ENCYCLOPÆDIA BRITANNICA.

FORDYCE, DAVID, an elegant and learned writer, was born at Aberdeen in the year 1711. Having received the early part of his education at the grammar school, at the age of 13 he was entered at the Greek class in Marischal college, Aberdeen; in 1728 he took the degree of A. M. and was afterwards, in 1742, admitted professor of philosophy in the same college. He was originally designed for the ministry; to prepare himself for which was the whole object of his ambition, and for a course of years the whole purpose of his studies. How well he was qualified to appear in that character, appears from his "Theodorus, a dialogue concerning the art of preaching." Having finished this work, he went abroad in 1750 on his travels, in order to obtain fresh stores of knowledge: but after a successful tour through several parts of Europe, he was, on his return home, unfortunately cast away in a storm on the coast of Holland, in the 41st year of his age. Besides the above work, he wrote Dialogues on Education, 8vo, and a Treatise of Moral Philosophy, published in the Preceptor. The third edition of his Theodorus was published in London, in 1751, after his death, by his brother James, the subject of the following article.

FORDYCE, *James*, a Scotch divine, justly esteemed for his piety and ingenuity, as well as for his pulpit eloquence, was born at Aberdeen in the year 1720. He received his classical education at the public grammar school, and went afterwards to the Marischal college, where he went through the usnal course of studies necessary for a minister of the gospel. His natural abilities were excellent, and he improved to the utmost the favourable opportunities he enjoyed at the university, which made him be considered as well qualified for a preacher of the gospel at an early period of life. His first appointment was that of second minister in the church of Brechin in the county of Angns, after which he accepted of a call to Alloa near Stirling. The people of that parish were prepossessed in favour of another, and prejudiced against Mr Fordyce, which could not fail to be a most unpleasant circumstance; yet by his impressive delivery, and indefatigable attention to every part of his ministerial duty, he soon changed their prejudice into esteem, and their esteem into admiration.

During his residence at Alloa, he drew on him the notice of the public by three excellent sermons; the first on the eloquence of the pulpit, the second on the method of promoting edification by public institutions, and the third on the delusive and bloody spirit of popery, preached before the synod of Perth and Stirling. But still greater wonder and astonishment were excited by his inimitable sermon on the folly, infamy, and misery of unlawful pleasure, preached before the general assembly of the church of Scotland in 1760. It contains such masterly composition with respect to description, spirit, and elegance, and was delivered with such uncommon solemnity, animation, and pathos, that it filled his learned fathers and brethren with astonishment, and justly raised him to unrivalled eminence among his clerical cotemporaries. About this time he was complimented with a degree of doctor in divinity by the university of Glasgow, probably on account of the fame he acquired by this extraordinary sermon.

The friends of Dr Fordyce being mostly in London, he was invited to that metropolis to be the colleague of Dr Lawrence, minister of a respectable congregation in Monkwell-street, on whose death, which happened a few months after, Dr Fordyce became once more famous for his pulpit eloquence, always preaching to overflowing audiences. This popularity he justly deserved, whether with respect to the elegance of his compositions, or their happy tendency to impress the heart with the love of virtue and religion. Yet even Dr Fordyce lived to see his popularity on the decline; for such as attend a place of worship from mere motives of curiosity must have fickle and unstable minds, changing their preachers as they do their dress, loving to be where others are, of doing what others do, and of admiring what others admire, for they have no taste of their own.

His pews were thinned from another cause, which was the failure of a younger brother, an extensive banker, which ruined many of the doctor's constant hearers and most liberal supporters. Although the doctor could not be reasonably blamed for the failure of his brother, yet it is certain that it brought a degree of odium on the whole family. Another cause of the diminution of his hearers was an unhappy difference between him and Mr Toller his colleague, which happened in the year 1755, and which ended in a division of the congregation, many respectable families following Mr Toller to another place of worship. Soon after this he declined officiating as a minister, the impaired state of his health rendering such a step necessary. The best specimen of pulpit eloquence which perhaps ever came from his pen, was delivered at the ordination

tion of his successor Mr James Lindsay, and highly meriting the attentive perusal of every clergyman. The remainder of his valuable life he spent chiefly at a retirement in Hampshire in the vicinity of the earl of Bute, with whom he lived in the greatest intimacy, and to whose valuable library he had unlimited access. He afterwards went to Bath, where he suffered much from an asthmatic affection, but bore it with the heroic fortitude of a Christian, and expired without a groan on the first of October 1796, in the 76th year of his age.

The doctor's writings discover much genius and imagination, a correct taste, extensive knowledge of the world, and a happy method of engaging the attention; full of ardent piety, and a zeal for the interests of genuine virtue. His religious sentiments were manly and rational; in private life he was highly amiable, and deservedly beloved by all who knew him. He was author of Sermons to Young Women, in two volumes 12mo, which have been translated into several European languages; A Sermon on the Character and Conduct of the Female Sex; Addresses to Young Men, in two volumes 12mo; Addresses to the Deity; A volume of Poems; A discourse on Pain, and Additions to his brother's Temple of Virtue.

FORDYCE, *George*, a writer and lecturer on medicine, was born in the year 1736, and studied at the university of Aberdeen, where he obtained the literary degree of M. A. at the early age of 14, perhaps not altogether owing to the superior cast of his genius, or the extent of his acquirements, which could not be extraordinary in a boy of his years. He became apprentice to an uncle who practised surgery at Uppingham in Rutlandshire, when he was only 15, and afterwards went to the university of Edinburgh, where his diligence and progress attracted the attention of Dr Cullen, at that time professor of chemistry, who very generously promoted his improvement. He graduated in 1758, when only 22 years of age; after which he resided one winter at Leyden. The greater part of his patrimony being spent on his education, he resolved to try his fortune in London, where he settled in the year 1759. He commenced with a course of lectures on chemistry; and although his encouragement at first was by no means flattering, yet he steadily and diligently persevered, notwithstanding such unfavourable appearances, till his literary merit began gradually to be discovered and properly appreciated. A number of young men who came to study in London did not think that their medical course was complete, without availing themselves of the benefit of his course of lectures.

In the year 1768, he published his Elements of the Practice of Physic, which formed the text book of his medical course, and were much read as a valuable epitome of medicine. His private practice was very respectable; and in the year 1770 his medical reputation was so great, that he was chosen physician to the hospital of St Thomas, although he had to contend against a gentleman with very powerful interest; and his merit as a man of science made him a member of the Royal Society in 1776. He was chosen in 1787 a fellow of the College of Physicians; and his chemical knowledge was of singular importance to that body for a new edition of their Pharmacopœia. By the influence of his connections, but probably more so by his literary reputation, he was appointed to furnish the navy with sour-krout, which we believe he executed with advantage both to himself and the public.

His constitution discovered symptoms of premature decay, yet he continued to discharge his professional duties till he fell a victim to an irregular gout, and a water in his chest, on the 25th of June 1802, in the 66th year of his age. If his lectures wanted the charms of an eloquent delivery, he made ample compensation by the originality of his ideas and his scientific information, and by a memory which was uncommonly retentive. His works are, Elements of Agriculture and Vegetation; Of the Practice of Physic; A Treatise on the Digestion of Food; and Four Dissertations on Fever.

FORE, applied to a ship, denotes all that part of a ship's frame and machinery which lies near the stem.

Fore and aft, is used for the whole ship's length, or from end to end.

FORECASTLE *of a Ship*, that part where the foremast stands. It is divided from the rest by a bulkhead.

FOREIGN, something extraneous, or that comes from abroad. The word is formed from the Latin *fores*, "doors;" or *foris*, "out of doors;" or *forum*, "market," &c.

Foreign minister, foreign prince, foreign goods, &c. are those belonging to other nations. See MINISTER, &c.

Foreign to the purpose, signifies a thing remote or impertinent.

FOREIGN, in the *English Law*, is used in various significations. Thus,

Foreign Attachment, is an attachment of the goods of foreigners found within a city or liberty, for the satisfaction of some citizen to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person.

Foreign Kingdom, a kingdom under the dominion of a foreign prince.

At the instance of an ambassador or consul, any offender against the laws here may be sent for hither from a foreign kingdom to which he hath fled. And, where a stranger of Holland, or any foreign country, buys goods at London, for instance, and there gives a note under his hand for payment, and then goes away privately into Holland; in that case, the seller may have a certificate from the lord mayor, on the proof of the sale and delivery of such goods, whereupon a process will be executed on the party in Holland.

Foreign Opposer, or *Apposer*, an officer in the exchequer that opposes or makes a charge on all sheriffs, &c. of their green wax; that is to say, fines, issues, amerciaments, recognizances, &c.

Foreign Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction.

Foreign Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural-born subjects.

FOREIGNER, the natural-born subject to some foreign prince.

Foreigners, though made denizens, or naturalized, are, Foreigner ‖ Fore-locks

are disabled to bear any office in government, to be of the privy council, or members of parliament, &c.—This is by the acts of the settlement of the crown.—Such persons as are not freemen of a city or corporation, are also called *foreigners*, to distinguish them from the members of the same.

FOREJUDGER, in *Law*, signifies a judgment whereby one is deprived or put by a thing in question.

To be *forejudged the court*, is where an officer or attorney of any court is expelled the same for malpractice, or for not appearing to an action on a bill filed against him, &c. And where an attorney of the common-pleas is sued, the plaintiff's attorney delivers the bill to one of the criers of the court, who calls the attorney defendant, and solemnly proclaims aloud, that, if he does not appear thereto, he will be forejudged: likewise a rule is given by the secondary for his appearance; and if the attorney appears not in four days, then the clerk of the warrants strikes such an attorney off the roll of attorneys; after which he becomes liable to be arrested like any other person; but where an attorney is forejudged, he may be restored on clearing himself from his contumacy, and making satisfaction to the plaintiff, &c.

FORELAND, or FORENESS, in *Navigation*, a point of land jutting out into the sea.

North FORELAND, in the isle of Thanet, Kent, of which it is the N. E. point, is the promontory ascertained by act of parliament to be the most southern part of the port of London, which is thereby extended N. in a right line to the point called the Nase on the coast of Essex, and forms what is properly called the Mouth of the Thames. A sea-mark was erected here by the Trinity-house corporation at the public expence, which is a round brick tower, near 80 feet high. The sea gains so much upon the land here by the winds at S. W. that within the memory of some that are living about 30 acres of land have been lost in one place. All vessels that pass on the south side of this head-land are said to enter the Channel, which is the name for the narrow sea between England and France; and all the towns or harbours between London and this place, whether on the Kentish or Essex shore, are called members of the port of London.

South FORELAND, in Kent, a head-land forming the east point of the Kentish shore; and called *South*, in respect to its bearing from the other Foreland, which is about six miles to the north. Its situation is of great security to the Downs, the road between both, which would be a very dangerous road for ships, did not this point break the sea off, that would otherwise come rolling up from the west to the Flats or banks of sand, which for three leagues together, and at about a league or a league and a half from the shore, run parallel with it, and are dry at low water; so that these two capes breaking all the force of the sea on the S. E. and S. W. make the Downs accounted a good road, except when the wind blows excessively hard from S. E., E. by N., or E. N. E., when ships in the Downs are driven from their anchors, and often run ashore, or are forced on the sands, or into Sandwich bay or Ramsgate pier.

FORE-LOCKS, in the sea language, little flat wedges made of iron, used at the end of bolts, to keep them from flying out of their holes.

Foremast, Forest.

FOREMAST of a SHIP, a large round piece of timber, placed in her fore part or fore-castle, and carrying the fore-sail and fore-top-sail yards. Its length is usually $\frac{8}{9}$ of the main mast, and the fore-top-gallant mast is $\frac{1}{2}$ the length of the fore-top.

FOREMAST-Men, are those on board a ship that take in the top-sails, sling the yards, furl the sails, howse, trice, and take their turn at the helm, &c.

FOREST, in *Geography*, a huge wood; or, a large extent of ground covered with trees. The word is formed of the Latin *foresta*, which first occurs in the capitulars of Charlemagne, and which itself is derived from the German *frost*, signifying the same thing. Spelman derives it from the Latin *foris restat*, by reason forests are out of towns. Others derive *foresta* from *feris*, q. d. *Foresta, quod sit tuta statio ferarum*, as being a safe station or abode for wild beasts.

The Caledonian and Hercynian forests are famous in history. The first was a celebrated retreat of the ancient Picts and Scots: the latter anciently occupied the greatest part of Europe; particularly Germany, Poland, Hungary, &c. In Cæsar's time it extended from the borders of Alsatia and Switzerland to Transylvania; and was computed 60 days journey long, and 9 broad: some parts or cantons thereof are still remaining.

The ancients adored forests, and imagined a great part of their gods to reside therein: temples were frequently built in the thickest forests; the gloom and silence whereof naturally inspire sentiments of devotion, and turn men's thoughts within themselves.

For the like reason, the Druids made forests the place of their residence, performed their sacrifices, instructed their youth and gave laws therein.

FOREST, in *Law*, is defined, by Manwood, a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren, to rest and abide under the protection of the king, for his princely delight; bounded with unremoveable marks and meres, either known by matter of record or prescription; replenished with wild beasts of venery or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of such antiquity in England, that, excepting the New Forest in Hampshire, erected by William the Conqueror, and Hampton Court, erected by Henry VIII. it is said, that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers and in several of our laws and statutes. Ancient historians tell us, "that New forest was raised by the destruction of 22 parish churches, and many villages, chapels, and manors, for the space of 30 miles together, which was attended with divers judgments on the posterity of William I. who erected it: for William Rufus was there shot with an arrow, and before him Richard the brother of Henry I.; and Henry nephew to Robert, the eldest son of the Conqueror, did hang by the hair of the head in the boughs of the forest, like unto Absalom." *Blount.*

Besides the New forest, there are 68 other forests in England, 13 chases, and more than 700 parks: the four principal forests are New forest on the sea, Shire-

Forest. wood forest on the Trent, Dean forest on the Severn, and Windsor forest on the Thames.

A forest in the hands of a subject is properly the same thing with a CHASE; being subject to the common law, and not to the forest laws. But a chase differs from a forest in that it is not enclosed: and likewise, that a man may have a chase in another man's ground as well as his own; being indeed the liberty of keeping beasts of chase, or royal game therein, protected even from the owner of the land, with a power of hunting them thereon. See PARK.

The manner of erecting a forest is thus: Certain commissioners are appointed under the great seal, who view the ground intended for a forest, and fence it round; this commission being returned into chancery, the king causeth it to be proclaimed throughout the country where the land lieth, that it is a forest; and prohibits all persons from hunting there, without his leave. Though the king may erect a forest on his own ground and waste, he may not do it on the ground of other persons without their consent; and agreements with them for that purpose ought to be confirmed by parliament.

A forest, strictly taken, cannot be in the hands of any but the king; for no person but the king has power to grant a commission to be justice in eyre of the forest: yet, if he grants a forest to a subject, and that on request made in the chancery, that subject and his heirs shall have justices of the forest, in which case the subject has a forest in law.

A second property of a forest is, the courts thereof. See *FOREST Courts, infra.*

A third property is the officers belonging to it, as the justices, warden, verderer, forester, agistor, regarder, keeper, bailiff, beadle, &c. See the articles AGISTOR, BAILIFF, FORESTER, &c.

By the laws of the forest, the receivers of trespasses in hunting, or killing of the deer, if they know them to be the king's property, are principal trespassers. Likewise, if a trespass be committed in a forest, and the trespasser dies, after his death it may be punished in the lifetime of the heir, contrary to common law. Our Norman kings punished such as killed deer in any of their forests with great severity; also in various manners; as by hanging, loss of limbs, gelding, and putting out eyes. By *magna charta de foresta*, it is ordained, that no person shall lose life or member for killing the king's deer in forests, but shall be fined; and if the offender has nothing to pay the fine, he shall be imprisoned a year and a day, and then be delivered, if he can give security not to offend for the future, &c. 9 Hen. III. c. 1.

Before this statute, it was felony to hunt the king's deer; and by a late act, persons armed and disguised, appearing in any forest, &c. if they hunt, kill, or steal any deer, &c. are guilty of felony. 9 Geo. I. c. 22.

He who has any license to hunt in a forest or chase, &c. is to take care that he does not exceed his authority; otherwise he shall be deemed a trespasser from the beginning, and be punished for that fact, as if he had no license. See further, the articles GAME, and *Game-Law.*

Beasts of the forest are, the hart, hind, buck, doe, boar, wolf, fox, hare, &c. The seasons for hunting whereof are as follow, viz. that of the hart and buck begins at the feast of St John Baptist, and ends at Holy-rood-day; of the hind and doe, begins at Holy rood, and continues till Candlemas; of the boar, from Christmas to Candlemas; of the fox, begins at Christmas, and continues till Lady-day; of the hare at Michaelmas, and lasts till Candlemas.

Forest. *FOREST-courts*, courts instituted for the government of the king's forests in different parts of the kingdom, and for the punishment of all injuries done to the king's deer or venison, to the vert or greensward, and to the covert in which such deer are lodged. These are the courts of ATTACHMENTS, of REGARD, of SWEINMOTE, and of JUSTICE-SEAT. 1. The court of attachments, woodmote, or forty days court, is to be held before the verderers of the forest once in every forty days; and is instituted to inquire into all offenders against vert and venison: who may be attached by their bodies, if taken with the mainour (or *mainœuvre, à manu*) that is, in the very act of killing venison, or stealing wood, or in the preparing so to do, or by fresh and immediate pursuit after the act is done; else they must be attached by their goods. And in this forty-days court the foresters or keepers are to bring in their attachments, or presentments *de viridi et venatione*; and the verderers are to receive the same, and to enrol them, and to certify them nnder their seals to the court of justice-seat or sweinmote: for this court can only inquire of, but not convict, offenders. 2. The court of regard, or survey of dogs, is to be holden every third year for the lawing or expeditation of mastiffs; which is done by cutting off the claws of the fore feet, to prevent them from running after deer. No other dogs but mastiffs are to be thus lawed or expeditated, for none other were permitted to be kept within the precincts of the forest; it being supposed that the keeping of these, and these only, was necessary for the defence of a man's house. 3. The court of sweinmote is to be holden before the verderers, as judges, by the steward of the sweinmote, thrice in every year; the sweins or freeholders within the forest composing the jury. The principal jurisdiction of this court is, first, to inquire into the oppressions and grievances committed by the officers of the forest; "*de super-oneratione forestariorum, et aliorúm ministrorum forestæ; et de eorum oppressionibus populo regis illatis;*" and, secondly to receive and try presentments certified from the conrt of attachments against offences in vert and venison. And this court may not only inquire, but convict also; which conviction shall be certified to the court of justice-seat under the seals of the jury, for this court cannot proceed to judgment. But the principal court is, 4. The court of justice-seat, which is held before the chief justice in eyre, or chief itinerant judge, *capitalis justiciarius in itinere*, or his deputy; to hear and determine all trespasses within the forest, and all claimes of franchises, liberties, and privileges, and all pleas and causes whatsoever therein arising. It may also proceed to try presentments in the inferior courts of the forests, and to give judgment upon conviction of the sweinmote. And the chief justice may therefore, after presentment made or indictment found, but not before, issue his warrant to the officers of the forest to apprehend the offenders. It may be held every third year; and 40 days notice ought to be given of its sitting. This court may

may fine and imprison for offences within the forest, it being a court of record: and therefore a writ of error lies from hence to the court of king's bench, to rectify and redress any mal-administrations of justice; or the chief justice in eyre may adjourn any matter of law into the court of king's bench.

Forest-Laws, are peculiar laws, different from the common law of England. Before the making of *Charta de Foresta*, in the time of King John and his son Henry III. confirmed in parliament by 9 Henry III. offences committed therein were punished at the pleasure of the king in the severest manner. By this charter, many forests were disafforested and stripped of their oppressive privileges, and regulations were made for the government of those that remained; particularly, killing the king's deer was made no longer a capital offence, but only punished by fine, imprisonment, or abjuration of the realm: yet even in the charter there were some grievous articles, which the clemency of later princes has since by statute thought fit to alter *per assisas forestæ*. And to this day, in trespasses relating to the forest, *voluntas reputabitur pro facto*; so that if a man be taken hunting a deer, he may be arrested as if he had taken a deer.

Forest Towns, in *Geography*, certain towns of Suabia in Germany, lying along the Rhine, and the confines of Switzerland, and subject to the house of Austria. Their names are *Rhinefield*, *Seckingen*, *Laufenburg*, and *Waldshut*.

FORE-STAFF, an instrument used at sea for taking the altitudes of heavenly bodies. The fore-staff, called also *cross-staff*, takes its denomination hence, that the observer, in using it, turns his face towards the object; in opposition to the back-staff, where he turns his back to the object.

The fore or cross-staff, consists of a straight square staff, graduated like a line of tangents, and four crosses or vanes, which slide on it. The first and shortest of these vanes, is called the *ten cross*, or *vane*, and belongs to that side of the instrument on which the divisions begin at three degrees and end at ten. The next longer vane, is called the *thirty cross*, belonging to that side of the staff in which the divisions begin at ten degrees and end at thirty, called the *thirty scale*. The next vane is called the *sixty cross*, and belongs to the side where the divisions begin at twenty degrees and end at sixty. The last and longest, called the *ninety cross*, belongs to the side where the divisions begin at thirty degrees and end at ninety.

The use of this instrument is to take the height of the sun and stars, or the distance of two stars: and the ten, thirty, sixty, or ninety crosses, are to be used according as the altitude is greater or less; that is, if the altitude be less than ten degrees, the ten cross is to be used; if above ten, but less than thirty, the thirty cross is to be used, &c. *Note*, For altitudes greater than thirty degrees, this instrument is not so convenient as a quadrant or semicircle.

To observe an Altitude by this instrument.—Apply the flat end of the staff to your eye, and look at the upper end of the cross for the centre of the sun or star, and at the lower end for the horizon. If you see the sky instead of the horizon, slide the cross a little nearer the eye; and if you see the sea instead of the horizon, slide the cross farther from the eye; and thus continue moving till you see exactly the sun or star's centre by the top of the cross, and the horizon by the bottom thereof. Then the degrees and minutes, cut by the inner edge of the cross upon the side of the staff peculiar to the cross you use, give the altitude of the sun or star.

If it be the meridian altitude you want, continue your observation as long as you find the altitude increase, still moving the cross nearer to the eye. By substracting the meridian altitude thus found from 90 degrees, you will have the zenith distance. To work accurately, an allowance must be made for the height of the eye above the surface of the sea, viz. for one English foot, 1 minute; for 5 feet, $2\frac{1}{4}$; for 10 feet $3\frac{1}{2}$; for 20 feet, 5; for 40 feet, 7, &c. These minutes subtracted from the altitude observed, and added to the zenith distance observed, give the true altitude and zenith distance.

To observe the distance of two stars, or the moon's distance from a star, by the fore-staff.—Apply the instrument to the eye, and looking to both ends of the cross, move it nearer or farther from the eye till you see the two stars, the one on the one end, and the other on the other end of the cross; then the degrees and minutes cut by the cross on the side proper to the vane in use give the stars distance.

FORESTALLER, a person who is guilty of forestalling. See the next article.

FORESTALLING, in *Law*, buying or bargaining for any corn, cattle, victuals, or merchandise, in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

The punishment for this offence, upon conviction at the quarter sessions by two or more witnesses, is, for the first time, two months imprisonment and the loss of the goods, or the value; for the second offence the offender shall be imprisoned six months, and lose double the value of the goods: for the third offence he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattels, and stand on the pillory: but the statute does not extend to maltsters buying barley, or to badgers licensed.

FORESTER, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest at all hours, and watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

If a man comes into a forest in the night, a forester cannot lawfully beat him before he makes some resistance; but in case such a person resists the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. do kill a person that opposes them, it is murder in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

FORETHOUGHT FELONY, in *Scots Law*, signifies premeditated murder. See MURDER.

FORFAR, a town of Scotland, and capital of the county of that name, situated in N. Lat. 56. 37. W. Long. 2. 55. This town, with Dundee, Cupar, Perth, and St Andrew's, jointly send one member to the British parliament. It stands in the great valley of Strathmore that runs from Perth north-east to the sea, almost in a straight line, about 50 miles long and betwixt four and five miles broad, bounded on the south side by gentle hills, and on the north by the Grampian mountains.

Forfar is a very ancient town, and was once a royal residence. Here Malcolm Canmore held his first parliament in 1057. The ruins of his palace are still to be seen on the top of an artificial mount of a circular form, resting upon a base of about three acres of ground, and rising 50 feet high above the plain. The lake of Forfar, stretching two miles in length from east to west, and half a mile in breadth, and covering the palace on the north, afforded not only a plentiful supply of water for every purpose, but also added to the strength of the place. This lake, which abounds with trout, pike, perch, and eel, has been greatly reduced by draining; and fine marl has been found in strata from two to six and eight feet deep, with moss below ten feet deep.

Within this lake were formerly two islands raised by art, with buildings on each; to which Margaret, Malcolm Canmore's queen, retired after the decease of her husband. Part of the ruins of these edifices are still to be seen.

Little is known of Forfar till the middle of the 17th century, except an act passed in the 13th parliament of James VI. 21st July, 1593, in the following words, which affords a specimen of the manners and language of the times: "Our soveraine Lorde, understanding that be acte and ordinance maid anent observation of the Sabbath daie within this realme, the mercatte-daie of the burgh of Forfare, being the head burgh of the schire, quhilk was Sundaie, is taken from them; and his hienesse not willing that they in onie waies suld be prejudged hereby, therefore his hienesse, with advise of the estaites of this present parliament, alteris and changis their said mercatte-daie from Sundaie to Fridaie, and willis the samen Fridaie oukly to be their mercatte-daie to them in all times hereafter; and the samin to stande with the like priveleges and freedomes as the Sundaie did of before." The market day has been long held on Saturday.

During the usurpation of Oliver Cromwell, a detachment of his forces, after sacking Dundee, came to Forfar and burnt all the public records of the place; and the only charter the town now has is one granted by Charles II. after his restoration, confirming all its ancient rights and privileges.

As an evidence of the ignorance and barbarity of the times, it appears from the records of the trials kept in the charter-chest of Forfar, that nine persons were condemned and burnt here for witchcraft betwixt the years 1650 and 1662. These innocent people were all tried by a special commission from the lords of the privy council at Edinburgh; and although the commission expressly discharged torturing them on purpose to extort a confession of their guilt, yet, as it was then thought meritorious to obtain confession of guilt by whatever means, many inhuman cruelties were exercised upon the unfortunate objects; particularly, an iron boot was drawn upon one of their legs, and a wedge driven with great force between it and the leg. Another instrument, still carefully preserved here, was likewise used, and is called the *witch bridle*. It is made of iron in the shape of a dog's collar, with two pikes on the inside, about four inches distant and two and a half long. These pikes were put into the mouth, and the collar afterwards buckled strait on the back of the head, to which was affixed an iron chain, whereby the condemned persons were led to the place of execution called the *Play field*, about a quarter of a mile to the northward of the town.

The streets of Forfar are rather irregular; but many of the houses are neat and well built. Osnaburgs and coarse linens are manufactured here; and many of the inhabitants are employed in making a coarse kind of shoes. Population 5652 in 1811.

Forfar-Shire, a county of Scotland, of which Forfar is the capital. Including Angus, Glenisla, Glenesk, and Glenprossin, it extends between 40 and 50 miles from east to west, and 16 where broadest, though in some places the breadth does not exceed five miles. On the north it is divided from the Brae of Mar by a ridge of the Binchinnan mountains; it is bounded on the south by the frith of Tay and the British ocean, on the east by Mearns, and on the west by Perthshire. Part of the Grampian mountains runs through this county, which is agreeably diversified with hill and dale. It produces some lead and iron, together with freestone, slate, and limestone. Coarse linens and sail cloth are the chief manufactures of the county. It is well watered with lakes, rivers, rivulets, and fountains, shaded with large forests, roughened with brown mountains, and waved with green hills interspersed with fields and meadows, and adorned with fine seats and plantations. Their heaths and woods abound with hart, hind, roebuck, and moor game; their streams are stocked with trout and salmon. Their hills are covered with flocks of sheep, and their fields afford plentiful harvests of wheat and all sorts of grain. The mountains to the west and north are inhabited by Highlanders: but the Lowlanders possess the towns and champaign country, and are remarkable for their politeness and hospitality.

The population of this county in 1811 amounted to 107,264. But in the following table is exhibited a view of its population, at two different periods.

	Parishes.	Population in 1755.	Population in 1790—1798.

See Forfarshire, Supplement.

FORFEITURE, originally signifies a transgression or offence against some penal law. The word is formed of the base Latin *forisfactura;* whence *forfaitura* and *forfaictura*, and the French *forfait*. *Forisfactura* comes of *forisfacere;* which, according to Isidore, signifies to "hurt or offend," *facere contra rationem;* and which is not improbably derived of *foris*, "out," and *facere*, "to do," q. d. an action out of rule or contrary to the rules. Borel will have *forfait* derived from the using of force or violence: Lobineau, in his glossary, will have *forisfacta* properly to signify a mulct or amend, not a *forfeit;* which latter he derives from the Bas-Breton *forfed*, "a penalty."

But, with us, it is now more frequently used for the effect of such transgression; or the losing some right, privilege, estate, honour, office, or effects, in consequence thereof; than for the transgression itself.

Forfeiture differs from *confiscation*, in that the former is more general; while confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods confiscated are said to be such as nobody claims.

Forfeitures may be either in *civil* or *criminal* cases.

I. With respect to the first, a man that hath an

2

Forfeiture.

estate for life or years, may forfeit it many ways, as well as by reason of felony; such as alienation, claiming a greater estate than he hath, or affirming the reversion to be in a stranger, &c. When a tenant in tail makes leases not warranted by the statute; a copyholder commits waste, refuses to pay his rent, or do suit of court; and where an estate is granted upon condition, or non-performance thereof, &c. they will make a forfeiture.

Entry for a forfeiture ought to be by him who is next in reversion, or remainder, after the estate forfeited. As if a tenant for life or years commits a forfeiture, he who has the immediate reversion or remainder ought to enter, though he has the fee, or only an estate-tail.

II. Forfeiture in criminal cases is twofold; of real, and personal estates.

1. As to real estates by Attainder in high treason, a man forfeits to the king all his lands and tenements of inheritance, whether fee-simple or fee-tail; and all his rights of entry on lands and tenements, which he had at the time of the offence committed, or at any time afterwards, to be for ever vested in the crown; and also the profits of all lands and tenements, which he had in his own right for life or years, so long as such interest shall subsist. This forfeiture relates backwards to the time of the treason committed; so as to avoid all intermediate sales and encumbrances, but not those before the fact: and therefore a wife's jointure is not forfeitable for the treason of her husband; because settled upon her previous to the treason committed. But her dower is forfeited, by the express provision of statute 5 and 6 Edw. VI. c. 11. And yet the husband shall be tenant by courtesy of the wife's lands, if the wife be attainted of treason; for that is not prohibited by the statute. But, though after attainder the forfeiture relates back to the time of the treason committed, yet it does not take effect unless an attainder be had, of which it is one of the fruits; and therefore, if a traitor dies before judgment pronounced, or is killed in open rebellion, or is hanged by martial law, it works no forfeiture of his lands: for he never was attainted of treason. But if the chief justice of the king's bench (the supreme coroner of all England) in person upon the view of the body of him killed in open rebellion, records it and returns the record into his own court, both lands and goods shall be forfeited.

Blackst. Comment.

The natural justice of the forfeiture or confiscation of property, for treason, is founded on this consideration: That he who hath thus violated the fundamental principles of government, and broken his part of the original contract between king and people, hath abandoned his connexions with society, and hath no longer any right to those advantages which before belonged to him purely as a member of the community; among which *social* advantages, the right of transferring or transmitting property to others is one of the chief. Such forfeitures, moreover, whereby his posterity must suffer as well as himself, will help to restrain a man, not only by the sense of his duty, and dread of personal punishment, but also by his passions and natural affections; and will interest every dependent and relation he has to keep him from offending: according to that beautiful sentiment of Cicero, "*nec vero me fugit quam sit acerbum, parentum scelera filiorum pœnis lui; sed hoc*

præclare

Forfeiture. *præclare legibus comparatum est, ut caritas liberorum amiciores parentes reipublicæ redderet.*" And therefore Aulus Cascellius, a Roman lawyer in the time of the triumvirate, used to boast that he had two reasons for despising the power of the tyrants, his old age and his want of children; for children are pledges to the prince of the father's obedience. Yet many nations have thought, that this posthumous punishment savours of hardship to the innocent; especially for crimes that do not strike at the very root and foundation of society, as treason against the government expressly does. And therefore, though confiscations were very frequent in the times of the earlier emperors, yet Arcadius and Honorius, in every other instance but that of treason, thought it more just, *ibi esse pœnam, ubi et noxa est;* and ordered, that "*peccata suos teneant auctores, nec ulterius progrediatur metus, quam reperiatur delictum;*" and Justinian also made a law to restrain the punishment of relations; which directs the forfeiture to go, except in the case of *crimen majestatis*, to the next of kin to the delinquent. On the other hand, the Macedonian laws extended even the capital punishment of treason, not only to the children, but to all the relations of the delinquent; and of course their estates must be also forfeited, as no man was left to inherit them. And in Germany, by the famous golden bull (copied almost *verbatim* from Justinian's code), the lives of the sons of such as conspire to kill an elector are spared, as it is expressed, by the emperor's *particular bounty*. But they are deprived of all their effects and rights of succession, and are rendered incapable of any honour ecclesiastical and civil: to the end, that being always poor and necessitous, they may for ever be accompanied by the infamy of their father; may languish in continual indigence; and may find (says this merciless edict) their punishment in living, and their relief in dying."

In England, forfeiture of lands and tenements to the crown for treason is by no means derived from the feodal policy, but was antecedent to the establishment of that system in this island; being transmitted from our Saxon ancestors, and forming a part of the ancient Scandinavian constitution. But in certain treasons relating to the coin (which seem rather a species of the *crimen falsi* than the *crimen læsæ majestatis*), it is provided by some of the modern statutes which constitute the offence, that it shall work no forfeiture of lands, save only for the life of the offenders; and by all, that it shall not deprive the wife of her dower. And, in order to abolish such hereditary punishment entirely, it was enacted by statute 7 Ann. c. 21. that, after the decease of the late pretender, no attainder for treason shall extend to the disinheriting of any heir, nor to the prejudice of any person, other than the traitor himself. By which the law of forfeitures for high treason would by this time have been at an end, had not a subsequent statute intervened to give them a longer duration. The history of this matter is somewhat singular, and worthy of observation. At the time of the union, the crime of treason in Scotland was, by the Scots law, in many respects different from that of treason in England; and particularly in its consequence of forfeitures of entailed estates, which was more peculiarly English; yet it seemed necessary, that a crime so nearly affecting government should, both in its essence and consequences, be put upon the same footing in both parts of the united kingdoms. In new modelling these laws, the Scots nation and the English house of commons struggled hard, partly to maintain, and partly to acquire, a total immunity from forfeiture and corruption of blood; which the house of lords as firmly resisted. At length a compromise was agreed to, which is established by this statute, viz. that the same crimes, and no other, should be treason in Scotland that are so in England; and that the English forfeitures and corruption of blood should take place in Scotland till the death of the then pretender, and then cease throughout the whole of Great Britain: the lords artfully proposing this temporary clause, in hopes (it is said) that the prudence of succeeding parliaments would make it perpetual. This has partly been done by the statute 17 Geo. II. c. 39. made in the year preceding the late rebellion, the operation of these indemnifying clauses being thereby still farther suspended till the death of the sons of the pretender.

In petit treason and felony, the offender also forfeits all his chattel interests absolutely, and the profits of all freehold estates during life; and after his death all his lands and tenements in fee simple (but not those in tail) to the crown, for a very short period of time: for the king shall have them for a year and a day, and may commit therein what waste he pleases; which is called the king's *year*, *day*, and *waste*. Formerly the king had only a liberty of committing waste on the lands of felons, by pulling down their houses, extirpating their gardens, ploughing their meadows, and cutting down their woods. And a punishment of a similar spirit appears to have obtained in the oriental countries, from the decrees of Nebuchadnezzar and Cyrus in the books of Daniel and Ezra; which, besides the pain of death inflicted on the delinquents there specified, ordain, "that their houses shall be made a dunghill." But this tending greatly to the prejudice of the public, it was agreed in the reign of Henry I. of England, that the king should have the profits of the land for one year and a day in lieu of the destruction he was otherwise at liberty to commit: and therefore *magna charta* provides, that the king shall only hold such lands for a year and a day, and then restore them to the lord of the fee, without any mention made of waste. But the statute 17 Edward II. *de prerogativa regis*, seems to suppose, that the king shall have his year, day, *and* waste; and not the year and day *instead* of waste: which Sir Edward Coke (and the author of the Mirror before him) very justly look upon as an encroachment, though a very ancient one, of the royal prerogative. This year, day, and waste, are now usually compounded for; but otherwise they regularly belong to the crown: and after their expiration the land would naturally have descended to the heir (as in gavelkind tenure it still does) did not its feudal quality intercept such descent, and give it by way of escheat to the lord. These forfeitures for felony do also arise only upon attainder; and therefore a *felo de se* forfeits no lands of inheritance or freehold, for he never is attainted as a felon. They likewise relate back to the time the offence was committed as well as forfeitures for treason, so as to avoid all intermediate charges and conveyances. This may be hard upon such as have unwarily engaged with the offender; but the cruelty and reproach must lie on the part, not of the law, but of of the criminal: who has thus knowingly and dishonestly involved others in his own calamities.

2. The forfeiture of goods and chattels accrues in every one of the high kinds of offence; in high treason, or misprision thereof, petit treason, felonies of all sorts whether clergyable or not, self murder or felony *de se*, petty larceny, standing mute, &c. For flight, also, on an accusation of treason, felony, or even petit larceny, whether the party be found guilty or acquitted, if the jury find the flight, the party shall forfeit his goods and chattels: for the very flight is an offence, carrying with it a strong presumption of guilt, and is at least an endeavour to elude and to stifle the course of justice prescribed by the law. But the jury very seldom find the flight: forfeiture being looked upon, since the vast increase of personal property of late years, as too large a penalty for an offence to which a man is prompted by the natural love of liberty.

There is a remarkable difference between the forfeiture of lands and of goods and chattels. (1.) Lands are forfeited upon *attainder*, and not before; goods and chattels are forfeited by *conviction*. Because in many of the cases where goods are forfeited, there is never any attainder; which happens only where judgment of death or outlawry is given: therefore, in those cases, the forfeiture must be upon conviction or not at all; and, being necessarily upon conviction in those, it is so ordered in all other cases, for the law loves uniformity. (2.) The forfeiture of lands has relation to the time the fact was committed, so as to avoid all subsequent sales and encumbrances: but the forfeiture of goods and chattels has no relation backwards; so that those only which a man has at the time of conviction shall be forfeited. Therefore a traitor or felon may *bona fide* sell any of his chattels, real or personal, for the sustenance of himself and family between the fact and conviction; for personal property is of so fluctuating a nature, that it passes through many hands in a short time; and no buyer could be safe, if he were liable to return the goods which he had fairly bought, provided any of the prior venders had committed a treason or felony. Yet if they be collusively and not *bona fide* parted with, merely to defraud the crown, the law (and particularly the statute 13 Eliz. c. 5.) will reach them; for they are all the while truly and substantially the goods of the offender: and as he, if acquitted, might recover them himself, as not parted with for a good consideration; so, in case he happens to be convicted, the law will recover them for the king.

FORFEX, in Roman antiquity, was a way of drawing up an army in the form of a pair of sheers. It was intended to receive the *cuneus* or wedge, if the enemy should make use of that figure. For when the forfex opened to admit the wedge, they had an opportunity of defeating their design, and cutting them in pieces.

FORFICULA, the EARWIG, a genus of insects belonging to the order of coleoptera. See ENTOMOLOGY *Index*.

FORGE, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red hot, in order to soften them and render them more malleable and manageable on the anvil.

An ordinary forge is nothing but a pair of bellows, the nozzle of which is directed upon a smooth area,

on which coals are placed. The nozzle of a pair of bellows may be also directed to the bottom of any furnace, to excite the combustion of the coals placed there, by which a kind of forge is formed. In laboratories, there is generally a small furnace consisting of one cylindrical piece, open at top, which has at its lower side a hole for receiving the nozzle of a double bellows. This kind of forge furnace is very convenient for fusions, as the operation is quickly performed, and with few coals. In its lower part, two inches above the hole for receiving the nozzle of the bellows, may be placed an iron plate of the same diameter, supported upon two horizontal bars, and pierced near its circumference with four holes diametrically opposite to each other. By this disposition, the wind of the bellows, pushed forcibly under this plate, enters at these four holes; and thus the heat of the fire is equally distributed, and the crucible in the furnace is equally surrounded by it. This contrivance is used in the forge-furnaces for melting copper, with this difference only, that these furnaces are square, which is a matter of no consequence.

As the wind of bellows strongly and rapidly excites the action of the fire, a forge is very convenient when a great heat is to be applied quickly: but it is not suitable when the heat is to be gradually increased.

The forge, or blast of bellows, is used in several operations in small; as to fuse salts, metals, ores, &c. It is also much used in works in the great, which require strong heat, without much management; and chiefly in the smelting of ores, and fusion of metallic matters.

FORGE is also used for a large furnace, wherein iron ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGE, in the train of artillery, is generally called a *travelling forge*, and may not be improperly called a portable smith's shop: at this forge all manner of smith's work is made, and it can be used upon a march as well as in camp. Formerly they were very ill contrived, with two wheels only, and wooden supporters to prop the forge for working when in the park. Of late years they are made with four wheels, which answers the purpose much better.

FORGE for red-hot Balls, is a place where the balls are made red hot before they are fired off: it is built about five or six feet below the surface of the ground, of strong brick-work, and an iron grate, upon which the balls are laid, with a large fire under them.

FORGER, in *Law*, one guilty of FORGERY.

FORGERY, (from the French *forger*, i. e. *accudare, fabricare*, " to beat on an anvil, forge, or form,") may be defined at common law, to be " the fraudulent making or alteration of a writing, to the prejudice of another man's right:" for which the offender may suffer fine, imprisonment, and pillory. And also, by a variety of statutes, a more severe punishment is inflicted on the offender in many particular cases, which are so multiplied of late as almost to become general. We shall mention the principal instance.

By statute 5 Eliz. c. 14. to forge or make, or knowingly

ingly to publish or give in evidence, any forged deed, court-roll, or will, with intent to affect the right of real property, either freehold or copyhold, is punished by a forfeiture to the party grieved of double costs and damages; by standing in the pillory, and having both his ears cut off, and his nostrils slit and seared; by forfeiture to the crown of the profits of his lands, and by perpetual imprisonment. For any forgery relating to a term of years or annuity, bond, obligation, acquittance, release, or discharge of any debt or demand of any personal chattels, the same forfeiture is given to the party grieved; and on the offender is inflicted the pillory, loss of one of his ears, and half a year's imprisonment: the second offence, in both cases, being felony without benefit of clergy.

