orleans and Marshal Luxemburg. A peace was at length concluded at Nimeguen in 1679, by which the king of France secured himself Franche Compté with a great many cities in the Netherlands; while the king of Sweden was reinstated in those places of which he had been stripped by the Danes and Germans. This tranquillity, however, was of no long duration. Louis emoloyed every moment in preparations for new conquests; possessed himself of the imperial city of Strasburg by treachery; and dispossessed the elector Palatine and the elector of Treves of the lordships of Falkemburg, Germansheim, and Valdentz. On the most frivolous pretences he had demanded Alost from the Spaniards; and on their refusal, seized upon Luxemburg. His conduct, in short, was so intolerable, that the prince of Orange, his inveterate enemy, found means to unite the whole empire in a league against him. Spain and Holland became parties in the same cause; and Sweden and Denmark seemed also inclined to accede to the general confederacy. Notwithstanding this formidable combination, however, Louis seemed still to have the advantage. He made himself master of the cities of Philipsburg, Manheim, Frankendal, Spires, Worms, and Oppenheim: the fruitful country of the Palatinate was ravaged in a dreadful manner; the towns were reduced to ashes; and the people, driven from their habitations, were everywhere left to perish through the inclemency of the weather and want of provisions. By this cruelty his enemies were rather exasperated than vanquished: the Imperialists, under the conduct of the duke of Lorrain, resumed their courage, and put a stop to the French conquests. At length all parties, weary of a destructive war, consented to the treaty of Ryswick in 1697. By this treaty Louis gave up to the empire, Fribourg, Brisac, Kheil, and Philipsburg; he consented also to destroy the fortifications of Strasburg. Fort Louis and Traerbach, the works of which had exhausted the skill of the great Vauban, with Lorrain, Treves, and the Palatinate, were resigned to their respective princes; insomuch that the terms to which the French monarch now consented, after so many victories, were such as could scarce have been expected under the pressure of the greatest misfortunes. The views of Louis, however, in consenting to this apparently humiliating treaty, were beyond the views of ordinary politicians. The health of the king of Spain was in such a declining way, that his death appeared to be at hand; and Louis now resolved to renew his pretensions to that kingdom, which he had formerly by treaty solemnly renounced. His designs in this respect could not be concealed from the vigilance of William III. of Britain; of which Louis being sensible, and knowing that the emperor had claims of the same nature on Spain, he thought proper to enter into a very extraordinary treaty with William. This was no less than the partition of the whole Spanish dominions, which were now to be distributed in the following manner. To the young prince of Bavaria were to be assigned Spain and the East Indies; the dauphin, son to Louis, was to have Naples, Sicily, and the province of Guipuscoa; while the archduke Charles, son to the emperor Leopold, was to have only the duchy of Milan. By this scandalous treaty the indignation of Charles was roused, so that he bequeathed the whole of his dominions to the prince of Bavaria. This scheme, however, was disconcerted by the sudden death of the prince; upon which a new treaty of partition was concluded between Louis and William. By this the kingdom of Spain, together with the East India territories, were to be bestowed on the archduke Charles, and the duchy of Milan upon the duke of Lorrain. The last moments of the Spanish monarch were disturbed by the intrigues of the rival houses of Austria and Bourbon; but the haughtiness of the Austrian ministers so disgusted those of Spain, that they prevailed upon their dying monarch to make a new will. By this the whole of his dominions were bequeathed to Philip duke of Anjou, grandson to the king of France; and Louis, prompted by his natural ambition, accepted the kingdom bequeathed to his grandson, excusing himself to his allies in the best manner he could for departing from his engagements with them. For this, however, he was made to pay dear. His insatiable ambition and his former successes had alarmed all Europe. The emperor, the Dutch, and the king of England, entered into a new confederacy against him; and a bloody war ensued, which threatened to to overthrow the French monarchy entirely. While this war (of which an account is given under the article BRITAIN) was carried on with such success, the emperor Leopold died in the year 1705.

He was succeeded by his son Joseph, who put the electors of Cologne and Bavaria to the ban of the empire; but being ill served by Prince Louis of Baden, general of the empire, the French partly recovered their affairs, notwithstanding their repeated defeats. The duke of Marlborough had not all the success he expected or deserved. Joseph himself was suspected of a design to subvert the Germanic liberties; and it was plain by his conduct, that he expected England should take the labouring oar in the war, which was to be entirely carried on for his benefit. The English were disgusted at his slowness and selfishness: but he died in 1711, before he had reduced the Hungarians; and leaving no male issue, he was succeeded in the empire by his brother Charles VI. whom the allies were endeavouring to place on the throne of Spain, in opposition to Philip duke of Anjou, grandson to Louis XIV.

When the peace of Utrecht took place in 1713, Charles at first made a show as if he would continue the war; but found himself unable, now that he was forsaken by the English. He therefore was obliged to conclude a peace with France at Baden in 1714, that he might attend the progress of the Turks in Hungary; where they received a total defeat from Prince Eugene at the battle of Peterwaradin. They received another of equal importance from the same general in 1717, before Belgrade, which fell into the hands of the Imperialists; and next year the peace of Passarowitz, between them and the Turks, was concluded. Charles employed every minute of his leisure in making arrangements for increasing and preserving his hereditary dominions in Italy and the Mediterranean. Happily for him, the crown of Britain devolved to the house of Hanover; an event which gave him a very decisive weight in Europe, by the connexions between George I. and II. and the empire. Charles was sensible of this; and carried matters with so high a hand, that, about the years 1724 and 1725, a breach ensued between him and George I. and so unsteady was the system of affairs all over Europe at that time, that the capital powers often changed their old alliances, and concluded new ones contradictory to their interest. Without entering into particulars, it is sufficient to observe, that the safety of Hanover, and its aggrandizement, was the main object of the British court; as that of the emperor was the establishment of the pragmatic sanction in favour of his daughter (the late empress queen), he having no male issue. Mutual concessions upon those great points restored a good understanding between George II. and the emperor Charles: and the elector of Saxony, flattered with the view of gaining the throne of Poland, relinquished the great claims he had upon the Austrian succession.

The emperor, after this, had very bad success in a war he entered into with the Turks, which he had undertaken chiefly to indemnify himself for the great sacrifices he had made in Italy to the princes of the house of Bourbon. Prince Eugene was then dead, and he had no general to supply his place. The system of France, however, under Cardinal Fleury, happened at that time to be pacific; and she obtained for him, from the Turks, a better peace than he had reason to expect. Charles, to keep the German and other powers easy, had, before his death, given his eldest daughter, the late empress queen, in marriage to the duke of Lorrain, a prince who could bring no accession of power to the Austrian family.

Charles died in 1740; and was no sooner in the grave, than all he had so long laboured for must have been overthrown, had it not been for the firmness of George II. The young king of Prussia entered and conquered Silesia, which he said had been wrongfully dismembered from his family. The king of Spain and the elector of Bavaria set up claims directly incompatible with the pragmatic sanction, and in this they were joined by France; though all those powers had solemnly guaranteed it. The imperial throne, after a considerable vacancy, was filled up by the elector of Bavaria, who took the title of *Charles VII.* in January 1742. The French poured their armies into Bohemia, where they took Prague; and the queen of Hungary, to take off the weight of Prussia, was forced to cede to that prince the most valuable part of the duchy of Silesia by a formal treaty.

Her youth, her beauty, and sufferings, and the noble fortitude with which she bore them, touched the hearts of the Hungarians, into whose arms she threw herself and her little son; and though they had been always remarkable for their disaffection to the house of Austria, they declared unanimously in her favour. Her generals drove the French out of Bohemia; and George II. at the head of an English and Hanoverian army, gained the battle of Dettingen, in 1743. Charles VII. was at this time miserable on the imperial throne, and would have given the queen of Hungary almost her own terms; but she haughtily and impolitically rejected all accommodation, though advised to it by his Britannic majesty, her best and indeed only friend. This obstinacy gave a colour for the king of Prussia to invade Bohemia, under pretence of supporting the imperial dignity; but though he took Prague, and subdued the greatest part of the kingdom, he was not supported by the French; upon which he abandoned all his conquests, and retired into Silesia. This event confirmed the obstinacy of the queen of Hungary: who came to an accommodation with the emperor, that she might recover Silesia. Soon after, his Imperial majesty, in the beginning of the year 1755, died; and the duke of Lorrain, then grand duke of Tuscany, consort to the queen of Hungary, after surmounting some difficulties, was chosen emperor.

The bad success of the allies against the French and Bavarians in the Low Countries, and the loss of the battle of Fontenoy, retarded the operations of the empress queen against his Prussian majesty. The latter beat the emperor's brother, Prince Charles of Lorrain, who had before driven the Prussians out of Bohemia; and the conduct of the empress queen was such, that his Britannic majesty thought proper to guarantee to him the possession of Silesia, as ceded by treaty. Soon after, his Prussian majesty pretended that he had discovered a secret convention which had been entered into between the empress queen, the empress of Russia, and the king of Poland as elector of Saxony, to strip him of his dominions, and to divide them

Germany.

them among themselves. Upon this his Prussian majesty, very suddenly, drove the king of Poland out of Saxony, defeated his troops, and took possession of Dresden; which he held till a treaty was made under the mediation of his Britannic majesty, by which the king of Prussia acknowledged the duke of Lorrain, great duke of Tuscany, for emperor. The war, however, continued in the Low Countries, not only to the disadvantage, but to the discredit of the Austrians and Dutch, till it was finished by the treaty of Aix-la-Chapelle, in April 1748. By that treaty Silesia was once more guaranteed to the king of Prussia. It was not long before that monarch's jealousies were renewed and verified; and the empress of Russia's views falling in with those of the empress queen and the king of Poland, who were unnaturally supported by France in their new schemes, a fresh war was kindled in the empire. The king of Prussia declared against the admission of the Russians into Germany, and his Britannic majesty against that of the French. Upon these two principles all former differences between these monarchs were forgotten, and the British parliament agreed to pay an annual subsidy of 670,000l. to his Prussian majesty during the continuance of the war.

The flames of war now broke out in Germany with greater fury and more destructive violence than ever. The armies of his Prussian majesty, like an irresistible torrent, burst into Saxony; totally defeated the imperial general Brown at the battle of Lowositz; forced the Saxons to lay down their arms; though almost impregnably fortified at Pirna; and the elector of Saxony fled to his regal dominions in Poland. After this, his Prussian majesty was put to the ban of the empire; and the French poured, by one quarter, their armies, as the Russians did by another, into the empire. The conduct of his Prussian majesty on this occasion is the most amazing that is to be met with in history; for a particular account of which, see the article PRUSSIA.

At last, however, the taking of Colberg by the Russians, and of Schweidnitz by the Austrians, was on the point of completing his ruin, when his most formidable enemy, the empress of Russia, died January 5. 1762; George II. his only ally, had died on the 25th of October 1760.

The deaths of those illustrious personages were followed by great consequences. The British ministry of George III. sought to finish the war with honour, and the new emperor of Russia recalled his armies. His Prussian majesty was, notwithstanding, so very much reduced by his losses, that the empress queen, probably, would have completed his destruction, had it not been for the wise backwardness of other German princes, not to annihilate the house of Brandenburg. At first the empress queen rejected all terms proposed to her, and ordered 30,000 men to be added to her armies. The visible backwardness of her generals to execute her orders, and new successes obtained by his Prussian majesty, at last prevailed on her to agree to an armstice, which was soon followed by the treaty to Hubertsburgh, which secured to his Prussian majesty the possession of Silesia. Upon the death of the emperor her husband, in 1765, her son Joseph, who had been crowned king of the Romans in 1764, succeeded him in the empire.

This prince showed an active and restless disposition, much inclined to extend his territories by conquest, and to make reformations in the internal policy of his dominions, yet without taking any proper methods for accomplishing his purposes. Hence he was almost always disappointed; insomuch that he wrote for himself the following epitaph: "Here lies Joseph, unfortunate in all his undertakings." In the year 1778, a war commenced betwixt him and the king of Prussia; in which, notwithstanding the impetuous valour of that monarch, Joseph acted with such caution that his adversary could gain no advantage over him; and an accommodation took place without any remarkable exploit on either side. In 1781 he took the opportunity of the quarrel betwixt Britain and the United Provinces, to deprive the latter of the barrier towns which had been secured to them by the treaty of Utrecht. These indeed had frequently been of great use to the house of Austria in its state of weakness; but Joseph, conscious of his own strength, looked upon it as derogatory to his honour to allow so many of his cities to remain in the hands of foreigners, and to be garrisoned at his expence. As at that time the Dutch were unable to resist, the imperial orders for evacuating the barrier towns were instantly complied with; nor did the court of France, though then in friendship with Holland, make any offer to interpose. Encouraged by this success, Joseph next demanded the free navigation of the Scheldt; but as this would evidently have been very detrimental to the commercial interests of Holland, a flat refusal was given to his requisitions. In this the emperor was much disappointed; having flattered himself that the Hollanders, intimidated by his power, would yield the navigation of the river as easily as they had done the barrier. Great preparations were made by the emperor, which the Dutch, on their part, seemed determined to resist. But while the emperor appeared so much set upon this acquisition, he suddenly abandoned the project entirely, and entered into a new scheme of exchanging the Netherlands for the duchy of Bavaria. This was opposed by the king of Prussia; and by the interference of the court of France, the emperor found himself at last obliged also to abandon his other scheme of obtaining the navigation of the Scheldt. A treaty of peace was concluded, under the guarantee of his most Christian majesty. The principal articles were, that the states acknowledged the emperor's sovereignty over the Scheldt from Antwerp to the limits of Seftingen; they agreed to demolish certain forts, and to pay a considerable sum of money in lieu of some claims which the emperor had on Maestricht, and by way of indemnification for laying part of his territories under water.

The treaty with the Dutch was no sooner concluded than a quarrel with the Turks took place, which terminated in an open war. It does not appear that the emperor had at this time any real provocation, but seems to have acted merely in consequence of his engagements with Russia to reduce the dominions of the Grand Signior. All these foreign engagements, however, did not in the least retard the progress of reformation which the emperor carried on throughout his dominions with a rapidity scarcely to be matched, and which at last produced the revolt of the Austrian Netherlands. In the course of his labours in this way, a complete

 complete code of laws was compiled. These were at first greatly commended for their humanity, as excluding almost entirely every species of capital punishment; yet, when narrowly considered, the commutations were found to be so exceedingly severe, that the most cruel death would, comparatively speaking, have been an act of mercy. Even for smaller crimes the punishments were severe beyond measure; but the greatest fault of all was, that the modes of trial were very defective, and the punishments so arbitrary, that the most perfect and innocent character lay at the mercy of a tyrannical judge. The innovations in ecclesiastical matters were, however, most offensive to his subjects in the Netherlands. Among the many changes introduced into this department, the following were some of the most remarkable. 1. An abridgment of divine service. 2. A total suppression of vocal performers in choirs. 3. The introduction of the vernacular language instead of the Latin in administering the sacraments. 4. The prohibition of chanting hymns in private houses. 5. The suppression of a great number of religious houses, and the reduction of the number of the clergy. 6. The total abolition of the papal supremacy throughout the imperial dominions. The same spirit of innovation displayed itself even in the most minute matters. Many favours were bestowed upon the Jews; and in 1786 the emperor wrote with his own hand to the different handicraft and trading corporations in Vienna, requesting that their youths might be received as apprentices in that city. Severe laws against gaming were enacted and put in execution with equal rigour. Heavy restrictions were also laid on all the societies of free masons in Germany, while those in the Netherlands were totally suppressed.

The great number of innovations in religious matters were highly resented by the inhabitants of the Netherlands, who have always been remarkable for their attachment to the Romish religion in its most superstitious form. Indeed the alterations in the civil constitution were so great, that even those who were least bigotted in this respect began to fear that their liberties were in danger, and an universal dissatisfaction was excited. The emperor behaved at first in a very haughty manner, and refused to yield the smallest point to the solicitations of his subjects. Finding, however, that a general revolt was about to take place, and being unable at that time, on account of the Turkish war, to spare such a force as would be necessary to reduce the provinces to obedience, he thought proper, in the autumn of 1787, to promise a restoration of their ancient constitution and privileges. His promises, however, were found to be so delusive, and his conduct was so arbitrary and capricious, that in the end of the year 1789 the states of all the provinces in the Austrian Netherlands came to a resolution of entirely throwing off the yoke. Articles of a federal union were drawn up, and a new republic was formed under the title of the *Belgic Provinces.* The situation of the emperor's affairs at that time did not allow him to take the measures necessary for preventing this revolt; to which perhaps his ill state of health also contributed. About the beginning of February 1790 his distemper increased to such a degree as to be thought dangerous; and continuing daily to grow worse, he sunk under it on the 20th of the same month, in the 40th year of his age, and 26th of his reign.

The leaders of the revolution, however, soon became so disagreeable to their countrymen, that they were obliged to fly. Joseph's successor, Leopold, adopted a more conciliatory policy, and the troubles in the Netherlands were at length calmed.

The Netherlands, which the French had overrun in 1794, were annexed to France by the treaty of Campo Formio in 1797. This was the amputation of a limb from the Germanic body; but the further changes which this measure introduced were not completed till 1801, when the three ecclesiastical electorates, Mentz, Triers, and Cologne, were abolished, and in their room were created four new electorates, Baden, Wirtemberg, Hesse Cassel, and Saltzburg. Many bishoprics and abbeys were at the same time secularized, and a number of free towns disfranchised, to afford indemnities to the princes who were deprived of their possessions on the left bank of the Rhine. In 1806, after the battle of Austerlitz, farther changes were made, which entirely abolished the ancient Germanic constitution. The emperor Francis renounced the title of emperor of Germany, and assumed that of emperor of Austria. The princes of Bavaria, Wirtemberg, and Saxony assumed the title of king; and these, with nearly all the other small states, were united into a body, named the Confederation of the Rhine, of which the emperor Napoleon was head. This body was dissolved in 1813, when the French were driven within the Rhine; but its constitution served as the model for the new Germanic confederation, which was established in 1814 by the congress of Vienna.

21 Constitution of the empire.

Monarchy was first established in Germany by Clodovick: after him Charlemagne extended his power and his dominions; and so great had the empire become, that during his reign, and that of his son, government was administered in the provinces by persons vested with power for that purpose under the title of *Dukes.* In the districts of these provinces, justice was distributed by a *comes* or count, which officer was in Germany called *Graf.* But from their courts lay an appeal to that of the emperor, before a president styled *Comes Palatinus*, that is, "Count Palatine, or of the palace," in German denominated *Psalzgraf.* The frontiers or marches were governed by a marquis, styled by the Germans *Markgraf*, similar to our lord warden. Generally the centre of the empire was ruled by an officer who possessed a similar power, but a greater extent of dominion, than the Grave, under the title of *Landgrave.* Towns and castles, which were occasionally honoured with the residence of the emperor, were governed by a Burggraf. It may be remarked, that the signification of the above-mentioned titles, and the extent of power which they conferred upon the persons honoured with them, differ according to the successive ages and the gradual developement of the German constitution.

By reason of family broils in the imperial house, and civil wars in their dominions, the dignity of the sovereign was depressed, and a new form in the government raised up. The dukes exalted themselves above the power of the emperor, and secured for their sons a succession to their greatness; while the interest of the

Germany. the sovereign, in order to strengthen the bond of personal attachment, ratified to others and their descendants that sway which had been formerly delegated and dependant on his will. Hence arose the modern constitution of distinct principalities, acknowledging one head in the person of an emperor. But shortly after the election of Conrade duke of Franconia to the throne, this new-gained authority of the princes became doubtful. However, after most violent disturbances and confusions, the regulations yielded to by Albert II. and his successors, particularly by Frederick III. laid the foundation of the German constitution; but the power and form of which were afterwards improved by Maximilian. Before Charles V. mounted the throne, on the death of Maximilian, the electors formed a bulwark against the Imperial power, by an instrument called the *capitulation;* to which articles of government he and all emperors elected since have sworn, previous to their investiture with the Imperial dignity.

22 Of the electors.

When the German monarchy received an elective form, the right of election was not limited to the great officers of state, for other princes participated of this privilege. But the empire being governed by four dukes, the princes under their authority, in order to court their favour, gave to them the disposal of their votes, and of those of their vassals. The three archbishops also, who were necessarily present at the coronation, obtained the electoral dignity. However, beside this origin of the modern electors, the high-stations about court procured their possessors an influence over other members, and their general residence there gave them a solid advantage in their constant and early presence at the diet of election. For in times of turbulence several emperors were elected, when the princes had not an opportunity to attend. And hence sprung up a sanction to that right, which the high officers of the household had assumed, of electing without any consultation of the other members of the empire. Pope Gregory X. too, either conceiving that they did possess, or willing that they should acquire, this right, exhorted them in a bull to terminate the troubles of Germany by electing an emperor. And since that period they have been held as the sole electors. But the possession of this high power was strengthened by a league amongst themselves, called the *electoral union*, which received additional confirmation from the emperor Louis of Bavaria, and was formally and fully ratified by that famous constitution of Charles IV. termed the *golden bull;* according to which, the territories and the high officers by which the electoral dignity is conveyed, must descend according to the right of primogeniture, and are indivisible.

The golden bull declares the following number and titles of the electors: The archbishop of Mentz as great chancellor of the German empire; the elector of Cologne as great chancellor of the empire in Italy; the elector of Triers as great chancellor of the empire in Gaul and Arles; the king of Bohemia as cupbearer; the count Palatine as high steward; the duke of Saxony as grand marshal; the margrave of Brandenburg as grand chamberlain. The number originally was seven, but the emperor Leopold created the duke of Lunenburg, ancestor to our present British sovereign, an elector; to whom the post of arch-treasurer was afterwards given; and thus Hanover forms the eighth electorate. But this number cannot be increased by the emperor without a previous election by the electors themselves; who, thus capable of electing and of being elected, may style themselves *Coimperantes;* and they exercise part of the imperial authority, if a vacancy of the throne happen. But when or before this occurs, the election of the emperor is proceeded to after the following manner: The elector of Mentz, before the lapse of a month after the death of the emperor, summons, as great chancellor of the empire, the rest of the electors to attend on some fixed day within the space of three months from the date of the summons. The electors generally send their ambassadors to the place of election, which is held at Frankfort on the Mayne; but saving the right of the city of Frankfort, it may be held elsewhere.

23 Election of the emperor.

When the diet of electors is assembled, they proceed to compose the capitulation, to which the emperor when elected is to swear. The capitulation being adjusted, the elector of Mentz appoints a day for the election. When this day arrives, the gates of the city are shut, and the keys delivered to the elector of Mentz. The electors or their ambassadors, Protestants excepted, repair in great pomp to mass; and after its celebration they take a solemn oath to choose, unbiassed and uninfluenced, the person that appears most proper for the imperial dignity. After this they repair to the sacristy, where the elector of Mentz first asks, if there be any impediment known against their proceeding at present to an election; and next he obtains a promise, that the person elected by the majority shall be received as emperor. The declarations of the electoral ambassadors, in respect to those two points, are recorded by two notaries of the empire. Then all witnesses withdraw; and the elector of Mentz collecting the suffrages, which are *viva voce*, and giving his own last, the witnesses are recalled, and he declares the person whom the electors have chosen. But the election is not complete, nor is the new emperor proclaimed, until the capitulation be sworn to either by himself or by his ambassadors if he be absent. From this time he is styled king of the Romans until the coronation takes place; which ceremony confers the title of emperor. According to the golden bull, it should be celebrated at Aix-la-Chapelle, out of respect to Charlemagne, who resided there; but saving the right to Aix-la-Chapelle, it may take place elsewhere. The coronation is performed by the archbishop of Mentz or elector of Cologne. And, when he is seated on his throne, the duke of Saxony delivers into his hand the sword of Charles the Great, with which he makes some knights of the holy Roman empire, and is also obliged to confer that honour upon such others as are nominated by the respective electors. When he proceeds to dinner in the great hall, he is seated at a table elevated two steps higher than that of the electors, and is served by counts of the empire. The electors, each of whom has also his table, are attended by the gentlemen of their respective courts. These electors, who assist personally at the ceremony,

 remony, sit and eat at their own tables; but those who are represented by ambassadors have only their tables covered out of form with plates, at which the ambassadors do not sit.

For the benefit of the empire during the reign of an emperor, his presumptive successor may be elected king of the Romans. But this election confers at first a mere title; for by an express article in his capitulation, the king of the Romans swears not to interfere with the government during the life of the emperor; but on his decease the coronation confirms him emperor without a second election.

Should there not be a king of the Romans, and the throne become vacant, the government is administered by vicars of the empire, who are the electors Palatine and of Saxony, as count palatine and arch-marshal of the empire. Each has his district and tribunal of the vicariate; and by the golden bull it is established, that all acts of the vicars are valid; but they are all fully confirmed by the emperor; which confirmation, by an article of his capitulation, he is bound to give.

There are also vicars of the emperor. These officers are constituted by a delegation of the imperial power from the emperor to any prince of the empire, when he is unable to execute his authority himself. But these vicars stand accountable to the emperor; their acts may be annulled and their offices revoked, all dependent on the will of the emperor, and determinable at his pleasure.

When the race of Charlemagne ceased to govern in Germany, the princes and states associated to continue the empire; and that its majesty might be visible, and its laws enforced, they agreed to choose an emperor. From this emperor all electors and princes except those before 1582 receive investiture of their dominions; counts and free cities from the Aulic council. But this investiture is no more than a sign of submission to the majesty of the empire, which is deposited in the emperor. For as the constituted members of the empire are dependent on that collective union from which they derive protection, they therefore show this dependence on the emperor, because he represents the majesty of that union or of that empire; but in all other respects they are independent and free.

These princes or sovereigns may even wage war with the prince wearing the imperial crown, as possessed of other titles and dominions unconnected with his imperial station. Nor can the sovereignty of any member be affected so long as he remains loyal to the empire; which loyalty constitutes his duty, and secures him its protection. But should he be guilty of any violation against the emperor, as head of the empire, such a crime would commit him to the punishment of its laws, and he would be put under the ban. For this crime would be against that collective body of sovereigns whose union constitutes the empire; and therefore any violation of that union is justly punished with deprivation of these territories which render such sovereigns members of the empire. Nor can this punishment of the ban derogate from the dignity of those princes who derive their sovereignty from this constitution, and whose subjection is an act of their own consent. However, no member of the empire can at present be put under the ban without being first heard, and without the concurrence of the electors, princes, and states, being previously obtained.

24 Powers of the emperor.

The emperor is endowed with many privileges, and his power partly appears in the exercise of his reserved rights, or the peculiar prerogatives annexed to the imperial dignity. He grants to princes the investiture of their dominions; but to this he is bound as the laws direct. He confers titles, but promises that they shall be bestowed only on such persons as will maintain their dignity, and can support their rank. Besides, he can give merely the title; for the power or privilege of prince or count can be obtained only from their respective bodies. But in some instances, even titles are of high importance. For the descendants of a prince are incapable of succession, if their mother be of inferior rank to their father; but the conferring of a title ennobles her and removes the bar, if the collateral line consents.

The emperor can also make cities, found universities, grant the privilege of fairs, &c. He can also dispense with the tedious terms of minority, and empower princes to assume at an earlier age the government of their own dominions. He decides all rank and precedency, and has a power of *primæ preces*, that is, of granting for once in every chapter of the empire a vacant seat. But he is not above the law; for electors have not only chosen but deposed emperors. However, the influence of the capitulation is to prevent such rigorous proceedings: but should the capitulation be violated, the college of electors might proceed to remonstrance; and if these remonstrances should be without effect, in conjunction with the diet, they might resort to more forcible remedies.

25 Diet of the empire.

The diet is that assembly of the states in which the legislative power of the empire resides; and is composed of the electors, princes, prelates, counts, and free cities of the empire. It has sat since 1663, and is held usually at Ratisbon. The emperor, when present, presides in person; when absent, by his commissary, whose communication of proposals from the emperor to the assembly is called the *commissorial decree*. The elector of Mentz, as chancellor of the empire, is director of the diet; and to his chancery are all things addressed that are to be submitted to the empire; the reading of which by his secretary to the secretaries of the other ministers at the diet is denominated *per dictaturam*, and constitutes the form of transmitting papers or memorials to the dictature of the empire.—The diet is composed of three distinct colleges, each of which has its particular director. The first college is that of electors; of which the archbishop of Mentz is director as first elector. The second college is that of princes. It consists of princes, archbishops, and bishops; and of prelates, abbots, and counts, who are not considered as princes. Each prince spiritual and temporal has a vote, but prelates and counts vote by benches. The prelates are divided into two benches, the counts into four; and each bench has only one vote. The archduke of Austria and the archbishop of Saltzburg are alternately directors of the college of princes. The third college is that of the free cities of the empire; the director of which is the minister of the city in which the diet happens to sit.

In

Germany.

In all these colleges, the sentiments of the majority are conclusive, except in respect of fundamental laws, which affect the whole empire, or such matters as relate to religion. In these they must be unanimous.

Where religion is interested, the proceedings are also different. The colleges are then considered as consisting of two bodies, the evangelic and the catholic; and if any religious point be proposed, it must meet not only the unanimous concurrence of the proposing body, but must have the majority of the other to establish it. This distinction arose from a conjunction called the *evangelic body;* which was formed by the Protestant states and princes to guard the Protestant interest in Germany, by watching over the laws for the security of their religion, and, in case of violation, by obtaining redress from the imperial throne. For in any part of the empire, as in the palatinate, where the count is a Papist and the subjects are Protestants, should oppressions arise, application would be made to the evangelic body through the director. The elector of Saxony is director of the evangelic body, though he is a Papist: but therefore his representations in favour of the Protestants have more force; and beside, should he abuse an office which invests him with considerable weight and influence, he could be instantly deprived of it.

The first two colleges are styled superior, and in effect constitute the diet: for all points that come before the diet, are generally first deliberated in the college of electors, and pass from that to the college of princes; in which, if any objection arise, a free conference takes place between the directors of each college. And should they, in consequence of this free conference, concur, they invite the third college to accede to their joint opinion; which invitation is generally complied with: but should this college return a refusal, the opinion of the other two colleges is in some few cases engrossed in the chancery, and delivered to the emperor's commissary as the opinion of the empire. The opinion of the third college is merely mentioned at the close. However, though the superior colleges do in effect constitute the diet; yet the received maxim is, that no two colleges constitute a majority, that is, the majority of voices at the diet; nor can the emperor confirm the opinion of two colleges as an opinion of the diet. By the peace of Westphalia, a decisive vote was recognized as a right of the imperial cities, which the two superior colleges should not infringe upon; their vote being, by the fundamental law, of equal weight with that of the electors and princes.

After a measure is approved of by the colleges, it is submitted to his Imperial majesty to receive his negative or confirmation. Should he approve the point, it is published in his name as the resolution of the empire, which states are exhorted to obey, and tribunals desired to consider as such.

The diet not only makes and explains laws, but decides ambiguous cases. It must also be consulted before war is made; appoints the field marshal who is to command the army, and assigns him his council of war. The diet also enters into and makes alliances, but usually empowers the emperor to negociate them; and foreign states have their ambassadors at the diet, but the diet sends no ministers to foreign courts.

26 Administration of justice, &c.

In the origin of the empire, justice was administered in the districts of the provinces by counts, and appeals lay from their courts to that of the emperor before the count palatine. But as civil broils shook the power of the emperor, they interrupted also the course of justice. The consequent inconveniences caused several solicitations to be preferred from the states to different emperors for the establishment of a court of justice, which should take cognizance of great as well as small causes. And at length such a court was erected by Maximilian I. under the title of the *Imperial Chamber at Worms*, in the year 1495; but was removed to Spires in 1533, and to Wetzlar in 1696, where it is now held. The members of this court are a judge of the chamber and 25 assessors, partly Protestants, partly Papists. The president is appointed by the emperor, the assessors by the states. The court receives appeals from inferior jurisdictions, and decides dubious titles; and all causes before it between prince and prince, or princes and private persons, are adjudged according to the laws of the respective parties, or according to the Imperial law. The tribunal is under the inspection of visitors appointed by the states; and, during their visitation, the sentences of the court are subject to revision. Appeals lie afterwards also from the judgment of the visitors to that of the diet.

27 Aulic council.

The emperors finding themselves deprived of many of their powers, wished to raise their prerogatives by forming a tribunal, of which they should name the judge, and before whom causes in the last resort should come. But Maximilian foresaw, in respect to the new tribunal, that though a consciousness of its importance made the states struggle for its erection, the expences of its establishment would make them neglect its support; and the event bore witness to his sagacity. But when, through the omissions and negligence of the states, there happened to be a cessation in the distribution of justice by the Imperial chamber, he revived his court of the count Palatine, or Aulic council. And in order to gain the quiet acquiescence of the states, under the mask of a partition of power, and of generous moderation, he desired them to add eight to the number of assessors, and the salaries of all should be discharged by him. The states swallowed the bait, but soon perceived that they had lost part of their liberty.

The emperor, by keeping the tribunal always open, by filling its seats with men of first-rate talents, and by having its sentences duly and speedily executed, drew all causes before it. The states remonstrated, declaring that the Imperial chamber ought to be not only the supreme, but sole tribunal of that kind. The emperor answered, that he had erected the Imperial chamber in consequence of their solicitations; but as they had not supplied the tribunal with judges, he provided for that deficiency by a constant administration of justice in the establishment of another.

The Aulic council now subsists with equal authority, each receiving appeals from inferior jurisdictions; but neither appealing to the other, as the *dernier resort* from both must be had to the diet. However, to the Aulic council belong the reserved rights of the emperor; and to the Imperial chamber also are annexed peculiar powers. The Imperial chamber subsists during a vacancy

Germany. cancy of the throne under the authority of the vicars of the empire; whereas the Aulic council does not exist until appointed by the succeeding emperor.

The Aulic council consists of a president, vice president, and 17 assessors, of whom six are Protestants. The vice chancellor of the empire is also entitled to a seat; and all decrees issuing from the council pass through his hands to those who are to execute them. This tribunal obtains for the emperor, through the appeals from the courts of other princes, a new authority beside that which he possesses from his reserved rights; but electors and some princes, as those of Hanover, Austria, Brunswick, Swedish Pomerania, Hesse, are free from this dependence on the emperor, to whose Aulic council their subjects cannot appeal; nor can it take cognizance of ecclesiastical or criminal causes, both of which appertain to territorial justice; which we shall presently consider when we have surveyed the executive instrument of Imperial justice.

The division of the empire into circles is a regulation coeval with the establishment of the Imperial chamber by Maximilian, in order to strengthen the arm of justice with vigour to enforce its decrees. The original division was into six circles, which are called the *ancient circles;* and are, Bavaria, Franconia, Suabia, Lower Saxony, the Upper Rhine, and Westphalia; but the powerful princes, who at first declined bringing their dominions under the form of circles, were led by a political finesse of the emperor to adopt the regulation, and increase the number to ten, by forming the four new circles of Austria, Burgundy, the Electorate Circle, and Upper Saxony.

Over these circles preside directors, to whom the tribunals of justice commit the execution of their decrees. The six old circles have two directors each, the four new have one each. The office of director is permanent and hereditary, as it belongs always to the first prince in the circle, upon whom it confers high authority; for all the decrees of the Imperial chamber and Aulic council are of no avail unless the director will execute them.

The directors of the circles are not only instruments of war but of peace: for in case of an Imperial war, they are to collect the troops of the circle; and if any state or prince of their respective circles suffers violation from others, they are to yield protection and enforce the peace; or should there be any tumultuous uprisings of the people, the suppression of such belongs to them.

The emperor is the executive instrument of the whole empire; the directors are such of the constitutive parts called circles. The prosperity and security of which being at stake, the directors, as presidents, must hold frequent diets in their respective circles, in order to consult on and adopt salutary measures for their safety and welfare: but as the interests of those near to us are generally so intimately blended with our own, that the good of either cannot be pursued without the mutual concurrence of both, there arise negotiations on particular points between the diets of different circles, which are therefore styled *confederate circles;* and these negotiations being more frequent amongst the circles of the Upper and Lower Rhine, or Westphalia, they are denominated the *corresponding circles.* Germany.

28 Powers of the German princes.

Every prince is sovereign in his own country; and may enter into alliances, and pursue by all political measures his own private interests, as other sovereigns do; for if even an imperial war be declared, he may remain neuter if the safety of the empire be not at stake.

Each state or sovereign appoints in general three colleges for its government. The first is the *geheimderath*, or privy council; the second is the *regierung*, or regency; the third the *renthcammer*, or chamber of finances. Each of these has a president; and a member of the first college is always president of the second. The geheimderath represents the prince, and superintends the other two. The regierung regulates limits of territories, holds conferences with other princes, and is in most countries a court of justice: however, in some states there is also a court of justice called *justitz department.* And besides the right of conferences assigned to the regierung by the sovereign, when there are disputes between princes, there is also an *austrage*, or arbitration appointed in order to decide them. Attention must be paid to this privilege of princes, who must be called on to appoint an austrage before resort be had to the Imperial tribunal, but to which there still lies an appeal from the judgment of the austrage. The renthcammer attends to the regulation of domains and estates, to the territorial revenues, and management of the taxes.

Such, before the French revolution, was the constitution of Germany, which is still worthy of a place in a work of this kind, from its connection with the history of that country, and indeed of Europe at large, for so many centuries. The present constitution of Germany was founded on that of the Rhenish Confederation (See CONFEDERATION OF THE RHINE, SUPPLEMENT), created by Bonaparte. The Germanic body includes *thirty-nine* states, among which are Austria, Prussia, Denmark, and the Netherlands; but these four powers rank as members only for a part of their territories. The common concerns of the whole body are managed by a diet which meets at Frankfort, and consists of 70 deputies sent from the thirty-nine states, the six greatest states sending four deputies each, others three or two, and the smallest states one. The thirty-nine states include a population of 30,355,069 (1818), upon a surface of 250,000 square miles. The military contingents of all the states amount to 120,000 in time of peace, and 301,000, or *one* in the 100 of the population, in time of war. The subjoined table exhibits the population and extent of each state, with the number of votes it has in the diet.

30 Character of the ancient Germans.

With regard to the character of the ancient Germans, they are described to us by the Greek and Roman writers as resembling the Gauls; and differing from other nations by the largeness of their stature, ruddy complexion, blue eyes, and yellow bushy hair, haughty and threatening looks, strong constitutions, and being proof against hunger, cold, and all kinds of hardship.

Their native disposition displayed itself chiefly in the martial genius, and in their singular fidelity. The former of these they did indeed carry to such an excess as came little short of downright ferocity; but, as to the latter, they not only valued themselves highly upon it, but were greatly esteemed by other nations for it; insomnch that Augustus, and several of his successors, committed the guard of their persons to them, and almost all other nations either courted their friendship and alliance, or hired them as auxiliaries; though it must be owned, at the same time, that their extreme love of liberty, and their hatred of tyranny and oppression, have often hurried them to treachery and murder, especially when they have thought themselves ill used by those who hired them; for in all such cases they were easily stirred up, and extremely vindictive. In other cases, Tacitus tells us, they were noble, magnanimous, and beneficent, without ambition to aggrandize their dominions, or invading those from whom they received no injury; rather choosing to employ their strength and valour defensively than offensively; to preserve their own, than to ravage their neighbours.

Their friendship and intercourse was rather a compound of honest bluntness and hospitality, than of wit, humour, or gallantry. All strangers were sure to meet with a kind reception from them to the utmost of their ability: even those who were not in a capacity to entertain them, made it a piece of duty to introduce them to those who could; and nothing was looked upon as more scandalous and detestable, than to refuse them either the one or the other. They do not seem, indeed, to have had a taste for grand and elegant entertainments; they affected in every thing, in their houses, furniture, diet, &c. rather plainness and simplicity, than sumptuousness and luxury. If they learned of the Romans and Gauls the use of money, it was rather because they found it more convenient than their ancient way of bartering one commodity for another; and then they preferred these ancient coins which had been stamped during the times of the Roman liberty, especially such as were either milled or cut in the rims, because they could not be so easily cheated in them as in some others, which were frequently nothing but copper or iron plated over with silver. This last metal they likewise preferred before gold, not because it made a greater show, but because it was more convenient for buying and selling: And as they became in time more feared by, or more useful to, the Romans; so they learned how to draw enough of it from them to supply their whole country, besides what flowed to them from other nations.

As they despised superfluities in other cases, so they did also in the connubial way: every man was contented with one wife, except some few of their nobles, who allowed themselves a plurality, more for show than pleasure; and both were so faithful to each other, and chaste, true, and disinterested in their conjugal affection, that Tacitus prefers their manners in this respect to those of the Romans. The men sought not dowries from their wives, bnt bestowed them npon them. Their youth, in those cold climes, did not begin so soon to feel the warmth of love as they do in hotter ones: it was a common rule with them not to marry young; and these were most esteemed who continned longest in celibacy, because they looked upon it as an effectual means to make them

Germany. them grow tall and strong; and to marry, or be concerned with a woman, before they were full 20 years old, was accounted shameful wantonness. The women shared with their husbands not only the care of the family, and the education of their children, but even the hardships of war. They attended them in the field, cooked the victuals for them, dressed their wounds, stirred them up to fight manfully against their enemies, and sometimes have, by their courage and bravery, recovered a victory when it was upon the point of being snatched from them. In a word, they looked upon such constant attendance on them, not as a servitude, like the Roman dames, but as a duty and an honour. But what appears to have been still a harder fate upon the ancient German dames was, that their great Odin excluded all those from his *valhalla* or paradise, who did not, by some violent death, follow their deceased husbands thither. Yet notwithstanding their having been anciently in such high repute for their wisdom and supposed spirit of prophecy, and their continuing such faithful and tender helpmates to their husbands, they sunk in time so low in their esteem, that, according to the old Saxon law, he that hurt or killed a woman was to pay but half the fine that he should have done, if he had hurt or killed a man.

31 Their funerals.

There is scarcely any one thing in which the Germans, though so nearly allied in most of their other customs to the Gauls, were yet more opposite to them than in their funerals. Those of the latter were performed with great pomp and profusion; those of the former were done with the same plainness and simplicity which they observed in all other things; the only grandeur they affected in them was, to burn the bodies of their great men with some peculiar kinds of wood; but then the funeral pile was neither adorned with the clothes and other fine furniture of the deceased, nor perfumed with fragrant herbs and gums: each man's armour, that is, his sword, shield, and spear, were flung into it, and sometimes his riding horse. The Danes, indeed, flung into the funeral pile of a prince, gold, silver, and other precious things, which the chief mourners, who walked in a gloomy guise round the fire, exhorted the bystanders to fling liberally into it in honour of the deceased. They afterwards deposited their ashes in urns, like the Gauls, Romans, and other nations; as it plainly appears, from the vast numbers which have been dug up all over the country, as well as from the sundry dissertations which have been written upon them by several learned moderns of that nation. One thing we may observe, in general, that whatever sacrifices they offered for their dead, whatever presents they made to them at their funerals, and whatever other superstitious rites they might perform at them, all was done in consequence of those excellent notions which their ancient religion had taught them, the immortality of the soul, and the bliss or misery of a future life.

32 The belief of a future state.

It is impossible, indeed, as they did not commit any thing to writing till very lately, and as none of the ancient writers have given us any account of it, to guess how soon the belief of their great Odin, and his paradise, was received among them. It may, for aught we know, have been older than the times of Tacitus, and he have known nothing of it, by reason of their scrupulous care in concealing their religion from strangers: but as they conveyed their doctrines to posterity by songs and poems, and most of the northern poets tell us that they have drawn their intelligence from those very poems which were still preserved among them; we may rightly enough suppose, that whatever doctrines are contained in them, were formerly professed by the generality of the nation, especially since we find their ancient practice so exactly conformable to it. Thus, since the surest road to this paradise was, to excel in martial deeds, and to die intrepidly in the field of battle; and since none were excluded from it but base cowards, and betrayers of their country; it is natural to think, that the signal and excessive bravery of the Germans flowed from this ancient belief of theirs: and, if their females were so brave and faithful as not only to share with their husbands all the dangers and fatigues of war, but at length to follow them by a voluntary death, into the other world; it can hardly be attributed to any thing else but a strong persuasion of their being admitted to live with them in that place of bliss. This belief, therefore, whether received originally from the old Celtes, or afterwards taught them by the since deified Odin, seems, from their general practice, to have been universally received by all the Germans, though they might differ one from another in their notions of that future life.

The notion of a future happiness obtained by martial exploits, especially by dying sword in hand, made them bewail the fate of those who lived to an old age, as dishonourable here, and hopeless hereafter: upon which account, they had a barbarous way of sending them into the other world, willing or not willing. And this custom lasted several ages after their receiving Christianity, especially among the Prussians and Venidi; the former of whom, it seems, despatched by a quick death, not only their children, the sick, servants, &c. but even their parents, and sometimes themselves: and among the latter we have instances of this horrid parricide being practised even in the beginning of the 14th century. All that need be added is, that, if those persons, thus supposed to have lived long enough, either desired to be put to death, or at least seemed cheerfully to submit to what they knew they could not avoid, their exit was commonly preceded with a fast, and their funeral with a feast; but if they endeavoured to shun it, as it sometimes happened, both ceremonies were performed with the deepest mourning. In the former, they rejoiced at their deliverance, and being admitted into bliss; in the latter, they bewailed their cowardly excluding themselves from it. Much the same thing was done towards those wives who betrayed a backwardness to follow their dead husbands.

33 Remarkable for drinking to excess.

We must likewise observe, that, in these funerals, as well as in all their other feasts, they were famed for drinking to excess; and one may say of them, above all the other descendants of the ancient Celtes, that their hospitality, banquets, &c. consisted much more in the quantity of strong liquors, than in the elegance of eating. Beer and strong mead, which were their natural drink, were looked upon as the chief promoters of health, strength, fertility, and bravery; upon which account, they made no scruple to indulge themselves to the

Germany.

34 Character of the modern Germans.

the utmost in them, not only in their feasts, and especially before an engagement, but even in their common meals.

The modern Germans in their persons are tall and strong built. The ladies have generally fine complexions; and some of them, especially in Saxony, have all the delicacy of features and shape that are so bewitching in a certain island of Europe.

Both men and women affect rich dresses, which in fashion are the same as in France and England, but the better sort of men are excessively fond of gold and silver lace, especially if they are in the army. The ladies at the principal courts differ not much in their dress from the French and English, only they are not so excessively fond of paint as the former. At some courts they appear in rich furs; and all of them are loaded with jewels, if they can obtain them. The female part of the burghers families, in many German towns, dress in a very different manner, and some of them inconceivably fantastic, as may be seen in many prints published in books of travels; but in this respect they are gradually reforming, and many of them make quite a different appearance in their dress from what they did 30 or 40 years ago. As to the peasantry and labourers, they dress as in other parts of Europe, according to their employments, conveniency, and opulence. In Westphalia, and most other parts of Germany, they sleep between two feather beds, or rather the upper one of down, with sheets stretched to them, which by use becomes a very comfortable practice. The most unhappy part of the Germans are the tenants of little needy princes, who squeeze them to keep up their own grandeur; but, in general, the circumstances of the common people are far preferable to those of the French.

The Germans are naturally a frank, honest, hospitable people, free from artifice and disguise. The higher orders are ridiculously proud of titles, ancestry, and show. The Germans, in general, are thought to want animation, as their persons promise more vigour and activity than they commonly exert even in the field of battle. But when commanded by able generals, especially the Italians, such as Montecuculi and Prince Eugene, they have done great things, both against the Turks and the French. The Imperial arms have seldom made any remarkable figure against either of those two nations, or against the Swedes or Spaniards, when commanded by German generals. This possibly might be owing to the arbitrary obstinacy of the court of Vienna; for in many wars the Austrians have exhibited prodigies of military valour and genius.

Industry, application, and perseverance, are the great characteristics of the German nation, especially the mechanical part of it. Their works of art would be incredible were they not visible, especially in watch and clockmaking, jewellery, turnery, sculpture, drawing, painting, and certain kinds of architecture. The Germans have been charged with intemperance in eating and drinking; and perhaps not unjustly, owing to the vast plenty of their country in wine and provisions of every kind. But those practices seem now to be wearing out. At the greatest tables, though the guests drink pretty freely during dinner, yet the repast is commonly finished by coffee, after three or four public toasts have been drank. But no people have more feasting at marriages, funerals, and birth-days.

The German nobility are generally men of so much honour, that a sharper in other countries, especially in England, meets with more credit if he pretends to be a German, than of any other nation.

The merchants and tradesmen are very civil and obliging. All the sons of noblemen inherit their father's titles, which greatly perplexes the heralds and genealogists of that country. This perhaps is one of the reasons why the German husbands are not quite so complaisant as they ought otherwise to be to their ladies, who are not entitled to any pre-eminence at the table; nor indeed do they seem to affect it, being far from either ambition or loquacity, though they are said to be somewhat too fond of gaming. From what has been premised, it may easily be conceived, that many of the German nobility, having no other hereditary estate than a high sounding title, easily enter into their armies, and those of other sovereigns. Their fondness for title is attended with many other inconveniencies. Their princes think that the cultivation of their lands, though it may treble their revenue, is below their attention; and that, as they are a species of beings superior to labourers of every kind, they would demean themselves in being concerned in the improvement of their grounds.

The domestic diversions of the Germans are the same as in England; billiards, cards, dice, fencing, dancing, and the like. In summer, people of fashion repair to places of public resort, and drink the waters. As to their field diversions, besides their favourite one of hunting, they have bull and bear baiting, and the like. The inhabitants of Vienna live luxuriously, a great part of their time being spent in feasting and carousing; and in winter, when the several branches of the Danube are frozen over, and the ground covered with snow, the ladies take their recreation in sledges of different shapes, such as griffins, tygers, swans, scallop-shells, &c. Here the lady sits, dressed in velvet, lined with rich furs, and adorned with laces and jewels, having on her head a velvet cap; and the sledge is drawn by one horse, stag, or other creature, set off with plumes of feathers, ribands, and bells. As this diversion is taken chiefly in the night-time, servants ride before the sledge with torches, and a gentleman sitting on the sledge behind guides the horse. 35 Amusements.

The Reformation first spread in Germany to most advantage; and since the religious peace of 1555, there have been established the Roman Catholic, prevailing mostly in the south; the Lutheran in the north; and the Calvinist, called also the *Reformed*, near the Rhine. Civil wars considerably deranged this settlement: it was, however, established by the celebrated peace of Westphalia, that the religion of the Seven States should remain as in 1624. The Romish superior clergy consist of 8 archbishops, 40 bishops, and many abbots. The Protestant clergy are governed by consistories under the sovereign of each state. The *Corpus Catholicorum* is under the direction of the archbishop, elector of Mentz; and the *Corpus Evangelicorum*, or Protestants, under the elector of Saxony; who have the care of the public concerns of their respective bodies. 36 Religion and learning.

Literature

Published by A. Constable & C^o. Edinburgh. 1819.

Engraved by S^t. Hall, Bury S^t. Bloomsb^y.

Literature is in a very advanced state throughout almost all Germany, but particularly in the Protestant states. It is but about half a century since the German language has been purified and cultivated; since which various works of taste and elegance, as well as superior productions in the different walks of science, have appeared in it. There are at present 19 universities in Germany, with about 850 professors; besides a number of literary societies and academic institutions: and education in general is particularly attended to even in the very lowest ranks.

A detailed account of the present statistical and political condition of Germany will be found in the article GERMANY, SUPPLEMENT.

GERMEN, the seed bud; defined by Linnæus to be the base of the pistillum, which contains the rudiments of the seed; and, in progress of vegetation, swells and becomes the seed vessel.

In assimilating the vegetable and animal kingdoms, Linnæus denominates the seed bud the *ovarium* or *uterus* of plants; and affirms its existence to be chiefly at the time of the dispersion of the male dust by the antheræ; as, after its impregnation, it becomes a seed vessel. See BOTANY.

GERMEN, by Pliny and the ancient botanists, is used to signify a bud containing the rudiments of the leaves. See GEMMA.

GERMINATION, among botanists, comprehends the precise time which the seeds take to rise after they have been committed to the soil.—The different species of seeds are longer or shorter in rising according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mustard, kidney beans, turnips, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; radish and beet, in six; barley, in seven; orach, in eight; purslain, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chesnut, peony, horned poppy, hypecoum, and ranunculus falcatus, in one year; rose bush, cornel tree, hawthorn, medlar, and hazel nut, in two. The seeds of some species of orchis, and of some liliaceous plants, never rise at all. Of seeds, some require to be sowed almost as soon as they are ripe, otherwise they will not sprout or germinate. Of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years. Mr Adanson asserts, that the sensitive plant retains that virtue for 30 or 40 years.

Air and water are the agents of germination. The humidity of the air alone makes several seeds to rise that are exposed to it. Seeds too are observed to rise in water, without the intervention of earth; but water without air is insufficient. Mr Homberg's experiments on this head are decisive. He put several seeds under the exhausted receiver of an air pump, with a view to establish something certain on the causes of germination. Some of them did not rise at all; and the greatest part of those which did, made very weak and feeble productions. Thus it is for want of air that seeds which are buried at a very great depth in the earth, either thrive but indifferently, or do not rise at all. They frequently preserve, however, their germinating virtue for many years within the bowels of the earth; and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants, which had not been seen there in the memory of man. Were this precaution frequently repeated, it would doubtless be the means of recovering certain species of plants which are regarded as lost; or which perhaps, never coming to the knowledge of botanists, might hence appear the result of a new creation.

GERONTES, in antiquity, a kind of judges, or magistrates, in ancient Sparta, answering to what the Areopagites were at Athens. See AREOPAGUS.

The word is formed of the Greek γερων, which signifies "old man." Whence also the words *gerontic*, something belonging to an old man; and *Geronicon*, a famous book among the modern Greeks, containing the lives of the ancient monks. The senate of gerontes was called *gerusia*, that is, assembly or council of old men.

The gerontes were originally instituted by Lycurgus: their number, according to some, was 28; and, according to others, 32. They governed in conjunction with the king, whose authority they were intended to balance, and to watch over the interests of the people. Polybius defines their office in few words, when he says, *per ipsos, et cum ipsis, omnia administrari.* None were to be admitted into this office under 60 years of age, and they held it for life. They were succeeded by the ephori.

GEROPOGON, a genus of plants belonging to the syngenesia class, and in the natural method ranking under the 49th order, *Compositæ*. See BOTANY *Index*.

GERRETZ. See REMBRANDT.

GERS, a department in the south-west of France Its surface is in general hilly but fertile, and abounds more in pasture soil than in arable land. In 1815 it contained 286,500 inhabitants, on an area of 2620 square miles. Auch is the chief town.

GERVAISE, or GERVASE, of Tilbury, a famous English writer of the 13th century; thus named from his being born at Tilbury on the Thames. He was nephew to Henry II. king of England; and was in great credit with Otho IV. emperor of Germany, to whom he dedicated a Description of the World, and a Chronicle. He also composed a History of England, that of the Holy Land, and other works.

GERUND, in *Grammar*, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*. The word is formed of the Latin *gerundivus*, and that from the verb *gerere*, "to bear."

The *gerund* expresses not only the *time*, but also the *manner* of an action; as, "he fell in running post."—It differs from the participle, in that it expresses the *time*, which

which the participle does not; and from the tense properly so called, in that it expresses the *manner*, which the tense does not. See GRAMMAR.

GERUNDA, in *Ancient Geography*, a town of the Ausetani, in the Hither Spain, on the south or right side of the river Sambroca. *Gerundenses*, the people. Now *Gironne* in Catalonia, on the Ter. E. Long. 2. 35. N. Lat. 42.

GESNER, CONRAD, a celebrated physician and naturalist, was born at Zurich in 1516. Having finished his studies in France, he travelled into Italy, and taught medicine and philosophy in his own country with extraordinary reputation. He was acquainted with the languages; and excelled so much in natural history, that he was surnamed the *Pliny of Germany*. He died in 1564, leaving many works behind him; the principal of which are, 1. A history of animals, plants, and fossils; 2. *Bibliotheca Universalis*. A Greek and Latin lexicon. This author is by Boerhaave emphatically styled *Monstrum Eruditionis*, "a prodigy of learning." Those indeed (as Mr Coxe observes in his Letters on Switzerland) "who are conversant with the works of this great scholar and naturalist, cannot repress their wonder and admiration at the amplitude of his knowledge in every species of erudition, and the variety of his discoveries in natural history, which was his peculiar delight. Their wonder and admiration is still further augmented, when they consider the gross ignorance of the age which he helped to enlighten, and the scanty succours he possessed to aid him in thus extending the bounds of knowledge; that he composed his works, and made those discoveries which would have done honour to the most enlightened period, under the complicated evils of poverty, sickness, and domestic uneasiness."

GESNER, *Solomon*, the celebrated author of the death of Abel and many other admired works in the German language, was born at Zurich in the year 1730. In his early years he showed very few signs of superior abilities; and his progress in the rudiments of education was so slow, that his master gave him up as incapable of any greater attainments than writing and the four first rules of arithmetic. Upon this he was placed under a clergyman in the neighbourhood, a relation of his father's, and who showed himself better acquainted with the art of discovering the natural inclinations of his pupils. This gentleman often carried young Gesner with him into the fields, where he made him observe the beauties of nature; and finding that he took greater pleasure in such lessons, and seemed to listen to them with peculiar attention, he occasionally repeated some of the most striking passages of the ancient authors, who have written on these subjects, in the most agreeable and pleasing manner. By this ingenious artifice, the mind of young Gesner began to open, and its powers to expand; and it is, perhaps, owing to this circumstance, that he became so fond of the language of Virgil and Theocritus. When he arrived at a proper age to think of pursuing some line of business, Mr Gesner made choice of that of a bookseller, which was the profession of his father, and in some measure of his family. Of five houses at Zurich in the printing and bookselling business, two were occupied by Gesners: one belonged to two brothers of that name; and the other, that in which our poet had a share, was known by the firm of *Orel, Gesner, and Company*. It was known also by the extent of its correspondence, and by the choice and elegance of the works which it gave to the public.

Though Mr Gesner was a bookseller, he did not, however, damp his genius, by submitting to the drudgery of business. He indulged himself freely in pursuing his favourite object, and his partners never envied him that time which he devoted to meditation and to study. In 1752, he made a tour through Germany, not so much for the purpose of extending his commerce, as to see and be acquainted with those authors who have done honour to their country. The following circumstance, which occurred during this tour, deserves to be mentioned, as it is strikingly characteristic of that timidity which often accompanies true genius. When Mr Gesner was at Berlin, he was admitted into a literary society, of which Gleim and Lessing were members. Each of the authors who composed it used to read in turn some pieces of their own composition, and Mr Genser was very desirous of submitting to these able critics a small work, which was his first attempt; but was far from resembling those poets, whom Horace and other satirists have ridiculed, and who stun every one they meet by reciting their verses before them. As each of the members had done reading, Gesner was observed to move his hand with a kind of tremor towards his pocket, and to draw it back again without the manuscript which he ought to have produced. Having not as yet published any thing, none of the company could guess the cause of a motion which his modesty prevented him from explaining. The work which he had not the courage to show, was his small poem, entitled *Night*, which he published on his return to Zurich in 1753. It was considered as an original, of which no model is to be found among the moderns; but in the opinion of the author, it was only a piece of imaginary painting, or, to use an expression of his own, in one of his letters to Mr Huber who has translated his works, "A caricature composed in the moments of folly or intoxication." In this little poem he has introduced a short episode on the origin of the glow-worm, containing a poetical explanation of this natural phosphorus, which has all the beauty of Ovid's Metamorphoses without their prolixity. The success of this essay emboldened the too timid muse of our young bookseller, and he published a pastoral romance, called *Daphnis*, in three cantos. The applause that was deservedly bestowed upon this performance induced the author to publish, some time after, his Idylls and some other rural poems in imitation of those of Theocritus. Pastoral poetry, which at this time was little known in Germany but by translations from foreign poets, began to find many partizans, and to be preferred to every other kind. Desirous, therefore, of tracing out a new path for himself, our poet thought that he could not do a more acceptable service to his countrymen, than to paint the felicity of innocence and rural life, and the tender emotions of love and gratitude. The only author worthy of notice who had preceded Mr Gesner in this career, was Mr Rost of Leipsic, whose pastoral poems appeared for the first time in 1744. This writer polished the language of the German shepherds; he had address enough to unite spirit and simplicity in a kind

of

Gesner.

of writing which appears insipid without the former, and which becomes unnatural and disgusting if it is too abundant. He sometimes throws a delicate veil over those images which are deficient in decency, but it is to be regretted that it is often too light. Such was the antagonist against whom Gesner had to contend. Our poet, however, pursued a different course. Instead of placing, like Rost, his scenes in modern times, he goes back with Theocritus to the golden age, that happy age which we are fond of reviewing when our passions are calm, and when freed from those anxious cares which hurry us beyond ourselves, we contemplate amidst tranquillity the beauties and fertility of the country. The characters of Gesner's Idylls, therefore, are taken from those societies which exist no longer but in the remembrance, or rather the imagination. His shepherds are fathers, children, and husbands, who blush not at these titles so dear to nature, and to whom generosity, beneficence, and respect for the Deity are sentiments no less familiar than love. These Idylls were the principal and favourite object of his pursuit, and that part of his works which acquired him the greatest reputation, especially among his countrymen. His death of Abel, which is well known, was published for the first time in 1758. It is written, like the rest of his pieces, in poetical prose; and was so much sought after, that it went through no less than three editions in the space of a year, without speaking of the spurious ones which appeared in Holland, at Berlin, and in France. The French edition was followed by several others. One came out in Italian; another in the Dutch language; a fourth in the Danish: and lastly, two in English, one of them in prose and the other in verse. Among the pieces which Mr Gesner published after the death of Abel was his First Navigator, a poem in three cantos, which many people in Germany consider as his masterpiece. He made an attempt also in the pastoral drama, but not with the same success as in other kinds of rural poetry. He produced likewise, in the same style, Evander and Alcimne, in three acts; and Erastus, a small piece of one act, which was represented with some applause in several societies, both at Leipsic and Vienna.

But though poetry was Gesner's darling pursuit, and though he enriched the literature of his country with works which will render his name immortal, he did not confine himself to one manner of imitating nature; he in turns took up the pencil and the pen, and his active genius equally directed them both. In his infancy he had received a few lessons in drawing, and he had afterwards pursued his study, but without any intention of becoming an artist. At the age of thirty he felt that violent desire, which may be considered as the voice of genius; and this was in some measure excited by the sight of a beautiful collection formed by Mr Heidegger, whose daughter he had married. To please his father-in-law, he studied this treasure, composed principally of the best pieces of the Flemish school; and to this new taste he had almost sacrificed every other. Mr Gesner at first ventured only to delineate some decorations for the frontispieces of curious books printed in his office; but by little and little he had the courage to make other attempts. In 1765, he published 10 landscapes etched and engraved by himself, and dedicated them to his friend Mr Watlet. Mr Gesner owed him this mark of respect for the care which he took to ornament with beautiful vignettes Mr Huber's translation of his Idylls. Twelve other pieces appeared in 1769; and after these attempts, Mr Gesner executed ornaments for many works which came from his presses, among which were his own works, a German translation of Swift, and several others.

Were we to judge from Mr Gesner's enthusiasm for his favourite pursuits, and from the time and attention which he bestowed upon them, we should be apt to conclude, that he found little leisure for discharging his duty as a citizen. The contrary, however, was the case, for he passed almost the half of his life in the first employments of the state. In 1765 he was called to the grand council, in 1767 to the lesser. In 1768 he was appointed bailiff of Elibach, that of the four guards in 1776, and in 1781 superintendant of waters, which office in 1787 was continued to him for six years. In all these stations Mr Gesner discharged his duty with the most scrupulous fidelity; and died of a paralytical disorder, lamented by his countrymen and by those who had the pleasure of his acquaintance, on the 2d of March 1788, at the age of 56.

As a pastoral poet, Gesner undoubtedly is entitled to a very distinguished rank: and we may justly say, that if he has been equalled by any, he has been excelled by none. It is commonly believed, that pastoral poetry is very limited and confined; but those who read the works of Gesner will be convinced, that it is susceptible of much variety when treated of by the hand of a master. His pastoral romance of Daphnis is not inferior in natural simplicity to the celebrated work of Longus; but it surpasses it far in variety of images and incident. Erastus and Evander are instructive and interesting poems, on account of the contrast between the world and nature which reigns throughout them; and his First Navigator unites the mildest philosophy to all the splendour and imagery of Fairy Land. If we analyze his dramatic poems, we shall find in them interesting fictions, characters well delineated, and situations replete with novelty. His language is that of the Graces, and the chastest ears might listen to the love which he has created. If he has sometimes the humour of Sterne and Fontaine, it is without their licentiousness. The severest taste can find in his writings, no lacuna to supply, no phrase deserving reprehension, nor could a more ingenious choice of expressions be substituted in the room of those which he has adopted.—Gesner's character as a man, appears to be no less amiable. In whatever point of view we consider him, whether as a husband, a father, a friend, a magistrate, or a citizen, his virtues are equally conspicuous. He was naturally of a melancholy turn, but he was no enemy to rational and well-timed mirth; while the mildness and affability of his temper rendered his company always engaging, and endeared him to those who had the pleasure of his acquaintance. Possessed of that nobleness of sentiment, united with great modesty, which is the usual attendant of true genius, he was simple in his external appearance, as well as in his conversation. His language was lively and animated; but his reserve before strangers resembled timidity, and

and it was only in the presence of those with whom he was acquainted, that his real character appeared in its full lustre.

Mr Gesner's reputation and virtues were known even to the remotest parts of Europe. The empress of Russia Catharine II. presented him with a gold medal as a mark of her esteem. Strangers of all nations gave him no less flattering testimonies of their admiration; and travellers thought they had seen only the half of Switzerland, if they had not been in the company of Gesner, or procured some of his landscapes or drawings. In this last way he had acquired so much reputation, that he was ranked among the best artists of Germany; and Mr Fuseli, his countryman, who was himself a painter, in the preface to the third volume of the new edition which he published of his 'Historical essay on the painters, engravers, architects, and sculptors, who have done honour to Switzerland,' gives a distinguished place to Mr Gesner, though then living.

GESNERIA, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 40th order, *Personatæ*. See BOTANY *Index*.

GESSORIACUM, in *Ancient Geography*, a port and station for ships of the Morini in Belgica. In Cæsar's time, according to Dio, there was no town; but Florus speaks of it as one: and the Gessoriacenses Muri are mentioned by Eumenius in his panegyric. The author of Tabula Theodosiana, commonly called *Peutinger's map*, says expressly, that Gessoriacum was in his time called *Bononia*. Now *Boulogne* in Picardy. E. Long. 1. 30. N. Lat. 50. 40.

GESTATION, among physicians. See PREGNANCY.

GESTRICIA, a province of Sweden, bounded by Helsingia on the north, by the Bothnic gulf on the east, by Upland on the south, and by Dalecarlia on the west.

GESTURE, a motion of the body, intended to signify some idea or passion of the mind. It consists principally in the action of the hands and face; and may be defined, a suitable conformity of the motions of the countenance, and of several parts of the body, in speaking, to the subject matter of the discourse. See DECLAMATION and ORATORY.

GETA, SEPTIMUS, a son of the emperor Severus, brother to Caracalla. In the eighth year of his age, he was moved with compassion at the fate of some of the partizans of Niger and Albinus who were to be executed, and his father struck with his humanity retracted the sentence. After Severus's death he reigned at Rome conjointly with his brother; but Caracalla, who envied his virtues and was jealous of his popularity, ordered him to be poisoned; and when this could not be effected, he murdered him in the arms of his mother Julia, who in the attempt of defending the fatal blows from his body received a wound in her arm, from the hand of her son, A. D. 212. Geta had not yet reached the 23d year of his age, and the Romans had reason to lament the death of so virtuous a prince, while they groaned under the cruelties and oppression of Caracalla.

GETHIN, LADY GRACE, an English lady of uncommon parts, was the daughter of Sir George Norton of Abbots Leigh in Somersetshire, and born in the year 1676. She had all the advantages of a liberal education; and became the wife of Sir Richard Gethin, of Gethin Grott in Ireland. She was mistress of great accomplishments, natural and acquired, but did not live long enough to display them to the world; for she died in the 21st year of her age. She was buried in Westminster abbey, where a beautiful monument with an inscription is erected over her; and, for perpetuating her memory, provision was made for a sermon to be preached in Westminster abbey yearly, on Ash Wednesday for ever. She wrote, and left behind her, in loose papers, a work, which, soon after her death, was methodized, and published under the title of "*Reliquiæ Gethinionæ*; or, Some remains of the most ingenious and excellent lady, Grace, lady Gethin, lately deceased. Being a collection of choice discourses, pleasant apophthegms, and witty sentences. Written by her, for the most part, by way of essay, and at spare hours." Lond. 1700, 4to; with her picture before it.

GETHSEMANE, in *Ancient Geography*, a village in the mount of Olives, whither Jesus Christ sometimes retreated in the night time. It was in a garden belonging to this village that he suffered the agony in which he sweated drops of blood; and here he was arrested by Judas and the rest who were conducted by this traitor. The place is by Maundrel described as an even plot of ground, not above 57 yards square, lying between the foot of Mount Olivet and the brook Cedron.

GETHYLLIS, a genus of plants belonging to the dodecandria class, and in the natural method ranking under the ninth order *Spathaceæ*. See BOTANY *Index*.

GEUM, AVENS, or *Herb Bennet*, a genus of plants belonging to the icosandria class, and in the natural method ranking under the 35th order, *Senticosæ*. See BOTANY *Index*.

GHENT, a city of the Austrian Netherlands, capital of the province of Flanders. It is seated on four navigable rivers, the Scheldt, the Lys, the Lieve, and the Moere, which run through it, and divide it into canals. These form 26 little isles, over which there are 300 bridges: among which there is one remarkable for a statue of brass of a young man, who was obliged to cut off his father's head; but as he was going to strike, the blade flew into the air, and the hilt remained in his hand, upon which they were both pardoned. There is a picture of the whole transaction in the townhouse. Ghent is surrounded with walls and other fortifications, and is tolerably strong for a place of its circumference. But all the ground within the walls is not built upon. The streets are large and well paved, the market places spacious, and the houses built with brick. But the Friday's market place is the largest, and is remarkable for the statue of Charles V. which stands upon a pedestal in the imperial habit. That of Cortere is remarkable for a fine walk under several rows of trees. In 1737 a fine opera house was built here, and a guard house for the garrison. Near the town is a very high tower, with a handsome clock and chimes. The great bell weighs 11,000 pounds.