Besides this general act, a multitude of others, since the Revolution (when paper credit was first established), have inflicted capital punishment on the forging, altering, or uttering as true when forged, of any bank bills or notes, or other securities; of bills of credit issued from the exchequer; of South Sea bonds, &c; of lottery tickets or orders: of army or navy debentures; of East India bonds; of writings under seal of the London or royal exchange assurance; of the hand of the receiver of the pre-sines, or of the accountant-general and certain other officers of the court of chancery; of a letter of attorney or other power to receive or transfer stock or annuities; and on the personating a proprietor thereof, to receive or transfer such annuities, stock or dividends: also on the personating, or procuring to be personated, any seaman or other person, entitled to wages or other naval emoluments, or any of his personal representatives; and the taking, or procuring to be taken, any false oath in order to obtain a probate or letters of administration, in order to receive such payments; and the forging or procuring to be forged, and likewise the uttering or publishing, as true, of any counterfeited seaman's will or power; to which may be added, though not strictly reducible to this head, the counterfeiting of Mediterranean passes under the hands of the lords of the admiralty, to protect one from the piratical states of Barbary; the forging or imitating of any stamps to defraud the public revenue; and the forging of any marriage register or license: all which are, by distinct acts of parliament, made felonies without benefit of clergy. By statutes 13 Geo. III. c. 52. and 59. forging or counterfeiting any stamp or mark to denote the standard of gold and silver plate, and certain other offences of the like tendency, are punished with transportation for 14 years. By statute 12 Geo. III. c. 48. certain frauds on the stamp-duties, therein described, principally by using the same stamps more than once, are made single felony, and liable to transportation for seven years. And the same punishment is inflicted by statute 13 Geo. III. c. 38. on such as counterfeit the common seal of the corporation for manufacturing plate glass (thereby erected), or knowingly demand money of the company by virtue of any writing under such counterfeit seal.

There are also two other general laws with regaid to forgery; the one 2 Geo. II. c. 25. whereby the first offence in forging or procuring to be forged, acting or assisting therein, or uttering or publishing as true, any forged deed, will, bond, writing obligatory, bill of exchange, promissory note, indorsement or assignment thereof, or any acquittance or receipt for money or goods, with intention to defraud any person (or corporation), is made felony without benefit of clergy. And by statute 7 Geo. II. c. 22. it is equally penal to forge, or cause to be forged, or utter as true, a counterfeit acceptance of a bill of exchange, or the number of any accountable receipt for any note, bill, or any other security for money, or any warrant or order for the payment of money or delivery of goods. So that, through the number of these general and special provisions, there is now hardly a case possible to be conceived, wherein forgery, that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime.

FORGING, in *Law*, the act of FORGERY.

FORGING, in smithery, the heating or hammering iron on an anvil, after having first made it red hot in the forge, in order to extend it into various forms, and fashion it into various works.

There are two ways of forging and hammering iron. One is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron chains fastened to the ceiling of the forge. See MILL.

This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it when it will not batter under the hammer; and if it be too hot, it will red sear, that is, break or crack under the hammer.

The several degrees of heat the smiths give their iron, are, first, a blood-red heat; secondly, a white-flame heat; and thirdly, a sparkling or welding heat.

FORISFAMILIATION, in *Law*, When a child, upon receiving a portion from his father, or otherwise, renounces his legal title to any further share of his father's succession, he is said to be *forisfamiliated*.

FORK, a well known instrument, consisting of a handle and blade, divided at the end into two or more points or prongs.

The *pitch-fork* is a large utensil of this construction employed in hay-making, &c.

The *table-fork*, an instrument now so indispensable, did not come into use in England till the reign of James I. as we learn from a remarkable passage in Coryat. The reader will probably smile at the solemn manner in which this important discovery or innovation is related: "Here I will mention a thing that might have been spoken of before in discourse of the first Italian townes. I observed a custom in all those Italian cities and townes through the which I passed, that is not used in any other country that I saw in my travels, neither do I thinke that any other nation of Christen-

dome

Fork || Form.

dome doth use it, but only Italy. The Italians and also most strangers that are commorant in Italy, doe always at their meals use a little forke when they eat their meate; for while with their knife which they hold in one hand they cut the meate out of the dish, they fasten the forke which they hold in the other hand upon the same dish, so that whatsoever he be that sitting in the company of any others at meale shall unadvisedly touch the dish of meat with his fingers from which all the table doe cut, he will give occasion of offence unto the company as having transgressed the lawes of good manners, insomuch that for his error he shall be at least brow-beaten if not reprehended in wordes. This form of feeding I understand is generally used in all parts of Italy, their forkes for the most part being made of yronn, steele, and some of silver, but those are used only by gentlemen. The reason of this their curiosity is, because the Italian cannot by any means indure to have his dish touched with fingers, seeing all men's fingers are not alike cleane. Hereupon I myself thought good to imitate the Italian fashion by this forked cutting of meate, not only while I was in Italy, but also in Germany, and often times in England since I came home: being once qnipped for that frequently using my forke, by a certain learned gentleman, a familiar friend of mine, Mr Lawrence Whitaker; who in his merry humour doubted not to call me a table *furcifer*, only for using a forke at feeding, but for no other cause."

FORLI, an ancient and considerable town of Italy, and capital of a territory of the same name, in Romagna, with a bishop's see. The public structures are very handsome; and it is seated in a fertile, healthy, and pleasant country, 10 miles south-east of Faenza, and 45 north-east of Florence. E. Long. 12. 1. N. Lat. 44. 28.

FORLORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or at a siege, to storm the counterscarp, mount the breach, or the like. They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

FORM, in *Physics*, denotes the manner of being peculiar to each body; or that which constitutes it such a particular body, and distinguishes it from every other.

Mr Harris uses the term *form* likewise in another sense, as an efficient animating principle; to which he supposes Ovid to refer in the first lines of his Metamorphoses.

> *In nova fert animus mutatas dicere* formas,
> *Corpora.*———

These animating forms are of themselves no objects either of the ear or of the eye; but their nature or character is understood in this, that were they never to exert their proper energies on their proper subjects, the marble on which the sculptor exercises his art would remain for ever shapeless, and the harp from which the harper calls forth sounds would remain for ever silent.

Thus also, the animating form of a natural body is neither its organization nor its figure, nor any other of those inferior forms which make up the system of its visible qualities: but it is the power, which is yet able to produce, preserve, and employ these. It is the power, which first moves, and then conducts that latent process, by which the acorn becomes an oak, and the embryo becomes a man; by which digestion is performed in plants and animals, and, which departing, the body ceases to live, and its members putrefy: and by which every being produces another like itself, and every species is continued. In animals, it is that higher faculty, which, by employing the organs of sense, peculiar to them as animals, distinguishes them as sensitive beings from vegetables; and it is also that more noble faculty, which by its own divine vigour, unassisted perhaps with organs, makes and denominates him a being intellective and rational. So that Mr Harris reckons two sorts of forms, those which are passive elements, and those which are efficient causes. And all of them agree in this, that they give to every being its peculiar and distinctive character: and on the whole he concludes, that form appears in part to be an element, and in part an efficient cause, i. e. a cause which associates the constituent elements of natural substances, and which employs them, when associated, according to their various and peculiar characters.

Form.

The philosophers generally allow two principles of bodies: *matter*, as the common basis or substratum of all; and *form*, as that which specifies and distinguishes each; and which added to a quantity of common matter, determines or denominates it this or that; wood, or fire, or ashes, &c.

Substantial forms seem to have been first broached by the followers of Aristotle, who thought matter, under different modes or modifications, not sufficient to constitute different bodies; but that something substantial was necessary to set them at a greater distance: and thus introduced substantial forms, on the footing of souls, which specify and distinguish animals. What led to this erroneous notion were the circumstances of life and death: For observing, that, as soon as the soul was departed out of a man, all motion, respiration, nutrition, &c. immediately ceased, they concluded, that all these functions depended on the soul, and consequently that the soul was the form of the animal body, or that which constituted it such: that the soul was a substance, independent of matter, nobody doubted; and hence the forms of other bodies were concluded equally substantial. But to this it is answered, that though the soul be that by which a man is man, and consequently is the form of the human body, as human; yet it does not follow, that it is properly the form of this body of ours, as it is a body; nor of the several parts thereof, considered as distinct from each other: For those several parts have their proper forms so closely connected with their matter, that it remains inseparable therefrom long after the soul has quitted the body; thus flesh has the form of flesh, bone of bone, &c. long after the soul is removed as well as before. The truth is, the body does not become incapable of performing its accustomed functions because the soul has deserted it; but the soul takes its leave, because the body is not in a condition to perform its functions.

The ancient and modern corpuscular philosophers, therefore, with the Cartesians, exclude the notion of substantial forms; and show, by many arguments, that

 the

the form is only the modus or manner of the body it is inherent in. And as there are only three primary modes of matter, viz. figure, rest, or motion, with two others arising therefrom, viz. magnitude and situation, the form of all bodies they hold to consist therein; and suppose the variations these modes are capable of, sufficient to present all the variety observable in bodies.

Forms are usually distinguished into *essential* and *accidental*.

Essential. Though the five modes above mentioned, generally taken, be adventitious; yet to this or that body, *e. gr.* to fire or water, they are essential: thus it is *accidental* to iron, to have this or that magnitude, figure, or situation, since it might exist in different ones; yet to a knife or hammer, the figure, magnitude, and position of parts, which constitute it a hammer or knife, are essential; and they cannot exist or be conceived without them. Hence it is inferred, that though there be no substantial, there are essential forms, whereby the several species of bodies become what they are, and are distinguished from all others.

Accidental forms, are those really inherent in bodies, but in such manner as that the body may exist in all its perfection without them. Such as whiteness in a wall, heat in water, a figure of a man in wax, &c.

Form is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

Form, in *Law*, the rules established and requisite to be observed in legal proceedings. The formal part of the law, or method of proceeding, cannot be altered but by parliament; for if once these outworks were demolished, there would be an inlet to all manner of innovation in the body of the law itself.

Form, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars, to sit on. Du Cange takes the name to be derived from hence, that the backs of the seats were anciently enriched with figures of painting and sculpture, called in Latin *formæ et typi*. In the life of St William of Roschild, we meet with *forma* as signifying a seat for an ecclesiastic, or religious, in a choir; and in that of St Lupicin, we have formula in the same sense. In the rule of the monastery of St Cæsarea, the man who presides over the choir is called *primiceria, vel formari*.

At schools, the word *form* is frequently applied to what is otherwise termed a *class*. See Class.

Form also denotes the external appearance or surface of a body, or the disposition of its parts as to the length, breadth and thickness.

Form is also used among mechanics, for a sort of mould wherein any thing is fashioned or wrought.

Printer's Form, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every form is enclosed in an iron chess, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages according to the size of the book.

Hatter's Form, is a large block or piece of wood, of a cylindrical figure; the top thereof rounded, and the bottom quite flat. Its use is, to mould or fashion the crown of the hat, after the matter thereof has been beaten and fulled.

Papermaker's Form, is the frame or mould wherein the sheets are fashioned. See Paper.

FORMA pauperis, in *Law*, is when a person has just cause of suit, but is so poor that he cannot defray the usual charges of suing at law or in equity; in which case, on making oath that he is not worth 5l. in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in *forma pauperis;* that is, without paying any fee to counsellors, attorneys, or clerk: the statute 11 Hen. VII. c. 12. having enacted, that counsel and attorneys, &c. shall be assigned to such poor persons *gratis*. Where it appears that any pauper has sold or contracted for the benefit of his suit whilst it is depending in court, such cause shall be thenceforth totally dismissed; and a person suing *in forma pauperis* shall not have a new trial granted him, but is to acquiesce in the judgment of the court.

FORMAL, something belonging to or constituting the form of a thing. See Form.

FORMALITY, the quality of a form, or formula; or that which constitutes and denominates them such.

Formality, as defined in the schools, is any manner wherein a thing is conceived; or a manner in any object, importing a relation for the understanding whereby it may be distinguished from another object. Thus animality and rationality are formalities. The Scottists made great use of formalities, in opposition to the virtualities of the Thomists.

Formalities, in matters of law, are frequently used for the formulas themselves, or the rules prescribed for judiciary proceedings. In contracts of strict law, all the formalities must be strictly observed: an omission of the least formality may ruin the whole convention.

The term is also used for a certain order or decorum to be observed.

FORMAN, Andrew, archbishop of St Andrew's, earl of Pittenweem, and of Cottingham in England, one of the lords of the regency appointed by the states during the minority of King James V. of Scotland, legate à latere, primate of all the kingdom of Scotland, and archbishop of Bourges in France, was descended from the family of the Formans of Hutton in the shire of Berwick, and is considered to have been one of the best statesmen of the age in which he lived. He was employed in 1501, along with Robert Blackader, archbishop of Glasgow, and Patrick earl of Bothwell to negotiate a match between Ja. IV. of Scotland and Margaret eldest daughter of Hen. VII. of England, which next year was ratified by the Scottish ambassadors. He was afterwards frequently employed as Scots ambassador to Rome, England, and France, upon the most important occasions. In 1514, he was translated from the see of Moray, to which he had been appointed in 1502, to that of St Andrews. During the time of his

his possessing the former, he was employed as mediator betwixt Pope Julius II. and Louis XII. of France, who were at that time at variance; and he happily succeeded in conciliating the difference. Having taken leave of the Pope, he passed through France on his return home, where he was kindly received by the king and queen, who bestowed upon him the bishopric of Bourges in France, which annually brought him in 400 tons of wine, 10,000 francs of gold, and other smaller articles. Besides all this, he was most liberally rewarded by Pope Julius, who promoted him to the archbishopric of St Andrew's, as has been already mentioned; conferred on him the two rich abbeys of Dunfermline and Aberbrothic; and made him his legate à latere. At that time, however, there were two other candidates for the archiepiscopal see. The learned Gavin Douglas, bishop of Dunkeld, having been nominated by the queen, had actually taken possession of it; but John Hepburn, a bold and factious man, having been preferred by the monks, drove out the officers of Gavin Douglas, and placed a strong garrison in the castle. So great was the power of this man, that when Forman was nominated by the Pope, no person could be found who durst proclaim the bulls for his election. At last Lord Home, at that time the most powerful nobleman in Scotland, was induced, by large promises, besides some gifts of great consequence, among which was the donation of the abbacy of Coldingham to his youngest brother David, to undertake the task. It was executed at Edinburgh and St Andrew's; to which places Lord Home's brother went with 10,000 men; though the doing of it, contrary to Forman's inclination, proved a source of much trouble to that nobleman afterwards. The quarrel betwixt Hepburn and Forman, however, was at last terminated by the latter surrendering the bishopric of Moray, as well as some years revenue of the archbishopric itself; paying Hepburn also 3000 French crowns annually out of his ecclesiastical revenues. On the appointment of the duke of Albany to the regency, Hepburn endeavoured to undermine the primate's credit with that nobleman, by representing him as one who had in a manner collected all the money in the country, and who consequently might endanger the tranquillity of the kingdom. These insinuations, however, were but little regarded by the regent; and Forman had the good fortune afterwards to make up a difference between him and the nobility, which was likely to be attended with much bloodshed. In 1517, the archbishop was appointed by the states one of the lords of the regency, on occasion of the duke of Albany's going to France. We have already mentioned his embassy to Pope Julius II. In M'Kenzie's Lives we are informed, that in the collection of the Letters of the Scottish Kings from the year 1505 till the year 1626, in the lawyers library, there is a letter from the pope to King James IV. wherein he not only highly commends Forman, but likewise promises that at the first creation of cardinals he should be made one. This letter is dated the 6th of May 1511: but the pope died before he had an opportunity of performing his promise. In the same collection there is a letter from the duke of Albany to Leo X. Julius's successor, wherein he presses the pope to advance him to the dignity of a cardinal promised him by his predecessor, and to continue him his legate à latere. Archbishop Forman died in 1521, and was buried at Dunfermline. Dempster says that he wrote a book against Luther, a book concerning the Stoic Philosophy, and a Collection out of the Decretals.

FORMATION, in *Philosophy*, an act whereby something is formed or produced. For the formation of the fœtus in the womb, see ANATOMY, N° 109, 110.

FORMATION of Stones. See STONE.

FORMATION of Metals and Minerals. See METAL and MINERAL.

FORMATION, in *Grammar*, signifies the manner of forming one word from another; thus *accountantship* is formed from *accountant*, and this last from *account*.

FORMEDON, in *Law*, (breve *de forma donationis*), a writ that lies for a person who has a right to lands or tenements, by virtue of any entail, arising from the statute of Westm. 2. Ch. II.

This writ is of three kinds, viz. a descender, remainder, and reverter. Formedon in *descender*, lies where a tenant in tail infeoffs a stranger, or is disseised and dies, and the heir may bring this writ to recover the lands. Formedon in *remainder*, lies where a man gives lands, &c. to a person in tail, and for the default of issue of his body, the remainder to another in tail: here if the tenant in tail die without issue, and a stranger abates and enters into the land, he in remainder shall have this writ. Formedon in *reverter*, lies where lands are entailed on certain persons and their issue, with remainder over for want of issue; and on that remainder failing, then to revert to the donor and his heirs: in this case, if the tenant in tail dies without issue, and also he in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, though the same be alienated, &c.

FORMIÆ, or FORMIA, in *Ancient Geography*, a maritime town of the Adjected or New Latium, to the south-east of Cajeta; built by the Lacedæmonians, (Strabo); called originally *Hormiæ*, on account of its commodious harbour. An ancient municipium. *Formiani*, the people; who were admitted to the liberty of the city the very year in which Alexandria was built; but not to the right of suffrage till a long time after the second Punic war, (Livy). *Formiæ* at this day lies in ruins, near a place now called *Mola*.

FORMICA, the ANT, a genus of insects belonging to the order of hymenoptera. See ENTOMOLOGY *Index*.

The insects called *white ants*, which abound in Africa and the East Indies, belong to the genus termes, which see in ENTOMOLOGY *Index*.

FORMICA Leo, the *Ant lion*, so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resembling the libellæ or dragon flies; and feeds chiefly upon ants.

FORMING is used for the act of giving being or birth to any thing.

The word is also simply used for giving the figure to any thing. The potter forms his vessels as he pleases. Geometry teaches how to form all kinds of figures.

It is likewise used for the producing of a thing: thus, the lineaments of the face began to be formed.

Forming, Formosa.

Forming of a Siege, is the making lines of circumvallation to fortify the camp, and disposing things for the attack of a place in form.

They also say, to form a squadron or battalion; meaning to range the soldiers in form of a squadron, &c.

Forming the Line, is drawing up infantry, cavalry, and artillery, into line of battle. See Line.

Forming is also used in grammar, in speaking of certain tenses of verbs, which are made from others by a change of certain letters. The present tense is formed from the infinitive. Compound and derivative words also, and even all that have any etymology, are said to be formed.

FORMOSA, an island in the Pacific ocean, between 119° and 122° of E. Long. and 22° and 25° N. Lat. about 100 miles east of Canton in China. It is subject to the Chinese; who, however, notwithstanding its vicinity, did not know of its existence until the year 1430. It is about 85 leagues in length, and 25 in breadth. A long chain of mountains, which runs from north to south, divides it into two parts, the eastern and western. The Dutch formed an establishment in the western part in 1634, and built the fort of Zealand, which secured to them the principal port of the island; but they were driven from thence in 1659 or 1661 by a celebrated Chinese pirate, who made himself master of all the western part, which afterwards submitted in 1682 to the authority of Kang-he emperor of China.

This western part of Formosa is divided into three distinct governments, all subordinate to the governor of Tai-ouan, the capital of the island, who is himself subject to the viceroy of the province of Fokien.

This island presents extensive and fertile plains, watered by a great number of rivulets that fall from the eastern mountains. Its air is pure and wholesome; and the earth produces in abundance, corn, rice, and the greater part of other grains. Most of the Indian fruits are found here, such as oranges, bananas, pine-apples, guavas, papaws, cocoa nuts; and part of those of Europe, particularly peaches, apricots, figs, raisins, chesnuts, pomegranates, water melons, &c. Tobacco, sugar, pepper, camphire, and cinnamon, are also common. Horses, sheep, and goats, are very rare in this island: there are even few hogs, although these animals abound in China. Domestic poultry, such as fowls, geese, and ducks, are exceedingly plenty; pheasants also are sometimes seen; and monkeys and stags have multiplied so much, that they wander through the country in large flocks.

The inhabitants of Formosa rear a great number of oxen, which they use for riding, from a want of horses and mules. They accustom them early to this kind of service, and by daily exercise train them to go as well and as expeditiously as the best horses. These oxen were furnished with a bridle, saddle, and crupper. A Chinese looks as big and proud when mounted in this manner, as if he were carried by the finest Barbary courser.

Wholesome water fit for drinking is the only thing wanting in the island of Formosa. It is very extraordinary, that every kind of water in it is a deadly poison to strangers, for which no remedy has hitherto been found. "One of the governor's servants," says Father de Mailla, "whom I had in my train (a strong and robust man), trusting too much to the force of his constitution, would not believe what had been told him concerning this water: he drank some of it; and died in less than five days, after every medicine and antidote had been administered without success. There is none but the water of the capital which can be drunk: the mandarins of the place therefore always took care to transport a sufficiency of it in carts for our use." Our author adds, that at the bottom of a mountain a league distant from Fong-kan-hien there is a spring that produces a stream, the water of which is of a whitish blue colour, and so noxious, that no one can approach it.

Formosa.

There are few mulberry trees in Formosa, consequently little silk is made in the country. Numerous manufactures, however, would soon be introduced into it, were the Chinese permitted indiscriminately to transport themselves thither, and to form establishments in the island. Those who go to it must be protected by passports from the Chinese mandarins, and these passports are sold at a dear rate; securities are besides required. This is not all: when they arrive, money must be given to the mandarins who are appointed to examine those who enter or quit the island, and who generally discharge this duty with the most rigid severity. If they give no present, or offer only a trifle, they meet with little mercy: and are sure to be sent back, whatever passport they may have. The Chinese, through policy, connive at these exactions, to prevent too great a number of people from emigrating to this island, which is rendered a place of great importance by its proximity to China. They fear, and with great reason (especially since Tartar emperors have been on the throne), that if any revolt should happen in Formosa, its influence might spread and occasion great disturbance in the whole empire. On this account, the Tartars keep a garrison there of 10,000 men: which they take care to change every three years, or even oftener if they judge it necessary.

Besides the capital, the Chinese have also two other cities, and some villages, where they inhabit alone; for they do not permit the Indians, who are their subjects, to live among them; they suffer none to remain but those who are either their slaves or domestics.—These Indians are united into 45 villages; 36 of which lie to the north, and 9 towards the south. The northern villages are very populous, and the houses are built almost after the Chinese manner. The habitations of the southern islanders are only heaps of huts or cottages of earth. In these huts they have neither chairs, benches, tables, beds, nor any piece of furniture; the middle part is occupied by a kind of hearth or chimney, raised two feet high, and constructed of earth, upon which they dress their victuals. Their ordinary food is rice, other small grain, and the game which they catch by coursing or kill with their arms. These islanders run with such surprising swiftnes, that they can almost outstrip the fleetest greyhound. The Chinese attribute this agility to the precaution they take of confining their knees and reins by a close bandage until the age of 14 or 15. Their favourite arms are lances, which they dart to the distance of 60 or 80 feet with the greatest dexterity and precision. They use bows and arrows, and can kill a pheasant on wing with

Formosa

as much certainty as an European sportsman could with a fusee. These people are very dirty in their manner of eating. They have neither plates, dishes, nor spoons, nor even the small sticks used in China. Whatever they dress is placed on a plain board or mat, and they make use of their fingers for conveying it to their mouths. They eat flesh half raw; and provided it has been only presented to the fire, it appears to them excellent. Their beds are formed of fresh gathered leaves. They go almost naked, and wear only a piece of cloth which hangs from their girdle to their knees. Those among them, who, according to the judgment of the chiefs of the village, have borne away the prize for agility in running, or dexterity in the chase, obtain the honourable privilege of making on their skin, by a very painful operation, several fantastical figures of flowers, trees, and animals. All have the right of blackening their teeth, and of wearing ornaments of bracelets and crowns made of shells and crystal.

The islanders who inhabit the northern part, where the climate is somewhat colder, clothe themselves with the skins of the stags which they kill in hunting. They make a kind of dress of them without sleeves, that pretty much resembles a dalmatic, or vestment worn at the altar by the Roman clergy. They wear on their heads caps in the form of a cylinder, made of palm leaves, and ornamented with several crowns placed one above another, on the top of which they fix plumes composed of the feathers of a cock or pheasant.

The marriage ceremonies of the inhabitants of Formosa approach near to the simple laws of nature. They neither purchase, as in China, the women whom they espouse, nor does interest ever preside over their unions. Fathers and mothers are scarcely ever consulted. If a young man has a mind to marry, and has fixed his affection on a young girl, he appears for several days following near the place where she lives with a musical instrument in his hand. If the young woman is satisfied with the figure of her gallant, she comes forth and joins him: they then agree and settle the marriage contract. After this, they give notice to their parents who prepare a wedding dinner, which is always given in the house where the young woman resides, and where the bridegroom remains without returning again to his father. The young man afterwards considers the house of his father-in-law as his own. He becomes the whole support of it, and he has no farther connection with that of his father; like married women in Europe, who generally quit their paternal home in order to live with their husbands. These islanders therefore seldom offer up vows for obtaining male children: they prefer daughters, because they procure them sons-in-law, who become their supports in old age.

Although the Formosans are entirely subjected to the Chinese, they still preserve some remains of their ancient government. Each village chooses three or four old men from among those who have the greatest reputation for probity. By this choice they become the rulers and judges of the rest of the hamlet. They have the power of finally determining all differences; and if any one should refuse to abide by their judgment, he would be immediately banished from the village, without hopes of ever being able to re-enter it, and none of the inhabitants would afterwards dare to receive him.

Formosa.

The natives pay in grain the tribute imposed on them by the Chinese. To regulate every thing that concerns the laying on and collecting of this impost, government has established a Chinese in every village, who is obliged to learn the language and act as interpreter to the mandarins. These interpreters are most cruel extortioners to the miserable people, whom they ought rather to protect: they are such insatiable leeches that they can scarcely ever be satisfied. This daily and domestic tyranny has already caused the defection of three villages in the southern part of the island, where formerly there were twelve. The inhabitants of these villages revolted, expelled their interpreters, refused to pay tribute any longer to the Chinese, and have united themselves to the independent nation in the eastern part of the island.

It was in the island of Formosa that John Struys affirms to have seen with his own eyes a man who had a tail more than a foot in length, covered with red hair, and greatly resembling that of an ox. This man with a tail said, that his deformity, if it was one, proceeded from the climate, and that all those of the southern part of the island were born with tails like his.—But John Struys is the only author who attests the existence of this extraordinary race of men; no other writer who has spoken of Formosa makes the least mention of them. Another circumstance, no less singular, and which appears to be little better authenticated, is, that in this island women are not permitted to bring forth children before they are 35, although they are at liberty to marry long before that age. Rechteren * thus expresses himself concerning this strange custom.

"When women are first married, they bring no children into the world: they must, before that is permitted, have attained the age of 35 or 37. When they are big with child, their priestesses pay them a visit, and tread on their bellies with their feet, if it be necessary, and make them miscarry, with perhaps greater pains than they would have in being brought to bed. It would be not only a shame, but an enormous crime, to bring forth a child before the time prescribed. I have seen some females who had already destroyed the fruit of their womb 15 or 16 times, and who were big for the 17th when it was lawful for them to bring forth a living child."

* *Dutch East Ind. Company Voyages*, vol. v. p. 9.

To our description of Formosa we shall add the following account of a dreadful disaster that befel this unhappy island. The details were conveyed by a letter from Peking, addressed to M. Bertin, and dated the 14th of July 1782.

"The waters of the ocean have well nigh deprived China of one of its most valuable maritime possessions. The island of Tay-ouan, known in Europe by the name of Formosa, has been almost swallowed up by them. It has been reported here, that part of the mountain which divides the island has sunk and disappeared; that the rest has been overturned; and that the greater part of the inhabitants have perished. Such have been for some days the popular reports in this capital. Government, however, has put a stop to them, by informing the public of the real truth; such as it

has

Formosa.

has been announced to the emperor by the officers who have this small portion of his territories under their jurisdiction. I cannot do better than transcribe what they have written. The dispatches of the Chinese officers, addressed to the emperor, run thus:

" Bechen, governor-general of the province of Fokien and Tche-Kyang-ya, viceroy of Fokien, and others, make known to your majesty the disaster that has lately befallen the island of Tay-ouan. Mon-ha-hon, and other principal officers of this island, have acquainted us, that on the 21st of the fourth moon (May 22. 1782), a most furious wind, accompanied with heavy rain and a swell of the sea greater than ever remembered, had kept them under continual apprehension of being swallowed up by the waves, or buried in the bowels of the earth, from the hour of *yn* until the hour *ouei* (A). This dreadful tempest seemed to blow at the same time from the four cardinal points of the compass, and continued with equal violence during the above-mentioned time. The buildings where the tribunals were held, the public granaries, the barracks, salt warehouses, and works, have been totally destroyed, and every thing they contained is lost: warehouses and workshops, as well as private houses, for the most part, present nothing but ruins and heaps of rubbish. Of 27 ships of war which were in the harbour, 12 have disappeared; two others have been dashed to pieces, and 10 are shattered in such a manner that they are rendered entirely unfit for service; other smaller vessels of different sizes, above 100 in number, have shared the same fate; eighty have been swallowed up; five others, which had just taken in a lading of rice for Fokien, have sunk, and their cargoes, which amounted to 100,000 bushels, are wholly lost. With regard to other vessels, whether small or great, which had not entered the harbour, 10 or 12 of the largest are reckoned to have been swallowed up; those of inferior size, as well as a prodigious number of barks, boats, and other small vessels of different kinds, have disappeared, without leaving the least piece of wreck behind them. As the whole island has been covered with water, the provisions have been either swept away, or spoilt so as to render them prejudicial to the health of those who use them in their present state. The crops are entirely lost. When we shall have been informed of particulars, we shall not fail to give your majesty the earliest intelligence of them.—After having received this letter from Mon-ha-hon, and the other principal officers residing at Tay-ouan, I employed the utmost diligence to give every assistance in my power to this unfortunate island; and I ordered the travelling commissary, and Trey-oner, general of the province, to get particular information of the number of those who have perished, of the houses destroyed, and of the quantity of salt and other provisions that has been lost: I have likewise enjoined them to rebuild with the utmost expedition the tribunals, granaries, and other public edifices; to dispatch proper persons to search for the vessels and ships that have disappeared; to repair those which are not altogether unfit for service, and to send immediately to the neighbouring countries for salt and other necessary provisions: but above all, to ascertain in the most accurate manner the different losses sustained by the inhabitants, and the precise number of people that have perished, in order that I may be able to give the fullest information to your majesty."

Formosa, Formula.

' The emperor of China caused a particular detail of these losses to be published, together with the following letter:

" Tchang-yu, &c. Tchem-hoeï-Thon-Tsong-tou of Fokien, and others, have informed me of the dismal event that hath taken place in the island of Tay-ouan, which is a district of the province of Fokien. They have written to me, that on the 21st of the fourth moon—[Here the emperor repeats what is contained in the preceding letter, and continnes thus]. I command Tsong-tou to get the best information he can of the different losses sustained by the inhabitants of the island, and to transmit the particulars to me, in order that I may give them every assistance to repair them. My intention is, that all the honses which have been thrown down shall be rebuilt entirely at my expence; that those be repaired which are only damaged; and that provisions, and every thing which the people stand in immediate want of, be supplied them. I should feel much pain, were even one among them to be neglected: I therefore recommend the utmost diligence and strictest inquiry, as I am desirous that none of my subjects should entertain the least doubt of the tender affection which I have for them; and that they should know that they are all under my eyes, and that I myself will provide for their wants. With regard to my ships of war, tribunals, and public edifices, let them be restored to their former state with money taken from the public treasury, and let the general account of the whole expence be laid before me."

The missionary who sent this account farther says, From these letters it evidently appears, that this disaster happened in consequence of an earthquake; but he adds, that the volcano which occasioned it must be at a prodigious depth below the sea. He does not pretend to give an explanation of it; he is contented with observing, that the same scene seems to have passed on the island of Formosa as at Lima and Lisbon.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in *Church History* and *Theology*, signifies a profession of faith.

FORMULA, in *Medicine*, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence.

FORMULA, a theorem or general rule, or expression, for solving certain particular cases of some problem, &c. so $\frac{1}{2}s+\frac{1}{2}d$ is a general formula for the greater of two

(A) The hours of the Chinese are double ours: the hour *yn* begins at three in the morning, and ends at five; *ouei* begins at three in the afternoon and ends at five.

Formula ‖ Fornication.

two quantities whose sum is s, and difference d; and $\frac{1}{2}s-\frac{1}{2}d$ is the formula, or general value, for the less quantity. Also $\sqrt{dx-x^2}$, is the formula, or general value, of the ordinate to a circle, whose diameter is d, and absciss x.

FORMULARY, a writing, containing the form or formula of an oath, declaration, attestation, or abjuration, &c. to be made on certain occasions.

There are also formularies of devotion, of prayers, &c. Liturgies are formularies of the public service in most churches.

FORNACALIA, or FORNICALIA, in Roman antiquity, a festival instituted by Numa, in honour of Fornax, the goddess of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNICATION (*Fornicatio*, from the *fornices* in Rome, where the lewd women prostituted themselves for money), is whoredom, or the act of incontinency, between single persons; for if either of the parties is married, it is *adultery*. Formerly court leets had power to inquire of and punish fornication and adultery; in which courts the king had a fine assessed on the offenders, as appears by the book of Domesday.

In the year 1650, when the ruling powers found it for their interest to put on the semblance of a very extraordinary strictness and purity of morals, not only incest and wilful adultery were made capital crimes, but also the repeated act of keeping a brothel, or committing fornication, was, upon a second conviction, made felony without benefit of clergy. But, at the Restoration, when men, from an abhorrence of the hypocrisy of the late times, fell into a contrary extreme of licentiousness, it was not thought proper to renew a law of such unfashionable rigour. And these offences have been ever since left to the feeble coercion of the spiritual court, according to the rules of the canon law; a law which has treated the offence of incontinence, nay, even adultery itself, with a great degree of tenderness and lenity; owing perhaps to the constrained celibacy of its first compilers. The temporal courts therefore take no cognizance even of the crime of adultery otherwise than as a private injury. See ADULTERY.

The evils of fornication, which too many wish to consider as no sin, may be judged of from the following particulars.

1. The malignity and moral quality of each crime is not to be estimated by the particular effect of one offence, or of one person's offending, but by the general tendency and consequence of crimes of the same nature. In the present case, let the libertine consider and say, what would be the consequence, if the same licentiousness in which he indulges were universal; or what should hinder its becoming universal, if it be innocent or allowable in him?

2. Fornication supposes prostitution; and by prostitution the victims of it are brought to almost certain misery. It is no small quantity of misery in the aggregate, which, between want, disease, and insult, is suffered by those outcasts of human society who infest populous cities; the whole of which is a general consequence of fornication, and to the increase and continuance of which every act and instance of fornication contributes.

Fornication.

3. Fornication produces habits of ungovernable lewdness, which introduce the more aggravated crimes of seduction, adultery, violation, &c. The criminal indulgences between the sexes prepare an easy admission for every sin that seeks it: they are, in low life, usually the first stage in men's progress to the most desperate villanies; and in high life, to that lamented dissoluteness of principle, which manifests itself in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity.

4. Fornication perpetuates a disease, which may be accounted one of the sorest maladies of human nature, and the effects of which are said to visit the constitution of even distant generations.

The passion being natural, proves that it was intended to be gratified; but under what restrictions, or whether without any, must be collected from different considerations.

In the Scriptures, fornication is absolutely and peremptorily condemned. 'Out of the heart proceed evil thoughts, murders, adulteries, fornication, thefts, false witness, blasphemies; these are the things which defile a man.' These are Christ's own words; and one word from him upon the subject is final. The apostles are more full upon this topic. One well-known passage in the Epistle to the Hebrews may stand in the place of all others; because, admitting the authority by which the apostles of Christ spake and wrote, it is decisive. 'Marriage and the bed undefiled is honourable amongst all men, but whoremongers and adulterers God will judge;' which was a great deal to say, at a time when it was not agreed even amongst philosophers that fornication was a crime.

Upon this subject Mr Paley adds the following observations *.

"The Scriptures give no sanction to those austerities which have been since imposed upon the world under the name of Christ's religion, as the celibacy of the clergy, the praise of perpetual virginity, the *prohibitio concubitus cum gravida uxore*; but with a just knowledge of, and regard to the condition and interest of the human species, have provided in the marriage of one man with one woman an adequate gratification for the propensities of their nature, and have restrained them to that gratification.

"The avowed toleration, and in some countries the licensing, taxing, and regulating of public brothels, has appeared to the people an authorizing of fornication, and has contributed, with other causes, so far to vitiate the public opinion, that there is no practice of which the immorality is so little thought of or acknowledged, although there are few in which it can more plainly be made out. The legislators who have patronized receptacles of prostitution ought to have foreseen this effect, as well as considered, that whatever facilitates fornication, diminishes marriages. And as to the usual apology for this relaxed discipline, the danger of greater enormities if access to prostitutes were too strictly watched and prohibited; it will be time enough to look to that, after the laws and the magistrates have done their utmost. The greatest vigilance of both will do no more, than oppose some bounds and some difficulties to this intercourse. And after all, these pretended fears

* *Moral and Political Philosophy*, p. 246.

fears are without foundation in experience. The men are in all respects the most virtuous in countries where the women are most chaste.

"If fornication be criminal, all those incentives which lead to it are accessaries to the crime: as lascivious conversation, whether expressed in obscene or disguised under modest phrases; also wanton songs, pictures, books; the writing, publishing, and circulating of which, whether out of frolic or for some pitiful profit, is productive of so extensive a mischief from so mean a temptation, that few crimes within the reach of private wickedness have more to answer for, or less to plead in their excuse.

"Indecent conversation, and by parity of reason all the rest, are forbidden by St Paul, Eph. iv. 29. 'Let no corrupt communication proceed out of your mouth;' and again, Col. iii. 8. 'Put filthy communication out of your mouth.'

"The invitation or involuntary admission of impure thoughts, or the suffering them to get possession of the imagination, falls within the same description, and is condemned by Christ, Matt. v. 28. "Whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart.' Christ, by thus enjoining a regulation of the thought, strikes at the root of the evil."

FORNIX, in *Anatomy*, is part of the corpus callosum in the brain; so called, on account of a distant resemblance to the arches of ancient vaults when viewed in a particular manner.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

It is the business of the quartermaster general to appoint the method of forrage, and post proper guards for the security of the forragers.

FORRES, a borough town of Scotland in the county of Murray, classing with Inverness, Fortrose, and Nairn. It is a small well built town, pleasantly situated on an eminence near the river Findhorn, with 2925 inhabitants in 1811. The country about it has a cheerful appearance, having a few gentlemen's seats. On a hill west of the town are the remains of a castle; and a melancholy view of a number of sand-hills, that now cover that tract of land which was formerly the estate of a Mr Cowben in the parish of Dyke. This inundation was occasioned by the influx of the sea and the violence of the wind. It had been the custom to pull up the bent, a long spiry grass near the shore, for litter for horses, by which means the sand was loosened, and gave way to the violence of the sea and wind, which carried it over several thousand acres of land. The people having been prevented from pulling up any more of the grass, the progress of the sand is now nearly stopped, and the sea has retired; but the wind has blown some of the sand from the hills over Colonel Grant's land, and destroyed near 100 acres. A sand bank, which is all dry at low water, runs out from this place for several miles into the Murray Frith. Some of the land, which has been long forsaken by the water, is now beginning to be useful again, and is turned into grazing land. At Forres, coarse linen and sewing thread are made. East from the town, and on the left hand side of the road, is a remarkable obelisk, which is said to be the most stately monument of the kind to be seen in Europe. It has been the subject of many able pens; but totally overlooked by Dr Johnson, who says, "At Forres we found good accommodation, but nothing worthy of particular remark."—It is thus described by Mr Cordiner, in a letter to Mr Pennant: "In the first division, underneath the Gothic ornaments at the top, are nine horses with their riders marching forth in order: in the next is a line of warriors on foot, brandishing their weapons, and appear to be shouting for the battle. The import of the attitudes in the third division is very dubious, their expression indefinite. The figures which form a square in the middle of the column are pretty complex but distinct; four serjeants with their halberts guard a canopy, under which are placed several human heads which have belonged to the dead bodies piled up at the left of the division; one appears in the character of executioner severing the head from another body; behind him are three trumpeters sounding their trumpets, and before him two pair of combatants fighting with sword and target. A troop of horse next appears, put to flight by infantry, whose first line have bows and arrows; the three following, swords and targets. In the lowermost division now visible, the horses seem to be seized by the victorious party, their riders beheaded, and the head of their chief hung in chains or placed in a frame; the others being thrown together beside the dead bodies under an arched cover. The greatest part of the other side of the obelisk, occupied by a sumptuous cross, is covered over with an uniform figure, elaborately raised, and interwoven with great mathematical exactness. Under the cross are two august personages, with some attendants, much obliterated, but evidently in an attitude of reconciliation; and if the monument was erected in memory of the peace concluded between Malcolm and Canute, upon the final retreat of the Danes, these large figures may represent the reconciled monarchs. On the edge below the fretwork are some rows of figures joined hand in hand, which may also imply the new degree of confidence and security which took place, after the feuds were composed, which were characterized on the front of the pillar. But to whatever particular transaction it may allude, it can hardly be imagined, that in so early an age of the arts in Scotland as it must have been raised, so elaborate a performance would have been undertaken but in consequence of an event of the most general importance; it is therefore surprising that no distincter traditions of it arrived at the era when letters were known. The height of this monument (called *King Sueno's Stone*) above the ground is 23 feet: besides 12 or 15 feet under ground. Its breadth is 3 feet 10 inches by one foot 3 inches in thickness."

FORSTER, John Reinhold, a celebrated German naturalist. See Suplement.

Forster, J. G. A. an eminent naturalist, and son of the preceding. See Supplement.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according

cording as the ground requires. Some are fortified with bastions, others with demibastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town.

Royal Fort, is one whose line of defence is at least 26 fathoms long.

Star Fort, is a sconce or redoubt, constituted by re-entering and salient angles, having commonly from five to eight points, and the sides flanking each other.

Vitrified Forts, a very singular kind of structures found in the highlands and northern parts of Scotland, in which the walls have the appearance of being melted into a solid mass, so as to resemble the lava of a volcano, for which indeed they have been taken by several persons who have visited them.

These walls were taken notice of by Mr Williams an engineer, who wrote a treatise upon the subject, and was the first who supposed them to be works of art; other naturalists having attributed them to a volcanic origin. These works are commonly situated on the tops of small hills, commanding an extensive view of the adjacent valley or low country. The area on the summit, varying, as is supposed, according to the number of cattle the proprietor had to protect, or the dependents he was obliged to accommodate, is surrounded with a high and strong wall, of which the stones are melted, most of them entirely; while others, in which the fusion has not been so complete, are sunk in the vitrified matter in such a manner as to be quite enclosed with it; and in some places the fusion has been so perfect, that the ruins appear like masses of coarse glass. Mr Williams has not only absolutely determined the walls in question to be the works of art, but has even hazarded a conjecture as to the manner in which they were constructed, and which, according to him, was as follows. Two parallel dikes of earth or sod being raised, in the direction of the intended wall, with a space between them sufficient for its thickness, the fuel was put in, and set on fire. The stones best adapted for the purpose, called the *plum-pudding stone*, are everywhere to be found in the neighbourhood. These were laid on the fuel, and when melted, were kept by the frame of earth from running off; and by repeating the operation, the wall was raised to a sufficient height. This opinion of the stones being thrown in without any order, is thought to be confirmed by the circumstance of there not being anywhere a large one to be seen, nor a stone laid in any particular direction, nor one piece which has not in some degree been affected by the fire. Mr Williams mentions a fact tending to confirm his hypothesis, viz. of a brick kiln situated on the declivity of an eminence, so as to be exposed to the wind, which happening to rise briskly one time when the kiln was burning, so increased the heat, that the bricks were melted, and ran, like a lava, for a considerable way down the hill.

The opinion of Mr Williams has been embraced by several other authors; particularly Mr Freebairn and Dr Anderson, the latter having published two treatises upon these buildings in the Archæologia. In the same work, however, we meet with a paper by the Hon. Daines Barrington, in which the author expresses quite different sentiments. He observes, that Mr Williams, and the other antiquarians, who suppose the walls in question to be works of art, imagine that the reason of their being constructed in this manner was the ignorance of cement, which in these remote ages prevailed in Scotland: but with respect to this circumstance, he says, that if one side of the wall only was heated, and that to any considerable height, the matter in fusion would in all likelihood drop down to the bottom, without operating as any cement to the loose stones thrown in amongst it. This circumstance of the walls being vitrified only on one side, is indeed remarkable, and takes place in most of the forts of this kind to be met with at present: but with regard to it, Mr Barrington observes, that he himself has been twice in the Highlands of Scotland, and has found very few hills of any height which were clothed with wood; the trouble therefore of carrying it up to the top of such a mountain would be very considerable. But to this it might easily be replied, that we cannot by any means argue from the present state of the hills in the Highlands to their state in a very remote period of antiquity. At that time, it is neither impossible, nor in the least improbable, that most of the hills in Scotland were overgrown with wood; or at any rate, there undoubtedly was plenty of peat, which is still used as fuel in Scotland, and which affords such a strong heat as to be advantageously employed in smelting iron, as we are informed by M. Magellan. A third particular mentioned by Mr Williams is, that these enclosures were intended as places of defence; and in support of this opinion he alleges, that there are dried wells found within most of them. But on this Mr Barrington observes, that shelter from the weather was also necessary, "upon the top of a bleak Scotch hill, whilst whisky (or a succedaneum for it) would be often in greater request than the bare element of water." This objection, however, as well as the last, is evidently very frivolous; for these buildings might have roofs as well as any other; and whatever necessity there might be for whisky occasionally, water was certainly an indispensable requisite.

Mr Barrington having thus given his reasons for dissenting from the opinion of Mr Williams and the antiquaries just mentioned, proceeds to state his own. He tells us, that having travelled for 21 years the most mountainous circuit in Wales, he has frequently observed enclosures of dry stones, particularly a long tract in the western part of Merionethshire, called in the language of the country *Duffryn*, i. e. the *vale*. On first viewing these small enclosures made with walls of thick stones, he was at a loss to imagine how it could be worth while to construct such strong fences for so inconsiderable a piece of ground as they enclosed; but, on examining the adjacent country, he found it almost entirely covered with stones of a similar kind; and, of consequence, the smaller the space to be cleared, the less expensive would be the removal. "For the same reason (says he), such dry walls are often of a great thickness, and sometimes the corners of the enclosures are filled with stones to a great width, this being the only possible means of procuring pasture." To a practice of the same kind our author would ascribe the origin of the works in question: but the objection occurs very strongly, that the walls in Scotland are vitrified, and it is not to be supposed that such trouble

 would

Vitrified Forts.

would be taken with fences made in such a fortuitous manner. This objection, our author owns, would indeed be unanswerable, on the supposition that the vitrification was made on purpose to strengthen the walls of the fortress; but (says he) may not the vitrification have been occasioned by volcanoes, or by what are called *bloomeries*? The same effect may be produced likewise on dry walls of stone by lightning passing along them. The loose stones in either case would not be rejected because they were glassy, and would be piled up in the fence of the enclosure: as the great point upon these occasions is to clear the ground, and remove the encumbering stones to the smallest distance. One of the advocates for the designed and not fortuitous vitrification, says, that the pieces he had produced did not resemble what is called *lava*. But every volcano is not necessarily an Etna or a Vesuvius; and consequently the matter disgorged from the crater must perpetually vary both in substance and form. Vitrified masses, larger or smaller, will likewise be produced by the same means. It may be contended, indeed, that pasture thus procured, by clearing the ground, would be more convenient at the bottom or on the sides, than on the top of the hill; but to this I answer, that in rocky countries you must get what pittance you can of soil, and often it will happen that the only detached and removeable stones are on the summit. When such enclosures have been made, they became very convenient for putting cattle into; and hence perhaps some of the wells which Mr Williams hath mentioned."

Our author concludes his dissertation on this subject by observing, that if vitrification answered the purpose of cement, it is very extraordinary that the ancient inhabitants of Scotland did not apply it to the houses or huts in which they constantly lived, but reserved this troublesome and expensive process merely for a fortification, which might not perhaps be used in half a century against an enemy. On this it is almost superfluous to observe, that in the ages of barbarity and bloodshed, in which these enclosures, whether natural or artificial, were supposed to be used as fortresses, war was so frequent, that a defence against an enemy might seem to be necessary every day, instead of once in half a century. Before we proceed further in the argument, however, it will be necessary to give some account of the situation and appearance of these fortresses.

According to Mr Cardonnel, the largest of them is situated on the hill of Knockfarril, to the south of the valley of Strathpeffer, two miles west from Dingwall in Ross-shire. The enclosure is 120 feet long and 40 broad within the walls; strengthened on the outside with works at each end. A range of habitations seems to have been erected against, or under, the shade of the outward wall; of which those on the south side seem to have been higher and larger than those on the north. There are two wells in the middle, which, on being cleared out, filled with water. On the skirts of the hill to the south are many detached buildings; which, from the stratum of dung found on removing the ruins, appear plainly to have been used for securing the cattle. This place seems to have been anciently of consequence, and the residence of some powerful chief, from a road which leads through the hills to the north-west sea. To the east of the works are a number of vitrified ruins, extending for a considerable way along the ridge of the hill. The end next the fort seems to have joined the outer wall, and consisted either of two parallel walls, closed above, with a passage between them under cover, or a high wall broad enough to walk on. In this wall there is the vestige of a break about the middle, over which a bridge has been laid, to be drawn up or removed as occasion might require.

The fort next in consequence to that of Knockfarril is situated on the hill of Craig-Phadrick near Inverness, "which (says Mr Cardonnel) has this peculiar circumstance, that there appears to have been two vitrified walls quite round the area. The inner one seems to have been very high and strong; the outer wall but low: probably the space between was intended for securing their cattle, as there are no remains of dry-stone buildings, such as are found near the rest. Several parts of this outer wall appear quite entire, sticking to the firm bare rock, where it was first run. The area within the inner wall is nearly 80 paces long and 27 broad." Of this we have an account * by Alexander Fraser Tytler, Esq. professor of civil history in the university of Edinburgh, who visited it in the year 1782. The hill itself is a small conical eminence, forming the eastern extremity of that ridge of mountains which bounds Loch Ness on the north-west side. It is situated about a mile to the north of Inverness, and is accessible on two different quarters, viz. the west and south-east; the forming affording entrance by a narrow level ridge adjoining the hills on Loch Ness, and the latter by an easy ascent from the high ground above Inverness. On approaching the hill from the west, we first meet with a road cut through the rock from the bottom to the top, in most places 10 feet broad and nearly as deep; winding, for about 70 feet, with an easy serpentine direction, by which we gain an ascent over a steep rock otherwise quite inaccessible from that quarter. This road, in our author's opinion, is undoubtedly the work of art, and the vitrified matter on the top is the only thing which indicates the effect of fire; there being neither the appearance of pumice-stone, lava, nor basaltes, about the hill otherwise. There is indeed plenty of plum-pudding stone; which some have supposed to be of the nature of volcanic tufa; but this opinion is rejected by our author as erroneous. "But the circumstance (says he) which in my apprehension evinces, in the most satisfactory manner, that these appearances of the effect of fire on the summit of this hill are not the operation of nature, but of art, is the regular order and disposition of those materials, the form of the ground, and the various traces of skill and contrivance which are yet discernible, though considerably defaced either by external violence or the obliterating hand of time." To investigate this matter regularly, he begins with the winding road already mentioned, and which is evidently cut through the rock for the purpose of gaining an easy ascent from the level ridge to the summit, which would otherwise have been impracticable. In ascending by this road, there appears towards the middle on the right hand, a small platform overhanging the passage, and inclining by a very gentle declivity to the very edge of the rock. Four enormous stones are placed upon the platform, and on the edge and extremity

* *Edin. Phil. Trans.* Vol. II. Class II. Art. 11.

extremity of it, which have evidently been guided by art into that position; it being impossible that they could have rested there, had they been rolled down from the higher parts. The obvious reason for placing them in such a position has been, that on an alarm of danger they might be projected into the path below, which could be done by the efforts of a very few men: and when this was done, the passage would be entirely obstructed, or at least rendered so difficult that it could be defended by a few against any number of assailants. Some other large stones are placed on an eminence to the left, probably with a view to block up a hollow channel, by which an enemy might have attempted to ascend. When we come to the top of the hill, a few feet below the rampart which crowns the whole, there appears an outward wall, approaching on the sides of the hill so near the upper rampart, as to have only a trench of 10 or 12 feet wide between them. This outward wall is in some places so low as to be almost level with the rock, though in other places it rises to the height of two or three feet; but even where lowest, it may be traced by a line of vitrified matter sticking fast to the rock all along, and nearly of the same breadth, which is about nine feet. The remains of this wall are strongly vitrified, except in one place on the north side, where, for about 70 yards, the rampart is formed only of dry stones and earth. At the east side, where the hill is more accessible, there is a prodigious mound of vitrified matter, extending itself to the thickness of above 40 feet. At the south-east corner, and adjoining to this immense mound is an outwork, consisting of two semicircular vitrified walls, with a narrow pass cut through them in the middle; which appears to have been another, and perhaps the principal entry to the fort.

The inner wall, surrounding the summit of the hill, encloses an oblong level area of about 75 yards long and 30 broad, rounded at each of the ends like the outward wall. It is of considerable height, and nearly of the same thickness with the outward one.—It has some appearance of having been defended with four turrets or bastions: but the traces are so imperfect, that Mr Tytler does not lay much stress on his observations in this respect; a number of small tumuli of earth, with a stone in the centre, were more discernible. On the east side a portion of the internal space appears separated from the rest by two ranges of stones fixed strongly in the earth, and forming a right-angled parallelogram. "This separation (says our author) is immediately discernible by the eye, from this circumstance, that the whole of the enclosed summit has been most carefully cleared from stones, of which there is not one to be seen, unless those that form this division, and the single one in the middle of the circle of tumuli above mentioned. What has been the design of this separated space, it is difficult to conjecture. It might perhaps have marked the residence of those of a higher rank, or served as a temple for the purposes of devotion." On the east end of the large area on the summit is a well of about six feet in diameter, which has probably been sunk very deep in the rock, though now it is filled up with rubbish to within a yard of the top.

The other fortified hills mentioned by Mr Cardonnel are those of Dun-Evan in the shire of Nairn; Tordun castle, near Fort Augustus; and another on the west side of Gleneves in Lochaber, three miles to the south of Fort William. The Castle hill of Finhaven, in the county of Angus, has likewise some considerable ruins of the same kind.

Dun-Evan and the hill of Finhaven have likewise been visited by Mr Tytler, who gives an account of them in the paper already quoted; of which the following is an abstract. "On the summit of the hill of Dun-Evan, whose name implies that it had been originally a place of defence, are the remains of two walls surrounding an oblong space like that of Craig Phadrick already described, but somewhat smaller in size. [Mr Cardonnel says that it is about 70 paces long and 30 broad]. There are likewise the traces of a well in the enclosed area; and at the east end are the remains of a prodigious mass of building, much more extensive than that on Craig Phadrick." Here, however, our author could not perceive any marks of fire; and Mr Williams owns that the vitrified ruins here are more wasted than on Knockfarril or Craig Phadrick. But with regard to the vitrifications here, our author is inclined to suppose Mr Williams to have been entirely in a mistake. On the Castle hill of Finhaven, however, the vitrified remains are very visible all round the summit, which is cleared of stones and levelled, unless at one end, where there is a great hollow space separated from the rest of the area, and probably destined exclusively for the keeping of cattle. The enclosed area is about 140 yards long, and upwards of 40 broad.

Besides these fortifications, the hill of Noth affords a remarkable appearance of the same kind: of which Mr Cordiner gives the following description, not from his own observations, but those of a gentleman of credit who visited the place. "On the top of the hill there is an oblong hollow, as I could guess, of about an English acre, covered with a fine sward of grass: in the middle toward the east end of this hollow is a large and deep well. The hollow is surrounded on all sides with a thick rampart of stones. On three sides of this rampart, from 8 to 12 feet thick, is one compact body of stones and minerals which have been in a state of fusion, resembling a mixture of stone and iron-ore, all vitrified, calcined, and incorporated. On the north side the rampart consists of broken pieces of rock, which have the appearance of having been torn to pieces by some extraordinary violence. If the calcined compact wall exists under them, it is not at present visible."

Such are the descriptions of the most remarkable of these curious fortifications which of late seem to have engaged the attention of the learned in a considerable degree. We have already taken notice, that by some they are supposed to be the works of art, by others the productions of a volcano. Mr Cardonnel adopts the opinion of Mr Williams as the most probable, both with respect to their use and manner of construction. Mr Tytler takes notice of the remarkable difference of opinion among those who have viewed the places in question. "It is curious to remark (says he) how the same appearances, to different observers, lead to the most opposite opinions and conclusions. The two gentlemen above mentioned (Mr Williams and Dr Anderson) seem not to have entertained the small-

Vitrified Forts.

est doubt, that the vitrified materials on the tops of these hills were the vestiges of works of art, and the remains of structures reared for the purposes of security and defence. The bishop of Derry, when on a tour to the north of Scotland, visited the hill of Craig Phadrick near Inverness, and expressed his opinion, that the mounds of vitrified matter were not the remains of any artificial work, but the traces of an ancient volcano. In the Phil. Trans. of the Royal Society of London for 1777, Part II. N° 20. is an account of *Creek Faterick*, there termed *a Volcanic hill near Inverness*, in a letter from Thomas West, Esq. to Mr Law, F. R. S. in which the writer does not hesitate to pronounce this hill an extinguished volcano; and having sent specimens of the burnt matter for the inspection of the Royal Society, the secretary subjoins a note to the paper, intimating, that these specimens having been examined by some of the members well acquainted with volcanic productions, were by them judged to be real lava. Such was likewise the opinion of the late Andrew Crosbie, Esq. who, in an account which he gave to the Philosophical Society of Edinburgh in 1780, offered some very curious conjectures with regard to the process of nature, by which he supposed the whole of this hill to have been thrown up from the bottom of the sea by the operation of intestine fire.

Mr Tytler agrees with those who think the vitrified structures to be artificial works: but he differs from Mr Williams and others, who think that they were vitrified on purpose for cementing the materials together. His reason for this is, that the number of forts that show marks of vitrification, is inconsiderable when compared with those that do not. He therefore considers the vitrification as accidental; and that it must have been accomplished in the following manner. In the rude state in which we must suppose Scotland to have been in early times, it is very probable that their buildings, both for habitation and defence, would be frequently constructed of loose stones of an irregular shape; of which, by themselves, it would scarce be possible to fabricate a wall of any tolerable strength. Hence it became necessary to use wood as well as stone in their construction. This kind of building, then, in our author's opinion, was begun by raising a double row of pallisades or strong stakes in the form of the intended structure, in the same way as in that ancient mode of building described by Palladio under the name of *riempiuta à cassa*, or coffer-work. These stakes were probably warped across by boughs of trees laid very closely together, so as to form two fences running parallel to each other at the distance of some feet, and so close as to confine all the materials of whatever size that were thrown in between them. Into this intermediate space, Mr Tytler supposes, were thrown boughs and trunks of trees, earth and stones of all sizes, large or small as they could quarry or collect them. Very little care would be necessary in the disposition of these materials, as the outward fence would keep the mound in form. In this way it is easy to conceive that a very strong bulwark might be reared with great dispatch; which, joined to the natural advantage of a very inaccessible situation, and that improved by artful contrivances for increasing the difficulty of access, would form a structure capable of answering every purpose of security or defence. The most formidable attack against such a building would be fire, which would no doubt be always attempted, and often with success, by an enemy who undertook the siege. If the besiegers prevailed in gaining an approach to the ramparts, and, surrounding the external wall, set fire to it in several places, the conflagration must speedily have become universal, and the effect may be easily imagined. If there happened to be any wind at the time to increase the heat, the stony parts could not fail to come into fusion; and as the wood burnt away, sinking by their own weight into a solid mass, there would remain a wreck of vitrified matter tracking the spot where the ancient rampart had stood; irregular, and of unequal height, from the fortuitons and unequal distribution of the stony materials of which it had been composed. This conjecture appears very probable from their appearance at this day. They do not seem to have ever been much higher than they are at present, as the fragments that have fallen from them, even where the wall is lowest, are very inconsiderable. The durable nature of the materials would prevent them from suffering any changes by time; though from the gradual increase of the soil, they must in some places have lost considerably of their apparent height, and in others been quite covered. Mr Williams, in making a cut through the ramparts at Knockfarril, found in many places the vitrified matter covered with peat moss half a foot thick.

In confirmation of this opinion, our author likewise urges that in the fortification on Craig Phadrick, a large portion of the outward rampart bears no marks of vitrification. The reason of this seems to be, that the steepness of the hill on that side renders a low fence of stones and turf sufficient; and no wood had probably been employed in its construction. "It appears therefore highly probable (concludes our author), that the effect of fire upon these hill fortifications has been entirely accidental; or to speak more properly, that fire has been employed not in the construction, but towards the demolition of such buildings: and for the latter purpose it would certainly prove much more efficacious than for the former. It is much to be doubted, whether it would be at all possible, even in the present day, by the utmost combination of labour and of skill, to surround a large space of ground with a double rampart of stones compacted by fire, of such height and solidity as to answer any purpose of security, or defence against an enemy. Any structure of this kind must have been irregular, low, fragile, easily scaled, and quite insecure; a much weaker rampart, in short, than a simple wall of turf or wooden pallisade. The vestiges yet remaining, as I have already observed, give no room to suppose that the vitrified mound has ever been much more entire than it is at present. The effect of fire upon structures reared in the manner I have supposed them to have been, will account most perfectly for their present appearance. It was from necessity that the builders of these fortifications betook themselves to a mode of structure so liable to be destroyed by fire. In those parts where stones could be easily quarried, of such size and form as to rear a rampart by themselves of sufficient strength and solidity, there was no occasion to employ wood or turf in its construction; and it was therefore proof against all assaults

Vitrified Forts.

saults by fire. Such are the ramparts which appear on the hill of Don Jardel, Dun-Evan, and many others, on which there is not the smallest appearance of vitrification. But on Craig Phadrick, and the other hills, above dscribed, where, from the nature of the rock, the stones could be procured only in irregular and generally small fragments, it was necessary to employ some such mode of construction as I have supposed; and these ramparts, though solid and well calculated for defence against every attack by force or stratagem, were not proof against an assault by fire."

Mr Cordiner is of opinion, that the vitrifications in question cannot have been the works of art, and ridicules the contrary hypothesis; though without adducing any argument against it. The hill of Noth is by him supposed to have been a volcano. He describes it as "a most majestic mountain, in general brown, with moss and heath, interspersed with bare rock, in many places crumbling down. The highest part of it is a circular hill, whose verdure, as well as height, distinguishes it from the rest of the mountain. This is called the *Top of Noth;* and bears the strongest resemblance to every description of a volcanic mount. At the distance of many miles, one can distinguish those ridges which are the boundaries of the crater, indicating the hollow in the top." The gentleman from whom Mr Cordiner received the account of the vitrifications on the summit, informs us, that on first seeing specimens of them, he imagined that they had been pieces of stone calcined by the burning down of a castle; as he had found something very like them on the castle-hill at Cullen, in parts where the sward of grass was broken: but on reaching the top, and viewing the appearances on it already described, he altered his opinion. "That men hardly beset (says he) might climb up with some provisions to this as a place of refuge, is probable: but that, on a barren mountain top, far from cultivated ground, half a day's journey from the plain; that there, in any period of society, man should have been tempted to build that amazing rampart, is not to be imagined: they have found it a natural and extensive fortress, and in critical circumstances have made use of it accordingly. That it has been occupied as a place of strength and of refuge, is very evident; for, some hundred yards lower down on the hill, there are the remains of another rampart or wall, consisting of loose stones piled together without any cement, carried quite round the hill. This last has been built for an additional defence to those who made their abode on the top. The top of Noth, for two-thirds downwards, is covered with a green sward; below that, it is brown with heath: this is the very reverse of the adjacent mountains; and the greater verdure of the upper part I imputed to a new soil created by the ashes of the volcano. The opening, called a *well*, I suppose to have been the latest crater. About a mile south, down towards the lower grounds of the *Cabrock*, there is a very pretty regular green hill, which I ascribe to a later eruption than those which may have formed the contiguous hills now covered with heath. There is an extraordinary luxuriant spring of water rushes out at once from the side of the hill of Noth; which is likewise some confirmation of the opinion that a volcano has some time existed there, which has occasioned great hollows and reservoirs of water in the heart of the mountain. And the wild irregularities of nature through all the Cabrock, the hideous and strange projection of rocks from the sides of the hills, would seem to indicate some vast convulsions which the earth must have suffered in these parts.

"The traces of ancient volcanoes (says Mr Cordiner) are far from being unfrequent in Scotland. The hill of Finhaven is one instance; and not only abundant in this species of lava, but with *tarras*, or the *pulvis puteolanus*, an *amalgama*, as Condamine calls it, of calcined stones mixed with scorias and iron rust reduced to powder. The hill of Beregonium, near Dunstaffnage castle, is another, yielding vast quantities of pumice or scoria of different kinds; many of which are of the same species with those of the volcanic Iceland. The noble assemblage of basaltic columns at Staffa, those in the isle of Sky, and the rock Humble, are but so many evidences of the ancient volcanoes of this country. And finally, the immense stratum of pumex vitreus or Iceland agate, on the hill of Dun-fuin in Arran, is the last proof I shall bring in support of the question."

On this dispute we can only observe, that whatever side we embrace, the difficulties seem to be very great, nay almost insurmountable. When we consider the great thickness of the walls on the top of Noth, from 8 to 12 feet, and the vast mound of vitrified matter, no less than 40 feet in breadth, mentioned by Mr Tytler, we can scarce conceive it possible that less than a volcanic fire could be able to form them. We may easily allow, that, in the way this gentleman mentions, there might be considerable vitrifications formed; but that such immense masses should be brought into perfect fusion by the small quantity of fuel which could be put round them in pallisades, or intermixed with the materials themselves, will be incredible to every one acquainted with the extreme difficulty with which stones of any magnitude are brought into complete fusion. We see even in the insides of furnaces, though sometimes built of no more infusible materials than common brick, no such effects follow. There is a slight vitrification indeed, but it scarcely ever penetrates to the depth of an inch or two, though very violent fires are kept up for a much longer time than we could suppose the wood surrounding those walls to require for its being consumed. In conflagrations, where houses are consumed, which are the only similar examples we have, no such effect is perceived. Even in the great fire at London in 1666, where so many buildings were destroyed, we do not hear of their walls being vitrified, though the materials of many of them were undoubtedly as fusible as the rocks and stones of Craig Phadrick, or the Top of Noth. If, on the other hand, we reject this, and adhere to the volcanic hypothesis, our difficulties are equally great. For where shall we find, in any other part of the world, an example of volcanoes ejecting lava in the form of walls enclosing a regular area? This would be attributing such a singularity to the volcanoes of Scotland as the most extravagant imagination cannot admit. We must therefore conclude, that though these ruins are certainly the works of art, we have not yet sufficient data to decide the question with respect to their construction, but that the subject requires a farther investigation.

In the paper already quoted, Mr Tytler observes, that "these ancient fortifications present a more curious and interesting object of speculation, than those uncertain and indeed fruitless conjectures as to the mode in which they have been reared." This, he justly observes, must have been before the use of mortar was known; for as the country abounded in limestone, and the builders certainly would exert all their powers in giving them a proper degree of strength, it would undoubtedly have been used. Hence we are led to ascribe to these a very considerable degree of antiquity; for as the Britons were taught the use of mortar by the Romans, it is probable that we must date the origin of the structures in question before the time of the invasion of that people, or at least soon after it: so that we must look upon them to be more than 1650 years old; but how far beyond that period we are to search for their origin, does not appear. "All that we can conclude with certainty (says our author) is, that they belong to a period of extreme barbarism. They must have been constructed by a people scarcely removed from the state of savages, who lived under no impression of fixed or regulated property in land; whose only appropriated goods were their cattle; and whose sole security, in a life of constant depredation, was the retreat to the summits of those hills of difficult access, which they had fortified in the best manner they could. As the space enclosed was incapable of containing a great number of men, especially if occupied in part by cattle, it is presumed, that these retreats were formed chiefly for the security of the women and children of the canton, and of their herds. They could be defended by a few men, while the rest of the tribe were engaged with their enemies in the field."

Our author concludes his dissertation with a conjecture, that the forts in question were constructed, not only before the Roman invasion, but before the introduction of the rites of the Druids into Britain.

FORTALICE, in *Scots Law*, signified anciently a small place of strength, originally built for the defence of the country; and which on that account was formerly reckoned *inter regalia*, and did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage, &c.

FORTAVENTURA, one of the Canary islands, 50 miles long, and from 8 to 24 broad, fertile in corn and excellent fruits; and remarkable for its numerous breed of goats and prodigious quantity of goat-milk cheese. The number of inhabitants amounts to 100,000. W. Long. 14. 32. N. Lat. 28. 4.

FORTESCUE, Sir John, lord chief justice of the King's Bench, and lord high chancellor of England, in the reign of King Henry VI. was descended from the ancient family of Fortescue, in the county of Devon. He studied the municipal laws of England in Lincoln's Inn, of which he was made one of the governors in the fourth and seventh years of the reign of King Henry VI. In 1430, he was called to the degree of a serjeant at law, and in 1441 was constituted the king's serjeant. The following year he was made lord chief justice of the King's Bench; in which honourable station he continued till near the end of that king's reign, who, showed him many particular marks of his favour, and advanced him to the post of lord high chancellor of England. During the reign of King Edward IV. he followed the fortunes of the house of Lancaster, and was many years in exile with Queen Margaret and Prince Edward her son. At length they having a prospect of retrieving their desperate fortunes, the queen and prince returned to England, and Sir John Fortescue, with many others, accompanied them; but soon after the decisive battle of Teweksbury, he was thrown into prison and attainted, with other Lancastrians; but found means to procure his pardon from Edward IV. He wrote, 1. A learned commentary on the politic laws of England, for the use of Prince Edward; to one edition of which Mr Selden wrote notes. 2. The difference between an absolute and limited monarchy, as it more particularly regards the English constitution (which was published, with some remarks, by John Fortescue, afterwards Lord Fortescue, in 8vo, in 1714; and a second edition was published with amendments, in 1719): And several works, which still remain in manuscript. He died near 90 years of age; and was buried in the parish church of Ebburton, where a monument was erected to his memory, in 1677, by one of his descendants.

FORTH, one of the most noble and commodious rivers in Scotland. It takes its rise near the bottom of Ben-Lomond; and running from west to east, receives in its passage many considerable streams, deriving their waters from the eminences in the midland counties of North Britain. Between Stirling and Alloa, the Forth winds in a most beautiful and surprising manner; so that, though it is but four miles by land, it is 24 by water between those two places. Below Alloa the river expands itself to a great breadth between the counties of Lothian and Fife, till at Queensferry it is contracted by promontories shooting into it from both coasts; so that, from being four or five, there it is not above two miles broad. In the middle of the channel lies a small island called *Inchgarvy*, which has a spring of fresh water: upon the island there is an ancient fort, which has been lately repaired; and if there were either forts or blockhouses on the opposite promontories, that part of the river which lies between Alloa and Queensferry would be as secure and convenient a harbour as could be desired. A little below this, near the north shore, lies Inchcolm, on which are the remains of an ancient monastery of considerable extent; and opposite to Leith stands the island of Inchkeith, formerly fortified, but now furnished with a light-house. Below Queensferry the north and south shores receding, the body of the water gradually enlarges till it becomes two or three leagues broad, affording several safe harbours on both sides, and excellent roads throughout, unembarrassed with latent rocks, shoals, or sands; and allowing secure anchorage to the largest ships within a league of the coast in almost any part of the Frith, and to vessels of a smaller size within a mile or less. The Firth, or (as it is commonly written) the *Frith*, of Forth, is, at the mouth of it, from North Berwick to Fifeness, full five leagues broad; having the little island of May (on which there is a light-house, and there might also be a fort) in the middle of it, and to the west of this the rocky island of Bass; notwithstanding

Forth.

standing which, the largest fleet may enter and sail up it many miles with the utmost facility and in the greatest safety. In 1781, Admiral Parker's fleet lay some weeks opposite to Edinburgh, accompanied by 500 sail of merchantmen, the whole in view of the city and castle.

The Forth was known to the ancients by the name of *Bodotria*, or (as Ptolemy calls it) *Boderia*, and has been ever famous for the number of its havens: some of which are, indeed, in their present condition, scarce worthy of that name. It is navigable for merchantmen as high as Alloa, 50 miles from the sea; and for coasters as far as Stirling, 24 miles further by water, though only four by land in a direct line, as already observed. The tide flows only a full mile above Stirling to a place called *Craigforth*, where the proprietor intercepts the passage of the salmon by a cruive or wear, very injurious to the large tract of country which stretches as far as Lomond westward. The river from Stirling to the bridge of Aberfoil, at the entrance into the West Highlands, is only passable for man or horse at few places, and these in dry seasons. It glides gently through a dead flat, from Gartmore eastward; "and on these accounts (says Mr Knox*) it might be made navigable for barges, at a trifling expence to the proprietors of the lands, an improvement much wanted in a rich, extensive, and populous valley, without market towns, coal and lime. Supposing this work to be executed, of which there is some probability, the whole extent of navigation on the Forth, will, including all its windings, exceed 200 miles, through a coast of nearly 100 miles; fertile, populous, industrious; and from Stirling eastward, almost lined with towns, anciently the seats of commerce and navigation, till they were ruined by the English depredations; in which miserable state some of them still remain, while others begin to resume the appearance of business. The principal object of these towns was the fisheries; which they prosecuted with great vigour as far as Iceland, till the time of the Union, from which period the eastern fisheries gradually dwindled away; and the poor fishermen, unable to subsist themselves upon air and water, took up the trade of smuggling; but so soon as the fishery laws shall be amended, the salt duties abolished, and an adequate bounty extended to boats as well as busses, these people will readily fall into the track of their ancestors, live by honest industry, and add new vigour to our naval strength. Many of the ports are nearly choked up, others want repairs, which neither the individuals nor the corporations of those decayed places can accomplish. Though the harbours on the Forth are in general small, the depth of water might be made sufficient for vessels of 200 tons burden, which fully answer the purposes of their coasting and Baltic trade; but to obtain this, or even a less depth of water, an aid of 50,000l. would be requisite."

* *View of the British Empire*, vol. ii. 518.

By this river and the Clyde, Scotland is almost divided into two parts. The Forth falls into the east sea below Edinburgh, and has an easy communication with the whole eastern coast of Great Britain; with France, Ostend, Holland, Hamburgh, Prussia, Dantzic, Russia, Sweden, Denmark, Norway, and Greenland. The Clyde falls into the Atlantic ocean below Glasgow, and communicates with the western coast of Great Britain; with Ireland, the south of France, Portugal, Spain, the Mediterranean, America, and the West Indies. These two rivers, thus falling in opposite directions into the two seas which environ our island, and the neck of land between them amounting scarcely to 24 miles, gave rise to the idea of a junction, so as to open a communication across the kingdom, and thereby cut off the long dangerous navigation by the Land's End, and the Pentland Frith: an object of vast utility, and which has been happily accomplished. See Canal.

FORTIFICATION;

THE art of fortifying a town, or other place; or of putting it in such a posture of defence, that every one of its parts defends, and is defended by, some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end that a small number of men within may be able to defend themselves for a considerable time against the assaults of a numerous army without, so that the enemy in attacking them must of necessity suffer great loss.

The origin and rise of fortification is undoubtedly owing to the degeneracy of mankind. In the first ages of the world, men were dispersed up and down the countries in separate families, as we are told in the histories of the Jews and Scythians, who wandered from one place to another, for the sake of finding pasture for their cattle. These families became in time so numerous as to form large communities, which settled all together in a place; from whence villages and towns had their origin and rise: but they found it was necessary, for the common security, to surround those towns with walls and ditches, to prevent all violences *from their neighbours, and sudden surprises.* This was sufficient for some time, till offensive weapons were invented, and conquering became a fashion. Then walls with loop holes were made at proper distances, in order to screen the defenders against the arrows of the assailants: but finding that, as soon as the enemy got once close to the walls, they could from no part be discovered or repulsed; for this reason they added square towers at proper distances from each other, so that every part of the wall might be defended, by the adjacent sides of the towers. This manner of enclosing towns, however, was found to be imperfect, because there remained still one of the faces of the towers which fronted the field that could not be seen from any other point, and therefore could not be defended. To remedy this, they made the towers round instead of square, imagining this figure to be the strongest to resist the battering engines, as likewise to be better defended from the other parts of the wall.

Notwithstanding the superiority of this method above the former, there remained yet a part of these towers

Vauban's Method.

towers unseen and incapable of being defended; which made them change the figure of the towers again; that is, they made them square as before; but, instead of presenting a face to the field as formerly, they presented an angle; by this means they effectually found out such a disposition of their works that no part could be attacked without being seen or defended by some other part.

This last method was long in use; and would in all probability have continued to this day, if gunpowder had not been found out; but the violence of the guns and mortars soon convinced the world, that such towers and walls were but a weak defence against these thundering engines; and besides, as the nature of the attack was entirely changed, it was also necessary to change that of fortifying likewise.

From that time ramparts were added to the walls, the towers enlarged into bastions, and all sorts of outworks have been added, such as ravelins, counterguards, horn and crown works, and others of the like nature, in order to render the defence in some measure equivalent to the attack.

Notwithstanding all the improvements which have been made in the art of fortifying since the invention of gunpowder, that of attacking is still superior to it; engineers have tried in vain to render the advantages of a fortification equal to those of the attack; the superiority of the besiegers fire, together with the greater number of men, obliges generally, sooner or later, the besieged to submit.

The greatest improvement made in the art of attacking happened in the year 1697, when M. Vauban made first use of ricochet firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been none; whereas, before, they had been secure as long as the parapet was not demolished; and the worst is, that there can be no remedy found to prevent this enfilading, without falling into inconveniences almost as bad as those which we endeavour to avoid.

Fortification is either regular or irregular. *Regular* fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket shot from each other. *Irregular* fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

Sect. I. *Of Regular Fortification.*

Although authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be both needless and superfluous to treat of all the different methods hitherto proposed, we shall content ourselves with explaining those only which are most esteemed by the best judges, and have been mostly put in practice.

Construction of M. Vauban's Method.

This method is divided into little, mean, and great; the *little* is chiefly used in the construction of citadels, the *mean* in that of all sorts of towns, and the *great* in particular cases only.

Vauban's Method.

We shall give the construction of the mean, as being most useful; and refer the reader to the table hereafter, for those dimensions which are different in these several fortifications.

Plate CCXXI. fig. 1.

Inscribe in the circle a polygon of as many sides as the fortification is designed to have fronts; let AB (fig. 1.) be one of the sides of half an hexagon, which bisect by the perpendicular CD; divide half AC of it into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is, six French feet; and therefore the whole side AB is supposed to be 180 toises.

As the dividing a line into so many equal parts is troublesome and tedious, it is more convenient to have a scale of equal parts by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have a hexagon inscribed; AB being bisected by the perpendicular CD as before, set off 30 toises from C to D, and draw the indefinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toises: from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or, which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification.

If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles, E, H, &c. so as to touch these arcs, their parts, *a b*, *b c*, &c. together with these arcs, will represent the outline of the ditch.

Definitions.

1. The part FEALN, is called the bastion.
2. AE, AL, the faces of the bastion.
3. EF, LN, the flanks.
4. FG, the curtain.
5. FN, the gorge of the bastion.
6. AG, BF, the lines of defence.
7. AB, the exterior side of the polygon.
8. CD, the perpendicular.
9. Any line which divides a work into two equal parts, is called the capital of that work.
10. *a b c*, the counterscarp of the ditch.
11. A, M, the flanked angles.
12. H, E, L, the angles of the shoulder, or shoulder only.
13. G, F, N, the angles of the flank.
14. Any angle whose point turns from the place is called a *salient angle*, such as A, M; and any angle whose

Of Orillons. Plate CCXXI.

whose point turns towards the place a *re-entering angle*, such as b, F, N.

15. If there be drawn two lines parallel to the principal or outline, the one at 3 toises distance, and the other at 8 from it; then the space $y\,x$ included between the principal one and that farthest distant, is called the *rampart*.

And the space $x\,x$, contained by the principal line, and that near to it, and which is generally stained black, is called the *parapet*.

16. There is a fine line drawn within four feet of the parapet, which expresses a step called *banquette*.

N. B. All works have a parapet of three toises thick, and a rampart of 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular constructions of engineers.

Of Ravelins. Plate CCXXI.

The parapet is a part of the rampart elevated from 6 to $7\frac{1}{2}$ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it they may just be able to fire over the parapet.

17. The body of the place, is all that which is contained within this first rampart: for which reason it is often said to construct the body of the place; which means properly, the construction of the bastions and curtains.

18. All the works which are constructed beyond the ditch before the body of the place are called *outworks*.

TABLE.

	Forts.						Little Fortif.				Mean.		Great.	
Side of Polyg.	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendicul.	10	11	$12\frac{1}{2}$	14	15	16	20	21	23	25	30	31	25	22
Faces bast.	22	25	28	30	33	35	40	42	45	47	50	53	55	60
Cape of ravel.	25	28	30	35	38	40	54	50	50	52	55	55	60	50

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260. In the second, the perpendiculars answering to these sides. In the third, the lengths of the faces of bastions: and in the fourth, the lengths of the capitals of the ravelins.

The forts are mostly, if not always, squares: for which reason, the perpendiculars are made one-eighth of the exterior sides; because if they were more, the gorges of the bastions would become too narrow.

The little fortification is chiefly designed for citadels, and are commonly pentagons; the perpendiculars are made one-seventh of the exterior side: the mean is used in all kinds of fortifications from an hexagon upwards to any number of sides; and the great is seldom used but in an irregular fortification, where there are some sides that cannot be made less without much expence, or in a town which lies near a great river, where the side next the river is made from 200 to 260 toises; and as that side is less exposed to be attacked than any other, the perpendicular is made shorter, which saves much expence.

The faces of the bastions are all $\frac{2}{7}$ths of the exterior sides, or nearly so, because the fractions are neglected.

It may be observed in general, that in all squares the perpendicular is $\frac{1}{8}$th of the exterior side, and all pentagons $\frac{1}{7}$th, and in all the rest upward $\frac{1}{6}$th.

1. *Construction of Orillons and retired Flanks.*

Describe the front MPQRST as before, and divide the flank into three equal parts, of which suppose S r to be one: from the opposite flanked angle M draw a line M r, in which take the part $m\,r$ of 5 toises; take likewise R n in the line of defence MR, produced, equal to 5 toises, and join $n\,m$, upon which as a base describe the equilateral triangle $n\,p\,m$, and from the angle p, opposite to the base as centre, is described the circular flank $n\,m$.

And if S r be bisected by the perpendicular 1, 2, and another be erected upon the face ST, at S; the intersection 2 of these two perpendiculars will be the centre of the arc which forms the orillon.

The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be if they were of any other figure.

2. *Construction of Ravelins or Half-moons.*

Fig. 2. Set off 55 toises, from the re-entering angle O of the counterscarp, on the capital OL or on the perpendicular produced, and from the point L draw lines to the shoulders AB; whose parts LM, LN, terminated by the counterscarp, will be the faces, and MO, ON, the semi-gorges, of the ravelin required. Fig. 2.

This is M. Vauban's method of constructing ravelins, according to some authors: and others will have the faces of the ravelin to terminate on those of the bastions within 3 toises of the shoulders; which seems to be the best way, for these ravelins cover the flanks much better than the others.

The ditch before the ravelin is 12 toises, its counterscarp parallel to the faces of the ravelins; and it is made in a circular arc, before the salient angle; as likewise all ditches are in general.

When the ravelins are made with flanks, as in fig. 3. the faces should terminate on those of the bastions, at least 5 toises from the shoulders. Fig. 3.

The flanks are made by setting off 10 toises from the extremities of the faces, from f to h, and from m to l; and from the points h, l, the flanks h, k, l, p, are drawn parallel to the capital LO of the ravelin.

There

Of Tenailles. Plate CCXXI.

There are sometimes redoubts made in the ravelin, such as in fig. 2. which is done by setting off 16 toises from the extremities of the faces on the semi-gorges from N to b, and from M to a; and from the points b, a, the faces are drawn parallel to those of the ravelin: the ditch before the redoubt is 6 toises, and its counterscarp parallel to the faces.

3. *Construction of Tenailles.*

A tenaille is a work made in the ditch before the curtains, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different sorts: the first are those as in fig. 4. which are made in the direction of the lines of defence, leaving a passage of 3 toises between their extremities and the flanks of the bastions, as likewise another of 2 in the middle for a bridge of communication to the ravelin. Fig. 4.