This town is famous for the pacification signed here, in 1526, for settling the tranquillity of the Seventeen Provinces, which was afterwards confirmed by the king of Spain. It was taken by Louis XIV. in 1678, who

who afterwards restored it. The French took possession of it again after the death of Charles II. of Spain. In 1706, it was taken by the duke of Marlborough; and by the French in 1708; but it was retaken the same year. Last of all, the French took it by surprise after the battle of Fontenoy; but at the peace of Aix-la-Chapelle, it was rendered back. It was also taken by the French in 1794; and was restored to the Netherlands in 1814. This is the birth-place of John of Gaunt. It is very well seated for trade, on account of its rivers and canals. It has linen, woollen, and silk manufactures. The number of inhabitants is abont 61,000. E. Long. 3. 50. N. Lat. 51. 14.

GHOST, an apparition, or spirit of a person deceased.

The ancients supposed every man to be possessed of three different ghosts, which after the dissolution of the human body were differently disposed of. These three ghosts were distinguished by the names of *Manes*, *Spiritus*, *Umbra*. The *manes*, they fancied, went down into the infernal region; the *spiritus* ascended to the skies; and the *umbra* hovered about the tomb, as being unwilling to quit its old connexions. Thus Dido (Virg. Æn. iv. 384.) threatens Æneas after death that she will haunt him with her umbra, whilst her manes rejoices in his torments below. This idea of a threefold soul is very clearly expressed in these lines, which have been attributed to Ovid.

Bis duo sunt homini: MANES, CARO, SPIRITUS, UMBRA:
Quatuor ista loci bis duo suscipiunt.
Terra tegit CARNEM, *tumulum circumvolat* UMBRA,
Orcus habet MANES, SPIRITUS *astra petit.*

The most striking outlines of the popular superstitions respecting ghosts among us, are thus humorously collected by Captain Grose in his Provincial Glossary: "A ghost is supposed to be the spirit of a person deceased, who is either commissioned to return for some special errand, such as the discovery of a murder, to procure restitution of lands or money unjustly withheld from an orphan or widow—or, having committed some injustice whilst living, cannot rest till that is redressed. Sometimes the occasion of spirits revisiting this world, is to inform their heir in what secret place, or private drawer in an old trunk, they had hidden the title deeds of the estate; or where, in troublesome times, they buried their money or plate. Some ghosts of murdered persons, whose bodies have been secretly buried, cannot be at ease till their bones have been taken up, and deposited in consecrated ground with all the rites of Christian burial.

"Sometimes ghosts appear in consequence of an agreement made, whilst living, with some particular friend, that he who first died should appear to the survivor.

"Glanvil tells us of the ghost of a person who had lived but a disorderly kind of life, for which it was condemned to wander up and down the earth, in the company of evil spirits, till the day of judgment.

"In most of the relations of ghosts, they are supposed to be mere aerial beings, without substance, and that they can pass through walls and other solid bodies at pleasure. A particular instance of this is given, in relation the 27th, in Glanvil's collection, where one David Hunter, neat-herd to the bishop of Down and Connor was for a long time haunted by the apparition of an old woman, whom he was by a secret impulse obliged to follow whenever she appeared, which he says he did for a considerable time, even if in bed with his wife: and because his wife could not hold him in his bed, she would go too, and walk after him till day, though she saw nothing; but his little dog was so well acquainted with the apparition, that he would follow it as well as his master. If a tree stood in her walk, he observed her always to go through it. Notwithstanding this seeming immateriality, this very ghost was not without some substance; for, having performed her errand, she desired Hunter to lift her from the ground; in the doing of which, he says, she felt just like a bag of feathers. We sometimes also read of ghosts striking violent blows; and that, if not made way for, they overturn all impediments, like a furious whirlwind. Glanvil mentions an instance of this, in relation 17th, of a Dutch lieutenant who had the faculty of seeing ghosts; and who being prevented making way for one which he mentioned to some friends as coming towards them, was, with his companions, violently thrown down, and sorely bruised. We further learn, by relation 16th, that the hand of a ghost is 'as cold as a clod.'

"The usual time at which ghosts make their appearance is midnight, and seldom before it is dark: though some audacious spirits have been said to appear even by day light: but of this there are few instances, and those mostly ghosts who have been laid, perhaps in the Red sea (of which more hereafter), and whose times of confinement were expired: these, like felons confined to the lighters, are said to return more troublesome and daring than before. No ghosts can appear on Christmas eve; this Shakespeare has put into the mouth of one of his characters in Hamlet.

"Ghosts commonly appear in the same dress they usually wore whilst living, though they are sometimes clothed all in white; but that is chiefly the churchyard ghosts, who have no particular business, but seem to appear *pro bono publico*, or to scare drunken rustics from tumbling over their graves.

"I cannot learn that ghosts carry tapers in their hands, as they are sometimes depicted, though the room in which they appear, if without fire or candle, is frequently said to be as light as day. Dragging chains is not the fashion of English ghosts; chains and black vestments being chiefly the accoutrements of foreign spectres seen in arbitrary governments: dead or alive, English spirits are free. One instance, however, of an English ghost dressed in black is found in the celebrated ballad of William and Margaret, in the following lines:

And clay cold was her lily hand
That held her *sable shroud.*

This, however, may be considered as a poetical license, used, in all likelihood, for the sake of the opposition of *lily* to *sable*.

"If, during the time of an apparition, there is a lighted candle in the room, it will burn extremely blue: this is so universally acknowledged that many eminent philosophers have busied themselves in accounting for it, without once doubting the truth of the fact. Dogs, too, have the faculty of seeing spirits, as is instanced in

Ghost.

David Hunter's relation above quoted; but in that case they usually show signs of terror, by whining and creeping to their master for protection; and it is generally supposed that they often see things of this nature when their owner cannot; there being some persons, particularly those born on a Christmas eve, who cannot see spirits.

"The coming of a spirit is announced some time before its appearance, by a variety of loud and dreadful noises; sometimes rattling in the old hall like a coach and six, and rumbling up and down the staircase like the trundling of bowls or cannon balls. At length the door flies open, and the spectre stalks slowly up to the bed's foot, and opening the curtains, looks steadfastly at the person in bed by whom it is seen; a ghost being very rarely visible to more than one person, although there are several in company. It is here necessary to observe, that it has been universally found by experience, as well as affirmed by diverse apparitions themselves, that a ghost has not the power to speak till it has been first spoken to; so that, notwithstanding the urgency of the business on which it may come, every thing must stand still till the person visited can find sufficient courage to speak to it: an event that sometimes does not take place for many years. It has not been found that female ghosts are more loquacious than those of the male sex, both being equally restrained by this law.

"The mode of addressing a ghost is by commanding it, in the name of the Three Persons of the Trinity, to tell you who it is, and what is its business; this it may be necessary to repeat three times; after which it will, in a low and hollow voice, declare its satisfaction at being spoken to, and desire the party addressing it not to be afraid, for it will do him no harm. This being premised, it commonly enters into its narrative; which being completed, and its request or commands given, with injunctions that they be immediately executed, it vanishes away, frequently in a flash of light; in which case, some ghosts have been so considerate as to desire the party to whom they appeared to shut their eyes: sometimes its departure is attended with delightful music. During the narration of its business, a ghost must by no means be interrupted by questions of any kind; so doing is extremely dangerous: if any doubts arise, they must be stated after the spirit has done its tale. Questions respecting its state, or the state of any of their former acquaintance, are offensive, and not often answered; spirits perhaps being restrained from divulging the secrets of their prison house. Occasionally spirits will even condescend to talk on common occurrences, as is instanced by Glanvil in the apparition of Major George Sydenham to Captain William Dyke, relation 10th, wherein the major reproved the captain for suffering a sword he had given him to grow rusty: saying, 'Captain, captain, this sword did not use to be kept after this manner when it was mine.' This attention to the state of arms, was a remnant of the major's professional duty when living.

"It is somewhat remarkable that ghosts do not go about their business like the persons of this world. In cases of murder, a ghost, instead of going to the next justice of the peace, and laying its information, or to the nearest relation of the person murdered, appears to some poor labourer who knows none of the parties, draws the curtains of some decrepit nurse or alms woman, or hovers about the place where his body is deposited. The same circuitous mode is pursued with respect to redressing injured orphans or widows; when it seems as if the shortest and most certain way would be, to go to the person guilty of the injustice, and haunt him continually till he be terrified into a restitution. Nor is the pointing out lost writings generally managed in a more summary way; the ghost commonly applying to a third person ignorant of the whole affair, and a stranger to all concerned. But it is presumptuous to scrutinize too far into these matters: ghosts have undoubtedly forms and customs peculiar to themselves.

"If after the first appearance, the persons employed neglect, or are prevented from, performing the message or business committed to their management, the ghost appears continually to them, at first with a discontented, next an angry, and at length with a furious, countenance, threatening to tear them in pieces if the matter is not forthwith executed; sometimes terrifying them, as in Glanvil's relation 26th, by appearing in many formidable shapes, and sometimes even striking them a violent blow. Of blows given by ghosts there are many instances, and some wherein they have been followed with an incurable lameness.

"It should have been observed, that ghosts, in delivering their commissions, in order to ensure belief, communicate to the persons employed some secret, known only to the parties concerned and themselves, the relation of which always produces the effect intended. The business being completed, ghosts appear with a cheerful countenance, saying they shall now be at rest, and will never more disturb any one; and, thanking their agents, by way of reward communicate to them something relative to themselves, which they will never reveal.

"Sometimes ghosts appear, and disturb a house, without deigning to give any reason for so doing: with these, the shortest and only way is to exorcise, and eject them; or, as the vulgar term is, lay them. For this purpose there must be two or three clergymen, and the ceremony must be performed in Latin; a language that strikes the most audacious ghost with terror. A ghost may be laid for any term less than 100 years, and in any place or body, full or empty; as, a solid oak—the pommel of a sword—a barrel of beer, if a yeoman or simple gentleman—or a pipe of wine, if an esquire or a justice. But of all places the most common, and what a ghost least likes, is the Red sea; it being related, in many instances, that ghosts have most earnestly besought the exorcists not to confine them in that place. It is nevertheless considered as an indisputable fact, that there are an infinite number laid there, perhaps from its being a safer prison than any other nearer at hand; though neither history nor tradition gives us any instance of ghosts escaping or returning from this kind of transportation before their time.

"Another species of human apparition may be here noticed, though it does not come under the strict description of a ghost. These are the exact figures and resemblances of persons then living, often seen not only by their friends at a distance, but many times by themselves;

selves; of which there are several instances in Aubery's Miscellanies; one of Sir Richard Napier, a physician of London, who being on the road from Bedfordsire to visit a friend in Berkshire, saw at an inn his own apparation lying on his bed as a dead corpse; he nevertheless went forward, and died in a short time: another of Lady Diana Rich, daughter of the earl of Holland, who met her own apparition walking in a garden at Kensington, and died a month after of the smallpox. These apparitions are called *fetches;* in Cumberland, *swarths;* and in Scotland, *wraiths;* they most commonly appear to distant friends and relations, at the very instant preceding the death of the person whose figure they put on. Sometimes, as in the instances above mentioned, there is a greater interval between the appearance and death." For a philosophical inquiry into the subject of apparitions in general, see the article SPECTRE.

GIAGH, in *Chronology*, a cycle of 12 years; in use among the Turks and Cathayans.

Each year of a giagh bears the name of some animal: the first that of a mouse; the second that of a bullock; the third of a lynx or leopard; the fourth of a hare; the fifth of a crocodile; the sixth of a serpent; the seventh of a horse; the eighth of a sheep; the ninth of a monkey; the tenth of a hen; the eleventh of a dog; and the twelfth of a hog.

They also divide the day into 12 parts, which they call *giaghs*, and distinguish them by the name of some animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIALLOLINO, in *Natural History*, a fine yellow pigment, much used under the name of NAPLES YELLOW.

GIANT, a person of extraordinary bulk and stature.

The romances of all ages have furnished us with so many extravagant accounts of giants of incredible bulk and strength, that the existence of such people is now generally disbelieved. It is commonly thought, that the stature of men hath been the same in all ages; and some have even pretended to *demonstrate* the impossibility of the existence of giants mathematically. Of these our countryman M'Laurin hath been the most explicit. "In general (says he) it will easily appear, that the efforts tending to destroy the cohesion of beams arising from their own gravity only, increase in the quadruplicate ratio of their lengths: but that the opposite efforts tending to preserve their cohesion, increase only in the triplicate proportion of the same lengths. From which it follows, that the greater beams must be in greater danger of breaking than the lesser similar ones; and that though a lesser beam may be firm and secure, yet a greater similar one may be made so long, that it will necessarily break by its own weight. Hence Galileo justly concludes, that what appears very firm, and succeeds very well in models, may be very weak and infirm, or even fall to pieces by its own weight, when it comes to be executed in large dimensions according to the model. From the same principle he argues, that there are necessary limits in the operations of nature and art, which they cannot surpass in magnitude. Were trees of a very enormous size, their branches would fall by their own weight. Large animals have not strength in proportion to their size; and if there were any land animals much larger than those we know, they could hardly move, and would be perpetually subject to the most dangerous accidents. As to the animals of the sea, indeed the case is different; for the gravity of the water in a great manner sustains those animals; and in fact these are known sometimes to be vastly larger than the greatest land animals. Nor does it avail against this doctrine to tell us, that bones have sometimes been found which were supposed to have belonged to giants of immense size; such as the skeletons mentioned by Strabo and Pliny, the former of which was 60 cubits high, and the latter 46: for naturalists have concluded on just grounds, that in some cases these bones had belonged to elephants; and that the larger ones were bones of whales, which had been brought to the places where they were found by the revolutions of nature that have happened in past times. Though it must be owned, that there appears no reason why there may not have been men who have exceeded by some feet in height the tallest we have seen."

It will easily be seen, that arguments of this kind can never be conclusive; because, along with an increase of stature in any animal, we must always suppose a proportional increase in the cohesion of the parts of its body. Large works sometimes fail when constructed on the plan of models, because the cohesion of the materials whereof the model is made, and of the large work, are the same; but a difference in this respect will produce a very remarkable difference in the ultimate result. Thus, suppose a model is made of firwood, the model may be strong and firm enough; but a large work made also of fir, when executed according to the plan of the model, may be so weak that it will fall to pieces by its own weight. If, however, we make use of iron for the large work instead of fir, the whole will be sufficiently strong, even though made exactly according to the plan of the model. The like may be said with regard to large and small animals. If we could find an animal whose bones exceeded in hardness and strength the bones of other animals as much as iron exceeds fir, such an animal might be of a monstrous size, and yet be exceedingly strong. In like manner, if we suppose the flesh and bones of a giant to be greatly superior in hardness and strength to the bones of other men, the great size of his body will be no objection at all to his strength. The whole of the matter therefore concerning the existence of giants must rest on the credibility of the accounts we have from those who pretend to have seen them, and not on any arguments drawn *à priori*.

In the Scripture we are told of *giants*, who were produced from the marriages of the *sons of God* with the *daughters of men* †. This passage indeed has been differently interpreted, so as to render it doubtful whether the word translated *giants* does there imply any extraordinary stature. In other parts of Scripture, however, giants, with their dimensions, are mentioned in such a manner that we cannot possibly doubt; as in the case of Og king of Bashan, and Goliath. In a memoir read before the Academy of Sciences at Rouen, M. Le Cat gives the following acconnt of giants that are said to have existed in different ages.

† See *Antediluvians.*

"Profane historians have given seven feet of height to

Giant.

to Hercules their first hero; and in our days we have seen men eight feet high. The giant who was shown in Rouen in 1735, measured eight feet some inches. The emperor Maximian was of that size; Shenkius and Platerus, physicians of the last century, saw several of that stature; and Goropius saw a girl who was ten feet high.—The body of Orestes, according to the Greeks, was eleven feet and a half; the giant Galbara, brought from Arabia to Rome under Claudius Cæsar, was near ten feet; and the bones of Secondilla and Pusio, keepers of the gardens of Sallust, were but six inches shorter. Funnam, a Scotsman, who lived in the time of Eugene II. king of Scotland, measured eleven feet and a half; and Jacob le Maire, in his voyage to the Straits of Magellan, reports, that on the 17th of December 1615, they found at Port Desire several graves covered with stones; and having the curiosity to remove the stones, they discovered human skeletons of ten and eleven feet long. The chevalier Scory, in his voyage to the peak of Teneriffe, says, that they found in one of the sepulchral caverns of that mountain the head of a Guanche which had 80 teeth, and that the body was not less than 15 feet long. The giant Ferragus, slain by Orlando nephew of Charlemagne, was 18 feet high. Rioland, a celebrated anatomist, who wrote in 1614, says, that some years before there was to be seen in the suburbs of St Germain the tomb of the giant Isoret, who was 20 feet high. In Rouen, in 1509, in digging in the ditches near the Dominicans, they found a stone tomb containing a skeleton whose skull held a bushel of corn, and whose shin bone reached up to the girdle of the tallest man there, being about four feet long, and consequently the body must have been 17 or 18 feet high. Upon the tomb was a plate of copper, whereon was engraved, "In this tomb lies the noble and puissant lord the chevalier Ricon de Vallemont, and his bones." Platerus, a famous physician, declares, that he saw at Lucerne the true human bones of a subject which must have been at least 19 feet high. Valence in Dauphiné boasts of possessing the bones of the giant Bucart, tyrant of the Vivarais, who was slain with an arrow by the count de Cabillon his vassal. The Dominicans had a part of the shin bone, with the articulation of the knee, and his figure painted in fresco, with an inscription, showing that this giant was 22 feet and a half high, and that his bones were found in 1705, near the banks of the Morderi, a little river at the foot of the mountain of Crussol, upon which (tradition says) the giant dwelt.

"January 11, 1613, some masons digging near the ruins of a castle in Dauphiné, in a field, which (by tradition) had long been called the *giant's field*, at the depth of 18 feet discovered a brick tomb 30 feet long, 12 feet wide, and 8 feet high; on which was a gray stone, with the words *Theutobochus Rex* cut thereon. When the tomb was opened, they found a human skeleton entire, 25 feet and a half long, 10 feet wide across the shoulders, and five feet deep from the breast bone to the back. His teeth were about the size each of an ox's foot, and his shin bone measured four feet.—Near Mazarino, in Sicily, in 1516, was found a giant 30 feet high; his head was the size of an hogshead, and each of his teeth weighed five ounces. Near Palermo, in the valley of Mazara, in Sicily, a skeleton of a giant 30 feet long was found, in the year 1548; and another of 33 feet high, in 1550; and many curious persons have preserved several of these gigantic bones.

"The Athenians found near their city two famous skeletons, one of 34 and the other of 36 feet high.

"At Totu, in Bohemia, in 758, was found a skeleton, the head of which could scarce be encompassed by the arms of two men together, and whose legs, which they still keep in the castle of that city, were 26 feet long. The skull of the giant found in Macedonia, September 1691, held 210 pounds of corn.

"The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt these facts; but thinks the bones were those of elephants, whales, or other enormous animals.

"Elephants bones may be shown for those of giants; but they can never impose on connoisseurs. Whales, which, by their immense bulk, are more proper to be substituted for the largest giants, have neither arms nor legs; and the head of that animal hath not the least resemblance to that of a man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been seen by anatomists, and by them have been reputed real human bones, the existence of giants is proved."

With regard to the credibility of all or any of these accounts, it is difficult to determine any thing. If, in any castle of Bohemia, the bones of a man's leg 26 feet in length are preserved, we have indeed a decisive proof of the existence of a giant in comparison of whom most others would be but pigmies. Nor indeed could these bones be supposed to belong to an elephant: for an elephant itself would but be a dwarf in comparison of such an enormous monster. But if these bones were really kept in any part of Bohemia, it seems strange that they have not been frequently visited, and particular descriptions of them given by the learned who have travelled into that country. It is certain, however, that there have been nations of men considerably exceeding the common stature. Thus, all the Roman historians inform us, that the Gauls and Germans exceeded the Italians in size; and it appears that the Italians in those days were of much the same stature with the people of the present age. Among these northern nations, it is also probable, that there would be as great differences in stature as there are among the present race of men. If that can be allowed, we may easily believe that some of the barbarians might be called *giants*, without any great impropriety. Of this superiority of size, indeed, the historian Florus gives a notable instance in Teutobochus, above mentioned, king of the Teutones: who being defeated and taken prisoner by Marius, was carried in triumph before him at Rome, when his head reached above the trophies that were carried in the same procession.

But whether these accounts are credited or not, we are very certain, that the stature of the human body is by no means absolutely fixed. We ourselves are a kind of giants in comparison of the Laplanders; nor are these the most diminutive people to be found upon the earth. The Abbé la Chappe, in his journey into Siberia in order to observe the last transit of Venus, passed through a village inhabited by people called *Wotiacks*,

Wotiacks, neither men nor women of whom were above four feet high. The accounts of the Patagonians also, which cannot be entirely discredited, render it very probable, that somewhere in South America there is a race of people very considerably exceeding the common size of mankind, and consequently that we cannot altogether discredit the relations of giants handed down to us by ancient authors; though what degree of credit we ought to give them is not easy to be determined. See PATAGONIA.

REBEL Giants, in ancient mythology, were the sons of Cœlus and Terra. According to Hesiod, they sprang from the blood of the wound which Cœlus received from his son Saturn, and Hyginus calls them sons of Tartarus and Terra. They are represented as men of uncommon stature, with strength proportioned to their gigantic size. Some of them, as Cottus, Briareus, and Gyges, had each 50 heads and 100 arms, and serpents instead of legs. They were of a terrible aspect, their hair hung loose about their shoulders, and their beard was suffered to grow unmolested. Pallene and its neighbourhood was the place of their residence. The defeat of the Titans, to whom they were nearly related, incensed them against Jupiter, and they all conspired to dethrone him. Accordingly they reared Mount Ossa upon Pelion, and Olympus upon Ossa; and from thence attacked the gods with huge rocks, some of which fell into the sea and became islands, and others fell on the earth and formed mountains. Jupiter summoned a council of the gods; when being informed that it was necessary to obtain the assistance of some mortal, he by the advice of Pallas called up his son Hercules; and with the aid of this hero he exterminated the giants Enceladus, Polybotes, Alcyon, Porphyrion, the two sons of Alœus, Ephialtes, Othus, Eurytus, Clytius, Tithyus, Pallas, Hippolitus, Agrius, Thoon, and Typhon; the last of whom it was more difficult to vanquish than all the others. Jupiter having thus gained a complete victory, cast the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the accounts of some of the poets, he buried them alive under Mount Ætna and different islands.

GIANTS Causeway, a vast collection of basaltic pillars in the county of Antrim, on the north coast of Ireland. See BASALTES.

The principal or grand causeway consists of a most regular arrangement of many hundred thousands of columns of a black kind of rock, very hard: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarce any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, may be about 20 feet; they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand, was never yet discovered. This grand arrangement extends nearly 200 yards, visible at low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway, which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width: which has been the cause of such wild and dissimilar representations of this causeway, which different accounts have exhibited. The highest part of this causeway is the narrowest, at the very foot of the impending cliff from whence the whole projects, where, for four or five yards, it is not above ten or fifteen feet wide. The columns of this narrow part incline from a perpendicular a little to the westward, and form a slope on their tops, by the very unequal height of the columns on the two sides, by which an ascent is made at the foot of the cliff, from the head of one column to the next above, *gradatim*, to the top of the great causeway, which, at the distance of half a dozen yards from the cliff, obtains a perpendicular position, and lowering in its general height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade, that may be easily walked on, rather inclining to the water's edge. But from high water mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff, it turns a little to the east for 20 or 30 yards, and then sinks into the sea. The figure of these columns is almost unexceptionably pentagonal, or composed of five sides; there are but very few of any other figure introduced: some few there are of three, four, and six sides, but the generality of them are five-sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are alike. Nor is the composition of these columns or pillars less deserving the attention of the curious spectator. They are not of one solid stone in an upright position; but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like ball and socket, or like the joints in the vertebræ of some of the larger kind of fish, the one end at the joint having a cavity, into which the convex end of the opposite is exactly fitted. This is not visible, but by disjoining the two stones. The depth of the concavity or convexity is generally about three or four inches. And what is still farther remarkable of the joint, the convexity, and the correspondent concavity, is not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the column will admit; and consequently as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagon, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still

still farther very remarkable, likewise, that the articulations of those joints are frequently inverted; in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length also of these particular stones, from joint to joint, is various: in general, they are from 18 to 24 inches long; and, for the most part, longer toward the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter likewise of the columns is as different as their length and figure; in general, they are from 15 to 20 inches in diameter. There are really no traces of uniformity or design discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns above water, there are others just by, of equal height, that are more or less convex or concave, which show them to have been joined to pieces that have been washed, or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made as even as might be; and the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon it and continually removing some of the upper stones and exposing fresh joints. And farther, as these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may with reason be inferred of the interior columns whose tops only are visible. Yet what is very extraordinary, and equally curious, in this phenomenon, is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either on the sides or angles.

The cliffs at a great distance from the causeway, especially in the bay to the eastward, exhibit at many places the same kind of columns, figured and jointed in all respects like those of the grand causeway: some of them are seen near to the top of the cliff, which in general, in these bays to the east and west of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, near a hundred roods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting, in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 130 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and, being longest in the middle of the arrangement, shortening on either hand in view, they have obtained the appellation of *organs*, from a rude likeness in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns that now appears is really the original exterior line, to the seaward, of this collection. But how far they extend internally into the bowels of the incumbent cliff, is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for besides the many pieces that are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly show them to be in an oblique position, and about half way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from their original upright, to their present inclining or oblique position, by the sinking or falling of the cliff.

GIBBET, or GIBET, a machine in manner of a gallow, whereon notorious criminals, after execution, are hung in irons or chains, as spectacles *in terrorem*. See GALLOWS.—The word in French, *gibet*, properly denotes what we call gallows: it is supposed to come originally from the Arabic *gibel*, "mount or elevation of ground;" by reason *gibets* are usually placed on hills or eminences.

GIBBON, EDWARD, a historian of distinguished eminence, was born at Putney in the year 1737. He was the son of a gentleman of fortune and family distinction, who sat as a member in two separate parliaments. Edward when a boy, was of such an extremely delicate constitution that his life was frequently despaired of. When at the school of Westminster, his progress was often retarded by repeated shocks of bad health. After being for a long time under the management of the best medical practitioners, his constitution was radically changed for the better, which induced his father to place him in Magdalen college as a gentleman commoner, that he might be pushed into manly acquisitions. This was prior to the completing of his fifteenth year. Before this time his reading had been of such a nature as to store his mind with much valuable historical knowledge, although his grammatical and philosophical knowledge at this time was not so extensive as that of some others at the same period of life. He says of himself; I arrived at Oxford with a stock of erudition that might have puzzled a doctor, and a degree of ignorance of which a school-boy would have been ashamed. Under such circumstances he was but ill prepared to receive the benefits of an university education, and this was no doubt the reason why he exclaimed so bitterly against the public and private instructions at Oxford.

He was fond of polemical divinity from his infancy, and during his leisure moments he turned his attention, when farther advanced, to the celebrated controversy between Papists and Protestants; and as he had not then acquired talents sufficient to enable him to combat error

Gibbon.

error and defend the truth, he fell a victim to the sophistry of the church of Rome. His father, with a view to reclaim him from the love of what he considered as the most destructive of all errors, sent him to Lausanne in Switzerland, and put him under the care of Mr Pavilliard, a clergyman of the Calvinistic persuasion. This gentleman called his pupil Edward, "A little thin figure, with a large head, disputing, and urging with the greatest ability, all the best arguments that had ever been used in favour of Popery." The masterly exertions of Mr Pavilliard, who had to deal with a young man of solid reason and matured reflection, accomplished the recantation of Mr Gibbon, and he received the sacrament in the Protestant church on the 25th of December 1754. At Lausanne, too, he made great progress in many branches of knowledge which he had hitherto neglected, and acquired a regular habit of study. He became master of the French and Latin languages, and was a profound logician. He gave full scope to the exercise of reading excellent authors, which was his ruling passion. He did not appear fond of mathematics, and therefore soon relinquished the study of them. At Lausanne he fell in love with a young lady, the daughter of a village clergyman; but he was frustrated in his hopes, and the lady became afterwards the wife of the celebrated Necker.

On his return home in April 1758, his father received him with every mark of tenderness and affection, and his mother-in-law found means to conciliate his good opinion and his confidence. It is a singular circumstance that he should have taken a captain's commission in the army, a profession, one would have imagined, for which he was very ill calculated. Indeed he soon evinced the truth of this, for his tent and quarters were frequently encumbered with the odd furniture of Greek and Latin authors. On the event of peace he resigned his commission, and paid a visit to Paris in the year 1763, where he resided a few months, and afterwards went to Lausanne, where he remained about a year, in order to prepare for a journey into Italy, which he accomplished in 1765. He thus speaks on the occasion of his entering Rome: "After a sleepless night, I trod, with a lofty step, the ruins of the forum; each memorable spot, where Romulus stood, or Tully spoke, or Cæsar fell, was at once present to my eye; and several days of intoxication were lost or enjoyed before I could descend to a cool and minute investigation." On the 15th of October, he informs us, the idea of writing the decline and fall of Rome first came into his mind, when the bare-footed friars were singing vespers in the temple of Jupiter.

In the year 1770 Mr Gibbon lost his father, and succeeded to an estate which was very much involved; yet he considered his circumstances as very well adapted to the great and extensive work he had undertaken to accomplish, which in his own opinion he had probably never finished, if he had been either poorer or richer than he was. He had an extensive circle of acquaintance in London, but the time necessarily devoted to their company, he made up by early rising and intense application. In the year 1774 he was chosen member of parliament for the borough of Liskeard, by the influence of Lord Elliot, which threatened to give his studies a very serious interruption. He sat eight years in the house of commons without having the courage so much as once to open his mouth, notwithstanding he was such an elegant writer. When the first volume of his "Decline and Fall of the Roman Empire," made its appearance in 1776, it met with a greater degree of applause than he expected; but by no praise was he so highly gratified as by that which the two great historians of Scotland, Hume and Robertson, bestowed upon him. For his two chapters which relate to the spread of Christianity he met with many antagonists, to whom he made no reply but to a Mr Davis, which was considered as a masterpiece. There can be no doubt that Gibbon was a real enemy to revelation in the disguise of a believer, a conduct not so abominable as at first sight may appear, so long as penal laws exist against an open declaration of opinion.

Gibbon, Gibbous.

Soon after the publication of the first volume of his history, he paid another visit to Paris, and did not appear to be in much haste to complete his extensive work. In 1781, however, the second and third volumes of his history were given to the world; and although in the estimation of many competent judges they were inferior to the first, they still were allowed to possess sufficient merit to support his reputation. Having lost his seat for Liskeard, the influence of ministry brought him in as representative for Lymington, and on the dissolution of Lord North's ministry, he lost his office as one of the lords of trade, which was a serious diminution of his income. He again determined to visit his favourite Lausanne, where he completed the remaining volumes of his history; but when the revolutionary mania began to rage on the continent, he quitted Lausanne, and sought for an asylum in England. He mortally hated innovations of every kind, whether necessary or not, as appears from the following exclamation: "I beg leave to subscribe my assent to Mr Burke's creed on the revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and can almost excuse his reverence for church establishments,"

During his consoling visit to Lord Sheffield, who had met with a trying domestic loss, his attention was called to the rapid progress of a distemper which had subsisted for about 30 years. A mortification at last ensued, which terminated his existence on the 16th of January 1794, in the 67th year of his age. Mr Gibbon gives himself a character which is perhaps pretty near the truth. "I am endowed with a cheerful temper, a moderate sensibility, and a natural disposition to repose rather than to activity: some mischievous appetites and habits have perhaps been corrected by philosophy or time. The love of study supplies each day, each hour, with a perpetual source of independent and rational pleasure." Mr Gibbon possessed the manners and sentiments of a gentleman in an eminent degree; he was easy in society, of which he was extremely fond, and beloved by all who had the pleasure of intimately knowing him.

GIBBOUS, a term in *Medicine*, denoting any protuberance or convexity of the body, as a person hunched or hump-backed.

Infants are much more subject to gibbosity than adults, and it oftener proceeds from external than internal causes. A fall, blow, or the like, frequently thus distorts the tender bones of infants. When it proceeds

from

from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebræ; though the spine may be inflected forward, and the vertebræ thrown out by a too strong and repeated action of the abdominal muscles. This, if not timely redressed, grows up and fixes as the bones harden, till in adults it is totally irretrievable: but when the disorder is recent, and the person young, there are hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally on the gibbous part; and this by long wearing may set all right. The surgeons, however, have a different instrument, which they call a *cross*, much more efficacious, though not quite so convenient in the wearing. By the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with Hungary water, spirit of lavender, or the like, and defended with a strengthening plaster.

GIBBOUS, in *Astronomy*, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter; for all that time the dark part appears horned or falcated; and the light one hunched out, convex, or gibbous.

GIBEAH, a city in the tribe of Benjamin, lying north of Jerusalem about 20 or 30 furlongs, and built upon a hill, as its name imports.—This city gave birth to Saul, the first king of Israel, for which reason it is frequently called Gibeah of Saul, or Gibeah the native country of Saul.

GIBELINS, or GIBELLINS, a famous faction in Italy, opposite to another called the GUELPHS.

Those two factions ravaged and laid waste Italy for a long series of years; so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The Gibelins stood for the emperor against the pope: but concerning their origin and the reason of their names we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederick II.'s being excommunicated by Pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIBEON, a city seated on an eminence about 40 furlongs from Jerusalem northward, and not far from the city of Gibeah. See GEBA.

This was the capital city of the Gibeonites, who took the advantage of Joshua's oath, and of that which the elders of Israel likewise swore to them, upon an artificial representation which they made of their belonging to a very remote country, and their desire of making an alliance with the Hebrews. Joshua (ix. 3. 4, *et seq.*) and the elders inconsiderately entered into a league with these people; but soon discovered their mistake. Upon this, sending for the Gibeonites, they reproached them with their fraud; and without revoking the promise which they had made to them, of giving them their lives, they condemned them to carry wood and water to the tabernacle of the Lord, as slaves and captives taken in war; in which state of servitude they remained till the ruin and entire dispersion of the Jewish nation.

The Gibeonites were descended from the Hivites, the old inhabitants of that country, and possessed four cities, whereof Gibeon was the capital. The cities were Chephirath, Beeroth, Kirjathjearim, and Gibeon, Josh. ix. 17. These cities were afterwards given to the tribe of Benjamin, except Kirjathjearim, which fell to the tribe of Judah. The Gibeonites continued ever after subject to those burdens which Joshua had imposed on them, and were very faithful to the Israelites.

GIBLETS, the offals or entrails of a goose; including the heart and liver, with the feet, gizzard, &c. The word is supposed to be formed of *goblets*, from the French *gobeau*, "mouthful."—Giblets make a considerable article in cookery: they boil giblets, stew giblets, make ragouts of giblets, giblet pies, &c.

GIBRALTAR, a famous promontory, or rather peninsula, of Spain, lying in N. Lat. 36. 6. W. Long. 5. 17. To the ancients it was known by the name of *Calpe*, and was also called one of the *Pillars of Hercules*; by the Arabians it is called *Gebel Tarek*, that is, "the mount of Tarek," from *Tarek*, the name of the Saracen general who conquered Spain in the beginning of the eighth century. The whole is an immense rock, rising perpendicularly about 440 yards, measuring from north to south about two English miles, but not above one in breadth from east to west. The town lies along the bay on the west side of the mountain on a declivity; by which, generally speaking, the rains pass through it, and keep it clean. The old town was considerably larger than the new. Many of the streets are narrow and irregular: the buildings are of different materials; some of natural stone out of the quarries, some of a factitious or artificial stone, and a few of brick. The people are supplied with fresh provisions chiefly from the coast of Barbary, with fruit, roots, and vegetables of all sorts from thence, or from their own gardens. Besides what is properly called the town, there are several spacious and commodious public edifices erected; such as barracks for the soldiers, with apartments for their officers, magazines of different kinds, storehouses for provisions, &c. The inhabitants, exclusive of the British subjects dependent on the garrison, or who reside there from other motives, consist of some Spaniards, a few Portuguese, a considerable number of Genoese, about as many Jews, and even some Moors; making in the whole a population of twelve thousand persons, without reckoning the garrison; though some make them much fewer. This town may be said to have two ports; the first lying to the north, and is proper only for small vessels; the other is very commodious for large vessels, and has a fine stone quay. The bay is very beautiful and capacious, being in breadth about five miles, and in length eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at one hundred fathoms depth, so that a squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise

Gibraltar. likewise to the subsistence of the inhabitants by supplying them with plenty of fish.

The strait of Gibraltar, through which the ocean passes into the Mediterranean, thereby dividing Europe from Africa, runs from west to east about 13 leagues. In this strait there are three remarkable promontories or capes on the Spanish side, and as many opposite to them on the Barbary side. The first of these, on the side of Spain, is Cape Trafalgar, opposite to which is Cape Spartal; and in the neighbourhood of this stood the fortress of Tangier, once in the possession of the British. The next on the Spanish side is Tariffa; and opposite it lies Malabata, near the town of Alcassar, where the straits are about five leagues broad. Lastly, Gibraltar facing the mountain of Abyla, near the fortress and town of Ceuta, which make the eastern entry of the straits.

1 rtress erected the Saens.

This important fortress seems to have been first particularly noticed as a place of consequence in the year 712 At that time the general of the caliph Al Walid landed with an army of 12,000 men on the isthmus between Mount Calpe and the continent; and that he might secure an intercourse with Africa, ordered a castle to be built on the face of that hill. Part of the building still remains; and, from an inscription discovered above the principal gate, appears to have been finished in 725. It continued in the possession of the Saracens till the beginning of the 14th century, when it was recovered by Ferdinand king of Castile. In 1333, however, it was obliged to surrender to the son of the emperor of Fez, who came to the assistance of the Moorish king of Granada. An attempt was made upon it in 1349 by Alonso king of Castile; but when the fortress had been reduced to the last extremity, a pestilential fever broke out in the Spanish camp, which carried off the king himself, with great part of his army; after which the enterprise was abandoned.

2 rious revtions.

The fortress continued in the possession of the Saracen descendants of the prince of Fez until the year 1410, when it was taken possession of by Joseph III. king of Granada. A design of attacking it was formed by Henry de Gusman in 1435; but the enterprise having miscarried through his imprudence, he was defeated and slain. However, it was at length taken after a gallant defence by his son John de Gusman in 1462; since which time it has remained in the hands of the Christians. In 1540, it was surprised and pillaged by Piali Hamet, one of Barbarossa's corsairs; but the pirates having fallen in with some Sicilian galleys, were by them defeated, and all either killed or taken.

3 Itrtificatiim pred and stgthened.

In the reign of Charles V. the fortifications of Gibraltar were modernized, and such additions made as to render them almost impregnable. It was taken by the English, however, in the reign of Queen Anne, and since that time has remained in their possession; and probably will always do so, unless ceded by treaty, as it appears altogether impossible to reduce it by any force of artillery, let it be ever so great. In the year 1704, in consequence of the resolution adopted by the court of Britain to assist the archduke Charles in his pretensions to the Spanish crown, Sir George Rooke was sent with a powerful fleet into the Mediterranean. His orders being limited, nothing of consequence was done for some time, until at last an attempt on Gibraltar was resolved upon; not so much on account of the importance of the conquest, as to prevent any reflections against the admiral for inactivity. On the 21st of July that year, 1800 troops were landed upon the isthmus, under the command of the prince of Hesse Darmstadt; and on the refusal of the governor to surrender, preparations were made for attacking the place. Early in the morning of the 23d, a cannonade was begun from the fleet, and kept up so briskly, that in five or six hours the Spaniards were driven from many of their guns, especially at the new mole head. The admiral perceiving, that, by gaining this part of the fortification, the reduction of the rest would be facilitated, ordered out some armed boats to take possession of it. On their approach the Spaniards sprung a mine, which demolished part of the works, killed two lieutenants and 40 private soldiers, wounding about 60 more. Notwithstanding this disaster, the assailants kept possession of the work, and took a small bastion, now the eight-gun battery, half way between the mole and the town. On this the governor thought proper to capitulate, and the prince of Hesse took possession of the gates on the 24th. The garrison, consisting at most of 150 men, marched out with the honours of war; and the Spaniards who chose to remain were allowed the same privileges they had enjoyed under the reign of Charles II. The works were found very strong, and the place well provided with ammunition and military stores.

4 Tn by Sieorge Re in 17

This conquest was achieved with the loss of about 60 killed and 216 wounded on the part of the English. The prince of Hesse remained governor; and 18 men of war were left at Lisbon under the command of Sir John Leake, to succour the garrison if there should be occasion. The loss of such an important fortress, however, having alarmed both the courts of Madrid and Paris, orders were sent to the Marquis de Villadarias, a Spanish grandee, to lay siege to it, in which he was to be assisted by a naval force from Toulon. The prince immediately applied to Sir John Leake for assistance; but before the latter had time to comply with his request, a French fleet arrived, and debarked six battalions to the assistance of the Spaniards; after which they proceeded to the westward, leaving only six frigates in the bay. The trenches were opened on the 11th of October, about which time Sir John arrived with 20 sail of English and Dutch ships; but hearing that the French were about to attack him with a superior force, he judged it proper to return and refit. Having very prudently left orders at Lisbon to make preparations for this purpose in his absence, he was enabled to accomplish this work with such expedition, that on the 29th of the same month, he returned and surprised in the bay three frigates, a fire ship, two English prizes, a tartan, and a store ship. After this exploit he landed some reinforcements, supplied the garrison with six months provision and ammunition; at the same time detaching on shore a body of 500 sailors to assist in repairing the breaches which had been made by the enemy's fire.

5 Besieged the same year by the Marquis de Villadarias.

6 The garrison supplied with reinforcements and provisions by Sir John Leake.

Thus the Spaniards were disappointed in their hopes of success from an attack which had been projected that very night, and for which purpose 200 boats had been collected. Still, however, they did not despair; and

Gibraltar. and supposing that the garrison would be off their guard and secure on account of the vicinity of their fleet, they formed the rash design of attempting to surprise the place, though the British admiral was still before it. In this mad attempt 500 volunteers associated, taking the sacrament never to return unless they accomplished their purpose. They were conducted by a goat-herd to the south side of the rock near the cave guard, at that time called *the pass of locust trees*. This they mounted, and lodged themselves the first night in the cave of St Michael: the next they scaled Charles V.'s Wall; surprised and massacred the guard at Middle hill; where afterwards, by ropes and ladders, several hundreds of the party designed to support them were hauled up: but being discovered, they were attacked by a strong party of grenadiers, and all of them at last either killed or taken. These brave adventurers were to have been supported by a body of French troops, and some feints were proposed to draw off the attention of the garrison; but, through the disagreement of the commanding officers, these proposals were not put in execution, and thus the volunteers were left to their fate.

7 Desperate attempt of some Spanish volunteers.

8 They are all killed or taken.

9 The siege still continued.

Notwithstanding these misfortunes, the Spaniards still continued the siege, and fitted out a strong squadron from Cadiz, with a design to intercept the convoys of provisions which might be sent to the garrison; flattering themselves at the same time, that, on the arrival of their fleet, Sir John would be obliged to retire, and the garrison of consequence to surrender to their united attacks. They continued their fire therefore with additional fury, dismounted many of the cannon, and did essential injury to the works in several different places. The prince of Hesse, however, was by no means deficient in his endeavours to disappoint their expectations. As it was probable that an attempt might be made to storm the curtain, a cuvette was dug in the ditch, which was filled by the tide, and a double row of palisades placed parallel to the works. The chambers of the mine under the glacis were loaded, and all means taken to defeat such an attempt; but on a sudden the Spaniards seemed to have altered their design, and threatened an attack on the lines which the garrison had on the declivity of the hill to flank the glacis, and overlook their advanced works. While affairs remained in this situation, part of the succours they had long expected arrived in the bay, December 7. 1704, and in two days after, the remainder came in with near 2000 men, along with a proportionable quantity of ammunition and provisions. These had sailed from Cape Spartel under convoy of four frigates; but were in imminent danger of falling into the hands of the enemy, whose fleet they mistook for their own; however, they escaped by the fortunate circumstance of being becalmed, so that they could not get up to them.

10 The garrison reinforced.

Sir John Leake having thus powerfully reinforced the garrison, thought his presence in the bay no longer necessary, and therefore set sail for Lisbon, where he arrived about the end of the year. In the beginning of January 1705 the Spaniards were reinforced by a considerable body of infantry, and on the 11th of the month made an attack on the extremity of the King's Lines, but were repulsed. The attack was renewed next day with 600 grenadiers, French and Walloons, supported by 1000 Spaniards, under Lieutenant General Fuy. They disposed themselves in such a manner as showed an intention to storm a breach which had been made in the Round Tower at the extremity of the King's Lines, and another in the intrenchment on the hill. The retrenchment which covered the latter breach, with part of the intrenchment joining the precipice of the rock, was defended at night by a captain, three subalterns, and 90 men; but it was customary for the captain to withdraw, with two subalterns and 60 men at daybreak. The Round Tower was defended by 180 men, commanded by a lieutenant-colonel. The marquis, by deserters from the garrison, had obtained intelligence of the strength of these posts, and planned his attack accordingly. The detachment for the upper breach mounted the rock at midnight, and concealed themselves in the clifts until the captain had withdrawn; after which, advancing to the point of the intrenchment, they threw grenades on the subaltern and his party, so that they were obliged to leave the place. At the same time 300 men stormed the Round Tower, where Lieutenant Colonel Bar made a vigorous defence, though the enemy, having passed the breach above, annoyed them on the flanks with great stones and grenades. Observing, however, the Spaniards marching down to cut off his retreat from the town, he retired; and, by getting over the parapet of the King's Lines, descended into the covered way, where the English guards were posted. Thus the garrison were alarmed; all the regiments were assembled at their proper posts; and Captain Fisher endeavoured to stop the progress of the enemy with 17 men, but they were repulsed, and himself taken prisoner. At last, however, the Tower was retaken by Lieutenant Colonel Moncal at the head of 400 or 500 men, after it had been in the possession of the enemy upwards of an hour.

11 Vigorous attack by the Spaniards.

12 They are repulsed.

The garrison was now farther reinforced by six companies of Dutch troops and 200 English soldiers, together with some provisions and stores. The assailants, however, were still determined to go on. The marquis de Villadarias was superseded by Mareschal Tesse, a Frenchman, with whom Admiral Pointis was desired to co-operate in blocking up the place. The mareschal therefore joined the army with four fresh battalions, besides eight companies which had been sent before; the ordnance, which had been greatly injured by constant use, was exchanged for others, and the works as they then stood, put into the best repair. On the part of the English, a reinforcement was ordered under the command of Sir Thomas Dilkes and Sir John Hardy, to join Admiral Leake at Lisbon: which junction being effected, the whole fleet, consisting of 28 English, 4 Dutch, and 8 Portuguese men of war, having on board two battalions of land forces, set sail from Lisbon. Happily for the besieged, however, the incessant rains and storms about this time had retarded the operations of the land forces, and greatly distressed the fleet of the enemy. Eight ships of the latter were forced from their anchors by the strong westerly wind, and obliged to drive aloft. At this critical period Sir John Leake, with the allied fleet, entered the straits. On his approach the few remaining French ships put out to sea; and the British admiral discovering five sail making out of the bay, and a gun fired at them from the garrison,

13 The siege carried on with fresh ardour.

14 The French fleet dispersed by a storm.

garrison, immediately gave chase. Three French men of war were taken, and the admiral's ship and another driven on shore, where they were burnt. The rest, on hearing the report of the guns, had made the best of their way to Toulon.

15 The siege turned into a blockade, and at last raised.

The garrison was now so well supplied, that Mariſchal Teſſe withdrew his troops from the trenches, and formed a blockade, drawing an intrenchment across the iſthmus to prevent the garrison from ravaging the country. The prince of Heſſe remained for some time in the place, where he repaired the batteries, and made some additions to the fortifications; after which he joined the archduke Charles at Lisbon. As the latter, however, was resolved to try his fortune with the earl of Peterborough in Valencia and Catalonia, the prince was sent back to Gibraltar to prepare part of the garrison for embarkation, and soon after was followed by the whole fleet. Major General Ramos was now appointed governor of Gibraltar, in which only two new battalions were left, as nothing was to be feared from the enemy. The new governor, however, brought with him 400 men for the greater security of the place; but soon resigned his government to Colonel Roger Elliot, during whose time Gibraltar was made a free port by a special order from the queen.

Colonel Elliot was succeeded by Colonel Congreve before the year 1714, and he by Colonel Cotton a short time after. In 1720 the Spaniards seem to have threatened another attack. Ceuta, a Spanish fortress in Barbary, had been for many years besieged by the Moors; and a powerful armament, commanded by the marquis de Lada, was now assembled in Gibraltar bay, under pretence of relieving the African fortress, but with a secret design of first surprising Gibraltar; for which purpose they had provided scaling ladders, &c. The armament, however, had not been fitted out with such secrecy, but that the British ministry had intelligence of it. On this they sent orders to Colonel Kane, governor of Minorca, to embark with part of his garrison for Gibraltar under convoy of the fleet in the Mediterranean. On his arrival he found the place in a critical situation. The garrison consisted only of three weak battalions under Major Hetherington, besides whom there was only one other field officer, Major Batteroux, in the place, and no more than 14 days provisions remaining. The posture of affairs, however, was altered by the arrival of Colonel Kane with 500 men, with provisions and ammunition; which reinforcement, together with the spirited behaviour of the British commodore, induced the Spanish commander to abandon his design, though he remained of opinion that the fortress might then have been carried by a general assault.

16 A new attempt threatened by the Spaniards in 1720.

17 The design given up.

18 Another attempt in 1726.

Notwithstanding this disappointment, the Spaniards continued to keep a watchful eye over Gibraltar; and, in the latter end of the year 1726, assembled an army in the neighbourhood of Algesiras, encamping, on the 20th of January following, on the plain below St Roch, and erecting a battery on the beach to protect their camp. Though Admiral Hopson was then at anchor in the bay of Gibraltar, yet, as he had received no intelligence of the actual commencement of hostilities between Britain and Spain, he was obliged to allow the boats of the latter to pass with provisions, arms, and ammunition, between Algesiras and the camp, at the same time that Colonel (afterwards Brigadier) Kane, who had been a second time sent from Minorca, lay under similar embarrassments. The operations of the Spaniards, however, seemed so evidently to tend towards an attack, that the governor thought proper to order such of that nation as were in the town to leave it, and to forbid their galleys to anchor under his guns (A).

The count de las Torres commanded the Spanish forces, amounting to near 20,000 men; and soon after forming his camp, he advanced within reach of the garrison. The brigadier then desired him to keep out of his reach, otherwise he should do his utmost to force him; but to this the Spanish commander replied, that, as the garrison could command no more than they had power to maintain, he should obey his Catholic majesty's orders, and encroach as far as possible. Hostilities, however, were not commenced until the 10th of February 1727, when the Spaniards, having brought materials for batteries to the old windmill on the neutral ground, it was determined in a council of war, that the Spanish general had commenced hostilities by encroaching so far on the liberties of the garrison. Still, however, the governor sent to the count to know the reason of breaking ground before the garrison; but received for answer, that "he was in his master's territories, and was not answerable to any other person for his conduct." On this the governor opened the batteries of the Old Mole and those of Willis upon the Spanish workmen: however, they persisted on carrying on their operations, and at night marched a party down to the Devil's Tower, where they immediately broke ground, and began a communication with their other works. The governor was now informed by some deserters, that the enemy were forming a mine in a cave under Willis's Battery, with a design to blow it up: but the plot being thus happily discovered, a party was immediately stationed to cut off the communication. On the 22d of February the Spaniards opened on the garrison with 17 pieces of cannon besides mortars; and the day following Brigadier Kane left Gibraltar to send a reinforcement from Minorca. On the 3d of March the enemy opened a new battery of 22 guns, on the Old Mole, and on the 8th another of 15 guns, bearing also upon the same mole, the guns of which had annoyed the western flank of their approaches.

All this time the garrison had kept up a constant and well directed fire from the batteries which bore upon the works of the enemy; but the ordnance in general being old, were frequently bursting; by which they suffered more than from the fire of the besiegers. The

4 U 2

(A) At this time the fortifications of Gibraltar were considerably different from what they had been in 1705. Several works were erected on the heights above the lines called *Willis's Batteries*; the Prince's Lines were extended to the extremity of the rock, and an inundation was formed out of the morass in front of the grand battery.

Gibraltar.

The latter were also greatly distressed by the fleet under Admiral Hopson and Sir Charles Wager, who, since the beginning of the siege, had intercepted their homebound ships, and at the same time greatly benefited the garrison, by bringing the prizes into the bay. Finding the Spaniards, however, obstinately bent on their enterprise, they formed a design, on the 2d of April, to bombard Algesiras, from whence the besiegers were supplied with various articles of ammunition; but the fleet happening to be becalmed, the design was afterwards unaccountably abandoned; and on the arrival of a reinforcement from Minorca, they sailed to the westward, leaving the garrison to defend themselves the best way they could.

The enemy continued to augment their batteries, and erect new ones, until they amounted at last to 60 cannon besides mortars; and, on the 3d of May, the governor received intelligence that a general assault was intended; to repel which he took every proper precaution. The enemy, however, still added to their approaches, and considerable reinforcements were received by both parties.

19 Cessation of hostilities.

Hostilities, however, ceased on the 12th, when news arrived that the preliminaries of a general peace were signed; from which time to the year 1779, no farther attempts were made on Gibraltar.

20 Great loss of the Spaniards in their attempts.

In the course of these two sieges the loss of the Spaniards was very considerable; that of 1705 costing them not less than 10,000 men, including those who died of sickness; and in that of 1727 their loss was computed at near 3000, besides casualties, which could not be ascertained. That of the garrison amounted in 1705 to 400; and in 1727 to 300; a very small number, considering that during the siege 70 cannon and 30 mortars burst on the batteries.

21 Gibraltar blocked up in 1779.

The hostile manifesto presented by the Spanish ambassador to the court of London at the commencement of the American war, was soon followed by an interruption of communication betwixt Spain and the fortress of Gibraltar. No direct intention of attacking or distressing it, however, was manifested till the 16th of July, when the port was completely blocked up by a squadron of two 74 gun ships, several frigates, galleys, &c. Ten days after they began to form a camp on the plain below St Roch, three miles from the fortress. The garrison at this time consisted of 5382 men, including officers, with a company of engineers and artificers; but the greatest expectations were formed from the abilities and valour of General Elliot the governor. As soon as the breaking off the communication with Spain indicated approaching hostilities, the governor took every precaution that could be suggested by military wisdom; but though informed of the rupture betwixt the two courts having actually taken place, and though he beheld the hostile operations of the enemy, no means were used to interrupt them till the 12th of September,

22 Hostilities commenced by the garrison.

when the batteries of Green's Lodge, Willis, and Queen Charlotte, were opened for a few hours, with a view to disturb the workmen.

From this time to the beginning of the year 1780 the enemy continued the blockade both by sea and land, but without doing any damage to the works or garrison, and it was not until the 12th of January

23 A woman first wounded in the fortress.

that a single person was wounded. This happened to be a woman, who, passing near one of the houses, was slightly hurt by a shot from the enemy. In the mean time, however, the usual supplies of provisions being cut off, the garrison began to feel all the horrors of famine. All the necessaries of life were very scarce,

24 Excessive dearness of provisions.

and to be procured only at exorbitant prices. Veal, mutton, and beef, sold from half a crown to four shillings per pound; fresh pork from two to three shillings; salted beef and pork fifteenpence; fowls eighteen shillings per couple; ducks a guinea; fire wood, five shillings per hundred weight; a pint of milk and water fifteenpence; a small cabbage cost five shillings, and a small bunch of outer leaves fivepence; Irish butter half a crown per pound; candles as much; and eggs sixpence each. As the rock, however, is almost surrounded by the sea, it was natural to suppose, that in such a scarcity of other provisions great benefit would have been derived from the ocean; but the fishermen, being all foreigners, and under no regulation, took advantage of the present scarcity of provisions in the garrison to exact a most exorbitant price for the fish they supplied.

25 The Spanish fleet defeated and their admiral taken by Rodney.

Had matters remained long in this state, it is plain that the fortress, however strong, must have fallen into the hands of the enemy. They were, however, effectually relieved in consequence of the victory gained by Admiral Rodney over the Spanish fleet commanded by Don Juan de Langara. The former had been furnished with a strong squadron, in order to relieve this important fortress; with which having set sail, he in a few days fell in with a Spanish fleet of 16 transports bound from Bilboa to Cadiz, and laden with provisions and naval stores, convoyed by a man of war of 64 guns, four frigates, and two armed vessels. Of these only a single transport escaped, the rest being all captured on the 8th of January 1780; and the loss of them, at the same time that it promised to be very serviceable to the garrison, was equally detrimental to the enemy, who were now in great want both of provisions and materials for their shipping.

This advantage was soon after followed by a much greater. On the 16th of the same month a Spanish squadron of 11 sail of the line was discovered off Cape St Vincent; and the British admiral having taken the proper methods to come up with them as quickly as possible, an engagement took place about four in the afternoon. At this time the headmost ships of the British line closed in with the nearest of the enemy, and in half an hour one of the Spaniards, mounting 70 guns, and having on board 600 men, blew up, and all on board perished. In two hours more another Spanish ship of the line was taken; notwithstanding which the fight continued with great vigour till two in the morning, when the headmost ship of the enemy struck to the Sandwich; after which the firing ceased. The weather throughout the night was so tempestuous that it was with the utmost difficulty the British could take possession of those ships which surrendered. These were six in number, but two of them drove ashore and were lost, only four being brought safe into Gibraltar. These were the admiral's ship of 80 guns and 700 men, with three others of 70 guns and 600 men. The engagement, however, happened so near the shore, and the British were so eager in securing the lee gage to prevent the enemy's escape, that Admiral Rodney's ship, together with some of the largest in the fleet, were in great danger of running on the shoals of St Lucar; nor

[Gib]raltar.

nor could they be got into deep water again without much labour and the exertion of great naval skill. It was the opinion of all who were present in the action, that had this engagement happened in the day time, or had the weather been less boisterous, not one of the Spanish ships could have escaped; and even as it was, those which got off were so essentially damaged as to be unfit for service.

25 [Th]e garrison relieved and reinforced.

The news of this important victory arrived at Gibraltar on the evening of the day after it was fought; and in two days more the garrison was completely relieved by the arrival of the fleet and convoy, at the same time that they were farther reinforced by a regiment of Highlanders, consisting of 1051 men, officers included. An opportunity was also taken of sending away with the fleet all the invalids and women in the garrison; with whom they set sail on the 10th of February, leaving in the bay only the Edgar and Panther ships of the line, with two frigates.

On the departure of the British fleet, the blockade was immediately resumed; and notwithstanding the ample supplies lately received, the garrison soon began again to experience the inconveniency of wanting fresh provisions. It had hitherto received these in abundance from the coast of Barbary; but an unaccountable alteration had now taken place, so that the friendship of the emperor of Morocco was transferred from Great Britain to Spain in a manner totally unprecedented. His partiality towards the latter was the more surprising, as Britain had given no provocation, and the enmity between Spain and Morocco seemed to be in a manner constitutional, and founded upon such causes

[2]7 The garrison again reduced to straits.

as could never cease to operate. Thus, however, the garrison became daily more and more distressed, from being obliged to make constant use of their salt provisions, and even this with the strictest economy. The industry and resolution of the British seamen and officers, indeed, sometimes overcame all obstacles, so that they found means to procure the necessary refreshments; though in so doing they were certainly exposed to the utmost danger from the enemy. At the same time the defence of the garrison was so vigorous, that while it continued to be supplied even in this scanty manner, the Spaniards began to lose all hope of reducing it; for which reason they formed a project of burning

[2]8 Unsuccessful attempts to burn the British shipping.

all the British shipping in the bay. The night appointed for putting this scheme in execution was the 6th of June 1780, when 10 fire-ships, favoured by an uncommon darkness, stood over from the Spanish to the British side of the bay. Their design was to set fire to the storehouses nearest to the water side, as well as to the shipping there; but having been too precipitate in firing their ships, and being received also by a very heavy cannonade, the attempt was frustrated. On this occasion the skill and intrepidity of the British seamen were eminently displayed. Having manned their boats, they grappled the fire-ships already in flames; and, notwithstanding their dreadful appearance and the danger of their exploding, towed them clear of the vessels under the walls and extinguished them.

The failure of this project was a grievous disappointment to Don Barcelo the Spanish admiral, who lay ready with his squadron to intercept the British vessels that might attempt to escape; at the same time that the batteries on their lines were in readiness to bombard the town, if the fire-ships had succeeded in causing any conflagration on shore. The failure of the present attempt, however, was soon followed by other disasters. As soon as they had, with great labour, pushed forward their new works, and constructed new batteries, they were certainly destroyed by the besieged; and their mortification on these occasions was the greater, as it was usual for the governor to allow them to complete their works before he commenced his destructive operations. Thus the labour of many days was often lost in a few hours, and afterwards was to be resumed with as little prospect of success as before. The garrison was now considerably annoyed by the Spanish gun boats, to which indeed the shipping were equally exposed with themselves. These were vessels from 30 to 40 tons burden, constructed so that they lay low in the water, which rendered them difficult to be aimed at. They had 15 oars on a side, carried 40 or 50 men, with a 26 pounder on the prow; and from the facility of managing them, two were deemed, in calm weather, to be a match for a frigate of moderate size. All their efforts, however, could still do no more than to reduce the garrison to great straits for want of provisions; and to this dreadful inconvenience the British submitted with the greatest cheerfulness. From the time of Admiral Rodney's departure in the month of February 1780 to the month of October, almost the only provisions in the garrison were such as tended to produce the scurvy; which accordingly raged in such a manner, as to threaten the most fatal consequences. An antidote, however, was happily procured by the capture of a Danish dogger from Malaga laden with lemons and oranges, which the governor immediately purchased for the use of the garrison and distributed among them. "At this time (says Captain Drinkwater) the scurvy had made dreadful ravages in our hospitals, and more were daily confined: many however, unwilling to yield to its first attacks, persevered in their duty to the more advanced stages. It was therefore not uncommon, at this period, to see men, who, some months before, were hale, and capable of enduring any fatigue, supporting themselves to their posts upon crutches, and even with that assistance scarcely able to move along. The most fatal consequences in short were to be apprehended to the garrison from this terrible disorder, when this Dane was happily directed to our relief." According to Mr Cairncross, an eminent surgeon, who was present during this siege, "the scurvy which now raged in Gibraltar, differed in no respect from that disease usually contracted by sailors in long sea voyages; and of which the immediate cause seemed to be the subsisting for a length of time upon salted provisions only, without a sufficient quantity of vegetables or other acescent foods. The circumstances related in the voyage of that celebrated circumnavigator Lord Anson of consolidated fractures disuniting, and the callosity of the bone being perfectly dissolved, occured frequently in our hospitals, and old sores and wounds opened anew from the nature of the disorder. Various antiscorbutics were used without success, such as acid of vitriol, sour crout, extract of malt, essence of spruce, &c.; but the only specifics were fresh lemons and oranges given liberally; or, when they could not be

Gibraltar.

29 Spanish works destroyed.

30 The garrison annoyed by the Spanish gun boats.

31 The scurvy rages in the garrison.

32 Cairncross's account of it.

Gibraltar. be procured, the preserved juice in such quantities, from one to four ounces per day, as the patient could bear. Whilst the lemons were sound, from one to three were administered each day as circumstances directed. The juice given to those in the most malignant state was sometimes diluted with sugar, wine, or spirits; but the convalescents took it without dilution. Women and children were equally affected; nor were the officers exempted from this dreadful disorder. It became almost general at the commencement of the winter season, owing to the cold and moisture, and in the beginning of spring when vegetables were scarce.

33 Method of preserving lemon juice. The juice was preserved by adding to 60 gallons of expressed liquor about five or ten gallons of brandy, which kept it in so wholesome a state, that several casks were opened in good condition at the close of the siege. The old juice, however, was not so speedily efficacious as the fruit, though by persevering longer in its use it seldom failed.

34 The garrison distressed for want of provisions. Till this month the allowance of salt provisions had continued undiminished; but now it was judged necessary to reduce the allowance of bread and meat, and to make some other regulations in order to enforce the strictest economy with regard to food. Every thing of this kind that could be practised, however, seemed insufficient to preserve the garrison from absolute want. In the beginning of the year 1781, provisions became exceedingly scarce, by reason of the almost total expenditure of what was contained in the public stores, and the vigilance of the enemy's cruisers. About the middle of February the town bakers left off work for want of flour; and many of the poorer sort wanted bread. The price of fresh provisions again rose to a most enormous height. Small pigs sold at two guineas; turkeys at three; geese at 30 shillings; fowls and ducks at 10 shillings; damaged biscuit a shilling the pound; pease 1s. 6d.; and all other necessaries in proportion; at the same time the scarcity of fuel was such, that it was sometimes scarcely procurable in quantity sufficient to dress the victuals.

35 The garrison entirely deprived of the use of the neutral ground. The garrison had hitherto derived assistance occasionally from the gardens on the neutral ground, though vast quantities of vegetables had been removed thence by the enemy. Towards the end of the month of October 1780, however, the Spaniards determined to expel the British from the gardens entirely: and this they accomplished in spite of all that could be done to prevent them. From this time the resources with regard to vegetables depended entirely upon the attention paid to cultivation; which, happily for the garrison, was attended with such success, especially during the winter months, that the produce came at last to be nearly equal to the demand.

36 Supplied by the British fleet. At last, on the 12th of April 1781, supplies were brought by the British fleet under Admirals Darby, Digby, and Ross, though they could not be got in without great difficulty. The gun boats already mentioned were now much increased in number and strength of construction; infesting the bay in such a manner as greatly to interrupt the debarkation of the stores. As no vessels of the same kind had been prepared to oppose them, they could scarce be prevented from effecting their purpose of burning the store ships. With this view they had approached them every morning in hazy weather to the number of between 20 and 30, several of them carrying mortar-pieces; and as they used both sails and oars, they eluded all pursuit, by withdrawing on the rise of any breeze. To keep off these troublesome guests, several stout frigates were obliged to station themselves along the bay for the protection of the shipping; but even this did not prevent them from continuing their molestation; and notwithstanding the vigilance and activity of the British sailors, it was seldom that they could come near enough to do them any damage. In spite of all their endeavours, however, the garrison was effectually relieved: an exploit which so exceedingly irritated the court of Spain, that they determined to exert the utmost force of the kingdom rather than fail in the execution of their favourite project.

37 The Spaniards resolve to exert themselves to the utmost. The works before the town were therefore carried on with more vigour than ever, and the most tremendous preparations made to cause the obstinate garrison feel the resentment of an exasperated enemy. Their batteries were now mounted with guns of the heaviest metal, and with mortar-pieces of the largest size; the number of the former augmented to near 200, and of the latter to upwards of 80. For three weeks this prodigious artillery continued to pour forth an almost incessant shower of shot and shells, insomuch that, in the time just mentioned, they had consumed 100,000lb. of gunpowder, and thrown into the town four or five thousand shot or shells every 24 hours.

38 The town entirely destroyed. By such an immense bombardment the town was almost totally laid in ruins. The inhabitants, computed at more than 3000 in number, experienced every difficulty that could arise from the destruction of their habitations: several of them were killed, and all forced to leave the town, and take shelter under tents with what accommodation could be provided for them in such scenes of horror and confusion. Numbers took the opportunity of retiring with the fleet; while many that remained were now reduced from a state of opulence to the greatest distress. The conduct of Governor Elliot was very humane and compassionate to such as were inclined to depart; allowing them a free passage to England, and supplying them with provisions for the voyage.

39 Disorderly behaviour of the soldiers. During this bombardment, not only the greatest part of the effects belonging to the inhabitants were destroyed, but the fortifications were in many places greatly injured; and the worst was, that the remainder were destroyed by the soldiers, who had arrived at such a pitch of licentiousness, that they neither regarded nor would obey their officers. They were incited to this destructive scheme by the avarice of some of the inhabitants who had hoarded up and concealed a quantity of necessary articles, in order to procure an advanced price. They now, therefore, kept no bounds in dissipation, waste, and extravagance; a remarkable instance of which is given by Captain Drinkwater, in their roasting a pig by a fire made of cinnamon. To put a stop to these atrocious proceedings, rigorous measures were of necessity adopted; and it was intimated, that any soldier convicted of being drunk or asleep upon his post, or found marauding, should be immediately executed. The loss of human lives during this dreadful bombardment was less than could have been expected; but many remarkable circumstances are taken notice

braltar. notice of by Captain Drinkwater, some of which are related in the note (B).

By the beginning of June 1781, the enemy had relaxed considerably in their firing, seldom exceeding 600 shot in a day; and continued gradually to diminish this number so remarkably, that towards the end of August, they seldom fired in the day, and only discharged six or seven, and sometimes not above three, shot in the night. The batteries at land, however, were succeeded by the gun-boats; which renewed their attacks every day, keeping the garrison in continual alarm, and never failing to do more or less execution. To restrain them, therefore, a battery of guns capable of throwing their shot to a great distance was erected as near as possible to the enemy; and as it reached their very camp, it was determined to open it upon them as often as the gun boats made their attacks; which being soon perceived, they thought it prudent to desist in some measure from that mode of hostility.

40 e works he ene- brought the ut- st per- tion.

They continued still, however, to improve their works, and for this purpose employed the best engineers both of France and Spain; so that by the latter part of November 1781, they had brought them to such a state of perfection as filled both kingdoms with the most sanguine expectations of success. Governor Elliot, however, far from being dismayed at these formidable bulwarks, suffered them to proceed without molestation to the end of their scheme, that he might as in a moment destroy the labour of so many months, and thus render the disappointment the greater.

Gibraltar.

41 They are entirely destroyed.

In the night of the 27th of November, a chosen party of 2000 men was detached, in order to destroy the enemy's works and batteries; and their success was equal to their most sanguine expectations. They marched out in great order and silence about two o'clock in the morning, under the command of Brigadier General Ross; after which they proceeded with the same circumspection, but with the utmost celerity, to the enemy's works, which they stormed and overthrew with astonishing rapidity. The Spaniards were instantly thrown into confusion, and fled on every side; the guns and mortars on the batteries were all spiked up; and

(B) Two boys belonging to the artificer company were endowed with such wonderful strength of vision, that they could see the shot of the enemy in the air almost as soon as it came from the mouth of the gun; and were therefore constantly placed upon some part of the works to give notice to the soldiers of the approaching danger. During the time of the hottest fire, however, the men were so habituated to the fall of shells and shot around them, that they contracted an insensibility of danger, and almost required to be cautioned by their officers to avoid the explosion of a shell when lying with the fusee burning at their feet. In consequence of this inattention, they frequently neglected the advice of the boys above mentioned, and their neglect could not but be productive of fatal effects. An instance of this happened on the Princess Amelia's battery, where a shot thus disregarded came through one of the capped embrasures, carried off one leg from each of three soldiers, and wounded a fourth in both. In other cases, in which the persons themselves have observed the shot or shells coming towards them, they have been fascinated by its appearance, and unable to move from the spot, as small birds are said to be by the rattlesnake. "This sudden arrest of the faculties (says our author) was nothing uncommon: several instances occurred to my own observation, where men, totally free, have had their senses so engaged by a shell in its descent, that though sensible of their danger, even so far as to cry for assistance, they have been immoveably fixed to the place. But what is more remarkable, these men have so instantaneously recovered themselves on its fall to the ground, as to remove to a place of safety before the shell burst." In this manner Lieutenant Lowe of the 12th regiment was fascinated by a shot which he saw coming, but had not power to remove from the place before it fell upon him and took off his leg.

Where these shells burst they produced instant and certain destruction, mangling in the most dreadful manner. The following are some instances: A matross had the misfortune of breaking his thigh by some accident; and being a man of great spirit, could scarce bear the confinement necessary for its reunion. In consequence of this he went abroad too soon, and thus unfortunately broke the bone a second time. Being now confined to bed, a shell happened to fall into the room where he was, and, rebounding, lodged itself directly upon him. The convalescents and sick instantly summoned all their strength, and crawled out of the room, while the poor matross lay below the shell, kept down by its weight, and utterly unable to stir. In a few seconds it burst, and took off both his legs, and scorched him in a dreadful manner. He survived the explosion, was sensible to the last moment, and died regretting that he had not been killed on the batteries. The case of a soldier of the 73d regiment shows, that even in the most dangerous cases we should never despair of recovery while life remains. This unfortunate man had been knocked down by the wind of a shell, which, instantly bursting, killed his companion, and mangled himself in a shocking manner. His skull was dreadfully fractured, his left arm broken in two places, one of his legs shattered, the skin and muscles torn off from part of his right hand, the middle finger broken to pieces, and his whole body most severely bruised and marked with gunpowder. He presented so horrid an object to the surgeons, that they had not the least hopes of saving his life, and were at a loss what part to attend to first. He was that evening trepanned; a few days afterwards his leg was amputated, and other wounds and fractures were dressed. Being possessed of a most excellent constitution, nature performed wonders in his favour, and in 11 weeks his cure was completely effected. On the 18th of September a shell from the lines fell into a house where the town major, Captain Burke, with Majors Mercier and Vignoles of the 39th regiment were sitting. It took off Major Burke's thigh; afterwards fell through the floor into the cellar: there it burst, and forced the flooring with the unfortunate major up to the ceiling. When assistance came, they found him almost buried in the ruins of the room. He was instantly conveyed to the hospital, where he died soon after the wounded part had been amputated. Majors Mercier and Vignoles

Gibraltar. and the artillerymen, artificers, and sailors, exerted themselves so vigorously, that in the space of an hour the magazines were blown up, the storehouses of arms, ammunition, and military implements of every kind, and all the works that had been constructed, were set on fire, and totally consumed; the whole damage done on this occasion being estimated at upwards of two millions sterling.

For several days after this disaster the Spaniards continued inactive, without even making any attempt to extinguish their batteries, which still continued in flames; but in the beginning of December, as if suddenly aroused from their reverie, upwards of 1000 men were set to work in order to prepare a great number of fascines, from whence it was concluded that they designed to repair their works. In this they proceeded with their usual perseverance and diligence; but as the former methods of attack had constantly failed, it was evident, that if the place could be reduced at all, it must be by some means hitherto unattempted; and for the reduction of this single fortress, the Spanish monarch, after the conquest of Minorca, determined to employ the whole strength of his empire.

42 Floating batteries invented by the chevalier D'Arcon.

Among the various projects formed at this time, that of the chevalier D'Arcon, a French engineer of distinction, proved the most acceptable to the court of Spain; and though the expence attending it was immense, this seemed in the present circumstances to be but a matter of small consideration. His plan was to construct such floating batteries as might neither be liable to be sunk nor set on fire. With this view their bottoms were made of the thickest timber, and their sides of wood and cork long soaked in water, with a layer of wet sand betwixt them. Their thickness was such, that they were impenetrable to cannon shot; and to prevent the effects of red-hot balls, a number of pipes were contrived to carry water through every part of the vessel, and pumps sufficient to furnish a constant supply for the purpose. The people at the batteries were sheltered from the bombs by a rope-netting, made sloping that they might roll off, and spread with wet skins to prevent fire. Ten of these batteries were constructed out of the hulls of large vessels, some of 50 or 60 guns, cut down for that purpose, and carrying from 10 to 28 guns each, with about half as many in reserve in case of accidents. Each gun was served by 36 artillery men; and these floating batteries were to be seconded by 80 large boats carrying guns and mortars of heavy metal; a great number of ships of force and frigates, with some hundreds of small craft, were to accompany them with troops, for the instant execution of what might be judged necessary. On this occasion upwards of 1000 pieces of artillery, and 80,000 barrels of gunpowder were provided. A body of 12,000 of the best troops of France were now added to the Spanish army before the place; the body of engineers was the best that both kingdoms could produce; and numbers of volunteers, of the best families in both, attended the siege. Numbers of military gentlemen also came from every part of Europe to be witnesses of what passed at this celebrated siege, which was now compared to the most famous recorded in history. The conducting of it was committed to the duke de Crillon, who had distinguished himself by the conquest of Minorca. Two princes of the blood royal of France, the count of Artois brother to the king, and the duke of Bourbon his cousin, came to be witnesses of this extraordinary enterprise. These behaved with the greatest politeness both to the governor and garrison. The count of Artois transmitted a packet of letters for various individuals in the garrison, which had been intercepted and carried to Madrid, and which he requested that he might be the means of conveying to those for whom they were designed. Both he and the duke of Bourbon signified to General Elliot the high regard they had for his person and character; and the duke de Crillon himself took this opportunity of expressing the same sentiments, and to entreat him to accept of some refreshments. General Elliot returned a polite answer, but accepted of the present with reluctance, and requested him for the future not to confer any favours of that kind upon him.

43 Prodigious armament brought before the fortress.

Such a prodigious armament raised the confidence of the besiegers so high, that they looked upon the conquest

---

Vignoles had time to escape before the shell burst; nevertheless they were slightly wounded by the splinters, as were a serjeant and his daughter who happened to be in the cellar when the shell entered.

The following are related as instances of very extraordinary escapes from the destructive power of these engines, and which indeed it seems difficult to account for.—A corporal had the muzzle of his firelock closed, and the barrel twisted like a French horn, by a shell, without any injury to his person. A shell happened to fall into a tent where two soldiers were asleep, without awakening them by its fall. A serjeant in an adjacent tent heard it, and ran near 40 yards to a place of safety, when he recollected the situation of his comrades. Thinking the shell had fallen blind, he returned and awakened them; both immediately rose, but continued by the place, debating on the narrow escape they had had, when the shell exploded, and forced them with great violence against a garden wall, but "miraculously" did no further mischief than destroying every thing in the tent. On the new year's day of 1782, an officer of artillery observed a shell falling towards the place where he stood, and got behind a traverse for protection. This he had scarcely done, when the shell fell into the traverse, and instantly entangled him in the rubbish: one of the guards, named *Martin*, observing his distress, generously risked his own life in defence of his officer, and ran to extricate him: but finding his own efforts ineffectual, called for assistance; when another of the guard joining him, they relieved the officer from his situation; and almost at the same instant the shell burst, and levelled the traverse with the ground. Martin was afterwards promoted, and rewarded by the governor; who at the same time told him, that "he should equally have noticed him for attending to his comrade." A shell happening to fall into the room where Ensign Mackenzie of the 73d regiment was sitting, carried away part of his chair, and fell into the room below, where it burst, lifting him and the chair from the floor without further injury.

Gibraltar. conquest of the place as an absolute certainty. They began to be impatient at the delays which arose in bringing matters to the utmost point of perfection; and the commander in chief was thought by far too modest, when he said that the garrison might hold out for a fortnight. "It appeared (says Captain Drinkwater) that they meant, previous to their final efforts, to strike if possible a terror through their opponents, by displaying an armament more powerful than had probably ever been brought before any fortress. Forty-seven sail of the line, including three inferior two-deckers; ten battering ships, deemed perfect in design, and esteemed invincible, carrying 212 guns; innumerable frigates, xebeques, bomb ketches, cutters, gun and mortar boats, and smaller craft for disembarking men, were assembled in the bay. On the land side were most stupendous and strong batteries and works, mounting 200 pieces of heavy ordnance, and protected by an army of near 40,000 men, commanded by a victorious and active general, and animated by the immediate presence of two princes of the blood royal of France, with other dignified personages, and many of their own nobility. In their certainty of success, however, the enemy seemed entirely to have overlooked the nature of that force which was opposed to them; for though the garrison scarcely consisted of more than 7000 effective men, including the marine brigade, they forgot that they were now veterans in this service, had long been habituated to the effects of artillery, and were by degrees prepared for the arduous conflict that awaited them. We were at the same time commanded by officers of approved courage, prudence, and activity; eminent for all the accomplishments of their profession, and in whom we had unbounded confidence. Our spirits too were not a little elevated by the success attending the firing of red-hot shot (c), which in this attack we hoped would enable us to bring our labours to a conclusion, and relieve us from the tedious cruelty of a vexatious blockade."

As a prelude to the dreadful storm which was about to be poured forth on this devoted garrison, the enemy, on the 9th of September 1782, opened a battery of 64 of their largest cannon, which was shortly accompanied with a terrible fire from other batteries, and a great number of mortars. On this and the following day an attack was made upon the batteries erected on Europa Point (so called from being the most southerly point of the continent of Europe), which at that time were entirely under the management of Captain Curtis of the Brilliant frigate, who had distinguished himself during the siege, and now commanded a brigade of seamen by whom the batteries were served. By these the fire of the Spaniards was so warmly returned, that they not only could make no impression, but were forced to retire, after having received so much damage, that two of their principal ships were obliged to withdraw to the bay of Algesiras opposite to Gibraltar, in order to refit. On the 12th the enemy made preparations for the ensuing day, which was allotted for their grand and decisive attack. Accordingly, on the morning of the 13th, the ten floating batteries came forward, under the command of Don Buenventura de Moreno, a Spanish officer of great gallantry, and who had signalized himself at the taking of Minorca. Before ten o'clock they had all got into their proper stations, anchoring in a line about a thousand yards distant from the shore. As soon as they were properly arranged, they began a heavy cannonade, and were seconded by all the cannon and mortars in the enemy's lines and approaches, at the same time that the garrison opened all its batteries both with hot and cold shot from the guns, and shells from the howitzers and mortars. This terrible fire continued on both sides without intermission until noon; when that of the Spaniards began to slacken, and the fire of the garrison to obtain a superiority. About two o'clock the principal battering ship commanded by Don Moreno was observed to emit smoke as if on fire, and some men were seen busy upon the roof searching from whence it proceeded. The fire from the garrison was now kept up without the least discontinuance or diminution, while that from the floating batteries was perceived sensibly to decrease; so that about seven in the evening they fired but few guns, and that only at intervals. At midnight the admiral's ship was plainly seen to burn, and in an hour after was completely in flames. Eight more of these batteries took fire successively; and on the signals of distress made by them, the multitude of feluccas, launches, and boats, with which they were surrounded, all came to their assistance, and began to take the men out of the burning vessels. Captain Curtis, who lay ready with the gunboats to take advantage of any favourable circumstance, came upon them at two in the morning, and forming a line on the enemy's flank, advanced upon them with such order and expedition as to throw them into immediate confusion. At this sudden and unexpected attack they were so astonished and disconcerted, that they fled precipitately with all their boats, totally abandoning the floating batteries to be burnt, and all who were in them to perish in the flames. This would undoubtedly have been their fate, had not Captain Curtis extricated them from the fire at the imminent danger of his own life and that of his men. In this work he was so eager, that while his boat was alongside of one of the largest batteries, it blew up, and the fragments of the wreck spreading all around to a vast distance, some heavy pieces of timber fell into his boat and pierced through its bottom, killing one man and wounding several others. He escaped with difficulty out of this boat, which was sunk, as well as another, by the same accident. The floating batteries were every one consumed; and the violence with which they exploded was such, that doors and windows at a great distance on shore were burst open. About 400 people were saved from them; many of whom were picked up floating on rafts and pieces of timber. Indeed the blowing up of the

Gibraltar.

44 Decisive attack on the 13th of September 1782.

45 Terrible destruction of the Spaniards.

(c) This was suggested by Lieutenant Governor Boyd, and had been attended with remarkable success, September 8th, when the enemy's advanced works were almost destroyed by it.

the batteries as the flames reached their powder rooms, and the discharge of the guns in succession as the metal became heated by the fire, rendered any attempt to save them very dangerous.

46 Inactivity of the combined fleet.

This terrible catastrophe took place in sight of the combined fleets of France and Spain. It had been proposed that they should co-operate upon this important occasion, by attacking the garrison at Europa Point, and such places as appeared most exposed to an attempt by sea. This, it was afterwards said, must have occasioned a material diversion of the garrison's force, and, by dividing it, have weakened considerably the vigorous means of defence used in those parts which were actually attacked. The reason assigned for this inactivity was the want of wind.

47 The blockade continued.

Though this terrible repulse effectually convinced the Spaniards that Gibraltar could not be taken by force, some hope still remained, that, without any further exertions on their part, the garrison would be obliged to surrender from want of ammunition and provisions. With this view they continued to blockade it closely, and to cut off all communication, flattering themselves that Britain would not be able to collect a naval force sufficient to drive their fleet from the bay before the fortress was reduced to extremity; and this they imagined must be the case in a few days. Such diligence, however, had been used on the part of the British, that a fleet was already assembled at Portsmouth, consisting of 35 sail of the line, in excellent condition, and filled with the best officers and sailors in Europe. The command was given to Lord Howe, who was accompanied in the expedition by Admirals Barrington, Milbank, Hood, Sir Richard Hughes, and Commodore Hotham, all of them men eminent in their profession. At the same time also it fortunately happened, that a large British fleet of merchantmen had just arrived in safety from the Baltic; and that a Dutch squadron which had been cruising on their own coasts, not being able to penetrate southwards in order to join the French, had retired into port, and given up the intention of effecting any junction for that season.

At this time the British nation was in the utmost anxiety about the fate of Gibraltar. The progress of the ships was delayed by contrary winds, and it was not until they had gained the southern coast of Portugal that they received information of the defeat of the enemy's attempt on the 13th of September. On the 11th of October, Lord Howe entered the Straits, and several of the store ships destined for Gibraltar came safe to anchor under the cannon of the fort without any molestation from the enemy. The combined fleet in the mean time had been much damaged by a storm; two ships of the line were driven ashore near Algesiras; two more were driven out of the bay into the Mediterranean; others lost their masts, and most of them suffered considerably. One in particular, a ship of 70 guns, was carried by the storm across the bay, and ran aground under the works of Gibraltar, where she was taken by the garrison, with her whole complement of men, consisting of 700. Notwithtanding the endeavours of the enemy to destroy her, she was safely got off, and properly repaired. The combined fleet, however, put to sea on the 13th, with a view to prevent the remaining storeships that had overshot the bay to the east from making good their entrance into it; and at the same time to rejoin the two ships that had been separated from the main body by the storm. Having the advantage of the wind, they bore down upon the British fleet, which drew up in order of battle to receive them; but notwithstanding their superiority, they declined coming to an engagement. On the wind becoming more favourable next day, Lord Howe took the opportunity to bring in the storeships that were in company; and the day following the remainder were conveyed to Gibraltar, the troops for the reinforcement of the garrison were landed, with a large supply of powder, and ample provision in every other respect. As they returned through the Straits they were threatened with an engagement by the combined fleets; but though the latter had a superiority of 12 ships of the line, they kept a wary distance. Some firing indeed took place, but it was attended with little effect on either side.

48 The garrison finally relieved.

This last relief proved entirely decisive; for though the blockade continued till news arrived of the preliminaries of peace being signed, in the beginning of February, 1783, no other attack was made. The news of the pacification was received with the utmost joy by the Spaniards. Mutual civilities passed between the commanders in chief, and the Duke de Crillon paid many handsome compliments to the governor and garrison for their noble defence; declaring that he had exerted himself to the utmost of his abilities, and though he had not proved successful, yet he was happy in having his sovereign's approbation of his conduct.

49 Importance of Gibraltar.

The possession of Gibraltar is esteemed of very great consequence to Britain. It not only gives us the command of the Straits, and their navigation; but affords refreshment and accommodation to our fleets in time of war, and to our merchantmen at all times; which, to a maritime power, is of very great advantage. From its situation, it divides both the kingdoms of France and Spain; that is, it hinders a ready communication by sea between the different parts of these kingdoms. This, of course, hinders the conjunction of their fleets and squadrons with each other, or at least renders it so difficult as to be a perpetual check upon these ambitious powers. It awes also the piratical states of Barbary, and in like manner the emperor of Morocco; insomuch, that our commerce is more safe than that of any other European power, which gives us great advantages in point of freight. It is otherwise highly favourable to our trade in the Mediterranean and Levant. It procures us the respect of the Italian and other powers; who, though far distant from Britain, must consider this as an instance of her power to hurt or assist them. It also saves us the expence of squadrons or convoys, upon any disputes or disturbances that may happen among these powers, and which would otherwise be necessary for the protection of our navigation.

"The form of this mountain is (says Major Imrie) oblong; its summit a sharp craggy ridge; its direction is nearly from north to south; and its greatest length, in that direction, falls very little short of three miles. Its breadth varies with the indentations of the shore, but it nowhere exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are somewhat higher than its centre.

50 Natural history.

"The summit of the Sugar Loaf, which is the point of of its greatest elevation towards the south, is 1439 feet; the Rock Mortar, which is the highest point to the north, is 1350; and the Signal House, which is nearly the central point between these two, is 1276 feet above the level of the sea. The western side of the mountain is a series of rugged slopes, interspersed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-west, where what are called the Lines intervene, and a narrow passage of flat ground that leads to the isthmus, and is entirely covered with fortification. The eastern side of the mountain mostly consists of a range of precipices; but a bank of sand, rising from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its southern extremity falls, in a rapid slope from the summit of the Sugar Loaf, into a rocky flat of considerable extent, called Windmill hill.

"The principal mass of the mountain rock consists of a gray, dense (what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it presents to Spain in a conical form. These beds, or strata, are of various thickness, from 20 to upwards of 40 feet, dipping in a direction from east to west, nearly at an angle of 35 degrees. In some parts of the solid mass of this rock are found testaceous bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not often occur in its composition, and its beds are not separated by any intermediate strata.

"The caves of Gibraltar are many, and some of them of great extent. That which most deserves attention and examination is called St-Michael's Cave, which is situated upon the southern part of the mountain, almost equally distant from the Signal Tower, and the Sugar Loaf. Its entrance is 1000 feet above the level of the sea: This entrance is formed by a rapid slope of earth, which has fallen into it at various periods, and which leads to a spacious hall, incrusted with spar, and apparently supported in the centre by a large massy stalactitical pillar. To this succeeds a long series of caves of difficult access. In these cavernous recesses, the formation and process of stalactites is to be traced, from the flimsy quilt-like cone, suspended from the roof, to the robust trunk of a pillar, three feet in diameter, which rises from the floor, and seems intended by Nature to support the roof from which it originated.

"The only inhabitants of these caves are bats, some of which are of a large size. The soil, in general, upon the mountain of Gibraltar is but thinly sown; and in many parts that thin covering has been washed off by the heavy autumnal rains, which have left the superficies of the rock, for a considerable extent, bare and open to inspection. In those situations, an observing eye may trace the effects of the slow, but constant, decomposition of the rock, caused by its exposure to the air, and the corrosion of sea-salts, which, in the heavy gales of easterly winds, are deposited with the spray on every part of the mountain. Those uncovered parts of the mountain rock also expose to the eye a phenomenon worthy of some attention, as it tends clearly to demonstrate, that, however high the surface of this rock may now be elevated above the level of the sea, it has once been the bed of agitated waters. This phenomenon is to be observed in many parts of the rock, and is constantly found in the beds of torrents. It consists of pot-like holes, of various sizes, hollowed out of the solid rock, and formed apparently by the attrition of gravel or pebbles, set in motion by the rapidity of rivers or currents in the sea.

"Upon the west side of the mountain, towards its base, some strata occur, which are heterogeneal to the mountain rock: the first, or highest, forms the segment of a circle; its convex side is towards the mountain, and it slopes also in that direction. This stratum consists of a number of thin beds; the outward one, being the thinnest, is in a state of decomposition, and is mouldering down into a blackish brown or ferruginous coloured earth. The beds, inferior to this, progressively increase in breadth to 17 inches, where the stratification rests upon a rock of an argillaceous nature.

"This last bed, which is 17 inches thick, consists of quartz of a blackish blue colour, in the septa or cracks of which are found fine quartz crystals, colourless, and perfectly transparent. These crystals are composed of 18 planes, disposed in hexangular columns, terminated at both extremities by hexangular pyramids. The largest of those that Major Imrie saw did not exceed one-fourth of an inch in length: They, in general, adhere to the rock by the sides of the column, but are detached without difficulty. Their great degree of transparency has obtained them the name of *Gibraltar diamonds*.

51 Bones found in fissures of the rock.

"In the perpendicular fissures of the rock, and in some of the caverns of the mountain (all of which afford evident proofs of their former communication with the surface), a calcareous concretion is found, of a reddish brown ferruginous colour, with an earthy fracture, and considerable induration, inclosing the bones of various animals, some of which have the appearance of being human. These bones are of various sizes, and lie in all directions, intermixed with shells of snails, fragments of the calcareous rock, and particles of spar; all of which materials are still to be seen in their natural uncombined states, partially scattered over the surface of the mountain. These have been swept, by heavy rains at different periods, from the surface into the situations above described, and having remained for a long series of years in those places of rest, exposed to the permeating action of water, have become enveloped in, and cemented by, the calcareous matter which it deposits.

"The bones, in this composition, have not the smallest appearance of being petrified; and if they have undergone any change, it is more like that of calcination than that of petrifaction, as the most solid parts of them generally admit of being cut and scraped down with the same ease as chalk.

"Bones combined in such concretions are not peculiar to Gibraltar: they are found in such large quantities in the country of Dalmatia and upon its coasts, in the islands of Cherso and Osero, that some naturalists have been induced to go so far as to assert, that there has been a regular stratum of such matter in that country, and that its present broken and interrupted appearance has been caused by earthquakes, or other convulsions, experienced in that part of the globe. But, of late years, a traveller (Abbé Alberto Fortis) has given a minute description of the concretion in which the bones are found in that country: And by his account it appears, that with regard to situation, composition, and colour, Gibraltar.

colour, it is perfectly similar to that found at Gibraltar. By his description, it also appears that the two mountain rocks of Gibraltar and Dalmatia consist of the same species of calcareous stone; from which it is to be presumed, that the concretions in both have been formed in the same manner and about the same periods.

" Perhaps if the fissures and caves of the rocks of Dalmatia were still more minutely examined, their former communications with the surface might yet be traced, as in those described above; and, in that case, there would be at least a strong probability, that the materials of the concretions of that country have been brought together by the same accidental cause which has probably collected those found in the caverns of Gibraltar. Major Imrie traced, in Gibraltar, this concretion, from the lowest part of a deep perpendicular fissure, up to the surface of the mountain. As it approached to the surface, the concretion became less firmly combined, and, when it had no covering of the calcareous rock, a small degree of adhesion only remained, which was evidently produced by the argillaceous earth, in its composition, having been moistened by rain and baked by the sun.

" The depth at which these materials had been penetrated by that proportion of stalactitical matter, capable of giving to the concretion its greatest adhesion and solidity, he found to vary according to its situation, and to the quantity of matter to be combined. In fissures, narrow and contracted, he found the concretion possessing a great degree of hardness at six feet from the surface; but in other situations more extended, and where a larger quantity of the materials had been accumulated, he found it had not gained its greatest degree of adhesion at double that depth. In one of the caves, where the mass of concretion is of considerable size, he perceived it to be divided into different beds, each bed being covered with a crust of the stalactitical spar, from one inch to an inch and a half in thickness, which seems to indicate, that the materials have been carried in at various periods, and that those periods have been very remote from each other.

" At Rosia bay, upon the west side of Gibraltar, this concretion is found in what has evidently been a cavern, originally formed by huge unshapely masses of the rock which have tumbled in together. The fissure, or cavern, formed by the disruption and subsidence of those masses, has been entirely filled up with the concretion, and is now exposed to full view by the outward mass having dropped down in consequence of the encroachments of the sea. It is to this spot that strangers are generally led to examine the phenomenon; and the composition having here attained to its greatest degree of hardness and solidity, the hasty observer, seeing the bones inclosed in what has so little the appearance of having been a vacuity, examines no further, but immediately adopts the idea of their being incased in the solid rock. The communication from this former chasm, to the surface from which it has received the materials of the concretion, is still to be traced in the face of the rock, but its opening is at present covered by the base of the line wall of the garrison. Here bones are found that are apparently human; and those of them that appear to be of the legs, arms, and vertebræ of the back, are scattered among others of various kinds and sizes, even down to the smallest bones of small birds. Major Imrie found here the complete jaw-bone of a sheep; it contained its full complement of teeth, the enamel of which was perfect, and its whiteness and lustre in no degree impaired. In the hollow parts of some of the large bones was contained a minute crystallization of pure and colourless calcareous spar; but, in most, the interior part consisted of a sparry crust of a reddish colour, scarcely in any degree transparent.

" At the northern extremity of the mountain, the concretion is generally found in perpendicular fissures. The miners there employed upon the fortifications, in excavating one of those fissures, found at a great depth from the surface, two skulls, which were supposed to be human; but, to the Major, one of them, if not both, appeared to be too small for the human species. The bone of each was perfectly firm and solid; from which it is to be presumed, that they were in a state of maturity before they were inclosed in the concretion. Had they appertained to very young children, perhaps the bone would have been more porous, and of a less firm texture. The probability is, that they belonged to a species of monkey, which still continues to inhabit, in considerable numbers, those parts of the rock which are to us inaccessible.

" This concretion varies, in its composition, according to the situation in which it is found. At the extremity of Prince's Lines, high in the rock which looks towards Spain, it is found to consist only of a reddish calcareous earth, and the bones of small birds cemented thereby. The rock around this spot is inhabited by a number of hawks, that, in the breeding season, nestle here and rear their young; the bones in this concretion are probably the remains of the food of those birds. At the base of the rock, below King's Lines, the concretion consists of pebbles of the prevailing calcareous rock. In this concretion, at a very considerable depth under the surface, was found the under parts of a glass bottle, uncommonly shaped, and of great thickness; the colour of the glass of a dark green *."

* *Phil. Trans.* vol. iv. 52

Subterraneous galleries.

" The subterranean galleries are very extensive, pierce the rock in several places and in various directions, and at various degrees of elevation; all of them have a communication with each other, either by flights of steps cut in the rock, or by wooden stairs where the passages are required to be very perpendicular.

" The centinels may now be relieved during a siege from one post to another in perfect safety; whereas, previously to the constructing of these galleries a vast number of men were killed by the Spaniards while marching to their several stations. The width of these galleries is about twelve feet, their height about fourteen. The rock is broken through in various places, both for the purpose of giving light and for placing the guns to bear on the enemy. In different parts there are spacious recesses, capable of accommodating a considerable number of men. To these recesses they give names, such as St Patrick's Chamber, St George's Hall, &c. The whole of these singular structures have been formed out of the solid rock by blasting with gunpowder. Through the politeness of an officer on duty, a place called Smart's Reservoir was opened for our inspection, which is a great curiosity, and not generally permitted to be shewn. It is a spring at a considerable depth in the body of the rock, and is above 700 feet above the level of the sea; we descended into the cavern that contains

Gibraltar, Gibson. tains it by a rope ladder, and with the aid of lighted candles proceeded through a narrow passage over crystallized protuberances of the rock till we came to a hollow, which appears to have been opened by some convulsion of nature. Here, from a bed of gems, arises the salutary fount, clear as the brilliant of the east, and cold as the icicle. We hailed the nymph of the grot, and, prostrating ourselves, quaffed hygean nectar from her sparry urn. When restored to the light of day, we obtained, through the medium of the same gentleman, the key of St George's Hall, at which we arrived by a very intricate and gloomy path to the spacious excavation, which is upwards of a hundred feet in length, its height nearly the same. It is formed in a semicircular part of the rock; spacious apertures are broken through, where cannons of a very large calibre command the isthmus, the Spanish lines, and a great part of the bay. The top of the rock is pierced through, so as to introduce sufficient light to enable you to view every part of it. It appears almost incredible that so large an excavation could be formed by gunpowder, without blowing up the whole of that part of the rock, and still more so, that they should be able to direct the operations of such an instrument, so as to render it subservient to the purpose of elegance. We found in the hall a table, placed, I suppose, for the conveniency of those who are traversing the rock. The cloth was spread, the wine went round, and we made the vaulted roof resound with the accents of mirth and the songs of conviviality *."

* Month. Mag. 1798.

GIBSON, Richard, an English painter, commonly called the *Dwarf*, was originally page to a lady at Mortlake; who, observing that his genius led him to painting, had the generosity to get him instructed in the rudiments of that part. He devoted himself to Sir Peter Lely's manner, and copied his pictures to admiration, especially his portraits: his paintings in water colours were also esteemed. He was in great favour with Charles I. who made him his page of the back stairs; and he had the honour to instruct in drawing Queen Mary and Queen Anne when they were princesses. He married one Mrs Anne Shepherd, who was also a dwarf; on which occasion King Charles I. honoured their marriage with his presence, and gave away the bride. Mr Waller wrote a poem on this occasion, entitled "The Marriage of the Dwarfs;" in which are these lines:

Design or chance makes others wive,
But nature did this match contrive;
Eve might as well have Adam fled,
As she deny'd her little bed
To him for whom heav'n seem'd to frame
And measure out this only dame."

Mr Fenton, in his notes on this poem, observes that he had seen this couple painted by Sir Peter Lely; and that they were of an equal stature, each being three feet ten inches high. They had nine children, five of whom arrived at maturity; these were well proportioned, and of the usual standard of mankind. But what nature denied this couple in stature, she gave them in length of days: for Mr Gibson died in the 75th year of his age; and his wife, having survived him almost 20 years, died in 1709, aged 89.

GIBSON, *Dr Edmund*, bishop of London, was born in Westmoreland, in 1699. He applied himself early and vigorously to learning, and displayed his knowledge in several writings and translations, which recommended him to the patronage of Archbishop Tennison. He was appointed domestic chaplain to his Grace; and we soon after find him rector of Lambeth, and archdeacon of Surry. Becoming thus a member of the convocation, he engaged in a controversy, which was carried on with great warmth by the members of both houses, and defended his patron's rights, as president, in eleven pamphlets; he then formed and completed his more comprehensive scheme of the legal duties and rights of the English clergy, which was at length published under the title of *Codex Juris Ecclesiastici Anglicani*, in folio. Archbishop Tennison dying in 1715, and Dr Wake bishop of Lincoln being made archbishop of Canterbury, Dr Gibson succeeded the latter in the see of Lincoln, and in 1720 was promoted to the bishopric of London. He now not only governed his diocese with the most exact regularity, but by his great care promoted the spiritual affairs of the church of England colonies in the West Indies. He was extremely jealous of the least of the privileges belonging to the church; and therefore, though he approved of the toleration of the Protestant Dissenters, he continually guarded against all the attempts made to procure a repeal of the corporation and test acts; in particular, his opposition to those licentious assemblies called *masquerades*, gave great umbrage at court, and effectually excluded him from all further favours. He spent the latter part of his life in writing and printing pastoral letters, visitation-charges, occasional sermons, and tracts against the prevailing immoralities of the age. His pastoral letters are justly esteemed as the most masterly productions against infidelity and enthusiasm. His most celebrated work, the *Codex*, has been already mentioned. His other publications are, 1. An edition of Drummond's *Polemo Middinia*, and James V. of Scotland's *Cantilena Rustica*, with notes. 2. The *Chronicon Saxonicum*, with a Latin translation, and notes. 3. *Reliquiæ Spelmannianæ*, the posthumous works of Sir Henry Spelman, relating to the laws and antiquities of England. 4. An edition of *Quintilian de Arte Oratoria*, with notes. 5. An English translation of Camden's *Britannia*, with additions, two volumes folio: and, 6. A number of small pieces, that have been collected together and printed in three volumes folio.—His intense application to study impaired his health; notwithstanding which, he attained the age of 79. He expired in September 1748, after an episcopate of near 33 years.—With regard to Bishop Gibson's private life and character, he was in every respect a perfect economist. His abilities were so well adapted to discharge the duties of his sacred function, that during the incapacity of Archbishop Wake, the transaction of ecclesiastical affairs was committed to the bishop of London. He was a true friend to the established church and government, and as great an enemy to persecution. He was usually consulted by the most learned and exalted personages in church and state, and the greatest deference was paid to his judgment. He possessed the social virtues in an eminent degree; his beneficence was very extensive; and he had such generosity,

rosity, that he freely gave two thousand five hundred pounds, left him by Dr Crow, who was once his chaplain, to Crow's own relations, who were very poor.

GIDEON, the son of Joash, of the tribe of Manasseh. He dwelt in the city of Ophrah; and had a very extraordinary call to deliver the Israelites from the oppression of the Midianites, to which they had become subject after the death of Barak and Deborah. Having effected their deliverance by supernatural aid, he was chosen judge of Israel in the year of the world 2759, and died in 2768. (See Judges, chap. vi. vii. and viii.).

GIFT, *Donum*, in *Law*, is a conveyance which passeth either lands or goods; and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken strictly, it is applicable only to lands and tenements given in tail; but *gift* and *grant* are too often confounded.

New Year's GIFTS, presents made on new year's day, as a token of the giver's good will, as well as by way of presage of a happy year.

This practice is very ancient, the origin of it among the Romans being referred to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who having considered as a good omen a present of some sprigs of vervain gathered in a wood consecrated to Strenia the goddess of strength, which he received on the first day of the new year, authorized this custom afterwards, and gave to these presents the name of Strenæ. However this may be, the Romans on that day celebrated a festival in honour of Janus, and paid their respects at the same time to Juno; but they did not pass it in idleness, lest they should become indolent during the rest of the year. They sent presents to one another of figs, dates, honey, &c. to show their friends that they wished them a happy and agreeable life. Clients, that is to say, those who were under the protection of the great, carried presents of this kind to their patrons, adding to them a small piece of silver. Under Augustus, the senate, the knights, and the people, presented such gifts to him, and in his absence deposited them in the Capitol. Of the succeeding princes some adopted this custom, and others abolished it, but it always continued among the people. The early Christians condemned it, because it appeared to be a relick of Paganism, and a species of superstition; but when it began to have no other object than that of being a mark of veneration and esteem, the church ceased to disapprove of it.

GIGG, GIGA, or JIG, in *Music* and *Dancing*, a gay, brisk, sprightly composition, and yet in full measure, as well as the allemand, which is more serious. Menage takes the word to arise from the Italian *gieg*, a musical instrument mentioned by Dante. Others suppose it to be derived from the Teutonic *giga*, or *ghiighe*, "a fiddle." This is a favourite air in most nations of Europe: its characteristic is duple time, marked $\frac{6}{8}$, or $\frac{12}{8}$: it consists of two strains, without any determinate number of bars.

GIGGLEWICK, a town in the west riding of Yorkshire, half a mile from Settle, stands on the river Ribble; where, at the foot of a mountain, is a spring, the most noted in England for ebbing and flowing sometimes thrice in an hour, and the water subsides three quarters of a yard at the reflux, though the sea is 30 miles off. At this town is an eminent free grammar school; and in the neighbourhood are dug up flags, slate, and stone.

GIHON, in *Ancient Geography*, one of the rivers of Paradise; according to Wells, the eastern branch of the Euphrates, into which it divides after its conjunction with the Tigris.

GILAN, or GHILAN, a considerable province of Persia, on the side of the Caspian sea, to the south-west. It is supposed to be the Hyrcania of the ancients. It is very agreeably situated, having the sea on one side and high mountains on the other; and there is no entering in but through narrow passes, which may easily be defended. The sides of the mountains are covered with many sorts of fruit trees, and in the highest parts of them there are deer, bears, wolves, leopards, and tygers; which last the Persians have a method of taming, and hunt with them as we do with dogs. Gilan is one of the most fruitful provinces of Persia, and produces abundance of silk, oil, wine, rice, and tobacco, besides excellent fruits. The inhabitants are brave, and of a better complexion than the other Indians, and the women are accounted extremely handsome. Resht is the capital town.

GILBERT, or GILBERD, *William*, a physician, was born at Colchester in the year 1540, the eldest son of the recorder of that borough. Having spent some time in both universities, he went abroad; and at his return settled in London, where he practised with considerable reputation. He became a member of the College of Physicians, and physician in ordinary to Queen Elizabeth, who, we are told, gave him a pension to encourage him in his studies. From his epitaph it appears that he was also physician to King James I. He died in the year 1603, aged 63; and was buried in Trinity church in Colchester, where a handsome monument was erected to his memory. His books, globes, instruments, and fossils, he bequeathed to the College of Physicians, and his picture to the school gallery at Oxford. He wrote, 1. *De Magnete, magneticisque corporibus, et de magno magnete tellure. physiologia nova;* London 1600, folio. 2. *De mundo nostro sublunari philosophia nova:* Amsterdam 1651, 4to. He was also the inventor of two mathematical instruments for finding the latitude at sea without the help of sun, moon, or stars. A description of these instruments was afterwards published by Thomas Blondeville in his *Theoriques of the Planets.*

GILBERT, *Sir Humphrey*, a brave officer and skilful navigator, was born about the year 1539, in Devonshire, of an ancient and honourable family. Though a second son, he inherited a considerable fortune from his father. He was educated at Eton, and afterwards at Oxford; where probably he did not continue long. It seems he was intended to finish his studies in the Temple; but being introduced at court by his aunt Mrs Catharine Ashley, then in the queen's service, he was diverted from the study of law, and commenced soldier. Having distinguished himself in several military expeditions, particularly that to Newhaven in 1563, he was sent over to Ireland to assist in suppressing a rebellion; where, for his signal services, he was made commander in chief and governor of Munster, and knighted by the lord deputy, Sir Henry Sidney, on the first day of the year 1570. He returned soon after to England, where he married a rich heiress, Nevertheless, in 1572, he sailed with a squadron of nine ships to reinforce Colonel Morgan, who at that time meditated the recovery of Flushing. Probably on his return to England he resumed his cosmographical studies, to which he was naturally inclined: for, in the year 1576, he published his book on the north-west passage to the East Indies; and as Martin Frobisher sailed in the same year, probably it was in consequence of this treatise. In 1578, he obtained from the queen a very ample patent, empowering him to discover and possess in North America any lands then unsettled. He sailed to Newfoundland, but soon returned to England without success; nevertheless, in 1583, he embarked a second time with five ships, the largest of which put back an account of a contagious distemper on board. Our general landed on Newfoundland on the third of August, and on the fifth took possession of the harbour of St John's. By virtue of his patent he granted leases to several people; but though none of them remained there at that time, they settled afterwards in consequence of these leases; so that Sir Humphrey deserves to be remembered as the real founder of the vast American empire. On the 20th of August he put to sea again, on board a small sloop; which on the 29th foundered in a hard gale of wind. Thus perished Sir Humphrey Gilbert; a man of quick parts, a brave soldier, a good mathematician, a skilful navigator, and of a very enterprising genius. We learn also, that he was remarkable for his eloquence, being much admired for his patriotic speeches both in the English and Irish parliaments. He wrote "A discourse to prove a passage by the north-west to Cathaia and the East Indies, printed London 1576." This treatise, which is a masterly performance, is preserved in Hakluyt's Collection of Voyages, vol. iii. p. 11. The style is superior to most, if not to all, the writers of that age; and shows the author to have been a man of considerable reading. He mentions, at the close of this work, another treatise on navigation, which he intended to publish: it is probably lost.

GILBERTINES, an order of religious, thus called from St Gilbert of Sempringham, in the county of Lincoln, who founded the same about the year 1148: the monks of which observed the rule of St Augustine; and were accounted canons; and the nuns that of St Benedict.

The founder of this order erected a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St Gilbert himself founded 13 monasteries of this order, viz. four for men alone, and nine for men and women together, which had in them 700 brethren and 1500 sisters. At the dissolution there were about 25 houses of this order in England and Wales.

GILBOA, in *Ancient Geography*, mountains of Samaria, stretching out from west to east, on the confines of the half tribe of Manasseh, and of the tribe of Issachar, and to the south part of the valley of Jezreel; beginning westward at the city of Jezreel, situated at the foot of these mountains, reaching almost quite to the Jordan, lying at the distance of six miles from Scythopolis. Famous for the death of Saul and his son Jonathan, and the defeat of the Israelites by the Philistines.

GILCHRIST, Dr Ebenezer, an eminent Scots physician, was born at Dumfries in 1707. He began the study of medicine at Edinburgh, which he afterwards prosecuted at London and Paris. He obtained the degree of doctor of medicine from the university of Rheims; and in the year 1732 he returned to the place of his nativity, where he afterwards constantly resided, and continued the practice of medicine till his death. It may with justice be said, that few physicians of the present century have exercised their profession in a manner more respectable or successful than Dr Gilchrist; and few have contributed more to the improvement of the healing art. Having engaged in business at an early period of life, his attention was wholly devoted to observation. Endowed by nature with a judgment acute and solid, and a genus active and inventive, he soon distinguished himself by departing, in various important particulars, from established but unsuccessful modes of practice. Several of the improvements which he introduced have procured him great and deserved reputation both at home and abroad. His practice, in ordinary cases, was allowed to be judicious, and placed him high in the confidence and esteem of the inhabitants of that part of the country where he lived. But his usefulness was not confined to his own neighbourhood. On many occasions he was consulted by letter from the most distant parts of the country. In different collections are to be found several of his performances, which prove that he had something new and useful to offer upon every subject to which he applied himself. But those writings which do him the greatest honour are two long dissertations on Nervous Fevers, in the Medical Essays and Observations published by a Society in Edinburgh; and a treatise on the use of Sea Voyages in Medicine, which first made its appearance in the year 1757, and was afterwards reprinted in 1771. By means of the former, the attention of physicians was first turned to a species of fever which is now found to prevail universally in this country; and the liberal use of wine, which he was the first among the moderns to recommend, has since been adopted in these fevers by the most judicious physicians of the present age, and has probably contributed not a little to the success of their practice. His treatise on Sea Voyages points out their utility in various distempers, and particularly in consumptions; but experience by no means confirms the observation, that there is now a prospect of our being able to employ a remedy in this untractable disease much more efficacious than any hitherto in use. Dr Gilchrist died in 1774.

GILD, or Guild. See Guild.

GILDAS, surnamed *the Wise*, was born in Wales in the year 511. Where he was educated is uncertain; but it appears from his own writings that he was a monk. Some writers say that he went over to Ireland; others, that he visited France and Italy. They agree however in asserting, that after his return to England he became a celebrated and most assiduous preacher of the gospel. Du Pin says he founded a monastery at Venetia in Britain. Gildas is the only British author of the sixth century whose works are printed;

Gildas, Gilding.

printed; they are therefore valuable on account of their antiquity, and as containing the only information we have concerning the times of which he wrote. His History of Britain is, however, a flimsy performance, and his style obscure and inelegant.

GILDING, the art of spreading or covering a thing over with gold, either in leaf or liquid. The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny assures us, that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, gild the very walls, vaults, &c. of their houses.

1 Gilding when first introduced at Rome.

We need not doubt but they had the same method with us, of beating gold, and reducing it into leaves; though it should seem they did not carry it to the same height, if it be true which Pliny relates, that they only made 750 leaves of four fingers square out of a whole ounce. Indeed he adds, that they could make more; that the thickest were called *bracteæ Prænestinæ*, by reason of a statue of the goddess Fortune at Præneste gilt with such leaves; and that the thinner sort was called *bracteæ questoriæ*.

The modern gilders do also make use of gold leaves of divers thicknesses; but there are some so fine, that a thousand do not weigh above four or five drachms. The thickest are used for gilding on iron and other metals; and the thinnest on wood. But we have another advantage over the ancients in the manner of using or applying the gold: the secret of painting in oil, discovered of late ages, furnishes us with means of gilding works that shall endure all the injuries of time and weather, which to the ancients was impracticable.—They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs or size, neither of which will endure the water; so that they could only gild such places as were sheltered from the moisture of the weather.

2 Ancient gilding inferior to the modern.

The Greek called the composition on which they applied their gilding on wood *leucophæum* or *leucophorum*; which is described as a sort of glutinous compound earth, serving in all probability to make the gold stick and bear polishing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed upon.

The lustre and beauty of gold have occasioned several inquiries and discoveries concerning the different methods of applying it to different substances. Hence the art of gilding is very extensive, and contains many particular operations and various management.

3 False gilding with laquer or Dutch leaf.

A colour of gold is given by painting and by varnishes, without employing gold; but this is a false kind of gilding. Thus a very fine golden colour is given to brass and to silver, by applying upon these metals a gold-coloured varnish, which, being transparent, shows all the brilliancy of the metals beneath. Many ornaments of brass were varnished in this manner, which is called *gold laquering*, to distinguish them from those which are really gilt. Silver leaves thus varnished are put upon leather, which is then called *gilt leather*. See Laquer.

Gilding.

Amongst the false gilding may also be reckoned those which are made with thin leaves of copper or brass, called *Dutch leaf*. In this manner are made all the kinds of what is called *gilt paper*.

In the true gilding, gold is applied to the surface of bodies. The gold intended for this purpose ought in general to be beat into thin leaves, or otherwise divided into very fine parts.

4 Gilding with size.

As metals cannot adhere well merely by contact to any but to other metallic substances, when gold is to be applied to the surface of some unmetallic body, that surface must be previously covered with some gluey and tenacious substance by which the gold shall be made to adhere. These substances are in general called *sizes*. Some of these are made of vegetable and animal glues, and others of oily, gluey, and drying matters. Upon them the leaves of gold are applied, and pressed down with a little cotton or a hare's foot; and when the whole is dry, the work is to be finished and polished with a hard instrument, called a *dog's tooth*, to give lustre.

5 With oil.

When the work is required to be capable of resisting rain or moisture, it ought to be previously covered with a composition of drying oil and yellow ochre ground together; otherwise a water size may be used, which is prepared by boiling cuttings of parchment or white leather in water, and by mixing with this some chalk or whiting: several layers of this size must be laid upon the wood, and over these a layer of the same size mixed with yellow ochre. Lastly, Another mixture, called *gold size*, is to be applied above these; upon which the gold leaves are to be fixed. This gold size, the use of which is to make the gold leaf capable of being burnished, is composed of tobacco-pipe clay, ground with some ruddle or black-lead, and tempered with a little tallow or oil of olives. The edges of glasses may be gilt by applying first a very thin coat of varnish, upon which the gold leaf is to be fixed; and when the varnish is hardened, may be burnished. This varnish is prepared by boiling powdered amber with linseed oil in a brass vessel to which a valve is fitted, and by diluting the above solution with four or five times its quantity of oil of turpentine; and that it may dry sooner, it may be ground with some white lead.

6 Of gilding metals.

The method of applying gold upon metals is entirely different. The surface of the metal to be gilt is first to be cleaned; and then leaves are to be applied to it, which, by means of rubbing with a polished bloodstone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver leaf is fixed and burnished upon brass in the making of what is called *French plate*, and sometimes also gold leaf is burnished upon copper and upon iron.

Gold is applied to metals in several other ways. One of these is by previously forming the gold into a paste or amalgam with mercury. In order to obtain a small amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one.

With

Gilding.

With this amalgam the surface of the metal to be gilded is to be covered; then a sufficient heat is to be applied to evaporate the mercury: and the gold is lastly to be burnished with a blood-stone.

This method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam; and is also preferable for its colour, which more resembles that of gold than the colour of copper. When the metal to be gilt is wrought or chased, it ought to be previously covered with quicksilver before the amalgam is applied, that this may be easier spread: but when the surface of the metal is plain, the amalgam may be applied directly to it. The quicksilver or amalgam is made to adhere to the metal by means of a little aquafortis, which is rubbed on the metallic surface at the same time, by which this surface is cleansed from any rust or tarnish which might prevent the union or adhesion of the metals. But the use of the nitrous acid in this operation is not, as is generally supposed, confined merely to cleanse the surface of the metal to be gilt from any rust or tarnish it may have acquired; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam; and when this solution is applied to the copper, this latter metal having a stronger affinity for nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates copper upon its surface from a solution of blue vitriol. When the metal to be gilt is thus covered over with a thin precipitated coat of mercury, it readily receives the amalgam. In this solution and precipitation of mercury, the principal use of the nitrous acid in the process of gilding appears to consist. The amalgam being equally spread over the surface of the metal to be gilt by means of a brush, the mercury is then to be evaporated by a heat just sufficient for that purpose; for if it be too great, part of the gold may also be expelled, and part of it will run together, and leave some of the surface of the metal bare: while the mercury is evaporating, the piece is to be from time to time taken from the fire, that it may be examined, that the amalgam may be spread more equally by means of a brush, that any defective parts of it may be again covered, and that the heat may not be too suddenly applied to it: when the mercury is evaporated, which is known by the surface being entirely become of a dull yellow colour, the metal must then undergo other operations, by which the fine gold colour is given to it. First, The gilded piece of metal is rubbed with a scratch brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called *gilding wax*, and is again exposed to the fire till the wax be burnt off. This wax is composed of bees wax, sometimes mixed with some of the following substances; red ochre, verdigrise, copper scales, alum, vitriol, borax: but according to Dr Lewis, the saline substances alone are sufficient, without any wax. By this operation the colour of the gilding is heightened; and this effect seems to be produced by a perfect dissipation of some mercury remaining after the former operation. This dissipation is well effected by this equable application of heat. The gilt surface is then covered over with a saline composition, consisting of nitre, alum, or other vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of nitre (which is disengaged by the vitriolic acid of the alum, or other vitriolic salt, during the exposure to heat) acting upon any particles of copper which may happen to lie on the gilded surface. Lastly, Some artists think that they give an additional lustre to their gilt work by dipping it in a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter, as the sulphur or turmeric, remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

7 [...]e of the [...]rous acid [...] gilding.

Iron cannot be gilt by amalgamation, unless, as it is said, it be previously coated with copper by dipping in a solution of blue vitriol. Iron may also receive a golden coat from a saturated solution of gold in aqua-regia, mixed with spirit of wine, the iron having a greater affinity with the acid, from which it therefore precipitates the gold. Whether any of these two methods be applicable to use, is uncertain: but the method commonly employed of fixing gold upon iron is that above mentioned, of burnishing gold leaf upon this metal when heated so as to become blue; and the operation will be more perfect if the surface has been previously scratched or graved.

Another method is mentioned by authors of gilding upon metals, and also upon earthen ware, and upon glass; which is, to fuse gold with regulus of antimony, to pulverize the mass which is sufficiently brittle to admit that operation, to spread this powder upon the piece to be gilt, and expose it to such a fire that the regulus may be evaporated, while the gold remains fixed. The inconveniences of this method, according to Dr Lewis, are, that the powder does not adhere to the piece, and cannot be equally spread; that part of the gold is dissipated along with the regulus; that glass is fusible with the heat necessary for the evaporation of regulus of antimony; and that copper is liable to be corroded by the regulus, and to have its surface rendered uneven.

8 Improvement by Dr Lewis. *Phil. Com. of Arts.*

On this subject of gilding by amalgamation Dr Lewis has the following remarks. "There are two principal inconveniences in this business: One, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them: the other, the loss of the mercury; for though part of it is said to be detained in cavities made in the chimney for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might in good measure be avoided, by means of a furnace of a due construction. If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open; the current of air, which otherwise would have entered beneath, Gilding. neath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel and the fumes of such matters as are placed upon it: the back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes and from being incommoded with the heat, and at the same time have full liberty of introducing, inspecting, and removing the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable: the upper end of the chimney may reach above a foot and a half higher than the level of the fire: over this is to be placed a larger tube, leaving an interval of an inch or more all round between it and the chimney, and reaching to the height of 10 or 12 feet, the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which, falling down to the bottom, is there catched in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed, by a pipe at one side, into a proper receiver.

9 M. du Fay's method of raising gold figures.

"Mr Hellot communicates, in the Memoirs of the French Academy for the year 1745, a method of making raised figures of gold on works of gold or silver, found among the papers of M. du Fay, and of which M. du Fay himself had seen several trials. Fine gold in powder, such as results from the parting of gold and silver by aquafortis, is directed to be laid in a heap on a levigating stone, a cavity made in the middle of the heap, and half its weight of pure mercury put into the cavity; some of the fetid spirit obtained from garlic root by distillation in a retort, is then to be added, and the whole immediately mingled and ground with a muller till the mixture is reduced into an uniform gray powder. The powder is to be ground with lemon juice to the consistence of paint, and applied on the piece previonsly well cleaned and rubbed over with the same acid juice; the figures drawn with it may be raised to any degree by repeating the application. The piece is exposed to a gentle fire till the mercury is evaporated so as to leave the gold yellow, which is then to be pressed down, and rubbed with the finger and a little sand, which makes it appear solid and brilliant; after this it may be cut and embellished. The author observes, that being of a spongy texture, it is more advisable to cut it with a chissel than to raise it with a graver; that it has an imperfection of being always pale; and that it would be a desirable thing to find means of giving it colour, as by this method ornaments might be made of exquisite beauty, and with great facility. As the paleness appears to proceed from a part of the mercury retained by the gold, I apprehend it might be remedied by the prudent application of a little warm aquafortis, which dissolving the mercury from the exterior part, would give at least a superficial high colour: if the piece is silver, it must be defended from the aquafortis by covering it with wax. Instruments and ornaments of gold, stained by mercury where the gold is connected with substances incapable of bearing fire, may be restored to their colour by the same means.

"The foregoing process is given entirely on the authority of the French writer. I have had no experience of it myself, but have seen very elegant figures of gold raised upon silver, on the same principle, by a different procedure. Some cinnabar was ground, not with the distilled spirit, but with the expressed juice of garlic, a fluid remarkably tenacious. This mixture was spread all over the polished silver; and when the first layer is dry, a second, and after this a third, was applied. Over these were spread as many layers of another mixture, composed chiefly of asphaltum and linseed oil boiled down to a due consistence. The whole being dried with a gentle heat on a kind of wire grate, the figures were traced and cut down to the silver so as to make its surface rough: the incisions were filled with an amalgam of gold, raised to different heights in different parts according to the nature of the design; after which a gentle fire, at the same time that it evaporated the mercury, destroyed the tenacity of the gummy juice, so that the coating, which served to confine the amalgam, and as a guide in the application of it, was now easily got off. The gold was then pressed down and embellished as in the former method; and had this advantage, that the surface of the silver under it having been made rough, it adhered more firmly, so as not to be in danger of coming off, as M. du Fay says the gold applied in his way sometimes did. The artist, however, found the process so troublesome, that though he purchased the receipt for a considerable sum, he has laid the practice aside."

10 Another method.

Finally, Some metals, particularly silver, may be gilt in the following manner:

11 Easy method of gilding silver.

Let gold be dissolved in aqua-regia. In this solution pieces of linen are to be dipt, and burnt to black ashes. These ashes being rubbed on the surface of the silver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the ashes is to be washed off; and the surface of the silver, which in this state does not seem to be gilt, is to be burnished with a blood-stone, till it acquire a fine colour of gold. This method of gilding is very easy, and consumes a very small quantity of gold. Most gilt ornaments upon fans, snuff boxes, and other toys of much show and little value, are nothing but silver gilt in this manner.

12 Methods of gilding glass.

Gold may also be applied to glass, porcelain, and other vitrified matters. As the surface of these matters is very smooth, and consequently is capable of a very perfect contact with gold leaves, these leaves adhere to them with some force, although they are not of metallic nature. This gilding is so much more perfect, as the gold is more exactly applied to the surface of the glass. The pieces are then to be exposed to a certain degree of heat, and burnished slightly to give them lustre.

A more substantial gilding is fixed upon glass, enamel, and porcelain, by applying to these subtances powder of gold mixed with a solution of gum arabic, or with some essential oil, and a small quantity of borax; after which a sufficient heat is to be applied to soften the glass and the gold, which is then to be burnished. With this mixture any figures may be drawn. The powders for this purpose may be made, 1. By grinding gold leaf with honey, which is afterwards to

Gilding of Gill. to be washed away with water. 2. By distilling to dryness a solution of gold in aqua-regia. 3. By evaporating the mercury from an amalgam of gold, taking care to stir well the mass near the end of the process. 4. By precipitating gold from its solution in aqua-regia, by applying to it a solution of green vitriol in water, or some copper, and perhaps some other metallic substances.

GILEAD, the son of Machir, and grandson of Manasseh, had his inheritance allotted him in the mountains of Gilead, from whence he took his name. The mountains of Gilead were part of that ridge which runs from Mount Lebanon southward, on the east of the Holy Land; gave their name to the whole country which lies on the east of the sea of Galilee, and included the mountainous region called in the New Testament *Trachonitis*. Jeremiah (xxii. 6.) seems to say, that Gilead begins from Mount Libanus. 'Thou art Gilead unto me, and the head of Lebanon.' Jacob, at his return from Mesopotamia, came in six days to the mountains of Gilead (Gen. xxxi. 21. &c.) where this patriarch, with Laban his father-in-law, raised a heap of stones, in memory of their agreement and covenant, and called it *Galeed*, i. e. "an heap of witnesses," and which Laban called *Jegar-sahadutha*. These mountains were covered with a sort of trees abounding with gum, called the *Balm of Gilead*, which the Scripture commends much (Jer. viii. 21. xlvi. 11. li. 8.). The merchants who bought Joseph came from Gilead, and were carrying balm into Egypt, (Gen. xxxvii. 25.).

The Gileadites being invaded by the Ammonites, &c. chose Jephthah for their general, who vanquished all their enemies.

Balm of GILEAD. See AMYRIS, BOTANY *Index*.

GILGAL, in *Ancient Geography*, a place between Jericho and Jordan, noted for the first encampment of the Israelites on this side Jordan, about a mile from Jericho. It sometimes also denotes Galilee, (Joshua xii. 23.).

GILL, JOHN, D. D. a Protestant dissenting minister of the Baptist denomination, and the son of Edward and Elizabeth Gill, was born at Kettering in Northamptonshire, November 23. 1697. At a very early period of life, his father, who was a deacon of the Baptist church at Kettering, discovered in him an uncommon capacity for learning; and his ability for literary pursuits afterwards appeared by the rapid progress in whatever became the object of his study. He was sent to a grammar school in the neighbourhood; where he soon surpassed those boys who were much his seniors in age and as pupils. At this school he continued till he arrived at his 11th year; where he read most of the Latin classics, and made considerable proficiency in the Greek language.

Mr Gill's celebrity as a scholar, and his strong attachment to books, were soon observed by the neighbouring clergy, who frequently met and conversed with him at a bookseller's shop, to which he resorted for the purpose of reading; and indeed such was his application to books, that it became a proverbial saying among the common people, "Such a thing is as certain, as that John Gill is in the bookseller's shop."

He left the grammar school, however, early in life. This was occasioned by the imperious conduct of his master, who insisted that the children of dissenting parents should, with other scholars that belonged to the establishment, attend him to church on week days during the performance of divine service. The dissenters considered this requisition as a stretch of power to which his engagements with them gave no claim; and as it was virtually making conformity a test by which his pupils were to expect the benefits of tuition, they resented his conduct; and the children of those parents that were in affluent circumstances were removed to seminaries where the same advantages might be obtained without being subject to the impositions of clerical bigotry. But as the parents of Mr Gill had it not in their power to confer on him the same privilege, the same steps could not be taken to facilitate his advancement in learning. To pave the way, however, for the completion of his studies, efforts were made by several ministers, of different denominations, to get him upon one or other of the funds in London. For this purpose specimens of his progress in the different branches of literature were transmitted to the metropolis: in answer to which it was objected, "that he was too young, and that should he continue, as it might be expected he would, to make such rapid advances in his studies, he would go through the common circle before he would be capable of taking care of himself, or of being employed in any public service." But these formidable objections were of no weight with our young scholar: his love of learning was unconquerable. Insuperable difficulties, it is true, obstructed the way in which literary eminence is usually acquired; but these difficulties could neither repress his ardent desire of knowledge, nor damp the zeal and application that had marked his former studies. For though his time was daily devoted to the business of his father; yet he had so far improved the hours of leisure, as to be able, before he arrived at his 19th year, to read all the Greek and Latin authors that fell in his way. He studied logic, rhetoric, moral and natural philosophy; and learnt the Hebrew language so as to read it with ease, without any other assistance than Buxtorf's grammar and lexicon.

Neither the pursuit of learning, however, nor the other necessary avocations incumbent on Mr Gill, could eradicate those religious impressions received in early life. On November 1. 1716, he made a public profession of his faith before the Baptist church at Kettering, and was baptized the same day by Mr Thomas Wallis. Of this church Mr Gill had not been long a member before he was called to the work of the ministry: soon after which, he removed to Higham-Ferrers, with a view to pursue his studies under the direction of Mr Davis; but his stay at this place was soon interrupted by an invitation from London in 1719, to preach to the Baptist church in Horslydown, over which he was the same year, being the 22d of his age, ordained pastor; which office he sustained upwards of 51 years.

Mr Gill had not been long in London, before rabbinical learning, of which he had before considerable knowledge, became an object of pursuit. To facilitate his progress through the intricacies of this labyrinth, he contracted an acquaintance with one of the most learned Jewish rabbies. He read the Targums, the Talmuds, the Rabbot, their ancient commentaries, the book Zohar, and whatever else of this kind he was able to procure. Of the oriental languages he made himself

himself a complete master: in short, there was no branch of knowledge that could either enlarge or enrich Biblical learning, which, however difficult, was not attempted and attained: and it may be truly asserted, that in this line he had but few equals, and that the annals of literature do not exhibit a character by whom he was excelled.

In 1748, Mr Gill published a commentary on the New Testament, in three volumes folio. The immense reading and learning discoverable in this arduous work, attracted the attention of the Marischal College and University of Aberdeen; and procured for him, without either his solicitation or his knowledge, a diploma, creating him doctor in divinity. This intelligence was communicated to the doctor in the most handsome terms by the professors Osborn and Pollock; who declared, "that on account of his knowledge of the Scriptures, of the Oriental languages, and of Jewish antiquities, of his learned defence of the Scriptures against Deists and Infidels, and the reputation gained by his other works; the university had, without his privity, unanimously agreed to confer on him the degree of doctor in divinity."

Dr Gill's sentiments, as a divine, were throughout Calvinistic: "And perhaps no man (says the Rev. Mr Toplady, a minister in the church of England) since the days of Austin, has written so largely in defence of the system of grace; and certainly no man has treated that momentous subject in all its branches, more closely, judiciously, and successfully. What was said of Edward the Black Prince, that he never fought a battle which he did not win; what has been remarked of the great duke of Marlborough, that he never undertook a siege which he did not carry; may be justly accommodated to our great philosopher and divine; who, so far as the distinguishing doctrines of the gospel are concerned, never besieged an error which he did not force from its strong holds, nor ever encountered an adversary whom he did not baffle and subdue. His learning and labours, if exceedable, were exceeded only by the invariable sanctity of his life and conversation. From his childhood to his entrance on the ministry, and from his entrance on the ministry to the moment of his dissolution, not one of his most inveterate opposers was ever able to charge him with the least shadow of immorality. Himself, no less than his writings, demonstrated that the doctrine of grace does not lead to licentiousness. Those who had the honour and happiness of being admitted into the number of his friends, can go still farther in their testimony. They know that his moral demeanor was more than blameless: it was from first to last consistently exemplary. And indeed an undeviating consistency, both in his views of evangelical truths, and in his obedience as a servant of God, was one of those qualities by which his cast of character was eminently marked. He was in every respect a burning and a shining light: Burning with love to God, to truth, and to souls; shining as an example to believers, in word, in faith, in purity; a pattern of good works, and a model of all holy conversation and godliness; and while true religion and sound learning have a single friend remaining in the British empire, the works and name of Gill will be precious and revered."

He died at Camberwell, October 14. 1771, aged 73 years 10 months and 10 days. In 1718, the Doctor married Mrs Elizabeth Negus; by whom he had many children, two of whom only survived him. Mrs Gill died in 1764.

His works are, A Commentary on the Old and New Testament in 9 vols folio. A Body of Divinity in 3 vols quarto. The Cause of God and Truth, 4 vols 8vo. A Treatise concerning the Prophecies of the Old Testament respecting the Messiah. A Dissertation on the antiquity of the Hebrew Language, Letters, Vowel Points, and Accents. Sermons on the Canticles, folio; besides a great number of sermons and controversial pieces on different subjects.

GILL, a measure of capacity, containing a quarter of an English pint.

GILLS or BRANCHIÆ of fishes. See ANATOMY *Index*.

GILLINGHAM, a parish in Dorsetshire, on the river Stour, near the forest of its own name; where, anno 1016, King Edmund Ironside vanquished the Danes. It is one of the largest parishes in the county, being 41 miles in circuit, containing 64,000 acres. It lies on the borders of Wilts and Somerset, four miles north-west of Shaftsbury. It has a manufacture of linen, but the chief produce is grazing and the dairies. Near it are the traces of an ancient residence of Norman or Saxon kings, 320 feet long and 240 broad, surrounded by a rampart of earth. Henry I. resided here, and King John repaired it at the expence of the county. Edward I. spent his Christmas here in 1270; but the whole of the materials are removed, and the foundation of the house only can be traced, which was in the form of the letter L, in length 180 feet by 80 broad, and the foot of the letter 48 by 40; the area of the house containing 168,000 square feet. It stood half a mile from the church, on the road to Shaston, encompassed by a moat, now dry, in some places nine feet deep and 20 broad. The rampart appears to have been 30 feet thick. Here is a free school, a large old building, and a workhouse, as well as two stone bridges. In 1694, it received damage of near 4000l. by a fire. Near it is Gillingham forest, four miles long and one mile broad. The church is a large ancient fabric.

GILLINGHAM, a parish of Kent, three miles below Chatham, and on the same side of the Medway. Part of Chatham dock is in this parish; and here is a castle well furnished with guns that commands the river, there being no less than 170 embrasures for cannon; which would stop the progress of any enemy that should happen to make way by Sheerness fort, before they could reach Chatham. Here are also copperas works. At this place 600 Norman gentlemen, who came over in the retinue of the two princes Alfred and Edward, were all barbarously murdered by Earl Godwin. It was in remote times the property of the archbishop of Canterbury, who had here an elegant palace, the old hall of which is now converted into a barn; it is built principally of flint, but the windows are filled up with brick. Near it are the remains of the chapel, &c. and a great part of the whole of its original outer walls may be traced.

GILOLO, a large island of the Pacific ocean, lying between 1° S. Lat. and 2° N. Lat. and between 125° and 128° E. Long. It belongs to the Dutch; but

but does not produce any of the fine spices, though it lies in the neighbourhood of the spice islands. The natives are fierce and cruel savages.

GILPIN, Bernard, rector of Houghton, distinguished by his extraordinary piety and hospitality, was descended from an ancient and honourable family in Westmoreland, and born in 1517. As he was bred in the Catholic religion, so he for some time defended it against the reformers, and at Oxford held a disputation with Hooper, afterward bishop of Worcester and a martyr for the Protestant faith; but was staggered in another disputation with Peter Martyr, and began seriously to examine the contested points by the best authorities. Thus, being presented to the vicarage of Norton in the diocese of Durham, he soon resigned it, and went abroad to consult eminent professors on both sides; and after three years absence returned a little before the death of Queen Mary, satisfied in the general doctrines of the reformation. He was kindly received by his uncle Dr Tonstall, bishop of Durham; who soon after gave him the archdeaconry of Durham, to which the rectory of Effington was annexed. When repairing to his parish, though the persecution was then at its height, he boldly preached against the vices, errors, and corruptions of the times, especially in the clergy, on which a charge consisting of 13 articles was drawn up against him, and presented in form to the bishop. But Dr Tonstall found a method of dismissing the cause in such a manner as to protect his nephew, without endangering himself, and soon after presented him to the rich living of Houghton le Spring. He was a second time accused to the bishop, and again protected; when his enemies, enraged at this second defeat, laid their complaint before Dr Bonner, bishop of London; who immediately gave orders to apprehend him. Upon which Mr Gilpin bravely prepared for martyrdom; and ordering his house steward to provide him a long garment that he might make a decent appearance at the stake, set out for London. Luckily, however, he broke his leg on the journey; which protracted his arrival until the news of the queen's death freed him from all further apprehensions. Being immediately set at liberty, he returned to Houghton, where he was received by his parishioners with the sincerest joy.

Upon the deprivation of the Popish bishops, he was offered the see of Carlisle, which he declined; and confining his attention to his rectory, discharged all the duties of his function in the most exemplary manner. To the greatest humanity and courtesy, he added an unwearied application to the instruction of those under his care. He was not satisfied with the advice he gave in public, but used to instruct in private; and brought his parishioners to come to him with their doubts and difficulties. He had a most engaging manner towards those whom he thought well disposed: nay, his very reproof was so conducted, that it seldom gave offence; the becoming gentleness with which it was urged made it always appear the effect of friendship. Thus, with unceasing assiduity, did he employ himself in admonishing the vicious, and engaging the well-intentioned; by which means, in a few years, he made a greater change in his neighbourhood than could well have been imagined. A remarkable instance, what reformation a single man may effect, when he hath it earnestly at heart!