The second sort are those as in fig. 5. Their faces are in the lines of defenee, and 16 toises long, besides the passage of 3 toises between them and the flanks of the bastions; their flanks are found by describing arcs from one shoulder of the tenaille as centre through the other, on which are set off 10 toises for the flanks desired. Fig. 5.

And the third sort are those as in fig. 6. Their faces are 16 toises, as in the second sort, and the flanks are parallel to those of the bastions. Fig. 6.

The use in general of tenailles is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which can be defended from nowhere else so well as from them.

The first sort do not defend the ditch so well as the others, as being too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be seen in the citadel of Lille, at Landau, New Brisac, and in a great many other places.

The second sort defend the ditch much better than the first, and add a low flank to those of the bastion: but as these flanks are liable to be enfiladed, they have not been much put in practice. This defect might however be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work.

As to the third sort, they have the same advantage as the second, and are likewise liable to the same objections; for which reason, they may be used with the same precautions which have been mentioned in the second.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them: and it is not without reason. For when the ditch is dry, the part behind the tenailles serves as a place of arms from which the troops may sally, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure: which is a great advantage; for by that means the ravelin may be a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the tenailles to the ravelin becomes likewise much easier than it would be without them.

Of Lunettes, &c. Plate CCXXI.

4. *Construction of Lunettes.*

Fig. 7. Lunettes are placed on both sides of the ravelin, such as B, to increase the strength of a place: they are constructed, by bisecting the faces of the ravelin with the perpendicular LN; on which is set off 30 toises from the counterscarp of the ditch, for one of its faces; the other face, PN, is found by making the semi-gorge TP of 25 toises; the ditch before the lunettes is 12 toises, the parapet 3, and the rampart 8, as in the ravelin. Fig. 7.

There is sometimes another work made to cover the salient angle of the ravelin, snch as A, called *bonnet*, whose faces are parallel to those of the ravelin, and when produced bisect those of the lunettes; the ditch before it is 10 toises.

There are likewise lunettes, such as D in fig. 8. whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their semi-gorges are only 20 toises. Fig. 8.

These kinds of works may make a good defence, and cost us very great expence; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

5. *Construction of Tenaillons.*

Fig. 9. Produce the faces of the ravelin beyond the counterscarp of the ditch, at a distance MN of 30 toises, and take on the counterscarp of the great ditch 15 toises from the re-entering angle p to q, and draw Nq; then qNMp will be the tenailles required; its ditch is 12 toises, that is, the same as that of the ravelin. Sometimes there is made a retired battery in the front of the tenaillons, as in B; this battery is 10 toises from the front to which it is parallel, and 15 toises long. Fig. 9.

There are commonly retrenchments made in the tenaillons, such as O; their parapets are parallel to the fronts MN, and bisect the side qN; the ditch before this retrenchment is 3 toises; and there is a banquette before the parapet next to the ditch of about 8 feet, called *berm*; which serves to prevent the earth of the parapet (which seldom has any revetment) from falling into the ditch.

It is to be observed, that the ravelin, before which tenaillons are constructed, must have its salient angles much greater than the former construction makes them; otherwise the salient angles of the tenaillons become too acute; for which reason we made the capital of this ravelin 45 toises, and the faces terminate within 3 toises of the shoulders.

6. *Construction of Counterguards.*

Fig. 10. 11. When the counterguard is placed before the ravelin, set off 40 toises on the capital of the ravelin from the salient angle A to the salient angle B, of the counterguard; and 10 from C to D, on the counterscarp of the ditch. Fig. 10. and 11.

When the counterguard is before the bastion, such as in

Of Hornworks, &c.

Plate CCXXI.

in fig. 2. its salient angle F is 50 toises from the salient angle E of the bastion, and the breadth near the ditch of the ravelin 10 toises as before.

The ditch before the counterguards is 12 toises, and its counterscarp parallel to the faces.

Counterguards are made before the ravelin on some particular occasions only; but are frequently constructed before the bastions, as covering the flanks wonderfully well. Some authors, as Mr Blondel and Mr Coehorn, will have them much narrower than they are here.

7. *Construction of Hornworks.*

Fig. 11.

Fig. 12. Produce the capital of the ravelin beyond the salient angle A, at a distance AB of about 80 toises; draw DBE at right angles to AB; in which take BD, BE, each equal to 55 toises; and on the exterior side DE, trace a front of a polygon in the same manner as that of the body of the place, making the perpendicular BF 10 toises, and the faces 30.

The branches D *a*, E *b*, of the hornwork, when produced, terminate on the faces of the bastions, within 5 toises of the shoulders. The ditch of the hornwork is 12 toises, and its counterscarp parallel to the branches; and in the front terminates at the shoulders, in the same manner as the great ditch before the bastions.

The capital of the ravelin before the front of the hornwork is 35 toises, and the faces terminate on the shoulders, or rather 2 or 3 toises beyond them: and the ditch before the ravelin is 8 toises.

There are sometimes retrenchments made within the hornwork, such as S, S; which are constructed by erecting perpendiculars to the faces of the ravelins, within 25 toises of their extremities. This retrenchment, like all others, has a parapet turfed only with a berm of 8 feet before it; as likewise a ditch from 3 to 5 toises broad.

Fig. 13.

Fig. 13. When a hornwork is made before the bastion, the distance DL of the front from the salient angle of the bastion is 100 toises, and the branches terminate on the faces of the adjacent ravelins within 5 toises from their extremities; all the rest is the same as before.

8. *Construction of Crownworks.*

Plate CCXXII. fig. 14.

From the salient angle, A (fig. 14) of the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin produced at C; from the point C, set off the cords CB, CF, each of them equal to 110 toises; and on each of which, as an exterior side, construct a front of a polygon of the same dimensions as in the hornwork; that is, the perpendicular should be 18 toises, the faces 30, and the branches terminate on the faces of the bastions within 25 toises of the shoulders.

The ditch is 12 toises, the capital of the ravelin 35, and its ditch 8; that is, the same as in the hornwork.

Fig. 15.

Sometimes the crownwork is made before the bastion, as in fig. 15. The arc is described from the salient angle A of the bastion, with a radius of 120 toises, as before; and the branches terminate on the faces of the adjacent ravelins, within 25 toises of their extremities; the rest of the dimensions and constructions are the same as before.

Of Covert-ways, &c.

Plate CCXXII.

Hornworks, as well as crownworks, are never made but when a large spot of ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town.

9. *Construction of Covert-ways and Glacis.*

Although we have not hitherto mentioned the covert-way, nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking the covert-way, when it is in a good condition and well defended, is generally the most bloody action of the siege.

After having constructed the body of the place, and all the outworks which are thought necessary, lines are drawn parallel to the outmost counterscarp of the ditches, at 6 toises distant from it; and the faces *m n*, *m n*, included between that line and the counterscarp, will be the covert-way required.

Fig. 16. There is in every re-entering angle of the counterscarp a place of arms *m*; which is found by setting off 20 toises from the re-entering angle *a*, on both sides from *a* to *b*, and from *a* to *c*; and from the points *b*, *c*, as centres, arcs are described with a radius of 25 toises, so as to intersect each other in *d*; then the lines drawn from this intersection to the points *b*, *c*, will be the faces of the places of arms. Fig. 16.

If lines are drawn parallel to the lines which terminate the covert-way, and the places of arms at 20 toises distant from them, the space *x*, *x*, *x*, between these lines and those which terminate the covert-way will be the glacis.

At the extremities of the places of arms, are traverses made, such as *v*, *v*, which serve to enclose them; these traverses are 3 toises thick, and as long as the covert-way is broad; and a passage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the rest of the covert-way.

There are also traverses of the same dimensions before every salient angle of the bastion and outworks, and are in the same direction as the faces of those works produced; and the thickness lies at the same side as the parapets.

The passages round these last traverses are likewise from 6 to 8 feet wide.

In each place of arms are two sally ports *zz*, which are 10 or 12 feet wide, for the troops to sally out; in time of a siege, they are shut up with barriers or gates.

10. *Construction of Arrows and Detached Redoubts.*

An arrow is a work made before the salient angles of the glacis, such as A, fig. 16. It is composed of a parapet of 3 toises thick, and 40 long; and the ditch before it 5 toises, terminating in a slope at both ends. The communication from the covert-way into these arrows is 4 or 5 toises wide; and there is a traverse, *r*, at the entrance, of 3 toises thick, with a passage of 6 or 8 feet round it.

A detached redoubt is a kind of work much like a ravelin, with flanks placed beyond the glacis; such as B: they are made in order to occupy some spot of ground

Of Covert-ways, &c. Plate CCXXII. ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise.

Their distance from the covert-way ought not to exceed 120 toises, that it may be defended by musket shot from thence.

The gorge *a b* is 40 toises; the flanks *a c*, *b f*, which are perpendicular to the gorge, 10; and the faces *c d*, *f d*, 30: the ditch before it is 6 toises, ending in slopes at both ends; the covert-way 4; the branches of the covert-way are 42 toises long, or thereabouts; the faces of the places of arms *y*, *y*, which are perpendicular to the branches, 10; and the other, which is parallel to them, 14.

The communication from the covert-way into the redoubt, is 5 or 6 toises wide; and there is a traverse made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis.

If these redoubts are above 50 toises distant from the covert-way, the besiegers carry their trenches round, and enter through the gorge; by which the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent which, some other outworks should be made to support them.

11. *Construction of Second Ditches and Covert-ways.*

Fig. 17. Fig. 17. When the ground is low, and water to be found, there is often a ditch about 10 or 12 toises made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch: such as D, whose breadth on the counterscarp of the ditch is 10 toises, from *b* to *a*, and from *c* to *d*; and the faces *a* L, *d* L, are parallel to those of the places of arms; the ditch before them is from 8 to 10 toises wide.

The second covert-way is 4 toises, the semi-gorges of the places of arms, *m*, about 15, and the faces perpendicular to the counterscarp; the second glacis is from 15 to 18 toises broad.

This second covert-way has traverses everywhere, in the same manner as the first.

12. *Construction of Profiles.*

A profile is the representation of a vertical section of a work; it serves to show those dimensions which cannot be represented in plans, and is necessary in the building of a fortification. Profiles are generally constructed upon a scale of 30 feet to an inch. It would be endless to describe all their particular dimensions; we shall therefore lay down the principal rules only, given by M. Vauban, on this subject.

1. Every work ought to be at least 6 feet higher than that before it, so that it may command those before it: that is, that the garrison may fire from all the works at the same time, with great and small arms, at the besiegers in their approaches. Notwithstanding this specious pretence, there are several authors who object against it. For, say they, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries; so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it.

But if all works were of the same height, those within cannot be deestroyed, till such time as those before them are taken: guns might be placed in the covert-way and outworks to obstruct the enemy's approach; and when they come near the place, they might be transported into the inner works: and as the body of the place would be much lower, the expence would be considerably diminished. Of Profiles. Plate CCXXII.

But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees; this might however be partly prevented, by making the parapets near the salient angles, for the space of 8 toises on each side, 5 or 6 feet higher than the rest of the works.

2. The covert-way should be lower than the level ground, otherwise the body of the place must be raised very high, especially where there are several outworks: this is to be understood only when the works exceed each other in height, otherwise it need not be below the level.

3. The bases of all inward slopes of earth should be at least equal to the height, if not more.

4. The bases of all outward slopes of earth, two-thirds of their height.

5. The slopes of all walls, or revetments, should be one-fifth of their height; or one-sixth might perhaps be sufficient: the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation.

6. The slopes of all parapets and traverses are one-sixth of their breadth; that is, 3 feet towards the field; or the inside, where the banquettes should be 3 feet higher than the outside.

7. When the revetment of a rampart goes quite up to the top, 4 feet of the upper part is a vertical wall of 3 feet thick, with a square stone at the top of it projecting 6 inches; and a circular one below, or where the slope begins, of 8 or 10 inches diameter: they go quite round the rampart, and the circular projection is called the *cordon*.

Where the straight part of the wall ends and the slope begins, the wall is always made 5 feet thick; and the counterforts or buttresses reach no higher than the place.

8. When the rampart is partly walled and partly turfed, then one-fifth of the height which is turfed must be added to 5 feet, to get the thickness of the wall above.

And having the thickness of any wall above, by adding one-fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a sixth part must be added.

For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed; then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 4 added to the thickness 7 above, gives 11 for the thickness near the foundation.

Fig. 18. represents (in military perspective) the profiles of the body of a place, the ravelin, and covert-way; which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived. Plate CCXXIII. fig. 81.

SECT.

Of Irregular Fortification.

Plate CCXXIII.

Sect. II. *Of Irregular Fortification.*

The most esssential principle in fortification consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides. This can happen no otherwise in a regular fortification situated in a plain or even ground: but as there are but few places which are not irregular either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular without too great expence; it is so much the more necessary to show in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise, if such a place is to be attacked, to know which is the strongest or weakest part.

1. *Construction of an Irregular Place situated in an open country.*

If the place to be fortified is an old town enclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature of the ground; and to regulate his plan accordingly, so as to avoid the disadvantages, and gain all the advantages possible: he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place can be reduced into a regular figure, or nearly so; for if that can be done without increasing the expence considerably, it should by no means be omitted. Old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and mended when it may be done. If there is a rampart without bastions or towers, it must be well considered whether bastions may not be added, or if it is not better to make only some outworks: if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions; otherwise ravelins and counterguards must be constructed. Special care must be taken to make all the sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of musket-shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest.

If it should happen that some of the sides are inaccessible or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others which are of easy access, and the flanks need not be so large as the rest; by doing so there will be some expences saved, which may be used in making the other sides stronger by adding more outworks.

There are few situations but what are more advantageous in some parts than in others; it is therefore the business of an engineer to distinguish them, and to render those sides strong by art which are not so by nature.

If the situation is low and watery, lunettes or tenaillons, and such other small outworks, should be constructed; because they are not of any great expence, and may make a very good defence. But if one side of the place only is low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing, that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled by means of dikes or sluices, so as to overflow the best part of the first glacis, it should be done: for by so doing these works will be able to make a very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis; which cannot be done but within a few toises of the first covert-way, where the besieged are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them.

But if the situation is of a dry nature, without any water upon it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries raised in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis so as to afford no cover for the enemy behind them. Arrows and detached redoubts are likewise very proper to be used in such a case; and sometimes horn or crownworks, if it should be thought convenient: but these works should never be constructed without an absolute necessity, either to occupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance into the town; for they are of great expence, and their defence seems not to be answerable to it.

Most of the places in Flanders are fortified with hornworks, such as Ypres, Tournay, Lisle, and others.

If the place to be fortified is new, and the situation will not admit of a regular construction, particular care must be taken in choosing such a spot of ground as is most advantageous, and least liable to any disadvantages either in the building or in the maintaining of it. All hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters for the same reason, excepting a lake is or may be made navigable. Good water should be had either within the place or near it, for it is absolutely necessary for men and cattle: the air should be wholesome; otherwise the continual sickness that may reign in such a place might prevent people to come and live in it, and the garrison would not be in a condition to defend themselves as they ought to do. In short, all the different circumstances attending such an undertaking should be maturely considered before a resolution is taken to fortify any place.

When a situation is fixed upon, the next thing to be considered is the bigness of the town and the number of its outworks; which must absolutely depend upon the consequence such a place is of to a nation. If it is only to guard a pass or entrance into a country, it need not be so large: but if it is to be a place either to promote or to protect trade, it should be large and commodious: the streets should be wide, and the buildings regular and convenient. As to what regards the fortification, its construction should depend on the nature of the situation, and the number of works, on the funds or expence a prince or a nation will be at; which, however, ought to be according to the benefit arising from

Of Irregular Fortification. Plate CCXXIII.

from such a place; for as such undertakings are of very great expence, an engineer cannot be too sparing in his works; on the contrary, the greatest economy should be used both in regard to the number of works and to their construction. The body of the place may have (A) revetments quite up to the top, or only in part and the rest turfed; but as to the outworks, they should have half revetments, or they may be made with turf only; as being not so necessary to prevent the place from being surprised, which may nevertheless make a good defence.

Fig. 19. Fig. 19. is the plan of an octagon, one half of which is similar and equal to the other half; it being supposed, that the situation would not admit of a fortification quite regular. The exterior sides are each 180 toises, and the works are constructed according to our method: but because the sides AB, EF, are weaker than the rest, as has been proved before, we have added tenailles, redoubts in the ravelins, and lunettes, to render them nearly equal in strength with the others; and if counterguards were made before the bastions A and B, it would effectually secure that front. Instead of lunettes, any other works may be made, as may be thought convenient and according to the nature of the ground. If it should be judged necessary to add other outworks to the ravelins all around the place, care must be taken to add likewise more to the fronts AB, EF, in order to render the advantages and disadvantages of attacking on either side equal.

2. *Construction of an Irregular Place situated on a hill or rock.*

In the construction of such places, care must be taken that no neighbouring hill commands any part of the works. The town should always be built on the highest part; but if it should be thought more convenient to place it lower, then the upper part must be fortified with a fort. The situation should be made level as near as possible, by removing the earth from some places to fill up others; and if it cannot well be levelled without extraordinary expence, works must be made on the highest part, so as to command and protect the lower. The works ought to occupy all the upper part of the hill; but if it should be too extensive to be all enclosed, or so irregular as not to be fortified without great inconvenience, the parts which fall without should be fortified with some detached works, and a communication with the place must be made either above or under ground. There should be no cavity or hollow roads within cannon shot round about the place, where the enemy might be able to approach under cover. If there should happen to be a spring near the top of the hill, it should be enclosed in the fortification, or, if that cannot be done, by some work or other; for there is nothing more necessary, and at the same time scarcer, in such situations than water; for which reason there cannot be too much care in providing it; several cisterns are to be made to receive the rain water, and to preserve it; wells should be dug likewise, though ever so deep, the water of which will serve for common use.

Places built on hills or rocks should never be large; for their use is generally to guard passes or inlets into a country, and are seldom useful in traffic; and it is a difficult matter to provide for a large garrison in such situations: neither should any such place be built without some very material reasons; but when it is absolutely necessary, great care and precaution should be taken to render the works as perfect as the situation will admit of, and at the same time to be as frugal in the expence as possible.

3. *Construction of Irregular Fortifications situated near rivers, lakes, or the sea.*

As the intent of building these kind of places is chiefly to facilitate and protect trade, they are of more importance than any other kind, especially in maritime countries, where the principal strength and power depends on them: for which reason, we shall treat of this construction more largely than of any other.

The first thing to be considered is their situation, which ought to be such as to afford a good harbour for shipping, or a safe and easy entrance in stormy weather; but as it is hardly possible to find any where ships may go in and lie secure with all winds, care should be taken to make them safe to enter with those winds which are most dangerous; but it is not sufficient that the harbour is safe against stormy weather, it should likewise be so against an enemy both by land and water, for it often happens, that ships are destroyed where it was imagined they were secure, which is of too great consequence not to be provided against; for which reason, forts or batteries must be built in the most convenient places, to prevent the enemy's ships from coming too near, so as to be able to cannonade those in the harbour, or fling shells amongst them; and if there is any danger of an enemy's approach by land, high ramparts and edifices must be built, so as to cover them.

When a river is pretty large, and it is not convenient for making a harbour without great expence, the ships may ride along the shore: which for that reason, must be made accessible for ships of burden: this may be done by advancing the quay into the river if the water is too shallow, or by digging the river sufficiently deep for that purpose.

And to prevent an enemy from coming up the river, forts must be built on both sides, especially when there are any turnings or windings. Antwerp is such a place; for the Scheldt is sufficiently deep to carry ships of great burden, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river.

When the river is but small, so that no ships of burden can come through it, it is sufficient to make it run through some of the works, where proper landing-places are contrived, from whence the goods may be carried into

(A) Revetments are chiefly made to prevent a place from being surprised: outworks do not want to be made so; the taking them by surprise is of no great consequence, except in a siege, when other precautions are used to prevent it.

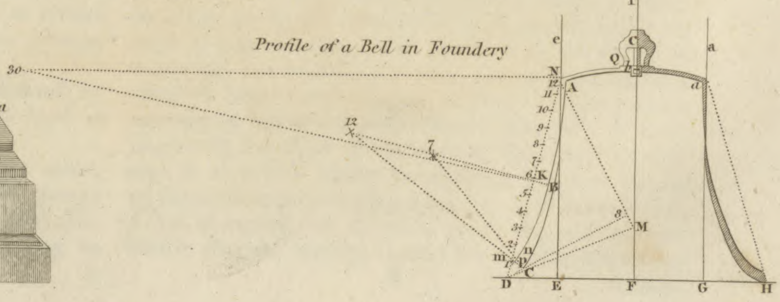
FOUNDERY.

Profile of a Bell in Foundery



Eng.d by Watson.

Of Irregular Fortification. Plate CCXXIII. into the place; as at Sarrelouis, where a hornwork is built beyond the Sarre, in the gorge of which the goods are landed.

If the breadth of the river does not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived, as that the river passes through the curtain, in order to have a bastion on each side to defend the coming in and going out.

When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others; such as Hunninghen on the Rhine, and Sarrelouis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author.

But it is plain that the sides which terminate at the river are the weakest; because the besiegers trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side: besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river longer, the angles of the extremities become wider, and consequently the adjacent sides stronger.

There are other advantages, besides those mentioned already, which arise from the lengthening that side: for if the river is pretty deep, so as not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water side to any part of the town.

Fig. 20. To illustrate this method of M. Vauban's, we shall give the plan of Hunninghen: this place was built for the sake of having a bridge over the Rhine, for which reason, he made it only a pentagon; the side AB next to the river is 200 toises, and each of the others but 180.

About the space *a b c*, which lies before the front AB, is a stone wall; and the passages *x x* are shut up with sluices, to retain the water in the ditches in dry seasons: and to prevent an enemy from destroying the sluice near the point *c*, whereby the water would run out and leave the ditches dry, the redoubt *y* was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulated from the river side, where the water is shallow in dry seasons.

The hornwork K beyond the Rhine was built to cover the bridge; but as this work cannot be well defended across the river, the hornwork H was made to support the other.

Before finishing the description of this plan, we shall show how to find the long side AB.

After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, so as to be equally distant from the line joining the points EF that is parallel to it. On this diameter set off 100 toises on each side of the centre; from these points draw two indefinite perpendiculars to the diameter; then if from the points EF, as centres, two arcs are described with a radius of 180 toises, their intersections A and B, with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever.

When a place near a river is to be fortified for the safety of commerce, particular care should be taken in leaving a good space between the houses and the water side, to have a quay or landing place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege; and as water-carriage is very advantageous for transporting goods from one place to another, as likewise for bringing the necessary materials, not only for building the fortifications, but also the place itself, the expences will be lessened considerably when this convenience can be had; for which reason, places should never be built anywhere else but near rivers, lakes, or the sea; excepting in extraordinary cases, where it cannot be avoided.

Fortin ‖ Fortitude. FORTIN, Forteler, or *Field-fort*, a sconce, or little fort, whose flanked angles are generally 120 fathoms distant from one another.

The extent and figure of fortins are different, according to the situation and nature of the ground; some of them having whole bastions, and others demi-bastions. They are made use of only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

FORTISSIMO, in *Music*, sometimes denoted by FFF, or *fff*, signifies, to sing or play very loud or strong.

FORTITUDE, a virtue or quality of the mind, generally considered as the same with Courage; though in a more accurate sense they seem to be distinguishable. Courage may be a virtue or a vice, according to circumstances; *fortitude* is always a virtue: we speak of desperate courage, but not of desperate fortitude. A contempt or neglect of danger, without regard to consequences, may be called *courage;* and this some brutes have as well as we: in them it is the effect of natural instinct chiefly; in man it depends partly on habit, partly on strength of nerves, and partly on want of consideration. But fortitude is the virtue of a rational and considerate mind, and is founded in a sense of honour and a regard to duty. There may be courage in fighting a duel, though that folly is more frequently the effect of cowardice; there may be courage in an act of piracy or robbery: but there can be no fortitude in perpetrating a crime. Fortitude implies a love of equity and of public good; for, as Plato and Cicero observe, courage exerted for a selfish purpose, or without

Fortitude. without a regard to justice, ought to be called audacity rather than fortitude.

This virtue takes different names, according as it acts in opposition to different sorts of evil; but some of those names are applied with considerable latitude. With respect to danger in general, fortitude may be termed *intrepidity;* with respect to the dangers of war, *valour;* with respect to pain of body or distress of mind, *patience;* with respect to labour, *activity;* with respect to injury, *forbearance;* with respect to our condition in general, *magnanimity*.

Fortitude is very becoming in both sexes; but courage is not so suitable to the female character; for in women, on ordinary occasions of danger, a certain degree of timidity is not unseemly, because it betokens gentleness of disposition. Yet from those of very high rank, from a queen or an empress, courage in emergencies of great public danger would be expected, and the want of it blamed; we should overlook the sex, and consider the duties of the station. In general, however, masculine boldness in a woman is disagreeable; the term *virago* conveys an offensive idea. The female warriors of antiquity, whether real or fabulous, Camilla, Thalestris, and the whole community of Amazons, were unamiable personages. But female courage exerted in defence of a child, a husband, or a near relation, would be true fortitude, and deserve the highest encomiums.

The motives to fortitude are many and powerful. This virtue tends greatly to the happiness of the individual, by giving composure and presence of mind, and keeping the other passions in due subordination. To public good it is essential; for without it, the independence and liberty of nations would be impossible. It gives to a character that elevation which poets, orators, and historians, have in all ages vied with one another to celebrate. Nothing so effectually inspires it as rational piety; the fear of God is the best security against every other fear. A true estimate of human life; its shortness and uncertainty; the numberless evils and temptations to which by a long continuance in this world we must unavoidably be exposed; ought by no means to discourage or to throw any gloom on our future prospects: they should teach us, that many things are more formidable than death; and that nothing is lost, but much gained, when, by the appointment of Providence, a well spent life is brought to a conclusion.

Let it be considered too, that pusillanimity and fearfulness can never avail us any thing. On the contrary, they debase our nature, poison all our comforts, and make us despicable in the eyes of others; they darken our reason, disconcert our schemes, enfeeble our efforts, extinguish our hopes, and add tenfold poignancy to all the evils of life. In battle, the brave soldier is in less danger than the coward; in less danger even of death and wounds, because better prepared to defend himself; in far less danger of infelicity; and has before him the animating hope of victory and honour. So in life, the man of true fortitude is in less danger of disappointment than others are, because his understanding is clear, and his mind disencumbered; he is prepared to meet calamity without the fear of sinking under it: and he has before him the near prospect of another life, in which they who piously bear the evils of this will obtain a glorious reward.

Fortitude ‖ Fortune.

FORTUNA, a goddess worshipped with great devotion by the ancient Greeks and Romans; who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure. See Fortune.

FORTUNATE islands, in *Ancient Geography*, certain islands (concerning the situation of which authors are not agreed), famous for the golden apples of the Hesperides.—The common opinion is, that they are the *Canary Islands*.

FORTUNE (Τυχη), a name which among the ancients seems to have denoted a principle of fortuity, whereby things came to pass, without being necessitated thereto; but what and whence that principle is, they do not seem to have ever precisely thought. Hence their philosophers are often intimating, that men only framed the phantom *Fortune* to hide their ignorance; and that they call *Fortune* whatever befals a man without his knowing for what purpose. Hence Juvenal (sat. x. ver. 366.) affirms, they were men who made a deity of fortune.

> *Nullum numen abest, si sit prudentia; sed te*
> *Nos facimus, Fortuna, deam, cæloque locamus.*

The ingenious Mr Spence gives another reading of this passage:

> *Nullum numen habes, si sit prudentia; sed te*
> *Nos facimus, Fortuna, deam, cæloque locamus.*

This reading, he thinks, agrees best with the context: Juvenal says, ver. 356, that the two things we should pray for are good health and good sense; that we might be the authors of our own happiness if we pleased, ver. 363.; that virtue is the only way to true happiness, ver. 364.; that if we ourselves are prudent, Fortune has no power over us; and that, in truth, she is no goddess at all, and has only usurped a seat in heaven from the folly of mankind, ver. 366. Fortune was not considered as a deity by the old Romans, but was made so by the devotion and folly of the vulgar; and Mr Spence says, that he has seen an ancient gem, in which Cybele, the mother of the gods, is represented as turning away her head from Fortune, in an attitude of disowning and rejecting her; (Polymetis, p. 150, 154, &c.)

According to the opinion of the heathens, therefore, fortune in reality was only the arrival of things in a sudden and unexpected manner, without any apparent cause or reason: so that the philosophical sense of the word coincides with what is vulgarly called *chance*.

But in religion it had a farther force; altars and temples in great numbers were consecrated to this Fortune, as a deity. This intimates, that the heathens had personified, and even deified, their chance; and conceived her as a sort of goddess, who disposed of the fate of men at her pleasure. Hence that invocation of Horace, *O diva, gratum quæ regis Antium*, in the 35th ode of the first book, where he recommends Augustus, then preparing for a visit to Britain, to her protection. From these different sentiments it may be inferred, that the ancients at one time took Fortune for a peremptory cause, bent upon doing good to some, Fortune, Forty. some, and persecuting others; and sometimes for a blind inconstant cause, without any view or determination at all.

If then the word *fortune* had no certain idea in the mouth of those who erected altars to her, much less can it be ascertained what it denotes in the minds of those who now use the word in their writings. They who would substitute the name *Providence* in lieu of that of *Fortune*, cannot give any tolerable sense to half the phrases wherein the word occurs.

Horace paints the goddess, preceded by Necessity, holding nails and wedges in her hands, with a cramp-iron, and melted lead to fasten it; rarely accompanied with Fidelity, unless when she abandons a family; for in that case Fidelity never fails to depart with her, as well as friends.

She is disrespectfully spoken of by most of the Roman writers, and represented as blind, inconstant, unjust, and delighting in mischief, (*Ovid. ad Liv.* ver. 52, ver. 374. (*Hor.* lib. i. od. 34. ver. 26. lib. iii. od. 29. ver. 15. *Statius*, Theb. xii. ver. 505.). However they had a good as well as a bad Fortune, a constant and inconstant Fortune; the latter of which was represented with wings, and a wheel by her, (*Hor.* lib. iii. od. 29. ver. 56.). Juvenal alludes to a statue of Fortune, which exhibited her under a very good character, as the patroness of the poor infants that were exposed by their parents in the streets, (*Sat.* vi. ver. 605.).

The painters represent her in a woman's habit, with a bandage before her eyes, to show that she acts without discernment; and standing on a wheel, to express her instability. The Romans, says Lactantius, represented her with a cornucopia, and the helm of a ship, to shew that she distributes riches, and directs the affairs of the world. In effect, it is with such characters that we see her represented on so many medals, with the inscription, FORTUNA AVG. FORTUNA REDVX, FORTVNÆ AVG. or REDVCIS, &c. Sometimes she is seen pointing at a globe before her feet, with a sceptre in one hand, and holding the cornucopia in the other.

The Romans had a virile as well as a muliebrian Fortune, for the objects of their adoration: the *Fortuna virilis* was honoured by the men, and the *Fortuna muliebris* by the women. They honoured fortune also under a variety of other appellations.

The Romans derived the worship of Fortune from the Greeks, under the reign of Servius Tullius, who dedicated the first temple to her in the public market. Nero also built a temple to Fortune. The Fortune worshipped at Antium was probably of the most exalted character of any among the Romans; if we may judge by the account which Horace gives us of the great solemn processions that were made to her, (*Hor.* lib. 1. od. 35. ver. 22.). But the most celebrated temple of Fortune was at Præneste. Statius speaks of several Fortunes there, and calls them the *Prænestinæ sorores*, (lib. i. Sylv. iii. ver. 80.).

FORTUNE-Tellers. Persons pretending to tell fortunes are to be punished with a year's imprisonment, and standing four times on the pillory. Stat. ix. Geo. II. c. 5.

FORTY DAYS *Court*, the conrt of *attachment* or *woodmote*, held before the verderors of the forest once every forty days, to inquire concerning all offenders against vert and venison. See ATTACHMENT.

Forum. FORUM, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

FORUM was also used for a place of traffic, answering to our market-place. These were generally called *fora venalia;* in contradistinction to the former, which were called *fora civilia.*

The *fora civilia* were public courts of justice, very magnificent in themselves, and surrounded with porticoes and stately edifices; of these there were six very remarkable: 1. *Forum Romanum.* 2. *Julianum.* 3. *Augustum.* 4. *Palladium.* 5. *Forum Trajani.* 6. *Forum Salustii.* The *Forum Romanum* was the most noted, and is often called simply *Forum*, by way of eminence. Here was the pleading place called *Rostra*, the *Comitium*, the sanctuary of *Saturn*, temple of *Castor*, &c. See ROSTRA, COMITIUM, &c.

The *fora venalia*, or market-places, were very numerous. The chief of them were the *forum boarium* for oxen or beef; *suarium* for swine; *pistorium* for bread; *cupedinarium* for dainties; *olitorium* for garden stuff.

The Grecian Αγοραι, exactly correspond with the Roman *fora*, being places where courts and markets were held. At Athens they had many *fora*, but the chief of them were the *old* and the *new.*

FORUM Indicere, was the act of the prætor appointing the place in Rome where causes were to be tried. *Agere forum* denoted the bringing on causes out of Rome, in a Roman province (Cicero, Suetonius); the same with *agere conventum* (Florus.)

The term *forum* added to a proper name, denoted some town or market borough; as,

FORUM Allieni, a place mentioned only by Tacitus; and, from what he says of it, thought to be *Ferrara*, capital of the duchy of that name in Italy. E. Long. 12. 5. N. Lat. 44. 46.

FORUM Appii (Cicero, Luke); a town of the Volsci, in Latium, on the Via Appia; a little beyond the Tres Tabernæ; set down in the Jerusalem Itinerary as situated near the river Nymphæus: now entirely extinct.

FORUM Cornelii, a town of the Cispadana, built by Sylla: Now *Imola*, a city in Romagna, and territory of the Pope. E. Long. 12. 12. N. Lat. 44. 30.

FORUM Domitii, a town of Gallia Narbonensis; probably built by Domitius Ahenobarbus, who commanded in those parts: Now *Frontignan*, or *Frontigniac*, in Languedoc, near the Mediterranean. E. Long. 3. 30. N. Lat. 43. 30.

FORUM Fulvii, a town of Liguria, surnamed *Valentinum:* from which it is conjectured that it it is now *Valenza*, in the duchy of Milan; which is confirmed by Peutinger's distances. E. Long. 9°. N. Lat. 45°.

FORUM Gallorum, a small town of the Cispadana, on the Via Æmilia, eight miles from Mutina, beyond the river Scultenna. Here Antony defeated Pansa, and was in his turn defeated by Hirtius: Now *Castelfranco*, in the territory of Bologna.—Another *Forum Gallorum*, a town of the Vascones in the Hither Spain: Now *Gurrea*, a small town of Arragon.

FORUM Julium. There are several towns of this name; as a *Forum Julium* of Gallia Narbonensis; or *Forojulium:* Now *Frejus*, or *Frejules*, in Provence, at the

the mouth of the Argens. *Forum Julium Carnorum*, to the north of Aquileia, in the Transpadana: Now *Cividal di Friuli*, formerly *Cividal d'Austria*, in the territory of Venice.

FORUM *Jutuntorum*, a town of the Insubres, in the Transpadana: Now *Crema*, capital of the Cremasco, in the territory of Venice. E. Long. 10. 15. N. Lat. 45. 20.

FORUM *Livii*, a town of the Semnones, in the Cispadana: Now *Forli*, in Romagna. E. Long. 12. 45. N. Lat. 44. 25.

FORUM *Segusianorum*, situated on the east side of the Liger, in Gallia Celtica: now *Feurs*, on the Loire, in the Lyonnois, capital of the territory of Forez. E. Long. 4. 15. N. Lat. 45. 44.

FORUM *Tiberii*, a town of the Pagus Tigurinus, in Belgica, on the left or south side of the Rhine: Now *Kayserstull;* literally the tribunal of Tiberius, which he held there when commander in the Rhetian war.

FORUM *Volcani* (Strabo); the *Campi Phlegræi* of Pliny; a place in Campania encompassed with rocky eminences, near Puteoli, and distant from it two miles towards Naples, emitting smoke, and in some places flame, like a large extensive furnace, and yielding sulphur: Now called *Solfatara*, in the Terra di Lavoro.

FORUM is also used, among casuists, &c. for jurisdiction; thus they say, *In foro legis*, &c.

FOSS, or FOSSE, in *Fortification*, &c. a ditch or moat. The word is French, formed of the Latin participle *fossum*, of the verb *fodio*, " I dig."

Foss, *Fossa*, in *Anatomy*, a kind of cavity in a bone, with a large aperture, but no exit or perforation. When the aperture is very narrow, it is called a *sinus*.

Foss is particularly used for the cavity or denture in the back part of the neck.

FOSSA MAGNA, or NAVICULARIS, is an oblong cavity, forming the inside of the *pudendum muliebre*, and which presents itself upon opening the labia; and in the middle whereof are the *carunculæ myrtiformes*. See ANATOMY.

FOSSA, in our ancient customs, was a ditch full of water, where women committing felony were drowned; as men were hanged: *Nam et ipsi in omnibus tenementis suis omnem ab antiquo legalem habuere justitiam, videlicet ferrum, fossam, furcas, et similia.* In another sense it is taken for a grave, as appears by these old verses:

Hic jacent in fossa Bedæ venerabilis ossa:
Hic est fossatus, qui bis erat hic cathedratus.

Foss Way was anciently one of the four great Roman highways of England: so called, according to Camden, because it was ditched on both sides, which was the Roman method of making highways.

FOSSARII, in antiquity, a kind of officers in the eastern church, whose business was to inter the dead.

Ciaconius relates, that Constantine created 950 fossaries, whom he took out of the divers colleges or companies of tradesmen: he adds, that they were exempted from taxes, services, burdensome offices, &c.

F. Goar, in his notes on the Greek Euchologion, insinuates that the fossarii were established in the times of the apostles; and that the young men, who carried off the body of Ananias, and those persons full of the fear of God who interred St Stephen, were of the number.

St Jerome assures us, that the rank of fossarii held the first place among the clerks; but he is to be understood of those clerks only who had the direction and intendance of the interment of the devout.

FOSSE, the Roman military way in South Britain, begins at Totness, and passes through Exeter, Ivelchester, Shepton Mallet, Bath, Cirencester, Leicester, the Vale of Belvoir, Newark, Lincoln, to Barton upon the Humber, being still visible in several parts, though of 1400 years standing. It had the name from the fosses or ditches made by the sides of it.

FOSSIL, in *Natural History*, denotes, in general, every thing dug out of the earth, whether it be a native thereof, as metals, stones, salts, earths, and other minerals; or extraneous, reposited in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c.

Native fossils are substances found in the earth, or on its surface, of a simple structure, exhibiting no appearances of organization; and these are included under the general names of simple and compound, earthy or metallic minerals. See MINERALOGY.

Extraneous fossils are bodies of the vegetable or animal kingdoms accidentally buried in the earth. Of the vegetable kingdom, there are principally three kinds; trees or parts of them, herbaceous plants, and corals: and of the animal kingdom there are four kinds; sea shells, the teeth or bony palates and bones of fishes, complete fishes, and the bones of land animals. See GEOLOGY.

These adventitious or *extraneous* fossils, thus found buried in great abundance in divers parts of the earth, have employed the curiosity of several of our latest naturalists, who have each their several system to account for the surprising appearances of petrified sea fishes, in places far remote from the sea, and on the tops of mountains; shells in the middle of quarries of stone; and of elephants teeth, and bones of divers animals, peculiar to the southern climates, and plants only growing in the east, found fossil in our northern and western parts.

Some will have these shells, &c. to be real stones, and stone plants, formed after the usual manner of other figured stones; of which opinion is the learned Dr Lister.

Another opinion is, that these fossil shells, with all the foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the universal deluge; and that, having been penetrated either by the bituminous matter abounding chiefly in watery places, or by the salts of the earth, they have been preserved entire, and sometimes petrified.

Others think, that those shells, found at the tops of the highest mountains, could never have been carried thither by the waters, even of the deluge; inasmuch as most of these aquatic animals, on account of the weight of their shells, always remain at the bottom of the water, and never move but close along the ground. They imagine, that a year's continuance of the waters of the deluge, intermixed with the salt waters of the sea, upon the surface of the earth, might well give occasion to the production of shells of divers kinds in different climates;

Fossil, Foster.

climates; and that the universal saltness of the water was the real cause of their resemblance to the sea shells, as the lakes formed daily by the retention of rain or spring water produce different kinds.

Others think, that the waters of the sea, and the rivers, with those which fell from heaven, turned the whole surface of the earth upside down; after the same manner as the waters of the Loire, and other rivers, which roll on a sandy bottom, overturn all their sands, and even the earth itself, in their swellings and inundations; and that in this general subversion, the shells came to be interred here, fishes there, trees there, &c. See DELUGE.

Dr Woodward, in his Natural History of the Earth, pursuing and improving the hypothesis of Dr Burnet, maintains the whole mass of earth, with every thing belonging thereto, to have been so broken and dissolved at the time of the deluge, that a new earth was then formed on the bosom of the water, consisting of different strata or beds of terrestrial matter, ranged over each other usually according to the order of their specific gravities. By this means, plants, animals, and especially fishes and shells, not yet dissolved among the rest, remained mixed and blended among the mineral and fossil matters; which preserved them, or at least assumed and retained their figures and impressions either indentedly or in relievo. See GEOLOGY.

Fossil Pitch. See PETROLEUM, MINERALOGY *Index*.

FOSTER, JAMES, a nonconformist divine, very highly celebrated for his pulpit eloquence and erudition, was born at Exeter in the year 1697. At the age of five years he was put to the free school of that city, where his progress in the acquisition of grammar was so rapid, that his master boasted of him as the most eminent genius in his school. From this seminary he went to the academy where young men designed for clergymen in the dissenting interest were educated, where his progress and applause were equally great. His apprehension was remarkably quick, his judgment solid, memory retentive, eloquence commanding, and his talents for argumentation were truly admirable; but above all, his piety was genuine, and few men possessed candour, modesty, liberality, integrity, tenderness and benevolence, in such a remarkable degree. He commenced preacher at the age of 21, and was much admired where he occasionally officiated. About this time the doctrine of the Trinity was much agitated in the west of England, which was not consonant to the notions of Mr Foster, and the honesty and openness of his heart would not allow him to conceal these, which brought so much odium upon him from the orthodox party, that he retired to another scene of action. He became pastor of a congregation at Milborne-port, in Somersetshire; but as soon as his hearers became zealously attached to what was deemed the orthodox opinion, he retired to Ashwick under the hills of Mendip, in the same county. In this asylum he preached to two congregations at a little distance from each other, as poor as they were plain, the united contributions of which did not amount to 15l. per annum. In this humble poverty and obscurity he lived for some years, honourable, however, as it was occasioned by his determined uprightness and sincerity. In the year 1720, he gave the world his "Essay on Fundamentals, with a particular regard to the doctrine of the ever-blessed Trinity," &c. The design of this work was to check an uncharitable and intolerant spirit, at that time extremely prevalent, by shewing that the trinitarian notion is not a fundamental article of Christianity, or made an express condition of salvation in the sacred scriptures. A sermon accompanied this essay, entitled "The resurrection of Christ proved, and vindicated against the most important objections of the ancient Jews, or modern Deists, and his disciples shown to be sufficient witnesses of the fact." From Ashwick he removed to Trowbridge in Wiltshire, where his congregation did not usually exceed 20 or 30 people.