But his hopes were not so much in the present generation, as in the succeeding. It was an easier task, he found, to prevent vice, than to correct it; to form the young to virtue, than to amend the bad habits of the old. He employed much of his time, therefore, in endeavouring to improve the minds of the younger part of his parish; suffering none to grow up in an ignorance of their duty; but pressing it as the wisest part to mix religion with their labour, and amidst the cares of this life to have a constant eye upon the next. He attended to every thing which might be of service to his parishioners. He was very assiduous in preventing all law suits among them. His hall is said to have been often thronged with people, who came to him about their differences. He was not indeed much acquainted with law; but he could decide equitably, and that satisfied: nor could his sovereign's commission have given him more weight than his own character gave him.

His hospitable manner of living was the admiration of the whole country. He spent in his family every fortnight 40 bushels of corn, 20 bushels of malt, and a whole ox; besides a proportionable quantity of other kinds of provision. Strangers and travellers found a cheerful reception. All were welcome that came; and even their beasts had so much care taken of them, that it was humorously said, "If a horse was turned loose in any part of the country, it would immediately make its way to the rector of Houghton's."

Every Sunday, from Michaelmas till Easter, was a sort of public day with him. During this season he expected to see all his parishioners and their families. For their reception, he had three tables well covered; the first was for gentlemen, the second for husbandmen and farmers, and the third for day labourers. This piece of hospitality he never omitted, even when losses, or a scarcity of provision, made its continuance rather difficult to him. He thought it his duty, and that was a deciding motive. Even when he was absent from home, no alteration was made in his family expences; the poor were fed as usual, and his neighbours entertained.

But notwithstanding all his painful industry, and the large scope it had in so extended a parish, Mr Gilpin thought the sphere of his benevolence yet too confined. It grieved him extremely to see everywhere, in the parishes around him, so great a degree of ignorance and superstition, occasioned by the shameful neglect of the pastoral care in the clergy of those parts. These bad consequences induced him to supply, as far as he could, what was wanting in others. For this purpose, every year he used regularly to visit the most neglected parishes in Northumberland, Yorkshire, Cheshire, Westmoreland, and Cumberland; and that his own parish in the mean time might not suffer, he was at the expence of a constant assistant. In each place he staid two or three days; and his method was, to call the people about him, and lay before them, in as plain a way as possible, the danger of leading wicked or even careless lives; explaining to them the nature of true religion; instructing them in the duties they owed to God, their neighbour, and themselves; and showing them how greatly a moral and religious conduct would contribute to their present as well as future happiness.

As Mr Gilpin had all the warmth of an enthusiast, though

Gilpin.

though under the direction of a very calm and sober judgment, he never wanted an audience, even in the wildest parts; where he roused many to a sense of religion, who had contracted the most inveterate habits of inattention to every thing of a serious nature. And wherever he came, he used to visit all the gaols and places of confinement; few in the kingdom having at that time any appointed minister. And by his labours, and affectionate manner of behaving, he is said to have reformed many very abandoned persons in those places. He would employ his interest likewise for such criminals whose cases he thought attended with any hard circumstances, and often procured pardons for them.

There is a tract of country upon the border of Northumberland, called *Reads-dale* and *Tine-dale*, of all barbarous places in the north at that time the most barbarous. Before the Union, this place was called the *debateable land*, as subject by turns to England and Scotland, and the common theatre where the two nations were continually acting their bloody scenes. It was inhabited by a kind of desperate banditti, rendered fierce and active by constant alarms: they lived by theft, used to plunder on both sides of the barrier; and what they plundered on one, they exposed to sale on the other; by that means escaping justice. And in this dreadful country, where no man would even travel that could help it, Mr Gilpin never failed to spend some part of every year.

He generally chose the Christmas holidays for his journey, because he found the people at that season most disengaged, and most easily assembled. He had set places for preaching, which were as regularly attended as the assize towns of a circuit. If he came where there was a church, he made use of it: if not, of barns, or any other large building; where great crowds of people were sure to attend him, some for his instructions, and others for his charity. This was a very difficult and laborious employment. The country was so poor, that what provision he could get, extreme hunger only could make palatable. The inclemency of the weather, and the badness of the roads through a mountainous country, and at that season covered with snow, exposed him likewise often to great hardships. Sometimes he was overtaken by the night, the country being in many places desolate for several miles together, and obliged to lodge out in the cold. At such times, we are told, he would make his servant ride about with his horses, whilst himself on foot used as much exercise at his age and the fatigues of the preceding day would permit. All this he cheerfully underwent; esteeming such services well compensated by the advantages which he hoped might accrue from them to his uninstructed fellow creatures.

The disinterested pains he took among these barbarous people, and the good offices he was always ready to do them, drew from them the warmest and sincerest expressions of gratitude. Indeed he was little less than adored among them, and might have brought the whole country almost to what he pleased. One instance that is related, shows how greatly he was revered. By the carelessness of his servants, his horses were one day stolen. The news was quickly propagated, and every one expressed the highest indignation at the fact. The thief was rejoicing over his prize, when, by the report of the country, he found whose horses he had taken. Terrified at what he had done, he instantly came trembling back, confessed the fact, returned the horses, and declared he believed the devil would have seized him directly, had he carried them off knowing them to have been Mr Gilpin's.

Gilpin.

We have already taken notice of Mr Gilpin's uncommonly generous and hospitable manner of living. The value of his rectory was about 400l. a year: an income, indeed, at that time very considerable, but yet in appearance very disproportionate to the generous things he did: indeed, he could not have done them, unless his frugality had been equal to his generosity. His friends, therefore, could not but wonder to find him, amidst his many great and continual expences, entertain the design of building and endowing a grammar school; a design, however, which his exact economy soon enabled him to accomplish, though the expence of it amounted to upwards of 500l. His school was no sooner opened, than it began to flourish; and there was so great a resort of young people to it, that in a little time the town was not able to accommodate them. He put himself, therefore, to the inconvenience of fitting up a part of his own house for that purpose, where he seldom had fewer than 20 or 30 children. Some of these were the sons of persons of distinction, whom he boarded at easy rates: but the greater part were poor children, whom he not only educated, but clothed and maintained: he was at the expence likewise of boarding in the town many other poor children. He used to bring several every year from the different parts where he preached, particularly Reads-dale and Tine-dale; which places he was at great pains in civilizing, and contributed not a little towards rooting out that barbarism which every year prevailed less among them.

As to his school, he not only placed able masters in it, whom he procured from Oxford, but himself likewise constantly inspected it. And, that encouragement might quicken the application of his boys, he always took particular notice of the most forward: he would call them *his own scholars*, and would send for them often into his study, and there instruct them himself. One method used by him to fill his school was a little singular. Whenever he met a poor boy upon the road, he would make trial of his capacity by a few questions, and if he found it such as pleased him, he would provide for his education. And besides those whom he sent from his own school to the universities, and there wholly maintained, he would likewise give to others, who were in circumstances to do something for themselves, what farther assistance they needed. By which means he induced many parents to allow their children a liberal education, who would otherwise not have done it. And Mr Gilpin did not think it enough to afford the means only of an academical education to these young people, but endeavoured to make it as beneficial to them as he could. He still considered himself as their proper guardian; and seemed to think himself bound to the public for their being made useful members of it, as far as it lay in his power to make them so. With this view he held a punctual correspondence with their tutors; and made the youths themselves frequently write to him, and give him an account of their studies. So solicitous indeed was he

about

about them, knowing the many temptations to which their age and situation exposed them, that once every other year he generally made a journey to the universities to inspect their behaviour. And this uncommon care was not unrewarded; for many of his scholars became ornaments to the church, and exemplary instances of piety.

To the account that hath been already given of Mr Gilpin's hospitality and benevolence, the following particulars may be added. Every Thursday throughout the year, a very large quantity of meat was dressed wholly for the poor; and every day they had what quantity of broth they wanted. Twenty-four of the poorest were his constant pensioners. Four times in the year a dinner was provided for them; when they received from his steward a certain quantity of corn, and a sum of money: and at Christmas they had always an ox divided among them.

Whenever he heard of any in distress, whether of his own parish or any other, he was sure to relieve them. In his walks abroad, he would frequently bring home with him poor people, and send them away clothed as well as fed. He took great pains to inform himself of the circumstances of his neighbours, that the modesty of the sufferer might not prevent his relief. But the money best laid out was, in his opinion, that which encouraged industry. It was one of his greatest pleasures to make up the losses of his laborious neighbours, and prevent their sinking under them. If a poor man had lost a beast, he would send him another in its room: or if any farmer had had a bad year, he would make him an abatement in his tythes. Thus, as far as he was able, he took the misfortunes of his parish upon himself; and, like a true shepherd, exposed himself for his flock. But of all kinds of industrious poor, he was most forward to assist those who had large families; such never failed to meet with his bounty, when they wanted to settle their children in the world.

In the distant parishes where he preached, as well as in his own neighbourhood, his generosity and benevolence were continually showing themselves; particularly in the desolate parts of Northumberland. "When he began his journey," says an old manuscript life of him, "he would have 10 pounds in his purse; and, at his coming home, he would be 20 nobles in debt, which he would always pay within a fortnight after." In the gaols he visited, he was not only careful to give the prisoners proper instructions, but used to purchase for them likewise what necessaries they wanted.

Even upon the public road, he never let slip an opportunity of doing good. He has often been known to take off his cloak, and give it to a half-naked traveller: and when he has had scarce money enough in his pocket to provide himself a dinner, yet would he give away part of that little, or the whole, if he found any who seemed to stand in need of it. Of this benevolent temper, the following instance is preserved. One day returning home he saw in a field several people crowding together; and judging something more than ordinary had happened, he rode up, and found that one of the horses in a team had suddenly dropped down, which they were endeavouring to raise; but in vain, for the horse was dead. The owner of it seemed much dejected with his misfortune; and declaring how grievous a loss it would be to him, Mr Gilpin bade him not be disheartened: "I'll let you have (says he), honest man, that horse of mine," and pointed to his servant's.—"Ah! master (replied the countryman), my pocket will not reach such a beast as that." "Come, come (said Mr Gilpin), take him, take him; and when I demand my money, then thou shalt pay me."

This worthy and excellent divine, who merited and obtained the glorious titles of *the Father of the Poor*, and the *Apostle of the North*, died in 1583, in the 66th year of his age.

GILTHEAD. See SPARUS, ICHTHYOLOGY *Index*.

GIN. See GENEVA.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved that goes over the wheel at the top: one end of this rope is seized to an iron monkey, that hooks to a beetle, of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground: then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GINGER, the root of a species of amomum. See AMOMUM, BOTANY *Index*.

GINGIDIUM, a genus of plants, belonging to the pentandria class. See BOTANY *Index*.

GINGIRO, or ZINDERO, a small territory of Africa, to the south of Abyssinia; being separated from it by the river Zebee, by which it is also almost entirely surrounded. This river is extremely large, having more water than the Nile, and being much more rapid; so that, during the rainy season, it would be altogether impassable, were it not for the large rocks which are in its channel. The extreme difficulty which occurs in passing this river, however, is the means of preserving the kingdom of Gingiro, which would otherwise be conquered in a single season by the Galla.

The most remarkable particular with regard to this kingdom is, that the sovereign is a professed votary of the devil. "This superstition (says Mr Bruce) reaches down all the western side of the continent on the Atlantic ocean, in the countries of Congo, Angola, and Benin. In spite of the firmest foundation in true philosophy, a traveller, who decides from the information and investigation of facts, will find it very difficult to treat these appearances as absolute fictions, or as owing to the superiority of cunning of one man in overreaching another. For my own part, I confess, I am equally at a loss to assign reasons for disbelieving the fiction on which their pretensions to some preternatural information are founded, as to account for them by the operation of ordinary causes."

In this kingdom every thing is conducted, or pretended to be conducted, by magic; and all those slaves, which in other African countries are sold to Europeans, are here sacrificed to the devil, human blood being a necessary part in all their accursed solemnities. "How far (says Mr Bruce) this reaches to the southward, I do not know; but I look upon this to be the geographical bounds of the reign of the devil

devil on the north side of the equator in the peninsula of Africa."

With regard to this country, very little farther is known, than some of the customs of the people transiently picked up by the Jesuit missionaries in Abyssinia. From them we learn, that the kingdom is hereditary in one family, though it does not regularly descend to the eldest son, the king being chosen by the nobles; in which they resemble their neighbours the Abyssinians. When the king dies, his body is wrapped in a fine cloth, and a cow is killed. The body so wrapped up is next enclosed in the cow's skin; and all the princes of the royal family fly and hide themselves in the bushes, while those who are intrusted with the election enter the thickets, beating about everywhere as if for game. At last a bird of prey, called in their language *liber*, appears, and hovers over the person destined to be king; crying and making a great noise without quitting his station. By this means the person destined to be elected is found out, surrounded, as is reported, by lions, tigers, panthers, and other wild beasts; all which are supposed to be brought by the power of magic or of the devil.—After the king is found, he flies upon those who came in quest of him with great fury, killing and wounding as many as he can reach, until at last he is dragged to the throne whether he will or not. One particular family have the privilege of conducting him to the throne; and if they should not happen to find him at first, they have a right to take him out of the hands of those who did so; and thus another battle ensues before the vacant throne can be filled. Lastly, Before he enters his palace, two men must be killed; one at the foot of a tree by which the house is supported; and the other at the threshold of the door, which is besmeared with the blood of the victim. It is the particular privilege of one family to afford these victims; and so far are they from seeking to avoid this fate, that they glory in the occasion, and willingly offer themselves to meet it. This last particular, Mr Bruce says, he had in Abyssinia from people coming from Gingiro.

GINGIVÆ, the gums. See GUMS.

GINGLYMUS, in *Anatomy*, one of the species of articulation. It is that jointure of the bones where each bone mutually receives the other; so that each bone both receives and is received. See ANATOMY *Index*.

GINKGO, the MAIDEN-HAIR TREE. See MAURITIA, BOTANY *Index*.

GINORA, a genus of plants belonging to the dodecandria class, and in the natural method ranking with those of which the order is doubtful. See BOTANY *Index*.

GINSENG. See PANAX, BOTANY and MATERIA MEDICA *Index*.

GIOIA, FLAVIO, of Amalfi, in the kingdom of Naples, the celebrated mathematician; who, from his knowledge of the magnetic powers, invented the mariner's compass, by which the navigation of the Europeans was extended to the most distant regions of the globe: before this invention, navigation was confined to coasting. The king of Naples being a younger branch of the royal family of France, he marked the north point with a fleur-de-lis, in compliment to that country. It is said the Chinese knew the compass long before; be this as it may, the Europeans are indebted to Gioia for this invaluable discovery. He flourished A. D. 1300.

GIORDANA, LUCA. See JORDANO.

GIORGIONE, so called from his comely aspect, was an illustrious Venetian painter, born in 1478. He received his first instructions from Giovanni Bellino; but studying afterwards the works of Leonardo da Vinci, he soon surpassed them both, being the first among the Lombards who found out the admirable effects of strong lights and shadows. Titian became his rival in this art; and was so careful in copying the life, that he excelled Giorgione in discovering the delicacies of nature, by tempering the boldness of his colouring. The most valuable piece of Giorgione in oil is that of Christ carrying his cross, now in the church of San Rovo in Venice; where it is held in great veneration. He died of the plague young, in 1511.

GIRAFFE. See CERVUS, MAMMALIA *Index*.

GIRALD, BARRY, or *Giraldus Cambrensis*. See BARRY.

GIRALDI, LILIO GREGORIO, an ingenious critic, and one of the most learned men that modern Italy has produced, was born at Ferrara in 1479. He was at Rome when it was plundered by the emperor Charles V.; and having thus lost all he had, and being tormented by the gout, he struggled through life with ill fortune and ill health. He wrote, neverthless, 17 performances, which were collected and published at Basil in 2 vols. folio in 1580, and at Leyden in 1696. Authors of the first rank have bestowed the highest eulogies on Giraldus; particularly Casaubon and Thuanus.

GIRALDI, *John Baptist Cintio*, an Italian poet of the same family with the foregoing Lilio, was born in 1504. He was secretary to the duke of Ferrara, and afterwards became professor of rhetoric at Pavia. He died in 1573. His works, which consist chiefly of tragedies, were collected and published at Venice by his son Celso Giraldi, in 1583; and some scruple not to rank him among the best tragic writers Italy has produced.

GIRARDON, FRANCIS, a celebrated French architect and sculptor, born at Troyes in 1627. Louis XIV. being informed of his great talents, sent him to Rome with a pension of 1000 crowns. At his return into France, he laboured for the royal palaces and the gardens of Versailles and Trianon; where there are many of his works executed in bronze and in marble, from the designs of Charles le Brun. The mausoleum of Cardinal de Richelieu, in the Sorbonne, and the equestrian statue of Louis XIV. at the Place de Vendome, where the statue and horse are cast in one piece, pass for his most excellent performances. Girardon was professor, rector, and chancellor, of the Academy of Painting and Sculpture; and had the post of inspector general of all the works done in sculpture. He died in 1715.

GIRDERS, in *Architecture*, the largest pieces of timber in a floor. Their ends are usually fastened into the summers, or brest summers; and the joists are framed at one end to the girders.

By the statute for rebuilding London, no girder is to to be less than ten inches into the wall, and their ends to be always laid in loam, &c.

GIRDLE (*Cingulus* or *Zona*), a belt or band of leather or other matter, tied about the reins, to keep that part more firm and tight.

It was anciently the custom for bankrupts and other insolvent debtors to put off and surrender their girdle in open court. The reason of this was, that our ancestors used to carry all their necessary utensils, as purse, keys, &c. tied to the girdle; whence the girdle became a symbol of the state. History relates that the widow of Philip I. duke of Burgundy, renounced her right of succession by putting off her girdle upon the duke's tomb.

The Romans always wore a girdle to tuck up the tunica when they had occasion to do any thing: this custom was so general, that such as went without girdles, and let their gowns hang loose, were reputed idle dissolute persons.

Maiden's or *Virgin's* GIRDLE. It was a custom among the Greeks and Romans for the husband to untie his bride's girdle. Homer, lib. xi. of his Odyssey, calls the girdle παρθενιην ζωνην, *maid's girdle*. Festus relates, that it was made of sheep's wool, and that the husband untied it in bed; he adds, that it was tied in the Herculanean knot; and that the husband unloosed it, as a happy presage of his having as many children as Hercules, who at his death left seventy behind him.

The poets attribute to Venus a particular kind of girdle called *cestus*, to which they annexed a faculty of inspiring the passion of love.

GIRGASHITES, or GERGESENES, an ancient people of the land of Canaan, whose habitation was beyond the sea of Tiberias, where we find some footsteps of their name in the city of *Gergesa*, upon the lake of Tiberias. The Jewish doctors inform us, that when Joshua first came into the land of Canaan, the Girgashites took a resolution rather to forsake their country than submit to the Hebrews, and accordingly retired into Africa. Nevertheless, it is certain that a good number of them staid behind, since Joshua (xxiv. 11.) informs us that he subdued the Girgashites, and they whom he overcame were certainly on this side Jordan.

GIRGENTI, a town of Sicily, which occupies part of the site of the ancient *Agrigentum*. It has only one street fit for carriages. It is inhabited by 15,000 persons; but has no remarkable buildings or works of art that deserve mention: the only antiquities to be seen were a Latin inscription of the time of the Antonines, as is pretended, relative to some association between Agrigentum and Lilybæum; and a piece of ancient masonry in the foundations of a church pretended to be the remains of a temple of Jupiter. At some distance, on the old ground in the vale, stands the cathedral, a clumsy building patched up by barbarous architects with various discordant parts. This church is enriched with no works of modern painters or sculptors that claim any title to praise, but the baptismal font is made out of an ancient sarcophagus faced with very beautiful basso relievos. This see is the richest in Sicily, but has the character of being less enlightened and polished than the rest of the island. Among the curiosities belonging to the cathedral is an Etruscan vase of rare size and preservation. There are also some golden pateras of extreme rarity. The monastery of San Nicolo stands on a little eminence in the centre of the old city, admirably situated. The range of hills towards the south-east sinks gradually, so as to admit a noble reach of sea and of plain, terminated on each side by thick groves of fruit trees. Above appear the remains of ancient grandeur, wonderfully contrasted with the humble straw cottages built at their feet. In the orchard of this convent is a square building with pilasters, which is supposed to have been part of the palace of the Roman prætor.

Girgenti has the convenience of a port; for which, however, it is less indebted to its natural situation than to the recent assistance of art. The harbour is formed by means of a pier carried out in three sides of an octagon, with a battery at the head; the lighthouse is to be erected on the cliffs on shore, as there is no possibility of raising it high enough on the mole without danger of sinking. The work is admirable as to strength and neatness, but the intention of creating a safe and complete haven has not been fully answered; the Sirocco commands it entirely, and drives in great quantities of sand, which it is feared will in time choke up the port; even now ships of burden find it difficult to get in, but the Caricatore is considerable, and the magazines in the rocks along the shore are very spacious.

GIRONNE, or GIRONNY, in *Heraldry*, a coat of arms divided into girons, or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GIRT, the situation of a ship which is moored so strait by her cables, extending from the *hawse* to two distant anchors, as to be prevented from swinging or turning about according to any change of the wind or tide, to the current of which her head would otherwise be directed. The cables are extended in this manner, by a strong application of mechanical powers within the ship; so that when she veers, or endeavours to swing about, her side bears upon one of the cables, which catches on her heel, and interrupts her in the act of traversing. In this position she must ride with her broadside to the wind or current, till one or both of the cables are slackened.

GISCO, son of Himilco the Carthaginian general, was banished from Carthage by the influence of his enemies. Being afterwards recalled, he was made general in Sicily against the Corinthians, about 309 years before the Christian era, and by his success and intrepidity he obliged the enemies of his country to sue for peace. See CARTHAGE.

GISBOROUGH, a town of England, in the west riding of Yorkshire, on the road from Whitby to Durham, 224 miles from London, and four miles from the mouth of the Tees, where is a bay and harbour for ships. It had formerly an abbey, which was once the common burial place of the nobility of these parts, and its church by the ruins seems to have been equal to the best cathedrals in England. The soil, besides its fertility in pasture and a constant verdure adorned with plenty of field flowers almost all the year, has earths of sundry colours, some iron, and mines of alum, which were first discovered in the reign of King James I. and have been since very much improved. Sir Paul

Pindar, who first farmed them, paid rents to the king 12,500l. to the Earl Musgrave 1640l. and to Sir William Penniman 600l. and had moreover 800 men by sea and land in constant pay; yet he was a considerable gainer, because there was then scarce any other to be had, and the price was 26l. a ton; but now there are several other alum works in this county, which have taken a great part of the trade from hence; so that the works here have for some years lain neglected. Population 1834 in 1811.

GITTITH, a Hebrew word occurring frequently in the Psalms, and generally translated *wine presses.* The conjectures of interpreters are various concerning this word. Some think it signifies a sort of musical instrument; others, that the psalms with this title were sung after the vintage; lastly, others, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion, that it was given to the class of young women or songstresses of Gath to be sung by them, Psal. viii. 1. lxxxi. 1. lxxxiv. 1. Dr Hammond thinks that the psalms with this title were all set to the same tune, and made on Goliath the Gittite.

GIULA, a strong town of Upper Hungary, on the frontiers of Transylvania. It was taken by the Turks in 1566, and retaken by the Imperialists in 1596. It is seated on the river Keresblan, in E. Long. 21. 1. N. Lat. 46. 25.

GIUSTANDEL, a large and strong town of Turkey in Europe, and in Macedonia, with a Greek archbishop's see. It is seated near the lake Ochrida, in E. Long. 20. 50. N. Lat. 41. 10.

GLACIERS, a name given to some very extensive fields of ice among the ALPS. Mr Coxe observes of these mountains in general, that they are composed of many parallel chains, the highest of which occupy the centre, and the others gradually diminish in proportion as we recede from thence. The central chain appears covers with pointed rocks; all parts of which, that are not absolutely perpendicular, lie hid under perpetual snow and ice even in summer. On each side of this ridge are fertile and cultivated valleys, interspersed with numerous villages, and watered by numerous streams. The elevated peaks of the central chain are covered with snow: but their declivities, excepting those that are extremely steep, have all a covering of ice as well as snow; the intermediate parts being filled with vast fields of ice, terminating in the cultivated valleys above mentioned. The same phenomena, though on a smaller scale, occur in those chains that are at a distance from the principal one: In those which are most remote, no ice, and scarcely any snow, is observed, unless upon some of the most elevated summits; and the mountains diminishing in height and ruggedness, appear covered with verdure, until at last they terminate in small hills and plains.

Thus the glaciers may be divided into two sorts; one occupying the deep valleys situated in the bosom of the Alps, and distinguished by the name of Ice valleys; the others are those which clothe the declivities and sides of the mountains. These two kinds of glaciers are distinguished by Mr Coxe into the upper and lower glaciers.

The lower glaciers are by far the most considerable; some of them extending several leagues in length. They do not communicate with each other, as has been generally supposed, few of them being parallel to the central chain; but, stretching mostly in a transverse direction, are bordered at the higher extremity by inaccessible rocks, and at the lower extending into the cultivated valleys. The thickness of the ice varies in different parts. In the glacier des Bois, which extends more than 15 miles in length, and upwards of three in breadth, M. Saussure found it generally from 80 to 100 feet; but he was credibly informed, that in some places it was not less than 600 feet, and even more. These vast masses of ice usually rest on an inclined plane; where, being pushed forward by their own weight, and but weakly supported by the rugged rocks beneath them, they are intersected by large crevices, and have an appearance of walls, pyramids, &c. according to the position of the eye in viewing them. In those parts, however, where they lie upon even ground, or such as has only a gentle inclination, the surface of the ice is nearly uniform, the crevices being few and narrow, and the glacier being crossed by travellers on foot without any difficulty. The surface of the ice is rough and granulated, so that people may walk upon it, excepting such places as have a steep descent. It is opaque, full of small bubbles about the size of a pea, very porous, and greatly resembles a mixture of snow and water congealed. A vast quantity of stones and earth falls down from the mountains upon the glaciers, and are by them thrown off on each side according to the descent of the ice, as will be afterwards explained. The place on which these rest is more hard and elevated than the rest of the ice, and is very difficult to walk upon; the earth is likewise laid upon them in such regular heaps, that it appears to have been done by art. This collection of earths and stones is termed by the natives the *Moraine.*

Mr Coxe, who visited the glacier des Bois, informs us, that the appearance of it at a distance was so tremendous, that it seemed impracticable to cross it. Numerous and broad chasms intersected it in every direction; but entering upon it, the company found that courage and activity were only required to accomplish the task. They had large nails in their shoes, and spiked sticks; which on this occasion were found to be particularly serviceable. Having passed the moraine, and descended upon the glacier itself, they found the ice softened by a warm wind which rendered it less slippery than usual. Having walked across it for about a quarter of an hour, they came again to the moraine, along which they continued their journey for half an hour, and then entered upon the great body of the glacier. "Here (says Mr Coxe) it was curious to observe the numerous little rills produced by the collection of drops occasioned by the thawing of the ice on the upper part of the glacier: these little rills hollow out small channels, and, torrent-like, precipitate themselves into the chasms, with a violent noise, increasing the body of waters formed by the melting of the interior surface, and finding an outlet under the immense arch of ice in the valley of Chamouni, from which the Arveron rushes." As our traveller proceeded on his journey, he was surprised by the noise of a large fragment of rock which had detached itself from one of the highest needles, and bounded from one precipice to another with great rapidity; but before it reached the plain, it was almost reduced to dust. "Having proceeded about an hour (says

Glaciers. (says he) we were astonished with a view more magnificent than imagination can conceive: hitherto the glaciers had scarcely answered my expectations, but now they far surpassed them. Nature had clad herself in all her terrors. Before us was a valley of ice 20 miles in extent, bounded by a circular glacier of pure unbroken snow, named Takul, which leads directly to the foot of Mount Blanc, and is surrounded by large conical rocks, terminating in sharp points like the towers on an ancient fortification; to the right rose a range of magnificent peaks, the intervals filled with glaciers; and far above the rest, the magnificent summit of Mount Blanc, his highest point obscured with clouds. He appeared of such immense magnitude, that, at his presence, the circumjacent mountains, however gigantic, seemed to shrink before him, and *hide their diminished heads.* In half an hour we arrived at the moraine, which forms a boundary of the valley, crossed it, and proceeded upou a body of ice about three quarters of a mile broad. Here the ice was more even and free from chasms than in the great valley. We then passed a second moraine, and beyond that another mass of ice to a third moraine: descending from thence we came upon the last ridge of ice, broader considerably than the two former, and full of large chasms: it separated from the rock only by a very narrow moraine. These moraines contain great quantities of crystal."

They continued to ascend the valley of ice, the scene constantly increasing in magnificence and horror; and having walked about five miles on the ice, they arrived at last at the foot of the eminence named *Couvercle*, where they were obliged to quit the ice. The doing this was extremely dangerous, and at one place very tremendous. It was a bulging smooth rock, with a precipice of considerable depth terminated by a vast crevice in the ice, which seemed to stop all further progress; a small hollow in the middle, however, afforded room for one foot; and having fixed this, they sprung over to the other side, being helped and directed by the guides who went over first. Having gained the top of the Couvercle, they had a view of three of the glaciers, viz. that of *Talefre* to the left *l'Echaut*, in front, and *Takul* on the right; all uniting in that great one called the *Glacier de Bois*. The Couvercle itself is a most extraordinary rock, having the appearance of a large irregular building with many sides; the substance of which is granite. Having reached the top, they were surprised with a thunder storm, from which they took shelter under an impending rock. The view was exceedingly magnificent; the glaciers appearing like a rugged expanse of frozen sea bounded by gigantic rocks, and terminated by Mount Blanc. A single rock appeared of a triangular figure covered with Alpine plants; and which by reason of its contrast with the rugged and snowy mountains in the neighbourhood, has obtained the name of the *Garden*. During this, as well as other excursions among the Alps, Mr Coxe had occasion to observe that the colour of the sky was of a much deeper blue than in the lower regions.

The upper glaciers may be subdivided into those which cover the summits, and those which extend along the sides of the Alps. Those on the very summit, however, though they have the appearance of ice, are not so in reality, but consist entirely of snow hardened by the extreme cold. M. Saussure found that which covered the top of Mount Blanc to be penetrable, though with difficulty, by a stick; but below this hard crust was a soft snow without coherence. The sides are covered with a mixture of ice and snow; by reason of the superior power of the summer sun to dissolve the snow, which afterwards congeals into hard ice.

Glaciers.

Several conjectures have been made concerning the formation of these extraordinary bodies of ice. Mr Coxe agrees with M. Gruner in opinion, that they are produced by the continual dissolution of the snow in summer, and its congelation by the succeeding frosts. Hence, on the snmmits of the mountains where the sun has very little power, the glacier is soft, and contains no ice: as we descend the mountains the consistence becomes firmer, because there is a considerable mixture of snow water, the congelation of which augments the hardness; and in the valleys, the glacier is hardest of all, because the portion of water is there much superior to that of the snow. Hence it seems plain that the glaciers derive their origin from the melting of the snow on the upper parts of the mountains, and the congelation of the water as it advauces: and to this cause M. Saussure adds the quantity of snow which often rolls down into the valleys, and congeals along with the water just mentioned.

Another question concerning the glaciers naturally occurs, namely, Whether they are to be considered as in a state of increase or diminution? Mr Coxe is of opinion, that they occasionally increase and decrease; in proof of which he adduces the following observation: "The borders of the glacier of Montanvert are mostly skirted with trees: towards its base a vast arch of ice rises to near 100 feet in height; under which the river Arveron rushes with considerable force, and in a large body of water. As we approached the ice, we passed through a wood of firs: those trees which stand at a little distance from the arch are about 80 feet high, and are undoubtedly of a very great age. Between these and the glacier the trees are of a later growth; as is evident from their texture and inferior size. Others, still smaller, have been overturned and enveloped in the ice: there seems to be a kind of regular gradation in the age of these several trees, from the largest which are standing to the smallest that lie prostrate."—Hence our author concludes, that the glacier once extended as far as the row of small firs; but that upon its gradual dissolution, a number of trees shot up on the spot it had occupied; since which time the ice has again advanced, and overturned the last grown trees before they had attained to any considerable height.—This he thinks also confirmed by the following fact.—"Large stones of granite are usually found at a small distance from the extremities of the glacier. These stones have certainly fallen from the mountains upon the ice; have been carried on in its progress; and have tumbled into the plain upon the dissolution or sinking of the ice which supported them. These stones, which the natives call *Moraine*, form a kind of border towards the foot of the valley of ice, and have been pushed forward by the glacier in its advances: they extend even to the place occupied by the larger pines."

In opposition to those who maintain that there is a constant accumulation of ice and snow in the Alpine regions, our author makes the following remarks: 1. Between the years 1776 and 1785 the glacier of

 Grindelevald

Grindelevald had diminished to such a degree, that the spot which its extremity occupied in the former year, was at least 400 paces from that occupied by it in the latter. 2. In the year 1785 the Murailles de Glace, which in 1776 he had described as forming the border of the glacier of Bosson no longer existed; and young trees had shot up in the parts which were then covered by the glacier of Montanvert. Still, however, it may be urged, that these changes only take place in the valleys where the power of the sun is considerable; and that from thence we cannot form any adequate idea of what passes in the more elevated regions, where in all probability more snow falls than can be dissolved. In support of this opinion, it is alleged, that the cold produced by the mass of ice already formed ought to augment it still more; and that within the memory of the present generation, many places have been covered with ice which were not so before. To these arguments, however, Mr Coxe replies, that the causes, which diminish the ice in the upper regions, are no less powerful than the cold which tends to augment it. These are, 1. Rain or sleet; which falling upon the lower glaciers, thaw the ice, increase the rills on its surface, excavate channels, and in many ways tend to diminish its quantity. 2. Evaporation, which takes place even from the surface of the ice itself, acts still more powerfully; and its action is not confined to any particular season. 3. The falling of the snow and ice; both that which comes gradually from the clouds; and that which descends from the mountains in great masses, called by the natives *avalanches*. When these last fall down into milder regions, though sometimes they may resist the influence of the sun and form ice valleys, yet they generally dissolve. They are most common in the upper glaciers, though sometimes they descend upon the lower, while the gradual descent of snow from the clouds, which chiefly takes place in the lower, contributes very much to lessen the mass. 4. All the lower glaciers or valleys of ice rest on an inclined plane, are hollow, and undermined by torrents which are constantly flowing from the upper glaciers, as well as from their own lowermost surface. Their foundation being thus constantly diminishing, the lower glaciers are carried imperceptibly forward into the cultivated fields, where an end is necessarily put to their progress by the heat of the sun. Hence we may see the reason of that strange phenomenon taken notice of by Mr Coxe, that with one hand he could touch ripe corn, and with the other solid ice. This descent of the glacier is demonstrable from the trees overturned by it, and the moraine always observed at the bottom of the lower glaciers. 5. The heat of the sun is an evident cause of the diminution of the glaciers. To this Mr Coxe adds another cause less generally known, viz. the warm winds which blow by night as well as by day both in the upper and lower glaciers. "These warm winds (says he) are during summer so common in those parts, that I never crossed a glacier without feeling in some particular positions a warmth similar to the air of a hot bath." 6. Another cause is the mean temperature of the earth itself; which, where it is not exposed to the piercing cold of the atmosphere, is found to have a temperature always above the freezing point. As the vast thickness of the superincumbent ice, therefore, is in the present case abundantly sufficient to prevent the access of the atmosphere, it is plain that the lower surface of it must, by being in contact with the earth, continually decay.—With regard to the other argument drawn from the known increase of the ice in some places, Mr Coxe does not deny it; but insists, that there is no continual increase of the whole, but that if it increases in some places, it diminishes in others; and his opinion in this respect was confirmed by those who frequent the mountains.

GLACIS, in building, an easy insensible slope or declivity.

The descent of the glacis is less steep than that of the talus. In gardening, a descent sometimes begins in talus, and ends in glacis.

The glacis of the corniche, is an easy imperceptible slope in the cymatium, to promote the descent and draining off the rain water.

Glacis, in *Fortification*, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign or field.

GLADE, in *Gardening* and *Agriculture*, an opening and light passage made through a wood, by lopping off the branches or trees along that way.

GLADIATORS, in antiquity, persons who fought, generally in the arena at Rome, for the entertainment of the people,

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like our prize-fighters, for a livelihood.

The Romans borrowed this cruel diversion from the Asiatics: some suppose that there was policy in the practice, the frequent combats of gladiators tending to accustom the people to despise dangers and death.

The origin of such combats seems to be as follows: From the earliest times with which we have any acquaintance in profane history, it had been the custom to sacrifice captives, or prisoners of war, to the manes of the great men who had died in the engagement; thus Achilles, in the Iliad, lib. xxiii. sacrifices twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81. Æneas sends captives to Evander, to be sacrificed at the funeral of his son Pallas.

In course of time they came also to sacrifice slaves at the funerals of all persons of condition: this was even esteemed a necessary part of the ceremony; but as it would have appeared barbarous to have massacred them like beasts, they were appointed to fight with each other, and endeavour to save their own lives by killing their adversary. This seemed somewhat less inhuman, because there was a possibility of avoiding death, by an exertion of skill and courage.

This occasioned the profession of gladiator to become an art: hence arose masters of the art, and men learned to fight and exercise. These masters, whom the Latins called *lanistæ*, bought them slaves to be trained up to this cruel trade, whom they afterwards sold to such as had occasion to present the people with so horrible a show.

These exhibitions were at first performed near the sepulchre of the deceased, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amusements.

The first show of gladiators, called *munus gladiatorium*, was exhibited at Rome, according to Valerius Maximus, by

Gladiators.

by M. and D. Brutus, upon the death of their father, in the year of the city 490. On this occasion there were probably only three pair of gladiators. In 537 the three sons of M. Æmilius Lepidus the augur, who had been three times consul, entertained the people with the cruel pleasure of seeing 22 gladiators fight in the forum. In 547, the first Africanus diverted his army at New Carthage with a show of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In process of time, the Romans became so fond of these bloody entertainments, that not only the heir of any great and rich citizen lately deceased, but all the principal magistrates, presented the people with shows of this nature, to procure their affection. The ædiles, prætors, consuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights: and the priests were sometimes the exhibitors of the barbarous shows; for we meet with the *ludi pontificales* in Suetonius, August. cap. 44. and with the *ludi sacerdotales*, in Pliny, Epist. lib. vii. As for the emperors, it was so much their interest to ingratiate themselves with the populace, that they obliged them with combats of gladiators almost upon all occasions; and as these increased, the number of combatants increased likewise. Accordingly, Julius Cæsar, in his ædileship, diverted the people with 320 couple. Titus exhibited a show of gladiators, wild beasts, and representations of sea fights, which lasted 100 days; and Trajan continued a solemnity of this nature for 123 days; during which time he brought out 1000 pair of gladiators. Before this time, under the republic, the number of gladiators was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dispersed into the garrisons and secured, lest they should have joined the disaffected party. See GLADIATORS *War*.

These sports were become so common, and their consequences in a variety of respects so dangerous, that Cicero preferred a law that no person should exhibit a show of gladiators within two years before he appeared candidate for any office. Julius Cæsar ordered, that only a certain number of men of this profession should be in Rome at a time; Augustus decreed, that only two shows of gladiators should be presented in a year, and never above sixty couple of combatants in a show; and Tiberius provided by an order of senate, that no person should have the privilege of gratifying the people with such a solemnity unless he was worth 400,000 sesterces. They were also considerably regulated by Nerva.

The emperor Claudius restrained them to certain occasions; but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure as usual; and some carried the brutal satisfaction so far as to have them at their ordinary feasts. And not slaves only, but other persons, would hire themselves to this infamous office.

The master of the gladiators made them all first swear that they would fight to death; and, if they failed, they were put to death either by fire, or swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or to ask for death or seek to avoid it when overcome; but it was usual for the emperor or the people to grant them life when they gave no signs of fear, but waited the fatal stroke with courage and intrepidity: Augustus even decreed that it should always be granted them.

From slaves and freemen the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict that none of the senatorian order should become gladiators; and soon after he laid the same constraint on the knights: nevertheless Nero is related to have brought upwards of 400 senators and 600 Roman knights upon the arena; though Lipsius takes both these numbers to be falsified, and not without reason reduces them to 40 senators and 60 knights: yet Domitian, that other monster of cruelty, refined upon Nero, exhibiting combats of women in the night time.

Constantine the Great is said to have first prohibited the combats of gladiators in the East. At least he forbade those who were condemned to death for their crimes to be employed; there being an order still extant to the *præfectus prætorii* rather to send them to work in the mines in lieu thereof; it is dated at Berytus in Phœnicia, the first of October 325.

The emperor Honorius forbade them at Rome on occasion of the death of Telemachus, who coming out of the East into Rome at the time of one of these spectacles, went down into the arena, and used all his endeavours to prevent the gladiators from continuing the sport; upon which the spectators of that carnage, fired with anger, stoned him to death. It must be observed, however, that the practice was not entirely abolished, in the West before Theodoric king of the Ostrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 500, abolished them finally.

Some time before the day of combat, the person who presented the people with the shows gave them notice thereof by programmas or bills, containing the names of the gladiators, and the marks whereby they were to be distinguished: for each had his several badge; which was most commonly a peacock's feather, as appears from the scholiast of Juvenal on the 158th verse of the third satire, and Turnebus Advers. lib. ii. cap. 8. They also gave notice how long the shows would last, and how many couples of gladiators there were; and it even appears, from the 52d verse of the seventh satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practised among us by those who have any thing to show at fairs.

The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves or wooden foils, called *rudes;* and the second were effective weapons, as swords, poniards, &c. The first were called *arma lusoria*, or *exercitoria;* the second *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second at the sound of the trumpets, with which they fought naked. Then they were said *vertere arma*. The terms of striking were *petere et repetere;* of avoiding a blow, *exire;* and

and when one of the combatants received a remarkable wound, his adversary or the people cried out, *Habet*, or *Hoc habet.* The first part of the engagement was called *ventilare, prœludere;* and the second *dimicare ad certum*, or *versis armis pugnare:* and some authors think, with much probability, that it is to these two kinds of combat that St Paul alludes in the passage 1 Cor. ix. 26, 27. "I fight not as one that beateth the air; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life; it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant the boon. The reward of the conqueror was a branch of palm tree, and a sum of money, probably collected among the spectators: sometimes they gave him his congé, or dismissed him by putting one of the wooden foils or *rudes* in his hand; and sometimes they even gave him his freedom, putting the pilæus on his head. The sign or indication, whereby the spectators showed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and so holding the two thumbs upright close together; and, when they would have the combat finished and the vanquished slain, *verterunt pollicem*, they bent back the thumb; which we learn from Juvenal, Sat. iii. ver. 36. The gladiators challenged or defied each other, by showing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Victi ostensam digiti veniam à populo postulabant*, says the old scholiast on Persius.

There were various kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. as, The *andabatœ*, mentioned under ANDABATÆ. The *catervarii*, who always fought in troops or companies, number against number; or, according to others, who fought promiscuously, without any certain order. The *dimachœ*, who fought armed with two poniards or swords, or with sword and dagger. The *essedarii*, who fought in cars. The *fiscales*, or *Cæsariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for, and therefore named also *postulatitii.* Several other kinds are mentioned in the ancient authors.

GLADIATORS *War* (*bellum Gladiatorium* or *Spartacum*), called also the *servile war*, was a war which the Romans sustained about the year of their city 680. Spartacus, Crinus, and Oenomaus, having escaped, with other gladiators to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman prætors. At length they were defeated in the year 862, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans. Crassus was not able to finish it: the great Pompey was forced to be sent as general.

The Dying GLADIATOR, a most valuable monument of ancient sculpture, which is now preserved in the palace of Chighi. This man, when he had received the mortal stroke, is particularly careful *ut procumbat honestè*, "that he might fall honourably." He is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm: and in his expiring moments it is plainly seen, that he does not abandon himself to grief and dejection; but is solicitous to maintain that firmness of aspect which the gladiators valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any tokens of fear by his countenance, nor to shed one tear: *quis mediocris gladiator ingemuit, quis vultum mutavit unquam, quis non modo stetit, verum etiam decubit turpiter*, says Cicero, in that part of his Tusculan where he is describing the astonishing firmness of those persons. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live; and we view him with attention, that we may see him expire and fall: thus the ancients knew how to animate marble, and give it almost every expression of life.

GLADIOLUS, CORN FLAG, a genus of plants belonging to the triandria class, and in the natural method ranking under the sixth order, *Ensatœ.* See BOTANY *Index*.

GLAIR of eggs, is the same as the white of eggs, and is used as a varnish for preserving paintings. For this purpose it is beat to an unctuous consistence, and commonly mixed with a little brandy or spirit of wine, to make it work more freely, and with a lump of sugar to give it body and prevent its cracking: and then spread over the picture or painting with a brush.

GLAMORGANSHIRE, a county of South Wales, said to have derived its name from a contraction of the Welsh words *Gwald Morgan*, or "the county of Morgan," and supposed to have been thus called from a prince of this part of the country, said to have been killed 800 years before the birth of our Saviour: but some other writers derive the name from the word *Mor*, which in the British tongue signifies the *sea;* this being a maritime county. It is bounded on the south and part of the west, by Bristol channel; on the north-west, by Caermarthenshire; on the north by Brecknockshire; and on the east, by Monmouthshire. It extends 48 miles in length from east to west, 27 in breadth from north to south, and is 116 in circumference. It is divided into 10 hundreds, in which are one city, 7 market towns, 118 parishes, 17,758 houses, and, in 1811, 85,067 inhabitants. It is in the diocese of Llandaff. This county, in the time of the Romans, was part of the district inhabited by the Silures, and had several Roman stations. Thus Boverton, a few miles to the south of Cowbridge, is supposed to be the Bovium of Antoninus: Neath to be his Nidum; and Loghor, to the west of Swansey, to be his Leucarum. The principal rivers of this county are the Rhymny, the Taff, the Ogmore, the Avon, the Cledaugh, and the Tave. The air, in the south part, towards the sea, is temperate and healthful; but the northern part, which is mountainous, is cold and piercing, full of thick woods, extremely barren, and thin of inhabitants. The mountains, however, serve to feed herds of cattle, and send forth streams which add greatly to the fertility of the other parts of the county:

Glamorganshire ‖ Glaris.

county: they have likewise coal and lead ore. The south part is so remarkably fertile, pleasant, and populous, that it is generally styled the garden of Wales; but it has no manufacture. This county was formerly full of castles, most of which are now fallen to decay. It has many small harbours on the coast for exporting coals and provisions. Of the former it sends large quantities both to England and Ireland; but of the latter, to England almost solely, especially butter. It sends two members to parliament, one for the shire, and one for the borough of Cardiff the capital. See GLAMORGANSHIRE, SUPPLEMENT.

GLAMOUR, or GLAMER, an old term of popular superstition in Scotland, denoting a kind of magical mist believed to be raised by sorcerers, and which deluded their spectators with visions of things which had no real existence, altered the appearance of those which really did exist, &c.—The eastern nations have a similar superstition, as we may learn from the Arabian Nights Entertainments and other works of oriental fiction.

GLAND, in *Anatomy*. See ANATOMY *Index*.

GLANDERS. See FARRIERY *Index*.

GLANDORE, a town of Ireland, situated in the county of Cork and province of Munster, near the harbour of that name.

GLANDORE Harbour, situated two leagues west of the Galley-head in the county of Cork, province of Munster, N. Lat. 51. 22. W. Long. 8. 56. Between this harbour and Ross the coast continues high and bold, with only two small coves; that to the east called *Millcove*, and that to the west *Cowcove*. This harbour lies three miles west of Ross; and though small, is an exceeding good one; near it is a castle of the same name, and on the upper end is a deep and dangerous glin, called the *Leap*. Glandore gives title of earl to the family of Crosbie.

GLANDULÆ RENALES. See ANATOMY *Index*.

GLANS, in *Anatomy*, the tip or button of the penis, or that part covered with the prepuce, called also *balanus*. See ANATOMY *Index*.

GLANS is also used to denote the tip or extremity of the clitoris, from its resemblance, both in form and use, to that of the penis. See ANATOMY *Index*.

GLANVIL, JOSEPH, a learned and ingenious, but fanciful and credulous, writer in the 17th century, was born at Plymouth in 1636, and bred at Oxford. He became a great admirer of Mr Baxter, and a zealous person for a commonwealth. After the Restoration, he published The Vanity of Dogmatizing; was chosen a fellow of the Royal Society; and, taking orders in 1662, was presented to the vicarage of Frome-Selwood in Somersetshire. The same year he published his *Lux Orientalis*: in 1665, his *Scepsis Scientifica*; and in the year following, Some Philosophical Considerations touching the being of Witches and Witchcraft, and other pieces on the same subject. In 1660, he published *Plus ultra*; or, The Progress and Advancement of Knowledge since the Days of Aristotle. He likewise published A seasonable Recommendation and Defence of Reason; and *Philosophia Pia*, or A Discourse of the Religious Temper and Tendencies of the Experimental Philosophy. In 1678 he was made a prebendary of Worcester, and died in 1680.

GLARIS, one of the cantons of Swisserland, is bounded on the east, partly by the Grisons, and partly by the territory of Sargans; on the north, by the bailiwick of Gaster, and by the lake Wahlestatt; on the east, by the canton of Schwits; and on the south, by part of the canton of Uri, and part of the league of the Grisons. It is a mountainous country, and contains about 20,000 inhabitants.

Glaris, Glasgow.

GLARIS, a town of Swisserland, capital of the canton of the same name, is seated in a plain, at the foot of high craggy mountains. The streets are large, and the houses kept in good repair. It has some public buildings; among which are two churches, one in the middle of the town, and the other without upon an eminence. In this eminence there is a cavern, with grotesque figures formed by the water that drops therein. The general assemblies of the country were formerly held on the first Sundays in May, where all the males above the age of sixteen were obliged to appear. Both the Calvinists and the Roman Catholics are tolerated in this town, and they have divine service by turns in the same church. It is seated on the river Lint, E. Long. 9. 13. N. Lat. 47. 6. Population about 2500.

GLASGOW, a large city of Lanerkshire or Clydesdale in Scotland, situated in W. Long. 4. 16. N. Lat. 55. 52.

Concerning the foundation of this city we have no authentic records. The word in the Gaelic language signifies a *gray smith*; from whence it has been inferred, that some spot in the most ancient part of the city was originally the residence of some blacksmith who had become eminent in his profession, so that the place went by his name.

1
Bishopric of Glasgow, when founded.

In the year 560, a bishopric is said to have been founded here by Saint Mungo, or Kentigern, supposed to be the son of Thamates, daughter of Loth king of the Picts; but in what state the town at that time was, is altogether uncertain. Most probably the priests and disciples who attended St Kentigern would contribute considerably towards its advancement; the aged and infirm, who were unfit for the purposes of war, or such as were religiously inclined, would come and settle round the habitation of the holy man, in order to have the benefit of his prayers; and as a number of miracles were said to have been wrought at his tomb, the same causes would still contribute to the increase of the town.

History has not informed us of the name of the prince who founded and endowed the bishopric of Glasgow in favour of St Kentigern. But from an abstract of the life of Kentigern (contained in Mr Innes's Critical Essay on the Ancient Inhabitants of Scotland), which was written in the 12th century, we learn, that the saint being ill used by Marken or Marcus, one of the kings of the Britons, retired into Wales. On the invitation of Roderic, however, one of Marken's successors, he returned to Glasgow, and enjoyed the see till 601, when he died. He was buried in the church of Glasgow, where his monument is still to be seen; and we find him marked among the saints in the Roman kalendar, January 13. 577.

The immediate successors of Kentigern were Baldrede and Conwal. The first established a religious house at Inchinnan; the second went into Lothian to preach to the Saxons; and both of them are ranked as saints in the Roman kalendar, Baldrede on the 6th of March

March 608, and Conwal on the 18th of May 612. From this time, however, till the 1115, we have no distinct accounts concerning the city or bishopric of Glasgow. We find then, that David I. king of Scotland made an attempt to retrieve the people from a state of gross barbarity into which they were fallen, and restored to the church those lands of which she had been robbed. The only account we have of the transactions with regard to Glasgow, during that period, is in the inquisition made by David concerning the church lands of Glasgow, and is as follows.—"This church, by the divine appointment, admitted St Kentigern into the bishopric, who furnished large draughts of knowledge to those thirsting after heavenly things, &c. But a fraudulent destroyer, employing his common wiles, brought in, after a long series of time, unaccountable scandals into the Cumbrian church. For after St Kentigern and many of his successors were removed to heaven, various disturbances everywhere arising, not only destroyed the church and her possessions, but, wasting the whole country, drove the inhabitants into exile. These good men being destroyed, various tribes of different nations flocking in from several quarters, possessed the foresaid deserted country; but being of different origins, and varying from each other in their language and customs, and not easily agreeing among themselves, they followed the manners of the Gentiles, rather than those of the true faith. The inhabitants of which unhappy and abandoned country, though living like brutes, the Lord, who chooses that none should perish, vouchsafed to visit in mercy," &c.

2
Barbarity of the people in the time of David I.

From the year 1116 to the Reformation, the records of the bishopric are tolerably complete. The most remarkable particulars furnished by them are the following.

In 1136, John Achaius, chosen bishop of Glasgow by David I. built and adorned a part of the cathedral, which he solemnly consecrated on the 9th of July. The king was present at the ceremony; and bestowed on the church the lands of Perdeyk, now Patrick. This prelate also divided the diocese into the two archdeanries of Glasgow and Teviotdale; and established the offices of dean, subdean, chancellor, treasurer, sacrist, chantor, and successor; and settled a prebendary upon each of them, out of the donatives he received from the king.

In 1174, Joceline, abbot of Melrose, was elected bishop, and consecrated by Eskilus, bishop of Lunden in Denmark, the pope's legate for that kingdom, on the 1st of June 1175. He rebuilt the cathedral, or rather made an addition to the church already built by John Achaius. He also procured a charter from William king of Scotland, erecting Glasgow into a royal borough, and likewise a charter for a fair to be held there annually for eight days.

3
Glasgow erected into a royal borough.

In 1335, John Lindsay, bishop of Glasgow, was killed in an engagement at sea with the English, as he was returning home from Flanders. His successor, William Rae, built the stone bridge over the Clyde. In the time of Matthew Glendoning, who was elected bishop in 1387, the great spire of the church, which had been built only of wood, was consumed by lightning. The bishop intented to have built another of stone: but was prevented by death, in 1408, from accomplishing his purpose. His successor, William Lauder, laid the foundation of the vestry of the cathedral, and built the great tower of stone as far as the first battlement. The great tower of the episcopal palace was founded about the year 1437, on which Bishop Cameron expended a great deal of money.

In 1447, William Turnbull, a son of the family of Bedrule in Roxburghshire, was chosen bishop. He obtained from King James II. in 1450, a charter erecting the town and the patrimony of the bishops into a regality. He also procured a bull from Pope Nicholas V. for erecting an university within the city, which he endowed, and on which he also bestowed many privileges. He died in 1454, leaving behind him a most excellent character. The establishment of the college contributed more than any thing that had been formerly done towards the enlargement of the town. Before this time the town seems to have been inconsiderable. Mr Gibson * is of opinion, that the number of its inhabitants did not exceed 1500. But though the establishment of the university greatly increased the number of inhabitants, it in fact destroyed the freedom of the town. Bishop Turnbull seems to have made a point of it with King James II. that the city of Glasgow, with the bishop's forest, should be erected into a regality in his favour; which was accordingly done at the time above mentioned; and this at once took away all power from the citizens, and transferred it to the bishop. As the powers of the bishop, however, were reckoned by Turnbull insufficient to convey to the members of the university all that freedom which he wished to bestow upon them, he therefore obtained from the king a great many privileges for them; and afterwards he himself, with the consent of his chapter, granted them many more.

4
Glasgow erected into a regality, and the university founded.

* Hist. of Glasgow, p. 74.

5
Which destroys the freedom of the city.

The good effects of the establishment of the college were very soon obvious in Glasgow. The number of inhabitants increased exceedingly; the high street, from the convent of the Black Friars, to where the cross is now placed, was very soon filled up; the ancient road which led to the common being too far distant for the conveniency of the new inhabitants, the Gallows-gate began to be built. Soon after, the collegiate church of the blessed Mary (now the Tron church) being founded by the citizens, occasioned the Trongate street to be carried to the westward as far as the church. The rest of the city increased gradually towards the bridge, by the building of the Saltmarket street. The borough roads, and the cattle that grazed on the commons, were now found insufficient to maintain the increased number of inhabitants; for which reason a greater degree of attention than formerly was paid to the fishing in the river. Many poor people subsisted themselves by this occupation; they were incorporated into a society; and in order that they might be at hand to prosecute their business, they built a considerable part of the street now called the *Bridge-gate*, but at that time *Fishers-gâte*.

6
Population of Glasgow increased by the university.

Notwithstanding all this, however, the city of Glasgow did not for a long time attain the rank among the other towns of Scotland which it holds at present. In 1556, it held only the 11th place among them, as appears by Queen Mary's taxation. The introduction of the reformed religion proved for some time prejudicial to the opulence of the city. The money which had

Glasgow.

had formerly been expended among the citizens by the bishop and his clergy, was now diverted into other channels: the advantages resulting from the university were also for a time lost; for as the reformers generally despised human learning, the college was in a manner deserted.

7
eat part
the town
stroyed
a fire.

In the time of the civil wars, Glasgow suffered severely. To the mischief attending intestine discord, were added a pestilence and famine; and to complete their misfortunes, a violent fire broke out in June 1652, which destroyed the greatest part of the Saltmarket, Trongate, and High street. The fronts of the houses at that time were mostly of wood, so that they became an easy prey to the flames. The fire continued with great violence for the space of 18 hours; by which a great many of the inhabitants were ruined, the habitations of almost 1000 families being totally destroyed. On this account collections were made through different parts of the country; and to prevent such accidents for the future, the fronts were built with freestone, which abounds in the neighbourhood.

By the charter given to Bishop Turnbull in 1450, the citizens had been deprived of the power of electing their own magistrates, which was thenceforth exercised by the bishop; which, however, was not done without some resistance on the part of the inhabitants. After the Reformation was introduced into Scotland, we find this power exercised by the citizens, the bishop, the earl of Lennox, and others. The idea that the town was a bishop's borough, and not a royal free borough, gave occasion to this unsettled manner of appointing the magistracy; and though, in 1633, they were declared to be a royal free borough by the parliament, yet their freedom of election was afterwards disturbed by the privy council, by Cromwell, and the duke of York.

Mary.

But on the 4th of June 1690, the town was declared free by a charter of William and Mary; and in confirmation of this charter it was inserted in the act of parliament, dated June 14th the same year, that they should have power to elect their own magistrates as fully and freely, in all respects, as the city of Edinburgh or any other royal borough within the kingdom; which freedom of election still continues.

By the assessment of the boroughs in 1695, we find the city of Glasgow reckoned the second in Scotland in point of wealth, which place it still continues to hold.

9
at in-
se of
wealth.

To account for this great increase of wealth, we must observe, that for a long time, even before the restoration of Charles II. the inhabitants of Glasgow had been in possession of the sale of both raw and refined sugars for the greatest part of Scotland; they had a privilege of distilling spirits from their molasses, free of all duty and excise; the herring fishery was also carried on to what was at that time thought a very considerable extent; they were the only people in Scotland who made soap; and they sent annually some hides, linen, &c. to Bristol, from whence they brought back in exchange, a little tobacco, sugar, and goods, of the manufacture of England, with which they supplied a considerable part of the kingdom. From the year 1707, however, in which the union betwixt Scotland and England took place, we may date the prosperity of Glasgow. By the union, the American trade was laid open to the inhabitants: and so sensible were they of their advantageous situation, that they began almost instantly to prosecute that commerce; an assiduous application to which, ever since, hath greatly contributed to raise the city to the pitch of affluence and splendour which it at present enjoys. The city was now greatly enlarged; and as the community were sensible of the inconvenience that attended the want of a sufficient quantity of water in the river for carrying on their commerce, they resolved to have a port of their own nigher the mouth of the river. At first, they thought of making their harbour at Dumbarton: but as this is a royal borough, the magistrates opposed it; because they thought that the influx of sailors and others, occasioned by the harbour, would be so great, that a scarcity of provisions would be occasioned. The magistrates and town council of Glasgow, therefore, purchased some lands on the south side of the river Clyde for this purpose; and so expeditious were they in making their harbour, and rearing their town, that in 1710 a bailie was appointed for the government of Port-Glasgow. It is now a very considerable parish, and lies 21 miles nigher the mouth of Clyde than Glasgow.

10
Erection of
Port Glasgow.

In 1725, Mr Campbell, the member of parliament for Glasgow, having given his vote for having the malt tax extended over Scotland, a riot ensued among the lower class of people. In this disturbance, Mr Campbell's furniture was destroyed, and some excisemen were maltreated for attempting to take an account of the malt. General Wade, who commanded the forces in Scotland, had sent two companies of soldiers, under the command of Captain Bushel, to prevent any disturbance of this kind. Captain Bushel drew up his men in the street, where the multitude pelted them with stones. He first endeavoured to disperse the mob by firing with powder only: but this expedient failing, he ordered his men to load their pieces with ball; and, without the sanction of the civil authority, commanded them to fire four different ways at once. By this discharge about 20 persons were killed and wounded; which enraged the multitude to such a degree, that having procured some arms, they pursued Bushel and his men to the castle of Dumbarton, about 14 miles distant. General Wade being informed of this transaction, assembled a body of forces, and being accompanied by Duncan Forbes, lord advocate, took possession of the town: the magistrates were apprehended and carried prisoners to Edinburgh; but on an examination before the lords, their innocence clearly appeared, upon which they were immediately dismissed. Bushel was tried for murder, convicted, and condemned; but, instead of suffering the penalties of law, he was indulged with a pardon, and promoted in the service. Mr Campbell petitioned the house of commons for an indemnification of his losses: a bill was passed in his favour; and this, together with some other expences incurred in the affair, cost the town 9000l. sterling.

11
Disturbance about
the excise
bill.

During the time of the rebellion 1745, the citizens of Glasgow gave proof of their attachment to revolution principles, by raising two battalions of 600 men each, for the service of government. This piece of loyalty, however, had like to have cost them dear. The rebels, in their journey south, took a resolution to plunder and burn the city: which would probably have been done, had not Mr Cameron of Lochiel threatened, in that case, to withdraw his clan. A heavy contribution, however, was laid on. The city was com-

Glasgow.

pelled to pay 5000l. in money, and 500l. in goods; and on the return of the rebels from England, they were obliged to furnish them with 12,000 linen shirts, 6000 cloth coats, 6000 pairs of shoes, 6000 pairs of hose, and 6000 bonnets. These goods, with the money formerly paid them, the expence of raising and subsisting the two city battalions, and the charge of maintaining the rebel army in free quarters for ten days, cost the community about 14,000l. sterling; 10,000l. of which they recovered in 1749, by an application to parliament.

12 Change of manners and method of living.

About the year 1750, a very considerable change took place in the manner of living among the inhabitants of Glasgow. Till this time, an attentive industry, and a frugality bordering upon parsimony, had been their general characteristic; the severity of the ancient manners prevailed in its full vigour: But now, when an extensive commerce and increased manufactures had produced wealth, the ideas of the people were enlarged, and bolder schemes of trade and improvement were adopted; a new style was introduced in living, dress, building, and furniture; wheel carriages were set up, public places of entertainment were frequented, and an assembly-room, ball-room, and playhouse, were built by subscription; and from this time we may date all the improvements that have taken place, not only in Glasgow, but all over the west of

13 Acts of parliament in favour of the city.

Scotland. In 1753, an act passed for repairing several roads leading into the city of Glasgow. In 1756, an act for erecting and supporting a light-house in the island of Little Cumray, at the mouth of the Clyde, and for rendering the navigation of the frith and river more safe and commodious.—In 1759, an act for improving the navigation of the river Clyde to the city of Glasgow, and for building a new bridge across the river.—In 1767, the people of Glasgow having proposed to make a small cut or canal from the frith of Forth to that of Clyde, for the conveniency of their trade to the eastern side of the island, several gentlemen at Edinburgh, and throughout different parts of the kingdom, proposed that this canal should be executed upon a much larger scale than what had been originally projected. An act was accordingly obtained, and the canal executed in the manner described under the article CANAL.—In 1770, another act was obtained for improving the navigation of the river, building the bridge, &c. being an amendment of the former act for these purposes. In 1771, an act for making and widening a passage from the Saltmarket to St Andrew's church; for enlarging and completing the churchyard of that church, and likewise for building a convenient exchange or square in the city; also for amending and explaining the former act relative to the navigation of the Clyde. In 1783, the society known by the name of the chamber of commerce and manufactures was established. The object was to unite the influence of the merchants and manufacturers, and to establish a public fund to give greater efficacy to plans in which these classes might be interested. A royal charter was obtained constituting them a body politic, under the management of 30 directors. This chamber has since been of essential service, in promoting objects and undertakings connected with the advancement of trade. But the introduction of the cotton manufacture on a considerable scale, about 1786, made a greater change in the state of the trade of Glasgow than any event which had previously occurred, and formed indeed a new era in its history. From that time the progress of the town in commerce, population, and wealth, has been surprising.

14 Description of the city.

The most ancient part of the city stands on a rising ground. The foundation of the cathedral is 104 feet higher than the bed of the river; and the descent from the high ground reaches to about 100 yards below the college. The rest of the city is built chiefly upon a plain, bounded southward by the Clyde, and northward by a gentle ridge of hills lying in a parallel direction with that river. These grounds, till lately, consisted of gardens and fields; but are now covered with buildings, in consequence of the increasing wealth and population of the city. The streets are all clean and well paved; and several of them intersecting one another at right angles, produce a very agreeable effect. The four principal streets, crossing one another in that manner, divide the city nearly into four equal parts; and the different views of them from the cross, or centre of intersection, have an air of great magnificence. The houses, consisting of four or five floors in height, are built of hewn stone, generally in very good taste, and many of them elegant. The most remarkable public buildings are,

15 Of the cathedral.

1. *The Cathedral*, or *High Church*, is a magnificent building, and its situation greatly to its advantage, as it stands higher than any part of the city. It has been intended to form a cross, though the transverse part has never been finished. The great tower is founded upon four large massy pillars, each of them about 30 feet in circumference. The tower itself is $25\frac{1}{2}$ feet square within; and is surrounded by a balustrade, within which rises an octangular spire terminated by a vane. The tower upon the west end is upon the same level, but appears not to have been finished, though it is covered over with lead. In this tower is a very large bell 11 feet four inches in diameter. The principal entry was from the west; the gate 11 feet broad at the base, and 17 feet in height. The west end of the choir is now appropriated for a place of divine worship; and is divided from the remaining part by a stone partition, which is enclosed by another stone wall parting it from the nave. It is impossible to form an adequate idea of the awful solemnity of the place occasioned by the loftiness of the roof and the range of pillars by which the whole is supported.

The nave of the church rises four steps higher than the choir; and on the west side stood the organ loft, formerly ornamented with a variety of figures, but now defaced. The pillars here are done in a better taste than those in the choir, and their capitals are ornamented with fruits. The arched roof of the altar is supported by five pillars, over which was a fine terrace walk, and above it a large window of curious workmanship, but now shut up. On the north side of the altar is the vestry, being a cube of 28 feet, the roof arched and vaulted at top, and supported by one pillar in the centre of the house. Arched pillars from every angle terminate in the grand pillar, which is 19 feet high. The lower part of the south cross is made use of as a burying place for the clergy of the city; and is by much the finest piece of workmanship in the whole building. It is 55 feet long, 28 broad, and

Glasgow. 15 high; arched and vaulted at top, and supported by a middle range of pillars, with their capitals highly ornamented; corresponding to which are columns adjoining to the walls, which, as they rise, spring into semi-arches, and are everywhere met at acute angles by their opposites, and are ornamented with carvings at the closing and crossing of the lines. At the east end of the choir you descend by flights of steps upon each side into passages which, in former times, were the principal entries to the burying vault, which is immediately under the nave. It is now made use of as a parish church for the barony of Glasgow; and is full of pillars, some of them very massy, which support the arched roof: but it is a very uncomfortable place for devotion. The space under the altar and vestry, though now made use of as a burying place by the heritors of the barony, was formerly, according to tradition, employed for keeping of the relicks; and indeed, from the beautiful manner in which this place is finished, one would imagine that it had not been destined for common use. Here is shown the monument of St Mungo, or Kentigern, with his figure lying in a cumbent posture.

The whole length of the cathedral within the walls is 284 feet, its breadth 65; the height of the choir, from the floor to the canopy, 90 feet; the height of the nave, 85 feet; the height of the middle tower, 220 feet. This fabric was begun by John Achaius in 1123, and consecrated in 1136: and continued by succeeding bishops till such time as it was finished in the manner in which it stands at present. The wealth of the see of Glasgow, however, was not sufficient for so great an undertaking, so that they were obliged to have recourse to all the churches of Scotland for assistance in it.

This venerable edifice was in danger of falling a victim to the frenzy of fanaticism in 1579; and owed its preservation to the spirit and good sense of the tradesmen, who, upon hearing the beat of drum for collecting the workmen appointed to demolish it, flew to arms, and declared that the first man who pulled down a single stone should that moment be buried under it.

Near the cathedral are the ruins of the bishop's palace or castle, enclosed with a wall of hewn stone by Archbishop James Beaton; the great tower built by Archbishop Cameron in 1426.

16 St Andrew's church. 2. *St Andrew's Church* was begun by the community in 1739, and finished in 1756. It is the finest piece of modern architecture in the city; and is built after the model of St Martin's in the Fields, London, whose architect was the famous Gibbs. The length of the church is 104 feet, and its breadth 66. It has a fine arched roof, well ornamented with figures in stucco, and sustained by stone columns of the Corinthian order. Correspondent to the model, it has a place for the altar on the east, in which is a very ancient Venetian window; but the altar place being seated, makes this end appear to no great advantage. The fronts of the galleries and the pulpit are done in mahogany in a very elegant manner. The spire by no means corresponds with the rest of the building; and, instead of being an ornament, disgraces this beautiful fabric. Its height is 170 feet.

Besides the cathedral (which contains three congregations) and St Andrew's church, there is a number of others, as the College church, Ram's-horn, Tron, St Enoch's and St George's; together with an English chapel, Highland church, several seceding meeting-houses, and others for sectaries of various denominations.

3. *The College.*—The front of this building extends along the east side of the High street, and is upwards of 330 feet long. The gate at the entrance is decorated with rustics, and over it are the king's arms. The building consists of two principal courts or squares. The first is 88 feet long and 44 broad. The west side is elevated upon stone pillars, on which are placed pilasters supporting the Doric entablature, and ornamented with arches forming a piazza. Above these is the public hall; the ascent to which is by a double flight of steps enclosed by a handsome stone balustrade, upon the right of which is placed a lion, and on the left an unicorn, cut in freestone. The spire stands on the east side, is 135 feet high, and has a very good clock. Under this is the gateway into the inner and largest court, which is 103 feet long and 79 broad. Over the entry, in a niche, is a statue of Mr Zacharias Boyd, who was a benefactor to the university. On the east side of the court is a narrow passage leading into a handsome terrace walk, gravelled, 122 feet long by 64 feet broad. This walk is enclosed to the east by an iron palisade, in the centre of which is a gate leading into the garden. This last consists of seven acres of ground, laid out in walks for the recreation of the students; and there is also a botanic garden. On the south side of the walk stands the library; a very neat edifice, well constructed for the purpose intended, and containing a very valuable collection of books. Underneath are preserved in cases all the Roman inscriptions found on Graham's Dike, together with altars and other antiquities collected from different parts of Scotland.—Adjoining there is an observatory, well furnished with astronomical instruments. The college also possesses, by bequest, the late Dr Hunter's famous anatomical preparations, library, and museum. A beautiful building was erected in 1806 for its reception. 17 The college.

4. *New Jail.*—The old jail having become much too small in consequence of the rapid growth of the town, a new one was projected in 1808. As the Glasgow jail receives prisoners from the neighbouring counties, application was made first to them, and afterwards to government for assistance in defraying the expence, but without effect. In consequence of this the plan was reduced, and the expence, amounting to 34,800l. was defrayed from the funds of the burgh. The new jail was opened in 1814, and is admitted to be one of the most commodious and best arranged in the country. It is situated at the west end of the Green, in a healthy and well aired position; and besides a court house capable of containing 500 persons, and several other public offices, it contains 122 apartments for prisoners, sixteen large galleries for air and exercise, and two paved court yards, 69 feet by 46. The jail is formed into sixteen distinct allotments—eight for debtors, and eight for criminals. The building is amply supplied with pure water, and is carefully cleaned. There are four well aired infirmary rooms, and a chapel which holds 200 persons. During the year ending 1st April 1819, no less than 1809 persons had been incarcerated;—683 debtors and 1126 delinquents. 18 New jail.

19 Bridewell. 5. *Bridewell.*—Till the year 1798 there was no regular Bridewell in Glasgow. The present Bridewell which is in Duke street, is six stories high, and contains a chapel, a work-room, and 105 cells, each eight feet by seven, with a public kitchen, apartments for the keeper, and several work-rooms. It has now, however, become too small for the city; and a scheme is at present in contemplation for erecting another on a more extensive scale, and a better plan.

20 Guild hall. 6. *The Guild Hall* or *Merchants House.* This building is situated upon the south side of Bridgegate street; and is in length 82 feet, in breadth 31. The great hall, which is the whole length and breadth of the building, is so capacious, that it is better adapted for the reception of great and numerous assemblies than any other in the city. This house is adorned with a very elegant spire 200 feet high.

21 Town's hospital. 7. *The Town's Hospital* is a very neat building, consisting of two wings and a large front; the length 156 feet, the breadth of the centre 30 feet, and the depth of the wings 68 feet. Behind the building is an infirmary 127 feet long by 25 feet broad, the ascent to which is by a flight of steps. The lower part of this building is appointed for the reception of lunatics. The area between the buildings is large, which, with the agreeable open situation of the hospital on the river, must conduce to the health of the inhabitants.

22 Grammar school. 8. *The Grammar School* is situated in the new part of the town, to the north-west, and was built in 1787. It is a very handsome building, containing a large hall, and six airy commodious teaching rooms. In this school there are four classes, the course being four years: each class is carried on the whole five years by the same master; so that, there being no rector, each master is head of the school one year in rotation. It is under the direction of a committee of the town council; who, assisted by the professors, clergy, and other persons of learning, frequently visit it during the session; and at an annual examination, prizes are distributed to the scholars according to their respective merits. The number of scholars is about 540. It is found that there are 10,200 persons educated in Glasgow who pay fees, besides 1100 educated at free or charity schools.

23 Bridges. 9. *Bridges.*—There are at Glasgow two stone bridges over the Clyde, and a wooden one. The *Old Bridge* at the foot of Stockwell street, was built by Bishop Rae in 1345. Ten feet were added to its breadth in 1777, and its present dimensions are, 415 feet in length, and 22 in breadth. The *New Bridge* is built in an elegant manner. It is 32 feet wide, with a commodious footway for passengers, five feet broad on each side, raised above the road made for carriages, and paved with freestone. This bridge is about 500 feet in length, and consists of seven arches, the faces of which are wrought in rustic, with a strong block cornice above. The arches spring but a little way above low water mark; which, though it renders the bridge stronger than if they sprung from taller piers, diminishes its beauty. This bridge was begun in 1768, and finished in 1772.

24 Markets, &c. 10. *The Markets in King's Street* are justly admired, as being the completest of their kind in Britain. They are placed on both sides of the street. That on the east side, appropriated entirely for butcher meat, is 112 feet in length, and 67 in breadth. In the centre is a spacious gateway, decorated on each side with coupled Ionic columns, set upon their pedestals, and supporting an angular pediment. At the north end is a very neat hall belonging to the incorporation of butchers, the front ornamented with rustics and a pediment. The markets upon the west side of the street consist of three courts, set apart for fish, mutton, and cheese. The whole of the front is 173 feet, the breadth 46 feet; in the centre of which, as on the opposite side, is a very spacious gateway of the Doric order, supporting a pediment. This is the entry to the mutton market. Each of the other two has a well proportioned arch faced with rustics for the entrance. All these markets are well paved with freestone, have walks all round them, and are covered over for shelter by roofs standing upon stone piers, under which the different commodities are exposed to sale. They have likewise pump wells within, for cleansing away all the filth; which render the markets always sweet and agreeable. These markets were erected in 1754.

11. *The Market for Vegetables* is neat and commodious; and the principal entry is decorated with columns. It is situated in the Candleriggs, and is laid out in the same manner with the markets in King's street.

12. *The Guard House* is a very handsome building, with a piazza formed by arches, and columns of the Ionic order set upon their pedestals. It was originally situated on the High street, at the corner of the Candleriggs street: but was afterwards carried near half way up the Candleriggs, where it occupies the ground on which the weigh-house formerly stood, and is made larger and more commodious than it was before. An excellent new weigh-house has been erected at the head of the Candleriggs: and at the foot of the Candleriggs, or corner next the High street, where the guard-house was formerly situated, a superb new hotel has been built, containing 75 fire rooms. 25 Guard house.

The most remarkable public charities in Glasgow are,

1. *Muirhead's* or *St Nicholas's Hospital.* This was originally appointed to subsist 12 old men and a chaplain; but its revenues have, from some unknown causes, been lost; so that no more of them now remains than the paltry sum of 139l. 2s. 5d. Scots money, 128l. of which is annually divided among four old men, at the rate of 2l. 13s. 4d. sterling each. 26 Public charities.

2. *Hutcheson's Hospital*, was founded and endowed in 1639 by George Hutcheson of Lamb-hill, notary public, and Mr Thomas Hutcheson his brother, who was bred a preacher, for the maintenance of old men and orphans. The funds of this hospital were increased by James Blair, merchant in Glasgow in 1710, and by subsequent donations. The income, which is now large, is distributed in pensions to old people from 3l. to 20l. and in educating about 70 children. The sum distributed in pensions in 1819 was 1790l. 7s.

3. *The Merchants House* likewise distributes in pensions and other charities about 800l. yearly.

4. *The Town's Hospital*, above described, was opened for the reception of the poor on the 15th of November 1733. The funds whence this hospital is subsisted are, the general session, the town council, the trades house,

Glasgow.

house, and merchants house, the interest of money belonging to their funds, which are sums that have been mortified for the use of the house. These supplies, however, are fonnd insufficient to defray the expences of the house; for which reason an assessment is annually made upon the inhabitants in the following manner. The magistrates nominate 12, 14, or sometimes more gentlemen of known integrity and character, who have a list laid before them of all the inhabitants in town. This list they divide into 16 or 18 columns, Each of these columns contains the names of such inhabitants as carry on trade to a certain extent, or are supposed to be well able to pay the sum affixed to the particular column in which their names are inserted. If it is necessary to raise 500l. for instance, then each name, in every separate column, is valued at as much as the fortunes of the persons in each particular column are supposed to be. If 1000l. or more is to be raised, it is only continuing a proportional increase through the whole of the columns. This assessment has been gradually increasing. In 1782 it was 1057l.; in 1800 it was 4534l., and in 1819 it was 10,303l. The rate of assessment has also increased during the war from 1 to 3 shillings on 100l. of property.

5. *Wilson's Charity* for the education of boys, was founded by George Wilson, who in 1778 left 3000l. for that purpose. This fund is now considerably increased, and gives education and clothing to 48 boys, who each continues four years, so that 12 are admitted annually.

Besides these, there are many public schools for the education of children; as well as many institutions of private societies for the purpose of relieving the indigent and instructing youth, such as *Graham's Society*, *Buchanan's Society*, the *Highland Society*, &c. These last put annually 20 boys apprentices to trades, and during the first three years give them clothing and education.

27 Members of the university.

The university of Glasgow owes its origin, as we have already observed, to Bishop Turnbull. The institution consisted at first of a rector, a dean of faculty, a principal who taught theology, and three professors of philosophy; and, soon after this, the civil and canon laws were taught by some clergymen. From the time of its establishment in 1450 to the Reformation in 1560, the college was chiefly frequented by those who were intended for the church; its members were all ecclesiastics, and its principal support was derived from the church. The Reformation brought the university to the verge of destruction: masters, students, and servants, all forsook it. The magistrates were so sensible of the loss which the community had sustained by this desertion, that they endeavoured to restore it in 1572, by bestowing upon it considerable funds, and prescribing a set of regulations for its management. These, however, proved insufficient; for which reason King James VI. erected it anew, by a charter called the *Nova Erectio*, 1577, and bestowed upon it the teinds of the parish of Govan. The persons who were to compose the new university were, a principal, three professors of philosophy, four students bursars, one œconomus, a principal's servant, a janitor, and cook.

Since the year 1577, the funds of the university have been considerably increased by the bounty of kings and the donations of private persons. The professors have therefore also been increased: so that at present the university of Glasgow consists of a chancellor, rector, dean of faculty, principal, and 14 professors (six of them in the gift of the crown), together with bursars, &c. The archbishop of Glasgow was formerly chancellor of the university *ex officio;* at present, the chancellor is chosen by the rector, dean of faculty, principal, and masters.

The chancellor, as being the head of the university, is the fountain of honour, and in his name are all academical degrees bestowed. The office of rector is to exercise that academical jurisdiction in disputes among the students themselves, or between the students and citizens, which is bestowed upon the greater part of the universities in Europe. He is chosen annually in the *comitia;* that is, in a meeting in which all the students, as well as the other members of the university, have a voice. Immediately after his admission, he has been in use to choose certain persons as his assessors; and counsellors in his capacity of judge; and, in former periods, it was customary to name the ministers of Glasgow, or any other gentlemen who had no connexion with the university; but, for a great while past, the rector has constantly named the dean of faculty, the principal, and masters, for his assessors; and he has always been, and still is, in the daily practice of judging in the causes belonging to him, with the advice of his assessors. Besides these powers as judge, the rector summons and presides in the meetings of the university for the election of his successor; and he is likewise in use to call meetings of the professors for drawing up addresses to the king, electing a member to the general assembly, and other business of the like kind.

The dean of faculty has, for his province, the giving direction with regard to the course of studies; the judging, together with the rector, principal, and professors, of the qualifications of those who desire to be created masters of arts, doctors of divinity, &c.; and he presides in meetings which are called by him for these purposes. He is chosen annually by the rector, principal, and masters.

The principal and masters, independent of the rector and dean, compose a meeting in which the principal presides; and as they are the persons for whose behoof chiefly the revenue of the college was established, the administration of that revenue is therefore committed to them. The revenue arises from the teinds of the parish of Govan, granted by King James VI. in 1557; from the teinds of the parishes of Renfrew and Kilbride, granted by the same monarch in 1617, and confirmed by King Charles I. on the 28th of June 1630; from the teinds of the parishes of Calder, Old and New Monkland, conveyed to them by a charter from Charles II. in 1670; from a tack of the archbishopric; and from several donations conferred by private persons.

The college of Glasgow, for a very considerable time after its erection, followed the mode of public teaching which is common even to this day in Oxford and Cambridge, and in many other universities throughout Europe; that is, each professor gave a few lectures every year, *gratis*, upon the particular science which he professed: but in place of this, the professors have, for a great while past, adopted the mode of private teaching: that is, they lecture and examine two hours every day during the session, viz. from the 10th of October to the 10th of June; a method which comes much cheaper to the student, as he has it in his power, if he is attentive, to acquire his education without being under the necessity of employing a tutor. They have also private classes, in which they teach one hour per day. The number of students who attended this college at the various classes in the session 1819-1820, was no less than 1264.

28
History of Glasgow.

The trade of Glasgow is said to have been first promoted by one Mr William Elphinstone in 1420. This trade was most probably the curing and exporting of salmon; but the first authentic document concerning Glasgow as a trading city is in 1546. Complaints having been made by Henry VIII. king of England, that several English ships had been taken and robbed by vessels belonging to Scotland, an order of council was issued, discharging such captures for the future; and among other places made mention of in this order is the city of Glasgow. The trade which at that time they carried on could not be great. It probably consisted of a few small vessels to France loaded with pickled salmon; as this fishery was, even then, carried on to a considerable extent, by Glasgow, Renfrew, and Dumbarton. Between the years 1630 and 1660, a very great degree of attention seems to have been paid to inland commerce by the inhabitants of Glasgow. Principal Baillie informs us, that the increase of Glasgow arising from this commerce was exceedingly great. The exportation of salmon and of herrings was also continued and increased. In the war between Britain and Holland during the reign of Charles II. a privateer was fitted out in Clyde to cruise against the Dutch. She was called the *Lion of Glasgow*, Robert M'Allan commander; and carried five pieces of cannon, and 60 hands.

A spirit of commerce appears to have arisen among the inhabitants of Glasgow between the years 1660 and 1707. The citizens who distinguished themselves most during this period were Walter Gibson and John Anderson. Gibson cured and packed in one year 300 lasts of herrings, which he sent to St Martin's in France on board of a Dutch vessel called the *St Agate* of 450 tons burden; his returns were brandy and salt. He was the first who imported iron from Stockholm into Clyde. Anderson is said to have been the first who imported white wines.

Whatever their trade was at this time, it could not be considerable: the ports to which they were obliged to trade lay all to the eastward: the circumnavigation of the island would therefore prove an almost unsurmountable bar to the commerce of Glasgow; and of consequence the people on the east coast would be possessed of almost all the commerce of Scotland. The union with England opened a field for commerce for which the situation of Glasgow, so convenient in respect to the Atlantic, was highly advantageous. Since that time the commerce of the east coast was declined, and that of the west increased to an amazing degree. No sooner was the treaty of union signed, than the inhabitants of Glasgow began to prosecute the trade to Virginia and Maryland; they chartered vessels from Whitehaven, sent out cargoes of goods, and brought back tobacco in return. The method in which they at first proceeded in this trade was certainly a very prudent one. A supercargo went out with every vessel. He bartered his goods for tobacco, until such time as he had either sold off his goods, or procured as much tobacco as was sufficient to load his vessel. He then immediately set out on his return; and if any of his goods remained unsold, he brought them home with him. While they continued to trade in this way, they were of great advantage to the country, by the quantity of manufactures which they exported; their own wealth began to increase; they purchased ships of their own; and, 1718, the first vessel of the property of Glasgow crossed the Atlantic. Their imports of tobacco were now considerable, and Glasgow began to be looked upon as a considerable port: the tobacco made at the ports of Bristol, Liverpool, and Whitehaven, was observed to dwindle away; the people of Glasgow began to send tobacco to these places, and to undersell the English even in their own ports. Thus the jealousy of the latter was soon excited, and they took every method in their power to destroy the trade of Glasgow. The people of Bristol presented remonstrances to the commissioners of the customs at London against the trade of Glasgow, in 1717. To these remonstrances the merchants of Glasgow sent such answers to the commissioners, as convinced them that the complaints of the Bristol merchants were without foundation. But in 1721, a most formidable confederacy was entered into by almost all the tobacco merchants in South Britain against the trade of Glasgow. Those of London, Liverpool, and Whitehaven, presented severally to the lords of the treasury, petitions, arraigning the Glasgow merchants of frauds in the tobacco trade. To these petitions the Glasgow people gave in replies; and the lords of the treasury, after a full and impartial hearing, were pleased to dismiss the cause with the following sentence: "That the complaints of the merchants of London, Liverpool, and Whitehaven, were groundless; and that they proceeded from a spirit of envy, and not from a regard to the interest of trade, or of the king's revenue."

But the efforts of these gentleman did not stop here. They brought their complaints into the house of commons. Commissioners were sent to Glasgow in 1722, who gave in their reports to the house in 1723. The merchants sent up distinct and explicit answers to these reports; but such was the interest of their adversaries, that these answers were disregarded. New officers were appointed at the ports of Greenock and Port Glasgow, whose private instructions seem to have been to ruin the trade if possible by putting all imaginable hardships upon it. Hence it languished till the year 1737; but after that time it began to revive, though even after its revival it was carried on but slowly for a considerable space of time.

At last, however, the active and enterprising spirit of the merchants, seconding the natural advantages of their situation, prevailed over all opposition; and the American trade continued to flourish and increase until the year 1775, insomuch that the importation of tobacco into Clyde that year from the provinces of Virginia, Maryland, and Carolina, amounted to 57,143 hogsheads. But since the breach with America, this trade has now greatly fallen off, and very large sums are said to remain due to the merchants from that quarter of the world.

29 With regard to the manufactures of Glasgow, Mr Gibson is of opinion that the commerce to America first suggested the idea of introducing them, in any considerable degree at least. The first attempts in this way were about the year 1725, and their increase for some time was very slow, nor did they begin to be considerable till great encouragement was given by the legislature to the linen manufacture in Scotland. The first causes of the success of this manufacture were the act of parliament in 1748, whereby the wearing of French cambrics was prohibited under severe penalties; that of 1751, allowing weavers in flax or hemp to settle and exercise their trades anywhere in Scotland free from all corporation dues; and the bounty of three halfpence per yard on all linens exported at and under 18d. per yard. Since that time a spirit of manufacture has been excited among the inhabitants of Glasgow; and great variety of goods, and in very great quantity, have been manufactured. Checks, linen, and linen and cotton, are manufactured to a great extent. Printed linens and cottons were begun to be manufactured in 1738; but they only made garments till 1754, when handkerchiefs were first printed.

Manufactures of Glasgow.

Besides these, a great variety of articles are manufactured at Glasgow, of which our limits will not permit us to enter into a detail, such as soap, refining of sugar, ironmongery, brass, jewellery, glass both common and white, pottery, &c. Types for printing are made in this city by Dr Wilson and Sons, equal, if not superior, in beauty to any others in Britain. Printing of books was first begun here by George Anderson about the year 1638. But there was no good printing in Glasgow till the year 1735, when Robert Urie printed several books in a very elegant manner. The highest perfection, however, to which printing hath yet been carried in this place, or perhaps in any other, was by the late Robert and Andrew Foulis, (who began in the year 1740); as the many correct and splendid editions of books printed by them in different languages sufficiently testify. Some of their classics, it is said, are held in such high esteem abroad, as to sell nearly at the price of ancient MSS. The same gentlemen also established an academy of painting; but the wealth of Scotland being unequal to the undertaking, it has been since given up.

The inventions and improvements introduced into the cotton manufacture by Hargreaves, Arkwright, and others, gave a new impulse to this species of industry. The people of Glasgow now found the manufacture of these articles very profitable, and about 1786 had begun to abandon the manufacture of cambrics, lawns, gauzes, and other light fabrics of linen, which had grown up there in the course of the century; and before 1792 the former of these manufactures had almost entirely superseded the latter. About 1782, the annual value of the whole manufactures of Glasgow did not exceed 800,000l. and in 1818 it was estimated that 105,000,000 yards of cotton cloth were manufactured at Glasgow, valued at 5,200,000l. In the spinning department there were in 1819 fifty-four mills employed, containing nearly 600,000 spindles; and the capital invested in buildings and machinery for carrying on this branch is estimated 1,000,000l. For weaving this yarn there are 2800 looms moved by mechanical power, producing weekly about 8400 pieces of cloth; and there are, as nearly as can be ascertained, 32,000 hand looms.

One of the late improvements most deserving of attention is the construction of steam boats. Glasgow was the first town in Britain to adopt this improvement, and it is now the centre of a greater amount of steam boat navigation than any other town in the island. These vessels were introduced by Mr Henry Bell, an ingenious self-taught engineer in 1812; and in 1819 there were no less than 28 of them plying on the Clyde, and sailing some of them as far as Liverpool. The passage between Glasgow and Greenock, which is 26 miles, is usually performed in three hours. So much has this new invention increased the intercourse between these two places, that previous to its introduction it is calculated that not more than fifty persons passed and repassed in a day, whereas now the number is seldom less than four or five hundred.

Besides various improvements in the old streets, several handsome new ones as well as new squares have been added. The site of these new buildings is the tract of rising ground already mentioned as the north boundary of the town previous to its late extension. The western part of it, which is perfectly level, is occupied by a spacious square, denominated *George's Square*. The grass plot in the middle is enclosed with a handsome iron railing. The square is deficient in regularity; the houses on the west side being a story higher than those of the east; but in other respects it is very neat. Farther west a variety of new streets have been built, all of which are in a neat, and many in a very elegant style of architecture. St George's church, a simple but elegant structure, with a very handsome tower, was opened in 1807. St John's church, which is considerably larger, was opened in 1819. The Roman Catholic chapel, erected a few years ago, is admired as a good specimen of the Gothic style. The New Theatre in Queen street, which was opened in 1804, is a handsome edifice, and cost 18,500l. Among the objects of a purely ornamental nature lately erected, may be mentioned the brass statue of Sir John Moore, placed at the south side of George's square, and the stone obelisk in honour of Lord Nelson, which stands in the Green.

On the same or south side of the town, westward, is the Broomielaw, where the quay is situated. Till within these few years, the river here, and for several miles distance, was so shallow and so obstructed by shoals, as to admit only of small craft from Greenock, Port Glasgow, and the Highlands; but of late it has been cleared and deepened so as to admit vessels of considerable burden; and it is intended to make the depth as nearly equal as possible to that of the canal, in order that the vessels from Ireland and the west coast may come up Clyde and unload at the Broomielaw.

The government of the city of Glasgow is vested in a provost and three bailies, a dean of guild, deacon convener, and a treasurer, with a common council of 13 merchants and 12 mechanics. The provost and two of the bailies must, by the set of the borough, be elected from the merchant rank, and the other bailie from 30

30 Government, revenue, &c. of the city.

Glasgow.

from the trades rank, i. e. the mechanics. The provost is, from courtesy and custom, styled *lord provost*. He is properly lord of the police of the city, president of the community, and is *ex officio* a justice of the peace for both the borough and county.

Many of the inhabitants of Glasgow were convinced of the necessity of a new system of police, a number of years before the sanction of parliament was obtained for that purpose, which was granted in the year 1800. The act vested the management of the police in the lord provost, bailies, dean of guild, deacon convener, and 24 commissioners, one being chosen out of each ward into which the city is divided. The object of the bill was to procure an extension of the royalty, to pave, light, and clean the streets, for regulating the police, and nominating officers and watchmen, appointing commissioners, raising funds, and granting certain powers to the magistrates and council, town and dean of guild courts, and for several other purposes.

In framing this system of police, it was wisely provided that the commissioners shall not enjoy the office for life; nor even for a long period, but upon the supposition of being re-elected, and that every person properly qualified may have a chance for the office, and by consequence be entitled to a voice in the management of the funds and the establishment.

In order to raise funds for defraying the expence of the police establishment, the lord provost, magistrates and commissioners, on the first Monday of September, annually assess all occupiers, renters, or possessors of dwelling houses, cellars, shops, warehouses, and other buildings within the royalty, in proportion to the rent. The act expired in 1807, and was then renewed for 14 years longer. The rates of assessment fixed by the second, are as follows:—

On the yearly rent of subjects valued		
At 4l. and under 6l. sterling annually,	5d.	per pound.
At 6l. and under 10l.	$7\frac{1}{2}$d.	do.
At 10l. and under 15l.	$11\frac{1}{4}$d.	do.
At 15l. and upwards,	1s. 3d.	do.

The rates actually levied however under the police act have generally been under this amount. In 1817–18 it was 4d. 6d. 9d. and 1s. The disbursements for lighting, watching, and cleaning, during the same year, amounted to 11,617l. The establishment consisted of 20 officers, 80 watchmen, 20 patrole, and 16 scavengers. The number of lamps was 1472. In 1819 about two-thirds of the lamps were lighted with gas. The officers have power to bring to justice persons guilty of street robberies, house-breakings, assaults, thefts, shop-lifting, picking pockets, frequenters of disorderly houses; to suppress mobs and riots; to assist in extinguishing fires, in guarding and watching the streets, and in assisting the magistrates in every thing which relates to the police, peace, and good order of the city. These officers have hitherto given general satisfaction in the discharge of their duty, by seeing that the streets are kept clean, well lighted and guarded. In a word, property and personal safety are well secured.

Many whole and elegant streets have of late years been added to it, so that its rapid extension, increasing population, and flourishing commerce, justly entitle it to rank with any city in Scotland, or perhaps in the British empire.

Glasgow.

The revenue of the town arises from a duty upon all grain and meal brought into the city (which tax is denominated *the ladles*); from the rents of lands and houses the property of the community; from an impost of two pennies Scots upon every Scots pint of ale or beer brewed, inbrought, or sold within the city; from certain duties payable out of the markets; from the rents of the seats in churches; from the duties of cranage at the quay, at the weigh-house, &c. As to the tonnage on the river, the pontage of the bridge, and statute work; these, making no part of the city revenue, are kept separate and distinct under the management of commissioners appointed by act of parliament.

31 Number of inhabitants.

About the time of the Union, the number of inhabitants in Glasgow was reckoned about 14,000. In 1765, when a new division of the parishes took place, they were estimated at 28,000. In 1785, when an accurate survey was made, the number was 45,889, including the inhabitants of the suburbs, the Calton, Gorbals, and Anderston. Since that time, the new buildings, as above noticed, have been erected, and the city has become greatly more populous. In 1791 the number of inhabitants was found to be 66,578. In 1811 they amounted to 110,460, and in 1820 to 147,197. Glasgow is therefore at present indisputably the second city in Britain for population. The rental of shops and houses in 1773 was 36,706l. and in 1820 it had increased to 286,340l.

The climate of Glasgow, similar to that of most other parts of the island, is variable; but there are some circumstances peculiar to its local situation which tend to affect it more than that of some other places nearer the middle of the country. That part of the country in which Glasgow is situated, is almost in the narrowest part of the isthmus betwixt the Forth and Clyde, from which position the air is frequently refreshed by temperate breezes from the sea. The wind is south-west and west for nearly two-thirds of the year, and is saturated with vapour in its passage across the Atlantic; and the sky being frequently clouded with it, the heats of summer are not so intense as in some other places. Fogs are not so common as in the neighbourhood of Edinburgh, and severe frosts are seldom of long continuance, nor are snows either very deep, nor do they lie long. Thunder and lightning are rare about Glasgow, and seldom destructive.

The soil in the vicinity is partly a rich clay and partly a light sand. The grain raised about the city is not sufficient for the consumpt of the inhabitants, but vast quantities are brought from Ireland, Ayrshire, and the east country. While digging the foundation for the Tontine buildings in the midst of the city, a piece of a boat was found several feet below the surface of the ground, imbedded in sand and gravel, from which it would appear that the channel of the river had once run in that direction. In August 1801, while repairing a division of the cathedral, below the pavement opposite the pulpit, about two feet deep, part of a human skeleton was found, and a gold chain about 30 inches long lying above the bones of the leg. The date on the stone was 1599, but the inscription in the Saxon character was wholly effaced.

The

Glasgow, Glass.

The general character of the people is that of industry and attention to business, by which many of them have arisen to a state of independence. They were formerly said to be remarkable for severity and apparent sanctity of manners; but at present they are not more distinguished in this respect than any of their neighbours. The crimes of robbery and house-breaking have, of course, increased with the increase of population; but many of these may be fairly charged upon strangers, and it would be uncandid on that account to attach blame to the inhabitants at large. See GLASGOW, SUPPLEMENT.

GLASS, a transparent, brittle, factitious body, produced from sand melted in a strong fire with fixed alkaline salts, lead, slags, &c. till the whole becomes perfectly clear and fine. The word is formed of the Latin *glastum*, a plant called by the Greeks *isatis*, by the Romans *vitrum*, by the ancient Britons *guadum*, and by the English *woad*. We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate that the ancient Britons painted or dyed their bodies with glastum, guadum, vitrum, &c. i. e. with the blue colour procured from this plant. And hence the factitious matter we are speaking of came to be called *glass;* as having always somewhat of this bluishness in it.

I History of glass-making.

At what time the art of glass-making was first invented, is altogether uncertain. Some imagine it to have been invented before the flood: but of this we have no direct proof, though there is no improbability in the supposition; for we know, that it is almost impossible to excite a very violent fire, such as is necessary in metallurgic operations, without vitrifying part of the bricks or stones wherewith the furnace is built. This indeed might furnish the first hints of glass-making; though it is also very probable, that such imperfect vitrifications would be observed a long time before people thought of making any use of them.

Neri traces the antiquity of glass as far back as the time of Job. That writer, speaking of the value of wisdom (chap. xxviii. verse 17.), says, that gold and *crystal* cannot equal it. But this word, which Neri will have to signify factitious glass, is capable of a great many different interpretations, and properly signifies only whatever is beautiful or transparent. Dr Merret will have the art to be as ancient as that of pottery or the making of bricks, for the reasons already given, viz. that by all vehement heat some imperfect vitrifications are produced. Of this kind undoubtedly was the fossil glass mentioned by Ferant. Imperator. to have been found under ground where great fires had been. But it is evident, that such imperfect vitrifications might have passed unnoticed for ages; and consequently we have no reason to conclude from thence, that the art of glass-making is of such high antiquity.

The Egyptians boast, that this art was taught them by their great Hermes. Aristophanes, Aristotle, Alexander Aphrodiseus, Lucretius, and St John the divine, put it out of all doubt that glass was used in their days. Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea; who being obliged to continue there and dress their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to ashes, its salts mixed and incorporated with the sand, or stones fit for vitrification, and thus produced glass; and that, this accident being known, the people of Sidon in that neighbourhood essayed the work, and brought glass into use; since which time the art has been continually improving. Be this as it will, however, the first glass-houses mentioned in history were erected in the city of Tyre, and here was the only staple of the manufacture for many ages. The sand which lay on the shore for about half a mile round the mouth of the river Belus was peculiarly adapted to the making of glass, as being neat and glittering; and the wide range of the Tyrian commerce, gave an ample vent for the productions of the furnace.

Mr Nixon, in his observations on a plate of glass found at Herculaneum, which was destroyed A. D. 80, on which occasion Pliny lost his life, offers several probable conjectures as to the uses to which such plates might be applied. Such plates, he supposes, might serve for *specula* or looking glasses; for Pliny, in speaking of Sidon, adds, *siquidem etiam specula excogitaverat:* the reflection of images from these ancient specula being effected by besmearing them behind, or tinging them through with some dark colour. Another use in which they might be employed, was for adorning the walls of their apartments, by way of wainscot, to which Pliny is supposed to refer by his *vitreæ cameræ*, lib. xxxvi. cap. 25. § 64. Mr Nixon farther conjectures, that these glass plates might be used for windows, as well as the lamina of *lapis specularis* and *phengites*, which were improvements in luxury mentioned by Seneca and introduced in his time, Ep. xc. However, there is no positive authority relating to the usage of glass windows earlier than the close of the third century: *Manifestius est* (says Lactantius*), *mentem esse, quæ per oculos ea quæ sunt opposita, transpiciat, quasi per fenestras lucente vitro aut speculari lapide obductas.*

* *De opif. Dei*, cap. 5.

The first time we hear of glass made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his house demolished for making glass malleable, or rather flexible; though Petronius Arbiter, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention.

It appears, however, that before the conquest of Britain by the Romans, glass-houses had been erected in this island, as well as in Gaul, Spain, and Italy.—Hence, in many parts of the country are to be found amulets of glass, having a narrow perforation and thick rim, denominated by the remaining Britons *gleineu naidreedh* or *glass adders*, and which were probably in former times used as amulets by the druids †. It can scarcely be questioned that the Britons were sufficiently well versed in the manufacture of glass, to form out of it many more useful instruments than the glass beads. History indeed assures us, that they did manufacture a considerable quantity of glass vessels. These, like their amulets, were most probably green, blue, yellow, or black, and many of them curiously streaked with other colours. The process in the manufacture would be nearly the same with that of the Gauls or Spaniards. The sand of their shores being reduced to a sufficient degree of fineness by art, was mixed with three-fourths of

† See *Anguinum Ovum.*

Glass.

of its weight of their nitre (much the same with our kelp), and both were melted together. The metal was then poured into other vessels, where it was left to harden into a mass, and afterwards replaced in the furnace, where it became transparent in the boiling, and was afterwards figured by blowing, or modelling in the lath, into such vessels as they wanted.

It is not probable that the arrival of the Romans would improve the glass manufacture among the Britons. The taste of the Romans at that time was just the reverse of that of the inhabitants of this island. The former preferred silver and gold to glass for the composition of their drinking vessels. They made indeed great improvements in their own at Rome, during the government of Nero. The vessels then formed of this metal rivalled the bowls of porcelain in their dearness, and equalled the cups of crystal in their transparency. But these were by far too costly for common use; and therefore, in all probability, were never attempted in Britain. The glass commonly made use of by the Romans was of a quality greatly inferior; and, from the fragments which have been discovered at the stations or towns of either, appears to have consisted of a thick, sometimes white, but mostly blue green, metal.

According to venerable Bede, artificers skilled in making glass for windows were brought over into England in the year 674, by Abbot Benedict, who were employed in glazing the church and monastery of Weremouth. According to others, they were first brought over by Wilfrid, bishop of Worcester, about the same time. Till this time the art of making such glass was unknown in Britain; though glass windows did not begin to be common before the year 1180; till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had them first, next France, from whence they came into England.

Venice, for many years, excelled all Europe in the fineness of its glasses; and in the thirteenth century, the Venetians were the only people that had the secret of making crystal looking glasses. The great glass works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest glasses.

The glass manufacture was first begun in England in 1557: the finer sort was made in the place called Crutched Friars, in London; the fine flint glass, little inferior to that of Venice, was first made in the Savoy house, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with sea coal or pit coal instead of wood, and a monopoly was granted to Sir Robert Mansell, who was allowed to import the fine Venetian flint glasses for drinking, the art of making which was not brought to perfection before the reign of William III. But the first glass plates, for looking glasses and coach windows, were made, 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glass into England, by means of Venetian artists, with amazing success. So that within a century past, the French and English have not only come up to, but even surpassed the Venetians, and we are now no longer supplied from abroad.

The French made a considerable improvement in the art of glass, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. That court applied itself with a laudable industry to cultivate and improve the glass manufacture. A company of glassmen was established by letters patent; and it was provided by an arret, not only that the working in glass should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

An extensive manufactory of this elegant and valuable branch of commerce was first established in Lancashire, about the year 1773, through the spirited exertions of a very respectable body of proprietors, who were incorporated by an act of parliament. From those various difficulties constantly attendant upon new undertakings, when they have to contend with powerful foreign establishments, it was for some time considerably embarrassed; but government, of late, having taken off some restrictions that bore hard upon it, and made some judicious regulations relative to the mode of levying the excise duty, it now bids fair to rival, if not surpass, the most celebrated continental manufactures, both with respect to the quality, brilliancy, and size of its productions.

2 Theory of vitrification uncertain.

With regard to the theory of vitrification, we are almost totally in the dark. In general, it seems to be that state in which solid bodies are, by the vehement action of fire, fitted for being dissipated or carried off in vapour. In all vitrifications there is a plentiful evaporation: and if any solid substance is carried off in vapour by the intense heat of a burning speculum, a vitrification is always observed previously to take place. The difference, then, between the state of fusion and vitrification of a solid body we may conceive to be, that in the former the element of fire acts upon the parts of the solid in such a manner as only to disjoin them, and render the substance fluid; but in vitrification the fire not only disjoins the particles, but combines with them in a latent state into a third substance; which, having now as much fire as it can contain, can receive no further change from that element except being carried off in vapour.

But though we are unable to effect this change upon solid bodies without a very violent heat, it is otherwise in the natural processes. By what we call *crystallization*, nature produces more perfect glasses than we can make with our furnaces. These are called *precious stones*; but in all trials they discover the essential properties of glass, and not of stones. The most distinguishing property of glass is its resisting the force of fire, so that this element cannot calcine or change it as it does other bodies, but can only melt it, and then carry it off in vapours. To this last all the precious stones are subject. The diamond (the hardest of them all) may be dissipated in a less degree of heat than what would dissipate common glass. Nor can it be any objection to this idea, that some kinds of glass are capable of being converted into a kind of porcelain by a long-continued cementation with certain materials. This change happens only to those kinds of glass which are made of alkaline salt and sand; and Dr Lewis hath shown that this change is produced by the dissipation of the saline principle, which is the least fixed of the two. Glass, therefore, we may still consider as a substance upon which the fire has

Glass. has no other effect than either to melt or dissipate it in vapour.

The other properties of glass are very remarkable, some of which follow:

3 Remarkable properties of glass.

1. It is one of the most elastic bodies in nature. If the force with which glass balls strike each other be reckoned 16, that wherewith they recede by virtue of their elasticity will be nearly 15.

2. When glass is suddenly cooled, it becomes exceedingly brittle; and this brittleness is sometimes attended with very surprising phenomena. Hollow balls made of unannealed glass, with a small hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be stopped with a finger. Some vessels, however, made of such unannealed glass have been discovered, which have the remarkable property of resisting very hard strokes given from without, though they shiver to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. These glasses may be made of any shape: all that needs be observed in making them is, that their bottom be thicker than their sides. The thicker the bottom is, the easier do the glasses break. One whose bottom is three fingers breadth in thickness flies with as much ease at least as the thinnest glass. Some of these vessels have been tried with strokes of a mallet sufficient to drive a nail into wood tolerably hard, and have held good without breaking. They have also resisted the shock of several heavy bodies, let fall into their cavities, from the height of two or three feet; as musket balls, pieces of iron or other metal, pyrites, jasper, wood, bone, &c. But this is not surprising, as other glasses of the same shape and size will do the same: but the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the glass only from the height of three inches, in about two seconds, the glass flies, and sometimes at the very moment of the shock; nay, a bit of flint no larger than a grain, dropped into several glasses successively, though it did not immediately break them, yet when set by, they all flew in less than three quarters of an hour. Some other bodies produce the same effect with flint; as sapphire, diamond, porcelain, hard tempered steel; also marbles such as boys play with, and likewise pearls.

4 Surprising fragility of unannealed glass.

These experiments were made before the Royal Society; and succeeded equally when the glasses were held in the hand, when they were rested on a pillow, put in water, or filled with water. It is also remarkable, that the glasses broke upon having their bottoms slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing. If the glasses are everywhere extremely thin, they do not break in these circumstances.

5 Attempts to account for it.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into the vessels cause a concussion which is stronger than the cohesive force of the glass, and consequently that a rupture must ensue. But why does not a ball of iron, gold, silver, or copper, which are perhaps a thousand times heavier than the flint, produce the same effect? It is because they are not elastic. But surely iron is more elastic than the end of one's finger. Mr Euler has endeavoured to account for these appearances from his principles of percussion. He thinks that this experiment entirely overthrows the opinion of those who measure the force of percussion by the *vis viva*, or absolute apparent strength of the stroke. According to his principles, the great hardness and angular figure of the flint, which makes the space of contact with the glass extremely small, ought to cause an impression on the glass vastly greater than lead, or any other metal; and this may account for the flint's breaking the vessel, though the bullet, even falling from a considerable height, does no damage. Hollow cups made of green bottle glass, some of them three inches thick at the bottom, were instantly broken by a shiver of flint weighing about two grains, though they had resisted the shock of a musket ball from the height of three feet.

That Mr Euler's theory cannot be conclusive more than the other, must appear evident from a very slight consideration. It is not by angular bodies alone that the glasses are broken. The marbles with which children play are round, and yet they have the same effect with the angular flint. Besides, if it was the mere force of percussion which broke the glasses, undoubtedly the fracture would always take place at the very instant of the stroke; but we have seen that this did not happen sometimes till a very considerable space of time had elapsed. It is evident, therefore, that this effect is occasioned by the putting in motion some subtle fluid with which the substance of the glass is filled; and that the motions of this fluid, when once excited in a particular part of the glass, soon propagate themselves through the whole or greatest part of it, by which means the cohesive power becomes at last too weak to resist them. There can be little doubt that the fluid just now mentioned is that of electricity. It is known to exist in glass in very great quantity; and it also is known to be capable of breaking glasses even when annealed with the greatest care, if put into too violent a motion. Probably the cooling of glass hastily may make it more electric than is consistent with its cohesive power, so that it is broken by the least increase of motion in the electric fluid by friction or otherwise. This is evidently the case when it is broken by rubbing with the finger; but why it should also break by the mere contact of flint and the other bodies above mentioned, has not yet been satisfactorily accounted for.

A most remarkable phenomenon also is produced in glass tubes placed in certain circumstances. When these are laid before a fire in a horizontal position, having their extremities properly supported, they acquire a rotatory motion round their axis, and also a progressive motion towards the fire, even when their supports are declining from the fire, so that the tubes will move a little way up hill towards the fire. When the progressive motion of the tubes towards the fire is stopped by any obstacle, their rotation still continues. When the tubes are placed in a nearly upright posture, leaning to the right hand, the motion will be from east to west; but if they lean to the left hand, their motion will be from west to east; and the nearer they are placed to the perfectly upright posture, the less will the motion be either way. 6 Rotation of glass tubes before a fire.

If the tube is placed horizontally on a glass pane, the fragment, for instance, of coach window-glass, instead

Glass.

stead of moving towards the fire, it will move from it, and about its axis in a contrary direction to what it had done before; nay, it will recede from the fire, and move a little up hill when the plane inclines towards the fire. These experiments are recorded in the Philosophical Transactions *. They succeeded best with tubes about 20 or 22 inches long, which had in each end a pretty strong pin fixed in cork for an axis.

* No. 476. § 1.

7 Attempts to account for it.

The reason given for these phenomena, is the swelling of the tubes towards the fire by the heat, which is known to expand all bodies. For, say the adopters of this hypothesis, granting the existence of such a swelling, gravity must pull the tube down when supported near its extremities; and a fresh part being exposed to the fire, it must also swell out and fall down, and so on.—But without going farther in the explanation of this hypothesis, it may be here remarked, that the fundamental principle on which it proceeds is false; for though fire indeed make bodies expand, it does not increase them in weight; and therefore the sides of the tube, though one of them is expanded by the fire, must still remain *in equilibrio;* and hence we must conclude, that the causes of these phenomena remain yet to be discovered.

4. Glass is less dilatable by heat than metalline substances, and solid glass sticks are less dilatable than tubes. This was first discovered by Col. Roy, in making experiments in order to reduce barometers to a greater degree of exactness than hath hitherto been found practicable; and since his experiments were made, one of the tubes 18 inches long, being compared with a solid glass rod of the same length, the former was found by a pyrometer to expand four times as much as the other, in a heat approaching to that of boiling oil.—On account of the general quality which glass has of expanding less than metal, M. de Luc recommends it to be used in pendulums: and he says it has also this good quality, that its expansions are always equable, and proportioned to the degrees of heat; a quality which is not to be found in any other substance yet known.

Phil. Trans. vol. lxvii. p. 663.

Ibid. vol. lxviii. p. 474.

5. Glass appears to be more fit for the condensation of vapours than metallic substances. An open glass filled with water, in the summer time, will gather drops of water on the outside, just as far as the water in the inside reaches; and a person's breath blown on it manifestly moistens it. Glass also becomes moist with dew, when metals do not. See Dew.

6. A drinking glass partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glass is more or less full; and will make the liquor frisk and leap. See Harmonica.

7. Glass is possessed of very great electrical virtues. See Electricity, *passim.*

8 Materials for glass.

Materials for Making of Glass. The materials whereof glass is made, we have already mentioned to be salt and sand or siliceous earth.

1. The salt here used is procured from a sort of ashes brought from the Levant, called *polverine*, or *rochetta;* which ashes are those of a sort of water plant called *kali* †, cut down in the summer, dried in the sun, and burnt in heaps, either on the ground or on iron grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use. It may also be procured from common kelp, or the ashes of the *fucus vesiculosus*. See Kelp.

† See *Salsola*, *Botany Index.*

To extract the salt, these ashes, or polverine, are powdered and sifted, then put into boiling water, and there kept till one-third of the water be consumed; the whole being stirred up from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted: then the vessel is filled up with new water, and boiled over again, till one half be consumed; what remains is a sort of ley, strongly impregnated with salt. This ley, boiled over again in fresh coppers, thickens in about 24 hours, and shoots its salt; which is to be ladled out, as it shoots, into earthen pans, and thence into wooden vats to drain and dry. This done, it is grossly pounded, and thus put in a sort of oven, called *calcar*, to dry. It may be added, that there are other plants, besides kali and fucus which yield a salt fit for glass: such are the common way thistle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c.

Pearl ashes form a leading flux in the manufacture of glass, and mostly supply the place of the Levant ashes, the barillas of Spain, and many other kinds, which were formerly brought here for making both glass and soap.

There are other fluxes used for different kinds of glass, and for various purposes, as calcined lead, nitre, sea salt, borax, arsenic, smiths clinkers, and wood-ashes, containing the earth and lixiviate salts as produced by incineration. With regard to these several fluxes, we may observe, in general, that the more calx of lead, or other metallic earth, enters into the composition of any glass, so much the more fusible, soft, coloured, and dense this glass is, and reciprocally.

The colours given to glass by calces of lead, are shades of yellow: on the other hand, glasses that contain only saline fluxes partake of the properties of salts; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle than the former; and glasses containing both saline and metallic fluxes do also partake of the properties of both these substances. Glasses too saline are easily susceptible of alteration by the action of air and water: especially those in which alkalies prevail; and these are also liable to be injured by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish and become opake when exposed to air. By attending to these properties of different fluxes, phlogistic or saline, the artist may know how to adjust the proportions of these to sand, or powdered flints, for the various kinds of glass. See the article Vitrification.

2. The sand or stone, called by the artists *tarso*, is the second ingredient in glass, and that which gives it the body and firmness. These stones, Agricola observes, must be such as will fuse; and of these such as are white and transparent are best; so that crystal challenges the precedency of all others.

At Venice they chiefly use a sort of pebble, found in the river Tesino, resembling white marble, and called *cuogolo*. Indeed Ant. Neri assures us, that all stones which will strike fire with steel, are fit to vitrify; but Dr Morret shows, that there are some exceptions from this

this rule. Flints are admirable; and when calcined, powdered, and searced, make a pure white crystalline metal; but the expence of preparing them makes the masters of our glass-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used. The best for this purpose is that which is white, small, and shining; examined by the microscope, it appears to be small fragments of rock crystal. For green glass, that which is of a soft texture, and more gritty; it is to be well washed, which is all the preparation it needs. Our glass-houses are furnished with white sand for their crystal glasses from Lynn in Norfolk, and Maidstone in Kent, and with the coarser for green glass from Woolwich.

Some mention a third ingredient in glass, viz. manganese, a kind of pseudo loadstone, dug up in Germany, Italy, and even in Mendip hills in Somersetshire. But the proportion hereof to the rest is very inconsiderable; beside, that it is not used in all glass. Its office is to purge off the natural greenish colour, and give it some other tincture required.

For this purpose it should be chosen of a deep colour, and free from specks of metalline appearance, or a lighter cast; manganese requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganese in destroying the colours of glass, and hence called the soap of glass, is accounted for by M. Montamy, in his *Traité des Couleurs pour la Peinture en Email*, in the following manner: the manganese destroys the green, olive, and blue colours of glass, by adding to them a purple tinge, and by the mixture producing a blackish brown colour; and as blackness is caused merely by an absorption of the rays of light, the blackish tinge given to the glass by the mixture of colours, prevents the reflection of so many rays, and thus renders the glass less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of glass which are required to be very transparent. Nitre or saltpetre is also used with the same intention; for by destroying, in a certain degree, the inflammable or carbonaceous matter, which gives a strong tinge of yellow to glass prepared with lead as a flux, it serves to free it from this colour; and in saline glasses, nitre is requisite in a smaller proportion to render them sufficiently transparent, as in the case of looking glass and other kinds of plates.

Kinds of Glass. The manufactured glass now in use may be divided into three general kinds; white transparest glass, coloured glass, and common green or bottle glass. Of the first kind there is a great variety; as the flint glass, as it is called with us, and the German crystal glass, which are applied to the same uses; the glass for plates, for mirrors, or looking glasses; the glass for windows and other lights; and the glass for phials and small vessels. And these again differ in the substances employed as fluxes in forming them, as well as in the coarseness or fineness of such as are used for their body. The flint and crystal, mirror and best window glass, not only require such purity in the fluxes, as may render it practicable to free the glass perfectly from all colour; but for the same reason likewise, either the white Lynn sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window glass, and the best kind of phial, will not be so clear as they ought, if either too brown sand or impure salts be suffered to enter into their composition.

Of coloured glass there is a great variety of sorts, differing in their colour or other properties according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artists by whom they are manufactured, as will be afterwards explained.

Furnaces for the Making of Glass. In this manufacture there are three sorts of furnaces; one called *calcar* is for the frit; the second is for working the glass; the third serves to anneal the glass, and is called the *leer*. See Plate CCXLVII.

The calcar resembles an oven ten feet, long, seven feet broad, and two deep; the fuel, which in Britain is sea coal, is put into a trench on one side of the furnace, and the flame reverberating from the roof upon the frit calcines it. The glass furnace, or working furnace, is round, of three yards diameter, and two high: or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part is properly called the *crown*, and is made in that form. Its use is to keep a brisk fire, which is never put out. The mouth is called the *bocca*. There are several holes in the arch of this crown, through which the flame passes into the second vault or partition, and reverberates into the pots filled with the ingredients above mentioned. Round the insides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccas or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in while he works out of the other. Through the working holes the metal is taken out of the pots, and the pots are put into the furnace; and these holes are stopped with moveable covers made of lute and brick, to screen the workmen's eyes from the scorching flames. On each side of the bocca or mouth is a bocarella or little hole, out of which coloured glass or finer metal is taken from the piling pot. Above this oven there is the third oven or *leer*, above five or six yards long, where the vessels or glass are annealed or cooled: this part consists of a tower, besides the leer, into which the flame ascends from the furnace. The tower has two mouths, through which the glasses are put in with a fork, and set on the floor or bottom: but they are drawn out on iron pans called *fraches*, through the leer, to cool by degrees; so that they are quite cold by the time they reach the mouth of the leer, which enters the sarosel or room where the glasses are to be stowed.

But the green-glass furnace is square; and at each angle it has an arch for annealing or cooling glasses. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnet holes for the fire to come from the furnace to bake the frit, and to discharge the smoke. Fires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick; and the inner part, to bear the fire, is made of a

sort

Glass.

sort of fullers earth, or tobacco-pipe clay, of which earth they also make their melting pots. In Britain the pots are made of Stourbridge clay.

Mr Blancourt observes that the worst and roughest work in this art is the changing the pots when they are worn out or cracked. In this case the great working hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, through the flames, by the hands only. For this work, the man guards himself with a garment made of skins, in the shape of a pantaloon, that covers him all but his eyes, and is made as wet as possible; the eyes are defended with a proper sort of glass.

Instruments for Making of Glass. The instruments made use of in this work may be reduced to these that follow. A blowing pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glass after it is blown, and to cut off the former. Scissars to cut the glass when it comes off from the first hollow iron. Shears to cut and shape great glasses, &c. An iron ladle with the end of the handle cased with wood, to take the metal out of the refining pot, to put it into the workman's pots. A small iron ladle cased in the same manner, to skim the alkalic salt that swims at top. Shovels, one like a peel, to take up the great glasses; another like a fire-shovel, to feed the furnace with coals. A hooked iron fork, to stir the matter in the pots. An iron rake for the same purpose, and to stir the frit. An iron fork, to change or pull the pots out of the furnace, &c.

Compositions for White and Crystal Glass. 1. To make *crystal glass*, take of the whitest tarso, pounded small, and searced as fine as flour, 200 pounds; of the salt of polverine 130 pounds; mix them together and put them into the furnace called the *calcar*, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which being now sufficiently calcined, is called *frit*. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months. Now to make the glass or crystal: take of this crystal frit, called also *bollito*; set it in pots in the furnace, adding to it a due quantity of magnesia or manganese: when the two are fused, cast the fluor into fair water, to clear it of the salt called *sandiver*; which would otherwise make the crystal obscure and cloudy. This lotion must be repeated again and again, as often as needful, till the crystal be fully purged; or this scum may be taken off by means of proper ladles. Then set it to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more manganese, at discretion, by little and little at a time, taking care not to overdose it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown or formed into vessels at pleasure.

2. *Flint glass*, as it is called by us, is of the same general kind with that which in other places is called crystal glass. It has this name from being originally made with calcined flints, before the use of the white sand was understood; and retains the name, though no flints are now used in the composition of it. This flint glass differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal glass are salts or arsenic, and the body consists of calcined flints or white river pebbles, tarso, or such stones. To the white sand and lead a proper proportion of nitre is added, to burn away the phlogiston of the lead, and also a small quantity of magnesia; and in some works they use a proportional quantity of arsenic to aid the fluxing ingredients. The most perfect kind of glass may be made by fusing with a very strong fire 120 pounds of the white sand, 50 pounds of red lead, 40 pounds of the best pearl ashes, 20 pounds of nitre, and five ounces of magnesia. Another composition of flint glass, which is said to come nearer to the kind now made, is the following: 120 pounds of sand, 54 pounds of the best pearl ashes, 36 pounds of red lead, 12 pounds of nitre, and 6 ounces of magnesia. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition of flint glass may be made with 120 pounds of white sand, 35 pounds of the best pearl ashes, 40 pounds of red lead, 13 pounds of nitre, 6 pounds of arsenic, and four ounces of magnesia; or instead of the arsenic may be substituted 15 pounds of common salt; but this will be more brittle than the other. The cheapest composition for the worst kind of flint glass consists of 120 pounds of white sand, 30 pounds of red lead, 20 pounds of the best pearl ashes, 10 pounds of nitre, 15 pounds of common salt, and six pounds of arsenic. The best German crystal glass is made of 120 pounds of calcined flints or white sand, 70 pounds of the best pearl ashes, 10 pounds of saltpetre, half a pound of arsenic, and five ounces of magnesia. And a cheaper composition is formed of 120 pounds of calcined flints or white sand, 46 pounds of pearl ashes, 7 pounds of nitre, 6 pounds of arsenic, and 5 ounces of magnesia.

A glass much harder than any prepared in the common way, may be made by means of borax in the following method: Take four ounces of borax, and an ounce of fine sand; reduce both to a subtile powder, and melt them together in a large close crucible set in a wind furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass capable of cutting common glass like a diamond. This experiment, duly varied, says Dr Shaw, may lead to several useful improvements in the arts of glass, enamels, and factitious gems, and shows an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glass, and it is not yet known whether calcined crystal or other substances being added to this salt instead of sand, it might not make a glass approaching to the nature of a diamond.

There are three principal kinds of glasses, distinguished by the form or manner of working them; viz. I. *Round glass*, as those of our vessels, phials, drinking glasses, &c. II. *Table* or *window glass*, of which there are divers kinds; viz. crown glass, jealous glass, &c. III. *Plate glass*, or *mirror glass*.

I. *Working or Blowing Round Glass.* The working furnace, we have observed, is round, and has six boccas

 or

or apertures: at one of these, called the *great bocca*, the furnace is heated, and the pots of frit are at this set in the furnace; two other small holes, called *bocarellas*, serve to lade or take out the melted metal, at the end of an iron, to work the glass. At the other holes they put in pots of fusible ingredients, to be prepared, and at last emptied into the lading pot.

There are six pots in each furnace, all made of tobacco-pipe clay, proper to sustain not only the heat of the fire, but also the effect of the polverine, which penetrates every thing else. There are only two of these pots that work: the rest serve to prepare the matter for them. The fire of the furnace is made and kept up with dry hard wood, cast in without intermission at six apertures.

When the matter contained in the two pots is sufficiently vitrified, they proceed to blow or fashion it. For this purpose the workman dips his blowing pipe into the melting pot; and by turning it about, the metal sticks to the iron more firmly than turpentine. This he repeats four times, at each time rolling the end of his instrument, with the hot metal thereon, on a piece of plate iron; over which is a vessel of water which helps to cool, and so to consolidiate and to dispose that matter to bind more firmly with what is to be taken next out of the melting pot. But after he has dipt a fourth time, and the workman perceives there is metal enough on the pipe, he claps his mouth immediately to the other end of it, and blows gently through the iron tube, till the metal lengthens like a bladder about a foot. Then he rolls it on a marble stone a little while to polish it; and blows a second time, by which he brings it to the shape of a globe of about 18 or 20 inches diameter. Every time he blows into the pipe, he removes it quickly to his cheek; otherwise he would be in danger, by often blowing, of drawing the flame into his mouth: and this globe may be flattened by returning it to the fire; and brought into any form by stamp irons, which are always ready. When the glass is thus blown, it is cut off at the collet or neck; which is the narrow part that stuck to the iron. The method of performing this is as follows: the pipe is rested on an iron bar, close by the collet; then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which, with a slight blow or cut of the shears will immediately separate the collet.

After this is done, the operator dips the iron rod into the melting pot, by which he extracts as much metal as serves to attract the glass he has made, to which he now fixes this rod at the bottom of his work, opposite to the opening made by the breaking of the collet. In this position the glass is carried to the great bocca or mouth of the oven, to be heated and scalded; by which means it is again put into such a soft state, that, by the help of an iron instrument, it can be pierced, opened, and widened, without breaking. But the vessel is not finished till it is returned to the great bocca; where being again heated thoroughly, and turned quickly about with a circular motion, it will open to any size, by the means of the heat and motion.

If there remain any superfluities, they are cut off with the shears; for till the glass is cool, it remains in a soft flexible state. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguished, keeping it turning; because that motion prevents any settling, and preserves an evenness in the face of the glass, where, as it cools, it comes to its consistency; being first cleared from the iron rod by a slight stroke by the hand of the workman.

If the vessel conceived in the workman's mind, and whose body is already made, requires a foot, or a handle, or any other member or decoration, he makes them separately; and now essays to join them with the help of hot metal, which he takes out of the pots with his iron rod: but the glass is not brought to its true hardness till it has passed the leer or annealing oven, described before.

II. *Working or blowing of Window or Table* Glass. The method of working round glass, or vessels of any sort, is in every particular applicable to the working of window or table glass, till the blowing iron has been dipt the fourth time. But then instead of rounding it, the workman blows, and so manages the metal upon the iron plate, that it extends two or three feet in the form of a cylinder. This cylinder is put again to the fire, and blown a second time, and is thus repeated till it is extended to the dimensions required, the side to which the pipe is fixed diminishing gradually till it ends in a pyramidal form; so that, to bring both ends nearly to the same diameter, while the glass is thus flexible, he adds a little hot metal to the end opposite the pipe, and draws it out with a pair of iron pincers, and immediately cuts off the same end with the help of a little cold water as before.

The cylinder being now open at one end, is carried back to the bocca; and there, by the help of cold water, it is cut about eight or ten inches from the iron pipe or rod; and the whole length at another place, by which also it is cut off from the iron rod. Then it is heated gradually on an earthen table, by which it opens in length; while the workman, with an iron tool, alternately lowers and raises the two halves of the cylinder; which at last will open like a sheet of paper, and fall into the same form in which it serves for use; in which it is preserved by heating it over again, cooling it on a table of copper, and hardening it 24 hours in the annealing furnace, to which it is carried upon forks. In this furnace an hundred tables of glass may lie at a time, without injury to each other, by separating them into tents, with an iron shiver between, which diminishes the weight by dividing it, and keeps the tables flat and even.

Of window or table glass there are various sorts, made in different places, for the use of building. Those most known among us are given us by the author of the Builder's Dictionary, as follows:

1. *Crown*, of which, says Neri, there are two kinds, distinguished by the places where they are wrought; viz. Ratcliff crown glass, which is the best and clearest, and was first made at the Bear garden, on the Bankside, Southwark, but since at Ratcliff: of this there are 24 tables to the case, the tables being of a circular form, about three feet six inches in diameter. The other kind, or Lambeth crown glass, is of a darker colour than the former, and more inclining to green.

The best window or crown glass is made of white sand 60 pounds, of purified pearl ashes 30 pounds, of saltpetre

saltpetre 15 pounds, of borax one pound, and of arsenic half a pound. If the glass should prove yellow, magnesia must be added. A cheaper composition for window glass consists of 60 pounds of white sand, 25 pounds of unpurified pearl ashes, 10 pounds of common salt, 5 pounds of nitre, 2 pounds of arsenic, and one ounce and a half of magnesia. The common or green window glass is composed of 60 pounds of white sand, 60 pounds of unpurified pearl ashes, 10 pounds of common salt, 2 pounds of arsenic, and 2 ounces of magnesia. But a cheaper composition for this purpose consists of 120 pounds of the cheapest white sand, 30 pounds of unpurified pearl ashes, 60 pounds of wood ashes, well burnt and sifted, 20 pounds of common salt, and 5 pounds of arsenic.

2. *French glass*, called also *Normandy glass*, and formerly *Lorraine glass*, because made in those provinces. At present it is made wholly in the nine glass works; five whereof are in the forest of Lyons, four in the county of Eu; the last at Beaumont near Rouen. It is of a thinner kind than our crown glass; and when laid on a piece of white paper, appears of a dirtyish green colour. There are but 25 tables of this to the case.

3. *German glass* is of two kinds, the *white* and the *green*: the first is of a whitish colour, but is subject to those small curved streaks observed in our Newcastle glass, though free from the spots and blemishes thereof. The green, besides its colour, is liable to the same streaks as the white; but both of them are straighter and less warped than our Newcastle glass.

4. *Dutch glass* is not much unlike our Newcastle glass either in colour or price. It is frequently much warped like that, and the tables are but small.

5. *Newcastle glass* is that most used in England. It is of an ash colour, and much subject to specks, streaks, and other blemishes; and besides is frequently warped. Leybourn says, there are 45 tables to the case, each containing five superficial feet: some say there are but 35 tables, and six feet in each table.

6. *Phial glass* is a kind betwixt the flint glass and the common bottle or green glass. The best kind may be prepared with 120 pounds of white sand, 50 pounds of unpurified pearl ashes, 10 pounds of common salt, 5 pounds of arsenic, and 5 ounces of magnesia. The composition for green or common phial glass consists of 120 pounds of the cheapest white sand, 80 pounds of wood ashes well burnt and sifted, 20 pounds of pearl ashes, 15 pounds of common salt, and 1 pound of arsenic.

The common bottle or green is formed of sand of any kind fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the *scoriæ* or clinkers of forges. When the softest sand is used, 200 pounds of wood ashes will suffice for 100 pounds of sand, which are to be ground and mixed together. The composition with the clinkers consists of 170 pounds of wood ashes, 100 pounds of sand, and 50 pounds of clinkers or *scoriæ*, which are to be ground and mixed together. If the clinkers cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

III. *Working of Plate or Mirror* GLASS. 1. The materials of which this glass is made are much the same as those of other works of glass, viz. an alkali, salt and sand.

The salt, however, should not be that extracted from polverine or the ashes of the Syrian kali, but that from BARILLA, growing about Alicant in Spain. It is very rare that we can have the barilla pure; the Spaniards in burning the herb make a practice of mixing another herb along with it, which alters its quality; or of adding sand to it to increase the weight, which is easily discovered if the addition be only made after the boiling of the ashes, but next to impossible if made in the boiling. It is from this adulteration that those threads and other defects in plate glass arise. To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax or common salt, in order to facilitate the fusion, and prevent the glass from stiffening in that degree of heat in which it is to be wrought into plates. For purifying the pearl ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there 24 hours or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone jars, well secured from air and moisture.

Pearl ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glass, by pulverizing three pounds of the best pearl ashes with six ounces of saltpetre in a glass or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red hot, throw in the rest gradually; and when the whole is red hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl ashes after their former calcination.

As to the sand, it is to be sifted and washed till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white: in this state they are called *frit* or *fritta*; and are to be laid up in a dry clean place, to give them time to incorporate: they lie here for at least a year.

When they would employ this frit, they lay it for some hours in the furnace, adding to some the fragments or shards of old and ill made glasses; taking care first to calcine the shards by heating them red hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added

Glass.

ed manganese, to promote the fusion and purification.

The best composition for looking glass plates consists of 60 pounds of white sand cleansed, 25 pounds of purified pearl ashes, 15 pounds of saltpetre, and 7 pounds of borax. If a yellow tinge should affect the glass, a small proportion of magnesia, mixed with an equal quantity of arsenic, should be added. An ounce of the magnesia may be first tried; and if this proves insufficient, the quantity should be increased.

A cheaper composition for looking glass plate consists of 60 pounds of the white sand, 20 pounds of pearl ashes, 10 pounds of common salt, 7 pounds of nitre, 2 pounds of arsenic, and 1 pound of borax. The matter of which the glasses are made at the famous manufacture of St Gobin in France, is a composition of solder and of a very white sand, which are carefully cleaned of all heterogeneous bodies; afterwards washed for several times, and dried so as to be pulverized in a mill, consisting of many pestles, which are moved by horses. When this is done, the sand is sifted through silk sieves and dried.

The matter thus far prepared is equally fit for plate glass, to be formed either for blowing or by casting.

The largest glasses at St Gobin are run; the middle sized and small ones are blown.

2. *Blowing the plates.* The workhouses, furnaces, &c. used in the making of this kind of plate glass, are the same, except that they are smaller, and that the carquaisses are disposed in a large covered gallery, over against the furnace, as those in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the glass is sufficiently refined, the workman dips in his blowing iron, six feet long, and two inches in diameter, sharpened at the end which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a small ball of matter, which sticks to the end of the tube by constantly turning it. He then blows into the tube, that the air may swell the annexed ball; and carrying it over a bucket of water, which is placed on a support at the height of about four feet, he sprinkles the end of the tube to which the matter adheres, with water, still turning it, that by this cooling the matter may coalesce with the tube, and be fit for sustaining a greater weight. He dips the tube again into the same pot, and proceeds as before; and dipping it into the pot a third time, he takes it out, loaded with matter, in the shape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the same time blowing into the tube, and with the assistance of a labourer, giving it a balancing motion, he causes the matter to lengthen; which, by repeating this operation several times, assumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The assistant is then placed on a stool three feet and a half high; and on this stool there are two upright pieces of timber, with a cross beam of the same, for supporting the glass and tube, which are kept in an oblique position by the assistant, that the master workman may with a puncheon set in a wooden handle, and with a mallet, make a hole in the mass: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glass is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron tressel, placed on the support of the aperture of the furnace. Having exposed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad shears, extremely sharp at the end, widens the glass, by insinuating the shears into the hole made with the puncheon, whilst the assistant, mounted on the stool, turns it round, till at last the opening is so large as to make a perfect cylinder at bottom. When this is done, the workman lays his glass upon the tressels at the mouth of the furnace to heat it: he then gives it to his assistant on the stool, and with large shears cuts the mass of matter up to half its height. There is at the mouth of the furnace an iron tool called *pontil*, which is now heating, that it may unite and coalesce with the glass just cut, and perform the office which the tube did before it was separated from the glass. This pontil is a piece of iron six feet long, and in the form of a cane or tube, having at the end of it a small iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glass, about four inches thick. This red hot pontil is presented to the diameter of the glass, which coalesces immediately with the matter round the pontil, so as to support the glass for the following operation. When this is done, they separate the tube from the glass, by striking a few blows with a chissel upon the end of the tube which has been cooled; so that the glass breaks directly, and makes this separation, the tube being discharged of the glass now adhering to the pontil. They next present to the furnace the pontil of the glass, laying it on the tressel to heat, and redden the end of the glass, that the workman may open it with his shears, as he has already opened one end of it, to complete the cylinder; the assistant holding it on his stool as before. For the last time, they put the pontil on the tressel, that the glass may become red hot, and the workman cuts it quite open with his shears, right over against the forementioned cut; this he does as before, taking care that both cuts are in the same line. In the mean time, the man who looks after the carquaisses comes to receive the glass upon an iron shovel two feet and a half long without the handle, and two feet wide, with a small border of an inch and a half to the right and left, and towards the handle of the shovel. Upon this the glass is laid, flattening it a little with a small stick a foot and a half long, so that the cut of the glass is turned upwards. They separate the glass from the pontil, by striking a few gentle blows between the two with a chissel. The glass is then removed to the mouth of the hot carquaisse, where it becomes red hot gradually; the workman, with an iron tool six feet long, and widened at the end in form of a club at cards four inches long, and two inches wide on each side, very flat, and not half an inch thick, gradually lifts up the cut part of the glass to unfold it out of its form of a flattened cylinder, and render it smooth, by turning it down upon the hearth of the carquaisse. The tool already described being insinuated within the cylinder, performs this operation by being pushed hard against all the parts of the glass. When the glass is thus made quite smooth, it is pushed to the bottom of the carquaisse

Glass.

carquaisse or annealing furnace with a small iron raker, and ranged there with a little iron hook. When the carquaisse is full, it is stopped and cemented as in the case of run glasses, and the glass remains there for a fortnight to be annealed; after which time they are taken out to be polished. A workman can make but one glass in an hour, and he works and rests for six hours alternately.

Such was the method formerly made use of for blowing plate glass, looking glasses, &c.; but the workmen, by this method, could never exceed 50 inches in length, and a proportional breadth, because what were larger were always found to warp, which prevented them from reflecting the objects regularly, and wanted substance to bear the necessary grinding. These imperfections have been remedied by the following invention of the Sieur Abraham Thevart, in France, about the year 1688.