Foster.

By reading Dr Gale's treatise on infant baptism, he became a convert to the doctrine, that immersion is the true scriptural rite, and was accordingly soon after baptised in London in conformity to that mode. This unreserved manner of adopting whatever his conscience believed to be truth, excluded him from almost every religious party among whom he might otherwise have expected preferment. But while he deliberated with himself whether he should abandon the ministry, and acquire the knowledge of some mechanical employment, Robert Houlston, Esq. took him to his house in the capacity of chaplain, where his circle of acquaintances became wider and more respectable. In 1724, he was appointed to succeed Dr Gale in the baptist congregation in Barbican, London. In the year 1728 he commenced a Sunday evening lecture in the Old Jewry, which he continued till within a short time of his death, with such a degree of popularity as few dissenters at that time experienced. In 1732 appeared his valuable work, entitled "The usefulness, truth, and excellency of the Christian revelation, defended against the objections contained in a late book, called Christianity as old as the Creation," &c. In this reply Mr Foster exhibited no ordinary share of talents and ingenuity, and it was admired by the candid and judicious of every description. Dr Tindal, against whom it was written, is said to have spoken of it always with great respect. He published a volume of sermons in the year 1734, followed by other three volumes, the last of which appeared in 1744. At this time he was appointed successor to Dr Jeremiah Hunt, in the protestant congregation at Pinner's-hall. In 1746, he attended the earl of Kilmarnock when under sentence of death for high-treason, after which he published an octavo pamphlet, with the title of "An account of the behaviour of the late earl of Kilmarnock after his sentence, and on the day of his execution."

He received from the Marischal college of Aberdeen the degree of doctor in divinity, accompanied with handsome letters from the principal and Professor Fordyce, the latter of whom thus addressed him. "We beg that you will be so good as to accept of the diploma, as a small mark of the sincere veneration we have for you, and of the sense we entertain of the eminent services you have done to the cause of liberty, religion, and virtue, by your writings as well as public instructions." The first volume in quarto of his 'Discourses on all the Principal Branches of Natural Religion and Social Virtue,' was published in the year 1749, and the second appeared in 1752. They were published by subscription; and to evince the high estimation in which

his

his talents and virtues were held, 2000 names were contained in the list, many of them distinguished by their dignified rank and literary abilities.

In the month of April 1750, he was seized with a violent distemper, from the effects of which he never thoroughly recovered; yet while at all able to officiate, he continued to preach till the beginning of 1752, when he had another attack, which seems to have been of a paralytic nature. After declining for some time, he expired like a genuine Christian on the 5th of November, in the 55th year of his age. His private and public life were alike irreproachable. Such was the wonderful extent of his beneficence, that he must have died in indigent circumstances, had it not been for the numerous subscriptions to his discourses on natural religion. Mr Rider gives him the following eulogium. "His voice was naturally sweet, strong, distinct, harmonious, always adapted to his matter, always varied as his method changed; as expressive of the sense as the most judicious recitative. Monotony was a fault he was never guilty of. His action, the soul of eloquence, was grave, expressive, free from distortions, animated without being theatrical; in short, such as became the pulpit. He reminded us of Paul at Athens, arresting the attention of his auditors." It was no doubt such rare accomplishments which induced Mr Pope to be an occasional hearer, and to pay him the following compliment:

> Let modest Foster, if he will, excel
> Ten metropolitans in preaching well.

In a poem describing the respective merits of dissenting ministers at that period, and supposed to have been the work of Mr Savage, we find the following lines upon Dr Foster.

> But see th' accomplish'd orator appear,
> Refin'd his language, and his reasoning clear;
> Thou only, Foster, hast the pleasing art,
> At once to charm the ear and mend the heart.

Besides the works formerly taken notice of, Dr Foster published three funeral sermons, one of which was intended for that celebrated confessor Mr Emyln; together with a number of essays in the Old Whig.

FOSTER, *Samuel*, an ingenious English mathematician of the last century, and astronomical professor in Gresham college, was one of that learned association which met for cultivating the new philosophy during the political confusions, and which Charles II. established into the Royal Society. Mr Foster, however, died in 1652, before this incorporation took place; but wrote a number of mathematical and astronomical treatises, too many to particularize. There were two other mathematical students of this name; William Foster, a disciple of Mr Oughtred, who taught in London, and Mark Foster, author of a treatise on trigonometry, who lived later than the former two.

FOTHER, or FODDER, is a weight of lead, containing eight pigs, and every pig one and twenty stone and a half; so that it is about a ton or common cart load. Among the plumbers in London, it is nineteen hundred and a half; and at the mines it is two and twenty hundred and a half. The word is of Teutonic origin, from *fuder*.

FOTHERGILL, DR GEORGE, was born in Westmorland in 1705, where his family had been long seated on a competent estate that had descended regularly for several generations. After an academical education in Queen's college, Oxford, of which he became a fellow, he was, in 1751, elected principal of St Edmund's hall, and presented to the vicarage of Brumley in Hampshire. Having been long afflicted with an asthma, he died in 1760. He was the author of a collection of much esteemed sermons, in 2 vols. 8vo. The first volume consists of occasional discourses, published by himself; the second printed from his MSS.

FOTHERGILL, *Dr John*, a late eminent physician, son of John and Margaret, Quakers, was born in 1712, at Carr End in Yorkshire, where his father, who had been a brewer at Knaresborough (after having travelled from one end of America to the other), lived retired on a small estate which he cultivated. The Doctor was the second of five children (four sons and a daughter), and received his education under the care of his grandfather Thomas Hough, a person of fortune in Cheshire, which gave him a predilection for that county), and at Sedbergh in Yorkshire. He afterwards served his time to one Mr Bartlett an apothecary at Bradford. From thence he removed to London, and became a pupil of Dr (afterwards Sir Edward) Wilmot, at St Thomas's hospital. He then went to the university of Edinburgh to study physic, and took his doctor's degree there. From Edinburgh he went to Leyden; whence, after a short stay, he returned to London, and began to practise about the year 1740, in a house in White-hart Court, Lombard-street, where he resided during the greatest part of his life, and acquired most of his fortune. In 1746, he was admitted a licentiate of the College of Physicians in London; and in 1754 a fellow of that of Edinburgh, to which he was a considerable benefactor. He afterwards became a member of the Royal Medical Society at Paris, and a member both of the Royal and Antiquarian Societies. He continued his practice with uninterrupted success till within the last two years of his life, when the illness which he had brought on himself by unremitted attention, obliged him to give up a considerable part of it. Besides his application to medical science, he had imbibed an early taste for natural history, improved by his friend Peter Collinson, and employed himself on conchology and smaller objects of botany. He was for many years a valuable contributor to the Gentleman's Magazine; where his observations on the weather and diseases were begun in April 1751, and discontinued in the beginning of 1756, being disappointed in his views of exciting other experienced physicians in different parts to imitate the example. He had very extensive practice, but he did not add to his art any great or various improvements. His pamphlet on the ulcerous sore throat is, on every account, the best of his publications; but owes much of its merit to the information of the late Dr Letherland. It was printed in 1748, on the re-appearance of that fatal disorder which in 1739 had carried off the two only sons of Mr Pelham. In 1762 Dr Fothergill purchased an estate at Upton in Essex; and formed a botanic garden there, the second in Europe; Kew is the first. In 1766 he began regularly to withdraw, from Midsummer to Michaelmas, from the excessive fatigue of his profession, to Lee Hall, near Middlewich, in Cheshire; which, though he only rented

Fothergill. ed it by the year, he had spared no expence to improve. He took no fees during this recess, but attended to prescribe gratis at an inn in Middlewich once a week. In 1767, after he found himself obliged to relax his attention to business, he removed from his house in the city, to reside in Harpur-street, Red-Lion Square. Some time before his death he had been industrious to contrive a method of generating and preserving ice in the West Indies. He was the patron of Sidney Parkinson, and drew up the preface prefixed to his account of the voyage to the South Seas. At his expence also was made and printed an entire new translation of the whole Bible, from the Hebrew and Greek originals, by Anthony Purver, a Quaker, in two volumes, 1764, folio, and also, in 1780, an edition of Bishop Percy's "Key to the New Testament," adapted to the use of a seminary of young Quakers, at Acworth, near Leeds in Yorkshire, founded in 1778 by the Society, who purchased, by a subscription in which Dr Fothergill stood foremost, the house and an estate of thirty acres which the Foundling Hospital held there, but which they found inconvenient for their purpose on account of distance. The Doctor himself first projected this on the plan of a smaller institution of the same kind at Gildersomes. He also endowed it handsomely by his will. It now contains above 300 children of both sexes, who are clothed and instructed. Among the other beneficent schemes suggested by Dr Fothergill were those of bringing fish to London by land carriage, which, though it did not in every respect succeed, tended to destroy a supposed combination; and of rendering bread much cheaper, though equally wholesome, to the poor, by making it with one part of potatoes and three parts of household flour. But his public benefactions, his encouragements of science, the instances of his attention to the health, the police, the convenience of the metropolis, &c. we cannot pretend to specify. The fortune which Dr Fothergill had acquired was immense; and, taking all things together, the house and moveables in Harpur-street, the property in Essex, and the estate in Cheshire (which he held on a lease), and his ready money, amounted to 80,000l. His business, when he was in full practice, was calculated at near 7000l. per annum. In the influenza of 1775 and 1776, he is said to have had 60 patients on his list daily, and his profit was estimated at 8000l. per annum.

The disorder which hastened his death was a scirrhus of the prostata, and an obstruction of the bladder (in which were found after his death two quarts of water), which had been gradually coming on him for six years past, occasioned by a delicacy, which made him unwilling to alight from his carriage, and when, after his temporary recovery from it the year before he died, he submitted to use relief in his carriage, it was too late. He died at his house in Harpur-street, December 26. 1780; and his remains were interred, January 5. in the Quakers burying-ground at Winchmore-hill, whither they were accompanied by more than 70 coaches and post-chaises, notwithstanding the intention of the executors to have the funeral private. The Doctor by his will appointed, that his shells and other pieces of natural history should be offered to the late Dr Hunter at 500l. under the valuation he ordered to be taken of them. Accordingly Dr Hunter bought them for 1200l. The drawings and collections in natural history were also to be offered to Mr (now Sir Joseph) Bankes at a valuation. His English portraits and prints, which had been collected by Mr John Nickolls of Ware, and purchased by him for 80 guineas, were bought for 200 guineas by Mr Thane. His books were sold by auction, April 30. 1781, and the eight following days. His house and garden at Upton, in which 15 men were constantly employed, were valued at 10,000l. He spared no expence to augment this as well as his other collections. He had an ingenious artist qualified to collect for him at the Cape of Good Hope, and another on the Alps, and employed for several years before his death a painter in natural history at Leeds.

Fothergill || Fotheringay.

Dr Fothergill's character was excellent. A transaction, indeed, with regard to one Dr Leeds, gave occasion to some of his enemies to blame him; but how unjustly, has been abundantly shown by his biographers Dr Elliot and Dr Lettsome. Besides the pamphlet already mentioned, Dr Fothergill wrote a considerable number of Tracts, which are now collected into one volume 8vo, by Dr Elliot. He sometimes wrote in the newspapers, and is said to be the author of more than 100 letters in the Gazetteer, concerning the New Pavement.

FOTHERGILLA, a genus of plants belonging to the polyandria class. See BOTANY *Index*.

FOTHERING, a peculiar method of endeavouring to stop a leak in the bottom of a ship while she is afloat, either under sail or at anchor. It is usually performed in the following manner: A basket is filled with ashes, cinders, and chopped rope yarns, and loosely covered with a piece of canvas; to this is fastened a long pole, by which it is plunged repeatedly in the water, as close as possible to the place where the leak is conjectured to lie. The oakum or chopped rope yarns being thus gradually shaken through the twigs, or over the top of the basket, are frequently sucked into the hole along with the water, so that the leak becomes immediately choked; and the future entrance of the water is thereby prevented.

FOTHERINGAY, a town of Northamptonshire, about four miles from Staneford, situated on the river Avon, or Nen, and consisting of one street. Edward duke of York, in the reign of Henry V. founded and endowed a fine collegiate church here, in which he was interred. At the dissolution, the college and the choir were pulled down, and the bodies of the founder and his family left exposed till Queen Elizabeth's time, who ordered them to be interred, and the present monuments to be erected. On the north side of the church is a free school, founded by Henry VII. or Edward VI. endowed with 20l. per annum for a master, payable out of the exchequer by the receiver of the county. The bridge over the river here was first built by Queen Elizabeth, 1573, of timber, with three pillars upon the foundation. Daniel, first earl of Nottingham, and the other trustees for William Saville, marquis of Halifax, rebuilt it in 1722, of freestone from King's Cliffe. On the south-east side of the cliffe stood the castle; which was of great antiquity and considerable strength. Mary queen of Scots, who had been in the custody of Sir

Amias

Amias Powlet here, was tried and beheaded in the hall; and her son afterwards, forgiving and even taking into favour her greatest enemy Cecil, only took the childish revenge of beating down the castle; which he so completely demolished, that no more than the earthworks now remain. Within the first work is a farm-house, with some carved stones wrought into it, and at the south-west corner of the inner trench are some masses of stone walls. Sir Robert Cotton carried the wainscot of the hall to Connington.

FOU-TCHEOU, a city of China, in the province of FO-KIEN. It carries on a considerable trade; but is chiefly remarkable for the magnificence of its principal bridge, which has more than 100 arches constructed of white stone, and ornamented with a double balustrade throughout. This city is the residence of a viceroy, and has under its jurisdiction nine cities of the third class.

FOUGADE, or FOUGASSE, in the art of war, a little mine, about 8 or 10 feet wide, and 10 or 12 deep, dug under some work or post, which is in danger of falling into the enemy's hands; and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a saucisse. See mine.

FOUL, or FOULE, in the sea language, is used when a ship has been long untrimmed, so that the grass weeds, or barnacles, grow on her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run or be overhauled.

FOUL imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a share. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury; but in cases where it is evidently the fault of the master of the vessel, he is alone to bear the damage.

FOUL-Water. A ship is said to make foul water, when, being under sail, she comes into such shoal water, that though her keel do not touch the ground, yet it comes so near it, that the motion of the water under her raises the mud from the bottom.

FOUL is also a disease in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell.

FOUL or *Pimpled Face.* See *GUTTA Rosacea.*

FOULA, or *FOUL Island*, one of the Shetland isles, lying between six and seven leagues west from the main land. It is about three miles long, narrow, and full of rough, steep, and bare rocks; one of which is so large, and runs up to such a height, that it may be clearly seen from Orkney. This, it is probable, is the Thule of Tacitus. It has scarcely any pasturage, and but little arable land. The only commodities exported are stock fish, train oil, and feathers.

FOULAHS, a people of Africa, which inhabit the confines of the great desert Sahara. The principal of the Foulah states is that within Sierra Leona, and of which Teembo is the capital. See SIERRA LEONA.

FOUMART, a species of MUSTELA. See MAMMALIA *Index.*

FOUNDATION, in *Architecture*, is that part of a building which is under ground. See ARCHITECTURE, N° 104.

Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging; unless there be cellars under ground, in which case he would have it somewhat lower.

FOUNDATION, denotes also a donation or legacy, either in money or lands, for the maintenance and support of some community, hospital, school, &c.

The king only can found a college, but there may be a college in reputation founded by others. If it cannot appear by inquisition who it was that founded a church or college, it shall be intended that it was the king, who has power to found a new church, &c. The king may found and erect an hospital, and give a name to the house upon the inheritance of another, or license another person to do it upon his own lands; and the words *fundo*, *creo*, &c. are not necessary in every foundation, either of a college or hospital, made by the king; but it is sufficient if there be words equivalent: the incorporation of a college or hospital is the very foundation; but he who endows it with lands is the founder; and to the erection of an hospital, nothing more is requisite but the incorporation and foundation. Persons seised of estates in fee simple, may erect and found hospitals for the poor by deed enrolled in chancery, &c. which shall be incorporated, and subject to such visitors as the founder shall appoint, &c. stat. 39 Eliz. c. 5. *Jacob's Law Dict.*

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. See FOUNDATION.

FOUNDER, also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See FOUNDERY.

FOUNDER, in the sea language: A ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lie like a log; and not being able to swim long, will at last sink.

FOUNDERED, applied to horses. See FARRIERY *Index.*

FOUNDERY, or FOUNDRY, the art of casting all sorts of metals into different forms. It likewise signifies the workhouse or smelting hut wherein these operations are performed.

FOUNDERY of Small Works, or casting in Sand. The sand used for casting small works is at first of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. The sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length, and breadth proportional to the things to be cast, and putting a ledge round it they fill it with sand, a little moistened, Foundery. moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them so to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all around, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame; only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame, thus moulded, is carried to the melter; who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and strewing mill dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins: and to prevent them giving way, by reason of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

When the moulds are coolish, the frames are unscrewed or unwedged, and the cast work taken out of the sand, which sand is worked over again for other casting.

Foundery of Statues. The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone or brick; or when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potters clay, mixed with hair and horse dung; or of plaster of Paris mixed with brick dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core: Though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick dust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent holes, to give passage to the air, which would otherwise occasion great disorder when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water to the consistence of a colour fit for painting: accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whiles. For the second impression they add horse dung and natural earth to the former composition. The third impression is only horse dung and earth. Lastly, The shell is finished by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron girths, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate.

If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone or brick. At the bottom is made a hole of the same materials, with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, At one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting furnace. For the rest, the method is the same in both. The mould being finished, and enclosed as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented, till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they

Foundery. they take out the bricks, and fill up their place with earth moistened, and a little beaten at the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen bason, over the mould, into the bottom of which all the big branches of the jets, or casts, which are to convey the metal into all the parts of the mould, are inserted.

These casts or jets are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence, may not enter any of them, till the bason be full enough of matter to run into them all at once. Upon which occasion they pull out the plugs, which are long iron rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest being the sculptor's or carver's business, who, taking the figure out of the mould and earth wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chissels, gravers, puncheons, &c.

Foundery of Bells. The metal, it is to be observed, is different for bells from what it is for statues; there being no tin in the statue metal; but there is a fifth, and sometimes more, in the bell metal.

The dimensions of the core and the wax, for bells, if a chime of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness, necessary for the several tones required.

It is on the wax that the several mouldings and other ornaments and inscriptions, to be represented in relievo on the outside of the bell, are formed. The clapper or tongue is not properly part of the bell, but is furnished from other hands. In Europe, it is usually of iron, with a large knob at the extreme; and is suspended in the middle of the bell. In China, it is only a huge wooden mallet, struck by force of arm against the bell; whence they can have but little of that consonancy so much admired in some of our chimes of bells. The Chinese have an extraordinary way of increasing the sound of their bells, viz. by leaving a hole under the cannon; which our bell-founders would reckon a defect.

The proportions of our bells differ very much from those of the Chinese. In ours, the modern proportions are, to make the diameter 15 times the thickness of the brim, and the height 12 times. The parts of a bell are, 1. The sounding bow, terminated by an inferior circle, which grows thinner and thinner. 2. The brim or that part of a bell whereon the clapper strikes, and which is thicker than the rest. 3. The outward sinking of the middle of the bell, or the point under which it grows wider to the brim. 4. The waist or furniture, and the part that grows wider and thicker quite to the brim. 5. The upper vase, or that part which is above the waist. 6. The pallet which supports the staple of the clapper within. 7. The bent and hollowed branches of metal uniting with the cannons, to receive the iron keys, whereby the bell is hung up to the beam, which is its support and counterpoise when rung out.

The business of bell foundery is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould. And, 3. The melting of the metal. There are two kinds of proportions, viz. the simple and the relative; the former are those proportions only that are between the several parts of a bell to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The method of forming the profile of a bell, previous to its being cast, in which the proportion of the several parts may be seen, is as follows: the thickness of the brim, C 1 (Plate CCXXIII.) is the foundation of every other measure, and is divided into three equal parts. First, draw the line HD, which represents the diameter of the bell; bisect it in F, and erect the perpendicular F*f*; let DF and HF be also bisected in E and G, and two other perpendiculars E *e*, G *a*, be erected at E and G: GE will be the diameter of the top or upper vase, i. e. the diameter of the top will be half that of the bell; and it will, therefore, be the diameter of a bell which will sound an octave to the other. Divide the diameter of the bell or the line HD into 15 equal parts, and one of these will give C 1 the thickness of the brim; divide again each of these 15 equal parts into three other equal parts, and then form a scale. From this scale take 12 of the larger divisions or $\frac{2}{15}$ of the whole scale in the compass, and setting one leg in D describe an arc to cut the line E *e* in N; draw ND, and divide this line into 12 equal parts; at the point 1 erect the perpendicular 1 C=10, and C 1 will be the thickness of the brim $=\frac{1}{15}$ of the diameter: draw the line CD; bisect DN; and at the point of bisection erect the perpendicular 6 K=$1\frac{1}{2}$ of the larger divisions on the scale. With an opening of the compass equal to twice the length of the scale or 30 brims, setting one leg in N, describe an arc of a circle, and with the same leg in K and the same opening describe another arc to intersect the former: on this point of intersection as a centre, and with a radius equal to 30 brims, describe the arc NK; in 6 K produced take KB=$\frac{1}{3}$ of the larger measure of the scale or $\frac{1}{3}$ of the brim, and on the same centre with the radius $30\frac{1}{3}$ brims describe an arc AB parallel to NK. For the arc BC, take 12 divisions of the scale or 12 brims in the compass; find a centre, and from that centre, with this opening, describe the arc BC, in the same manner as NK or AB were described. There are various ways of describing the arc K *p*; some describe it on a centre at the distance of nine brims from the points *p* and K; others, as it is done in the figure, on a centre at the distance only of seven brims from those points. But it is necessary first to find the point *p*, and to determine the rounding of the

Plate CCXXIII.

Foundery. the bell p 1. For this purpose, on the point C as a centre, and with the radius C 1, describe the arc 1 p n; bisect the part 1, 2 of the line D n, and erecting the perpendicular p m, this perpendicular will cut the arc 1 p n in m, which terminates the rounding 1 p. Some founders make the bendings K a third of a brim lower than the middle of the line DN; others make the part C 1 D more acute, and instead of making C 1 perpendicular to DN at 1, draw it $\frac{1}{8}$th of a brim higher, making it still equal to one brim; so that the line 1 D is longer than the brim C 1. In order to trace out the top part N a, take in the compass eight divisions of the scale or eight brims, and on the points N and D as centres, describe arcs to intersect each other in 8: on this point 8, with a radius of eight brims, describe the arc N b; this arc will be the exterior curve of the top or crown: on the same point 8 as a centre, and with a radius equal to $7\frac{2}{3}$ brims, describe the arc A e, and this will be the interior curve of the crown, and its whole thickness will be one-third of the brim. As the point 8 does not fall in the axis of the bell, a centre M may be found in the axis, by describing, with the interval of eight brims on the centres D and H, arcs which will intersect in M; and this point may be made the centre of the inner and outer curves of the crown as before. The thickness of the cap which strengthens the crown at Q is about one-third of the thickness of the brim; and the hollow branches or ears about one-sixth of the diameter of the bell. The height of the bell in proportion to its diameter as 12 to 15, or in the proportion of the fundamental sound to its third major: whence it follows, that the sound of a bell is principally composed of the sound of its extremity or brim as a fundamental, of the sound of the crown which is an octave to it, and of that of the height which is a third.

The particulars necessary for making the mould of a bell are, 1. The earth: the most cohesive is the best; it must be well ground and sifted, to prevent any chinks. 2. Brick stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards ranged upon tressels. Upon this they carry the earth, grossly diluted, to mix it with horse dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consist of two different legs joined by a third piece. And last of all the founders shelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case or cannon, under ground; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole, or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a *millstone*. The parts of the moulds are, the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying of each brick, they bring near it the branch of the compasses on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse dung; on which they move the compasses of construction, to make it of an even smoothness everywhere.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth that has been separately baked. The first fire consumes the stake, and the fire is left in the core half, or sometimes a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chafing dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine: while it is tempering in water, it is mixed with cows hair to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but somewhat thicker; when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cows hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses.

passes. The thickness of the shell comes to four or five inches lower than the millstone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings: the seventh is called the *bridge*, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire in order to have the hollow of them. Those rings are gently pressed upon a layer of earth and cows hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated 12 times for 12 half moulds, that two and two united may make the hollows of the six rings: the same they do for the hollow of the bridge, and bake them all to unite them together.

Upon the open place left for the coals to be put in are placed the rings that constitute the ear. They first put into this open place the iron ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapt upon the opening, and soldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist to fix on the place, which is strewed at several times upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal, they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the millstone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould, they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and solder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame revibrates; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross or scoriæ of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

Foundery of Great Guns and Mortar Pieces. The method of casting these pieces is little different from that of bells; they are run massy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trepan, that is worked either by horses or a water-mill.

For the metal, parts, proportions, &c. of these pieces, see Gunnery.

Letter Foundery, or *Casting of Printing Letters.* In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a vice, hand-vice, hammers, and files of all sorts for watchmakers use; as also gravers and sculpters of all sorts, and an oil-stone, &c. suitable and sizeable to the several letters to be cut: a flat gage made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using file: a sliding gage, whose use is to measure and set off distances between the shoulder and the tooth, and to mark it off from the end, or from the edge of the work; a face gage, which is a square notch cut with a file into the edge of a thin plate of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending letters, and short letters. So there must be three gages; and the gage for the long letters is the length of the whole body supposed to be divided into 42 equal parts. The gage for the ascending letters Roman and Italic are, $\frac{5}{7}$ or 30 parts of 42, and 33 parts for the English face. The gage for the short letters is $\frac{3}{7}$, or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the English face.

The Italic and other standing gages are to measure the scope of the Italic stems, by applying the top and bottom of the gage to the top and bottom lines of the letters, and the other side of the gage to the stem; for when the letter complies with these three sides of the gage, that letter has its true shape.

The next care of the letter cutter is to prepare good steel punches, well tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact shape of the letter with pen and ink if the letter be large, or with a smooth blunted point of a needle if it be small; and then with sizeable and proper shaped and pointed gravers and sculpters, digs or sculps out the steel between the strokes or marks he made on the face of the punch, and leaves the marks standing

standing on the face. Having well shaped the inside strokes of his letter, he deepens the hollows with the same tools; for if a letter be not deep in proportion to its width, it will, when used at press, print black, and be good for nothing. This work is generally regulated by the depth of the counter-punch. Then he works the outside with proper files till it be fit for the matrice.

But before we proceed to the sinking and justifying of the matrices, we must provide a mould to justify them by, of which there is a draught in Plate CCXXIII. fig. 1. 2.

Plate CCXXIII. fig. 1. & 2.

Every mould is composed of an upper and an under part. The under part is delineated in fig. 1. The upper part is marked fig. 2. and is in all respects made like the under part, excepting the stool behind, and the bow or spring also behind: and excepting a small roundish wire between the body and carriage, near the break, where the under part hath a small rounding groove made in the body. This wire, or rather half wire, in the upper part makes the nick in the shank of the letter, when part of it is received into the groove in the under part. These two parts are so exactly fitted and gaged into one another (viz. the male gage marked *c* in fig. 2. into the female marked *g* in fig. 1.), that when the upper part of the mould is properly placed on, and in the upper part of the mould, both together make the entire mould, and may be slid backwards for use so far, till the edge of either of the bodies on the middle of either carriage comes just to the edge of the female gages cut in each carriage; and they may be slid forward so far, till the bodies on either carriage touch each other: and the sliding of these two parts of the mould backwards makes the shank of the letter thicker, because the bodies on each part stand wider asunder; and the sliding them forwards makes the shank of the letter thinner, because the bodies on each part of the mould stand closer together. The parts of the mould are as follow: viz. a, The carriage. b, The body. c, The male gage. d e, The mouth-piece. f i, The register. g, The female gage. h, The hag, *a a a a*, The bottom-plate. *b b b*, The wood on which the bottom-plate lies. *c c c*, The mouth. *d d*, The throat. *e d d*, The pallat. *f*, The nick. *g g*, The stool. *h h*, The spring or bow.

Then the mould must be justified: and first the founder justifies the body, by casting about 20 proofs or samples of letters; which are set up in a composing stick, with all their nicks towards the right hand; and then by comparing these with the pattern letters, set up in the same manner, he finds the exact measure of the body to be cast. He also tries if the two sides of the body are parallel, or that the body be no bigger at the head than at the foot, by taking half the number of his proofs and turning them with their heads to the feet of the other half; and if then the heads and the feet be found exactly even upon each other, and neither to drive out nor get in, the two sides may be pronounced parallel. He farther tries whether the two sides of the thickness of the letter be parallel, by first setting his proofs in the composing stick with their nicks upwards, and then turning one-half with their heads to the feet of the other half; and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two sides of the thickness are parallel.

The mould thus justified, the next business is to prepare the matrices. A matrice is a piece of brass or copper of about an inch and a half long, and of thickness in proportion to the size of the letter it is to contain. In this metal is sunk the face of the letter intended to be cast, by striking the letter punch about the depth of an n. After this the sides and face of the matrice must be justified and cleared with files of all bunchings made by sinking the punch.

Every thing thus prepared, it is brought to the furnace; which is built of brick upright, with four square sides, and a stone on the top, in which stone is a wide round hole for the pan to stand in. A foundery of any consequence has several of these furnaces in it.

As to the metal of which the types are to be cast, this, in extensive founderies, is always prepared in large quantities; but cast into small bars, of about 20 pounds weight, to be delivered out to the workmen as occasion requires. In the letter foundery which has been long carried on with reputation under the direction of Mess. Wilson and Sons at Glasgow, we are informed, that a stock of metal is made up at two different times of the year, sufficient to serve the casters at the furnace for six months each time. For this purpose, a large furnace is built under a shade, furnished with a wheel vent, in order the more equally to heat the sides of a strong pot of cast iron, which holds when full 15 hundred weight of the metal. The fire being kindled below, the bars of lead are let softly down into the pot, and their fusion promoted by throwing in some pitch and tallow, which soon inflame. An outer chimney, which is built so as to project about a foot over the farthest lip of the pot, catches hold of the flame by a strong draught, and makes it act very powerfully in melting lead; whilst it serves at the same time to convey away all the fumes, &c. from the workmen, to whom this laborious part of the business is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients are put in, and some more tallow inflamed to make the whole incorporate sooner. The workmen now having mixed the contents of the pot very thoroughly by stirring long with a large iron ladle, next proceed to draw the metal off into the small troughs of cast iron, which are ranged to the number of fourscore upon a level platform, faced with stone, built towards the right hand. In the course of a day 15 hundred weight of metal can be easily prepared in this manner; and the operation is continued for as many days as are necessary to prepare a stock of metal of all the various degrees of hardness. After this, the whole is disposed into presses according to its quality, to be delivered out occasionally to the workmen.

The founder must now be provided with a ladle, which differs nothing from other iron ladles but in its size; and he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle his fire in the furnace to melt the metal in the pan. Therefore he takes the pan out of the hole in the stone, and there lays in coals and kindles them; and, when they are well kindled, he sets the pan in again,

again, and puts in metal into it to melt; if it be a small-bodied letter he casts, or a thin letter of great bodies, his ladle must be very hot, nay sometimes red hot, to make the letter come. Then having chosen a ladle that will hold about so much as the letter and break is, he lays it at the stoking hole, where the flame bursts out, to heat. Then he ties a thin leather, cut with its narrow end against the face to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek, and places the foot of the matrice on the stool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not tight up, lest it might hinder the foot of the matrice from sinking close down upon the stool in a train of work. Then laying a little rosin on the upper wood of the mould, and having his casting ladle hot, he with the boiling side of it melts the rosin: and, when it is yet melted, presses the broad end of the leather hard down on the wood, and so fastens it to the wood; all this is the preparation.

Now he comes to casting. Wherefore, placing the under half of the mould in his left hand, with the hook or hag forward, he clutches the ends of its wood between the lower part of the ball of his thumb and his three hind fingers; then he lays the upper half of the mould upon the under half, so that the male gages may fall into the female gages, and at the same time the foot of the matrice places itself upon the stool; and, clasping his left hand thumb strong over the upper half of the mould, he nimbly catches hold of the bow or spring with his right hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the backside of the matrice, pressing it as well forwards towards the mould, as downwards by the shoulder of the notch close upon the stool, while at the same time with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of his thumb, and thrusts by the ball of his thumb the upper part towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both halves of the mould close together.

Then he takes the handle of his ladle in his right hand, and with the boll of it gives a stroke, two or three, outwards upon the surface of the melted metal, to scum or clear it from the film or dust that may swim upon it; then takes up the ladle full of metal, and having his mould, as aforesaid, in his left hand, he a little twists the left side of his body from the furnace, and brings the geat of his ladle (full of metal) to the mouth of the mould, and twists the upper part of his right hand towards him to turn the metal into it, while at the same moment of time he jilts the mould in his left hand forwards, to receive the metal with a strong shake (as it is called), not only into the body of the mould, but while the metal is yet hot running, swift and strongly, into the very face of the matrice, to receive its perfect form there, as well as in the shank.

Then he takes the upper half of the mould off the under half, by placing his right hand thumb on the end of the wood next his left hand thumb, and his two middle fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould (as most commonly by reason of its weight it does), he throws or tosses the letter, break and all, upon a sheet of waste paper laid for that purpose on the bench, just a little beyond his left hand, and is then ready to cast another letter as before; and also, the whole number that is to be cast with that matrice. A workman will ordinarily cast about 3000 of these letters in a day.

When the casters at the furnace have got a sufficient number of types upon the tables, a set of boys come and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who pass them swiftly under their fingers, defended by leather, upon smooth flat stones, in order to polish their broadsides. This is a very dexterous operation, and is a remarkable instance of what may be effected by the power of habit and long practice; for these boys, in turning up the other side of the type, do it so quickly by a mere touch of the fingers of the left hand, as not to require the least perceptible intermission in the motion of the right hand upon the stones. The types, thus finely smoothed and flattened on the broad sides, are next carried to another set of boys, who sit at a square table, two on each side, and there are ranged upon long rulers or sticks, fitted with a small projection, to hinder them from sliding off backwards. When these sticks are so filled, they are placed two and two, upon a set of wooden pins fixed into the wall, near the dresser, sometimes to the amount of an hundred, in order to undergo the finishing operations. This workman, who is always the most expert and skilful in all the different branches carried on at the foundery, begins by taking one of these sticks, and, with a peculiar address, slides the whole column of types off upon the dressing-stick: this is made of well-seasoned mahogany, and furnished with two end-pieces of steel, a little lower than the body of the types, one of which is moveable, so as to approach the other by means of a long screw-pin, inserted in the end of the stick. The types are put into the stick with their faces next to the back or projection; and after they are adjusted to one another so as to stand even, they are then bound up, by screwing home the moveable end-piece. It is here where the great and requisite accuracy of the moulds comes to be perceived; for in this case the whole column, so bound up, lies flat and true upon the stick, the two extreme types being quite parallel, and the whole has the appearance of one solid continuous plate of metal. The least inaccuracy in the exact parallelism of the individual type, when multiplied so many times, would render it impossible to bind them up in this manner, by disposing them to rise or spring from the stick by the smallest pressure from the screw. Now, when lying so conveniently with the narrow edges uppermost, which cannot possibly be smoothed in the manner before mentioned by the stones, the workmen does this more effectually by scraping the surface of the column with a thick-edged but sharp razor, which at every stroke brings on a very fine smooth skin, like to polished silver: and thus he proceeds till in about half a minute he comes to the farther end of the stick. The other edges of

Foundery, Fount. of the types are next turned upwards, and polished in the same manner. It is whilst the types thus lie in the dressing-stick that the operation of bearding or barbing is performed, which is effected by running a plane, faced with steel, along the shoulder of the body next to the face, which takes more or less off the corner, as occasion may require. Whilst in the dressing stick, they are also grooved, which is a very material operation. In order to understand this, it must be remembered, that wheu the types are first broken off from the jets, some superfluous metal always remains, which would make them bear very unequally against the paper whilst under the printing press, and effectually mar the impression. That all these inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the shoulders imparted to them all alike from the mould, the workman or dresser proceeds in the following manner: The types being screwed up in the stick, as before mentioned, with the jet end outermost, and projecting beyond the wood about one-eighth of an inch, the stick is put into an open press, so as to present the jet end uppermost, and then every thing is made fast by driving a long wedge, which bears upon a slip of wood, which lies close to the types the whole length: then a plough or plane is applied, which is so constructed as to embrace the projecting part of the types betwixt its long sides, which are made of polished iron. When the plane is thus applied, the steel cutter bearing upon that part between the shoulders of the types, where the inequalities lie, the dresser dexterously glides it along, and by this means strips off every irregular part that comes in the way, and so makes an uniform groove the whole length, and leaves the two shoulders standing; by which means every type becomes precisely like to another, as to the height against paper. The types being now finished, the stick is taken out of the press, and the whole column replaced upon the other stick; and after the whole are so dressed, he proceeds to pick out the bad letters, previous to putting them up into pages and papers. In doing this he takes the stick into his left hand, and turning the faces near to the light, he examines them carefully, and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a sharp bodkin, which he holds in the right hand for that purpose. Those letters which, from their form, project over the body of the type, and which cannot on this account be rubbed on the stones, are scraped on the broadsides with a knife or file, and some of the metal next the face pared away with a pen-knife, in order to allow the type to come close to any other. This operation is called *kerning*.

The excellence of printing types consists not only in the due performance of all the operations above described, but also in the hardness of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another.

FOUNT, or Font, among printers, &c. a set or quantity of characters or letters of each kind, cast by a letter-founder, and sorted.—We say, a founder has cast a fount of pica, of english, of pearl, &c. meaning that he has cast a set of characters of these kinds.

A complete fount not only includes the running letters, but also large and small capitals, single letters, double letters, points, commas, lines, and numeral characters.

Fount, Fountain. Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When the printer orders a fount of 500, he means that the fount should weigh 500lb. When he demands a fount of 10 sheets, it is understood, that with that fount he shall be able to compose 10 sheets, or 20 forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons 120 pounds for a sheet, including the quadrates, &c. or 60 pounds for a form, which is half a sheet: not that the sheet always weighs 120 pounds, or the form 60 pounds; on the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the cases.

The letter-founders have a kind of list, or tariff, whereby they regulate their founts: the occasion thereof is, that some letters being in much more use, and oftener repeated than others, their cells or cases should be better filled and stored than those of the letters which do not return so frequently. Thus the *o* and *i*, for instance, are always in greater quantity than the *k* or *z*.

This difference will be best perceived from a proportional comparison of those letters with themselves, or some others. Suppose a fount, of 100,000 characters, which is a common fount; here the *a* should have 5000, the *c* 3000, the *e* 11,000, the *i* 6000, the *m* 3000, the *k* only 30, and the *x*, *y* and *z*, not many more. But this is only to be understood of the letters of the lower case; those of the upper having other proportions, which it would be, here, too long to insist on.

FOUNTAIN, a spring or source of water rising out of the earth. Among the ancients, fountains were generally esteemed as sacred; but some were held to be so in a more particular manner. The good effects received from cold baths gave springs and rivers this high reputation; for their salutary influence was supposed to proceed from some presiding deity. Particular reasons might occasion some to be held in greater veneration than others. It was customary to throw little pieces of money into those springs, lakes, or rivers, which were esteemed sacred, to render the presiding divinities propitious; as the touch of a naked body was supposed to pollute their hallowed waters. For the phenomena, theory, and origin of fountains or springs, see Spring.

Artificial Fountain, called also a *jet d'eau*, is a contrivance by which water is violently spouted upwards. See Hydrodynamics.

Boiling Fountain. See Iceland.

Fountain-*Tree*, a very extraordinary vegetable growing in one of the Canary islands, and likewise said to exist in some other places, which distils water from its leaves in such plenty as to answer all the purposes of the inhabitants who live near it. Of this tree we have the following account in Glasse's history of the Canary islands.—"There are only three fountains of water in the whole island of Hierro, wherein the fountain-tree grows. One of these fountains is called *Acof*, which, in the language of the ancient inhabitants, signifies *river*; a name, however, which does not seem to

Fountain. to have been given it on account of its yielding much water, for in that respect it hardly deserves the name of a fountain. More to the northward is another called *Hapio*; and in the middle of the island is a spring, yielding a stream about the thickness of a man's finger. This last was discovered in the year 1565, and is called the *fountain of Anton. Hernadez*. On account of the scarcity of water, the sheep, goats, and swine, here do not drink in the summer, but are taught to dig up the roots of fern, and chew them to quench their thirst. The great cattle are watered at those fountains, and at a place where water distils from the leaves of a tree. Many writers have made mention of this famous tree, some in such a manner as to make it appear miraculous: others again deny the existence of any such tree: among whom is Father Feyjoo, a modern Spanish author, in his Theatro Critico. But he, and those who agree with him in this matter, are as much mistaken as those who would make it appear to be miraculous. This is the only island of all the Canaries which I have not been in; but I have sailed with natives of Hierro, who, when questioned about the existence of this tree, answered in the affirmative.

"The author of the *History of the discovery and conquest* has given us a particular account of it, which I shall here relate at large.