3. *Casting or Running of Large Mirror* GLASS *Plates.* The furnace is of a very large dimension, environed with several ovens, or annealing furnaces, called *carquaisses*, besides others for making of frit and calcining old pieces of glass. This furnace, before it is fit to run glass, costs 3500l. It seldom lasts above three years, and even in that time it must be refitted every six months. It takes six months to rebuild it, and three months to refit it. The melting pots are as big as large hogsheads, and contain about 2000 weight of metal. If one of them bursts in the furnace, the loss of the matter and time amounts to 250l. The materials in these pots are the same as described before. When the furnace is red hot, these materials are put in at three different times, because that helps the fusion; and in 24 hours they are vitrified, refined, settled, and fit for casting. A is the bocca, or mouth of the furnace; B is the cistern that conveys the liquid glass it receives out of the melting pots in the furnace to the casting table. These cisterns are filled in the furnace, and remain therein six hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pulley, placed upon a carriage with four wheels marked C, by two men. This carriage has no middle piece; so that when it has brought the cistern to the casting table D, they slip off the bottom of the cistern, and out rushes a torrent of flaming matter upon the table: this matter is confined to certain dimensions by the iron rulers EE, which are moveable, retain the fluid matter, and determine the width of the glass; while a man, with the roller F resting on the edge of the iron rulers, reduceth it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trustles for the convenience of moving to the annealing furnace; into which, strewed with sand, the new plate is shoved, where it will harden in about 10 days.

Plate CCXLVII. fig. 2.

What is most surprising throughout the whole of this operation, is the quickness and address wherewith such massy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the glass spread, &c. The whole is inconceivable to such as have not been eye witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. Thus they continue to do so long as there are any full cisterns; laying as many plates in each carquaisse as it will hold, and stopping them up with doors of baked earth, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about 14 days.

The first running being dispatched, they prepare another, by filling the cisterns anew from the matter in the pots; and after the second, a third; and even a fourth time, till the melting pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting table is to be carried to another. It need not here be observed, that the carquaisses, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven full, or the quantity of matter, commonly prepared, supplies the running of 18 glasses, which is performed in 18 hours, being an hour for each glass. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what glass remains, which otherwise would grow green by continuance of fire, and spoil the glasses. They are not filled again in less than 36 hours; so that they put the matter into the furnace, and begin to run it every 54 hours.

The manner of heating the large furnaces is very singular; the two tisors, or persons employed for that purpose, in their shirts, run swiftly round the furnace without making the least stop: as they run along, they take two billets, or pieces of wood, which are cut for the purpose: these they throw into the first tissart; and continuing their course, do the same for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such that a large bar of iron, laid at one of the mouths of the furnace, becomes red hot in less than half a minute.

The glass, when taken out of the melting furnace, needs nothing farther but to be ground, polished, and foliated.

4. *Grinding and Polishing of Plate* GLASS. Glass is made transparent by fire; but it receives its lustre by the skill and labour of the grinder and polisher; the former of whom takes it rough out of the hands of the maker.

In order to grind plate glass, they lay it horizontally upon a flat stone table made of a very fine grained freestone; and for its greater security they plaster it down with lime or stucco; for otherwise the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This stone table is supported by a strong frame A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel to which this plank is fastened, and from the weights laid upon it to promote the grinding or triture of the glasses. The whole is covered with a wheel B, made

W. & D. Lizars Edinburgh.

made of hard light wood, about six inches in diameter, by pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen, who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the work advanceth, till at last they must pour in the powder of smalt. As the upper or incumbent glass polishes and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a *mill* by the artist, and is used only in the largest sized glasses; for in the grinding of the lesser glasses, they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glass to an exact plainness, it is turned over to the polisher; who, with the fine powder of tripoli stone or emery, brings it to a perfect evenness and lustre. The instrument made use of in this branch is a board, *c c*, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist, in working this roller, is assisted with a wooden hoop or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

Colouring of GLASS. That the colours given to glass may have their full beauty, it must be observed, that every pot when new, and first used, leaves a foulness in the glass from its own earthy parts; so that a coloured glass made in a new pot can never be bright or perfectly fine. For this reason, the larger of these, when new, may be glazed with white glass; but the second time of using the pots lose this foulness. The glazing may be done by reducing the glass to powder, and moistening the inside of the pot with water; while it is yet moist, put in some of the powdered glass, and shake it about, till the whole inner surface of the pot be covered by as much as will adhere to it, in consequence of the moisture. Throw out the redundant part of the powdered glass; and the pot being dry, set it in a furnace sufficiently hot to vitrify the glass adhering to it, and let it continue there some time; after which, care must be taken to let it cool gradually. Those pots which have served for one colour must not be used for another; for the remainder of the old matter will spoil the colour of the new. The colours must be very carefully calcined to a proper degree; for if they were calcined ether too much or too little, they never do well; the proper proportion, as to quantity, must also carefully be regarded, and the furnaces must be fed with dry hard wood. And all the processes succeed much the better if the colour be used dividedly, that is, part of it in the frit, and the rest in the melted meltal.

A hard glass, proper for receiving colours, may be prepared by pulverizing 12 pounds of the best sand cleansed by washing in a glass or flint mortar, and mixing seven pounds of pearl ashes or any fixed alkaline salt purified with nitre, one pound of saltpetre, and half a pound of borax, and pounding them together. A glass less hard may be prepared of twelve pounds of white sand cleansed, seven pounds of pearl ashes purified with saltpetre, one pound of nitre, half a pound of borax, and four ounces of arsenic prepared as before.

Amethyst colour. See *Purple* below, and the article AMETHYST.

Balas colour. Put into a pot crystal frit, thrice washed in water; tinge this with manganese, prepared into a clear purple; to this add *alumen cativum*, sifted fine, in small quantities, and at several times: this will make the glass grow yellowish, and a little reddish, but not blackish, and always dissipates the manganese. The last time you add manganese give no more of the *alumen cativum*, unless the colour be too full. Thus will the glass be exactly of the colour of the balas ruby. See *Ruby* GLASS.

The common black colour. The glassmakers take old broken glass of different colours, grind it to powder, and add to it, by different parcels, a sufficient quantity of a mixture of two parts zaffer and one part manganese: when well purified, they work it into vessels, &c.

Glass beads are coloured with manganese only.

Black velvet colour. To give this deep and fine colour to glass, take of crystalline and pulverine frit, of each 20 pounds; of calx of lead and tin, four pounds; set all together in a pot in the furnace, well heated: when the glass is formed and pure, take steel well calcined and powdered, scales of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well; then put six ounces of this powder to the above-described metal while in fusion: mix the whole thoroughly together, and let them all boil strongly together; then let it stand in fusion 12 hours to purify, and after this work it. It will be a most elegant velvet black.

There is another way of doing this, which also produces a very fair black. It is this: take a hundred weight of rochetta frit, add to this two pounds of tartar and six pounds of manganese, both in fine powder; mix them well; and put them to the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it.

A glass perfectly black may also be formed by adding to ten pounds of either of the compositions for hard glass above described, one ounce of zaffer, six drachms of manganese, and an equal quantity of iron strongly calcined.

Blue colour. A full blue may be made by adding six drachms of zaffer and two drachms of manganese to ten pounds of either of the compositions for hard glass, described above. For a very cool or pure blue glass, half an ounce of calcined copper may be used instead of the manganese, and the proportion of zaffer diminished by one half. Glass resembling sapphire may be made with ten pounds of either of the compositions for hard glass, three drachms and one scruple of zaffer, and one drachm of the *calx cassii* or precipitation of gold by tin; or, instead of this latter ingredient, two drachms and two scruples of mangauese. Or a sapphire-coloured glass may be made by mixing with any quantity of the hard glass one-eighth of its weight of smalt. A beautiful blue glass is also produced from the oxide of cobalt.

Venetian brown, with gold spangles, commonly called the

the *philosopher's stone*, may be prepared in the following manner: take of the second composition for hard glass above described, and of the composition for paste, of each five pounds, and of highly calcined iron an ounce; mix them well, and fuse them till the iron be perfectly vitrified, and has tinged the glass of a deep transparent yellow brown colour. Powder this glass, and add to it two pounds of powdered glass of antimony; grind them together, and thus mix them well. Take part of this mixture, and rub into it 80 or 100 leaves of the counterfeit leaf gold called *Dutch gold;* and when the parts of the gold seem sufficiently divided, mix the powder containing it with the other part of the glass. Fuse the whole with a moderate heat till the powder run into a vitreous mass, fit to be wrought into any of the figures or vessels into which it is usually formed; but avoid a perfect liquefaction, because that in a short time destroys the equal diffusion of the spangles, and vitrifies, at least in part, the matter of which they are composed; converting the whole into a kind of transparent olive-coloured glass. This kind of glass is used for a great variety of toys and ornaments with us, who at present procure it from the Venetians.

Chalcedony. A mixture of several ingredients with the common matter of glass, will make it represent the semi-opake gems, the jaspers, agates, chalcedonies, &c. The way of making these seems to be the same with the method of making marbled paper, by several colours dissolved in several liquors, which are such as will not readily mix with one another when put into water, before they are cast upon the paper which is to be coloured. There are several ways of making these variously coloured glasses, but the best is the following.

Dissolve four ounces of fine leaf silver in a glass vessel in strong aquafortis; stop up the vessel, and set it aside.—In another vessel, dissolve five ounces of quicksilver in a pound of aquafortis, and set this aside.—In another glass vessel, dissolve in a pound of aquafortis three ounces of fine silver, first calcined in this manner: amalgamate the silver with mercury, mix the amalgam with twice its weight of common salt well purified; put the mixture in an open fire in a crucible, that the mercury may fly off, and the silver be left in form of powder. Mix this powder with an equal quantity of common salt well purified, and calcine this for six hours in a strong fire; when cold, wash off the salt by repeated boilings in common water, and then put the silver into the aquafortis. Set this solution also aside.—In another vessel, dissolve in a pound of aquafortis three ounces of sal ammoniac; pour off the solution and dissolve in it a quarter of an ounce of gold. Set this also aside.—In another vessel, dissolve three ounces of sal ammoniac in a pound of aquafortis; then put into the solution cinnabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this also aside.—In another vessel, dissolve in a pound of aquafortis three ounces of sal ammoniac; then put into it crocus martis made with vinegar, calcined tin, zaffer, and cinnabar, of each half an ounce; let each of these be powdered very fine, and put gently into the aquafortis. Set this also aside.—In another vessel, dissolve three ounces of sal ammoniac in a pound of aquafortis, and add to it brass calcined with brimstone, brass thrice calcined, manganese, and scales of iron which fall from the smith's anvil, of each half an ounce; let each be well powdered, and put gently into the vessel. Then set this also aside.—In another vessel, dissolve two ounces of sal ammoniac in a pound of aquafortis, and put to it verdigrise an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put these well powdered leisurely into the vessel, and set this also aside.—In another vessel, dissolve two ounces of sal ammoniac in a pound of aquafortis, and add orpiment, white arsenic, painters lake, of each half an ounce.

Keep the above nine vessels in a moderate heat for 15 days, shaking them well at times. After this pour all the matters from these vessels into one large vessel, well luted at its bottom; let this stand six days, shaking it at times; and then set it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purplish green.

When this is to be wrought, put into a pot very clear metal, made of broken crystalline and white glass that has been used; for with the virgin frit, or such as has never been wrought, the chalcedony can never be made, as the colours do not stick to it, but are consumed by the frit. To every pot of 20 pounds of this metal put two or three ounces of this powder at three several times; incorporate the powder well with the glass; and let it remain an hour between each time of putting in the powders. After all are in, let it stand 26 hours; then let the glass be well mixed, and take an essay of it, which will be found of a yellowish blue; return this many times into the furnace; when it begins to grow cold, it will show many waves of different colours very beautifully. Then take tartar eight ounces, soot of the chimney two ounces, crocus martis made with brimstone, half an ounce; let these be well powdered and mixed, and put them by degrees into the glass at six times, waiting a little while between each putting in. When the whole is put in, let the glass boil and settle for 24 hours; then make a little glass body of it; which put in the furnace many times, and see if the glass be enough, and whether it have on the outside veins of blue, green, red, yellow, and other colours, and have, beside these veins, waves like those of the chalcedonies, jaspers, and oriental agates, and if the body kept within looks as red as fire.

When it is found to answer this, it is perfect, and may be worked into toys and vessels, which will always be beautifully variegated; these must be well annealed, which adds much to the beauty of their veins. Masses of this may be polished at the lapidary's wheel as natural stones, and appear very beautiful. If in the working the matter grow transparent, the work must be stopped, and more tartar, soot, and crocus martis, must be put to it, which will give it again the necessary body and opacity, without which it does not show the colours well.

Chrysolite colour may be made of ten pounds of either of the compositions for hard glass described above, and six drachms of calcined iron.

Red cornelian colour may be formed by adding one pound of glass of antimony, two ounces of the calcined vitriol called *scarlet ochre,* and one drachm of manganese or magnesia, to two pounds of either of the compositions

positions for hard glass. The glass of antimony and magnesia are first fused with the other glass, and then powdered and ground with the scarlet ochre: the whole mixture is afterwards fused with a gentle heat till all the ingredients are incorporated. A glass resembling the white cornelian may be made of two pounds of either of the compositions for hard glass, and two drachms of yellow ochre well washed, and one ounce of calcined bones: grind them together, and fuse them with a gentle heat.

Emerald colour. See *Green* below.

Garnet colour. To give this colour to glass, the workmen take the following method. They take equal quantities of crystal and rochetta frit, and to every hundred weight of this mixture they add a pound of manganese and an ounce of prepared zaffer: these are to be powdered separately, then mixed and added by degrees to the frit while in the furnace. Great care is to be taken to mix the manganese and zaffer very perfectly; and when the matter has stood 24 hours in fusion, it may be worked.

Glass of this kind may be made by adding one pound of glass of antimony, one drachm of manganese, and the same quantity of the precipitate of gold by tin, to two pounds of either of the compositions for hard glass; or the precipitate of gold may be omitted, if the quantities of the glass of antimony and manganese be doubled.

Gold colour. This colour may be produced by taking ten pounds of either of the compositions for hard glass, omitting the saltpetre; and for every pound adding an ounce of calcined borax, or, if this quantity doth not render the glass sufficiently fusible, two ounces; ten ounces of red tartar of the deepest colour; two ounces of magnesia; and two drachms of charcoal of sallow, or any other soft kind. Precipitates of silver baked on glass will stain it yellow, and likewise give it a yellow colour on being mixed and melted with 40 or 50 times their weight of vitreous compositions; the precipitate from aquafortis by fixed alkali seems to answer best. Yellow glasses may also be obtained with certain preparations of iron, particularly with Prussian blue. But Dr Lewis observes, that the colour does not constantly succeed, nor approach to the high colour of gold, with silver or with iron. The nearest imitations of gold which he has been able to produce have been effected with antimony and lead. Equal parts of the glass of antimony, of flint calcined and powdered, and of minium, formed a glass of a high yellow; and with two parts of glass of antimony, two of minium, and three of powdered flint, the colour approached still more to that of gold. The last composition exhibited a multitude of small sparkles interspersed throughout its whole substance, which gave it a beautiful appearance in the mass, but were really imperfections, owing to air bubbles.

Neri directs, for a gold yellow colour, one part of red tartar and the same quantity of manganese, to be mixed with a hundred parts of frit. But Kunckel observes, that these proportions are faulty; that one part, or one and a quarter, of manganese, is sufficient for a hundred of frit; but that six parts of tartar are hardly enough, unless the tartar is of a dark red colour, almost blackish; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glass swells up very much in melting, and that it must be left unstirred, and worked as it stands in fusion. Mr Samuel More, in repeating and varying this process in order to render the colour more perfect, found that the manganese is entirely unessential to the gold colour; and that the tartar is no otherwise of use than in virtue of the coaly matter to which it is in part reduced by the fire, the phlogiston or inflammable part of the coal appearing in several experiments to be the direct tinging substance. Mr Pott also observes, that common coals give a yellow colour to glass; that different coaly matters differ in their tinging power; that caput mortuum of soot and lamp black answer better than common charcoal: and that the sparkling coal, which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the most active of these preparations. This preparation, he says, powdered, and then burnt again a little in a close vessel, is excellent for tinging glass, and gives yellow, brown, reddish, or blackish colours, according to its quantity; but the frit must not be very hard of fusion, for in this case the strong fire will destroy the colouring substance before the glass melts: and he has found the following composition to be nearly the best; viz. sand two parts, alkali three parts; or sand two, alkali three, calcined borax one; or sand two, alkali two, calcined borax one: and though saltpetre is hardly used at all, or very sparingly, for yellow glasses, as it too much volatilizes the colouring substance; yet here for the most part a certain proportion of it, easily determined by trial, is very necessary; for without it the concentrated colouring matter is apt to make the glass too dark, and even of an opake pitchy blackness. It does not certainly appear that there is any material diversity in the effects of different coals, the difference being probably owing to the different quantities of the inflammable matter which they contain; so that a little more shall be required of one kind than of another for producing the same degree of colour in the glass. Nor does the softness or fusibility of the frit appear to be in any respect necessary.

Gold-coloured spangles may be diffused through the substance of glass, by mixing the yellow talcs with powdered glass, and bringing the mixture into fusion.

Green. This colour may be imparted to glass by adding three ounces of copper precipitated from aquafortis, and two drachms of precipitated iron, to nine pounds of either of the compositions for hard glass. The finest method of giving this beautiful colour to glass is this: Take five pounds of crystalline metal that has been passed several times through water, and the same quantity of the common white metal of polverine, four pounds of common polverine frit, and three pounds of red lead; mix the red lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole mass will be well purified: then cast the whole into water, and separate and take out the lead; then return the metal into the pot, and let it stand a day longer in fusion; then put in the powder of the residuum of the vitriol of copper, and a very little crocus martis, there will be produced a most lively and elegant green, scarce inferior to that of the oriental emerald. There are many ways of giving a green to glass, but all are greatly inferior to this.—To make a *sea green*, the finest crystalline glass only must be used, and no manganese must

Glass. must be added at first to the metal. The crystal frit must be melted thus alone; and the salt, which swims like oil on its top, must be taken off with an iron ladle very carefully. Then to a pot of twenty pounds of this metal add six ounces of calcined brass, and a fourth part of the quantity of powdered zaffer: this powder must be well mixed, and put into the glass at three times; it will make the metal swell at first, and all must be thoroughly mixed in the pot. After it has stood in fusion three hours, take out a little for a proof: if it be too pale, add more of the powder. Twenty-four hours after the mixing the powder the whole will be ready to work; but must be well stirred together from the bottom, lest the colour should be deepest there, and the metal at the top less coloured, or even quite colourless. Some use for this purpose half crystal frit and half rochetta frit, but the colour is much the finest when all crystal frit is used.

Lapis lazuli colour. See *Lapis* LAZULI.

Opal colour. See OPAL.

Purple of a deep and bright colour may be produced by adding to ten pounds of either of the compositions for hard glass, above described, six drachms of zaffer and one drachm of gold precipitated by tin; or to the same quantity of either composition one ounce of manganese and half an ounce of zaffer. The colour of amethyst may be imitated in this way.

Red. A blood-red glass may be made in the following manner: Put six pounds of glass of lead, and ten pounds of common glass, into a pot glazed with white glass. When the whole is boiled and refined, add by small quantities, and at small distances of time, copper calcined to a redness as much as on repeated proofs is found sufficient: then add tartar in powder by small quantities at a time, till the glass is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

Ruby. The way to give the true fine red of the ruby, with a fair transparence, to glass, is as follows: Calcine in earthen vessels gold dissolved in aqua-regia; the menstruum being evaporated by distillation, more aqua regia added, and the abstraction repeated five or six times, till it becomes a red powder. This operation will require many days in a hot furnace. When the powder is of a proper colour, take it out: and when it is to be used, melt the finest crystal glass, and purify it by often casting it into water; and then add, by small quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect transparence.

The process of tinging glass and enamels by preparations of gold was first attempted about the beginning of the last century. Libavius, in one of his tracts entitled *Alchymia*, printed in 1606, conjectures that the colour of the ruby proceeds from gold, and that gold dissolved and brought to redness might be made to communicate a like colour to factitious gems and glass. On this principle Neri, in his Art of Glass, dated in 1611, gives the process above recited. Glauber in 1648 published a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect glass. For this purpose he ground powdered flint or sand with four times its weight of fixed alkaline salt: this mixture melts in a moderately strong fire, and when cool looks like glass, but exposed to the air runs into a liquid state. On adding this liquor to solution of gold in aqua-regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple. By mixing this powder with three or four times its weight of the alkaline solution of flint, drying the mixture, and melting it in a strong fire for an hour, a mass is obtained of a transparent ruby colour and of a vitreous appearance; which nevertheless is soluble in water, or by the moisture of the air, on account of the redundance of the salt. The Honourable Mr Boyle, in a work published in 1680, mentions an experiment in which a like colour was introduced into glass without fusion; for having kept a mixture of gold and mercury in digestion for some months, the fire was at last immoderately increased, so that the glass burst with a violent explosion; and the lower part of the glass was found tinged throughout of a transparent red colour, hardly to be equalled by that of rubies.

About the same time Cassius is said to have discovered the precipitation of gold by tin, and that glass might be tinged of a ruby colour by melting it with this precipitate; though he does not appear, says Dr Lewis, from his treatise *De Auro*, to have been the discoverer of either. He describes the preparation of the precipitate and its use; but gives no account of the manner of employing it, only that he says one drachm of gold duly prepared will tinge ten pounds of glass.

Commerce of Arts, p. 171. 621. &c.

This process was soon after brought to perfection by Kunckel; who says, that one part of the precipitate is sufficient to give a ruby colour to 1280 parts of glass, and a sensible redness to upwards of 1900 parts; but that the success is by no means constant. Kunckel also mentions a purple gold powder, resembling that of Neri; which he obtained by inspissating solution of gold to dryness; abstracting from it fresh aqua-regia three or four times, till the matter appears like oil; then precipitating with strong alkaline ley, and washing the precipitate with water. By dissolving this powder in spirit of salt and precipitating again, it becomes, he says, extremely fair; and in this state he directs it to be mixed with a due proportion of Venice glass.

Orschal, in a treatise entitled *Sol sine Veste*, gives the following process for producing a very fine ruby. He directs the purple precipitate made by tin to be ground with six times its quantity of Venice glass into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous composition to be tinged. His frit consists of equal parts of borax, nitre, and fixed alkaline salt, and four times as much calcined flint as of each of the salts; but he gives no directions as to the proportion of the gold precipitate or mode of fusion. Hellot describes a preparation, which, mixed with Venice glass, was found to give a beautiful purple enamel. This preparation consists of equal parts of solution of gold and of solution of zinc in aqua-regia mixed together, with the addition of a volatile salt prepared from sal ammoniac by quicklime, in sufficient quantity to precipitate the two metals. The precipitate is then gradually heated till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glass or enamels, and introduced into the mass by fusion, the way of equally diffusing such

such a colour through a quantity of fluid glass is still, says Dr Lewis, a secret. The following process for making the ruby glass was communicated to Dr Lewis by an artist, who ascribed it to Kunckel. The gold is directed to be dissolved in a mixture of one part of spirit of salt and three of aquafortis, and the tin in a mixture of one part of the former of these acids with two of the latter. The solution of gold being properly diluted with water, the solution of tin is added, and the mixture left to stand till the purple matter has settled to the bottom. The colourless liquor is then poured off, and the purple sediment, while moist and not very thick, is thoroughly mixed with powdered flint or sand. This mixture is well ground with powdered nitre, tartar, borax, and arsenic, and the compound melted with a suitable fire. The proportions of the ingredients are 2560 parts of sand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arsenic, five of tin, and five of gold.

Topas Colour. Glass resembling this stone may be made by pulverizing ten pounds of either of the compositions for hard glasses with an equal quantity of the gold-coloured glass, and fusing them together.

White opake and *semitransparent* glass may be made of ten pounds of either of the compositions for hard glass, and one pound of well calcined horn, ivory, or bone; or an opake whiteness may be given to glass by adding one pound of very white arsenic to ten pounds of flint glass. Let them be well powdered and mixed by grinding them together, and then fused with a moderate heat till they are thoroughly incorporated. A glass of this kind is made in large quantities at a manufactory near London; and used not only for different kinds of vessels, but as a white ground for enamel in dial plates and snuff boxes, which do not require finishing with much fire, because it becomes very white and fusible with a moderate heat.

Yellow. See *Gold colour* above.

Painting in Glass. The ancient manner of painting in glass was very simple: it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called *mosaic work*. See Mosaic.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades; yet they proceeded no farther than the contours of the figures in black with water colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright red colour; and upon this they drew the principal lineament of the face, &c. with black.

At length, the taste for this kind of painting improving considerably, and the art being found applicable to the adorning of churches, basilics, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree; having first laid on the colours. A French painter at Marseilles is said to have given the first notion of this improvement, upon going to Rome under the pontificate of Julius II.; but Albert Durer and Lucas of Leyden were the first that carried it to any height.

This art, however, has frequently met with much interruption, and sometimes been almost totally lost; of which Mr Walpole gives us the following account, in his Anecdotes of Painting in England.

"The first interruption given to it was by the reformation, which banished the art out of churches; yet it was in some measure kept up in the escutcheons of the nobility and gentry in the windows of their seats. Towards the end of Queen Elizabeth's reign it was omitted even there; yet the practice did not entirely cease. The chapel of our Lady at Warwick was ornamented anew by Robert Dudley earl of Leicester, and his countess, and the cipher of the glass-painter's name yet remains, with the date 1574: and in some of the chapels at Oxford the art again appears, dating itself in 1622, by the hand of no contemptible master.

"I could supply even this gap of 48 years by many dates on Flemish glass; but no body ever supposed that the secret was lost so early as the reign of James I. and that it has not perished since will be evident from the following series, reaching to the present hour.

"The portraits in the windows of the library at All Souls, Oxford. In the chapel at Queen's College there are twelve windows dated 1518. P. C. a cipher on the painted glass in the chapel at Warwick, 1574. The windows at Wadham's College; the drawing pretty good, and the colours fine, by Bernard Van Linge, 1622. In the chapel at Lincoln's Inn, a window, with the name Bernard, 1623. This was probably the preceding Van Linge. In the church of St Leonard, Shoreditch, two windows by Baptista Sutton, 1634. The windows in the chapel at University College, Hen. Giles *pinxit*, 1687. At Christ Church, Isaac Oliver, aged 84, 1700. Window in Merton Chapel, William Price 1700. Windows at Queen's New College, and Maunlin, by William Price, the son, now living, whose colours are fine, whose drawing is good, and whose taste in ornaments and mosaic is far superior to any of his predecessors; is equal to the antique, to the good Italian masters, and only surpassed by his own singular modesty.

"It may not be unwelcome to the curious reader to see some anecdotes of the revival of taste for painted glass in England. Price, as we have said, was the only painter in that style for many years in England. Afterwards one Rowell, a plumber at Reading, did some things, particularly for the late Henry earl of Pembroke; but Rowell's colours soon vanished. At last he found out a very durable and beautiful red; but he died in a year or two, and the secret with him. A man at Birmingham began the same art in 1756 or 1757, and fitted up a window for Lord Lyttleton, in the church of Hagley; but soon broke. A little after him, one Peckitt at York began the same business, and has made good proficiency. A few lovers of that art collected some dispersed panes from ancient buildings, particularly the late Lord Cobham, who erected a Gothic temple at Stowe, and filled it with arms of the old nobility, &c. About the year 1753, one Asciotti, an Italian, who had married a Flemish woman, brought a parcel of painted glass from Flanders, and sold it for a few guineas to the Honourable Mr Batemen, of Old Windsor. Upon that I sent Asciotti again to Flanders, who brought me 450 pieces, for which, including the expence of his journey, I paid him thirty-six guineas. His wife made more journeys for the same pur-

pose;

pose; and sold her cargo to one Palmer a glazier in St Martin's lane, who immediately raised the price to one, two, or five guineas for a single piece, and fitted up entire windows with them, and with mosaics of plain glass of different colours. In 1761, Paterson, an auctioneer at Essex house in the Strand, exhibited the two first auctions of painted glass, imported in like manner from Flanders. All this manufacture consisted in rounds of Scripture stories, stained in black and yellow, or in small figures of black and white; birds and flowers in colours, and Flemish coats of arms.

The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce: reduce them to powder, and mix them. For blue, take powder of blue, one pound; sal nitre, half a pound: mix them and grind them well together. For carnation, take red chalk, eight ounces; iron scales, and litharge of silver, of each two ounces; gum arabic, half an ounce; dissolve in water: grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle 14 days. For green, take red lead one pound; scales of copper, one pound; and flint, five pounds: divide them into three parts; and add to them as much sal nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, take silver, an ounce; antimony, half an ounce: melt them in a crucible; then pound the mass to powder, and grind it on a copper plate; add to it yellow ochre, or brick dust calcined again, 15 ounces; and grind them well together with water. For purple, take minium, one pound; brown stone, one pound; white flint, five pounds: divide them into three parts, and add to them as much sal nitre as one of the parts; calcine, melt, and grind as you did the green. For red, take jet, four ounces; litharge of silver, two ounces; red chalk, one ounce: powder them fine, and mix them. For white, take jet, two parts; white flint, ground on a glass very fine, one part: mix them. For yellow, take Spanish brown, ten parts; leaf silver, one part; antimony, half a part: put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one-third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glass, though already coloured, they could show other kinds of colours where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass till such time as they were got through the colour to the clear glass, This done, they applied the proper colours on the other side of the glass. By these means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their light and heightenings on all kinds of colour.

The first thing to be done, in order to paint or stain glass, in the modern way, is to design, and even colour, the whole subject on paper. Then they choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts; and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again: which done, applying every part of the design upon the glass intended for it, they copy or transfer the design upon this glass with the black colour diluted in gum water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black; and repeat it several times, according as the shades are desired to be heightened; with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in their respective places with a wooden point, or the handle of the pencil.

As to the other colours above mentioned they are used with gum water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay, till such time as the former are well dried.

It may be added that the yellow is the only colour that penetrates through the glass and incorporates therewith by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven to anneal or bake the colours.

The furnace here used is small, built of brick, from 18 to 30 inches square. At six inches from the bottom is an aperture to put in the fuel and maintain the fire.

Glass. fire. Over this aperture is a grate made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less every way than the perimeter of the furnace. On the other side hereof is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed in the following manner: First, The bottom of the pan is covered with three strata or layers of quicklime pulverized; those strata being separated by two others of old broken glass, the design whereof is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthen ware, closely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

Glass Balls, which are circular, or otherwise shaped hollow vessels of glass, may be coloured within, so as to imitate the semipellucid gems. The method of doing it is this: make a strong solution of ichthyocolla, or isinglass, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glass vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it stick and run in waves and pretty figures. Then throw in some of the painters blue smalt, and make it run in waves in the ball as the red lead; then do the same with verdigrise, next with orpiment, then with red lake, all well ground; always casting in the colours in different places, and turning the glass, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the ball; shake it also nimbly about; this will everywhere stick firmly to the glass, and give it a strong inner coat, keeping all the colours on very fairly and strongly. These are set on frames of carved wood, and much esteemed as ornaments in many places. Glass.

Glass Drop. See *Rupert's Drops*.

Engraving on Glass. Professor Beckmann has proved, that so early as the year 1670 the art of etching upon glass was discovered by Henry Schwanhard, son of George Schwanhard, who was a celebrated glass-cutter, patronized by the emperor Ferdinand III. about the middle of the last century. At the time of his death, 1697, the father practised his art at Prague and Ratisbon. Whether the son followed the same business at the same towns, or removed to Nuremberg, is not very evident; but in the year above mentioned, some *aqua-regia* (nitro-muriatic acid) having accidentally fallen on his spectacles, he was surprised to find the glass corroded by it, and become quite soft. He thus, it is said, found himself in possession of a liquid by which he could etch writing and figures upon plates of glass.

But it is probable, as Beckmann seems to think, that he had discovered the fluoric acid itself; for in the year 1725 there appeared in a periodical work the following receipt for making a powerful acid, by which figures of every kind can be etched upon glass.

"When the *spiritus nitri per distillationem* has passed into the recipient, ply it with a strong fire, and when well dephlegmated, pour it, as it corrodes ordinary glass, into a Weldenberg flask. Then throw into it a pulverized green Bohemian emerald, otherwise called *hesphorus*, (which, when reduced to powder, and heated, emits in the dark a green light), and place it in warm sand for 24 hours. Take a piece of glass well cleaned, and freed from all grease by means of a ley; put a border of wax round it, about an inch in height, and cover it all over with the above acid. The longer you let it stand so much the better; and at the end of some time the glass will be corroded, and the figures which have been traced out with sulphur and varnish will appear as if raised above the pane of glass.

That the Bohemian emerald or *hesphorus* mentioned in this receipt it green sparry fluor, cannot, says the professor, be doubted; and he seems to have as little doubt of the receipt itself having passed from Schwanhard and his scholars to the periodical work of 1725, from which it was inserted in the Oekonomische Encyclopedie of Krunitz. This supposition certainly acquires a considerable degree of probability from the similarity of Schwanhard's method of etching to that which is here recommended, and which is so different from what is now followed. At present, the glass is covered with a varnish either of isinglass dissolved in water, or of turpentine oil mixed with a little white lead, through which the figures to be etched are traced as on copper; but Schwanhard, when he had drawn his figures, covered them with varnish, and then by his liquid corroded the glass around them. His figures, therefore, when the varnish was removed, remained smooth and clear, appearing raised from a dim or dark ground; and M. Beckmann who persuaded some ingenious artists to make trial of this ancient method of etching, declares, that such figures have a much better effect than those which are cut into the glass.

Foliating of Glass. See *Foliating and Looking-glass.*

Glass.

Gilding of Glass. See Gilding.

Impressions of antique Gems taken in Glass. See Gems.

Glass of Lead, a glass made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making it is this: Put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a gray loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder become of a fair yellow; then take it out, and sift it fine: this is called *calcined lead*. Take of this calcined lead 45 pounds, and crystalline or other frit 12 pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then cast the whole, which will be now perfectly melted, into water; separate the loose lead from it, and return the metal into the pot; and after standing in fusion 12 hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon.

It is well known that ceruse or white lead, minium, litharge, and all the other preparations and calces of lead, are easily fused by a moderate fire, and formed into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater consistence, in order to render it fit for use. With this view, two parts of calx of lead, *e. g.* minium, and one part of sand or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated for an hour, or an hour and a half; and afterwards let the heat be increased so as to obtain a complete fusion, and continued in that state for the same time: let the crucible remain to cool in the furnace; and when it is broken a very transparent yellow coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the sand. This glass of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the assays of ores to facilitate their scorification.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take pulverine frit 20 pounds, lead calcined 16 pounds; sift both the powders very fine; then melt them into a glass, separating the unmixed lead, by plunging the mass in water; after this return it into the pot, and add brass thrice calcined six ounces, and one pennyweight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined brass the same quantity of the caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaz colour, take crystal frit 15 pounds, calcined lead 12 pounds; mix them well together, by sifting the powders through a fine sieve; then set them in a furnace not too hot, and separate the superfluous unmixed lead, by casting the whole into water; repeat this twice: then add half gold yellow glass, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For sea green, take crystal frit 16 pounds, calcined lead 10 pounds; mix and sift them together, and set them in a pot in a furnace; in 12 hours the whole will be melted; then cast it into water, and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more.

Muscovy Glass. See Mica, Mineralogy *Index*.

Painting on Glass by means of Prints. See *Back-painting*.

Glass Porcelain, the name given by many to a modern invention of imitating the china ware with glass. The method given by M. Reaumur, who was the first that carried the attempt to any degree of perfection, is shortly this: The glass vessels to be converted into porcelain are to be put into a large earthen vessel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaster stone burnt into what is called plaster of Paris, and all the interstices are to be filled up with the same powder, so that the glass vessels may nowhere touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down and luted, and the fire does the rest of the work; for this is only to be put into a common potter's furnace, and when it has stood there the usual time of the baking the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted into a white opaque substance, which is a very elegant porcelain, and has almost the properties of that of China.

The powder which has served once will do again as well as fresh, and that for a great many times: nay, it seems, ever so often. The cause of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its basis of calcareous earth, and unites with the alkaline salt and saline earth of the glass, with which it forms a kind of salt, different from the calcareous selenite, by the interposition of which matter the glass acquires the qualities of porcelain.

Glass Pots, the vessels in the glass trade used for melting the glass. Those for the white glass works are made of a tobacco pipe clay, brought from the isle of Wight, which is first well washed, then calcined, and afterwards ground to a fine powder in a mill; which being mixed with water, is then trod with the bare feet till it is of a proper consistence to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green glass works are made of the nonsuch, and another sort of clay from Staffordshire; they make these so large as to hold three or four hundred weight of metal. And besides these, they have a small sort called piling pots, which they set upon the larger, and which contain a finer and more nice metal fit for the nicest works.

The clay that is used for this purpose should be of the purest and most refractory kind, and well cleansed from all sandy, ferruginous, and pyritous matters; and to to this it will be proper to add ground crucibles, white sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on the quality of the crude clay, which is more or less fat. M. D'Antic, in a memoir on this subject, proposes the following method of ascertaining it: The burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state be examined; and the cake, he says, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

Tin GLASS, the same with Bismuth. See BISMUTH, CHEMISTRY *Index*.

GLASSES are distinguished, with regard to their form, use, &c. into various kinds, as drinking glasses, optical glasses, looking glasses, burning glasses, &c.

Drinking GLASSES, are simple vessels of common glass or crystal, usually made in form of an inverted cone.

Each glass consists of three parts, viz. the bowl, the bottom, and the foot; which are all wrought or blown separately.

Nothing can be more dexterous and expeditious than the manner of blowing these parts: two of them opened, and all three joined together. An idea is only to be had thereof, by seeing it actually done. For the method of gilding the edges of drinking glasses, see GILDING *on Enamel and Glass*.

Optical GLASSES. See OPTICS.

The improvements hitherto made in telescopes by means of combining lenses made of different kinds of glass, though very great, are yet by no means adequate to the expectations that might reasonably be formed, if opticians could fall on any method of obtaining pieces of glass sufficiently large for pursuing the advantages of Mr Dollond's discovery. Unfortunately, however, though the board of longitude have offered a considerable reward for bringing this art to the requisite perfection, no attempt of any consequence has hitherto been made. Mr Keir is of opinion, that the accomplishment of this is by no means an easy task; as it requires not only a competent knowledge of the properties of glass fitted for the purpose (the faults not being evident to common inspection), but a considerable degree of chemical knowledge is also necessary in order to invent a composition by which these faults may be avoided; and lastly, a kind of dexterity in the execution of the work, which can only be acquired by practice. Our author, however, thinks, that if the subject were more generally understood, and the difficulties more fully pointed out, for which purpose he makes the following remarks, the end may be more easily accomplished.

1. The rays of light passing through a glass lens or prism, or through any other medium of unequal thickness, are refracted; but not in an equal manner, the blue, violet, &c. being more refracted than the red.

2. Hence it happens, that the rays of light, when refracted by a common lens, do not all unite in one focus, but in reality form as many different foci as there are colours; and hence arise the prismatic colours, or irises, which appear towards the borders of the image formed by the common convex lenses, and which render the vision extremely indistinct.

3. The indistinctness of vision produced by this cause, which is sensible in telescopes of a small aperture, increases in so great a proportion, viz. as the cubes of the diameters, that it seemed impossible to increase the power of dioptric telescopes greatly, without extending them to a very inconvenient length, unless this confusion of colours could be corrected.

4. It was known that different transparent bodies possessed different degrees of refractive power; and until Mr Dollond discovered the contrary, it was supposed, that the refractions of the coloured rays were always in a determined ratio to one another. On this supposition it seemed impossible to correct the faults of refracting telescopes: for it was supposed, that if the dispersion of light produced by a convex lens were counteracted by another lens or medium of a concave form, the refraction would be totally destroyed; and this indeed would be the case, if the two mediums were made of the same matter; and from some experiments made by Sir Isaac Newton, this was supposed to be actually the case in all substances whatever.

5. From considering that the eyes of animals are formed of mediums of different colours, it occurred first to Mr David Gregory, the celebrated professor of astronomy at Oxford, and then to Mr Euler, that, by a combination of mediums which had different refractive powers, it might be possible to remedy the imperfections of dioptric telescopes. It does not, however, appear, that either of these gentlemen understood the true principle on which these phenomena depend. Mr Euler executed his idea by forming a compound object lens from two glass lenses with water interposed, but his attempt was not attended with success. Mr Dollond, however, was led by some arguments adduced by Mr Klingenstierna of Sweden, to repeat one of Sir Isaac Newton's experiments, and which had induced even that great philosopher himself to suppose that the improvement afterwards executed by Mr Dollond was impossible. This experiment was made by Sir Isaac Newton, by placing a glass prism within a prismatic vessel filled with water, in such a manner that the rays of light which were refracted by the glass prism should pass through and be refracted in a contrary direction by the water prism. In this manner the refraction of the light was entirely destroyed. But when Mr Dollond repeated the experiment, he found, that, contrary to his own expectations, when the angles of the two prisms were so proportioned that they counteracted each other's mean refraction, then colours appeared; and on the other hand, when they were so proportioned that the dispersion of the coloured rays was counteracted, the mean refraction still subsisted; which evidently proved, that the mean refractive and dispersive powers of glass and water were not proportional to one another.

6. To apply this to the proposed improvement, Mr Dollond examined several kinds of glass. Crown glass was found to possess the smallest dispersive power in proportion to its refraction; while flint glass possessed the

the greatest dispersive power in proportion to its refraction, which was also very great. On comparing these two exactly together, he found, that a wedge of white flint glass whose angle was about 25 degrees, and another of crown glass whose angle was 29 degrees, refracted very nearly alike. He found also, that, when the wedges were ground to such angles, the refraction produced by the flint glass was to that produced by the crown glass nearly as two to three; the refracted light was then free from colour. On measuring the general refracting powers of these two glasses, he found, that in flint glass, the sine of incidence of the rays was to the sine of mean refraction as 1 to 1.583; and that in crown glass, the sine of incidence was to the sine of mean refraction as 1 to 1.53.

The methods of determining the different refractive powers of glass are given under the the article OPTICS. Here we shall only observe, that two kinds of glass are necessary for the construction of achromatic telescopes; one of which shall possess as small, and the other as great, dispersive powers, relative to their mean refracting powers, as can be produced. The difference of glasses in this respect depends on the quality of the ingredients employed in their composition. Crown glass, which is composed of sand melted by means of the ashes of sea weeds, barilla or kelp, both which fluxes are known to consist of vegetable earth, alkali, and neutral salt, is found to give the smallest dispersive power. Plate glass, which consists of sand melted by means of fixed vegetable alkali, with little or no vegetable earth, gives a greater dispersive power; but both these give much less than flint glass, which consists of sand melted by means of minium and fixed alkali. It appears, therefore, that the dispersion of the rays is greatest when minium, or probably other metallic calces, are made use of; and that alkalies give a greater power of dispersion than vegetable or other earths. Mr Zieher of Petersburgh, however, informs us, that he has made a kind of glass, much superior in this respect to flint glass; but it does not as yet appear whether it be more fit for optical purposes than that commonly made use of. There seems no difficulty in augmenting the dispersive power, as that is found to depend on the quantity of minium or other flux: but thus we unfortunately increase also the capital fault to which flint glass and all compositions of that kind are subject; namely, the being subject to veins or small threads running through it. By these, even when so small as to be imperceptible to the naked eye, the rays which fall on them are diverted from their proper direction, and thereby render the images confused. This is owing to the greater density of the veins, as appears by their image being received on white paper, when the glass is held between the paper and the sun or a candle at a proper distance. The rays of light being then made to converge by the superior density of the veins, their images will appear as bright lines bordered with obscure edges on the paper. Flint glass is so much subject to this kind of imperfection, that it is with difficulty the opticians can pick out pieces of the size commonly used from a large quantity of the glass. It is farther to be regretted, that the minium which produces the greatest dispersive power, is likewise the very substance which renders flint glass much more subject to these imperfections than any other. The reason is, that the sand and earthy matters mix uniformly in fusion; and having not only a considerable degree of affinity towards each other, but also being not much different from each other, they are not apt to separate. On the other hand, when such a heavy substance as minium is added to these earthy substances, though it has a pretty strong tendency to unite with the earthy substances, it has none with the fixed alkali, which is another ingredient in this glass. Hence some parts of the glass will contain more metallic matter than the rest; particularly that near the bottom of the pot, which is so full of large veins as to be applied only to the making of wares of little value. The veins in this case are formed by the descent of the minium at the bottom, which in its passage forms threads or veins by dragging other parts of the glass along with them.

The correction of this fault appears therefore to be very difficult. M. Macquer informs us, that he had in vain tried to remove it by very long fusion and a fierce fire; which indeed others have found by experience not to correct, but to augment the evil. Mr Keir is of opinion that some new composition must be discovered, which, along with a sufficient refractive power should possess a greater uniformity of texture; but he is likewise of opinion, that scarce any alteration in this respect could be made without injuring the colour of the glass. For optical purposes, however, our author does not think that an alteration in the colour of the ingredients would be very detrimental. "I am convinced (says he), that glasses sensibly tinged with colour, might transmit as much or more light than the best flint glass. For the colourless appearance of flint glass is an optical deception. The minium gives it a considerable tinge of yellow, and the alkali inclines it to a bluish cast, besides the colour arising from a greater or less impurity of the materials; so that the glass would actually be very sensibly coloured, unless by the addition of manganese, which is known to give a purplish red. Thus the other tinges are counteracted, but not effaced or destroyed as has been frequently imagined. By the mixture of the three principal colours, red, yellow, and blue, more or less exactly counterpoised, a certain dark shade is introduced, in which, as not any one of the colours predominates, no coloured tinge appears, but the effect is merely a diminution of the transparency of the glass, which, however, is too small for ordinary observation." Mr Keir is even of opinion, that a certain tinge of yellow would in many cases be of service, because it would exclude some of the blue rays, which being most refrangible are most injurious to the distinctness of vision.

Very considerable difficulties, however, must arise in attempting improvements of this kind; as the experiments must all be tried on a very large scale. This is not only attended with a very heavy expence in itself on account of the quantity of materials employed, but from the heavy duty of excise, which is rigorously exacted whether the glass be manufactured into saleable articles or not. It is observed in the manufacture of every kind of glass, that the glass in the middle of the area or transverse section of a pot is much purer and freer from veins and other imperfections than the part which is near the sides, and that the glass at the bottom is the worst of all. Consequently it is chiefly in large pots, such as are used in manufactures, that there is is a probability of success. Very fine and beautiful glasses, called *paste* and *artificial gems*, may be made in smaller pots or crucibles; but this glass is suffered to cool and subside in the vessel, by which means the contiguous parts are more uniform in their texture than can be expected in a piece of glass taken out of the pot while hot in the common way, by making it adhere and twist round an iron rod or pipe. But although the method of allowing the glass to cool in the pots is very advantageous for the purposes of the jeweller, it is by no means applicable to those of the optician. Glass cooled in that gradual manner, suffers some degree of crystallization or peculiar arrangement of its parts; the consequence of which is, that the rays of light undergo certain refractions independent on the form of the glass, which greatly affect the distinctness of vision in telescopes.

GLASTONBURY, a town of Somersetshire in England; situated in W. Long. 2. 41. N. Lat. 51. 9. —It is noted for a famous abbey, some magnificent ruins of which still remain. The curious structure called *the Abbot's kitchen* is still pretty entire. The monks pretend that it was the residence of Joseph of Arimathea, and of St Patrick. The king of the West Saxons erected a church here, which he and the succeeding kings enriched to such a degree, that the abbot lived like a prince, had the title of *lord*, and sat among the barons in parliament; and no person, not even a bishop or prince, durst set foot on the isle of Avalon, in which the abbey stands, without his leave. The revenue of the abbey was above 40,000l. per ann. besides seven parks well stored with deer. The last abbot (Richard Whiting), who had 100 monks, and 300 domestics, was hanged in his pontificals, with two of his monks, on the Tor, a high hill in the neighbourhood, for refusing to take the oath of supremacy to Henry VIII. and surrender his abbey when required. Edgar and many other Saxon kings were buried here; and, as some will have it, Arthur the British king. Every cottage here has part of a pillar, a door, or a window of this fabric; of which there still remain the ruins of the choir, the middle tower and the chapels. The walls that remain of the abbey are overgrown with ivy, and the aspect of the whole is both melancholy and venerable. Here are two parish churches. This town, while under the protection of its abbots, was a parliamentary borough, but it lost that and its privilege of a corporation; the latter of which was, however, restored by Queen Anne, who granted it a new charter for a mayor and burgesses. The only manufactory here is stockings. At a little distance from the old church, and facing the monks churchyard, are two remarkable pyramids, with inscriptions, that are in characters unintelligible, and an image in bishop's vestments. The story of the Glastonbury thorn, and of its budding upon Christmas day, is well known. This is not correctly true; but if the winter is mild, it always buds about the latter end of December, but later if the weather is severe. Population 2337 in 1811.

GLATZ, a strong town of Silesia, capital of a county of the same name, seated on the river Neisse; and well fortified with a castle. The town contains about 6700 inhabitants. The county was ceded to the king of Prussia by the queen of Hungary in 1742; and is about 45 miles in length, and 25 in breadth. It has mines of pit coal, silver, and iron; good quarries, plenty of cattle, and fine springs of mineral water. The town is situated in E. Long. 16. 26. N. Lat. 50. 16.

GLAUBER, JOHN RHODOLPHUS, a celebrated German chemist, who flourished about the year 1646. He wrote a great number of different treatises on chemistry, some of which have been translated into Latin and French. All his works have been collected into one volume, entitled *Glauberus concentratus*, which was translated into English, and printed at London, in folio, in 1689.

GLAUBER'*s Salts*, or *Sulphate of Soda*. See CHEMISTRY *Index*.

GLAUCOMA, in *Medicine* and *Surgery*, the name of a disease in the eye, wherein the crystalline humour is turned of a blueish or greenish colour, and its transparency hereby diminished.—The word comes from γλαυκος, *cæsius*, "sea-green, sky-coloured or grayish."

Those in whom this disorder is forming, discover it hence, that all objects appear to them as through a cloud or mist; when entirely formed, the visual rays are all intercepted, and nothing is seen at all.

It is reckoned incurable, when inveterate, and in aged persons: and even under other circumstances, is very difficult of cure, externals proving of little service.

The internals best suited to it, are those used in the gutta serena. Jul. Cæsar Claudinus, Consul. 74. gives a remedy for the glaucoma.

The glaucoma is usually distinguished from the cataract or suffusion, in this, that in the cataract the whiteness appears in the pupil, very near the corner; but it shows deeper in the glaucoma. See SURGERY *Index*.

GLAUCUS, a marine god, or deity of the sea. There are a great many fabulous accounts of this divinity: but the poetical history of him is, that before his deification, he was a fisherman of the town of Anthedon, who having one day taken a considerable number of fishes, which he laid upon the bank, on a sudden perceived, that these fishes, having touched a kind of herb that grew on the shore, received new strength, and leaped again into the sea: upon the sight of which extraordinary accident, he was tempted to taste of the herb himself, and presently leaped into the sea after them, where he was metamorphosed into a Triton, and became one of the sea gods.

GLAUX, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 17th order, *Calycanthemæ*. See BOTANY *Index*.

GLAZIER, an artificer who works in glass.—The principal part of a glazier's business consists in fitting panes of glass to the sashes and window frames of houses, pictures, &c. and in cleaning the same.

GLAZING, the crusting over earthen ware with a vitreous substance, the basis of which is lead. See GLASS *of Lead*.

The workers of common earthen ware, however, are

Glazing.

not at the trouble of thus previously making a pure glass of lead. Their usual composition for glazing their ware is formed of white sand 40 pounds, of red lead 20 pounds, of pearl ashes 20 pounds, and of common salt 12 pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. The ware after being turned on the wheel and dried in the open air, is covered over with the above composition by means of a brush; and when set in the furnace the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel.

We may observe, however, in general, that lead ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead, by calcining 40 pounds of white sand, 25 pounds of pearl ashes, and 15 pounds of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand 40 pounds, of wood ashes perfectly burnt 50 pounds, of pearl ashes 10 pounds, and of common salt 12 pounds. The following receipts are taken for the most part from Kunckel, who says, that they are the true glazings used at Delft and other Dutch manufactories.

Black is made of eight parts of red lead, iron filings three, copper ashes three, and zaffer two measures. This when melted will make a brown black; and if you want it blacker, add more zaffer to it.

Blue is thus prepared: Take lead ashes or red lead one pound, clear sand or powdered flints two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, zaffer half a pound; mix them well together and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last receipt. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before. Or, again, take of red lead one part, of sand three parts, and of zaffer one part. For a violet blue glazing, take four ounces of tartar, two ounces of red lead, five ounces of powdered flints, and half a drachm of manganese.

Brown is made of red lead and flints of each 14 parts, and of manganese two parts fused; or of red lead 12 parts, and manganese one part fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red lead and white glass of each one part, twice fused.

Flesh coloured is made of 12 parts of lead ashes, and one of white glass.

Gold coloured. Take of litharge three parts, of sand or calcined flint one part; pound and mix these very well together, then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which moisten with a well saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of a hair pencil you may apply it upon the vessels or any piece of earthen ware. The vessels that are painted or covered over with this glazing must be first well heated, then put under a muffle; and as soon as the glass runs, you must smoke them, by holding them over burning vegetables, and take out the vessels. Mr Heinsius of Petersburgh, who sent this receipt to the Royal Society, uses the words *afflare debes fumum*, which is rendered *smoke them*, in the Transactions. Phil. Trans. N° 465. § 6.

Kunckel gives several preparations for a gold coloured yellow glazing. This may be produced by fusing a mixture of three parts of red lead, two parts of antimony, and one part of saffron of Mars; by again melting the powdered mass, and repeating the operation four times, or by fusing four or five times a composition of red lead and antimony of each an ounce, and of scales of iron half an ounce: or by calcining and fusing together eight parts of red lead, six parts of flints, one part of yellow ochre, one part of antimony, and one part of white glass. A transparent gold-coloured glazing may be obtained by twice fusing red lead and white flints, of each 12 parts, and of filings of iron one part.

Green may be prepared of eight parts of litharge or red lead, eight parts of Venice glass, four parts of brass dust or filings of copper; or of ten parts of litharge, twelve of flint or pebble, and one of *æs ustum* or copper ashes.—A fine green glazing may be produced by fusing one part of the Bohemian granate, one part of filings of copper, one part of red lead, and one part of Venetian glass; or by fusing one part of white glass, the same quantity of red lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and teints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea green is made of five pounds of lead ashes, one pound of tin ashes, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper dust.

Iron colour is prepared of 15 parts of lead ashes or red lead, 15 of white sand or flints, and five of calcined copper. This mixture is to be calcined and fused.

Liver colour is prepared of 12 parts of litharge, eight of salt, six of pebble or flint, and one of manganese.

Purple brown consists of lead ashes 15 parts, clean sand or powdered flints 18 parts, manganese one part, and white glass 15 measures, to which some add one measure of zaffer.

Red is made of antimony three pounds, litharge or red lead three, and rust of iron one: grind them to a fine powder. Or, take two pounds of antimony, three of red lead, and one of calcined saffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear sand, 75 pounds of litharge or lead ashes, 26 of pot ashes, and ten pounds of salt: these are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean sand, 70 of lead ashes, 30 of wood ashes, and 12 of salt.

For a fine white: Take two pounds of lead and one of tin; calcine them to ashes; of this take two parts, calcined flint, white sand, or broken white glass, one part, and salt one part; mix them well together and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented by procuring them in a proper state.

A very fine white glazing may be obtained by calcining two parts of lead and one part of tin; and taking one part of this mass, and of flints and common salt of each one part, and fusing the mixture.

A white glazing may be also prepared by mixing 100 pounds of masticot, 60 pounds of red lead, 20 pounds of calcined tin or putty, and 10 pounds of common salt, and calcining and powdering the mixture several times.

Yellow is prepared of red lead three pounds; calcined antimony and tin, of each two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times; or it may be made of 15 parts of lead ore, three parts of litharge of silver, and 15 parts of sand.—A fine yellow glazing may be procured by mixing five parts of red lead, two parts of powdered brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white glass, one part of antimony, three parts of red lead, and one part of iron scales, and fuse the mixture; or fuse 16 parts of flints, one part of iron filings, and 24 parts of litharge. A light yellow glazing may be produced with ten parts of red lead, three parts of antimony, and three of glass, and two parts of calcined tin. See *Gold colour*, above.—A *citron yellow* is made of six parts of red lead, seven parts of fine red brick dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash hole of a glass-house furnace, and at last urged to fusion.

For the glazing of Delft ware, Porcelain, Stoneware, &c. see the articles *Delft Ware*, Porcelain, and Pottery.

The Romans had a method of glazing their earthen vessels, which in many respects appears to have been superior to ours. The common brown glazing easily scales off, cracks, and in a short time becomes disagreeable to the eye. Besides, it is very easily destroyed by acids; nor can vessels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is also very destructive to the human body; and if acids are unwarily put into vessels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be seen upon urns dug up in several places, appears to have been made of some kind of varnish; and Pliny gives us a hint that it was made of bitumen. He tells us that it never lost its beauty, and that at length it became customary to glaze over statues in this manner. As this varnish sunk deep into the substance of the ware, it was not subject to those cracks and flaws which disfigure our vessels; and as it was not liable to be corroded by acids, it could not be subject to any of the accidents which may ensue from the use of vessels glazed with lead.

GLEAD, or Glade, a name used in the northern parts of the kingdom for the kite. See Falco, Ornithology *Index*.

GLEAM is popularly used for a ray or beam of light. Among falconers a hawk is said to gleam when she casts or throws up filth from the gorge.

GLEANING, the act of gathering or picking up the ears of corn left behind after the field has been reaped and the crop carried home. By the customs of some countries, particularly those of Melun and Estampes, all farmers and others are forbid, either by themselves or servants, to put any cattle into the fields, or prevent the gleaning in any manner whatever for the space of 24 hours after the carrying off the corn, under the penalty of confiscation.

GLEBE, among miners, signifies a piece of earth in which is contained some mineral ore.

Glebe, in *Law*, the land belonging to a parish church besides the tithes.

GLECHOMA, Ground Ivy, a genus of plants belonging to the didynamia class, and in the natural method ranking under the 42d order, *Verticillatæ*. See Botany *Index*.

GLEDITSIA, Triple Thorned Acacia, or *Honey Locust*, a genus of plants belonging to the polygamia class, and in the natural method ranking under the 33d order, *Lomentaceæ*. See Botany *Index*.

GLEET, in *Medicine*, the flux of a thin limpid humour from the urethra. See Medicine *Index*.

GLENDALAGH, otherwise called *the Seven Churches*, anciently a celebrated town of Ireland, situated five miles north-west of Rathdrum, in the county of Wicklow, and province of Leinster. The name signifies "the valley of the two lakes." In this valley, surrounded by high and almost inaccessible mountains, St Kevin or Cavan, called also *St Coemgene*, about the middle of the 6th century, founded a monastery, which in a short time from the sanctity of its founder was much resorted to, and at length became a bishoprick and a religious city. St Kevin died 3d June 618, aged 120; and on that day annually numbers of persons flock to the Seven Churches to celebrate the festival of that venerated saint. During the middle ages the city of Glendalagh, called by Hovedon, *Episcopatus Bistagniensis*, was held in great esteem, and received several valuable donations and privileges, its episcopal jurisdiction extending to the walls of Dublin.—About the middle of the 12th century, on some account or other, it was much neglected by the clergy; and became, instead of a holy city, a den of thieves, wherefore Cardinal Papiro, in 1214, united it to the see of Dublin, which union was confirmed by King John. The O'Tools, chiefs of of Firthual, however, by the assistance of the Pope, continued long after this period to elect bishops and abbots to Glendalagh, though they had neither revenues or authority, beyond the district of Tuathal, which was the western part of the county of Wicklow; in consequence of which the city was suffered to decay, and had become nearly a desert, in 1497, when Dennis White, the last titular bishop, surrendered his right in the cathedral church of St Patrick, Dublin. From the ruins of this ancient city still remaining, it appears to have been a place of consequence, and to have contained seven churches and religious houses; small indeed, but built in a neat elegant stile, in imitation of the Greek architecture: the cathedral, the walls of which are yet standing, was dedicated to St Peter and St Paul. South of the cathedral stands a small church roofed with stone, nearly entire; and in several parts of the valley are a number of stone crosses, some of which are curiously carved, but without any inscriptions. In the north-west corner of the cemetery belonging to the cathedral stands a round tower, 95 feet high, and 15 in diameter; and in the cemetery of a small church, on the south side of the river, near the great lake, called the *Rhefeart church*, are some tombs, with Irish inscriptions, belonging to the O'Tools. In a perpendicular projecting rock on the south side of the great lake, 30 yards above the surface of the water, is the celebrated bed of St Kevin, hewn out of the rock, exceedingly difficult of access and terrible of prospect. Amongst the ruins have been discovered a number of stones, curiously carved, and containing inscriptions in the Latin, Greek, and Irish languages. As this city was in a valley, surrounded on all sides, except the east, by high, barren, and inaccessible mountains, the artificial roads leading thereto are by no means the least curious part of the remains; the principal is that leading into the county of Kildare through Glendason. This road for near two miles is yet perfect, composed of stones placed on their edges, making a firm and durable pavement, about 10 feet broad. At a small distance from St Kevin's bed, on the same side of the mountain, are to be seen the ruins of a small stone building called *Saint Kevin's cell.*

GLENOIDES, the name of two cavities, or small depressions, in the inferior part of the first vertebra of the neck.

GLIMMER, or GLIST. See MICA, MINERALOGY *Index*.

GLINUS, in *Botany*, a genus of plants belonging to the decandria class; and in the natural method ranking under the 22d order, *Caryophyllæ*. See BOTANY *Index*.

GLIRES, the name of Linnæus's fourth order of mammalia. See MAMMALIA *Index*.

GLISSON, FRANCIS, a learned English physician in the 17th century, was educated at Cambridge, and was made regius professor of that university. In 1634 he was admitted a fellow of the College of Physicians in London. During the civil wars, he practised physic at Colchester, and afterwards settled in London. He greatly improved physic by his anatomical dissections and observations, and made several new discoveries of singular use towards establishing a rational practice. He wrote, 1. *De rachitide*, &c. 2. *De lymphæductis nuper repertis:* with the *Anatomica prolegomena, et Anatomia hepatis.* 3. *De naturæ substantia energitica; seu de via vitæ naturæ, ejusque tribus primis facultatibus*, &c. quarto. 4. *Tractatus de ventriculo et intestinis*, &c. The world is obliged to him for the *capsula communis*, or *vagina portæ*.

GLISTER, in *Surgery*. See CLYSTER.

GLOBBA, a genus of plants belonging to the monandria class. See BOTANY *Index*.

GLOBE, in *Geometry*, a round or spherical body, more usually called a *Sphere*. See SPHERE.

GLOBE is more particularly used for an artificial sphere of metal, plaster, paper, or other matter; on whose convex surface is drawn a map, or representation either of the earth or heavens, with the several circles conceived thereon. See GEOGRAPHY.

Globes are of two kinds, *terrestrial* and *celestial*; each of very considerable use, the one in astronomy, and the other in geography, for performing many of the operations thereof in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world; and a spherical shell, or cover, which makes the body of the globe, on the external surface of which the representation is drawn. See GEOGRAPHY *Index*.

Globes, we have observed, are made of different materials, viz. silver, brass, paper, plaster, &c. Those commonly used are of plaster and paper. For the construction of globes, see GEOGRAPHY *Index*.

For the uses, &c. of the globes, see GEOGRAPHY and ASTRONOMY.

GLOBE Animal. See ANIMALCULE.

GLOBE Fish. See OSTRACION, ICHTHYOLOGY *Index*.

GLOBULARIA, GLOBULAR BLUE DAISY; a genus of plants, belonging to the tetrandria class; and in the natural method ranking under the 48th order, *Aggregatæ*. See BOTANY *Index*.

GLOBULE, a diminutive of globe, frequently used by physicians in speaking of the red particles of the blood. See BLOOD.

GLOCESTER, the capital of Glocestershire, in England, 106 miles from London. It is an ancient city; and by Antoninus is called *Clevum*, or *Glevum*, which Camden thinks was formed from the British *Caer-Glowe*, signifying "a fair city." It was one of the 28 cities built by the Britons before the arrival of the Romans, who made it one of their colonies, and in the eighth century it was esteemed one of the noblest cities in the kingdom. It has suffered considerably by fire at different periods. It stands upon a hill; and from the middle of the city, where the four principal streets meet, there is a descent every way, which makes it not only clean and healthy, but adds to the beauty of the place. Forging of iron seems to have been its manufacture so early as the time of William the Conqueror. King Henry VIII. made it the see of a bishop with a dean and six prebends. Its castle, which was erected in the time of William the Conqueror, is very much decayed; part of it is leased out by the crown; and the rest serves for a prison, one of the best in England. In its cathedral, which is an ancient but magnificent fabric, and has a tower reckoned

one

Glocester. one of the most curious pieces of architecture in England, are the tombs of Robert duke of Normandy, son to William the Conqueror, and of Edward II. and there is a whispering place like to that of St Paul's at London. In the chapter house lies Strongbow who conquered Ireland. There are 12 chapels in it, with the arms and monuments of many great persons. King John made it a borough to be governed by two bailiffs. Henry III. who was crowned here, made it a corporation. By its present charter from Charles I. it is governed by a steward, who is generally a nobleman; a mayor; a recorder; 12 aldermen, out of whom the mayor is chosen; a town clerk; two sheriffs, chosen yearly out of 26 common councilmen; a sword-bearer; and four serjeants at mace. Here are 12 incorporated trading companies, whose masters attend the mayor on all public occasions, &c. Besides the cathedral, there are five parish churches in this city; which is likewise well provided with hospitals, particularly an infirmary upon the plan of those at London, Winchester, Bath, &c. Here is a good stone bridge over the river Severn, with a quay, wharf, and customhouse; but most of its business is engrossed by Bristol. King Edward I. held a parliament here in 1272, wherein some good laws were made, now called the *Statutes of Glocester;* and he erected a gate on the south side of the abbey, still called by his name, though almost demolished in the civil wars. King Richard II. also held a parliament here: and King Richard III. in consideration of his having (before his accession to the crown) borne the title of *Duke of Glocester*, added the two adjacent hundreds of Dudston and King's Barton to it, gave it his sword and cap of maintenance, and made it a county of itself by the name of the *county of the city of Glocester*. But after the Restoration the hundreds were taken away by act of parliament, and the walls pulled down; because the city shut the gates against Charles I. when he besieged it in 1643; by which, though the siege was raised by the earl of Essex, it had suffered 20,000l. damage, having 241 houses destroyed, which reduced it so much that it has scarce recovered its former size and grandeur. Before that time it had 11 parish churches, but six of them were then demolished. Here are abundance of crosses, and statues of the English kings, some of whom kept their Christmas here; several market houses supported with pillars; and large remains of monasteries, which were once so numerous, that it gave occasion to the monkish proverb, *As sure as God is in Glocester*. Here is a barley market; and a hall for the assizes, called the *Booth Hall*. Its chief manufacture is pins. Under the bridge is a water engine to supply the town, and it is served with it also from Robin Hood's well, to which is a fine walk from the city. Camden says, that the famous Roman way, called *Ermin Street*, which begins at St David's in Pembrokeshire, and reaches to Southampton, passes through this city. Here is a charity school for above 80 children, of whom above 70 are also clothed; and a well endowed blue-coat school. Population 8280 in 1811. The city sends two members to parliament. W. Long. 2. 13. N. Lat. 51. 48.

Glocester, Glocestershire.

GLOCESTER is also the name of two counties and of several towns in America; such as the county of Glocester in New Jersey, bounded on the north by Burlington, on the south by Salem and Cumberland, on the east by the Atlantic ocean, and on the west by the river Delaware. It contains 13,172 inhabitants, besides 191 slaves. Glocester in Virginia is a well cultivated and fruitful county, about 55 miles long and 30 broad, with a population of 13,498 souls, among whom are included 7063 slaves.

GLOCESTERSHIRE, a county of England, is bounded on the west by Monmouthshire and Herefordshire, on the north by Worcestershire, on the east by Oxfordshire and Warwickshire, and on the south by Wiltshire, and part of Somersetshire. It is sixty miles in length, twenty-six in breadth, and one hundred and sixty in circumference; containing 1,100,000 acres, 320 parishes, 1229 villages, 2 cities, and 28 market towns. In 1811 it contained 54,040 houses, and 285,514 inhabitants. It sends only 8 members to parliament, 6 for three towns, viz. Glocester, Tewkesbury, and Cirencester; and two for the county. Its manufactures are woollen cloths of various kinds, men's hats, leather, pens, paper, bar iron, edge tools, nails, wire, tinned plates, brass, &c.: and of the principal articles of commerce of the county, it exports cheese 8000 tons; bacon, grain, cyder, 5000l. worth; perry, fish, 4000l. worth, &c. It lies in the diocese that takes its name from the capital, and in the Oxford circuit. The air of the county is very wholesome, but the face of it is very different in different parts: for the eastern part is hilly, and is called *Cotteswold;* the western woody, and called the *Forest of Dean;* and the rest is a fruitful valley, through which runs the river Severn. This river is in some places between two and three miles broad; and its course through the county, including its windings, is not less than seventy miles. The tide of flood, called the *Boar*, rises very high, and is very impetuous. It is remarkable, that the greatest tides are one year at the full moon, and the other at the new; one year the night tides, and the next the day. This river affords a noble conveyance for goods and merchandise of all sorts to and from the county; but it is watered by several others, as the Wye, the Avon, the Isis, the Leyden, the Frome, the Stroud, and Windrush, besides lesser streams, all abounding with fish, the Severn in particular with salmon, conger eels, and lampreys. The soil is in general very fertile, though pretty much diversified, yielding plenty of corn, pasture, fruit, and wood. In the hilly part of the county, or Cotteswold, the air is sharper than in the lowlands; and the soil, though not so fit for grain, produces excellent pasture for sheep; so that of the four hundred thousand that are computed to be kept in the county, the greater part are fed here. Of these sheep the wool is exceeding fine; and hence it is that this shire is so eminent for its manufacture of cloth, of which fifty thousand pieces are said to have been made yearly, before the practice of clandestinely exporting English wool became so common. In the vale, or lower part of the county, through which the Severn passes, the air and soil are very different from those of the Cotteswold: for the former is much warmer, and the latter richer, yielding the most luxuriant pastures; in consequence of which, numerous herds of black cattle are kept, and great quantities of that excellent cheese, for which it is so much celebrated, made in it. The remaining part of the county, called the Forest

Forest of Dean, was formerly almost entirely overrun with wood, and extended 20 miles in length, and 10 in breadth. It was then a nest of robbers, especially towards the Severn; but now it contains many towns and villages, consisting chiefly of miners, employed in the coal pits, or in digging for or forging iron ore, with both which the forest abounds. These miners have their particular laws, customs, courts, and judges: and the king, as in all royal forests, has a swain-mote for the preservation of the vert and venison. This forest was anciently, and is still noted for its oaks, which thrive here surprisingly; but as there is a prodigious consumption of wood in the forges, it is continually dwindling away. A navigable canal is made from Stroud to Framilode, forming a junction between the Severn and Thames. Its chalybeate springs are, St Anthony's well, in Abbenhall parish; at Barrow and Maredon, in Bodington parish; at Ash-church, near Tewkesbury; at Dumbleton, near Winchcomb; at Easington, near Dursley; and at Cheltenham. Its ancient fortifications, attributed to the Romans, Saxons, or Danes, are Abston and Wick, and at Dointon, Dixton, Addlesthorp, Knole, Over Upton, and Hanham. See GLOCESTERSHIRE, SUPPLEMENT.

GLOCHIDON, a genus of plants, belonging to the monœcia class. See BOTANY *Index*.

GLOGAW, a strong town of Germany, in Silesia, and capital of a duchy of the same name. It is not very large, but is well fortified on the side of Poland. It has a handsome castle, with a tower, in which several counsellors were condemned by Duke John, in 1498, to perish with hunger. Besides the Papists, there are a great number of Protestants and Jews. It was taken by assault, by the king of Prussia, in 1741, and the garrison made prisoners. After the peace in 1742, the king of Prussia settled the supreme court of justice here, it being, next to Breslaw, the most populous place in Silesia. It is seated on the river Oder, in E. Long. 16. 15. N. Lat. 51. 39.

GLOGAW *the* LESS, a town of Silesia, in the duchy of Oppeln, now in the possession of the king of Prussia. It is 19 miles south of Oppeln, and 45 northwest of Breslaw. E. Long. 16. 15. N. Lat. 51. 38.

GLORIA PATRI, among ecclesiastical writers. See DOXOLOGY.

GLORIOSA, SUPERB LILY, a genus of plants, belonging to the hexandria class, and in the natural method ranking under the 11th order, *Sarmentosæ*. See BOTANY *Index*.

GLORY, renown or celebrity. The love of renown, or desire of fame and reputation, appears to be one of the principal springs of action in human society. Glory, therefore, is not to be contemned, as some of the ancient philosophers affected to teach: but it imports us to regulate our pursuit after it by the dictates of reason; and if the public approbation will not follow us in that course, we must leave her behind.—We ought to have our judgments well instructed as to what actions are truly glorious; and to remember, that in every important enterprise, as Seneca observes, *Rectè facti fecisse merces est; officii fructus, ipsum officium est:* "The reward of a thing well done, is to have done it; the fruit of a good office, is the office itself." Those who by other methods scatter their names into many mouths, show they rather hunt after a great reputation than a good one, and their reward is oftener infamy than fame.

Men generally, and almost instinctively, affix glory only to such actions as have been produced by an innate desire for public good; and we measure it by that degree of influence which any thing done has upon the common happiness.

If the actions of the hero conduct soonest to glory and with the greatest splendour, and if the victorious general is so great after a signal engagement; it is because the service he has done is for the moment, and for all; and because we think without reflecting, that he has saved our habitations, our wealth, and our children, and every thing that attaches us to life. If the man of science, who in his study has discovered and calculated the motions of the heavenly bodies, who in his alembics has unveiled some of the secrets of nature, or who has exhibited to mankind a new art, rises to fame with less noise; it is because the utility which he procures is more widely diffused, and is often of less service to the present than to succeeding generations.

The consequences, therefore, of these two advantages are as opposite as the causes are different; and while the benefits procured by the warrior appear to have no more influence, and while his glory becomes obscure, that of a celebrated writer or inventor still increases, and is more and more enlarged. His works every day bring back his name to that age which uses them, and thus still add to his celebrity and fame.

This posthumous fame indeed has been decried by some writers. In particular, the author of the *Religion of Nature delineated* has treated it as highly irrational and absurd. "In reality (says he) the man is not known ever the more to posterity, because his name is transmitted to them: He doth not live, because his name does. When it is said Julius Cæsar subdued Gaul, conquered Pompey, &c. it is the same thing as to say, the conqueror of Pompey was Julius Cæsar; i. e. Cæsar and the conqueror of Pompey is the same thing; Cæsar is as much known by one designation as by the other. The amount then is only this, that the conqueror of Pompey conquered Pompey; or somebody conquered Pompey; or rather, since Pompey is as little known now as Cæsar, somebody conquered somebody. Such a poor business is this boasted immortality! and such is the thing called glory among us! To discerning men this fame is mere air, and what they despise if not shun."

But surely it were to consider too curiously (as Horatio says to Hamlet) to consider thus. For (as the elegant author of Fitzosborne's Letters observes) although fame with posterity should be, in the strict analysis of it, no other than what is here described, a mere uninteresting proposition, amounting to nothing more than that somebody acted meritoriously; yet it would not necessarily follow, that true philosophy would banish the desire of it from the human breast: for this passion may be (as most certainly it is) wisely implanted in our species, notwithstanding the corresponding object should in reality be very different from what it appears in imagination. Do not many of our most refined and even contemplative pleasures owe their existence to our mistakes? It is but extending some of our senses to to a higher degree of acuteness than we now possess them, to make the fairest views of nature, or the noblest productions of art, appear horrid and deformed. To see things as they truly and in themselves are, would not always, perhaps, be of advantage to us in the intellectual world, any more than in the natural. But, after all, who shall certainly assure us, that the pleasure of virtuous fame dies with its possessor, and reaches not to a farther scene of existence? There is nothing, it should seem, either absurd or unphilosophical in supposing it possible at least, that the praises of the good and the judicious, the sweetest music to an honest ear in this world, may be echoed back to the mansions of the next; that the poet's description of Fame may be literally true, and though she walks upon earth, she may yet lift her head into heaven.

To be convinced of the great advantage of cherishing this high regard to posterity, this noble desire of an after life in the breath of others, one need only look back upon the history of the ancient Greeks and Romans. For what other principle was it which produced that exalted strain of virtue in those days, that may well serve, in too many respects, as a model to these? Was it not the *consentiens laus bonorum*, the *incorrupta vox benè judicantium* (as Tully calls it), "the concurrent approbation of the good, the uncorrupted applause of the wise," that animated their most generous pursuits?

In short, can it be reasonable to extinguish a passion which nature has universally lighted up in the human breast, and which we constantly find to burn with most strength and brightness in the noblest and best formed bosoms? Accordingly revelation is so far from endeavouring to eradicate the seed which nature has thus deeply planted, that she rather seems, on the contrary, to cherish and forward its growth. To be *exalted with honour*, and to be *had in everlasting remembrance*, are in the number of those encouragements which the Jewish dispensation offered to the virtuous; and the person from whom the sacred Author of the Christian system received his birth, is herself represented as rejoicing that *all generations should call her blessed*.

GLOSS, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language or any other. See the article COMMENTARY.—The word, according to some, comes from the Greek γλωσσα, "tongue;" the office of a gloss being to explain the text, as that of the tongue is to discover the mind.

GLOSS is likewise used for a literal translation, or an interpretation of an author in another language word for word.

GLOSS is also used in matters of commerce, &c. for the lustre of a silk, stuff, or the like.

GLOSSARY, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's Latin and Greek Glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his Parochial Antiquities.

GLOSSOPETRA, or GLOTTOPETRA, in *Natural History*, a kind of extraneous fossil, something in form of a serpent's tongue; frequently found in the island of Malta and other places.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of γλωσσα, "tongue" and πετρα, "stone." Hence also their traditionary virtue in curing the bites of serpents. The general opinion of naturalists is, that they are the teeth of fishes, left at hand by the waters of the deluge, and since petrified.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, bluish, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspidate, having a small point on each side of the large one: many of them are quite straight; but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain; some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other substances, and are frequent in the clay pits of Richmond and other places. They are very frequent also in Germany, but nowhere so plentiful as in the island of Malta.

The Germans attribute many virtues to these fossil teeth; they call them cordials, sudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral.

GLOTTIS, in *Anatomy*, the narrow slit at the upper part of the aspera arteria, which is covered by the epiglottis when we hold our breath and when we swallow. The glottis, by its dilatation and contraction, modulates the voice. See ANATOMY, N° 183.

GLOVE, a covering for the hand and wrist.

Gloves, with respect to commerce, are distinguished into leathern gloves, silk gloves, thread gloves, cotton gloves, worsted gloves, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. Gloves now pay a duty to the king, which increases according to their value.

To throw the glove, was a practice or ceremony very usual among our forefathers; being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings; when the king's champion casts his glove in Westminster hall. See CHAMPION.

Favyn supposes the custom to have arisen from the eastern nations, who in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove* what the common version renders by *shoe*. He adds, that the Rabbins interpret by *glove* that passage in the cviiith Psalm, *In Idumeam extendam calceamentum meum*, "Over *Edom* will I cast out my shoe." Accordingly, among us, he who took up the *glove*, declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the *glove* off his own right hand, and cast it upon the ground, Glove, Glover.

ground, to be taken up by the challenger. This had the force of a mutual engagement on each side, to meet at the time and place which should be appointed by the king, parliament, or judges. The same author asserts, that the custom which still obtains of blessing *gloves* in the coronation of the kings of France, is a remain of the eastern practice of giving possession with the *glove*, lib. xvi. p. 1017, &c.

Anciently it was prohibited the judges to wear gloves on the bench. And at present in the stables of most princes, it is not safe going in without pulling off the gloves.

GLOVER, Richard, the author of Leonidas and several other esteemed works, was the son of Richard Glover, a Hamburgh merchant in London, and was born in St Martin's lane in the year 1712. He very early showed a strong propensity to and genius for poetry; and while at school, he wrote, amongst other pieces, a poem to the memory of Sir Isaac Newton, prefixed to the view of that incomparable author's philosophy, published in 4to, in 1728, by his intimate friend Dr Pemberton. But though possessed of talents which were calculated to excel in the literary world, he was content to devote his attention to commerce, and at a proper period commenced a Hamburgh merchant. He still, however, cultivated literature, and associated with those who were eminent in science. One of his earliest friends was Matthew Green, the ingenious but obscure author of some admirable poems, which in 1737, after his death, were collected and published by Mr Glover. In 1737, Mr Glover married Miss Nunn, with whom he received a handsome fortune; and in the same month published Leonidas, a poem in 4to, which in this and the next year passed through three editions. This poem was inscribed to Lord Cobham; and on its first appearance was received by the world with great approbation, though it has since been unaccountably neglected. Lord Lyttleton, in a popular publication called Common Sense, and in a poem addressed to the author, praised it in the warmest terms; and Dr Pemberton published, Observations on Poetry, especially epic, occasioned by the late poem upon Leonidas, 1738, 12mo, merely with a view to point out its beauties. In 1739, Mr Glover published "London, or the Progress of Commerce," 4to; and a ballad entitled, Hosier's Ghost. Both these pieces seem to have been written with a view to incite the public to resent the misbehaviour of the Spaniards; and the latter had a very considerable effect. The political dissensions at this period raged with great violence, and more especially in the metropolis; and at different meetings of the livery on those occasions, Mr Glover was always called to the chair, and acquitted himself in a very able manner, his conduct being patriotic and his speeches masterly. His talents for public speaking, his knowledge of political affairs, and his information concerning trade and commerce, soon afterwards pointed him out to the merchants of London as a proper person to conduct their application to parliament on the subject of the neglect of their trade. He accepted the office; and in summing up the evidence gave very striking proofs of his oratorical powers. This speech was pronounced Jan. 27. 1742.

In the year 1744 died the duchess of Marlborough, and by her will left to Mr Glover and Mr Mallet 500l. each, to write the History of the Duke of Marlborough's Life. This bequest, however, never took place. It is supposed, that Mr Glover very early renounced his share of it; and Mallet, though he continued to talk of performing the task almost as long as he lived, is now known never to have made the least progress in it. About this period Mr Glover withdrew a good deal from public notice, and lived in retirement. He had been unsuccessful in his business; and with a very laudable delicacy had preferred an obscure retreat to popular observation, until his affairs should put on a more prosperous appearance. He had been honoured with the attention of Frederick prince of Wales, who once presented him with a complete set of the classics, elegantly bound; and, on his absenting himself for some time on account of the embarrassment in his circumstances, sent him, it is said, 500l. The prince died in March 1751; and in May following Mr Glover was once more drawn from his retreat by the importunity of his friends, and stood candidate for the place of chamberlain of London. It unfortunately happened that he did not declare himself until most of the livery had engaged their votes; by which means he lost his election.

Glover.

In 1753, Mr Glover produced at Drury Lane his tragedy of Boadicea; which was acted nine nights, in the month of December. It had the advantage of the performance of Mr Garrick, Mr Mossop, Mrs Cibber, and Mrs Pritchard. From the prologue it seems to have been patronized by the author's friends in the city; and Dr Pemberton wrote a pamphlet to recommend it.—In 1761, Mr Glover published Medea, a tragedy written on the Greek model; but it was not acted until 1767, when it appeared for the first time on the stage at Drury Lane for Mrs Yates's benefit. At the accession of his present majesty, he appears to have surmounted the difficulties of his situation. In the parliament which was then called, he was chosen member for Weymouth, and continued to sit as such until the dissolution of it. He, about this time, interested himself about India affairs, at one of Mr Sullivan's elections; and in a speech introduced the fable of the man, horse, and bear; and drew this conclusion, that, whenever merchants made use of armed forces to maintain their trade, it would end in their destruction.

In 1770, the poem of Leonidas requiring a new edition, it was republished in two volumes 12mo, corrected throughout, and extended from nine books to twelve. It had also several new characters added, besides placing the old ones in new situations. The improvements made in it were very considerable; but we believe the public curiosity, at this period, was not sufficiently alive to recompense the pains bestowed on this once popular performance. The calamities arising from the wounds given to public credit, in June 1772, by the failure of the bank of Douglas, Heron, and Co. in Scotland, occasioned Mr Glover's taking a very active part in the settling those complicated concerns, and in stopping the distress then so universally felt. In February 1774, he called the annuitants of that banking-house together, at the King's Arms tavern, and laid proposals before them for the security of their demands, with which they were fully satisfied. He also undertook to manage the interests of the merchants and traders of London concerned in the trade to Germany

many and Holland, and of the dealers in foreign linens, in their application to parliament in May 1774. Both the speeches made on these occasions were published in a pamphlet in that year. In the succeeding year he engaged on behalf of the West India merchants in their application to parliament, and examined the witnesses and summoned up the evidence in the same masterly manner he had done on former occasions. For the assistance he afforded the merchants in this business, he was complimented by them with a service of plate, of the value of 300l. The speech which he delivered in the house was in the same year printed. This, we believe, was the last opportunity he had of displaying his oratorical talents in public. Having now arrived at a period of life which demanded a recess from business, Mr Glover retired to ease and independence, and spent the remainder of his days with dignity and with honour. It is probable that he still continued his attention to his muse, as we are informed that, besides an epic poem of considerable length, he has left some tragedies and comedies behind him in manuscript. After experiencing for some time the infirmities of age, he departed this life 25th November 1785; leaving behind him a most estimable character as a man, a citizen, and a writer.

GLOW-WORM. See LAMPYRIS, ENTOMOLOGY *Index*.

GLUCINA, in *Chemistry*, an earthy substance which was discovered by Vauquelin in 1798, in analyzing the emerald, of which it forms a component part. For an account of its properties and combinations, see CHEMISTRY, N° 1165.

GLUCKSTADT, a strong and considerable town of Germany, in the circle of Upper Saxony, and duchy of Holstein, with a strong castle, and subject to Denmark. It is seated on the river Elbe, near its mouth, and 28 miles from Hamburgh. E. Long. 9. 20. N. Lat. 53. 31.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uses they are designed for, as the common glue, glove glue, and parchment glue; whereof the two last are more properly called *size*.

Hamel du Monceau has written one of the best works on the subject of glue. According to this author, glue was at first principally prepared from the membranous, tendinous, and cartilaginous parts of animals, and after being dried, they were melted into tablets. It is certain, however, that every animal substance containing jelly, may be used in the manufacture of glue; and, according to Du Hamel himself, a strong, but black-coloured glue may be obtained from bones and hartshorn, after they are dissolved in Papin's digester. Of the truth of this fact Papin himself likewise assures us, for he prepared a jelly from bones, and even from ivory, by which he glued together some pieces of broken glass; and subsequent experiments made by other chemists have confirmed his assertion.

To the information contained on this subject in the works of Papin, Spielman has added many valuable remarks. He not only extracted glue from bones, but also from all the solid parts of animals, by boiling alone, as well as from the teeth of the sea horse, the wild boar, the wood-louse, and the viper.

The glue manufactured in Europe is of different kinds; but that which is made in England is esteemed the best. Its colour is of a brownish red. The Flanders glue is considered as of an inferior quality to that made in England, while the glue manufactured in France is not so good as either. The reason assigned for this difference of quality is, that bones and sinews are made use of by the Flemish and French in the manufacture of this article, while the English employ skins, which yield a much stronger glue. Dr Lewis informs us that the English steep and wash the cuttings of the hides in water, then boil them in fresh water till the liquor becomes of a proper consistence; after which they strain it through baskets, allow it to settle, then expose it to further evaporation, and pour it into flat moulds, where it unites. When thoroughly cooled, it is converted into solid cakes, which are cut into pieces, and dried on a kind of net.

Grenet for many years turned his attention to the manufacturing of glue. Having made a number of experiments on every substance formerly employed for this purpose, he found that bones afford the most abundant quantity of glue, and yield it with facility. Having deprived them of the fat they contain, he procured a jelly by simply boiling them, which, when dried, and thus changed into glue, he found superior to that which was prepared in France, and nearly equal to the best glue of commerce.

From the experiments of Parmentier, it appears that six pounds of button-makers raspings yielded a pound of excellent glue, not inferior to that which is manufactured in England. The glue which he obtained from the filings of ivory was equally as good, but more highly coloured. The filings of horn yielded none of this substance.

To obtain glue as colourless as possible, a very small quantity of water should be employed for extracting the jelly, by which means it may be concentrated without long evaporation, as exposure to heat has always a greater or less influence on the colour in proportion to the time. The whiteness and transparency of the Flanders glue are said to originate from an adherence to this plan.

In their consistence, colour, taste, smell, and solubility, glues are found to differ from each other. Some glues will dissolve by agitation in cold water, while others are only soluble at the point of ebullition. It is generally admitted that the best glue is transparent, of a brownish yellow colour, and having neither taste nor smell. It is perfectly soluble in water, forming a viscous fluid, which, when dry, preserves its tenacity and transparency in every part, and has more solidity, colour and viscidity, in proportion to the age and strength of the animal from which it is produced.

For the following account of the manufacture of glue, we are indebted to Mr John Clennel of Newcastle. "The improvement (he observes) of any manufacture depends upon its easy access to men of science, and a prudential theorist can never be better employed than in attempting to reduce to regularity or to system the manufactures that may fall under his attention. In conformity to the first principle, I made some notes whilst visiting a glue manufactory a few years ago in Southwark, and those, interwoven with the remarks on that subject of some chemists of the first respectability, I take the liberty of sending

sending you: at the same time I must beg of you, or your correspondents, that where it may be corrected in any manner, it may be done, and I shall feel myself obliged by the attention.

"Glue is an inspissated jelly, made of the parings of hides or horns of any kind, the pelts obtained from furriers, and the hoofs and ears of horses, oxen, calves, sheep, &c. quantities of all which are imported in addition to the home supply, by many of the great manufacturers of this article: these are first digested in lime water, to cleanse them as far as it can from the grease or dirt they may have contracted; they are then steeped in clean water, taking care to stir them well from time to time; afterwards they are laid in a heap, and the superabundant water pressed out; then they are boiled in a large brass caldron with clean water, skimming off the dirt as it rises, and further cleansed by putting in, after the whole is dissolved, a little melted alum or lime finely powdered, which, by their detersive properties, still further purge it: the skimming is continued for some time, when the mass is strained through baskets, and suffered to settle, that the remaining impurities, if any, may subside; it is then poured gently into the kettle again, and further evaporated by boiling a second time, and skimming, until it becomes of a clear but darkish brown colour: when it is thought to be strong enough (which is known either by the length of time a certain quantity of water and materials have boiled, or by its appearance during ebullition), it is poured into frames or moulds of about six feet long, one broad, and two deep, where it hardens gradually as the heat decreases: out of these troughs or receivers it is cut, when cold, by a spade, into square pieces or cakes, and each of these placed within a sort of wooden box, open in three divisions to the back; in this the glue, as yet soft, is taken to a table by women, where they divide it into three pieces (A) with an instrument not unlike a bow, having a brass wire for its string; with this they stand behind the box and cut by its openings, from front to back; the pieces thus cut are taken out into the open air, and dried on a kind of coarse net work, fastened in moveable sheds of about four feet square, which are fastened in rows in the gluemaker's field (every one of which contains four or five rows of net work); when perfectly dry and hard, it is fit for sale.

"That is thought the best glue which swells considerably without melting, by three or four days immersiou in cold water, and recovers its former dimensions and properties by drying. Glue that has got frost, or that looks thick and black, may be melted over again and refined, with a sufficient quantity added of fresh to overcome any injury it may have sustained; but it is generally put into the kettle after what is in it has been purged in the second boiling. To know good from bad glue, it is necessary for the purchaser to hold it between his eye and the light, and if it appears of a strong dark brown colour, and free from cloudy or black spots, the article is good."

A glue that is colourless and of superior quality, is obtained from the skins of eels, and known by the name of *size*. It is even procured from vellum, parchment, and some of the white species of leather; but for common purposes this is by far too expensive, and is only made use of in those cases of delicate workmanship where glue would be too gross. The skins of the rabbit, hare, and cat, are made use of in the manufacturing of size, by those who are employed in gilding gold, polishing, and painting, in various colours.

From the experiments of Mr Hatchett it appears, that membrane yields different quantities of gelatine, the solutions of which evaporated to dryness, afforded him an opportunity of observing the different degrees of viscidity and tenacity of mucilage, size, and glue. He also found that the more viscid glues are obtained with greater difficulty than such as are less so. When a cake of glue has been steeped three or four days in cold water, it is considered of the best quality, if it swell much without being dissolved, and if, when taken out, it recovers its original figure and hardness by drying.

On comparing the skins of different animals, Mr Hatchett found, that such as were most flexible more readily yielded their gelatine, and that produced from the skin of the rhinoceros was by far the most viscid of any. The true skin of any animal was most affected by long boiling; but the hide of the rhinoceros was the most insoluble.

He found that hair was not so much affected as skin; but the cartilages of the joints, when boiled long in water, were as perfectly soluble as the cutis, which is not the case with the other cartilages, as they afford little or no gelatine. The horns of the ox, ram, and goat, are very different from those of the stag; and the small quantity of gelatine they are found to contain, is produced more gradually, and with greater difficulty.

According to Hatchett, the effects of diluted nitric acid on the substances commonly employed in the manufacturing of glue, were exactly analogous to those of boiling water, and were always most powerful on those substances which contained the greatest quantity of gelatine. Almost all animal substances are convertible either into glue or soap, with this additional advantage, that those parts of them which would not be employed in making the one, are the most proper in the manufacture of the other.

Another fine species of glue, known by the name of *isinglass*, is the produce of certain fish, very common in the Russian seas, found on entering the rivers Wolga, Lyak, Don, and Danube. In Muscovy it is prepared of the *sturgeon* and the *storled*, which yield the most beautiful isinglass. The fish from fresh water are esteemed the best, as they afford an isinglass more flexible and transparent than any other.

When the bladder is extracted, it is washed in water to free it from the blood, if any adheres to it, but, not otherwise. It is then cut longitudinally, and the outer membrane taken off, the colour of which is brown, while the other membrane is so fine and white as to be with

(A) When the women, by mistake, cut only two, that which is double the size is called a *bishop*, and thrown into the kettle again.

with difficulty separated from the fish. They are formed into rolls of the size of the finger, with the fine membrane in the middle, and hung in the air to dry by degrees. Good isinglass is white, perfectly dry, semitransparent, and without smell. It is soluble in water with a gentle heat, but is easily dissolved in alcohol, in which it differs essentially from common glue. That which is made from different parts of sea wolves, sea cows, sharks, and whales, is employed in the clarifying of different wines and other liquors. Isinglass is of all shades of colour, from pure transparency to black; but such as are large and yellow are reckoned the worst. They are opaque, and their smell is disagreeable.

From 500 grains of isinglass Mr Hatchett obtained 56 grains of coal, from which $1\frac{1}{2}$ grain of earthy residuum were obtained by reducing it to ashes. Of consequence there were only 54.5 grains of pure coal, and the remaining 1.5 he found to be phosphate of soda, with an extremely small proportion of phosphate of lime.

GLUME (*gluma*), among botanists, a species of calyx, consisting of two or three membranous valves, which are often pellucid at the edges. This kind of calyx belongs to the grasses.

GLUT, among falconers, the slimy substance that lies in a hawk's paunch.

GLUTA, a genus of plants belonging to the gynandria class. See BOTANY *Index*.

GLUTÆUS, a name common to three muscles whose office it is to extend the thigh. See ANATOMY, *Table of the Muscles*.

GLUTTON. See MUSTELA, MAMMALIA *Index*.

GLUTTONY, a voracity of appetite, or a propensity to gormandizing.

There is a morbid sort of gluttony, called *fames canina*, "dog-like appetite," which sometimes occurs, and renders the person seized with it an object of pity and of cure as in other diseases: (see BULIMY).—But professed habitual gluttons may be reckoned amongst the monsters of nature, and deemed in a manner punishable for endeavouring to bring a dearth or famine into the places where they live. For which reason, people think King James I. was in the right, when a man being presented to him who could eat a whole sheep at one meal, he asked "What he could do more than another man?" and being answered "He could not do so much, said "Hang him then; for it is unfit a man should live that eats so much as 20 men, and cannot do so much as one."

The emperor Clodius Albinus would devour more apples at once than a bushel would hold. He would eat 500 figs to his breakfast, 100 peaches, 10 melons, 20 pound weight of grapes, 100 gnat-snappers, and 400 oysters. "Fye upon him (saith Lipsius); God keep such a curse from the earth."

One of our Danish kings named *Hardiknute* was so great a glutton, that a historian calls him *Bacca de Porco*, "Swine's mouth." His tables were covered four times a-day with the most costly viands that either the air, sea, or land, could furnish; and as he lived he died; for, revelling and carousing at a wedding banquet at Lambeth, he fell down dead. His death was so welcome to his subjects, that they celebrated the day with sports and pastimes, calling it *Hock tide*, which signifies scorn and contempt. With this king ended the reign of the Danes in England.

One Phagon, under the reign of the emperor Aurelianus, at one meal, ate a whole boar, 100 loaves of bread, a sheep, a pig, and drank above three gallons of wine.

We are told by Fuller *, that one Nicholas Wood, of Harrison in Kent, ate a whole sheep of 16s. price at one meal, raw; at another time 30 dozen of pigeons. At Sir William Sidley's in the same county, he ate as much victuals as would have sufficed 30 men. At Lord Wotton's mansion house in Kent, he devoured at one dinner 84 rabbits; which, by computation, at half a rabbit a man, would have served 168 men, He ate to his breakfast 18 yards of black pudding. He devoured a whole hog at one sitting down; and after it, being accommodated with fruit, he ate three pecks of damosins.

* *Worthies*, p. 86.

A counsellor at law, whose name was Mallet, well known in the reign of Charles I. ate at one time an ordinary provided in Westminster for 30 men at 12d. a-piece. His practice not being sufficient to supply him with better sort of meat, he fed generally on offals, ox livers, hearts, &c. He lived to almost 60 years of age, and for the seven last years of his life ate as moderately as other men. A narrative of his life was published.

GLYCINE, KNOBBED-ROOTED LIQUORICE-VETCH; a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

GLYCIRRHIZA, LIQUORICE; a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY and MATERIA MEDICA *Index*.

GLYNN, a county in the lower district of Georgia, in America, bounded on the east by the ocean, on the north by the river Alatamaha, by which it is separated from Liberty county, and on the south by Camden. The principal produce is cotton and rice. The chief town is Brunswick.

GLYPH, in *Sculpture* and *Architecture*, denotes any canal or cavity used as an ornament.

GMELIN, JOHN GEORGE, M. D. public lecturer on botany and physic at Tubingen, member of the Royal Society of Gottingen, and of the Academy of Sciences at Stockholm, was born on the 12th of August 1709, at Tubingen, where his father was an apothecary. Such was his diligence while at school, that he was qualified to attend the academical lectures at the age of 14, and was created doctor of medicine when only 19. He paid a visit about this time to the metropolis of the Russian empire, that he might have the pleasure of seeing some of his former teachers. There he became acquainted with Blumentrost, director of the academy, who introduced him to the meetings of the members, and procured for him an annual pension. At Petersburgh he was so much esteemed, that when he intimated a wish in 1729 to return to Tubingen, he was honoured with a place among the regular members of the academy, and chosen professor of chemistry and natural history in the year 1731. In order to carry into execution a plan which had been formed by Peter the Great, for exploring a passage to China and Japan along the coast of the Russian empire, Gmelin.

Gmelin was selected along with two others, as properly qualified for that undertaking, and likewise to ascertain the boundaries of Siberia. The department of natural history was assigned to our author. He had with him and his companions, six students, two draftsmen, two hunters, two miners, four land-surveyors, and 12 soldiers, with a serjeant and drummer. They began their journey on the 19th of August 1733; and in 1736, Steller and a painter joined their society, in order to assist Gmelin in his arduous labours.

By exploring Kamtschatka, they hoped to accomplish their mission in a satisfactory manner, for which purpose Steller proceeded to this place, and the rest of the society continued their travels through Siberia. In February 1743 Gmelin returned to Petersburgh in safety after a dangerous journey which lasted nine years and a half, but proved of the utmost importance to various branches of science. He resumed the offices which he had filled before; and having paid a visit in 1747 to his native country, he was chosen professor, while absent, in the room of Bachmeister deceased. He was seized with a violent fever in May 1755, which put a period to his valuable life, in the 45th year of his age. He was undoubtedly one of the most eminent botanists of the last century, and has rendered his name immortal by his *Flora Sibirica, seu historia plantarum Siberiæ*, in four parts, large quarto. He determined the boundaries between Europe and Asia, which every celebrated geographer has adopted since his day. Through all his works the traces of great modesty, a sacred regard to truth, and the most extensive knowledge of nature, are remarkably conspicuous.

Gmelin, *Dr Samuel*, was born in 1743 at Tubingen, where he also studied, and became doctor in medicine in 1763. He was afterwards admitted a member of the Imperial Academy of Sciences at St Petersburg. He commenced his travels in June 1768; and having traversed the provinces of Moscow, Voronetz, New Russia, Azof, Casan, and Astracan, he visited, in 1770 and 1771, the different harbours of the Caspian, and examined with peculiar attention those parts of the Persian provinces which border upon that sea, of which he has given a circumstantial account in the three volumes of his travels already published. Actuated by a zeal for extending his observations, he attempted to pass through the western provinces of Persia, which are in a perpetual state of warfare, and infested by numerous banditti. Upon this expedition, he quitted, in April 1772, Einzillee, a small trading place in Ghilan, upon the southern shore of the Caspian; and, on account of many difficulties and dangers, did not, until December 2. 1773, reach Sallian, a town situated upon the mouth of the river Koor. Thence he proceeded to Baku and Kuba, in the province of Shirvan, where he met with a friendly reception from Ali Feth Khan, the sovereign of that district. After he had been joined by 20 Uralian Cossacks, and when he was only four days journey from the Russian fortress Kislar, he and his companions were, on the 5th of February 1774, arrested by order of Usméi Khan, a petty Tartar prince, through whose territories he was obliged to pass. Usméi urged as a pretence for this arrest, that 30 years ago several families had escaped from his dominions, and had found an asylum in the Russian territories; adding, that Gmelin should not be released until these families were restored. The professor was removed from prison to prison; and at length, wearied out with continued persecutions, he expired, July 27th, at Achmet-Kent, a village of Mount Caucasus. His death was occasioned partly by vexation for the loss of several papers and collections, and partly by disorders contracted from the fatigues of his long journey. Some of his papers had been sent to Kislar during his imprisonment, and the others were not without great difficulty rescued from the hands of the barbarian who had detained him in captivity. The arrangement of these papers, which will form a fourth volume of his travels, was at first consigned to the care of Guildenstaedt, but upon his death has been transferred to the learned Pallas.

Gmelin ‖ Gnostics.

GMELINA, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 40th order, *Personatæ*. See Botany *Index*.

GNAPHALIUM, Cud-weed, Goldy-Locks, Eternal Flower, &c.; a genus of plants belonging to the syngenesia class; and in the natural method ranking under the 49th order, *Compositæ*. See Botany *Index*.

GNAT. See Culex, Entomology *Index*.

GNESNA, a large and strong town of Prussian Poland, in the palatinate of Calish, with an archbishop's see, whose prelate was primate of Poland, and viceroy during the vacancy of the throne. It was the first town built in the kingdom, and formerly more considerable than at present. E. Long. 17. 42. N. Lat. 52. 26.

GNETUM, a genus of plants belonging to the monœcia class. See Botany *Index*.

GNIDIA, a genus of plants belonging to the octandria class. See Botany *Index*.

GNOMES, Gnomi, certain imaginary beings, who, according to the cabbalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See Fairy.

GNOMON, in *Dialling*, the style, pin, or cock of a dial, which by its shadow shows the hour of the day. The gnomon of every dial represents the axis of the earth: (See Dial and Dialling).—The word is Greek, γνωμων, which literally implies something that makes a thing known; by reason that the style or pin indicates or makes the hour known.

Gnomon, in *Astronomy*, a style erected perpendicular to the horizon, in order to find the altitude of the sun. See Astronomy.

By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See Quadrant.

By the same instrument the height of any object may be found: for as the distance of the observer's eye from the gnomon, is to the height of the style; so is the distance of the observer's eye from the object, to its height.

For the uses and application of gnomons, see Geography.

Gnomon of a Globe; the index of the hour circle.

GNOMONICS, the art of dialling. See Dialling.

GNOSTICS, ancient heretics, famous from the first rise of Christianity, principally in the east.

It

Gnostics.

It appears from several passages of the sacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many persons were infected with the Gnostic heresy in the first century; though the sect did not render itself conspicuous, either for number or reputation, before the time of Adrian, when some writers erroneously date its rise.

The name is formed of the Latin *gnosticus*, and that of the Greek γνωστικος, "knowing," of γινωσκω, "I know;" and was adopted by those of this sect, as if they were the only persons who had the true knowledge of Christianity. Accordingly, they looked on all other Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings, in a too low, literal, and unedifying signification.

At first the Gnostics were only the philosophers and wits of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of Scripture. But

GNOSTICS afterwards became a general name, comprehending divers sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

GNOSTICS was sometimes also more particularly attributed to the successors of the first Nicolaitans and Carpocratians, in the second century, upon their laying aside the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and visions, may consult St Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St Epiphanius; particularly the first of these writers, who relates their sentiments at large: and confutes them at the same time: indeed, he dwells more expressly on the Valentinians than any other sort of Gnostics; but he shows the general principles whereon all their mistaken opinions were founded, and the method they followed in explaining scripture. He accuses them of introducing into religion certain vain and ridiculous genealogies, i. e. a kind of divine processions or emanations which had no other foundation but in their own wild imaginations.

In effect, the Gnostics confessed that these æons or emanations were nowhere expressly delivered in the sacred writings; but insisted at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St Paul, but also on the law of Moses and the prophets. These last laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound, which are capable of different interpretations: Though their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and filled them with an abhorrence of Moses and the religion he taught; alleging, that he was actuated by the malignant author of this world, who consulted his own glory and authority, and not the real advantage of men. Their persuasion that evil resided in matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its re-union with the immortal spirit. Their notion, that malevolent genii presided in nature, and occasioned diseases and calamities, wars, and desolations, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of their malignant agents.

The Gnostics considered Jesus Christ as the Son of God, and consequently inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings; but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and therefore the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St John, where they fancied they saw a great deal of their æons, or emanations, under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, viz. *hylic*, or material; *psychic*, or animal; and *pneumatic*, or spiritual. On the like principle they also distinguished three sorts of men; *material*, *animal*, and *spiritual*. The first, who were material and incapable of knowledge, inevitably perished, both soul and body; the third, such as the Gnostics themselves pretended to be, were all certainly saved; the psychic, or animal, who were the middle between the other two were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of the sect adopted very austere rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained, that there was no moral difference in human actions; and thus confounding right and wrong, they gave a loose rein to all the passions, and asserted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities; some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ, and his apostles; others boasted, that they had deduced their sentiments from secret doctrines of Christ, concealed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others asserted, that they were instructed in these mysterious parts of theological science by Theudas, a disciple of St Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnostics were revived in Spain, in the fourth century, by a sect called the *Priscillianists*.

The appellation *Gnostic* sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his Stromata, where he shows that none but the Gnostic or learned person, has any true religion. He affirms, that were it possible for the knowledge

ledge of God to be separated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of any thing he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures. In this sense the father uses Gnostics, in opposition to the heretics of the same name; affirming, that the true Gnostic is grown old in the study of the holy scriptures; and that he preserves the orthodox doctrine of the apostles and of the church; whereas the false Gnostic abandons all the apostolical traditions, as imagining himself wiser than the apostles. At length the name *Gnostic*, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it.

GNU, or GNOU. See CAPRA, MAMMALIA *Index*.

GOA, a large and strong town of Asia, in the peninsula on this side the Ganges, and on the Malabar coast. It was taken by the Portuguese in 1508, and is the chief town of all their settlements on this side the Cape of Good Hope. It stands in an island of the same name, about 12 miles in length, and six in breadth; and the city is built on the north side of it, having the conveniency of a fine salt-water river, capable of receiving ships of the greatest burden, where they lie within a mile of the town. The banks of the river are beautified with a great number of handsome structures; such as churches, castles, and gentlemen's houses. The air within the town is unwholesome, for which reason it is not so well inhabited now as it was formerly. The viceroy's palace is a handsome building; and stands at a small distance from the river, over one of the gates of the city, which leads to a spacious street, terminated by a beautiful church. This city contains a great number of handsome churches, convents, and cloisters, with a stately large hospital; all well endowed, and kept in good repair. The market place occupies an acre of ground; and in the shops about it may be had the produce of Europe, China, Bengal, and other countries of less note. Every church has a set of bells, some of which are continually ringing. There are a great many Indian converts; but they generally retain some of their old customs, particularly they cannot be brought to eat beef. The clergy are very numerous and illiterate; but the churches are finely embellished, and have great numbers of images. In one of these churches, dedicated to Bon Jesus, is the chapel of St Francisco de Xaviere, whose tomb it contains: this chapel is a most superb and magnificent place; the tomb of the saint is entirely of fine black marble brought from Lisbon; on the four sides of it the principal actions of the life of the saint are most elegantly carved in basso relievo; these represent his converting the different nations to the Catholic faith: the figures are done to the life, and most admirably executed: it extends to the top in a pyramidical form, which terminates with a coronet of mother-of-pearl. On the sides of this chapel are excellent paintings, done by Italian masters; the subjects chiefly from Scripture. This tomb and the chapel appertaining to it, must have cost an immense sum of money; the Portuguese justly esteem it the greatest rarity in the place. The houses are large, and make a fine show; but within they are but poorly furnished. The inhabitants are contented with greens, fruits, and

roots; which, with a little bread, rice, and fish, is their principal diet, though they have hogs and fowls in plenty. The river's mouth is defended by several forts and batteries, well planted with large cannon on both sides; and there are several other forts in different places.

Goa is the residence of a captain general, who lived formerly in great splendour. He is also commander in chief of all the Portuguese forces in the East Indies. They kept here formerly two regiments of European infantry, three legions of sepoys, three troops of native light horse, and a militia; in all about 5000 men. But Goa is at present on the decline, and in little or no estimation with the country powers; indeed their bigotry and superstitious attachment to their faith is so general, that the inhabitants of the city and island are now reduced to about 20,000; the chief part of whom have been baptized; for they will not suffer any Mussulman or Gentoo to live within the precincts of the city: and these few are unable to carry on the husbandry or manufactures of the country. The court of Portugal is obliged to send out annually a very large sum of money, to defray the current expences of the government; which money is generally swallowed up by the convents and soldiery.

There was formerly an inquisition at this place, but it is now abolished; the building still remains, and by its black outside appears a fit emblem of the cruel and bloody transactions that passed within its walls! Provisions are to be had at this place in great plenty and perfection. E. Long. 73. 46. N. Lat. 15. 28.

GOAL. See GAOL.

GOAT. See CAPRA, MAMMALIA *Index*.

GOAT's Beard. See TRAGOPOGON, BOTANY *Index*.

GOAT-Sucker. See CAPRIMULGUS, ORNITHOLOGY *Index*.

GOBELIN, GILES, a celebrated French dyer, in the reign of Francis I. discovered a method of dyeing a beautiful scarlet, and his name has been given ever since to the finest French scarlets. His house, in the suburb of St Marcel at Paris, and the river he made use of, are still called *the Gobelins*. An academy for drawing, and a manufactory of fine tapestries, were erected in this quarter in 1666; for which reason the tapestries are called *the Gobelins*.

GOBIUS, a genus of fishes belonging to the order of thoracici. See ICHTHYOLOGY *Index*.

GOBLET, or GOBELET, a kind of drinking cup, or bowl, ordinarily of a round figure, and without either foot or handle. The word is French, *gobelet*; which Salmasius, and others, derive from the barbarous Latin *cupa*. Budeus deduces it from the Greek κυπελλον, *a sort of cup*.

GOD, one of the many names of the Supreme Being. See CHRISTIANITY, METAPHYSICS, MORAL PHILOSOPHY, and THEOLOGY.

GOD is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid.

The Greeks and Latins, it is observable, did not mean by the name of *God*, an all-perfect being, whereof eternity, infinity, omnipresence, &c. were essential attributes; with them, the word only implied an excellent and superior nature; and accordingly they gave the

the appellation *gods* to all beings of a rank or class higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one Supreme. Thus men themselves, according to their system, might become gods after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, Father Bossu observes, were the poets: the two functions, though now separated, were originally combined; or, rather, were one and the same thing.

Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put these poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons; because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God, under that of Minerva; the justice of God, under that of Juno.

The first idols or false gods that are said to have been adored, were the stars, sun, moon, &c. on account of the light, heat, and other benefits, which we derive from them. Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then fire and water became objects of divine worship, for their usefulness to human life. In process of time, and by degrees, gods became multiplied to infinity: and there was scarce any thing but the weakness or caprice of some devotee or other elevated into the rank of deity; things useless or even destructive not excepted. See MYTHOLOGY.

GODALMING, a town of England, in the county of Surrey, 35 miles from London. It is situated on the Wye, which has been rendered navigable for barges from Guildford, whence the communication is open to the Thames. The church is much admired for its neat and lofty spire. Here are manufactories of mixed and blue kerseys, of stockings, blankets, &c. Population 3543 in 1811. W. Long. 0. 31. N. Lat. 51. 1.

GODDARD, JONATHAN, an eminent physician and chemist, and one of the first promoters of the Royal Society, was born about the year 1617. He was elected a fellow of the college of physicians in 1646, and appointed reader of the anatomical lecture in that college in 1647. As he took part against Charles I. accepted the wardenship of Merton-college, Oxford, from Oliver Cromwell when chancellor, and sat sole representative of that university in Cromwell's parliament, he was removed from his wardenship in a manner disgraceful to him by Charles II. He was however then professor of physic at Gresham college, to which he retired, and continued to attend those meetings that gave birth to the Royal Society; upon the first establishment of which he was nominated one of the council. Being fully persuaded that the preparation of medicines was no less the physician's duty than the prescribing them, he constantly prepared his own; and in 1668 published a treatise recommending his example to general practice. He died of an apoplectic fit in 1674; and his memory was preserved by the drops that bore his name, otherwise called *Guttæ Anglicanæ*, the secret of which he sold to Charles II. for 5000l. and which Dr Lister assures us was only the volatile spirit of raw silk rectified with oil of cinnamon or some other essential oil. But he claims more particular regard, if what Bishop Seth Ward says be true, that he was the first Englishman who made that noble astronomical instrument, the telescope.

GODDESS, a heathen deity of the female sex.

The ancients had almost as many goddesses as gods: such were, Juno the goddess of air, Diana the goddess of woods, &c. and under this character were represented the virtues, graces, and principal advantages of life; truth, justice, piety, liberty, fortune, victory, &c.

It was the peculiar privilege of the goddesses to be represented naked on medals; for it was supposed that the imagination must be awed and restrained by the consideration of the divine character.

GODFATHERS and GODMOTHERS, persons who, at the baptism of infants, answer for their future conduct, and solemnly promise that they will renounce the devil and all his works, and follow a life of piety and virtue; and by this means lay themselves under an indispensable obligation to instruct them, and watch over their conduct.

This custom is of great antiquity in the Christian church; and was probably instituted to prevent children being brought up in idolatry, in case their parents died before they arrived at years of discretion.

The number of godfathers and godmothers is reduced to two, in the church of Rome; and three, in the church of England: but formerly they had as many as they pleased.

GODFREY of Bouillon, prince of Lorrain, a most celebrated crusader, and victorious general. He was chosen general of the expedition which the Christians undertook for the recovery of the Holy Land, and sold his dukedom to prepare for the war. He took Jerusalem from the Turks in 1099; but his piety, as historians relate, would not permit him to wear a diadem of gold in the city where his Saviour had been crowned with thorns. The sultan of Egypt afterwards sent a terrible army against him; which he defeated, with the slaughter of about 100,000 of the enemy. He died in 1160.

GODMANCHESTER, a town of Huntingdonshire 16 miles from Cambridge, and 57 from London. It has a bridge on the Ouse, opposite to Huntingdon; was formerly a Roman city, by the name of Durosiponte, where many Roman coins have been often dug up; and according to old writers, in the time of the Saxons it was the see of a bishop, and had a castle built by one Gorman a Danish king, from which the town was called *Gormanchester*. It is a large village, containing 1779 inhabitants in 1811, and is seated in a fertile soil, abounding with corn. It is said that no town in England kept more ploughs at work than this has done. The inhabitants boast they formerly received our kings as they made a progress this way, with nine score ploughs at a time, finely adorned with their trappings, &c. James I. made it a corporation by the name of two bailiffs, 12 assistants, and the commonalty of the borough of Godmanchester. Here is a school, called the Free Grammar-School of Queen Elizabeth. On the west side of the town is a noble though ancient seat of of the earl of Sandwich. Near this place, in the London road between Huntingdon and Caxton, is a tree well known to travellers by the name of Beggar's Bush.

GODSTOW, a place north-west of Oxford, in a sort of island formed by the divided streams of the Isis after being joined by the Evenlode. It is noted for catching of fish and dressing them; but more so for the ruins of that nunnery which fair Rosamond quitted for the embraces of Henry II. The people show a great hole in the earth here, where they say is a subterraneous passage, which goes under the river to Woodstock, by which she used to pass and repass. Little more remains at present than ragged walls, scattered over a considerable extent of ground. An arched gateway, and another venerable ruin, part of the tower of the conventual church, are still standing. Near the altar in this church fair Rosamond was buried, but the body was afterwards removed by order of a bishop of Lincoln, the visitor. The only entire part is small, formerly a private chapel. Not many years since a stone coffin, said to have been Rosamond's, who, perhaps, was removed from the church to this place, was to be seen here. The building has been put to various uses, and at present serves occasionally for a stable.

GODWIN, Francis, successively bishop of Llandaff and Hereford, was born in 1567. He was eminent for his learning and abilities; being a good mathematician, an excellent philosopher, a pure Latinist, and an accurate historian. He understood the true theory of the moon's motion a century before it was generally known. He first started those hints afterwards pursued by Bishop Wilkins, in his "Secret and swift messenger;" and published "A catalogne of the lives of English bishops." He has nevertheless been accused as a great simoniac, for omitting no opportunity of disposing of preferments in order to provide for his children. He died in 1648.

Godwin or *Goodwin Sands*. See Kent.

GODWIT. See Scolopax, Ornithology *Index*.

GOES, or Ter Goes, a strong and considerable town of the United Provinces, in Zealand, and capital of the island of South Beverland. It communicates with the sea by a canal; and is 10 miles east of Middleburgh, and 30 north of Ghent. Population 3700. E. Long. 3. 50. N. Lat. 51. 33.

GOG and Magog, two names generally joined together in scripture, (Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, &c. Rev. xx. 8.). Moses speaks of Magog the son of Japhet, but says nothing of Gog, (Gen. x. 2. 1 Chr. i. 5.). Gog was prince of Magog, according to Ezekiel. Magog signifies the country or people, and Gog the king of that country. The generality of the ancients made Magog the father of the Scythians and Tartars; and several interpreters discovered many footsteps of their name in the provinces of Great Tartary. Others have been of opinion that the Persians were the descendants of Magog; and some have imagined that the Goths were descended from Gog and Magog; and that the wars described by Ezekiel, and undertaken by Gog against the saints, are no other than those which the Goths carried on in the fifth age against the Roman empire.

Bochart has placed Gog in the neighbourhood of Caucasus. He derives the name of this celebrated mountain from the Hebrew *Gog chasan* "the fortress of Gog." He maintains that Prometheus, said to be chained to Caucasus by Jupiter, is Gog, and no other. There is a province in Iberia called the *Gogarene*.

Lastly, the generality believe, that Gog and Magog, mentioned in Ezekiel and the Revelation, are to be taken in an allegorical sense, for such princes as were enemies to the church and saints. Thus many by Gog in Ezekiel understand Antiochus Epiphanes, the persecutor of the Jews who were firm to their religion; and by the person of the same name in the Revelations, they suppose Antichrist to be meant, the great enemy of the church and faithful. Some have endeavoured to prove that Gog, spoken of in Ezekiel, and Cambyses king of Persia, were one and the same person; and that Gog and Magog in the Revelation denote all the enemies of the church, who should be persecutors of it to the consummation of ages.

GOGGLES, in *Surgery*, are instruments used for curing squinting, or that distortion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the daytime, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected.

GOGMAGOG hills, are hills so called, three miles from Cambridge, remarkable for the intrenchments and other works cast up here: whence some suppose it was a Roman camp; and others, that it was the work of the Danes.

GOGUET, Antony Yves, a French writer, and author of a celebrated work, intitled, *L'Origine des Loix, des Arts, des Sciences, et de leur Progrès chez les anciens Peuples*, 1758, 3 vols 4to. His father was an advocate, and he was born at Paris in 1716. He was very unpromising as to abilities, and reckoned even dull, in his early years; but his understanding developing itself, he applied to letters, and at length produced the above work. The reputation he gained by it was great; but he enjoyed it a very short time; dying the same year of the smallpox, which disorder, it seems, he always dreaded. It is remarkable, that Conrad Fugere, to whom he left his library and his MSS. was so deeply affected with the death of his friend, as to die himself three days after him. The above work has been translated into English, and published in 3 vols 8vo.

GOITO, a town of Italy, in the duchy of Mantua, taken by the Germans in 1701, and by the prince of Hesse in 1706. It is seated on the river Mincio, between the lake of Mantua and that of Garda, 10 miles north-west of Mantua. E. Long. 11. 0. N. Lat. 45. 16.

GOLCONDA, a province of Hindostan, now called Hyderabad. It is bounded on the north by that of Orixa, on the west by that of Balagate, on the south by Bisnagar, and on the east by the gulf of Bengal. It abounds in corn, rice, and cattle; but that which renders it most remarkable are the diamond-mines, which

which were formerly the most considerable in the world: they were usually purchased of the black merchants, who bought parcels of ground to search for these precious stones in. They have also mines of salt, fine iron for sword-blades, and curious callicoes and chintzes. As this is one of the few of the old Mogul governments remaining, more of the old forms and ceremonies of that great dynasty are retained at the nizam's court than at any other in Hindostan. There is a town of the same name, seated at the foot of a mountain. It was formerly the residence of the kings, and is now much frequented by the European merchants. E. Long. 78. 42. N. Lat. 17. 10.

GOLD, the most valuable of all the metals, is of a bright yellow colour when pure, but becomes more or less white in proportion as it is alloyed with other metals. It is the heaviest of all known bodies, platina only excepted. See CHEMISTRY and MINERALOGY *Index*.

Method of Recovering GOLD *from Gilt Works.* The solubility of gold, and the indissolubility of silver, in aqua regia, affords a principle on which gold may be separated from the surface of silver; and, on this foundation, different processes have been contrived, of which the two following appear to be the best.—Some powdered sal ammoniac, moistened with aquafortis into the consistence of a paste, is spread upon the gilt silver, and the piece heated till the matter smokes and becomes nearly dry: being then thrown into water, it is rubbed with a scratch brush composed of fine brass wire bound together; by which the gold easily comes off. The other way is, by putting the gilt silver into common aqua regia, kept so hot as nearly to boil, and turning the metal frequently till it becomes all over black; it is then to be washed with a little water, and rubbed with the scratch brush, to get off what gold the aqua regia may have left. This last method appears preferable to the other; as the same aqua regia may be made to serve repeatedly till it becomes saturated with the gold, after which the gold may be recovered pure by precipitation with sulphate of iron.

For separating gold from gilt copper, some direct a solution of borax to be applied on the gilt parts, but nowhere else, with a pencil, and a little powdered sulphur to be sprinkled on the places thus moistened; the principal use of the solution of borax seems to be to make the sulphur adhere; the piece being then made red hot, and quenched in water, the gold is said to be so far loosened as to be wiped off with a brush. Others mix the sulphur with nitre and tartar, and form the mixture with vinegar into a paste, which is spread upon the gilt parts.

Schlutter recommends mechanical means, as being generally the least expensive, for separating gold from the surface both of silver and copper. If the gilt vessel is round, the gold is conveniently got off by turning it in a lathe, and applying a proper tool, a skin being placed underneath for receiving the shavings: he says it is easy to collect into two ounces of shavings all the gold of a gilt vessel weighing thrice as many pounds. Where the figure of the piece does not admit of this method, it is to be properly fixed, and scrapers applied of different kinds according to its size and figure; some large, and furnished with two handles, one at each end; others small and narrow, for penetrating into depressed parts. If the gold cannot be got off by either of these ways, the file must be had recourse to, which takes off more of the metal underneath than the turning tool or the scraper, particularly than the former. The gold scrapings or filings may be purified from the silver or copper they contain, by the methods described under the article METALLURGY.

The editors of the *Encyclopédie* give a method of recovering the gold from wood that has been gilt on a water size: this account is extracted from a memoir of the same subject, presented to the Academy of Sciences by M. de Montamy. The gilt wood is steeped for a quarter of an hour in a quantity of water sufficient to cover it, made very hot: the size being thus softened, the wood is taken out, and scrubbed piece by piece, in a little warm water, with short stiff bristle brushes of different sizes, some small for penetrating into the carvings, and others large for the greater dispatch in flat pieces. The whole mixture of water, size, gold, &c. is to be boiled to dryness, the dry matter made red hot in a crucible to burn off the size, and the remainder ground with mercury, either in a mortar, or, where the quantity is large, in a mill.

GOLD-Coast. See GUINEA.

GOLD-Wire, a cylindrical ingot of silver, superficially gilt or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See *WIRE-Drawing*.

It may be observed that, before the wire be reduced to this excessive fineness, it is drawn through above 140 different holes; and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

GOLD-Wire flatted, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is, without spinning, in certain stuffs, laces, embroideries, &c. See STUFF, &c.

GOLD-Thread, or *Spun-gold*, is flatted gold, wrapped or laid over a thread of silk, by twisting it with wheel and iron bobbins.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two is rendered quite flat, but without losing any thing of its gilding; and is rendered so exceedingly thin and flexible, that it is easily spun on silk-thread, by means of a hand-wheel, and so wound on a spool or bobbin. See *WIRE-Drawing*.

GOLD-Leaf or *Beaten Gold*, is gold beaten with a hammer into exceeding thin leaves, so that it is computed, that an ounce may be beaten into 1600 leaves, each three inches square, in which state it takes up more than 159,052 times its former surface.

The preparation of gold leaf, according to Dr Lewis, is as follows:

"The gold is melted in a black-lead crucible, with some

Gold. some borax, in a wind furnace, called by the workmen a *wind-hole:* as soon as it appears in perfect fusion, it is poured out into an iron ingot mould, six or eight inches long, and three quarters of an inch wide, previously greased, and heated, so as to make the tallow run and smoke, but not to take flame. The bar of gold is made red hot, to burn off the unctuous matter, and forged on an anvil into a long plate, which is further extended by being passed repeatedly between polished steel rollers, till it becomes a ribbon as thin as paper. Formerly the whole of this extension was procured by means of the hammer, and some of the French workmen are still said to follow the same practice: but the use of the flatting mill both abridges the operation, and renders the plate of more uniform thickness. The ribbon is divided by compasses, and cut with sheers into equal pieces, which consequently are of equal weights: these are forged on an anvil till they are an inch square; and afterwards well nealed, to correct the rigidity which the metal has contracted in the hammering and flatting. Two ounces of gold, or 960 grains, the quantity which the workmen usually melt at a time, make 150 of these squares, whence each of them weighs six grains and two-fifths; and as 902 grains of gold make a cubic inch, the thickness of the square plates is about the 766th part of an inch.

"In order to the further extension of these pieces into fine leaves, it is necessary to interpose some smooth body between them and the hammer, for softening its blow, and defending them from the rudeness of its immediate action: as also to place between every two of the pieces some proper intermedium, which, while it prevents their uniting together, or injuring one another, may suffer them freely to extend. Both these ends are answered by certain animal membranes.

"The goldbeaters use three kinds of membranes; for the outside cover, common parchment made of sheep skin; for interlaying with the gold, first the smoothest and closest vellum, made of calf skin; and afterwards the much finer skins of ox gut, stript off from the large straight gut slipt open, curiously prepared on purpose for this use, and hence called *goldbeater's skin.* The preparation of these last is a distinct business, practised by only two or three persons in the kingdom, some of the particulars of which I have not satisfactorily learned. The general process is said to consist, in applying one upon another, by the smooth sides, in a moist state, in which they readily cohere and unite inseparably; stretching them on a frame, and carefully scraping off the fat and rough matter, so as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out what unctuosity may remain in them; moistening them once or twice with an infusion of warm spices; and lastly, drying and pressing them. It is said, that some calcined gypsum, or plaster of Paris, is rubbed with a hare's foot both on the vellum and the ox gut skins, which fills up such minute holes as may happen in them, and prevents the gold leaf from sticking, as it would do to the simple animal membrane. It is observable, that, notwithstanding the vast extent to which the gold is beaten between these skins, and the great tenuity of the skins themselves, yet they sustain continual repetitions of the process for several months, without extending or throwing thinner. Our workmen find, that, after 70 or 80 repetitions, the skins, though they contract no flaw, will no longer permit the gold to extend between them; but that they may be again rendered fit for use by impregnating them with the virtue which they have lost, and that even holes in them may be repaired by the dexterous application of fresh pieces of skin: a microscopical examination of some skins that had been long used plainly showed these repairs. The method of restoring their virtue is said in the *Encyclopédie* to be, by interlaying them with leaves of paper moistened with white wine vinegar, beating them for a whole day, and afterwards rubbing them over as at first with plaster of Paris. The gold is said to extend between them more easily, after they have been used a little, than when they are new.

"The beating of the gold is performed on a smooth block of black marble, weighing from 200 to 600 pounds, the heavier the better; about nine inches square on the upper surface, and sometimes less, fitted into the middle of a wooden frame, about two feet square, so as that the surface of the marble and the frame form one continuous plane. Three of the sides are furnished with a high ledge; and the front, which is open, has a leather flap fastened to it, which the gold-beater takes before him as an apron, for preserving the fragments of gold that fall off. Three hammers are employed, all of them with two round and somewhat convex faces, though commonly the workman uses only one of the faces: the first, called the *cutch hammer*, is about four inches in diameter, and weighs 15 or 16 pounds, and sometimes 20, though few workmen can manage those of this last size: the second, called the *shoddering hammer*, weighs about 12 pounds, and is about the same diameter: the third, called the *gold hammer*, or *finishing hammer*, weighs 10 or 11 pounds, and is nearly of the same width. The French use four hammers, differing both in size and shape from those of our workmen: they have only one face, being in figure truncated cones. The first has very little convexity, is near five inches in diameter, and weighs 14 or 15 pounds: the second is more convex than the first, about an inch narrower, and scarcely half its weight: the third, still more convex, is only about two inches wide, and four or five pounds in weight: the fourth or finishing hammer is near as heavy as the first, but narrower by an inch, and the most convex of all. As these hammers differ so remarkably from ours, I thought proper to insert them, leaving the workmen to judge what advantage one set may have above the other.

"A hundred and fifty of the pieces of gold are interlaid with leaves of vellum, three or four inches square, one vellum leaf being placed between every two of the pieces, and about 20 more of the vellum leaves on the outsides; over these is drawn a parchment case, open at both ends, and over this another in a contrary direction, so that the assemblage of gold and vellum leaves is kept tight and close on all sides. The whole is beaten with the heaviest hammer, and every now and then turned upside down, till the gold is stretched to the extent of the vellum; the case being from time to time opened for discovering how the extension goes on, and the packet, at times, bent and rolled

Gold.

rolled as it were between the hands, for procuring sufficient freedom to the gold, or, as the workmen say, to make the gold work. The pieces taken out from between the vellum leaves, are cut in four with a steel knife; and the 600 divisions, hence resulting, are interlaid, in the same manner, with pieces of the ox-gut skins five inches square. The beating being repeated with a lighter hammer till the golden plates have again acquired the extent of the skins, they are a second time divided in four: the instrument used for this division is a piece of cane cut to an edge, the leaves being now so light, that the moisture of the air or breath condensing on a metalline knife would occasion them to stick to it. These last divisions being so numerous, that the skins necessary for interposing between them would make the packet too thick to be beaten at once, they are parted into three parcels, which are beaten separately, with the smallest hammer, till they are stretched for the third time to the size of the skins: they are now found to be reduced to the greatest thinness they will admit of; and indeed many of them, before this period, break or fail. The French workmen, according to the minute detail of this process given in the *Encyclopédie*, repeat the division and the beating once more; but as the squares of gold, taken for the first operation, have four times the area of those used among us, the number of leaves from an equal area is the same in both methods, viz. 16 from a square inch. In the beating, however simple the process appears to be, a good deal of address is requisite, for applying the hammers so as to extend the metal uniformly from the middle to the sides: one improper blow is apt not only to break the gold leaves, but to cut the skins.

"After the last beating, the leaves are taken up by the end of a cane instrument, and, being blown flat on a leather cushion, are cut to a size, one by one, with a square frame of cane made of a proper sharpness, or with a frame of wood edged with cane: they are then fitted into books of 25 leaves each, the paper of which is well smoothed, and rubbed with red bole to prevent their sticking to it. The French, for sizing the leaves, use only the cane knife; cutting them first straight on one side, fitting them into the book by the straight side, and then paring off the superfluous parts of the gold about the edges of the book. The size of the French gold leaves is from somewhat less than three inches to three and three quarters square; that of ours, from three inches to three and three-eighths.

"The process of gold-beating is considerably influenced by the weather. In wet weather, the skins grow somewhat damp, and in this state make the extension of the gold more tedious: the French are said to dry and press them at every time of using; with care not to overdry them, which would render them unfit for farther service. Our workmen complain more of frost, which appears to affect the metalline leaves themselves: in frost, a gold leaf cannot easily be blown flat, but breaks, wrinkles, or runs together.

"Gold leaf ought to be prepared from the finest gold; as the admixture of other metals, though in too small a proportion to affect sensibly the colour of the leaf, would dispose it to lose of its beauty in the air. And indeed there is little temptation to the workman to use any other; the greater hardness of alloyed gold occasioning as much to be lost in point of time and labour, and in the greater number of leaves that break, as can be gained by any quantity of alloy that would not be at once discoverable by the eye. All metals render gold harder and more difficult of extension. Even silver, which in this respect seems to alter its quality less than any other metal, produces with gold a mixture sensibly harder than either of them separately, and this hardness is in no art more felt than in the goldbeater's. The French are said to prepare what is called the *green gold leaf*, from a composition of one part of copper and two of silver with eighty of gold. But this is probably a mistake: for such an admixture gives no greenness to gold: and I have been informed by our workmen, that this kind of leaf is made from the same fine gold as the highest gold-coloured sort, the greenish hue being only a superficial teint induced upon the gold in some part of the process: this greenish leaf is little otherwise used than for the gilding of certain books.

"But though the goldbeater cannot advantageously diminish the quantity of gold in the leaf by the admixture of any other substance with the gold, yet means have been contrived for some particular purposes, of saving the precious metal, by producing a kind of leaf, called *party-gold*, whose basis is silver, and which has only a superficial coat of gold upon one side: a thick leaf of silver and a thinner one of gold, laid flat on one another, heated and pressed together, unite and cohere; and being then beaten into fine leaves, as in the foregoing process, the gold, though its quantity is only about one-fourth of that of the silver, continues everywhere to cover it, the extension of the former keeping pace with that of the latter."

But it is to be observed by Mr Nicholson, that pure gold is too ductile to be worked between the goldbeater's skin. The newest skins will work the finest gold, and make the thinnest leaf, because they are the smoothest. Old skins, being rough or foul, require coarser gold. The finer the gold, the more ductile; insomuch, that pure gold, when driven out by the hammer, is too soft to force itself over the irregularities, but would pass round them, and by that means become divided into narrow slips. The finest gold for this purpose, has three grains of alloy in the ounce, and the coarsest twelve grains. In general the alloy is six grains, or one-eightieth part. That which is called pale gold contains three pennyweights of silver in the ounce. The alloy of gold leaf is silver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold is delivered by the master to the workman, who, if extraordinarily skilful, returns two thousand leaves, or eighty books of gold, together with one ounce and six pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure 3.3 inches in the side, the thickness of the leaf is one two hundred and eighty-two thousandth part of an inch.

The yellow metal called Dutch gold is fine brass. It is said to be made from copper plates, by cementation with calamine, without subsequent fusion. Its thickness, compared with that of leaf gold, proved as 19 to 4, and under equal surfaces it is considerably more than twice as heavy as the gold. *Jour.* vol. i.

It

It must be observed, however, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire-drawers to gild their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. See GILDING.

GOLD Brocade. See BROCADE.

Fulminating GOLD. See CHEMISTRY *Index.*

Mosaic GOLD, is gold applied in pannels on a proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See MOSAIC.

GOLD Plates for Enamelling are generally made of ducat gold, whose fineness is from $23\frac{1}{2}$ to $23\frac{3}{4}$ carats; and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish and turn green. See ENAMELLING.

Shell-Gold is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold-beaters fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper or kept in shells; whence its name. When it is used, it is diluted with gum-water or soap-suds.—The German gold-powder, prepared from the Dutch gold leaf in the same manner, is generally used; and when it is well scoured with varnish, answers the end in japanners gilding as well as the genuine.

GOLD Size for burnished gilding is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the clay, chalk, and black lead, separately, very fine in water; then mix them together, add the oil and tallow, and grind the mixture to a due consistence.

Gold size of japanners may be made by pulverizing gum animi and asphaltum, of each one ounce; red lead, litharge of gold, and umber, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears on growing cold of the consistence of tar: strain the mixture through a flannel, and keep it stopped up in a bottle for use. When it is used, it must be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil; let it continue to boil till it becomes of the consistence of tar; strain it through a coarse cloth; keep and use it as the other.

GOLD Fish. See CYPRINUS, ICHTHYOLOGY *Index.*

GOLDEN, something that has a relation to gold or consists of gold.

GOLDEN-Calf, was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness to worship during Moses's absence in the mount; and which that legislator at his return burnt, grinded to powder, and mixed with the water the people were to drink off; as related in Exod. xxxii. The commentators have been divided on this article; the pulverizing of gold, and rendering it potable, is a very difficult operation in chemistry. Many, therefore, suppose it done by a miracle; and the rest, who allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process. Moses could not have done it by simple calcination, nor amalgamation, nor antimony, nor calcination; nor is there one of those operations that quadrates with the text.

M. Stahl has endeavoured to remove this difficulty. The method Moses made use of, according to this author, was by dissolving the metal with hepar sulphuris; only, instead of the vegetable alkali, he made use of the Egyptian natron, which is common enough throughout the east.

GOLDEN-Fleece, in the ancient mythology, was the skin or fleece of the ram upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; and which being sacrificed to Jupiter, was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monstrous dragon that never slept; but was taken and carried off by Jason and the Argonauts.

Many authors have endeavoured to show that this fable is an allegorical representation of some real history, particularly of the philosophers stone. Others have explained it by the profit of the wool trade to Colchis, or the gold which they commonly gathered there with fleeces in the rivers. See ARGONAUTS.

Order of the GOLDEN Fleece, is a military order instituted by Philip the Good, duke of Burgundy, in 1429. It took its denomination from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and steels. The king of Spain is now grand-master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir, wrote on the fleece of a sheep.

Oliver de la Marche writes, that he had suggested to Philip I. archduke of Austria, that the order was instituted by his grandfather Philip the Good duke of Burgundy, with a view to that of Jason; and that John Germain bishop of Chalons, chancellor of the order, upon this occasion made him change his opinion, and assured the young prince that the order had been instituted with a view to the fleece of Gideon. William bishop of Tournay, chancellor likewise of the order, pretends that the duke of Burgundy had in view both the golden fleece of Jason and Jacob's fleece; i. e. the specked sheep belonging to this patriarch, according to agreement made with his father-in-law Laban. Which sentiment gave birth to a great work of this prelate in two parts: in the first, under the symbol of the fleece of Jason, is represented the virtue of magnanimity, which a knight ought to possess; and under the symbol of the fleece of Jacob he represents the virtue of justice.