"The district in which this tree stands is called *Tigulahe*; near to which, and in the cliff or steep rocky ascent that surrounds the whole island, is a narrow gutter or gully, which commences at the sea, and continues to the summit of the cliff, where it joins or coincides with a valley, which is terminated by the steep front of a rock. On the top of this rock grows a tree, called in the language of the ancient inhabitants *Garse*, "Sacred or Holy Tree," which for many years has been preserved sound, entire, and fresh. Its leaves constantly distil such a quantity of water as is sufficient to furnish drink to every living creature in Hierro; nature having provided this remedy for the drought of the island. It is situated about a league and a half from the sea. It is not certainly known of what species it is, only that it is called *Til*. It is distinct from other trees, and stands by itself; the circumference of the trunk is about 12 spans, the diameter four, and in height from the ground to the top of the highest branch, 40 spans: the circumference of all the branches together is 120 feet. The branches are thick and extended; the lowest commence about the height of an ell from the ground. Its fruit resembles the acorn, and tastes something like the kernel of a pine apple, but is softer and more aromatic. The leaves of this tree resemble those of the laurel, but are larger, wider, and more curved; they come forth, in a perpetual succession, so that the tree always remains green. Near to it grows a thorn which it fastens on many of its branches, and interweaves with them; and at a small distance from the garse are some beech trees, bresos, and thorns. On the north side of the trunk are two large tanks or cisterns, of rough stone, or rather one cistern divided, each half being 20 feet square, and 16 spans in depth. One of these contains water for the drinking of the inhabitants: and the other that which they use for their cattle, washing, and such like purposes. Every morning, near this part of the island, a cloud or mist arises from the sea, which the south and easterly winds force against the fore-mentioned steep cliff; so that the cloud having no vent but by the gutter, gradually ascends it, and from thence advances slowly to the extremity of the valley, where it is stopped and checked by the front of the rock which terminates the valley, and then rests upon the thick leaves and wide-spreading branches of the tree, from whence it distils in drops during the remainder of the day, until it is at length exhausted, in the same manner that we see water drip from the leaves of trees after a heavy shower of rain. This distillation is not peculiar to the garse or til; for the bresos, which grow near it, likewise drop water; but their leaves being but few and narrow, the quantity is so trifling, that though the natives save some of it, yet they make little or no account of any but what distils from the til, which, together with the water of some fountains, and what is saved in the winter season, is sufficient to serve them and their flocks. This tree yields most water in those years when the Levant or easterly winds have prevailed for a continuance; for, by these winds only the clouds or mists are drawn hither from the sea. A person lives on the spot near which this tree grows, who is appointed by the council to take care of it and its water; and is allowed a house to live in, with a certain salary. He every day distributes to each family of the district seven pots or vessels full of water, besides what he gives to the principal people of the island."

"Whether the tree which yields water at this present time be the same as that mentioned in the above description, I cannot pretend to determine: but it is probable there has been a succession of them; for Pliny, describing the Fortunate islands, says, "In the mountains of Ombrion are trees resembling the plant ferula, from which water may be procured by pressure. What comes from the black kind is bitter, but that which the white yields is sweet and potable.""

Trees yielding water are not peculiar to the island of Hierro; for travellers inform us of one of the same kind in the island of St Thomas, in the bight or gulf of Guinea. In Cockburn's voyages we find the following account of a dropping tree, near the mountains of Vera Paz, in America.

"On the morning of the fourth day, we came out on a large plain, where were great numbers of fine deer, and in the middle stood a tree of unusual size, spreading its branches over a vast compass of ground. Curiosity led us up to it. We had perceived, at some distance off, the ground about it to be wet; at which we began to be somewhat surprised, as well knowing there had no rain fallen for near six months past, according to the certain course of the season in that latitude: that it was impossible to be occasioned by the fall of dew on the tree, we were convinced, by the sun's having power to exhale away all moisture of that nature a few minutes after its rising. At last, to our great amazement as well as joy, we saw water dropping, or as it were distilling, fast from the end of every leaf of this wonderful (nor had it been amiss if I had said *miraculous*) tree; at least it was so with respect to us, who had been labouring four days through extreme heat, without receiving the least moisture, and were now almost expiring for want of it.

"We could not help looking on this as liquor sent from heaven to comfort us under great extremity. We catched

catched what we could of it in our hands, and drank very plentifully of it; and liked it so well, that we could hardly prevail with ourselves to give over. A matter of this nature could not but incite us to make the strictest observations concerning it; and accordingly we staid under the tree near three hours, and found we could not fathom its body in five times. We observed the soil where it grew to be very strong; and upon the nicest inquiry we could afterwards make, both of the natives of the country and the Spanish inhabitants, we could not learn there was any such tree known throughout New Spain, nor perhaps all America over: but I do not relate this as a prodigy in nature, because I am not a philosopher enough to describe any natural cause for it; the learned may perhaps give substantial reasons in nature for what appeared to us a great and marvellous secret."

FOUQUIERES, James, an eminent painter, was born at Antwerp in 1580, and received his chief instructions from Velvet Breughel. He applied himself to the study of landscapes, and went to Italy to improve himself in colouring. He succeeded so happily, that his works are said to be nearly equal to those of Titian. —He was engaged and much caressed at the court of the elector Palatine, and in France. By some misconduct, however, he sunk into poverty, and died in 1659, in the house of an inconsiderable painter. He had resided for several years at Rome and Venice, where he acquired that excellent style of colouring and design for which his works have been distinguished.

FOURCHEE, or Fourchy, in *Heraldry*, an appellation given to a cross forked at the end. See Heraldry.

FOURCROY, Antony Francis de, a late celebrated French chemist. See Supplement.

FOURMONT, Stephen, professor of the Arabic and Chinese languages, and one of the most learned men of his time, was born at Herbelai, a village four leagues from Paris, in 1683. He studied in Mazarine college, and afterwards in the Seminary of Thirty-three. He was at length professor of Arabic in the Royal College, and was made a member of the Academy of Inscriptions. In 1738, he was chosen a member of the Royal Society of London, and of that of Berlin in 1741. He was often consulted by the duke of Orleans, first prince of the blood; who had a particular esteem for him, and made him one of his secretaries. He wrote a great number of books; the most considerable of those which have been printed are, 1. The Roots of the Latin Tongue, in verse. 2. Critical Reflections on the Histories of ancient Nations, 2 vols. 4to. 3. *Meditationes Sinicæ*, folio. 4. A Chinese Grammar, in Latin, folio. 5. Several dissertations printed in the Memoirs of the Academy of Inscriptions, &c. He died at Paris in 1744.

He ought not to be confounded with *Michael Fourmont*, his youngest brother; who took orders, was professor of the Syriac language in the Royal College, and a member of the Academy of Inscriptions. He died in 1746.

FOURNESS, in Loynsdale, Lancashire, is a tract, between the Kent, Leven, and Dudden sands, which runs north parallel with the west sides of Cumberland and Westmoreland; and on the south runs out into the sea as a promontory. Here, as Mr Camden expresses it, "the sea, as if enraged at it, lashes it more furiously, and in high tides has even devoured the shore, and made three large bays; viz. Kentsand, into which the river Ken empties itself; Levensand and Duddensand, between which the land projects in such a manner that it has its name hence; Foreness and Foreland, signifying the same with us as *promontorium anterius* in Latin." Bishop Gibson, however, derives the name of *Fourness* or *Furness*, from the numerous furnaces that were there anciently, the rents and services of which (called *Bloomsmithy rents*) are still paid. This whole tract, except on the coast, rises in high hills and vast piles of rocks called *Fourness-Fells;* among which the Britons found a secure retreat, trusting to these natural fortresses, though nothing was inaccessible to the victorious Saxons; for we find the Britons settled here 228 years after the arrival of the Saxons: because at that time Egfrid king of Northumberland gave St Cuthbert the land called *Carthmell*, and all the Britons in it, as is related in his life. In these mountainous parts are found quarries of a fine durable blue slate to cover buildings with, which are made use of in many other parts of the kingdom. Here are several cotton mills lately erected; and if fuel for fire were more plentiful, the trade of this country would much increase: but there being no coals nearer than Wigan or Whitehaven, and the coast duties high, firing is rather scarce, the country people using only turf or peat, and that begins to be more scarce than formerly. In the mosses of Fourness much fir is found, but more oak: the trunks in general lie with their heads to the east, the high winds having been from the west. High Furness has ever had great quantities of sheep, which browse upon the hollies left in great numbers for them; and produces charcoal for melting iron ore, and oak bark for tanners use, in great abundance. The forests abound with deer and wild boars, and the *legh* or *scofe*, or large stags, whose horns are frequently found under ground here. The low or plain part of Fourness, which is so called to distinguish it from the woody or mountainous part, produces all sorts of grain, but principally oats, whereof the bread eaten in this country is generally made; and there are found here veins of a very rich iron ore, which is not only melted and wrought here, but great quantities are exported to other parts to mix with poorer ores. The three sands above mentioned are very dangerous to travellers, by the tides and the many quicksands. There is a guide on horseback appointed to Kent or Lancaster sands at 10l. per ann. to Leven at 6l. per ann. out of the public revenue; but to Dudden, which are most dangerous, none; and it is no uncommon thing for persons to pass over in parties of 100 at a time like caravans, under the direction of the carriers, who go to or fro every day. The sands are less dangerous than formerly, being more used and better known, and travellers never going without the carriers or guides. "Furnis abbey up in the mountains," was begun at Tulket in Amounderness 1124, by Stephen earl of Boulogne, afterwards king of England, for the monks of Savigni in France, and three years after removed to this valley, then called *Bekangesgill*, or, "the vale of nightshade." It was of the Cistertian order, endowed with

above

above 800l. per ann. Out of the monks of this abbey, Mr Camden informs us, the bishops of the Isle of Man, which lies opposite to it, used to be chosen by ancient custom; it being as it were the mother of many monasteries in Man and Ireland. Some ruins, and part of the fosse which surrounded the monastery, are still to be seen at Tulket. The remains at Fourness breathe that plain simplicity of the Cistertian abbeys; the chapter-house was the only piece of elegant Gothic about it, and its roof has lately fallen in. Part of the painted glass from the east window, representing the crucifixion, &c. is preserved at Windermere church in Bowlness, Westmoreland. The church (except the north side of the nave), the chapter-house, refectory, &c. remain, only unroofed.

FOURTH REDUNDANT, in *Music*. See INTERVAL.

FOWEY, or FOY, a town of Cornwall in England, 240 miles from London, with a commodious haven on the Channel. It contained 1319 inhabitants in 1811, and extends above one mile on the east side of a river of its own name; and has a great share in the fishing trade. It rose so much formerly by naval wars and piracies, that in the reign of Edward III. its ships refusing to strike when required as they sailed by Rye and Winchelsea, were attacked by the ships of those ports, but defeated them; whereupon they bore their arms mixed with the arms of those two cinque-ports, which gave rise to the name of the "Gallants of Fowey." And we learn from Camden, that this town quartered a part of the arms of every one of the cinque-ports with their own; intimating, that they had at times triumphed over them all: and indeed once they were so powerful, that they took several of the French men of war. In the reign of Edward III. they rescued certain ships of Rye from distress, for which this town was made a member of the cinque-ports. Edward IV. favoured Fowey so much, that when the French threatened to come up the river to burn it, he caused two towers, the ruins of which are yet visible, to be built at the public charge for its security: but he was afterwards so disgusted with the inhabitants for attacking the French after a truce proclaimed with Louis XI. that he took away all their ships and naval stores, together with a chain drawn across the river between the two forts above mentioned, which was carried to Dartmouth. It is said they were so insolent, that they cut off the ears of the king's pursuivants; for which some lives were forfeited as well as estates. The corporation consists of a mayor, recorder, 8 aldermen, a town clerk, and 2 assistants. The market is on Saturday, the fairs May-day and Sept. 10. Here are a fine old church, a free school, and an hospital. The toll of the market and fairs, and keyage of the harbour, were vested in the corporation on the payment of a fee-farm rent of about 40s. It does not appear to have sent members to parliament before the 13th of Queen Elizabeth. Here is a coinage for the tin; of which a great quantity is dug in the country to the north and west of it. The river Foy, or Foath, is very broad and deep here, and was formerly navigable as high as Lestwithiel. W. Long. 5. N. Lat. 50.27.

FOWL, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such as geese, pheasants, partridges, turkeys, ducks, &c.

Tame fowl make a necessary part of the stock of a country farm. See POULTRY.

Fowls are again distinguished into two kinds, viz. *land* and *water* fowl, these last being so called from their living much in and about water: also into those which are accounted *game*, and those which are not. See GAME.

FOWLING, the art of catching birds by means of bird-lime, decoys, and other devices, or the killing of them by the gun. See *BIRD-Catching*, *BIRD-Lime*, DECOY, SHOOTING, and the names of the different birds in the order of the alphabet.

FOWLING, is also used for the pursuing and taking birds with hawks, more properly called FALCONRY or HAWKING. See these articles.

FOWLING Piece, a light gun for shooting birds. That piece is always reckoned best which has the longest barrel, from $5\frac{1}{2}$ to 6 feet, with a moderate bore; though every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal bigness from one end to the other; which may be proved, by putting in a piece of pasteboard, cut of the exact roundness of the top: for if this goes down without stops or slipping, you may conclude the bore good. The bridge-pan must be somewhat above the touch-hole, and ought to have a notch to let down a little powder: this will prevent the piece from recoiling, which it would otherwise be apt to do. As to the locks, choose such as are well filled with true work, whose springs must be neither too strong nor too weak. The hammer ought to be well hardened, and pliable to go down to the pan with a quick motion.

FOX, in *Zoology*. See CANIS, MAMMALIA *Index*.

The fox is a great nuisance to the husbandman, by taking away and destroying his lambs, geese, poultry, &c. The common way to catch him is by gins; which being baited, and a train made by drawing raw flesh across in his usual paths or haunts to the gin, it proves an inducement to bring him to the place of destruction.

The fox is also a beast of chase, and is taken with greyhounds, terriers, &c. See HUNTING.

FOX, *John*, the martyrologist, was born at Boston in Lincolnshire, in the year 1517. At the age of 16 he was entered a student of Brazen-Nose college in Oxford; and in 1543 he proceeded master of arts, and was chosen fellow of Magdalen college. He discovered an early genius for poetry, and wrote several Latin comedies, the subjects taken from Scripture, which his son assures us were written in an elegant style. Forsaking the muses, he now applied himself with uncommon assiduity to the study of divinity, particularly church-history; and, discovering a premature propensity to the doctrine of reformation, he was expelled the college as an heretic. His distress on this occasion was very great; but it was not long before he found an asylum in the house of Sir Thomas Lucy of Warwickshire, who employed him as a tutor to his children. Here he married the daughter of a citizen of Coventry. Sir Thomas's children being now grown up, after residing a short time with his wife's father, he came to London; where finding no immediate means of subsistence, he was reduced to the utmost degree of want; but was at length

length (as his son relates) miraculously relieved in the following manner: As he was one day sitting in St Paul's church, emaciated with hunger, a stranger accosted him familiarly, and, bidding him to be of good cheer, put a sum of money into his hand; telling him, at the same time, that in a few days new hopes were at hand. He was soon after taken into the family of the duchess of Richmond, as tutor to the earl of Surrey's children, who, when their father was sent to the Tower, were committed to her care. In this family he lived at Ryegate in Surrey, during the latter part of the reign of Henry VIII. the entire reign of Edward VI. and part of that of Queen Mary: but at length, persecuted by his implacable enemy Bishop Gardiner, he was obliged to seek refuge abroad. Basil in Switzerland was the place of his retreat, where he subsisted by correcting for the press. On the death of Queen Mary he returned to England; where he was graciously received by his former pupil the duke of Norfolk, who retained him in his family as long as he lived, and bequeathed him a pension at his death. Mr Secretary Cecil also obtained for him the rectory of Shipton near Salisbury; and we are assured that he might have had considerable church preferment, had it not been for his unwillingness to subscribe to the canons. He died in the year 1587, in the 70th year of his age; and was buried in the chancel of St Giles's, Cripplegate. He was a man of great industry, and considerable learning; a zealous, but not a violent reformer; a nonconformist, but not an enemy to the church of England. He left two sons; one of whom was bred a divine, the other a physician. He wrote many pieces; but his principal work is, the Acts and Monuments of the Church, &c. commonly called *Fox's Book of Martyrs.* His facts are not always to be depended on, and he often loses his temper; which, considering the subject, is not much to be wondered at.

Fox, *George*, the founder of the sect of English Quakers, was a shoemaker in Nottingham. The accounts of those times tell us, that as he wrought at his trade, he used to meditate much on the Scriptures; which, with his solitary course of life, improving his natural melancholy, he began at length to fancy himself inspired; and in consequence thereof set up for a preacher. He proposed but few articles of faith, insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the Spirit; he required a plain simple worship, and a religion without ceremonies, making it a principal point to wait in profound silence the directions of the Holy Spirit. Fox met with much rough treatment for his zeal, was often imprisoned, and several times in danger of being knocked on the head, But all discouragements notwithstanding, his sect prevailed much, and many considerable men were drawn over to them; among whom were Barclay and Penn. He died in 1681. His followers were called *Quakers.* See Quakers.

Fox, *Right Honourable Charles James*, a late distinguished British statesman and orator. See Supplement.

Fox-Glove. See Digitalis, Botany and Materia Medica *Index.*

Fox Islands, the name of a group of islands, 16 in number, situated between the eastern coast of Kamtschatka and the western coast of the continent of America. Each island has a particular name; but the general name *Fox Islands* is given to the whole group, on account of the great number of black, gray, and red foxes with which they abound. The dress of the inhabitants consist of a cap, and a fur coat which reaches down to the knee. Some of them wear common caps of a party-coloured bird skin, upon which they leave part of the wings and tail. On the fore part of their hunting and fishing caps, they place a small board like a skreen, adorned with the jaw bones of sea bears, and ornamented with glass beads, which they receive in barter from the Russians. At their festivals and dancing parties they use a much more showy sort of caps. They feed upon the flesh of all sorts of sea animals, and generally eat it raw. But if at any time they choose to dress their victuals, they make use of a hollow stone; having placed the fish or flesh therein, they cover it with another, and close the interstices with lime or clay. They then lay it horizontally upon two stones, and light a fire under it. The provision intended for keeping is dried without salt in the open air. Their weapons consist of bows, arrows, and darts; and for defence they use wooden shields. The most perfect equality reigns among these islanders. They have neither chiefs nor superiors, neither laws nor punishments. They live together in families, and societies of several families united, which form what they call a *race*, who, in case of an attack or defence, mutually help and support each other. The inhabitants of the same island always pretend to be of the same race; and every person looks upon his island as a possession, the property of which is common to all the individuals of the same society. Feasts are very common among them, and more particularly when the inhabitants of one island are visited by those of the others. The men of the village meet their guests beating drums, and preceded by the women, who sing and dance. At the conclusion of the dance, the hosts serve up their best provisions, and invite their guests to partake of the feast. They feed their children when very young with the coarsest flesh, and for the most part raw. If an infant cries, the mother immediately carries it to the seaside, and whether it be summer or winter, holds it naked in the water, until it is quiet. This custom is so far from doing the children any harm, that it hardens them against the cold, and they accordingly go barefooted through the winter without the least inconvenience. They seldom heat their dwellings; but when they are desirous of warming themselves, they light a bundle of hay, and stand over it; or else they set fire to train-oil, which they pour into a hollow stone. They have a good share of plain natural sense, but are rather slow of understanding. They seem cold and indifferent in most of their actions; but let an injury, or even a suspicion only, rouse them from this phlegmatic state, and they become inflexible and furious, taking the most violent revenge without any regard to the consequences. The least affliction prompts them to suicide; the apprehension of even an uncertain evil often leads them to despair; and

 they

they put an end to their days with great apparent insensibility.

FRACASTOR, Jerome, an eminent Italian poet and physician, was born at Verona in the year 1482. Two singularities are related of him in his infancy: one is, that his lips adhered so closely to each other when he came into the world, that a surgeon was obliged to divide them with his incision knife; the other, that his mother was killed with lightning, while he, though in her arms at the very moment, escaped unhurt. Fracastor was of parts so exquisite, and made such progress in every thing he undertook, that he became eminently skilled not only in the belles lettres, but in all arts and sciences. He was a poet, a philosopher, a physician, an astronomer, and a mathematician. He was a man of vast consequence in his time; as appears from Pope Paul III.'s making use of his authority to remove the council of Trent to Bologna, under the pretext of a contagious distemper, which, as Fracastor deposed, made it no longer safe to continue at Trent. He was intimately acquainted with Cardinal Bembus, Julius Scaliger, and all the great men of his time. He died of an apoplexy at Casi near Verona, in 1553: and in 1559, the town of Verona erected a statue in honour of him.

He was the author of many performances, both as a poet and a physician: yet never man was more disinterested in both these capacities than he: evidently so as a physician, for he practised without fees; and as a poet, whose usual reward is glory, nothing could be more indifferent. It is owing to this indifference, that we have so little of his poetry, in comparison of what he wrote; and that, among other compositions, his Odes and Epigrams, which were read in manuscript with infinite admiration, yet, never passing the press, were lost. What we have now of his, are the three books of "Siphilis, or of the French disease;" a book of Miscellaneous Poems; and two books of his poem, entitled *Joseph*, which he began at the latter end of his life, but did not live to finish. And these works, it is said, would have perished with the rest, if his friends had not taken care to preserve and communicate copies of them: For Fracastor, writing merely for amusement, never troubled himself in the least about what became of his works after they once got out of his hands. Fracastor composed also a poem, called *Alcon, sive de cura canum venaticorum.* His poems as well as his other works are all written in Latin. His medical pieces are, *De Sympathia et Antipathia,—De contagione et contagiosis morbis,—De causis criticorum dierum,—De vini temperatura*, &c. His works have been printed separately and collectively. The best edition of them is that of Padua 1234, in 4 vols. 4to.

FRACHES, in the glass trade, are the flat iron pans into which the glass vessels already formed are put when in the tower over the working furnace, and by means of which they are drawn out through the leers, that they may be taken gradually from the fire, and cool by degrees.

FRACTION, in *Arithmetic* and *Algebra*, a part or division of an unit or integer; or a number which stands to an unit in the relation of a part to its whole. The word literally imports a broken number.

Fractions are usually divided into decimal, sexagesimal, and vulgar. See Algebra and Arithmetic.

FRACTURE, in *Surgery*, a rupture of a bone or a solution of continuity in a bone when it is crushed or broken by some external cause. See Surgery *Index*.

FRÆNUM, or Frenum, *Bridle*, in *Anatomy*, a name given to divers ligaments, from their office in retaining and curbing the motions of the parts they are fitted to.

Frænum Linguæ, or *Bridle of the Tongue;* a membranous ligament, which ties the tongue to the os hyoides, larynx, fauces, and lower parts of the mouth. In some subjects the *frænum* runs the whole length of the tongue to the very tip; in which cases, if it were not cut, it would take away all possibility of speech. See *Tongue-Tied.*

Frænum Penis, a slender ligament, whereby the prepuce is tied to the lower parts of the glans of the penis. Nature varies in the make of this part; it being so short in some, that unless divided it would not admit of perfect erection. There is also a kind of little *frænum*, fastened to the lower part of the clitoris.

FRAGA, a strong town with a handsome castle, in the kingdom of Arragon in Spain. It is strong by situation among the mountains; having the river Cinca before it, whose high banks are difficult of access; and at its back a hill, which cannot easily be approached with large cannon. Alphonso VII. king of Arragon, and the first of that name of Castile, was killed by the Moors in 1134, when he besieged this town. E. Long. 0. 23. N. Lat. 41. 28.

FRAGARIA, the Strawberry, a genus of plants belonging to the icosandria class; and in the natural method ranking under the 35th order, *Senticosæ.* See Botany *Index;* and for an account of the varieties and culture, see Gardening *Index.*

FRAIL, a basket made of rushes or the like, in which are packed up figs, raisins, &c. It signifies also a certain quantity of raisins, about 75 pounds.

FRAISE, in *Fortification*, a kind of defence consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half moon, or the like, to prevent any approach or scalade.

Fraises differ from pallisades chiefly in this, that the latter stand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly so, being usually made a little sloping, or with the points hanging down. Fraises are chiefly used in retrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone works.

To Fraise a Battalion, is to line the musqueteers round with pikes, that in case they should be charged with a body of horse, the pikes being presented, may cover the musqueteers from the shock, and serve as a barricade.

FRAME, in *Joinery*, a kind of case, wherein a thing is set or inclosed, or even supported; as a window frame, a picture frame, &c.

Frame is also a machine used in divers arts; as,

Frame, among printers, is the stand which supports the cases. See Case.

Frame,

Frame. FRAME, among founders, a kind of ledge enclosing a board; which, being filled with wetted sand, serves as a mould to cast their works in. See FOUNDERY.

FRAME is more particularly used for a sort of loom, whereon artificers stretch their linens, silks, stuffs, &c. to be embroidered, quilted, or the like.

FRAME, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called *reticula*. It serves to reduce figures from great to small; or, to augment their size from small to great.

Frame || Franc.

FRAMLINGHAM, a town in Sussex, 88 miles from London. It is a large old place, with a castle, supposed to have been built by some of the first kings of the East Angles; the walls yet standing, are 44 feet high, 8 thick, with 13 towers 14 feet above them, two of which are watch-towers. Population 1965 in 1811.

FRANC. See FRANK.

FRANCE.

France.

FRANCE, a large kingdom of Europe, situated between 5° W. and 8° E. Long. and between 42° and 51° N. Lat. being bounded by the English channel and the Netherlands on the north; by Germany, Switzerland, Savoy, and Piedmont, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and by the bay of Biscay on the west.

1 First subdued by Julius Cæsar.

The kingdom of France was originally possessed by the *Celtes* or *Gauls*. They were a very warlike people, and often checked the progress of the Roman arms: nor did they yield till the time of Julius Cæsar, who totally subdued their country, and reduced it to the form of a Roman province *. The Romans continued in quiet possession of Gaul, as long as their empire retained its strength, and they were in a condition to repress the incursions of the German nations, whom even in the zenith of their power they had not been able to subdue. But in the reign of the emperor Valerian, the ancient Roman valour and discipline had begun to decline, and the same care was not taken to defend the provinces as formerly. The barbarous nations, therefore, began to make much more frequent incursions; and among the rest the *Franks*, a German nation, inhabiting the banks of the Rhine, proved particularly troublesome. Their origin is variously accounted for; but the most probable supposition is, that about the time of the emperor Gordian, the people inhabiting the banks of the Lower Rhine, entered into a confederacy with those who dwelt on the Weser, and both together assumed the name of *Franks* or *Freemen*. Their first irruption, we are told by Valesius, happened in the year 254, the second of Valerian's reign. At this time they were but few in number; and were repulsed by Aurelian, afterwards emperor. Not discouraged by this check, they returned two years after in far greater numbers; but were again defeated by Gallienus, whom Valerian had chosen for his partner in the empire. Others, however, continued to pour in from their native country in such multitudes, that Gallienus, no longer able to drive them out by force of arms, made advantageous proposals to one of their chiefs, whom he engaged to defend the frontiers against his countrymen as well as other invaders.

* See *Gaul*.

2 Invaded by the Franks.

This expedient did not long answer the purpose. In 260 the Franks, taking advantage of the defeat and captivity of Valerian in Persia, broke into Gaul, and afterwards into Italy, committing everywhere dreadful ravages. Five years afterwards they invaded Spain; which they possessed, or rather plundered, for the space of 12 years: nor could they be driven out of Gaul till the year 275, when the emperor Probus not only gave them a total overthrow in that country, but pursued them into their own, where he built several forts to keep them in awe. This intimidated them so much, that nine of their kings submitted to the emperor, and promised an annual tribute.—They continued quiet till the year 287; when, in conjunction with the Saxon pirates, they plundered the coasts of Gaul, carrying off an immense booty. To revenge this insult, the emperor Maximian entered the country of the Franks the following year, where he committed such ravages that two of their kings submitted to him; and to many of the common people who chose to remain in Gaul, he allowed lands in the neighbourhood of Treves and Cambray.

The restless disposition of the Franks, however, did not allow them to remain long in quiet. About the year 293, they made themselves masters of Batavia and part of Flanders; but were entirely defeated, and forced to surrender at discretion, by Constantius the father of Constantine the Great, who transplanted them into Gaul. Their countrymen in Germany continued quiet till the year 306, when they renewed their depredations; but being overtaken by Constantine the Great, two of their kings were taken prisoners, and thrown to the wild beasts in the shows exhibited on that occasion.

All these victories, however, as well as many others said to have been gained by the Romans, were not sufficient to prevent the incursions of this restless and turbulent nation: insomuch that, in the year 355, they had made themselves masters of 40 cities in the province of Gaul. Soon after, they were totally defeated by the emperor Julian, and again by Count Theodosius, father to the emperor of that name; but in the year 388, they ravaged the province with more fury than ever, and cut off a whole Roman army that was sent against them. As the western empire was at this time in a very low state, they for some time found more interruption from other barbarians than from the Romans, till their progress was checked by Aetius.

3 Pharamond the first king.

When the war with Aetius broke out, the Franks were governed by one *Pharamond*, the first of their kings of whom we have any distinct account. He is supposed to have reigned from the year 417 or 418, to 428; and is thought by Archbishop Usher to have been killed in the war with Aetius. By some he is supposed

supposed to have compiled the Salic laws, with the assistance of four sages named *Wisegast*, *Losegast*, *Widegast*, and *Solegast*. But Valesius is of opinion that the Franks had no written laws till the time of Clovis.

4
Clodio.

Pharamond was succeeded by his son Clodio, who likewise carried on a war against the Romans. He is said to have received a terrible overthrow from Aetius near the city of Lens; notwithstanding which, he advanced to Cambray, and made himself master of that city, where for some time he took up his residence. After this he extended his conquests as far as the river Somme, and destroyed the cities of Treves and Cologne, Tournay and Amiens. He died in the year 448, and was succeeded by Merovæus.

5
Merovæus.

Authors are not agreed whether the new king was brother, or son, or any relation at all, to Clodio. It seems probable indeed, that he was of a different family; as from him the first race of French kings were styled *Merovingian*. He was honoured and respected by his people, but did not greatly enlarge the boundaries of his kingdom. He died in 458.

6
Childeric.

Merovæus was succeeded by his son Childeric; who being no longer kept in awe by Aetius, made war on the Romans, and extended his conquests as far as the river Loire. He is said to have taken the city of Paris after a siege of five years, according to some, and of ten, according to others. The Roman power was now totally destroyed in Italy; and therefore *Clodovæus*, *Clovis*, or *Louis*, for his name is differently written, who succeeded Childeric, set himself about making an entire conquest of Gaul. Part of the province was still retained by a Roman named *Syagrius*, who probably had become sovereign of the country on the downfall of the western empire in 476. He was defeated and taken prisoner by Clovis, who afterwards caused him to be beheaded, and soon after totally reduced his dominions.

7
French monarchy established by Clovis.

Thus was the French monarchy established by Clovis in the year 487. He now possessed all the country lying between the Rhine and the Loire; which, though a very extensive dominion, was yet considerably inferior to what it is at present.

Clovis had been educated in the Pagan religion, and continued in that profession till the 30th year of his age; notwithstanding which, he allowed his subjects full liberty of conscience. Having married, however, Clotilda, daughter of the duke of Burgundy; this princess, who was a zealous Christian, used all her influence with her husband to persuade him to embrace her religion. For some time he continued to waver; but happening to gain a battle, where, being in great danger, he had invoked the god of Clotilda and the Christians, he afterwards gave such a favourable ear to the discourses of Remigius bishop of Rheims, that he soon declared himself a convert, and was baptized in the year 496. His acknowledgment of the truths of the gospel was not followed by any amendment of life; on the contrary, he employed the remainder of his life in the aggrandizement of himself and extension of his dominions by the most abominable treachery, fraud, and violence. In his attacks on Armorica he proved unsuccessful. The inhabitants of this country, which comprehended the maritime part of ancient Gaul lying between the rivers Seine and Loire, had united for their defence; and though abandoned by the Romans, made a powerful defence against the barbarians who assaulted them on all sides. Clovis, finding them too powerful to be subdued by force, proposed an union with his people, which they readily accepted, and this the more easily on account of his professing the Christian religion. Thus the Christianity of Clovis in several instances proved subservient to the purposes of his ambition, and his power became gradually very formidable. The Burgundians at this time possessed all the country from the forest of Vosges to the sea of Marseilles, under Gondebaud the uncle of Clotilda; who, to secure his own authority, had put to death two of his brothers, one of whom was the father of the French queen. The third brother, *Godagesil*, whom he had spared and allowed to possess the principality of Geneva, conspired with Clovis to drive him from his dominions. A war having commenced between the French and Burgundian monarchs, the latter was deserted in a battle by Godagesil, and obliged to fly to Avignon, leaving his antagonist master of the cities of Lyons and Vienne. The victor next laid siege to Avignon; but it was defended with such vigour, that Clovis at last thought proper to accept of a sum of money and an annual tribute from Gondebaud; who was likewise obliged to cede to Godagesil the city of Vienne, and several other places taken during the war.

Gondebaud no sooner found himself at liberty from his enemies, than he assembled a powerful army; with which he advanced towards Vienne, where Godagesil himself resided at that time. The place was garrisoned by 5000 Franks, and might have made considerable resistance; but Gondebaud being admitted through the subterraneous passage of an aqueduct, massacred most of the Franks, sent the rest prisoners to the king of the Visigoths, and put Godagesil to death. This was quickly followed by the submission of all the other places which had owned the authority of Godagesil: and Gondebaud, now thinking himself able to resist the power of Clovis, sent a message to inform him, that he must no longer expect the promised tribute; and though Clovis was very much mortified with this defection, he found himself obliged for the present to put up with the injury, and accept of the alliance and military service of the king of Burgundy.

His next expedition was against the Visigoths, who possessed considerable territories on both sides of the Pyrenean mountains. His motives for this undertaking were expressed in the following speech to his nobility when assembled in the city of Paris, which he considered as the capital of his dominions. "It is with concern (said the religious monarch) that I suffer the Arians to possess the most fertile part of Gaul: let us, with the aid of God, march against them; and having conquered them, annex their kingdom to our dominions." The nobility approved of the scheme; and Clovis marched against a prince for whom he had but lately professed the greatest regard, vowing to erect a church in honour of the holy apostles, if he succeeded in his enterprise. Alaric the king of the Visigoths was a young man destitute of military experience, though personally brave. He did not therefore hesitate at engaging his antagonist; but unable to contend with the veteran troops of Clovis, his army was utterly defeated on the banks of the Clain, 10 miles

 miles south of Poictiers, in the year 507. Alaric, perceiving the ruin of his troops, rushed against Clovis in person, by whom he was killed, and the remainder of the army pursued for some time with great slaughter. After this victory the province of Aquitaine submitted, and Clovis established his winter quarters at Bourdeaux. Thoulouse surrendered next spring: and the royal treasures of the Visigoths were transported to Paris. Angouleme was next reduced, and the city of Arles invested. But here the victorious career of Clovis was stopped by Theodoric king of the Ostrogoths, who had overturned the dominion of Odoacer in Italy. He had married Abolfleda the sister of Clovis, but had also given his own daughter in marriage to the king of the Visigoths, and had endeavoured, as much as was in his power, to preserve a good understanding between the two sovereigns. Finding this impossible, however, and that no bounds could be set to the ambition of Clovis, he sent one of his generals with a powerful army against him; by whom the French monarch was defeated with the loss of 30,000 men. By this misfortune Clovis was obliged to raise the siege of Arles with precipitation: however, the Franks still retained the greatest part of their conquests, and the province of Aquitaine was indissolubly annexed to their empire.

8
honoured with the title of Roman consul.

In 509, Clovis had the title of Roman consul; by which means the people of Rome were insensibly led to pay a peculiar regard to the French monarchs: and Clovis was now supposed to be invested with a just title to all his conquests in whatever manner they had been acquired. He was solemnly invested with his new dignity in the church of St Martin in the city of Tours; after which he entered the cathedral clothed in a purple tunic and mantle, the badges of his office.

Clovis now proceeded to augment his power by the murder of his kinsmen the princes of the Merovingian race. Among those who perished on this occasion were Sigebert king of Cologne, with his son Cloderic; Cararic, another prince whose dominions have not been accurately pointed out by historians; Ranacaire, who governed the present diocese of Cambray; and Renomer, king of the territory of Maine. All these murders, however, were expiated, according to the views of the clergy of those times, by the great zeal he expressed in the cause of Christianity, and his liberality to the church.

Clovis died in the year 511, after having reformed and published the Salic laws: a few lines of which, debarring women from inheriting any part of the Salic lands, have been extended so far as to deprive the females of the royal family of France of their right of succession to the throne of that kingdom.

9
His dominions divided among his children.

Clovis was buried in the church of St Peter and St Paul, now Genevieve, in the city of Paris, where his tomb is still to be seen. His dominions were divided among his four sons. Thieri, or Theodoric, the eldest, had the eastern part of the empire: and, from his making the city of Metz his capital, is commonly called the *king of Metz*. Clodomir, the eldest son by Clotilda, had the kingdom of Orleans; Childebert, and Clotaire, who were both infants, had the kingdoms of Paris and Soissons, under the tutelage of their mother. The prudence of Clotilda kept matters quiet in all the parts of the empire for eight years; but about the year 520, a numerous fleet of Danes arrived at the mouth of the Meuse; and their king Cochiliac, having landed his forces, began to destroy the country with fire and sword. Against him Thieri sent his son Theodobert, who defeated the Danish army and navy, and killed their king, forcing the rest to retire with precipitation.

In 522, Hermanfroi king of Thuringia, having destroyed one of his brethren named *Berthaire*, and seized on his dominions, applied to Thieri for assistance against his other brother Balderic, whom he intended to treat in the same manner. In this infamous enterprise Thieri embarked, on condition that he should have one half of Balderic's dominions; but after the unhappy prince was overcome and killed in battle, Hermanfroi seized all his dominions. Thieri had no opportunity of revenging himself till the year 531; when perceiving the power of the Ostrogoths, whom he much dreaded, to be considerably lessened by the death of King Theodoric, he engaged his brother Clotaire to assist him: and they accordingly entered Thuringia with two powerful armies. They joined their forces as soon as they had passed the Rhine, and were quickly after reinforced by a considerable body of troops under the command of Theodobert. The allies attacked the army of Hermanfroi, which was advantageously posted; and having totally defeated it, he was forced to fly from place to place in disguise. Soon after this the capital was taken, and Hermanfroi himself being invited to a conference by Thieri, was treacherously murdered; after which his extensive dominions became feudatory to Thieri.

In the mean time, Clotilda had excited her children to make war on the Burgundians, in order to revenge the death of her father Chilperic, whom Gondebaud king of Burgundy had caused to be murdered. Gondebaud was now dead, and had left his dominions to his sons Sigismund and Godemar. Sigismund's forces were quickly defeated; and he himself was soon after delivered up by his own subjects to Clodomir, who caused him to be thrown into a pit where he perished miserably. By his death Godemar became sole master of Burgundy. Clodomir marched against him, and defeated him; but pursuing his victory too eagerly, was surrounded by his enemies and slain. After the reduction of Thuringia, however, Childebert and Clotaire entered the kingdom of Burgundy at the head of a powerful army, and in 534 completed the conquest of it; in which, according to some, Godemar was killed; according to others, he retired into Spain, and from thence into Africa.

In 560 Clotaire became sole monarch of France. He had murdered the sons of Clodomir, who was killed in Burgundy as above related. Thieri and his children were dead, as was also Childebert; so that Clotaire was sole heir to all the dominions of Clovis. He had five sons; and the eldest of them, named *Chramnes*, had some time before rebelled against his father in Auvergne. As long as Childebert lived, he supported the young prince; but on his death, Chramnes was obliged to implore his father's clemency. He was at this time pardoned; but he soon began to cabal afresh, and engaged the count of Bretagne to assist him in another rebellion. The Bretons, however, were defeated, and Chramnes determined to make his escape; but perceiving

10
Clotaire becomes sole monarch.

ing that his wife and children were surrounded by his father's troops, he attempted to rescue them. In this attempt he was taken prisoner, and with his family was thrust into a thatched cottage near the field of battle; of which the king was no sooner informed, than he commanded the cottage to be set on fire, and all that were in it perished in the flames.

11 The empire again divided.

Clotaire did not long survive this cruel execution of his son, but died in 562; and after his death the French empire was divided among his four remaining sons, Caribert, Gontran, Sigebert, and Chilperic.—The old king made no division of his dominions before he died, which perhaps caused the young princes to fall out sooner than they would otherwise have done. After his death, however, they divided the kingdom by lot; when Caribert, the eldest, had the kingdom of Paris; Gontran, the second, had Orleans; Sigebert, had Metz (or the kingdom of Austrasia); and Chilperic had Soissons. Provence and Aquitain were possessed by all of them in common. The peace of the empire was first disturbed in 563 by an invasion of the Abares; a barbarous nation, said to be the remains of the Hunns. They entered Thuringia, which belonged to the dominions of Sigebert: but by him they were totally defeated, and obliged to repass the Elbe with precipitation. Sigebert pursued them close, but readily concluded a peace with them on their first proposals. To this he was induced, by hearing that his brother Chilperic had invaded his dominions, and taken Rheims and some other places in the neighbourhood. Against him, therefore, Sigebert marched with his victorious army, made himself master of Soissons his capital, and of the person of his eldest son Theodobert. He then defeated Chilperic in battle; and not only recovered the places which he had seized, but conquered the greater part of his dominions: nevertheless, on the mediation of the other two brothers, Sigebert abandoned all his conquests, set Theodobert at liberty, and thus restored peace to the empire.

12 Infamous conduct of Chilperic.

Soon after this, Sigebert married Brunehaut daughter to Athanagilde king of the Visigoths in Spain; and in a little time after the marriage, died Caribert king of Paris, whose dominions were divided among his three brethren. In 567 Chilperic married Galswintha, Brunehaut's eldest sister, whom he did not obtain without some difficulty. Before her arrival, he dismissed his mistress called *Fredegonde*, a woman of great abilities and firmness of mind, but ambitious to the highest degree, and capable of committing the blackest crimes in order to gratify her ambition. The queen, who brought with her immense treasures from Spain, and made it her whole study to please the king, was for some time entirely acceptable. By degrees, however, Chilperic suffered Fredegonde to appear again at court, and was suspected of having renewed his intercourse with her; which gave such umbrage to the queen, that she desired leave to return to her own country, promising to leave behind her all the wealth she had brought. The king knowing that this would render him extremely odious, found means to dissipate his wife's suspicions, and soon after caused her to be privately strangled, upon which he publicly married Fredegonde.

Such an atrocious action could not fail of exciting the greatest indignation against Chilperic. His dominions were immediately invaded by Sigebert and Gontran, who conquered the greatest part of them; after which they suddenly made peace, Chilperic consenting that Brunehaut should enjoy those places which on his marriage he had bestowed upon Galswintha, viz. Bourdeaux, Limoges, Cahors, Bigorre, and the town of Bearn, now called *Lescar*.

The French princes, however, did not long continue at peace among themselves. A war quickly ensued, in which Gontran and Chilperic allied themselves against Sigebert. The latter prevailed; and having forced Gontran to a separate peace, seemed determined to make Chilperic pay dear for his repeated perfidy and infamous conduct; when he was assassinated by a contrivance of Fredegonde, who thus saved herself and Chilperic from the most imminent danger. Immediately on his death, Brunehaut fell into the hands of Chilperic; but Gondebaud, one of Sigebert's best generals, made his escape into Austrasia with Childebert, the only son of Sigebert, an infant of about five years of age, who was immediately proclaimed king in room of his father. In a short time, however, Meroveus, eldest son to Chilperic, fell in love with Brunehaut, and married her without acquainting his father. Chilperic on this news, immediately went to Rouen, where Meroveus and his consort were; and having seized them, sent Brunehaut and her two daughters to Metz, and carried Meroveus to Soissons. Soon after one of his generals being defeated by Gontran, who espoused Brunehaut's cause, Chilperic, in a fit of rage, caused Meroveus to be shaved and confined in a monastery. From hence he found means to make his escape, and with great difficulty arrived in Austrasia, when Brunehaut would gladly have protected him; but the jealousy of the nobles was so strong, that he was forced to leave that country; and being betrayed into the hands of his father's forces, was murdered at the instigation of Fredegonde, as was generally believed. 13 Sigebert assassinated.