Paradin is of the same mind; and tells us, that the duke designed to insinuate that the fabulous conquest which Jason is said to have made of the golden fleece in Colchis, was nothing else but the conquest of virtue, which gains a victory over those horrible monsters vice and our evil inclinations.

Golden Number, in *Chronology*, a number showing what year of the moon's cycle any given year is. See CHRONOLOGY, N° 27—30.

Golden Rod, in *Botany*. See SOLIDAGO, BOTANY *Index*.

Golden Rose. The pope annually consecrates a golden rose on the fourth Sunday in Lent, which is sent to princesses, or to some church, as a mark of his peculiar affection.

Golden Rule, in *Arithmetic*, a rule or praxis, of great use and extent in the art of numbers; whereby we find a fourth proportional to three quantities given.

The golden rule is also called the *Rule of Three*, and *Rule of Proportion*. See its nature and use under the article ARITHMETIC, N° 13.

GOLDENGEN, a town of Poland in the duchy of Courland, with a handsome castle, seated on the river Weia, in E. Long. 21. 44. N. Lat. 56. 48.

GOLDONI, CHARLES, a comic writer of considerable eminence, was born at Venice in the year 1707, in which city his father acted in the capacity of physician. His attachment to the drama became conspicuous even in childhood, which his father was fond of countenancing, erecting a theatre in his own house, where young Goldoni and some of his companions were the actors. It is said that he even drew the outlines of a comedy of his own invention when he was no more than eight years of age—a most extraordinary indication of his future eminence. He studied rhetoric at Perugia, in the college of the Jesuits, and prosecuted his philosophical studies at Rimini. The stage, however, had too many charms to allow him to pay much attention to Aristotle or Quintilian, and he eloped from Rimini with a company of comedians when they removed to Chiozza. In vain did his father attempt to make him fall in love with physic, or the study of the law; yet his ardent imagination was so forcibly struck with a particular church-ceremony, that he formed the resolution of commencing capuchin, but the dissipation of Venice soon destroyed this resolution. After the demise of his father, he was prevailed upon by his surviving parent to take up the profession of the law for immediate support, but some unknown reasons induced him to quit the bar after which he went to Milan, where he was appointed secretary to the Venetian resident.

At Milan he brought out his first performance, under the title of *Il Gondoliere Veneziano*. He removed afterwards to Verona, where he joined himself to a company of players; and here too he entered into a state of wedlock. He composed a number of pieces for the players to whom he attached himself. While at Venice, he formed the laudable resolution of reforming the Italian stage, which at that time was disgraced by contemptible farce and low buffoonery. He made himself acquainted with the true nature of comedy, and kept within the limits of nature and decorum. Such was the fertility of his genius, and such his indefatigable industry, that he produced no fewer than sixteen comedies and 42 other theatrical pieces in the course of twelve months! And what is most astonishing, some of these hasty performances are deemed his masterpieces.

His works in 10 vols. 8vo. were first printed in 1753, and in 1761 his new pieces amounted to 59. About this time he was invited to Paris by the manager of the Italian theatre in that city, to compose pieces for the stage, of which invitation he accepted. His first attempt was unsuccessful, because he had to contend with the pantomime drollery, which was most agreeable to the depraved taste of the times. When about to leave Paris on the expiration of his engagement, he was introduced to the court, and appointed teacher of the Italian languages to the princesses. He had lodgings in Versailles, but his pension was not sufficient to keep him from writing for the stage. When 62 years old, he ventured to compose in a foreign language, his *La Bourru Bienfaisant*, which was received in the court theatre with extraordinary applause. He was deprived of his pension in consequence of the revolution, and reduced to indigence. It ought to be confessed, however, that this versatile nation was just about to make him amends when he expired in 1792, and in the 85th year of his age. If the rapidity with which Goldoni composed was such as to prevent him from ranking with authors of the first class, it cannot be denied that his talent for comedy was very great. Some have given him the appellation of the *Moliere of Italy*, but this perhaps is too flattering a title. His whole works were printed at Leghorn about the years 1788 and 1791, in 31 volumes 8vo.

GOLDSMITH, or, as some choose to express it, *silversmith*, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures are cast in a mould, and afterwards polished and finished; plates or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beat, not cast. The business of the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted; but there are now invented flatting-mills, which reduce metals to the thinness that is required, at a very small expence. The goldsmith is to make his own moulds; and for that reason, ought to be a good designer, and have a taste in sculpture: he ought also to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy.

The goldsmiths in London employ several hands under them for the various articles of their trade; such are the jeweller, the snuff-box and toy-maker, the silver-turner, the gilder, the burnisher, the chaser, the refiner, and the gold-beater.

Goldsmiths are superior tradesmen; their wares must be assayed by the wardens of the company of this name in London, and marked; and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of

Goldsmith.

of York, Exeter, Bristol, &c. are places appointed for the assaying wrought plate of goldsmiths; also a duty is granted on silver-plate of sixpence an ounce, &c. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting 10l. and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken and defaced; and the fees for assaying are particularly limited.

GOLDSMITH, *Oliver*, a celebrated English writer, was born at Roscommon in Ireland in the year 1731. His father, who possessed a small estate in the county, had nine sons, of whom Oliver was the third. He was originally intended for the church; and with that view, after being well instructed in the classics, was, with his brother, the Rev. Henry Goldsmith, placed in Trinity College, Dublin, about the latter end of the year 1749. In this seminary of learning he continued a few years, when he took a bachelor's degree: but his brother not being able to obtain any preferment after he left the college, Oliver, by the advice of Dean Goldsmith of Cork, turned his thoughts to the study of physic; and, after attending some courses of anatomy in Dublin, proceeded to Edinburgh in the year 1751, where he studied the several branches of medicine under the different professors in that university. His beneficent disposition soon involved him in unexpected difficulties; and he was obliged precipitately to leave Scotland, in consequence of engaging himself to pay a considerable sum of money for a fellow-student.

A few days after, about the beginning of the year 1754, he arrived at Sunderland, near Newcastle, where he was arrested at the suit of a taylor in Edinburgh, to whom he had given security for his friend.

By the good offices of Laughlan Maclane, Esq. and Dr Sleigh, who were then in the college, he was soon delivered out of the hands of the bailiff; and took his passage on board a Dutch ship to Rotterdam, where, after a short stay, he proceeded to Brussels; he then visited great part of Flanders; and after passing some time at Strasburg and Louvain, where he obtained a degree of bachelor of physic, he accompanied an English gentleman to Berne and Geneva.

It is undoubtedly fact, that this ingenious unfortunate man travelled on foot most part of his tour. He had left England with very little money; and being of a philosophical turn, and at that time possessing a body capable of sustaining every fatigue, and a heart not easily terrified at danger, he became an enthusiast to the design he had formed of seeing the manners of different countries. He had some knowledge of the French language and of music, and he played tolerably well on the German flute; which, from an amusement, became at some times the means of subsistence. His learning produced him a hospitable reception at most of the religious houses; and his music made him welcome to the peasants of Flanders and other parts of Germany. "Whenever I approached," he used to say, "a peasant's house towards night-fall, I played one of my most merry tunes; and that procured me not only a lodging, but subsistence for the next day: but in truth (his constant expression), I must own, whenever I attempted to entertain persons of a higher rank, they always thought my performance odious, and never made me any return for my endeavours to please them."

Goldsmith.

On Mr Goldsmith's arrival at Geneva, he was recommended as a proper person for a travelling tutor to a young man, who had been unexpectedly left a considerable sum of money by his uncle Mr S——, formerly an eminent pawnbroker near Holborn. This youth, who had been articled to an attorney, on receipt of his fortune determined to see the world; and, on his engaging with his preceptor, made a proviso that he should be permitted to govern himself; and Goldsmith soon found his pupil understood the art of directing in money-concerns extremely well, as avarice was his prevailing passion. His questions were usually how money might be saved, and which was the least expensive course of travelling; whether any thing could be bought that would turn to account when disposed of again in London? Such curiosities on the way as could be seen for nothing he was ready enough to look at; but if the sight of them was to be paid for, he usually asserted that he had been told they were not worth seeing. He never paid a bill that he would not observe how amazingly expensive travelling was; and all this, though he was not yet twenty-one. During Goldsmith's continuance in Switzerland, he assiduously cultivated his poetical talent, of which he had given some striking proofs while at the college of Edinburgh. It was here he sent the first sketch of his delightful poem called the *Traveller*, to his brother the clergyman in Ireland, who, giving up fame and fortune, had retired with an amiable wife, to happiness and obscurity, on an income of only 40l. a-year.

From Geneva Mr Goldsmith and his pupil visited the south of France; where the young man, upon some disagreement with his preceptor, paid him the small part of his salary which was due, and embarked at Marseilles for England. Our wanderer was left once more upon the world at large, and passed through a variety of difficulties in traversing the greatest part of France. At length his curiosity being satiated, he bent his course towards England, and arrived at Dover the beginning of the winter 1758. When he came to London, his stock of cash did not amount to two livres. An entire stranger in this metropolis, his mind was filled with the most gloomy reflections on his embarrassed situation. With some difficulty he discovered that part of the town in which his old acquaintance Dr Sleigh resided. This gentleman received him with the warmest affection, and liberally invited him to share his purse till some establishment could be procured for him. Goldsmith, unwilling to be a burden to his friend, a short time after eagerly embraced an offer which was made him to assist the late Rev. Dr Milner in instructing the young gentlemen at the academy at Peckham; and acquitted himself greatly to the Doctor's satisfaction for a short time: but having obtained some reputation by the criticisms he had written in the Monthly Review, Mr Griffith, the proprietor, engaged him in the compilation of it; and, resolving to pursue the profession of writing, he returned to London, as the mart where abilities of every kind were sure of meeting distinction and reward. As his finances were by no means in a good state, he determined to adopt a plan of the strictest economy: and took

Goldsmith. took lodgings in an obscure court in the Old Bailey, where he wrote several ingenious little pieces. The late Mr Newberry, who at that time gave great encouragement to men of literary abilities, became a kind of patron to our young author; and introduced him as one of the writers in the Public Ledger, in which his Citizen of the World originally appeared, under the title of *Chinese Letters*.

Fortune now seemed to take some notice of a man she had long neglected. The simplicity of his character, the integrity of his heart, and the merit of his productions, made his company very acceptable to a number of respectable families; and he emerged from his shabby apartments in the Old Bailey to the politer air of the Temple, where he took handsome chambers, and lived in a genteel style. The publication of his Traveller, and his Vicar of Wakefield, was followed by the performance of his comedy of the Good-natured Man at Covent Garden theatre, and placed him in the first rank of the poets of the age.

Among many other persons of distinction who were desirous to know him was the duke of Northumberland; and the circumstance that attended his introduction to that nobleman is worthy of being related, in order to show a striking trait of his character. "I was invited," said the Doctor, (as he was then universally called), "by my friend Mr Percy, to wait upon the duke, in consequence of the satisfaction he had received from the perusal of one of my productions. I dressed myself in the best manner I could; and, after studying some compliments I thought necessary on such an occasion, proceeded to Northumberland-house, and acquainted the servants that I had particular business with his Grace. They showed me into an antichamber; where, after waiting some time, a gentleman very genteelly dressed made his appearance. Taking him for the duke, I delivered all the fine things I had composed in order to compliment him on the honour he had done me; when, to my great astonishment, he told me I had mistaken him for his master, who would see me immediately. At that instant the duke came into the apartment; and I was so confused on the occasion, that I wanted words barely sufficient to express the sense I entertained of the duke's politeness, and went away extremely chagrined at the blunder I had committed."

Another feature of his character we cannot help laying before the reader. Previous to the publication of his Deserted Village, the bookseller had given him a note for one hundred guineas for the copy, which the Doctor mentioned a few hours after to one of his friends: who observed, it was a very great sum for so short a performance. "In truth," replied Goldsmith, "I think so too; I have not been easy since I received it; therefore I will go back and return him his note;" which he absolutely did; and left it entirely to the bookseller to pay him according to the profits produced by the sale of the piece, which turned out very considerable.

During the last rehearsal of his comedy intitled She stoops to Conquer, which Mr Coleman had no opinion would succeed, on the Doctor's objecting to the repetition of one of Tony Lumkin's speeches, being apprehensive it might injure the play, the manager with great keenness replied, "Psha, my dear Doctor, do not be fearful of squibs, when we have been sitting almost these two hours upon a barrel of gunpowder." The piece, however, contrary to Mr Coleman's expectation, was received with uncommon applause by the audience; and Goldsmith's pride was so hurt by the severity of the above observation, that it entirely put an end to his friendship for the gentleman that made it. Goldsmith.

Notwithstanding the great success of his pieces, by some of which it is asserted, upon good authority, he cleared 1800l. in one year, his circumstances were by no means in a prosperous situation; which was partly owing to the liberality of his disposition, and partly to an unfortunate habit he had contracted of gaming; the arts of which he knew very little of, and consequently became the prey of those who were unprincipled enough to take advantage of his simplicity.

Just before his death he had formed a design for executing an Universal Dictionary of Arts and Sciences, the prospectus of which he actually published. In this work several of his literary friends, (particularly Sir Joshua Reynolds, Dr Johnson, Mr Beauclerc, and Mr Garrick), had undertaken to furnish him with articles upon different subjects. He had entertained the most sanguine expectations from the success of it. The undertaking, however, did not meet with that encouragement from the booksellers which he had imagined it would undoubtedly receive; and he used to lament this circumstance almost to the last hour of his existence.

He had been for some years afflicted, at different times, with a violent strangury, which contributed not a little to embitter the latter part of his life; and which, united with the vexations which he suffered upon other occasions, brought on a kind of habitual despondency. In this unhappy condition he was attacked by a nervour fever, which, being improperly treated, terminated in his dissolution on the 4th of April 1774.

As to his character, it is strongly illustrated by Mr Pope's line,

In wit a man, simplicity a child.

The learned leisure he loved to enjoy was too often interrupted by distresses which arose from the liberality of his temper, and which sometimes threw him into loud fits of passion: but this impetuosity was corrected upon a moment's reflection; and his servants have been known, upon these occasions, purposely to throw themselves in his way, that they might profit by it immediately after; for he who had the good fortune to be reproved, was certain of being rewarded for it. The universal esteem in which his poems were held, and the repeated pleasure they give in the perusal, is a striking test of their merit. He was a studious and correct observer of nature; happy in the selection of his images, in the choice of his subjects, and in the harmony of his versification; and, though his embarrassed situation prevented him from putting the last hand to many of his productions, his Hermit, his Traveller, and his Deserted Village, bid fair to claim a place among the most finished pieces in the English language.

Besides the works already mentioned, he wrote, 1. History of the earth and animated nature, 6 vols 8vo. 2. History of England, 4 vols 8vo. 3. History of Rome, 2 vols. 4. Abridgements of the two last, for the

the use of schools. 5. A view of experimental philosophy, 3 vols 8vo; a posthumous work, not esteemed. 6. Miscellanies, &c.

GOLF, the name of a certain game among the Scots, and said to be peculiar to their country.—Among them it has been very ancient; for there are statutes prohibiting it as early as the year 1457, lest it should interfere with the sport of archery. It is commonly played on rugged broken ground, covered with short grass, in the neighbourhood of the sea shore. A field of this sort is in Scotland called *links*. The game is generally played in parties of one or two on each side. Each party has an exceeding hard ball, somewhat larger than a hen's egg. This they strike with a slender and elastic club, of about four feet long, crooked in the head, and having lead run into it, to make it heavy. The ball being struck with this club, will fly to the distance of 200 yards, and the game is gained by the party who puts his ball into the hole with the fewest strokes. But the game does not depend solely upon the striking of the longest ball, but also upon measuring the strength of the stroke, and applying it in such direction as to lay the ball in smooth ground, whence it may be easily moved at the next stroke. To encourage this amusement, the city of Edinburgh, A. D. 1744, gave to the company of golfers a silver club, to be played for annually by the company, the victor to append a gold or silver piece to the prize. It has been played for every year since, except the years 1746 and 1747. For their better accommodation, 22 members of the company subscribed 30l. each in the year 1768, for building a house, where their meetings might be held. The spot chosen for this purpose was the south-west corner of Leith Links, where an area was taken in feu from the magistrates of Edinburgh, and a commodious house and tavern built upon it.

GOLIUS, James, a celebrated professor of Arabic and the mathematics at Leyden, was descended from a very honourable family, and born at the Hague in the year 1596. He was put to the university of Leyden, where he studied under Erpinius; and having made himself master of all the learned languages, applied himself to the mathematics, physic, and divinity. He afterwards travelled into Africa and Asia; and became greatly esteemed by the king of Morocco, and the sultan of the Turks. He at length returned to Leyden, loaded with manuscripts; and in 1624, succeeded Erpinius in the Arabic chair. As he had been an eyewitness of the wretched state of Christianity in the Mahometan countries, he was filled with the compassion of a fellow-Christian; and none ever solicited for a place of honour and profit with greater eagerness, than he for procuring a new edition of the New Testament, in the original language, with a translation into the vulgar Greek, by an Archimandrite; and as there are some of these Christians who use the Arabic tongue in divine service, he also took care to have dispersed among them an Arabic translation of the confession of the Protestants, together with the Catechism and Liturgy. In 1626, he was also chosen professor of mathematics; and discharged the functions of both professorships with the greatest applause during 40 years. He was likewise appointed interpreter in ordinary to the states for the Arabic, Turkish, Persian, and other eastern languages, for which he had an annual pension, and a present of a gold chain, with a very beautiful medal, which he wore as a badge of his office. He published, 1. The life of Tamerlane, written in Arabic. 2. The history of the Saracens, written by Elmarin. 3. Alferganus's Elements of Astronomy, with a new version, and learned commentaries. 4. An excellent Arabic lexicon. 5. A Persian Dictionary. He died in 1667.

GOLTZIUS, Henry, a famous engraver and painter, born in 1558, at Mulbreck in the duchy of Juliers. He was taught the art of engraving by Theodore Cuerenhert; and succeeded very wonderfully in it, notwithstanding the disadvantage of a lame hand, which was occasioned by his falling into the fire whilst young. He was first employed by his master, and afterwards he worked for Philip Galle. Domestic troubles and ill health occasioned him to travel. He went through Germany into Italy; and passed under a feigned name, that his studies might not be interrupted. He visited Bologna, Florence, Naples, and Venice, constantly applying himself to drawing from the antique statues; and the works of the great masters. At Rome he resided the longest; and there he produced several excellent engravings from Polidoro Raphael, and other eminent painters. On his return to his native country he established himself at Haerlem, where he engraved many of the drawings which he had made during his abode in Italy. He died at Haerlem in 1617, aged 59. He is said to have been 40 years old before he began to paint: yet his pictures are spoken of with great commendation; but as he did not produce any great number of them, they are rarely to be met with. As an engraver, he deserves the highest commendation. No man ever surpassed, and few have equalled, him in the command of the graver and freedom of execution. He copied the style of Albert Durer, Lucas of Leyden, and other old masters, with astonishing exactness. Sometimes his engravings are neat in the extreme; at other times they are performed in a bold open manner, without the least restraint. He also engraved several of his own designs on wood, in that manner which is distinguished by the appellation of *chiaro-scuro*. Of his prints, which are very numerous, it may here suffice to specify two or three of the most celebrated: 1. Six large upright plates, known by the name of his *master-pieces*. These, it is said, he engraved to convince the public that he was perfectly capable of imitating the styles of Albert Durer, Lucan Van Leyden, and other masters, whose works were then held in higher estimation than his own: for he had adopted a new manner, which he pursued because he thought it superior, and not because he was incapable of following the others. It is reported that with one of them, the Circumcision, which he smoked to give it the more plausible air of antiquity, he actually deceived some of the most capital connoisseurs of the day; by one of whom it was bought for an original engraving of Albert Durer. The subjects of these plates are, The Annunciation of the Virgin; the Meeting of the Virgin with Elizabeth, called the Visitation; the Nativity of Christ; the Circumcision of Christ; the Adoration of the Wise Men; the Holy Family. 2. The Judgment of Midas, a large plate lengthwise. 3. The Venetian Ball, a large plate lengthwise, from Theodore Bernard. 4. The Boy and Dog, Goltzius ‖ Gombroon.

Dog, a middling-sized upright plate, from a design of his own; an admirable print. 5. The Necromancer, a middling-sized upright oval print, in chiaro-scuro. 6. Night in her Chariot, the same.

GOMBAULD, John Ogier de, one of the best French poets in the 17th century, and one of the first members of the French academy, was born at St Just de Lussac. He acquired the esteem of Mary de Medicis, and of the wits of his time. He was a Protestant, and died in a very advanced age. He wrote many works in verse and prose. His epigrams, and some of his sonnets, are particularly esteemed.

GOMBROON, by the natives called *Bander Abassi*, a city of Persia, situated in N. Lat. 27. 20. E. Long. 55. 40. The name of *Gombroon*, or *Comerong*, Captain Hamilton tells us, it had from the Portuguese; because it was remarkable for the number of prawns and shrimps caught on its coasts, by them called *comerong*. This city owes its wealth and grandeur to the demolition of Ormus, and the downfal of the Portuguese empire in the East Indies. It is now justly accounted one of the greatest marts in the East, was built by the great Shah Abas, and from him, as some think, obtained the name of *Bander Abassi*, which signifies the court of Abas. It stands on a bay about nine leagues to the northward of the east end of the island of Kishmish, and three leagues from the famous Ormus. The English began to settle here about the year 1631, when, in consideration of their services against the Portuguese, Shah Abas granted them half the customs of that port. This was confirmed by a phirmaund, and duly regarded, till the English began to neglect the services they had stipulated. Whether the company has any emolument from the customs at present, is what we cannot pretend to ascertain. The town is large, but its situation bad; wanting almost every thing that contributes to the happiness and even support of life. Towards the land it is encompassed by a sort of wall; and towards the sea are several small forts with a platform, and a castle or citadel, mounted with cannon to secure it and the road from the attempts of an enemy by sea. The houses in most of the streets are so out of repair, some half down, others in a heap of rubbish, that a stranger would imagine the town had been sacked and ravaged by a barbarous people; not a vestige of the wealth really contained in the place appearing in view. The bazars and shops round them are kept, for the most part, by Banians, whose houses are generally in good order. Most of the houses are built with earth and lime, but some of the best with stone. Many of them have a sort of ventilators at top, which contributes greatly to the health of the inhabitants in the hot seasons of the year. The most sickly months here are April, May, September, and October. With fish and mutton the inhabitants are well supplied. Rice is imported from India; and wheat is so plenty, that the poor subsist chiefly on bread and dates. The country hereabouts abounds in the most delicious fruits, as apricots, peaches, pomegranates, pears, mangoes, grapes, quavas, plums, sweet quinces, and water melons. The apricots, however, are small, and extremely dangerous if eaten to excess.

Those conveniences are more than overbalanced by the scarcity of fresh water, with which the inhabitants are supplied from Asseen, a place seven miles distant, there not being a spring or well in the town. Persons of condition keep a camel constantly employed in bringing fresh and wholesome water. Captain Hamilton gives it as his opinion, that one cause of the unwholesomeness of this city is the reflection of the rays of light from a high mountain to the north of it. He says, that when the beams are reflected from this mountain, they almost fire the air, and, for two or three months in the year, render the situation intolerable. For this reason the people of condition retire into the country, to pass the heats of June, July, and August. The very sea, during this season, is affected, insomuch that the stench is no less disagreeable than that of putrid carcases; and this is increased by the quantities of shell-fish left on the shore, from which an exhalation arises that tarnishes gold and silver, and is less tolerable than the bilge-water of a tight ship. At Asseen the English factory have a country house and gardens, to which they retire occasionally. Here they have whole groves of Seville orange trees, which, though not natural to the country, thrive very well, and are always verdant, bearing ripe and green fruit, with blossoms, all at the same time. They have likewise tanks and ponds of fine fresh water, with every thing else that can moderate the heat of the climate, and render life agreeable and elegant. About 10 miles from Asseen is a place called *Minoa*, where are cold and hot natural baths, reckoned infallible in the cure of all scrophulous disorders, rheumatisms, and other diseases, by bathing.

Gombroon ‖ Gomera.

Gombroon is extremely populous, on account of the commerce carried on by the Dutch and English factories, as well as the natives. The English factory is close by the sea, at some distance from the Dutch, which is a commodious and fine new building. A great part of the company's profits arises from freights. As the natives have not one good ship of their own, and are extremely ignorant of navigation, they freight their goods for Surat, and other Indian marts, in English and Dutch bottoms, at an exorbitant rate. The commodities of the Gombroon market are, fine wines of different kinds, raisins, almonds, kish-mishes, prunellas, dates, pistachio-nuts, ginger, silks, carpets, leather, tutty, galbanum, ammoniac, assafœtida, tragacanth, with other gums, and a variety of shop medicines. These are in a great measure the produce of Carmania, which they bring to Gombroon in caravans. The English company had once a small factory in the province of Carmania, chiefly for the sake of a fine wool produced there, and used by the hatters. The said company had once a project of carrying a breed of the Persian goats to St Helena; but whether it was executed, or what success it met with, we cannot say. Although the company pay no customs, yet they usually make a present to the shabander, to avoid the trouble he has it in his power to give them. All private traders with the company's passes, enjoy the same privileges, on paying two per cent. to the company, one to the agent, and one to the broker. All private trade, either by European or country ships, has long been engrossed by the company's servants.

GOMERA, one of the Canary islands, lying between Ferro and Teneriffe. It has one good town of the same name, with an excellent harbour, where the Spanish

Spanish fleet often taken in refreshments. It is about 20 miles long and 10 broad, and is extremely fertile, though little cultivated. It is subject to the Spaniards, who conquered it in 1445. W. Long. 17. 10. N. Lat. 28. 0.

GOMORRAH, in *Ancient Geography*, one of the cities of the plain or of the vale of Siddim in Judea, destroyed together with Sodom by fire from heaven, on account of the wickedness of the people. To determine its particular situation at present is impossible.

GOMOZIA, a genus of plants belonging to the tetrandria class. See BOTANY *Index*.

GOMPHOSIS, in *Anatomy*, that kind of articulation by which the teeth are fixed in the jaw-bone. See ANATOMY, N° 2.

GOMPHRÆNA, GLOBE AMARANTH; a genus of plants belonging to the pentandria class; and in the natural method ranking under the 54th order, *Miscellaneæ*. See BOTANY *Index*.

GONAQUA, the name of a nation inhabiting about the Cape, and supposed by Dr Sparrman to be a mixture of Hottentots and Caffres. See HOTTENTOTS.

GONDAR, the capital of Abyssinia; situated, according to Mr Bruce's observations, in latitude 12. 30. north, and longitude 57. 40. east from Greenwich. It lies upon the top of a hill of considerable height, and consists of about 10,000 families in times of peace. The houses are chiefly of clay, with roofs thatched in the form of cones. At the west end of the town is the king's palace; formerly, as Mr Bruce informs us, a structure of considerable consequence, being a large square building four stories high, flanked with square towers, and affording from the top of it a magnificent view of all the country southward to the lake Tzana. It was built in the time of Facilidas, by masons from India, and by such Abyssinians as had been instructed in architecture by the Jesuits before their expulsion. Great part of it is now in ruins, having been burnt at different times; but there is still ample lodging in the two lowest floors, the audience chamber being above 120 feet long. By the side of this structure there have been built by different kings apartments of clay only, in the fashion of their own country. The palace, with all its contiguous buildings, is surrounded by a double stone wall thirty feet high and a mile and a half in circumference, with battlements upon the outer wall, and a parapet roof between the outer and inner, by which you can go along the whole and look into the street. The hill on which the town is built rises in the middle of a deep valley, through which run two rivers: one of which, the Kakha, coming from the Mountain of the Sun, flanks all the south of the town; while the other, called the *Angrab*, falling from the mountain Woggora, encompasses it on the north and north-east; and both rivers unite at the bottom of the hill about a quarter of a mile south of the town. Upon the bank opposite to Gondar, on the other side of the river, is a large town of Mahometans; a great part of whom are employed in taking care of the king's and nobility's equipage, both when they take the field and when they return from it. They are formed into a body under proper officers; but never fight on either side, being entirely confined to the occupation just mentioned, in which by their care and dexterity in pitching and striking the tents, and in leading and conducting the baggage-waggons, they are of great service.—The valley of Gondar is described as having three outlets; one south, to Dembea, Maitsha, and the Agows; another on the north-west, towards Sennaar, from which it is distant 180 miles, over the Mountain of the Sun; and the third north, leading to Woggora, over the high mountain Lamalmon, and so on through Tigre to the Red sea.

GONDI, JOHN FRANCIS PAUL, Cardinal de Retz, was the son of Philip Emanuel de Gondi, Count de Joigny, lieutenant-general, &c. and was born in 1613. From a doctor of the Sorbonne, he first became coadjutor to his uncle John Francis de Gondi, whom he succeeded in 1654 as archbishop of Paris; and was finally made a cardinal. This extraordinary person has drawn his own character in his memoirs with impartiality. He was a man who, from the greatest degree of debauchery, and still languishing under its consequences, made himself adored by the people as a preacher. At the age of 23, he was at the head of a conspiracy against the life of Cardinal Richelieu; he precipitated the parliament into cabals, and the people into sedition: he was (says M. Voltaire) the first bishop who carried on a civil war without the mask of religion. However, his intrigues and schemes turned out so ill, that he was obliged to quit France; and he lived the life of a vagrant exile for five or six years, till the death of his great enemy Cardinal Mazarin, when he returned on certain stipulated conditions. After assisting in the conclave at Rome, which chose Clement IX. he retired from the world, and ended his life like a philosopher in 1679; which made Voltaire say, that in his youth he lived like Catiline, and like Atticus in his old age. He wrote his Memoirs in his retirement; the best edition of which is that of Amsterdam, 4 vols 12mo, 1719.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian, *gondola*. Du Cange derives it from the vulgar Greek *κουντελας*, "a bark," or "little ship;" Lancelot deduces it from *γονδυ*, a term in Athenæus for a sort of vase.

The middle-sized gondolas are upwards of thirty feet long and four broad: they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man.

The address of the Venetian gondoliers, in passing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pushing before them. The fore-man rests his oar on the left side of the gondola: the hind man is placed on the stern, that he may see the head over the tilt or covering of the gondola, and rests his oar, which is very long, on the right side of the gondola.

GONDOLA is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONIOMETRY, a method of measuring angles, so called by M. de Lagny, who gave several papers, on this method, in the Memoirs of the Royal Academy an. 1724, 1725, 1729. M. de Lagny's method of goniometry consists in measuring the angles with a pair of compasses, and that without any scale whatever, except an undivided semicircle. Thus, having any angle drawn

drawn upon paper, to be measured; produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large semicircle from the angular point as a centre, cutting the sides of the proposed angle, which will intercept a part of the semicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semicircle, to find how often it is contained in it, after which there is commonly some remainder: then take this remainder in the compasses, and in like manner find how often it is contained in the last of the integral parts of the first arc, with again some remainder: find in like manner how often this last remainder is contained in the former; and so on continually, till the remainder become too small to be taken and applied as a measure. By this means he obtains a series of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the first arc to the semicircle, or of the proposed angle to two right angles, or 180 degrees, and consequently that angle itself in degrees and minutes. *Hutton's Math. Dict.*

GONORRHOEA, an efflux of white, greenish, or differently-coloured matter, from the urethra; most commonly owing to venereal infection. See MEDICINE and SURGERY *Index*.

GONZAGA, LUCRETIA, was one of the most illustrious ladies of the 16th century; and much celebrated for her wit, her learning, and her delicate style. Hortensio Lando wrote a beautiful panegyric upon her, and dedicated to her his dialogue of moderating the passions. Her beautiful letters have been collected with the greatest care. We learn from these, that her marriage with John Paul Manfrone was unhappy.—She was married when she was not 14 years of age, and his conduct afterwards gave her infinite uneasiness. He engaged in a conspiracy against the duke of Ferrara; was detected and imprisoned by him; but, though condemned by the judges, not put to death. She did all in her power to obtain his enlargement, but in vain; for he died in prison, having shown such impatience under his misfortunes, as made it imagined he had lost his senses. She never would listen afterwards to any proposals of marriage, though several were made to her. All that came from her pen was so much esteemed, that a collection was made even of the notes she writ to her servants; several of which are to be met with in the edition of her letters.

GOOD, in general, whatever is apt to increase pleasure, to diminish pain in us; or, which amounts to the same, whatever is able to procure or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

Moral GOOD, denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations. See MORALS.

GOOD *Abearing* (*bonus gestus*), signifies an exact carriage or behaviour of a subject towards the king and the people, whereunto some persons upon their misbehaviour are bound: and he that is bound to this, is said to be more strictly bound than to the peace: because where the peace is not broken, the surety *de bono gestu* may be forfeited by the number of a man's company, or by their weapons.

GOOD *Behaviour*, in *Law*, an exact carriage and behaviour to the king and his people.

A justice of the peace may, at the request of another, or where he himself sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any persons whatsoever, under the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's bench, where such nobleman may be bound to keep the peace. Infants and feme-coverts, who ought to find surety by their friends, may be bound over to their good behaviour; as also lunatics, that have sometimes lucid intervals, and all others who break the peace, or being suspected to do it by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. A person may be likewise bound to his good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whoremongers, common whores, cheats, libellers, &c. He who demands surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

GOOD *Breeding*. See *Good* MANNERS.

GOOD *Friday*, a fast of the Christian church, in memory of the sufferings and death of Jesus Christ. It is observed on the Friday in *holy* or *passion week*; and it is called, by way of eminence, *good*, because of the blessed effects of our Saviour's sufferings, which were a propitiatory or expiating sacrifice for the sins of the world. The commemoration of our Saviour's sufferings has been kept from the very first ages of Christianity, and was always observed as a day of the strictest fasting and humiliation. Among the Saxons it was called *Long-Friday*; but for what reason, except on account of the long fastings and offices then used, is uncertain. On Good Friday the pope sits on a plain form: and, after service is ended, when the cardinals wait on him back to his chamber, they are obliged to keep a deep silence, as a testimony of their sorrow. In the night of Good-Friday, the Greeks perform the obsequies of our Saviour round a great crucifix laid on a bed of state, adorned with flowers; these the bishops distribute among the assistants when the office is ended. The Armenians, on this day, set open a holy sepulchre, in imitation of that of Mount Calvary.

GOOD *Hope*, or *Cape of Good Hope*, a promontory of Africa, with a town and a considerable territory, now subject to Britain. It is situated in the country of the Hottentots: for an account of whom, see the article HOTTENTOTS.

The Cape of Good Hope has been generally esteemed the most southerly point of Africa, though it is not truly so. In *Phillips's Voyage to Botany Bay* *, we are told, that the land which projects farthest to the south is a point to the east of it, called by the English *Cape Lagullus*; a name corrupted from the original Portuguese *das Agulhas* which, as well as the French appellation *des Aiguilles*, is descriptive of its form, and would rightly be translated *Needle cape*.

* P. 35.

On approaching the cape, a very remarkable eminence

Good Hope. nence may in clear weather be discovered at a considerable distance; and is called the *Table-mountain* from its appearance, as it terminates in a flat horizontal surface, from which the face of the rock descends almost perpendicularly. In the mild or summer season, which commences in September, and continues till March, the Table Land or Mountain, is sometimes suddenly capped with a white cloud, by some called the *spreading of the Table-cloth.* When this cloud seems to roll down the steep face of the mountain, it is a sure indication of an approaching gale of wind from the south-east; which generally blows with great violence, and sometimes continues a day or more, but in common is of short duration. On the first appearance of this cloud, the ships in Table Bay begin to prepare for it, by striking yards and top-masts, and making every thing as snug as possible.—A little to the westward of the Table Land, divided by a small valley, stands on the right-hand side of Table Bay a round hill, called the *Sugar Loaf;* and by many the *Lion's Head,* as there is a continuance from it contiguous to the sea, called the *Lion's Rump;* and when you take a general view of the whole, it very much resembles that animal with his head erect. The Sugar Loaf or Lion's Head, and the Lion's Rump, have each a flag staff on them, by which the approach of ships is made known to the governor, particularizing their number, nation, and the quarter from which they come. To the eastwards, separated by a small chasm from the Table Land, stands Charles's Mount, well known by the appellation of the *Devil's Tower,* or *Devil's Head;* and so called from the violent gusts of wind supposed to issue from it when it partakes of the cap that covers the Table Land, though these gusts are nothing more than a degree of force the wind acquires in coming through the chasm. When this phenomenon appears in the morning, which is by no means so frequent as in the evening, the sailors have a saying, as the Devil's Tower is almost contiguous to the Table Land, that the old gentleman is going to breakfast; if in the middle of the day, that he is going to dinner; and if in the evening, that the cloth is spread for supper. Table-mountain rises about 3567 feet above the level of the sea; the Devil's Tower, about 3368; and the Lion's Head, 2764. In the neighbourhood of the latter lies *Constantia,* a district consisting of two farms, wherein the famous wines of that name are produced.

The above-described high lands form a kind of amphitheatre about the Table-valley, where the Cape-town stands. This is situated at the bottom of the middle height, or Table-mountain; and almost in the centre of the Table Bay, so called from that mountain.—This bay, it is observed in Phillips's Voyage, "cannot properly be called a port, being by no means a station of security; it is exposed to all the violence of the winds which set into it from the sea; and is far from sufficiently secured from those which blow from the land. The gusts which descend from the summit of Table-mountain are sufficient to force ships from their anchors, and even violently to annoy persons on the shore, by destroying any tents or other temporary edifices, which may be erected, and raising clouds of fine dust, which produce very troublesome effects. A gale of this kind, from the south-east, blew for three days successively when Captain Cook lay here in his first voyage; at which time, he informs us, the Resolution was the only ship in the harbour that had not dragged her anchor. The storms from the sea are still more formidable; so much so, that ships have frequently been driven by them from their anchorage, and wrecked at the head of the bay. But these accidents happen chiefly in the *quaade mousson,* or winter months, from May 14th to the same day of August; during which time few ships venture to anchor here. Our fleet arriving later, lay perfectly unmolested as long as it was necessary for it to remain in this station.—False Bay, on the south-east side of the Cape, is more secure than Table Bay during the prevalence of the north-west winds, but still less so in strong gales from the south-east. It is, however, less frequented, being 24 miles of very heavy road distant from Cape Town, whence almost all necessaries must be procured. The most sheltered part of False Bay is a recess on the west side, called *Simon's Bay.*"

Mr White, in his Journal of a Voyage to New South Wales, thus describes Cape Town. From the shipping, he observes *, the town appears pleasantly situated, but at the same time small; a deception that arises from its being built in a valley with such stupendous mountains directly behind it. On landing, however, you are surprised, and agreeably disappointed, to find it not only extensive, but well built, and in a good style; the streets spacious, and intersecting each other at right angles with great precision. This exactness in the formation of the streets, when viewed from the Table Land, is observed to be very great. The houses in general are built of stone, cemented together with a glutinous kind of earth which serves as mortar, and afterwards neatly plastered and whitewashed with lime. As to their height they do not in common exceed two stories, on account of the violence of the wind, which at some seasons of the year blows with great strength and fury. For the same reason thatch has been usually preferred to tiles or shingles; but the bad effects that have proceeded from this mode when fires happen, has induced the inhabitants in all their new buildings to give the preference to slates and tiles. The lower parts of the houses, according to the custom of the Dutch nation, are not only uncommonly neat and clean in appearance, but they are really so; and the furniture is rather rich than elegant. But this is by no means the case with the bed-rooms or upper apartments; which are very barely and ill furnished. The streets are rough, uneven, and unpaved. But many of the houses have a space flagged before the door; and others have trees planted before them, which form a pleasant shade, and give an agreeable air to the streets.

* Page 87.

The only landing-place is at the east end of the town, where there is a wooden quay running some paces into the sea, with several cranes on it for the convenience of loading and unloading the scoots that come alongside. To this place excellent water is conveyed by pipes, which makes the watering of ships both easy and expeditious. Close to the quay, on the left hand, stands the castle and principal fortress; a strong extensive work, having excellent accommodations for the troops, and for many of the civil officers belonging to the company. Within the gates, are the principal stores; which are spacious as well as convenient. This fort covers and defends the east part of the town and harbour

Good Hope. bour, as Amsterdam fort does the west part. The latter, which has been built since Commodore Johnston's expedition, and whereon both French and Dutch judgment have been united to render it effectual and strong, is admirably planned and calculated to annoy and harass ships coming into the bay. Some smaller detached fortifications extend along the coast, both to the east and west, and make landing, which was not the case before the late war, hazardous and difficult. In a word, Cape Town is at this time fortified with strength, regularity, and judgment. It consists of 1145 houses, inhabited by about 5500 whites and people of colour, and 10,000 blacks.

There are two churches in the town; one large, plain, and unadorned, for the Calvinists, the prevailing sect; and a smaller one for the Lutherans. The hospital, which is large and extensive, is situated at the upper end of the town, close to the company's garden; where the convalescents reap the benefit of a wholesome pure air, perfumed with the exhalations of a great variety of rich fruit trees, aromatic shrubs, and odorous plants and flowers; and likewise have the use of every production of it.

The territory round the Cape is distinguished by three chains of mountains, running parallel to one another and to the coast. The first chain, called Lange Kloof, or Long Pass, runs parallel to the southern coast, at the distance of from 20 to 60 miles, widening towards the west. The second chain, called Zwarte Berg, or Black Mountain, is considerably higher and more rugged than the first, and consists often of double or triple ranges. The belt interposed between the Zwarte Berg and the Lange Kloof is nearly of the same breadth as that between the Lange Kloof and the sea, and is considerably more elevated. Beyond the Zwarte Berg, at an interval of 80 or 100 miles, rises the Nieuweldts Gebirg, the highest chain in southern Africa, and the summits of which are generally covered with snow. Its elevation is supposed to be 10,000 feet. The belt or plain interposed between the two last ridges is more elevated than any of the former, so that southern Africa forms as it were a succession of terraces rising above one another. The plain next the sea is covered with a deep and fertile soil, watered by numerous rivulets, well clothed with grass and with a beautiful varicty of trees and shrubs. Rains are frequent, and from its proximity to the sea, it enjoys a more mild and equable temperature than the interior and remoter parts of the colony. The second terrace contains a considerable proportion of well watered and fertile lands, but these are mixed with large tracts of the arid desert called Karroo. The third terrace, called the Great Karroo, is composed of a vast plain 300 miles in length, and nearly 100 in breadth, the soil of which is of a hard and impenetrable texture, and destitute almost of any trace of vegetation.

It is obvious, from this outline, that a large portion of the settlement must be devoted to complete and hopeless sterility. The Karroo, of which the greatest part of the second, and the whole of the third and largest belt is composed, is quite unoccupied by man or animal. Only a few shrivelled and parched plants occasionally meet the eye, faintly extending their half withered fibres along the ground. The surface consists of clay, thinly sprinkled over with sand, and is scarcely ever moistened with a shower of rain. The hills, which sometimes break the surface of these plains, are equally destitute of plants as the plain beneath. The upper regions of all the chains of mountains consist of masses of naked sandstone. Mr Barrow, in short, concludes, that seven-tenths of the settlement for a great part of the year, and a large proportion of it at all times, is destitute of the least appearance of verdure. The climate of the Cape is besides subject to various disadvantages. It is deluged with rain during the cold season; while, in the hot months, scarcely a shower falls to refresh the earth. During this season also a dry wind blows, having the pernicious effects of the African sirocco, blasting vegetation, and relaxing the human frame. Tempestuous winds are besides extremely common, and often uproot trees and destroy the the crops. There are, however, many spots about the Cape of extreme fertility. But the want of roads, or other means of transporting commodities, renders the good soil often of no value. The Cape town is supplied with grain from places generally at more than *one* and less than *three* days' journey distant. Beyond that, ground can only be applied to the purpose of grazing with advantage.

Wine and brandy are the staple produce of the Cape. The Constantia wine, raised only on two farms, is pretty much esteemed; but the mode of management is far too rude and slovenly to produce good wine generally; and notwithstanding the encouragement given to the Cape wines, by diminishing the duties, they are not relished in Britain. Some attempts, it is understood, are now making to improve the processs of manufacture. Tobacco, aloes, with almonds, and fruits of almost all kinds, succeed extremely well, but are not much cultivated. Attempts are now making to colonize the country round the Cape with British settlers; time can only shew whether it will succeed.

The inhabitants of the Cape, though in their persons large, stout, and athletic, have not all that phlegm about them which is the characteristic of Dutchmen in general. The physical influence of climate may in some degree account for this; for it is well known that in all southern latitudes the temper and disposition of the people are more gay, and that they are more inclined to luxury and amusements of every kind, than the inhabitants of the northern hemisphere. The ladies are lively, good natured, and familiar; and from a peculiar gay turn, they admit of liberties that would be thought reprehensible in England, shough perhaps they as seldom overleap the bounds of virtue as the women of other countries.

The heavy draft work about the Cape is mostly performed by oxen; which are here brought to an uncommon degree of usefulness and docility. It is not uncommon to see 14, 16, and sometimes 18, in one of their teams; when the roads are heavy, they sometimes, though rarely, yoke 20; all which the Hottentots, Malays, and Cape slaves, have in the most perfect subjection and obedience. One of these fellows places himself on the fore part of the waggon, or, when loaded, on the top of the load, and with a tremendous long whip, which from its size he is obliged to hold in both his

his hands, manages these creatures with inexpressible address. When he finds expedition needful, he can make them keep whatever pace he chooses, either trot or gallop, (a gait performed or kept up with difficulty by European oxen), and that with as much ease as if he was driving horses. They likewise manage horses with the same dexterity; and to see one of them driving three, four, five, and sometimes six pair, in hand, with one of these long whips, would make the most complete master of the whip in England cut a despicable figure. Carriages are not very numerous at the Cape, as the inhabitants in general travel in covered waggons, which better suit the roughness of the country. The governor and some few of the principal people keep coaches, which are a good deal in the English style, and always drawn by six horses.

Its geographical position on the globe is so commanding a feature, that the mere looking at a map, independent of any other information, must shew its value and importance in various respects. Its distance from the coast of Brazil is a month's voyage; from the Dutch colonies of Surinam, Berbice, and Essequibo, it is a voyage of six weeks; it is about equally distant from the Red sea, and two months from Coromandel and Malabar. It is half way between Britain and India, in a temperate climate, and productive of every species of refreshment in great abundance.

Considered in the light of a naval station, the importance of the Cape is equally conspicuous. It may serve as a port for refreshing and refitting the ships of the East India Company; a station for ships of war keeping the entrance into the Indian seas, and affording, by its geographical position, a ready communication with every part of the globe. There is no place, in the homeward bound voyage from India, so proper or convenient for East India ships to assemble at for convoy, as the Cape of Good Hope. Their crews might be refreshed with fruits, vegetables, and fresh provisions, at a very reasonable rate. Salt beef for the remainder of the voyage might there be laid in. An establishment for curing salt provisions, would be an incalculable saving, as well as a singular convenience. The moderate expence at which a fleet could here be maintained, is a circumstance that deserves attention. At the Cape a sailor may be furnished his ration of fresh beef or mutton, biscuit and wine, for one-fourth of what the same ration of salt beef costs the government when sent out from Britain.

If a naval establishment was formed at Saldanha bay, many coasting vessels and fishing ships would be constructed in it, as it abounds with every convenience that could be required for building ships, which would be the means of very much increasing the coasting trade.

It is thought also, that were a depot for the southern whale fishery established at the Cape, it might be attended with beneficial consequences. By promoting navigation, the strength and security of the British empire are also promoted, and its very existence as an independent nation is owing to the superiority of its navy. A nation of fishermen implies a nation of seamen, a race of bold and hardy warriors. The cultivation of the fisheries would afford a never-failing supply of men so instructed, increase our conveniency, and promote our commerce.

The colony of the Cape comprehends at least 120,000 square miles; yet the whole population of whites, blacks, and Hottentots, does not exceed 60,000 souls, or a single individual for every two square miles. The rural occupants may be divided into the wine-growers, the corn-farmers, and the graziers. The first, who reside in the immediate vicinity of the Cape, are the most civilized and comfortably situated of the peasantry. Their property is usually about 120 acres in extent, and held in freehold. The corn-boors or farmers, reside generally at the distance of two or three days journey from the Cape. The agriculture is extremely rude. Their plough, an unwieldy machine, drawn by 14 or 16 oxen, does little more than skim the surface. They use almost no manure, and tread out the corn by the feet of horses. The grazier is the least cultivated, and indeed is half a savage. All these classes employ Hottentots, who are not slaves, strictly speaking, but in a condition nearly as bad.

Good Manners. See Manners.

GOOINGS, in sea-language, are clamps of iron bolted on the stern-post of a ship, whereon to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOSE. See Anas, Ornithology *Index*. The goose was held in great esteem amongst the Romans for having saved the Capitol from the invasion of the Gauls by cackling and clapping its wings. Geese were kept in the temple of Juno; and the censors, when they entered upon their office, provided meat for them. There was also an annual feast at Rome, at which they carried a silver image of a goose in state; and hanged a dog, to punish that animal because he did not bark at the arrival of the Gauls.

Goose-Ander. See Mergus, Ornithology *Index.*

Goose-Berry. See Ribes, Botany *Index.*

Goose-Neck, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whip-staff or the wheel-rope comes, for steering the ship.

Goose-Wing, in the sea language. When a ship sails before, or with a quarter-wind on a fresh gale, to make the more haste, they launch out a boom and sail on the lee-side; and a sail so fitted is called a *goose-wing*.

GORCUM, a town in South Holland, which carries on a considerable trade in cheese and butter. It is situated on the rivers Ligne and Maese, in E. Long. 4. 55. N. Lat. 51. 49.

GORDIANUS I. a Roman general, was for his valour and virtues chosen emperor by the army in the reign of Maximinus, A. D. 237; but his son, whom he had associated with himself in the throne, being slain by Capellian, the governor of Mauritania for Maximinus, Gordianus killed himself the same year. See Rome.

Gordianus III. grandson of the former, a renowned warrior, and styled *The guardian of the Roman commonwealth.* He was treacherously assassinated by Philippus, an Arabian, one of his generals; who, to the eternal disgrace of the Romans of that era, succeeded him in the empire, A. D. 244. See Rome.

GORDIAN-knot,

GORDIAN-KNOT, in antiquity, a knot made in the leathers or harness of the chariot of Gordius king of Phrygia, so very intricate, that there was no finding where it began or ended. The inhabitants had a tradition, that the oracle had declared, that he who untied this knot should be master of Asia. Alexander having undertaken it, was unable to accomplish it; when fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

GORDIUS, the HAIR-WORM, a genus of insects belonging to the class of *vermes intestina*. See HELMINTHOLOGY *Index*.

GORDIUS, king of Phrygia, and father of Midas, was a poor husbandman, with two yokes of oxen, wherewith he ploughed his land and drew his wain. An eagle sitting a long while upon one of his oxen, he consulted the soothsayers; a virgin bid him sacrifice to Jupiter in the capacity of king. He married the virgin, who brought forth Midas. The Persians, instructed by the oracle to set the first person they met in a wain upon the throne, met Gordius, and made him king. Midas for this good fortune dedicated to Jupiter his father's cart, The knot of the yoke, they say, was so well twisted, that he who could unloose it was promised the empire of Asia; hence the proverb of *the Gordian knot* had its original. See *GORDIAN KNOT*.

GORDON, ALEXANDER, an excellent draughtsman, and a good Greek scholar, who resided many years in Italy, visited most parts of that country, and had also travelled into France, Germany, &c. was secretary to the Society for Encouragement of Learning; and afterwards to the Egyptian Club, composed of gentlemen who had visited Egypt, viz. Lord Sandwich, Dr Shaw, Dr Pococke, &c. He succeeded Dr Stukeley as secretary to the Antiquarian Society, which office he resigned in 1741 to Mr Joseph Ames. He went to Carolina with Governor Glen, where, besides a grant of land, he had several offices, such as register of the province, &c.; and died a justice of the peace, leaving a handsome estate to his family. He published, 1. *Itinerarium Septentrionale*, or a Journey through most parts of the Counties of Scotland, in two parts, with 66 copperplates, 1726, folio. 2. Supplement to the *Itinerarium*, 1732, folio. 3. The Lives of Pope Alexander VI. and his son Cæsar Borgia. 4. A complete History of the Ancient Amphitheatres, 1730, 8vo. afterwards enlarged in a second edition. 5. An Essay towards explaining the hieroglyphical figures on the Coffin of the ancient Mummy belonging to Captain William Lethieulier, 1737, folio, with cuts. 6. Twenty-five Plates of all the Egyptian Mummies and other Egyptian Antiquities in England, 1739, folio.

GORDON, *Thomas*, noted for his translations and political writings, was born at Kirkcudbright in North Britain. He came young to London; where he supported himself by teaching languages, until he procured employment under the earl of Oxford in Queen Anne's time, but in what capacity is not now known. He first distinguished himself in the defence of Dr Hoadley in the Bangorian controversy; which recommended him to Mr Trenchard, in conjunction with whom he wrote the well-known Cato's Letters, upon a variety of important public subjects. These were followed by another periodical paper, under the title of the Independent Whig; which was continued some years after Mr Trenchard's death, by Gordon alone, against the hierarchy of the church; but with more acrimony than was shown in Cato's Letters. At length Sir Robert Walpole retained him to defend his administration, to which end he wrote several pamphlets. At the time of his death, July 28th 1750, he was first commissioner of the wine licenses, an office which he had enjoyed many years. He was twice married. His second wife was the widow of his great friend Trenchard, by whom he had children.—He published English translations of Sallust and Tacitus, with additional discourses to each author, which contain much good matter. Also, two collections of his tracts have been preserved: the first entitled, A Cordial for Low-spirits, in three volumes: and the second, The Pillars of Priestcraft and Orthodoxy shaken, in two volumes. But these, like many other posthumous things, had better have been suppressed. In his translations as well as his other works he places his verbs at the ends of sentences, according to the Latin idiom, in a very stiff and affected manner.

GORDONIA, a genus of plants, belonging to the monadelphia blass. See BOTANY *Index*.

GORE, in *Heraldry*, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point. See HERALDRY.

GOREE, a small island of Africa, near Cape de Verd, subject to the French. It is a small spot not exceeding two miles in circumference, but its importance arises from its situation for trade so near Cape Verd, and it has been therefore a bone of contention between European nations. It was first possessed by the Dutch, from whom, in 1663, it was taken by the English; but in 1665 it was retaken by the Dutch, and in 1677 subdued by the French, in whose possession it remained till the year 1759, when the British arms were everywhere triumphant; and it was reduced by Commodore Keppel, but restored to the French at the treaty of peace in 1763. It was retaken by the English in the American war, but again restored at the peace of 1783. E. Long. 17. 20. N. Lat. 14. 43.

GOREE, the capital town of an island of the same name in Holland, eight miles south of Briel. E. Long. 3. 50. N. Lat. 51. 55.

GOREY, a borough, fair, and post-town in the county of Wexford, province of Leinster, otherwise called *Newborough*. It stands about 18 miles north of Wexford town, and 45 from Dublin. N. Lat. 52. 40. W. Long. 6. 30. It sent formerly two members to the Irish parliament.

GORGE, in *Architecture*, the narrowest part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar, and the annulets.

GORGE, in *Fortification*, the entrance of the platform of any work. See FORTIFICATION.

GORGED, in *Heraldry*, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c.

&c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

GORGED is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGET, a kind of breast-plate, like a half-moon, with the arms of the prince thereon; worn by the officers of foot. They are to be either gilt or silver, according to the colour of the buttons on the uniforms.

GORGET, or GOGERET, in *Surgery*, is the name which the French give to the concave or cannulated conductor, used in lithotomy. See SUGERY *Index*.

GORGONA, a small island of Italy, in the sea of Tuscany, and near that of Corsica, about eight miles in circumference; remarkable for the large quantity of anchovies taken near it. E. Long. 10. 0. N. Lat. 43. 22.

GORGONA, a small island of the South sea, 12 miles west of the coast of Peru, in America. It is indifferent high land, very woody, and some of the trees are very tall and large, and proper for masts. It is about 10 miles in circumference, and has several springs and rivulets of excellent water, but is subject to constant rains. W. Long. 73. 3. S. Lat. 30.

GORGONIA, in *Natural History*, a genus of zoophytes, which formerly were called *ceratophytons*, and are known in English by the names of *sea-fans*, *sea-feathers*, and *sea-whips*. Linnæus and Dr Pallas consider them as of a mixed nature in their growth, between animals and vegetables; but Mr Ellis shows them to be true animals of the polype kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh water polype in many of their qualities, and particularly in producing from their own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed from a concreting juice thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the osseous liquor exudes, and concreting, forms the layers of that hard part of the annular circles, which some, judging from the consistence rather than the texture, have erroneously denominated *wood*. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other as to serve for defence from external injuries: and the flesh, or, as some have called it, the *bark* or *cortex*, consists of proper muscles and tendons for extending the openings of their cells; for sending forth from thence their polype suckers in search of food; and for drawing them in suddenly, and contracting the sphincter muscles of these starry cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the osseous matter that forms the stem and branches as well as the base of the bone. Mr Ellis affirms, that there are ovaries in these animals, and thinks it very probable that many of them are viviparous. See ZOOPHYTES.

GORGONS, in *Antiquity* and *Mythology*. Authors are not agreed in the account they give of the Gorgons. The poets represent them as three sisters, whose names were *Stheno*, *Euryale*, and *Medusa;* the latter of whom was mortal, and, having been deflowered by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind. After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto.

Multaque præterea variarum monstra ferarum—
GORGONES, Harpyiæque——

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Libya which lay on the lake Tritonidis. The extermination of these female nations was not effected till Hercules undertook and performed it.

Pausanias says, the Gorgons were the daughters of Phorbus; after whose death, Medusa, his daughter, reigned over the people dwelling near the lake Tritonidis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, he found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen the Greeks, who could not behold it without being struck with astonishment.

Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others, again, make them animals, resembling wild sheep, whose eyes had a poisonous and fatal influence.

GORITIA, or GORITZ, a strong town of Germany, in the circle of Anstria, and duchy of Carniola, with a castle; seated on the river Lizonzo, 20 miles north-east of Aquileia, and 70 north-east of Venice. E. Long. 13. 43. N. Lat. 46. 12.

GORLÆUS, ABRAHAM, an eminent antiquary, was born at Antwerp, and gained a reputation by collecting medals and other antiques. He was chiefly fond of the rings and seals of the ancients, of which he published a prodigious number in 1601, under this title, *Dactyliotheca; sive Annulorum Sigillarium, quorum apud priscos tam Græcos quam Romanos usus ex ferro, ære, argento, et auro, Promptuarium.* This was the first part of the work: the second was entitled, *Variarum Gemmarum, quibus antiquitas in signando uti solita sculpturæ.* This work has undergone several editions, the best of which is that of Leyden, 1695: for it not only contains a vast number of cuts, but also a short explication of them by Gronovius. In 1680, he published a collection of medals: which, however, if we may believe the *Scaligerana*, it is not safe always to trust. Gorlæus pitched upon Delft for the place of his residence, and died there in 1609. His collections of antiques were sold by his heirs to the prince of Wales.

GORLITZ, a town of Germany, in Upper Lusatia, now subject to Prussia. It is a handsome strong place, and seated on the river Neisse, in E. Long. 15. 15. N. Lat. 51. 10.

GORTERIA, a genus of plants belonging to the syngenesia class, and in the natural method ranking under the 49th order, *Compositæ*. See BOTANY *Index*.

GOSHAWK. See FALCO, ORNITHOLOGY *Index*.

GOSHEN,

GOSHEN, in *Ancient Geography*, a canton of Egypt, which Joseph procured for his father and his brethren when they came to dwell in Egypt. It was the most fruitful part of the country: and its name seems to be derived from the Hebrew, *Geshem*, which signifies "rain;" because this province lying very near the Mediterranean, was exposed to rains, which were very rare in other cantons, and more especially in Upper Egypt. Calmet does not question but that Goshen, which Joshua (x. 41. xi. 16. xv. 51.) makes part of the tribe of Judah, is the same as the land of Goshen, which was given to Jacob and his sons by Pharaoh king of Egypt; (Gen. xlvi. 28.). It is certain that this country lay between Palestine and the city of Tanais, and that the allotment of the Hebrews reached southward as far as the Nile, (Josh. xiii. 3.).

GOSLAR, a large and ancient town of Lower Saxony, and in the territory of Hildesheim. It was here that gunpowder was first invented, by a monk as is generally supposed. It is a large place, but the buildings are in the ancient taste. It was formerly a free city, but was given to Prussia in 1802, and ceded by that power to Hanover in 1814. It is seated on a mountain, near the river Gose, and near it are rich mines of iron. The inhabitants are famous for brewing excellent beer. E. Long. 10. 26. N. Lat. 51. 55.

GOSPEL, the history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.—The word is Saxon, and of the same import with the Latin term *evangelium*, which signifies "glad tidings," or "good news."

This history is contained in the writings of St Matthew, St Mark, St Luke, and St John; who from thence are called *evangelists*. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSPORT, a town of Hampshire, 79 miles from London, in the parish of Alverstock. It has a ferry over the mouth of the harbour to Portsmouth, and is a large town and of great trade, especially in time of war. Travellers choose to lodge here, where every thing is cheaper and more commodious for them than at Portsmouth. The mouth of the harbour, which is not so broad here as the Thames at Westminster, is secured on this side by four forts, and a platform of above 20 cannon level with the water. Here is a noble hospital built for the cure of the sick and wounded sailors in the service of the navy; besides a free school.

GOSSAMER is the name of a fine filmy substance, like cobwebs, which is seen to float in the air, in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSYPIUM, or COTTON, a genus of plants belonging to the monadelphia class, and in the natural method ranking under the 37th order, *Columniferæ*. See BOTANY *Index*.

The American islands produce cotton shrubs of various sizes, which rise and grow up without any culture; especially in low and marshy grounds. Their

produce is of a pale red; some paler than others; but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making of hats. The little that is picked up, serves to make mattresses and pillows.

The cotton-shrub that supplies our manufactures, requires a dry and stony soil, and thrives best in grounds that have already been tilled. Not but that the plant appears more flourishing in fresh lands than in those which are exhausted; but while it produces more wood, it bears less fruit.

A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and, if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the prospect of an advantage that will compensate the trouble.

This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth; but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being discoloured and spotted.

When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill; which is an engine composed of two rods of hard wood, about 18 feet long, 18 lines in circumference, and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the seed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the seed contained in it.

GOTHA, a town of Germany, in the circle of Upper Saxony, and capital of the duchy of Saxe-Gotha, in E. Long. 10. 40. N. Lat. 50. 57. Some fancy this town had its name from the Goths, and that they fortified it in their march to Italy; but it was only a village till surrounded with walls by the bishop of Mentz in 964. It is situated in a fine plain on the river Leina, well built and strongly fortified. Here are two handsome churches and a very good hospital. Its chief trade is in dyers weed, of which they have three crops, but the third grows wild. The neighbouring country produces a vast deal of corn. The castle or ducal palace of Gotha was rebuilt in the 16th century by duke Ernest, surnamed *the Pious*, who caused both that and the town to be encompassed with ditches and ramparts; and gave it the name of *Friedenstein*, or the *Castle of Peace*, in opposition to its ancient name of *Grimmerstein*, or the *Castle of the Furies*. It is situated on a neighbouring eminence, from whence there is a vast prospect of a fruitful plain. In one of the apartments there is a collection of valuable rarities, and a noble library. The town has 11,600 inhabitants.

The dukedom of Saxe Gotha is about 30 miles long, and 20 broad. It contains an area of about 500 square miles, and its population is estimated at 82,000. The duke is the head of the Ernestine line of Saxony, descended from the elector John Frederick the Magnanimous, who was deprived of the electorate by the emperor Charles V. in 1574; since which the youngest branch, called the *Albertine*, has enjoyed it. He has several other principalities besides that of Saxe Gotha; and his revenues are computed at 150,000l. a-year, with which he maintains about two thousand regular troops. As he is the most powerful of all the Saxon princes of the Ernestine branch; so of all the courts of Saxony, next to that of Dresden, he has the most numerous and the most magnificent. His guards are well clothed, his liveries rich, and his tables served with more elegance than profusion. And yet by the prudent management of his public finances, his subjects are the least burdened with taxes of any state in Germany. The religion is Lutheran.

GOTHARD, one of the highest mountains of Switzerland; and from the top, where there is an hospital for monks, is one of the finest prospects in the world. It is eight miles from Aldorf.

GOTHEBORG, Gothenburg, or *Gottenburg*. See Gottenburg.

GOTHIC, in general, whatever has any relation to the Goths: thus we say, Gothic customs, Gothic architecture, &c. See Architecture.

GOTHLAND, the most southern province of Sweden, being a peninsula, encompassed on three sides by the Baltic sea, or the channel at the entrance of it. It is divided into several parts, which are, East Gothland, West Gothland, Smaland, Halland, Bleaking, and Schonen. It was a long time in the possession of the kings of Denmark, but was ceded to Sweden in 1654. The principal towns of Gothland are Calmar, Landscroon, Christianople, Daleburg, Gothenburgh, Helmstat, Lunden, Malmone, and Vexio.

GOTHS, a warlike nation, and above all others famous in the Roman history, came originally out of Scandinavia (the name by which the ancients distinguished the present countries of Sweden, Norway, Lapland, and Finmark). According to the most probable accounts they were the first inhabitants of those countries; and from thence sent colonies into the islands of the Baltic, the Cimbrian Chersonesus, and the adjacent places yet destitute of inhabitants. The time of their first settling in Scandinavia, and the time when they first peopled with their colonies the above-mentioned islands and Chersonesus, are equally uncertain; though the Gothic annals suppose the latter to have happened in the time of Serug the great grandfather of Abraham. This first migration of the Goths is said to have been conducted by their king Eric; in which all the ancient Gothic chronicles, as well as the Danish and Swedish ones, agree. Their second migration is supposed to have happened many ages after; when, the above-mentioned countries being overstocked with people, Berig, at that time king of the Goths, went out with a fleet in quest of new settlements. He landed in the country of the Ulmerugians, now Pomerania, drove out the ancient inhabitants, and divided their lands among his followers. He fell next upon the Vandals, whose country bordered on that of the Ulmerugians, and overcame them; but instead of forcing them to abandon their country, he only made them share their possessions with the Goths.

The Goths who had settled in Pomerania and the adjacent parts of Germany being greatly increased, insomuch that the country could no longer contain them, they undertook a third migration in great numbers, under Filimer surnamed the *Great*, the fifth prince after leaving Scandinavia; and taking their route eastward, entered Scythia, advanced to the Cimmerian Bosphorus, and driving out the Cimmerians, settled in the neighbourhood of the Palus Mæotis. Thence, in process of time, being greatly increased in Scythia, they resolved to seek new settlements; and accordingly taking their route eastward, they traversed several countries, and at length returned into Germany.

Their leader in this expedition was the celebrated Woden, called also *Voden*, *Othen*, *Oden*, *Godan*, and *Guadan*. Of this Woden many wonderful things are related in the Sueo-gothic chronicles. He was king of the Asgardians, whom the northern writers will have to be the same with a people called *Aspurgians* mentioned by Strabo and Ptolemy. By Strabo they are placed near the Cimmerian Bosphorus. Aspurgia was the metropolis of a province which Strabo calls *Asia;* and Woden and his followers are styled by the ancient Gothic writers *Asæ*, *Asianæ*, and *Asiotæ*. The kings of Aspurgia were masters of all that part of Scythia which lay to the westward of Imaus, and was by the Latins called *Scythia intra Imaum*, or "Scythia within Imaus."

At what time Woden reigned in this country, is quite uncertain; but all historians agree, that he went out in quest of new settlements with incredible numbers of people following him. He first entered Roxolania, comprehending the countries of Prussia, Livonia, and great part of Muscovy. From thence he went by sea into the north parts of Germany; and having reduced Saxony and Jutland, he at last settled in Sweden, where he reigned till his death, and became so famous that his name reached all countries, and he was by the northern nations worshipped as a god. He is supposed to have brought with him the Runic characters out of Asia, and to have taught the northern nations the art of poetry; whence he is styled the father of the Scaldi or Scaldri, their poets, who described in verse the exploits of the great men of their nation, as the bards did among the Gauls and Britons.

The Romans distinguished the Goths into two classes; the Ostrogoths and Visigoths. These names they received before they left Scandinavia, the *Visigoths* being softened by the Latins from *Westerogoths*, or those who inhabited the western part of Scandinavia, as the Ostrogoths were those who inhabited the eastern part of that country. Their history affords nothing of moment till the time of their quarrelling with the Romans; which happened under the reign of the emperor Caracalla, son to Severus. After that time their history

tory becomes so closely interwoven with that of the Romans, that for the most remarkable particulars of it we must refer to the article ROME. After the destruction of the Roman empire by the Heruli, the Ostrogoths, under their king Theodoric, became masters of the greatest part of Italy, having overcome and put to death Odoacer king of the Heruli in 494. They retained their dominion in this country till the year 553; when they were finally conquered by Narses, the emperor Justinian's general. See (History of) ITALY. The Visigoths settled in Spain in the time of the emperor Honorius, where they founded a kingdom which continued till the country was subdued by the Saracens. See SPAIN.

The Goths were famous for their hospitality and kindness to strangers, even before they embraced the Christian religion. Nay, it is said, that from their being eminently good, they were called *Goths*, by the neighbouring nations; that name, according to Grotius and most others writers, being derived from the German word *goten*, which signifies "good." They encouraged, says Dio, the study of philosophy above all other barbarous or foreign nations, and often chose kings from among their philosophers. Polygamy was not only allowed but countenanced among them; every one being valued or respected according to the number of his wives. By so many wives they had an incredible number of children, of whom they kept but one at home, sending out the rest in quest of new settlements; and hence those swarms of people which overran so many countries. With them adultery was a capital crime, and irremissibly punished with death. This severity, and likewise polygamy, prevailed among them when they were known to the Romans only by the name of *Getæ* (their most ancient name); as appears from the poet Menander, who was himself one of that nation; and from Horace, who greatly commends the chastity of their women. Their laws fell little short of those of the ancient Romans. Their government was monarchical; their religion was much the same with that of the ancient Germans or Celtes; and their dress is described by Apollinaris Sidonius in the following words: "They are shod (says he) with high shoes made of hair, and reaching up to their ankles; their knees, thighs, and legs, are without any covering; their garments of various colours scarce reaching to the knee; their sleeves only cover the top of their arms; they wear green cassocks with a red border; their belts hang on their shoulders; their ears are covered with twisted locks; they use hooked lances and missile weapons."