The French empire was at this time divided between Gontran king of Orleans, called also king of Burgundy, Chilperic king of Soissons, and Childebert king of Austrasia. Chilperic found his affairs in a very disagreeable situation. In 579, he had a dispute with Varoc count of Bretagne, who refused to do him homage. Chilperic dispatched a body of troops against him; who were defeated, and he was then forced to submit to a dishonourable peace. His brother and nephew lived in strict union, and had no reason to be very well pleased with him. His own subjects, being oppressed with heavy taxes, were miserably poor and discontented. His son Clovis, by a former queen named *Andovera*, hated Fredegonde, and made no secret of his aversion. To add to his embarrassment, the seasons were for a long time so unfavourable, that the country was threatened with famine and pestilence at the same time. The king and queen were both attacked by an epidemic disease which then raged. They recovered; but their three sons Clodobert, Samson, and Dagobert, died; after which, the sight of Clovis became so disagreeable to Fredegonde, that she caused him to be murdered, and likewise his mother Andovera, lest Chilperic's affection for her should return after the tragical death of her son.

In 583 Chilperic himself was murdered by some unknown assassins, when his dominions were on the point of 14 and likewise Chilperic.

France. of being conquered by Gontran and Childebert, who had entered into a league for that purpose. After his death Fredegonde implored the protection of Gontran for herself and her infant son Clotaire; which he very readily granted, and obliged Childebert to put an end to the war. He found himself, however, greatly difficulted to keep Fredegonde and Brunehaut in awe; for these two princesses having been long rivals and implacable enemies, were continually plotting the destruction of each other. This, however, he accomplished, by favouring sometimes Brunehaut and sometimes Fredegonde; so that, during his life, neither of them durst undertake any thing against the other.

15 Death of Gontran; On the 28th of March 593, died Gontran, having lived upwards of 60, and reigned 32 years. Childebert succeeded to the kingdom without opposition, but did not long enjoy it; he himself dying in the year 596, and his queen shortly after. His dominions were divided between his two sons Theodobert and Thierri; the first of whom was declared king of Austrasia, and the latter king of Burgundy. As Theodobert was only in the 11th year of his age, and Thierri in his 10th, Brunehaut governed both kingdoms with an absolute sway. Fredegonde, however, took care not to let slip such a favourable opportunity as was offered her by the death of Childebert, and therefore made herself mistress of Paris and some other places on the Seine. Upon this Brunehaut sent against her the best part of

16 and Fredegonde. the forces in Austrasia, who were totally defeated; but Fredegonde died before she had time to improve her victory, leaving her son Clotaire heir to all her dominions.

For some time Brunehaut preserved her kingdom in peace; but in the end her own ambition proved her ruin. Instead of instructing Theodobert in what was necessary for a prince to know, she took care rather to keep him in ignorance, and even suffered him to marry a young and handsome slave of his father's. The new queen was possessed of a great deal of affability and good nature; by which means she in a short time gained the affection of her husband so much, that he readily

17 Brunehaut banished. consented to the banishment of Brunehaut. Upon this disgrace she fled to Thierri king of Burgundy, in the year 599. By him she was very kindly received; and instead of exciting jealousies or misunderstandings between the two brothers, she engaged Thierri to attempt the recovery of Paris and the other places which had been wrested from their family by Fredegonde, procuring at the same time a considerable body of auxiliaries from the Visigoths. This measure was so acceptable to Theodobert, that he likewise raised a numerous army, and invaded Clotaire's dominions in conjunction with his brother. A battle ensued, in which the forces of Clotaire were totally defeated, and himself obliged soon after to sue for peace: which was not granted, but on condition of his yielding up the best part of his dominions.

This treaty was concluded in the year 600; but three years afterwards, it was broken by Clotaire. He was again attacked by the two brothers, and the war carried on with great vigour till the next spring. At this time Thierri having forced Landri, Clotaire's general, to a battle, gave him a total overthrow, in which the king's infant son Meroveus, whom he had sent along with Landri, was massacred; to gratify, as Clotaire pretended, the malice of Brunehaut. After this victory, Thierri marched directly to Paris; fully bent on the destruction of his cousin, which now seemed inevitable. This, however, was prevented by Theodobert; who no sooner heard of the victory gained by Thierri, than he became jealous of his success, and offered Clotaire such terms of peace as he gladly accepted. The latter having then nothing to fear on the side of Austrasia, quickly compelled Thierri to listen to terms of accommodation also.

This behaviour of Theodobert greatly provoked his brother; and his resentment was highly inflamed by Brunehaut, who never forgot her disgrace in being banished from his court. A war was therefore commenced between the two brothers in 605; but it was so highly disapproved of by the nobility, that Thierri found himself obliged to put an end to it. The tranquillity which now took place was again disturbed in 607, by Theodobert's sending an embassy to demand some part of Childebert's dominions, which had been added by the will of that monarch to those of Burgundy. The nobility of both kingdoms were so much averse to war, that they constrained their kings to consent to a conference, attended by an equal number of troops; but Theodobert, by a scandalous breach of his faith, brought double the number, and compelled his brother to submit to what terms he pleased. This piece of treachery instantly brought on a war; for Thierri was bent on revenge, and his nobility no longer opposed him. It was necessary, however, to secure Clotaire by a negotiation; and accordingly a promise was made of restoring those parts of his dominions which had formerly been taken from him, provided he would remain quiet. This treaty being finished, Thierri entered Theodobert's dominions, defeated him in two battles, took him prisoner, used him with the utmost indignity; and having caused an infant son of his to be put to death, sent him to his grandmother Brunehaut. By her orders he was first shaved and confined in a monastery; but afterwards, fearing lest he should make his escape, she caused him to be put to death.—Clotaire, in the mean time, thought that the best method of making Thierri keep his word was to seize on those places which he had promised to restore to him, before his return from the war with Theodobert. This he accordingly did; and Thierri no sooner heard of his having done so, than he sent him a message requiring him to withdraw his forces, and, in case of his refusal, declared war. Clotaire was prepared for this; and accordingly assembled all the forces in his dominions, in order to give him a proper reception. But before Thierri could reach his enemies, he was seized with a dysentery; of which he died in the year 612, having lived 26 years, and reigned 17. 18 Death of Thierri.

On the death of Thierri, Brunehaut immediately caused his eldest son, named *Sigisbert*, then in the 10th year of his age, to be proclaimed king. It is probable that she intended to have governed in his name with an absolute sway; but Clotaire did not give her time to discover her intentions. Having great intelligence in Austrasia and Burgundy, and knowing that the nobility in both kingdoms were disaffected to Brunehaut, he declared war against her; and she being betrayed by her generals, fell into the hands of her enemies. Clotaire gave her up to the nobles; who generally

France.

19 Brunehaut put to a cruel death.

hated her, and who used her in the most cruel manner. After having led her about the camp, exposed to the insults of all who had the meanness to insult her, she was tied by the leg and arm to the tail of an untamed horse, which, setting off at full speed, quickly dashed out her brains. After this her mangled body was reduced to ashes, which were afterwards interred in the abbey of St Martin at Autun.

Thus in the year 613, Clotaire became sole monarch of France; and quietly enjoyed his kingdom till his death, which happened in 628. He was succeeded by Dagobert; who proved a great and powerful prince, and raised the kingdom of France to a high degree of splendour. Dagobert was succeeded by his sons Sigebert and Clovis; the former of whom had the kingdom of Austrasia, and the latter that of Burgundy. Both the kings were minors at the time of their accession to the throne, which gave an opportunity to the mayors of the palace (the highest officers under the crown) to usurp the whole authority. Sigebert died in 640, after a short reign of one year; leaving behind him an infant son named *Dagobert*, whom he strongly recommended to the care of Grimoalde his mayor of the palace. The minister caused Dagobert to be immediately proclaimed king, but did not long suffer him to enjoy that honour. He had not the cruelty, however, to put him to death; but sent him to a monastery in one of the Western islands of Scotland; and then, giving out that he was dead, advanced his own son Childebert to the throne. Childebert was expelled by Clovis king of Burgundy; who placed on the throne Childeric, the second son of Sigebert. Clovis died soon after the revolution, and was succeeded in his dominions by his son Clotaire; who died in a short time, without issue. He was succeeded by his brother Childeric; who, after a short reign, was murdered with his queen, at that time big with child, and an infant son named *Dagobert;* though another, named *Daniel*, had the good luck to escape.

20 Miserable situation of France.

The affairs of the French were now in the most deplorable situation. The princes of the Merovingian race had been for some time entirely deprived of their power by their officers called *mayors of the palace*. In Austrasia the administration had been totally engrossed by Pepin and his son Grimaulde; while Archambaud and Ebroin did the same in Neustria and Burgundy. On the reunion of Neustria and Burgundy to the rest of the Freuch dominions, this minister ruled with such a despotic sway, that the nobility of Austrasia were provoked to a revolt; electing for their dukes two chiefs named *Martin* and *Pepin*. The forces of the confederates, however, were defeated by Ebroin; and Martin having surrendered on a promise of safety, was treacherously put to death. Pepin lost no time in recruiting his shattered forces; but before he had any occasion to try his fortune a second time in the field of battle, the assassination of Ebroin delivered him from all apprehensions from that quarter. After his death, Pepin carried every thing before him, overthrew the royal army under the command of the new minister Bertaire; and, having got possession of the capital, caused himself to be declared mayor of the palace; in which station he continued to govern with an absolute sway during the remainder of his life.

Pepin (who had got the surname of *Heristal* from his palace on the Meuse) died in the year 714, having enjoyed unlimited power for 26 years. He appointed his grandson Theudobalde, then only six years of age, to succeed him in his post of mayor of the palace. This happened during the reign of Dagobert already mentioned; but this prince had too much spirit to suffer himself to be deprived of his authority by an infant. The adherents of the young mayor were defeated in battle, and this defeat was soon followed by his death.

21 Exploits of Charles Martel.

Charles, however, the illegitimate son of Pepin, was now raised to the dignity of duke by the Austrasians, and by his great qualities seemed every way worthy of that honour. The murder of Dagobert freed him from a powerful opponent; and the young king Chilperic, who after Dagobert's death was brought from a cloister to the throne, could by no means cope with such an experienced antagonist. On the 19th of March 717, Charles had the good fortune to surprise the royal camp as he passed through the forest of Arden; and soon after a battle ensued, in which the king's forces were entirely defeated. On this Chilperic entered into an alliance with Eudes duke of Aquitain, whose friendship he purchased by the final cession of all the country which Eudes had seized for himself. Charles, however, having placed on the throne another of the royal family named *Clotaire*, advanced against Chilperic and his associate, whom he entirely defeated near Soissons. After this disaster, Eudes, despairing of success, delivered up Chilperic into the hands of his antagonist: after having stipulated for himself the same terms which had been formerly granted him by the captive monarch.

Charles, now advanced to the summit of power, treated Chilperic with great respect; and on the death of Clotaire, caused him to be proclaimed king of Austrasia; by which, however, his own power was not in the least diminished; and from this time the authority of the kings of France became merely nominal; and so inactive and indolent were they accounted, that historians have bestowed upon them the epithet of *faineans*, i. e. "lazy or idle." Charles, however, had still one competitor to contend with. This was Rainfroy, who had been appointed mayor of the palace; and who made such a vigorous resistance, that Charles was obliged to allow him the peaceable possession of the country of Anjou. No sooner, however, had Charles thus set himself at liberty from domestic enemies, than he was threatened with destruction from foreign nations. The Suevians, Frisons, and Alemanni, were successively encountered and defeated. Eudes also, who had perfidiously broken the treaties to which he had bound himself, was twice repulsed; after which Charles invaded Aquitain, and obliged the treacherous duke to hearken to reason. This was scarce accomplished, when he found himself engaged with a more formidable enemy than any he had yet encountered. The Saracens having overrun great part of Asia, now turned their victorious arms westward, and threatened Europe with total subjection. Spain had already received the yoke; and having passed the Pyrenees, they next invaded France, appearing in vast numbers under the walls of Thoulouse. Here they were encountered and defeated by Eudes; but this proved only a partial check. The barbarians once more passing the Pyrenees, entered France with such a powerful army, that Eudes was no longer able to to resist. He encountered them indeed with his accustomed valour; but being forced to yield to superior power, he solicited the protection and assistance of Charles. On this occasion the latter, on account of his valour and personal strength, acqnired the name of *Martel*, i. e. "the hammer," alluding to the violence of the strokes he bestowed on his enemies†. Three hundred and seventy-five thousand of the Infidels, among whom was the commander Abdelrahman himself, are said to have perished in the battle; notwithstanding which they soon made another irruption: but in this they were attended with no better success, being again defeated by Charles; who by so many victories established his power on the most solid foundation. Having again defeated the Frisons, and with his own hand killed their duke, he assumed the sovereignty of the dominions of Eudes, after his decease, reserving to himself the claim of homage, which he ought to have yielded to Thierri his lawful sovereign. At last, his fame grew so great, that he was chosen by Pope Gregory III. for his protector. He offered to shake off the yoke of the Greek emperor, and to invest Charles with the dignity of Roman consul; sending him at the same time the keys of the tomb of St Peter; but while this negotiation was going on successfully, the pope, the emperor, and Charles Martel, himself, died. After his death, which happened in the year 741, his dominions were divided among his three sons, Carloman, Pepin, and Grippon, according to the dispositions he had made in his lifetime. By this, Carloman, the eldest, had Austrasia; Pepin, the second, Neustria and Burgundy; while Grippon, the third, had only some lands assigned him in France; by which he was so much displeased, that the tranquillity of the empire was soon disturbed. With the assistance of his mother Sonnechilde he seized on the city of Lahon, where he endured a violent siege. In the end, however, he was obliged to submit; Sonnechilde was put into a monastery, and Grippon imprisoned in a castle at Arden. The two brothers, having thus freed themselves from their domestic enemy, continued to govern the empire with uninterrupted harmony; but their tranquillity was soon disturbed by the intrigues of Sonnechilde. That enterprising and ambitious woman had negotiated a marriage between Odilon duke of Bavaria and Hiltrude the sister of the two princes. This was no sooner accomplished than Odilon, instigated by Sonnechilde, and alarmed at the growing power of the two princes, entered into an alliance with Theodobald duke of the Alemanni and Theodoric duke of the Saxons; who having assembled a formidable army, advanced directly against the princes. They posted themselves in an advantageous manner, with the river Lech in their front; but Carloman and Pepin, passing the river at different fords in the night time, attacked the camp of the allies with great vigour. The engagement continued doubtful for five hours; but at last the entrenchments were forced on all sides, the Bavarians and Saxons entirely routed, and the vanquished dukes obliged to submit to the clemency of the victors. During their absence on this expedition, Hunalde, whom Charles Martel had appointed duke of Aquitain, having likewise entered into a confederacy with Odilon, passed the Loire, ravaged the open country, and burnt the magnificent cathedral of the city of Chartres. The two princes, however, having returned with their victorious army, Hunalde found himself obliged to retreat: and even this availed him but little: for the Franks entering the duchy of Aquitain, committed such devastations, that Hunalde in despair resigned his dominions to his son, and retired into a convent. This event was soon followed by a similar resignation of Carloman, notwithstanding the uninterrupted success he had met with. He suddenly took the resolution of retiring into a convent, and persisted in his design notwithstanding the entreaties of Pepin, who, to appearance at least, did all he could to dissuade him.

† See *Arabia*, N°174.

22 France divided among the sons of Charles.

23 Pepin becomes sole master of the kingdom.

By the resignation of Carloman, which happened in the year 746, Pepin was left sole master of France; and in this exalted station he acquitted himself in such a manner as has justly rendered his name famous to posterity. One of the first acts of his new administration was to release his brother Grippon from prison: but that treacherous prince had no sooner regained his liberty, than he again excited the Saxons to take up arms. His enterprise, however, proved unsuccessful: the Saxons were defeated, their duke Theodoric taken, and his subjects obliged to submit to the will of the conqueror; who upon this occasion caused them make a profession of the Christian religion. Grippon then fled to Hiltrude, his half sister, whose husband Odilon was now dead, and had left an infant son named *Tassilon*. He met with a favourable reception from her; but with his usual treachery, seized both her and her son by the assistance of an army of malecontent Franks, whom he had persuaded to join him. His next step was to assume the sovereignty and title of duke of Bavaria; but being driven from the throne by Pepin, he was obliged to implore his clemency, which was once more granted. All these misfortunes, however, were not yet sufficient to cure Grippon of his turbulence and ambition: He once more endeavoured to excite disturbances in the court of Pepin; but being finally detected and baffled, he was obliged to take refuge in Aquitain.

24 Assumes the title of king.

Pepin having now subdued all his foes, both foreign and domestic, began to think of assuming the title of *king*, after having so long enjoyed the regal power. His wishes in this respect were quite agreeable to those of the nation in general. The nobility, however, were bound by an oath of allegiance to Childeric the nominal monarch at that time: and this oath could not be dispensed with but by the authority of the pope. Ambassadors for this purpose were therefore dispatched both from Pepin and the nobility to Pope Zachary, the reigning pontiff. His holiness replied, that it was lawful to transfer the regal dignity from hands incapable of maintaining it to those who had so successfully preserved it; and that the nation might unite in the same person the authority and title of *king*. On this the unfortunate Childeric was degraded from his dignity, shaved, and confined in a monastery for life; Pepin assumed the title of *king of France*, and the line of Clovis was finally set aside.

This revolution took place in the year 751. The attention of the new monarch was first claimed by a revolt of the Saxons; but they were soon reduced to subjection, and obliged to pay an additional tribute: and during this expedition against them, the king had the satisfaction of getting rid of his restless and treacherous competitor Grippon. This turbulent prince,

having

having soon become weary of residing at the court of Aquitain, determined to escape from thence, and put himself under the protection of Astolphus king of the Lombards; but he was killed in attempting to force a pass on the confines of Italy. Pepin in the mean time continued to push his good fortune. The submission of the Saxons was soon followed by the reduction of Brittany; and that by the recovery of Narbonne from the Infidels. His next exploit was the protection of Pope Stephen III. against Astolphus the king of the Lombards, who had seized on the exarchate of Ravenna, and insisted on being acknowledged king of Rome. The pope, unable to contend with such a powerful rival, hasted to cross the Alps and implore the protection of Pepin, who received him with all the respect due to his character. He was lodged in the abbey of St Dennis, and attended by the king in person during a dangerous sickness with which he was seized. On his recovery, Stephen solemnly placed the diadem on the head of his benefactor, bestowed the regal unction on his sons Charles and Carloman, and conferred on the three princes the title of *patrician of Rome*. In return for these honours, Pepin accompanied the pontiff into Italy at the head of a powerful army. Astolphus, unable to withstand such a powerful antagonist, shut himself up in Pavia, where he was closely besieged by the Franks, and obliged to renounce all pretensions to the sovereignty of Rome, as well as to restore the city and exarchate of Ravenna, and swear to the observance of the treaty. No sooner was Pepin gone, however, than Astolphus broke the treaty he had just ratified with such solemnity. The pope was again reduced to distress, and again applied to Pepin. He now sent him a pompous epistle in the style and character of St Peter himself; which so much inflamed the zeal of Pepin, that he instantly set out for Italy and compelled Astolphus a second time to submit to his terms, which were now rendered more severe by the imposition of an annual tribute. Pepin next made a tour to Rome; but finding that his presence there gave great uneasiness both to the Greeks aud to the pope himself, he thought proper to finish his visit in a short time. Soon after his return Astolphus died, and his dominions were usurped by his general Didier; who, however, obtained the papal sanction for what he had done, and was recognized as lawful sovereign of the Lombards in the year 756.

Pepin returned to France in triumph; but the peace of his dominions was soon disturbed by the revolt of the Saxons, who always bore the French yoke with the utmost impatience. Their present attempts, however, proved equally unsuccessful with those they had formerly made; being obliged to submit and purchase their pardon not only by a renewal of their tribute, but by an additional supply of 300 horse. But while the king was absent on this expedition, Vaisar duke of Aquitain took the opportunity of ravaging Burgundy, where he carried his devastations as far as Chalons. Pepin soon returned, and entering the dominions of Vaisar, committed similar devastations, and would probably have reduced the whole territory of Aquitain, had he not been interrupted by the hostile preparations of his nephew Tassilon the duke of Bavaria. The king, however, contented himself at present with securing his frontiers by a chain of posts, against any invasion; after which he resumed his enterprise on the dominions of Vaisar. The latter at first attempted to impede the progress of his antagonist by burning and laying waste the country: but finding this to no purpose, he determined to try his fortune in an engagement. Victory declared in favour of Pepin; but he refused to grant a peace upon any terms. The French monarch advanced to the banks of the Garonne; while Vaisar was abandoned by his ally the duke of Bavaria, and even by his own subjects. In this distress he retired with a band of faithful followers into the country of Saintonge, where he defended himself as long as possible, but was at last deprived both of his crown and life by the victor.

Thus the duchy of Aquitain was once more annexed to the crown of France; but Pepin had scarce time to indulge himself with a view of his new conquest when he was seized with a slow fever, which put an 25
end to his life in the year 768, the 54th of his age, Death of
and 17th of his reign. He was of a short stature, Pepin.
whence he had the surname of *Le Bref*, or *the Short*; but his great actions justly entitled him to the character of a hero: though under the succeeding reign his own fame seemed to have been entirely forgot, and on his tomb was only inscribed, "Here lies the father of Charlemagne." 26

Pepin was succeeded in his authority by his two Succeeded
sons Charles and Carloman; to whom with his dying by his two
breath he bequeathed his dominions. They continued sons.
to reign jointly for some time; but the active and enterprising spirit of Charles gave such umbrage to the weak and jealous Carloman, that he regarded him with envy, and was on the point of coming to an open rupture with him, when he himself was taken off by death, and thus the tranquillity of the empire was preserved.

The first military enterprise of Charles was against Hunalde, the old duke of Aquitain; who leaving the monastery where he had resided upwards of 20 years, assumed the royal title, and was joyfully received by his subjects, already weary of the French yoke.—Charles took the field with the utmost expedition, and with difficulty prevailed upon his brother Carloman, who was then alive, to join him with his forces. But the junction was scarce effected, when Carloman withdrew his forces again, and left his brother to carry on the war in the best manner he could. Charles, though thus deserted, did not hesitate at engaging the enemy; and having overthrown them in a great battle, Hunalde was obliged to fly to the territories of Lupus duke of Gascony. Charles quickly sent an embassy demanding the fugitive prince; and Lupus, not daring to disobey the orders of such a powerful monarch, yielded up the unfortunate Hunalde, who was instantly cast into prison, from which, however, he afterwards made his escape.

The death of Carloman, which happened in the year 27 Reign of
771, left Charles sole master of France, but the revolt Charles the
of the Saxons involved him in a series of wars from Great.
which he did not extricate himself for 33 years. These had long been tributaries to the French, but frequently revolted: and now, when freed from the terror of Pepin's arms, thought they had a right to shake off the yoke altogether. Charles entered their country with a powerful army; and having defeated them in a number

ber of small engagements, advanced towards Eresbourg near Paderborn, where they had their capital post, and where was the image of their god Irminsul, represented as a man completely armed, and standing on a column. The Saxons made an obstinate defence, but were at last obliged to submit; and Charles employed his army three days in demolishing the monuments of idolatry in this place; which so much disheartened the whole nation, that for the present they submitted to such terms as he pleased to impose; and which were rendered easier than they probably would have been, by the news which Charles now received from Italy.—He had concluded a marriage with the daughter of Didier king of the Lombards; but this had been dissolved by the pope, who reproached the Lombards with the first stain of the leprosy. Thus all friendship was dissolved betwixt Didier and Charles; and as the Lombard monarchs seem to have had a kind of natural enmity towards the popes, it is not surprising that it should now break out with uncommon fury. Didier having seized and frighted to death Pope Stephen IV. used his utmost endeavours to reduce his successor Adrian I. to a state of entire dependence on himself. Adrian applied to the French monarch, the usual resource of the pontiffs in those days. Charles was very willing to grant the necessary assistance, but the nobility were averse to an Italian war; so that he was obliged to act with great circumspection. Several embassies were therefore sent to Didier, entreating him to restore to the Pope those places which he had taken from him, and at last even offering him a large sum of money if he would do so; but this proposal being rejected, he obtained the consent of his nobility to make war on the Lombards. Didier disposed his troops in such a manner, that the officers of Charles are said to have been unanimously of opinion, that it would be impossible to force a passage. This, however, was accomplished, either through the superior skill of Charles, according to some historians, or a panic which seized the Lombard soldiers, according to others; after which Didier, with the old duke of Aquitain, who had escaped from his prison, and taken refuge at his court, shut themselves up in Pavia. Adalgise, the only son of the Lombard monarch, with the widow and children of Carloman, fled to Verona. That city was immediately invested by the conqueror, and in a short time obliged to submit. Adalgise had the good luck to escape to Constantinople, but we are not informed what became of Carloman's widow and children.—Charles, after paying a short visit to Rome, returned to the siege of Pavia. The place was vigorously defended, until famine and pestilence obliged the inhabitants to implore the clemency of Charles. Hunalde fell a sacrifice to his own obstinacy in opposing the intention of the people; Didier was taken prisoner and carried into France; but we are not informed of his fate afterwards. His kingdom, however, was totally dissolved, and Charles was crowned king of Lombardy at Milan in the year 774.

Having received the oaths of allegiance from his new subjects, Charles set out for Saxony, the inhabitants of which had again revolted, and recovered Eresbourg their capital. The king soon recovered this important post; but a detachment of his army being cut off, and new troubles arising in Italy, he was obliged to accept of the proposals of the Saxons, though their sincerity was very doubtful. Having therefore only strengthened the fortifications of Eresbourg, and left a sufficient garrison in the place, he set out for Italy, which was all in commotion through the intrigues of the emperor of the East, and Adalgise the son of Didier. The presence of Charles restored tranquillity in that quarter; but in the mean time, the Saxons having taken Eresbourg and destroyed the fortifications, threatened to annihilate the French power in that quarter. On the king's return, he found them employed in the siege of Sigebourg. His sudden arrival struck the barbarians with such terror, that they instantly sued for peace; which the king once more granted, but took care to secure their obedience by a chain of forts along the river Lippe, and repairing the fortifications of Eresbourg. An assembly of the Saxon chiefs was held at Paderborn, and a promise was made, that the nation should embrace the Christian religion: after which the king set out on an expedition to Spain in the year 778.

This new enterprise was undertaken at the request of Ibunala, the Moorish sovereign of Saragossa, who had been driven from his territory. He was restored, however, by the prowess of Charles, who reduced the cities of Pampeluna and Saragossa. He reduced also the city of Barcelona, and the kingdoms of Navarre and Arragon; but, on his return, he met with a severe check from the Gascons, who attacked and defeated the rear-guard of his army with great slaughter as they passed the Pyrenean mountains. This engagement, which seems to imply some defect in the prudence or military skill of Charles, has been much celebrated among romance writers, on account of the death of Roland a famous warrior.

Next year, 779, he paid a visit to Italy with his two sons Carloman and Louis. Having passed the winter at Pavia, he entered Rome next spring amidst the acclamations of the inhabitants. Here, in the 39th year of his age, he divided his dominions in presence of the pope betwixt his two sons Carloman and Louis. The former, who now took the name of Pepin, had Lombardy; the latter Aquitain. Having then received the submission of Tassilon duke of Bavaria, he set out for Saxony, where he took a most severe revenge on the people of that country for the many treacheries they had been guilty of. The present revolt was chiefly owing to a chief named Witikind, who had twice before fled from the victorious arms of Charles, and taken refuge at the court of Denmark. Returning from thence, in the king's absence, he roused his countrymen to action, while the generals of Charles, disagreeing among themselves, neglected to take the proper methods for repelling the enemy. In consequence of this, they were entirely defeated on the banks of the Weser in the year 782. Charles arrived in time to prevent the total destruction of his people, and directly penetrated into the heart of the country. Witikind unable to resist his antagonist, once more fled into Denmark; but 4500 of his followers perished at once by the hands of the executioner. An universal insurrection was the consequence of this unheard of cruelty; and though during three years the French monarch was constantly successful in the field, he found it impossible by any force whatever to subdue the spirit

spirit of the people. At last therefore he was obliged to have recourse to negotiation. Witikind and several other chiefs were invited to an interview; where Charles represented to them in such strong colours the ruin which must necessarily ensue to their country by persisting obstinately in opposition to him, that they were induced not only to persuade their countrymen finally to submit, but to embrace the Christian religion.

Charles having thus brought his affairs in Saxony to a happy conclusion, turned his arms against Tassilon duke of Bavaria, who had underhand supported the Saxons in their revolt. Having entered his country with a powerful army in the year 787, he made such rapid advances, that the total destruction of Tassilon seemed inevitable. Charles had advanced as far as the river Lech, when Tassilon privately entered his camp, and threw himself at his feet. The king had compassion on his faithless kinsman on seeing him in this abject posture; but no sooner did the traitor find himself at liberty, than he stirred up the Hunns, the Greek emperor, and the fugitive Adalgise, against the king. He fomented also the discontents of the factious nobles of Aquitain and Lombardy: but his subjects, fearing lest these intrigues should involve them in destruction, made a discovery of the whole to Charles. Tassilon, ignorant of this, entered the diet at Ingelheim, not suspecting any danger, but was instantly arrested by order of the French monarch. Being brought to a trial, the proofs of his guilt were so apparent, that he was condemned to lose his head; the punishment, however, was afterwards mitigated to perpetual confinement in a monastery, and the duchy of Bavaria was annexed to the dominions of Charles.

The Hunns and other enemies of the French monarch continued to prosecute their enterprises without regarding the fate of their associate Tassilon. Their attempts, however, only served to enhance the fame of Charles. He defeated the Hunns in Bavaria, and the Greek emperor in Italy; obliging the latter to renounce for ever the fortune of Adalgise. The Hunns, not disheartened by their defeat, continuing to infest the French dominions, Charles entered their country at the head of a formidable army; and having forced their intrenchments, penetrated as far as Raab on the Danube, but was compelled by an epidemic distemper to retire before he had finished his conquest. He was no sooner returned to his own dominions, than he had the mortification to be informed, that his eldest son Pepin had conspired against his sovereignty and life. The plot was discovered by a priest who had accidentally fallen asleep in a church where the conspirators were assembled. Being awakened by their voices, he overheard them consulting on the proper measures for completing their purpose; on which he instantly set out for the palace, and summoned the monarch from his bed to inform him of the guilt of his son. Pepin was seized, but had his life spared, though condemned to expiate his offences by spending the remainder of his days in a monastery.

Charles was no sooner freed from this danger than he was again called to arms by a revolt of the Saxons on the one hand, while a formidable invasion of the Moors distressed him on the other; the Hunns at the same time renewing their depredations on his dominions. The king did not at present make war against the Moors; probably foreseeing that they would be called off by their Christian enemies in Spain. This accordingly happened; the victories of Alonso the Chaste obliged them to leave France; after which Charles marched in person to attack the Saxons and Hunns. The former consented again to receive the Christian religion, but were likewise obliged to deliver up a third part of their army to be disposed of at the king's pleasure; but the Hunns defended themselves with incredible vigour. Though often defeated, their love of liberty was altogether invincible; so that the war was not terminated but by the death of the king, and an almost total destruction of the people: only one tribe could be induced to acknowledge the authority of the French monarch.

These exploits were finished betwixt the years 793 and 798: after which Charles invaded and subdued the islands of Majorca and Minorca; which the dissensions of the Moorish chiefs gave him an opportunity of doing. The satisfaction he felt from this new conquest, however, was soon damped by the troubles which broke out in Italy. After the death of Pope Adrian, his nephew aspired to the papal dignity; but a priest named Leo being preferred, the disappointed candidate determined on revenge. He managed matters so well, that his designs were concealed for four years. At last, on the day of a procession, a furious assault was made on the person of Leo. The unfortunate pontiff was left for dead on the ground; but having with difficulty recovered, and made his escape to the Vatican, he was protected by the duke of Spoleto, at that time general of the French forces. His cause was warmly espoused by Charles, who invited him to his camp at Paderborn in Westphalia; whence he dispatched him with a numerous guard to Rome, promising soon after to visit that metropolis, and redress all grievances. His attention for the present, however, was called by the descents of the Normans on the maritime provinces of his dominions; so that he was obliged to defer the promised assistance for some time longer. Having constructed forts at the mouths of most of the navigable rivers, and further provided for the defence of his territories, by instituting a regular militia, and appointing proper squadrons to cruise against the invaders, he set out for the fourth and last time on a journey to Rome. Here he was received with the highest possible honours. Leo was allowed to clear himself by oath of the crimes laid to his charge by the enemies, while his accusers were sent into exile. On the festival of Christmas, in the year 800, after Charles had made his appearance in the cathedral of St Peter, and assisted devoutly at mass, the pope suddenly put a crown on his head; and the place instantly resounded with acclamations of "Long life to Charles the Augustus, crowned by the hand of God! Long life and victory to the great and pacific emperor of the Romans!" His body was then consecrated and anointed with royal unction; and after being conducted to a throne, he was treated with all the respect usually paid to the ancient Cæsars; from this time also being honoured with the title of *Charlemagne*, or *Charles the Great*. In private conversation, however, he usually protested, that he was ignorant of the pope's intention at this time; and that, had he known it, he would have disappointed

28
He is crowned emperor of the West.

 disappointed him by his absence: but these protestations were not generally believed; and the care he took to have his new title acknowledged by the eastern emperors, evidently showed how fond he was of it.

Charles, now raised to the supreme dignity in the west, proposed to unite in himself the whole power of the first Roman emperors, by marrying Irene the empress of the East. But in this he was disappointed by the marriage of that princess by Nicephorus; however, the latter acknowledged his new dignity of Augustus, and the boundaries of the two empires were amicably settled. Charles was further gratified by the respect paid him by the great Haroun Al-Rashid, caliph of the Saracens, who yielded to him the sacred city of Jerusalem, and holy sepulchre there. But in the mean time his empire was threatened with the invasion of a very formidable enemy, whom even the power of Charles would have found it hard to resist. These were the Normans, at this time under the government of Godfrey a celebrated warrior, and who by their adventurous spirit, and skill in maritime affairs, threatened all the western coasts of Europe with desolation. From motives of mutual convenience a transitory peace was established, and Charles made use of this interval to settle the final distribution of his dominions. Aquitain and Gascony, with the Spanish Marche, were assigned to his son Louis; Pepin had Italy confirmed to him; and to this was added the greatest part of Bavaria, with the country now possessed by the Grisons. Charles the eldest had Neustria, Austrasia, and Thuringia. The donation was supposed to be rendered more authentic by the sanction of the pope. This division, however, had scarce taken place, when the princes were all obliged to defend their dominions by force of arms. Louis and Pepin were attacked by the Saracens, and Charles by the Sclavonians. All these enemies were defeated; but while Charles hoped to spend the short remainder of his life in tranquillity, he was once more called forth to martial exertions by the hostile behaviour of Godfrey the Norman leader. Charles sent him a message of defiance, which was returned in the same style by Godfrey: but the former, by artfully fomenting divisions among the northern powers, prevented for a while the threatened danger; but, these disturbances being quelled, the Normans renewed their depredations, and Charles was obliged to face them in the field. An engagement, however, was prevented by the death of Godfrey, who was assassinated by a private soldier; on which the Norman army retreated, and the dominions of the empire still remained free from these invaders. Still the latter days of Charles were embittered by domestic misfortunes. His favourite daughter Rotrude died, as did also Pepin king of Italy; and these misfortunes were soon followed by the death of his eldest son Charles. The emperor then thought proper to associate his only surviving son Louis with him in the government; which was formally done at Aix-la-Chapelle. Charles himself survived this transaction only a few months: his death happened on the 27th of January 814, in the 71st year of his age, and 47th of his reign.

29 Death of Charles the Great.

30 Extent of his territories.

By the martial achievements of this hero, the French monarchy was raised to its utmost pitch of splendour. He had added the province of Aquitain to the territories of his ancestors; he had confined the inhabitants of Brittany to the shores of the ocean, and obliged them to submit to a disgraceful tribute. He had reduced under his dominion all that part of Spain which extends from the Pyrenees to the river Ebro, and includes the kingdoms of Rousillon, Navarre, Arragon, and Catalonia. He possessed Italy from the Alps to the borders of Calabria; but the duchy of Beneventum, including most of the present kingdom of Naples, escaped the yoke after a transitory submission. Besides these extensive countries, Charles added to his territories the whole of Germany and Pannonia; so that the French now had the jurisdiction of all the country from east to west, from the Ebro in Spain to the Vistula; and from north to south, from the duchy of Beneventum to the river Eyder, the boundary between Germany and the dominions of Denmark. In acquiring these extensive dominions Charles had been guilty of horrid and repeated massacres, for which, however, he had been in some measure excusable by the barbarity and rebellious disposition of the people with whom he had to deal, upon whom no mild measures would probably have had any effect. His establishing of schools throughout the conquered provinces, showed also his inclination to govern his subjects in peace, and to take proper steps for their civilization; though indeed many parts of his private conduct showed no small inclination to cruelty; particularly the fate of the sons of Carloman, of whom no account could ever be obtained. His advice to his son Louis indeed was excellent; exhorting him to consider his people as his children; to be very mild and gentle in his administration, but firm in the execution of justice; to reward merit; promote his nobles gradually; choose ministers deliberately, but not remove them capriciously or without sufficient reason. All these prudent maxims, however, were not sufficient to enable Louis to govern dominions so extensive, and people so turbulent as he had to deal with. At the time of the decease of his father this prince was about 36 years of age, and had married Ermengarde, daughter of the count of Hesbai of the diocese of Liege, by whom he had three sons, Lothaire, Pepin, and Louis. Lothaire, the eldest, was associated with himself in the empire, and the two youngest were intrusted with the governments of Aquitain and Bavaria. Every one of the princes proved unfaithful to their father, as well as enemies to one another. The death of Ermengarde, and the marriage of the emperor with Judith a princess of Bavaria, artful but accomplished, proved the first source of calamity to the empire. In the year 823, Charles, the emperor's youngest son, was born; and his pretensions became in time more fatal to the public tranquillity than the ambition and disobedience of all the rest. Various parts of the Imperial dominions were likewise assaulted by foreign enemies. The inhabitants of Brittany and Navarre revolted; the Moors invaded Catalonia; while the ambition of Judith produced a war amongst the brothers themselves.

31 Decline of his empire.

32 Civil wars among the sons of Louis the Gentle.

Charles at first had been appointed sovereign of that part of Germany bounded by the rivers Danube, the Maine, the Neckar, and the Rhine; the country of the Grisons and Burgundy, comprehending Geneva and the Swiss cantons; but this was opposed by the three elder sons. Pepin and Louis advanced with the united forces of Aquitain and Bavaria, while the Imperial

perial

France. perial forces deserted their standard and joined the malecontents. The emperor was taken prisoner, and the empress retired to a monastery. Lothaire, the eldest of the younger princes, to whom the rest found themselves obliged to submit, was the person who retained the emperor in his possession; but notwithstanding his breach of duty, his heart was touched with remorse on account of the crimes he had committed. Dreading the reproach of the world at large, and being threatened with the censures of the church, he threw himself at his father's feet, and begged pardon for his guilt, consenting to relinquish the authority he had unjustly usurped. Thus Louis was re-established in his authority by the diet of the empire which had met to depose him. His first step was to recal his empress from the monastery to which she had retired; but this princess, implacable in her resentment, now persecuted Lothaire to such a degree, that he was obliged to join his two brothers Pepin and Louis in a confederacy against their father. The old emperor thought to check this rebellious disposition by revoking his grant of Aquitain to Pepin, and conferring it on his youngest son Charles, then only nine years of age; but Pope Gregory IV. conferred the Imperial dignity itself on Lothaire, deposing the unhappy monarch, and again sending the empress to a nunnery in the forest of Arden. The unnatural behaviour of his son, however, once more excited the compassion of his subjects. Dreux, the bishop of Mentz, used his interest with Louis king of Bavaria to arm his subjects in defence of his father and sovereign. In this enterprise the Bavarian monarch was joined by the French and Saxons; so that the aged emperor was once more restored, the empress released from her nunnery, and Charles from his prison, in the year 833.

The ambition of Judith now set matters once more in a flame. Taking advantage of the affection her husband bore her, she persuaded him to invest her son Charles with the sovereignty of Neustria as well as the dominions formerly assigned him. This was productive of great discontent on the part of Lothaire and Pepin; but their power was now too much broken to be able to accomplish any thing by force of arms. The death of Pepin, which happened soon after, produced a new division of the empire. The claims of young Pepin and Charles, sons of the deceased prince, were entirely disregarded, and his French dominions divided between the two brothers Charles and Lothaire, the latter being named guardian to his infant nephew. This enraged Louis of Bavaria, whose interest was entirely neglected in the partition, to such a degree, that he again revolted; but the unexpected appearance, with the hostile preparations of the Saxons, obliged him to submit and ask pardon for his offences. Still, however, the ambition of the empress kept matters in a continual ferment, and the empire was again threatened with all the calamities of civil war; but before these took place, the emperor died, in 841, after a most unfortunate reign of 27 years.

Louis was eminent for the mildness of his manners and peaceful virtues, which procured him the title of *Le Debonnaire*, or, "the gentle:" but such was the turbulence and excessive barbarity of the age in which he lived, that all his virtues, instead of procuring him respect and esteem, were productive only of contempt and rebellion from those whom both duty and nature ought to have rendered the most submissive and obedient. France.

The decease of the emperor was followed by a civil war among his sons. The united forces of Lothaire and his nephew Pepin were defeated by those of Charles and Louis in a very bloody battle in the plains of Fontenoy, where 100,000 Franks perished, in the year 842. This victory, however, bloody as it was, did not decide the fortune of the war. The conquerors having, through motives of interest or jealousy, retired each into their own dominions, Lothaire found means not only to recruit his shattered forces, but pressed the other two princes so vigorously, that they were glad to consent to a new partition of the empire. By this Lothaire was allowed to possess the whole of Italy, with the whole tract of country between the rivers Rhone and Rhine, as well as that between the Meuse and Scheldt. Charles had Aquitain, with the country lying between the Loire and the Meuse; while Louis had Bavaria, with the rest of Germany, from whence he was distinguished by the appellation of *Louis the Great*. 33

33 Division of the empire.

By this partition, Germany and France were disjoined in such a manner as never afterwards to be united under one head. That part of France which was allowed to Lothaire, was from him called *Lotharingia*, and now *Lorrain*, by the gradual corruption of the word. The sovereignty, however, which that prince had pursued at the expence of every filial duty, and purchased with so much blood, afforded him now but little satisfaction. Disgusted with the cares and anxieties of his situation, he sought relief in a monastery in the year 855. On his retreat from the throne, he allotted to his eldest son Louis II. the sovereignty of Italy; to his second son Lothaire the territory of Lorrain, with the title of king; and to his youngest son Charles, surnamed the *Bald*, Provence, Dauphiny, and part of the kingdom of Burgundy; so that he may be considered as properly the king of France. From the year 845 to 857 the provinces subjected to his jurisdiction had been infested by the annual depredations of the Normans, from whom Charles was at last fain to purchase peace at a greater expence than might have carried on a successful war. The people of Brittany had also revolted; and though obliged by the appearance of Charles himself, at the head of a powerful army, to return to their allegiance, they no sooner perceived him again embarrassed by the incursions of the Normans, than they threw off the yoke, and under the conduct of their duke Louis subdued the neighbouring diocese of Rennes; after which exploit Louis assumed the title of king, which he transmitted to his son Herispee. By him Charles was totally defeated; and his subjects, perceiving the weakness of their monarch, put themselves under the protection of Louis the German. His ambition prompted him to give a ready ear to the proposal; and therefore, taking the opportunity of Charles's absence in repelling an invasion of the Danes, he marched with a formidable army into France, and was solemnly crowned by the archbishop of Sens in the year 857. Being too confident of success, however, and fancying himself already established on the throne, he was persuaded to

34 Lothaire resigns.

35 Reign of Charles the Bald.

to dismiss his German forces; which he had no sooner done, than Charles marched against him with an army, and Louis abandoned his new kingdom as easily as he had obtained it.

Notwithstanding this success, the kingdom of Charles continued still in a very tottering situation. The Normans harassed him in one quarter, and the king of Brittany in another. He marched against the latter in the year 860; but had the misfortune to receive a total defeat, after an engagement which lasted two days. The victory was chiefly owing to a noted warrior named Robert le Fort, or the Strong, who commanded the Bretons; but Charles found means to gain him over to his party, by investing him with the title of duke of France, including the country which lies between the rivers Seine and Loire.

For some time the abilities of Robert continued to support the tottering throne of Charles; but the difficulties returned on the death of that hero, who was killed in repelling an invasion of the Danes. Some amends was indeed made for his loss by the death of the king of Lorrain in the year 869; by which event the territories of Charles were augmented by the cities of Lyons, Vienne, Toul, Besançon, Verdun, Cambray, Viviers and Urez, together with the territories of Hainault, Zealand, and Holland. Cologne, Utrecht, Treves, Mentz, Strasburg, with the rest of the territories of Lothaire, were assigned to Louis the German.

All this time the Normans still continued their incursions to such a degree, that Solomon king of Brittany was persuaded to join his forces to those of Charles, in order to repel the common enemy. The event proved unfortunate to the Normans; for their principal leaders were besieged in Angiers, and obliged to purchase leave to depart by relinquishing all the spoil they had taken. Charles thus freed from a formidable enemy, began to aspire to the Imperial crown, which about this time became vacant by the death of Louis. This belonged of right to Louis the German; but Charles, having instantly assembled a powerful army, marched with it into Italy before Louis could be apprised of his designs; and being favourably received at Rome, the Imperial crown was put on his head without any hesitation by the pope, in the year 873. Louis, enraged at his disappointment, discharged his fury on the defenceless country of Champagne; and though the approach of Charles obliged him for the present to retire, yet he continued his preparations with such vigour, that Charles would in all probability have found him a very formidable adversary, had he not been taken off by death in the year 877. Charles was no sooner informed of his brother's decease, than he invaded the dominions of his son Louis, who possessed Franconia, Thuringia, the Lower Lorrain, with some other territories in that quarter. The enterprise, however, proved unsuccessful. Charles, though superior in numbers, was defeated with great slaughter, and had scarcely time to reunite his scattered forces, when he was informed that the Normans had invaded his territories, laid waste part of that country, and taken possession of the city of Rouen. So may disasters affected him in such a manner that he fell dangerously ill, and was scarcely recovered of his sickness when he found himself called into Italy to the assistance of the pope against the Saracens, whose invasions were encouraged by the duke of Beneventum and the Greek emperor. Charles passed into Italy with only a few followers; but when he came to Pavia, at which place the pontiff had appointed to meet him, he was informed that Carloman king of Bavaria, and son of Louis the German, was already in Italy with a powerful army, and laid claim to the imperial title in virtue of his father's right. Charles prepared to oppose him by force of arms; but his generals conspired against him, and the soldiers declared their resolution not to pass the Alps. On this he was obliged to retire to France, at the very moment that Carloman, dreading his power, prepared to return to Germany. This was the last of Charles's enterprises. His journey brought on a return of his indisposition, which was rendered fatal through the treachery of a Jewish physician named Zedechius, who administered poison to him under pretence of curing his malady. He expired in a miserable cottage upon Mount Cenis, in the 54th year of his age, and 38th of his reign over the kingdom of France.

36 He is poisoned.

37 Reign of Louis the Stammerer.

The ambition of Charles had been productive of much distress both to himself and to his subjects. His son Louis, surnamed, from a defect in his speech, *the Stammerer*, was of a quite different disposition; but his feeble administration was ill calculated to retrieve matters in their present situation. He died on the 10th of April 879, while on a march to suppress some insurrections in Burgundy. He left his queen Adelaide pregnant; who some time after his decease was delivered of a son, named *Charles*. After his death followed an interregnum; during which a faction was formed for setting aside the children of Louis the Stammerer, in favour of the German princes, sons to Louis the brother of Charles the Bald. This scheme, however, proved abortive; and the two sons of the late king, Louis and Carloman, were crowned kings of France. Another kingdom was at that time erected by an assembly of the states, namely the kingdom of Provence, which consisted of the countries now called *Lyonnois*, *Savoy*, *Dauphiny*, *Franche Compte*, and part of the duchy of Burgundy; and the kingdom was given to Duke Boson, brother-in-law to Charles the Bald. In 881, both kings of France died; Louis, as was suspected, by poison; and Carloman, of a wound he received accidentally while hunting. This produced a second interregnum; which ended with the calling in of Charles the Gross, emperor of Germany. His reign was more unfortunate than that of any of his predecessors. The Normans, to whom he had given leave to settle in Friesland, sailed up the Seine with a fleet of 700 ships, and laid siege to Paris. Charles, unable to force them to abandon their undertaking, prevailed on them to depart by a large sum of money. But as the king could not advance the money at once, he allowed them to remain in the neighbourhood of Paris during the winter; and they in return plundered the country, thus amassing vast wealth besides the sum which Charles had promised. After this ignominous transaction Charles returned to Germany, in a very declining state of health both as to body and mind. Here he quarrelled with his empress; and being abandoned by all his friends, he was deposed, and reduced to such distress, that he would not even have had bread to eat, had

 had he not been supplied by the archbishop of Mentz, out of the principle of charity.

On the deposition of Charles the Gross, Eudes count of Paris was chosen king by the nobility during the minority of Charles the son of Adelaide, afterwards named *Charles the Simple*. He defeated the Normans, and repressed the power of the nobility; on which account a faction was formed in favour of Charles, who was sent for, with his mother, from England. Eudes did not enter into a civil war; but peaceably resigned the greatest part of the kingdom to him, and consented to do homage for the rest. He died soon after this agreement, in the year 898.

During the reign of Charles the Simple, the French government declined. By the introduction of fiefs, those noblemen who had got into the possession of governments, having these confirmed to them and their heirs for ever, became in a manner independent sovereigns: and as these great lords had others under them, and they in like manner had others under them, and even these again had their vassals; instead of the easy and equal government which prevailed before, a vast number of insupportable little tyrannies was erected. The Normans, too, ravaged the country in the most terrible manner, and desolated some of the finest provinces in France. At last Charles ceded to Rollo, the king or captain of these barbarians, the duchy of Neustria; who thereupon became a Christian, changed his own name to *Robert*, and that of his principality to *Normandy*.

During the remainder of the reign of Charles the Simple, and the entire reign of Louis IV. surnamed the *Stranger*, Lothaire, and Louis V. the power of the Carlovingian race continually declined; till at last they were supplanted by Hugh Capet, who had been created duke of France by Lothaire. This revolution happened in the year 987, and was brought about much in the same manner as the former one had been by Pepin. He proved an active and prudent monarch, and possessed such other qualities as were requisite for keeping his tumultuous subjects in awe. He died on the 24th of October 997, leaving his dominions in perfect quiet to his son Robert.

38 Family of Charles the Great supplanted by Hugh Capet.

39 Robert.

The new king inherited the good qualities of his father. In his reign the kingdom was enlarged by the death of Henry duke of Burgundy, the king's uncle, to whom he fell heir. This new accession of territory, however, was not obtained without a war of several years continuance, on account of some pretenders to the sovereignty of that duchy; and had it not been for the assistance of the duke of Normandy, it is doubtful whether the king would have succeeded.—As Robert was of opinion, that peace and tranquillity were preferable to wide extended dominions with a precarious tenure, he refused the kingdom of Italy and imperial crown of Germany, both which were offered him. He died on the 20th of July 1030; having reigned 33 years, and lived 60.

40 Henry I.

Robert was succeeded by his eldest son Henry I. who in the beginning of his reign met with great opposition from his mother. She had always hated him; and preferred his younger brother Robert, in whose favour she now raised an insurrection. By the assistance of Robert duke of Normandy, however, Henry overcame all his enemies, and established himself firmly upon the throne. In return for this, he supported William, Robert's natural son, and afterwards king of England, in the possession of the duchy of Normandy. Afterwards, however, growing jealous of his power, he not only supported the pretenders to the duchy of Normandy secretly, but invaded that country himself in their favour. This enterprise proved unsuccessful, and Henry was obliged to make peace: but no sincere reconciliation ever followed; for the king retained a deep sense of the disgrace he had met with, and the duke never forgave him for invading his dominions. The treaty between them, therefore, was quickly broken; and Henry once more invaded Normandy with two armies, one commanded by himself, and the other by his brother. The first was harassed by continual skirmishes, and the last totally defeated; after which Henry was obliged to agree to such terms as the duke thought proper; but the rancour between them never ceased, and was in reality the cause of that implacable aversion which for a long series of years produced perpetual quarrels between the kings of France and those of the Norman race in England.

Henry died in 1059, not without a suspicion of being poisoned; and was succeeded by his eldest son Philip, at that time in the eighth year of his age. Baldwin earl of Flanders was appointed his guardian; and died in the year 1066, about the time that William of Normandy became king of England. After the death of his tutor, Philip began to show a very insincere, haughty, and oppressive disposition. He engaged in a war with William the Conqueror, and supported his son Robert in his rebellion against him §. But after the death of William, he assisted Robert's brothers against him; by which means he was forced to consent to a partition of his dominions. 41 Philip.

§ See *England*, N° 89.

In 1092, King Philip being wearied of his queen Bertha, procured a divorce from her under pretence of consanguinity, and afterwards demanded in marriage Emma daughter to Roger count of Calabria. The treaty of marriage was concluded; and the princess was sent over, richly adorned with jewels, and with a large portion in ready money: but the king, instead of espousing her, retained her fortune, and dismissed the princess herself, carrying off from her husband the countess of Anjou, who was esteemed the handsomest woman in France. With her he was so deeply enamoured, that not satisfied with the illegal possession of her person, he procured a divorce between her and her husband, and prevailed upon some Norman bishops to solemnize his own marriage with her. The whole of these transactions, however, were so scandalous, that the pope having caused them to be revised in a council at Autun, in the year 1094, pronounced sentence of excommunication against Philip in case he did not part with the countess. On his repentance, the censure was taken off; but as the king paid no regard to his promises, he was, in 1095, excommunicated a second time. He again professed repentance, and was absolved; but soon after, living with the countess of Anjou as formerly, he was excommunicated a third time. This conduct, so unworthy of a prince, exposed him to the contempt of the people. Too many of the nobility followed his example, and at the same time despised his authority; not only making war upon on each other, but spoiling and robbing his subjects with impunity.

In the year 1110, Philip prevailed on the court of Rome to have his affaïr reviewed in an assembly at Poictiers; where, notwithstanding his utmost efforts, sentence of excommunication was a fourth time pronounced against him. Yet, in spite of all these sentences, as Queen Bertha was dead, and the count of Anjou offered, for a large sum of money, to give whatever assistance was requisite for procuring a dispensation, Philip at last prevailed, and the countess was proclaimed queen of France. But though the king's domestic affairs were now in some degree quieted, his negligence in government had thrown the affairs of the nation into the greatest disorder. He therefore associated with him in the government his eldest son Louis. This prince was the very reverse of his father; and by his activity and resolution, keeping constantly in the field with a considerable body of forces, he reduced the rebellious nobility to subjection, and according to the best historians, at this time saved the state from being utterly subverted.

For these services the queen looked upon the young prince with so jealous an eye, and gave him so much disturbance, that he found it necessary to retire for some time into England; where he was received by King Henry I. with the greatest kindness. He had not been long at court, before Henry received by an express a letter from Philip; telling him, that, for certain important reasons, he should be glad if he closely confined his son, or even despatched him altogether. The king of England, however, instead of complying with this infamous request, shewed the letter to Louis, and sent him home with all imaginable marks of respect. Immediately on his return he demanded justice; but the queen procured poison to be given him, which operated so violently that his life was despaired of. A stranger, however, undertook the cure, and succeeded; only a paleness remained in the prince's face ever afterwards, though he grew so fat that he was surnamed *the Gross.*

On his recovery, the prince was on the point of revenging his quarrel by force of arms; but his father having caused the queen to make the most humble submissions to him, his resentment was at length appeased, and a perfect reconciliation took place.

42 Louis the Gross. Nothing memorable happened in the reign of King Philip after this reconciliation. He died in the year 1118, and was succeeded by his son Louis the Gross. The first years of his reign were disturbed by insurrections of his lords in different places of the kingdom; and these insurrections were the more troublesome, as they were secretly fomented by Henry I. of England, that by weakening the power of France his duchy of Normandy might be the more secure. This quickly brought on a war; in which Henry was defeated, and his son William obliged to do homage to Louis for the duchy of Normandy. As the kings of England and France, however, were rivals, and exceedingly jealous of each other, the latter espoused the cause of William the son of Robert duke of Normandy, whom Henry had unjustly deprived of that duchy. This brought on a new war; in which Louis, receiving a great defeat from Henry, was obliged to make peace upon such terms as his antagonist thought proper. The tranquillity, however, was but of short duration. Louis renewed his intrigues in favour of William, and endeavoured to form a confederacy against Henry; but the latter found means not only to dissipate this confederacy, but to prevail upon Henry V. emperor of Germany to invade France with the whole strength of the empire on one side, while he prepared to attack it on the other. But Louis having collected an army of 200,000 men, both of them thought proper to desist. Upon this the king of France would have marched into Normandy, in order to put William in possession of that duchy. His great vassals, however, told him they would do no such thing; that they had assembled in order to defend the territories of France from the invasion of a foreign prince, and not to enlarge his power by destroying that balance which arose from the king of England's possession of Normandy, and which they reckoned necessary for their own safety. This was followed by a peace with Henry; which, as both monarchs had now seen the extent of each other's power, was made on pretty equal terms, and kept during the life of Louis, who died in 1137, leaving the kingdom to his son Louis VII.

The young king was not endowed with any of those qualities which constitute a great monarch. 43 Louis VII. a weak prince. From the superstition common to the age in which he lived, he undertook an expedition into the Holy Land, from whence he returned without glory. In this expedition he took his queen Eleanor along with him; but was so much offended with her gallantries during her stay there, as well as her behaviour afterwards, that he divorced her, and returned the duchy of Guienne which he received with her as a portion. Six weeks after this she married Henry duke of Normandy, count of Anjou and Maine, and heir apparent to the crown of England. This marriage was a very great mortification to Louis; and procured him the surname of *the Young*, on account of the folly of his conduct. When Henry ascended the throne of England, some wars were carried on between him and Louis, with little advantage on either side: at last, however, a perfect reconciliation took place; and Louis took a voyage to England, in order to visit the shrine of St Thomas of Canterbury. On his return he was struck with an apoplexy; and though he recovered for that time, yet he continued ever after paralytic on the right side. After having languished for about a year under this malady, he died on the 18th of September 1180, leaving the kingdom to his son Philip.

This prince, surnamed *The Gift of God*, *The Magnanimous*, and *The Conqueror*, during his lifetime; and, as 44 Philip the Great. if all these titles had fallen short of his merit, styled *Augustus* after his death,—is reckoned one of the greatest princes that ever sat on the throne of France, or any other. It doth not, however, appear, that these titles were altogether well founded. In the beginning of his reign he was opposed by a strong faction excited by his mother. This indeed he suppresed with a vigour and spirit which did him honour; but his taking part with the children of Henry II. of England in their unnatural contests with their father, and his treacherous combination with John to seize his brother's kingdom when he was detained in prison by the emperor of Germany, must be indelible stains in his character, and for ever exclude him from the title of *Magnanimous.* As to military skill and personal valour, he was evidently inferior to Richard I. of England; nor can his recovering of the provinces held by the English in France, from such a mean and dastardly prince as King John, entitle him with any justice to the surname of *Conqueror*. In politics he was evidently the dupe of the pope, who made use of him to intimidate John into a submission, by promising him the kingdom of England, which he never meant that he should enjoy. An account of these transactions, which are the principal ones of this reign, is given under the article ENGLAND, N° 121—141.

45 Reign of Louis IX.

Philip died in 1223, and was succeeded by his son Louis VIII. and he, in 1226, by Louis IX. afterwards styled *St Louis*. This prince was certainly possessed of many good qualities, but deeply tinctured with the superstition of the times. This induced him to engage in two croisades. The first was against the Saracens in Egypt: in which he was taken prisoner by the Infidels, and treated with great cruelty; but at last obtained his ransom, on condition of paying a million of pieces of gold, and surrendering the city of Damietta. He no sooner regained his liberty, than he entered Syria with a view of doing something worthy of his rank and character. From this expedition he was obliged to return sooner than he intended, by the news of the decease of his mother Queen Blanch, whom he had appointed regent in his absence, and who had managed the national affairs with the greatest prudence. The king, however, found many disorders in the kingdom upon his return; and these he set himself to reform with the utmost diligence. Having succeeded in this, he yielded to Henry III. of England, the Limousin, Querci, Perigord, and some other places; in consideration of Henry and his son Prince Edward their renouncing, in the fullest manner, all pretensions to Normandy and the other provinces of France which the English had formerly possessed.

The reputation of this monarch for candour and justice was so great, that the barons of England, as well as King Henry III. consented to make him umpire of the differences which subsisted between them. But though he decided this matter very justly, his decision was not productive of any good effect. At last the king, having settled every thing relating to his kingdom in a proper manner, set out on another croisade for Africa; where he died of the plague, on the 25th of August 1270.

46 Philip the Hardy.

Notwithstanding the misfortunes of Louis, his successor Philip, surnamed *the Hardy*, continued the war against the Infidels with great vigour. Being reinforced by his uncle Charles king of Sicily, he brought the war to a more fortunate conclusion than his predecessor had been likely to do. The Saracens were defeated in two engagements, and the king of Tunis obliged to sue for peace; offering at the same time to double the tribute he formerly paid to the crown of Sicily; to reimburse the expences of the war; and to permit the Christian religion to be freely propagated throughout his dominions. Having accomplished this, the two princes set sail for Europe; but the seeds of the distemper which had infected the army in Africa not being eradicated, broke forth on their arrival in Sicily, and raged for some time with great violence. Besides a vast number of common people, the king's brother John, his queen Isabella, with his brother and sister-in-law the king and queen of Navarre, and his uncle and aunt the count and countess of Poictiers, perished by this dreadful malady.

On his return to France, Philip took possession of the counties of Provence and Thoulouse; married his second son, though then very young, to the only daughter of the king of Navarre; while he himself espoused Mary the daughter of the duke of Brabant, reckoned one of the most beautiful princesses of the age. He steadily enforced the regulations of his predecessor, who had prohibited the barons from making private wars upon one another; procured the friendship of Edward I. of England by ceding to him the county of Agenois; and entered into a war with Spain in order to support the pretensions of his nephews, the Infants de la Cerda, to the throne of Castile.

The events of this war were of no great importance; and the king's attention was quickly called off from them by the death of his eldest son Louis at the age of twelve years. This disastrous event happened in the year 1275, not without a suspicion of poison; and the young queen, Mary, was accused by a surgeon named La Brosse as guilty of his death. Philip gave some credit to the accusation: but having applied to a nun, who pretended to be inspired, for full satisfaction, her answer proved fatal to La Brosse. The queen being cleared by this pretended prophetess, La Brosse was accused of a treasonable correspondence with the king of Castile, and condemned to death. The manner of his trial and execution, however, were such, that the tide of popular favour was turned; La Brosse was by the voice of the people declared to be innocent, and the king and queen themselves loudly condemned. During these unfavourable circumstances, the Sicilians, over whom Charles of Anjou had established his authority, instigated by John of Procida, a noble exile, came to a resolution of freeing themselves at once from the French yoke by a general massacre. This cruel

47 French massacred in Sicily.

resolution was accordingly put in execution; and the French, to the number of 8000, murdered in one night; after which Peter of Arragon, sailed to the island, where he was received by the inhabitants as their king and saviour. Charles was sensibly affected by this misfortune: and having laid siege to Messina, sailed directly to Marseilles, where he obtained a powerful reinforcement. But during his absence on this occasion, his son, to whom he had entrusted the care of the siege, having rashly ventured an engagement with the Spanish fleet, was entirely defeated and taken prisoner; which so much affected the father that he died of grief, and Sicily was inseparably attached to the house of Arragon.

The misfortunes of Charles were followed by others equally great to Philip himself. Pope Martin IV. in the warmth of his zeal for the cause of the duke of Anjou, had excommunicated Pedro king of Arragon, and bestowed his kingdom on Charles of Valois, a younger son of the king of France. In attempting to defend himself against the execution of this unjust sentence, Pedro was mortally wounded; but, soon after, the French fleet being defeated by that of Arragon, the king was so much affected by the misfortune that he fell sick. His disease was augmented by the heat

heat of the climate and the fatigues of war; so that, quite worn out with grief and infirmities, he expired at Perpignan in the 41st year of his age, and 16th of his reign.

48 Reign of Philip the Fair.

By the death of Philip the Hardy the French crown devolved on his second son, called also Philip, and from the beauty of his person surnamed *the Fair;* who had espoused the princess of Navarre, and at the time of his accession was in his 17th year. By the marriage with this princess he had obtained the counties of Champagne and Brie; yet with all this increase of power he found himself unable to support the war in which his predecessor had engaged. For this reason he thought proper to abandon the interest of the Infants de la Cerda, and settle the differences with Castile. The treaty was concluded by the mediation of Edward I. of England; at whose intercession Charles the Lame, son to the duke of Anjou already mentioned, was released from his captivity; Edward himself paying part of his ransom. On this Charles consented to renounce his claim on Sicily; and Philip himself promised that his kinsman Philip of Valois should renounce all pretensions to the crown of Arragon. In return for this generosity, the latter obtained the eldest daughter of Charles, with the territories of Anjou and Maine as a dowry.

The tranquillity procured by this treaty, however, was soon interrupted by differences with Edward the promoter of it; Pope Boniface VIII. and Guy de Dampier, count of Flanders. The difference with England took place by a mere accident. A Norman and an English vessel having met off the coast of Bayonne, and having both occasion for water, the crews met and quarrelled at the same spring. A Norman was killed in the squabble by his own weapon, with which he assaulted an Englishman, as the latter pretended: but however the matter was, complaints were made by the Normans to Philip; who, without giving himself much trouble to inquire into the merits of the cause, instantly allowed them to redress their supposed injuries. On this a kind of piratical war commenced between the two nations, in which the two sovereigns for some time took no active part; though other nations interfered; the Irish and Dutch seamen siding with the English, and those of Flanders and Genoa with the French. Thus the powers on both sides were gradually augmented, till at last the affair became so serious, that in one engagement 15,000 French are said to have perished. Philip, alarmed at such a carnage, summoned the king of England as his vassal to attend; and, on his refusal, declared his estates in France to be forfeited. After a number of negotiations, Philip declared that he would be satisfied with the nominal cession of the province of Guienne, which he engaged instantly to restore to the king of England as soon as it should be put into his hands. Edward complied with his demands; but no sooner had the French monarch obtained possession of that country, than he persisted in the forfeiture of the English possessions in France; which treacherous proceeding instantly produced a war betwixt the two nations. Edward, that he might defend himself the better against such a formidable adversary, concluded a treaty with the emperor Adolphus, together with the counts of Brittany, Holland, Bar, Juliers, Gueldres, and Flanders; while Philip strengthened himself by an alliance with John Baliol of Scotland; and thus laid the foundation of that strict union which took place between France and Scotland for two centuries. During this war the French made a descent on the coast of England, and destroyed the town of Dover; while Edward, in revenge, landed in Gascony with an army of 50,000 men. No great exploits, however, were performed with this mighty armament; and both parties finding themselves pretty equally matched, consented to a suspension of arms for two years; during which a peace was finally concluded by the mediation of Pope Boniface VIII. Guienne was restored: Edward espoused Margaret the sister of Philip; while his daughter Isabella was given in marriage to the prince of Wales.

49 Difference with England.

50 Peace concluded.

Both Philip and Edward behaved to the allies whom they had engaged in their cause with equal perfidy. Baliol was abandoned by Philip to the resentment of Edward; while Guy, earl of Flanders, was left equally exposed to the resentment of Philip.

51 Difference with Pope Boniface.

The reconciliation betwixt the French and English monarchs was soon followed by a difference with Pope Boniface, whom they had appointed mediator between them. Sensible of his assuming disposition, however, they had inserted in the reference made to him, that he was chosen as a private man, and not as the successor of St Peter. The haughty pontiff, however, soon showed, that he was not by any means to be treated as a private person, and a contest with Philip quickly ensued. Boniface began with forbidding the clergy to grant the king any subsidies without first obtaining the consent of the Holy See, under the pain of excommunication. Philip revenged himself by prohibiting any ecclesiastics from sending money out of the kingdom without his leave; and by protecting the Colonnas, who were the implacable enemies of Boniface. By this his holiness was so much irritated that he sent a most abusive letter to Philip; after which he summoned the clergy of France to a council at Rome; which Philip retaliated, by seizing the temporalities of those who obeyed the summons, and recalling his brother Charles of Valois, who had the title of the *Pope's General.* Sensible, however, of the danger that attended this contest, he despatched two emissaries, under pretence of conciliating the differences, to levy such a body of troops as might execute his hostile purposes against the holy father. With these he suddenly invested the pope in his native city of Anegnia; and while the bull was preparing for the excommunication of Philip, and releasing his subjects from their obedience, the pope himself was obliged to surrender prisoner to the troops of the prince whom he designed to anathematize.

Though Boniface had been at this time delivered up to the troops of Philip through the treachery of the people of Anegnia, yet he was no sooner taken prisoner and brought to distress, than they rescued him from his guards and conveyed him to Rome, where he soon after died of grief and shame. His successor Benedict revoked the excommunication of Boniface, and attempted to regain the allegiance of Philip by gentle means: but, before this could be effected, he himself was cut off by death, not without strong suspicions of poison. After his decease Philip offered to procure the

52 Death of Boniface.

France.

the papal chair for Bertrand archbishop of Bourdeaux, provided he would condemn the memory of Boniface, restore the honours and estates of the Colonnas which had been forfeited, allow him, for five years, the tenths of the clergy of France, and comply with a request which at that time it was not proper to divulge.

Bertrand having complied with the terms proposed by the king, ascended the papal throne by the name of *Clement V.* but narrowly escaped being killed on his return from the cathedral of Lyons, by the falling of a wall which had been overloaded by the number of people who came to see the procession; by which accident the duke of Brittany was killed, and the king and count of Valois considerably bruised. The new pope fixed his residence at Avignon, where he punctually complied with all the conditions of the treaty, except that of condemning the conduct of Boniface, which he absolutely refused to do; and, instead of doing so, vindicated it with much solemnity, after having inquired into the matter, or pretended to do so. The other condition, which Philip had at first concealed, was discovered by the death of the emperor Albert of Austria; after which event he desired Clement to assist him in placing his brother Charles of Valois on the Imperial throne. But his holiness, apprehensive of the danger which might accrue to himself from being surrounded with the powerful relations of Philip, urged the diet to proceed instantly to an election; recommending to them Henry of Luxemburg as a proper person to fill the Imperial throne. In this scheme he succeeded so well, that the election was over before Philip could arrive at Avignon; and the only consolation the French monarch could obtain for his disappointment, was the possession of the city of Lyons, which had hitherto maintained an independency under its archbishop; but was now persuaded to submit to the authority of Philip.

53 The Pope fixes his residence at Avignon.

54 Expedition of Philip against the earl of Flanders.

In the mean time Guy, earl of Flanders, being abandoned by his ally Edward king of England, was obliged to throw himself on the mercy of the French monarch, who had sent his brother Charles of Valois, with a powerful army to invade his dominions. From the latter indeed he had obtained a promise, that if he could not, within a year, compose the differences subsisting between him and Philip, he should be at liberty to retire, and pursue what measures he pleased. But Philip, in order to gratify the resentment which his queen entertained against the captive prince, detained him, with two of his sons, in close confinement, while he himself entering Flanders in triumph, was everywhere received as sovereign of the country; and at his departure appointed John de Chatillon, a relation of the queen, to govern those newly acquired territories.

The new governor took care to repair the fortifications which had been suffered to decay by reason of the assiduous application of the Flemings to trade; but being of a very haughty and tyrannical disposition, and the poverty of the times not allowing his master to keep regular garrisons, an insurrection quickly took place. This would have been effectually quelled by the diligence of the magistrates, had not Chatillon unluckily entered Bruges, and publicly displayed two hogsheads of ropes, which he threatened to employ in the execution of the inhabitants. On this they flew to arms, and massacred 1500 French; Chatillon himself being obliged to escape their fury by swimming over the town ditch. The insurgents, now daily gathering strength, soon amounted to an army of 60,000 men, who laid siege to Courtray. Here they were rashly attacked in their trenches by the count d'Artois, who met with the reward of his temerity, being cut off with 20,000 of his troops. Philip determined on revenge; though the raising another army obliged him to debase the coin of the kingdom. Thus, however, he was enabled to enter Flanders with such a force as would probably have subdued the whole country, had not Edward artfully communicated to the queen of France, as a secret, a feigned correspondence between the French nobility and the court of Rome; by which false intelligence the king was induced to abandon the enterprise without performing any thing worthy of the armament he had fitted out. The war was continued for some time longer; but the attempts of Philip were constantly defeated by the steady valour of the Flemings; and the only recompense Philip obtained for all his trouble and expence was the city of Courtray.

(53) The conquest of the country prevented by Edward III of England.

(54) Expulsion of the knights Templars.

The other remarkable transactions of this reign were the expulsion and confiscation of the estates of the Templars, who at that time enjoyed immense possessions in France. The confiscations took place without any form of trial, and upwards of 50 of them were put to death in a cruel manner. The grand master, with three of his principal officers, were burnt by a slow fire in the presence of the king himself. The whole body of these unfortunate knights had been accused of the most gross and abominable sensualities. The particulars were revealed, or pretended to be so, by two criminals who received their pardon for the discoveries they made; and these discoveries were confirmed by the confession of the Templars themselves. But this confession was afterwards retracted, as being extorted from them by the fear of absolute destruction; and those who suffered, maintained their purity to the last: and on the whole, it was believed that Philip consulted his avarice rather than his justice by this cruel execution. The latter part of his life was embittered by domestic misfortunes. His three daughters-in-law, Margaret daughter of the duke, and Jean and Blanch of the count, of Burgundy, who had married his three sons, Louis, Philip, and Charles, were accused of infidelity to their husbands. After a severe examination, Margaret and Blanch were condemned to perpetual imprisonment; in which situation Margaret was afterwards strangled by order of her husband Louis. Their paramours, Philip and Walter de Launay, two brothers, were flayed alive, and afterwards hung upon a gibbet, with an usher of the chamber, who had been their confidant. The uneasiness of mind which Philip suffered on this account is supposed to have impaired his health, and he died of a consumption in the year 1295, the 47th of his age, and 30th of his reign.

55 Reign of Louis the Boisterous.

On the accession of Louis, surnamed the *Boisterous*, on account of his violent temper, he found his treasury so much exhausted, that he was obliged to delay for some time the ceremony of his coronation with his new queen Clemence, daughter of the king of Hungary. Finding the kingdom otherwise in a very distracted state, he applied himself very diligently to appease the discontents of his subjects, and conciliate their affection by

France.

by every means in his power. In this he was assisted by his uncle Charles of Valois, on whom he at length entirely devolved the government of the kingdom. This regent, however, behaved with such cruelty as is supposed to have proved fatal to the king himself; for having put to death a nobleman named *Enguerrand de Poitier de Marigni*, who enjoyed the confidence of the late king, this cruelty was so much resented, that his friends were thought to have administered poison to the king; who expired suddenly after drinking a glass of cold water, in the 26th year of his age, and second of his reign. Immediately after his death, Charles prepared to dispute the sovereignty with the brothers of the late sovereign. Philip count of Poictou, the eldest brother, was at that time at Rome assisting in the election of a new pope; and it was not until a month after the death of his brother that he was able to put an end to the intrigues which took place on that occasion: but on his arrival in France, the throne was assigned to him by the unanimous voice of the people. His prospects, however, were for a short time clouded by the queen dowager Clemence being delivered of a son, who has been enrolled among the kings of France under the name of *John I.* His death in three weeks secured the throne to Philip; who, on account of the tallness of his stature, was surnamed the *Long*. His conduct proved superior to that of his predecessor, who had unsuccessfully attempted to subdue the Flemings, and had even suffered himself to be duped by their count; but Philip, by his vigorous behaviour, so reduced them, that they compelled their sovereign to consent to a peace upon honourable terms. He summoned Edward II. of England to do homage for his possessions in France; but that monarch, finding himself involved in difficulties, which rendered the visit inconvenient, sent excuses to Philip, which he was pleased to accept. As the French monarch had formerly taken the cross during the lifetime of his father, he now proposed to put his vow in execution; but was dissuaded from this by the pope himself, at whose instance he sent an army into Italy to put an end to the contending factions of the Guelphs and Gibbelines, who for so long time filled the country with blood and slaughter. The event proved unfortunate; and the disgrace was rendered more mortifying by a contagious distemper, which swept off many thousands of French subjects. This was supposed by the superstitious people of those times to be occasioned by the Jews, who had conspired with the Saracens to poison the springs; and that the execution of the project was committed to some lepers who lived by themselves in hospitals richly endowed. On this a persecution was instantly commenced against these unfortunate men, and great numbers of them were burnt alive; while the Jews in general were abandoned to the rage of the populace, who insulted their persons, and plundered their houses without remorse.

56 Reign of Philip the Long.

Unfortunate expedition into Italy.

The remaining part of the reign of Philip was spent in attempting to regulate the internal concerns of his kingdom. A design had been formed by his predecessors of establishing a certain standard for the coin, weights, and measures, throughout France: and this was adopted by Philip; who, in order to carry it more effectually into execution, purchased from the counts of Valois, Clermont, and Bourbon, their right of coinage within their own dominions. But notwithstanding all his endeavours for this purpose, he never could bring the scheme to bear: nor indeed could he in any degree conciliate the affection of his subjects. He died of a fever and dysentery in the year 1322, the 28th year of his age, and 9th of his reign.

By the death of Philip, the crown of France devolved on his brother Charles IV. who had obtained the surname of *Fair*. After settling some disputes with the duke of Burgundy, his next step was to dissolve his marriage with Blanch, who still continued in prison, and to espouse Mary the daughter of Henry emperor of Germany. This marriage was contracted with a view to the Imperial crown itself, which had been so long separated from that of France; and in 1325 an opportunity offered for Charles to gratify his ambition. At that time the Imperial dignity was disputed between Louis of Bavaria and Frederic of Austria; the latter of whom had been taken prisoner in a battle with Louis. But Pope John, who entertained an implacable hatred against Louis, fulminated the sentence of excommunication against him, intrusting the execution of it to Leopold the brother of Ferdinand. The king of France was induced to embark in the same cause, by a promise of the spoils of Bavaria; while Frederic himself consented to relinquish his pretensions to the empire which he had so unsuccessfully maintained. Louis, however, by instantly releasing his prisoner, and dismissing him in an honourable manner, engaged his friendship, and disarmed his most formidable antagonist. But the pope was not to be disappointed. A considerable sum of money induced Leopold to persevere in his hostilities, while it was determined that a new council of electors should be held in order to transfer the Imperial crown to Charles. In pursuit of this visionary scheme, the king of France set out for the frontiers of Germany with a splendid army; but soon found that there was no possibility of accomplishing his wishes. Leopold alone, from motives of interest, remained his friend; the rest shewed the greatest indifference; and even his brother-in-law the king of Bohemia absented himself from the diet; while in a short time the death of the queen put an end to all connexions with that crown.

58 Reign of Charles the Fair.

On the decease of Mary, Charles espoused Joanna daughter to the count of Evreux: and in order to avert the calamities to be feared from an infant succession, he entered into an alliance with Robert king of Scotland; by which it was provided, that should either of the sovereigns die without an heir apparent, the states of the kingdom should fill the vacant throne, and the survivor of the two kings should with his whole force support the legality of the nomination against any other competitor; though even this proved insufficient to avert the danger which now threatened the kingdom, as shall be explained in the sequel.

Charles died in the year 1328, in the 34th year of his age, leaving his queen pregnant; and as the succession depended on the fruit of the queen's pregnancy, a regent in the mean time was necessary; and two candidates instantly appeared for this important post, urging at the same time their right to the crown as well as to the regency. These were, Philip de Valois, cousin-german to the deceased king; the other, Edward III. king of England, who aspired to the throne in in right of his mother, and the nephew of Charles the Fair. His pretensions, however, were easily set aside, and Philip was confirmed in the regency: from which he soon after stepped into the throne, on the queen being delivered of a daughter; from which circumstance he acquired the surname of *Fortunate*. But though the pretensions of Edward, both to the regency and crown, were unanimously rejected by the people, it was still impossible for Philip to think of the claims of such a formidable rival without uneasiness.

60 Disputes with Edward III. of England.

He therefore summoned the English monarch to do homage for his possessions in France; and, upon his not answering his summons, forfeited them, and seized his revenues. This at last induced Edward to cross the sea and pay his homage; which Philip consented to receive in any form, upon condition of a proper explanation being afterwards given: but as this was studiously delayed after the return of the king of England, the province of Guienne was again seized by the French monarch. Edward, unwilling to lose his continental dominions, or involve himself in a war for the sake of a mere ceremony, sent over a formal deed, by which he acknowledged that he owed liege homage to France. Thus the flame was smothered for the present; and would perhaps have been entirely extinguished, had it not been for the intrigues of Robert of Artois, brother-in-law to the king of France himself, who had been expelled his country, and had taken refuge in England. By him he was persuaded to renew his pretensions to the crown of France, which of necessity produced a war.

For some time, indeed, neither party made any open declaration of hostility; but as both monarchs were possessed of great prudence and sagacity, they soon penetrated each other's designs. Philip, under pretence of taking the cross, began to make prodigious armaments, strengthening himself at the same time by alliances on every side; while Edward, determining to renew his claim to the crown of France, projected the conquest of Scotland. This, however, he could not accomplish; and in the mean time Philip, in order to favour the Scots, with whom he was in alliance, suffered his subjects to make irruptions into Guienne.

61 Edward's first expedition.

In 1337, the war broke out openly. Philip having detached a squadron of his fleet against the Infidels, employed the rest, consisting chiefly of Genoese vessels, against the English. As in this war it was of great importance which side was taken by the Flemings, these people were courted by both parties. Louis count of Flanders declared for Philip, but his subjects were more inclined to King Edward. James Arteville a brewer, the most able and artful man in the country, governed them at that time as much as if he had been their prince; and the advantages arising from the English commerce determining him in favour of Edward, that prince, at his request, embarked for Sluys with a numerous army. Here he arrived in 1338; and on his first landing, it was resolved that the German princes in alliance with him should act against France. But for this a pretence was wanting. The vassals of the empire could not act by Edward's orders, or even as his allies, without directions from the emperor, and he was in league with France. This difficulty, however, was soon overcome: the French had made themselves masters of Cambray, and the emperor resolved that it should be retaken. With this view he created Edward *Vicar General of the Empire*; an empty title, but which seemed to give him a right of commanding the services of the princes of Germany. The Flemings, who were vassals of France, likewise pretended scruples at invading the territories of their liege lord. To quiet these, Edward, by the advice of Arteville, assumed the title of *King of France;* and by virtue of this right challenged their assistance for dethroning Philip de Valois, the usurper of his kingdom. This step, which he feared would beget endless animosities and jealousies, he did not take without hesitation; and, according to Mr Hume, from this time we may date the commencement of that great animosity which the English have always borne to the French.

Edward's first attempt was upon the city of Cambray, to which he laid siege; but in a short time he was prevailed upon by Robert d'Artois to raise the siege and march into Picardy. This country he entered with an army of near 50,000 men, composed mostly of foreigners. Philip came within sight of him with an army of near 100,000, composed chiefly of native subjects; and it was daily expected that a battle would ensue. But the English monarch was averse to engage against so great a superiority: and Philip thought it sufficient if he eluded the attacks of his enemy, without running any unnecessary hazard. The two armies faced each other for several days; mutual defiances were sent; and Edward at last retired into Flanders, and dispersed his army.

Such was the fruitless and almost ridiculous conclusion of Edward's first expedition, which had plunged him into the greatest difficulties. He had contracted near 300,000l. of debt; he had anticipated all his revenue; he had pawned every thing of value which belonged either to himself or his queen; nay, he was obliged in some measure even to pawn himself to his creditors, by desiring their permission to go over to England in order to procure supply, and by promising on his word of honour to return in person if he did not remit their money. On his arrival in England, however, he procured a large supply, sufficient to enable him to make all the necessary preparations for a new invasion; and so certain were the English that France would now be conquered, that the parliament, before Edward's departure, protested that they owed him no obedience as king of France, but that the two kingdoms must remain for ever distinct and independent.

62 His second expedition.

The king of England set out on his second expedition with a fleet of 240 vessels. Philip had prepared a fleet of 400 vessels, manned with 40,000 men; which he stationed off Sluys, in order to intercept him in his passage. The two fleets met on the 13th of June 1340; but the English, either by the superior abilities of Edward, or the greater dexterity of his seamen, gained the wind of the enemy, and had the sun in their backs; and with these advantages began the action. The battle was fierce and bloody: The English archers, whose force and address were now much celebrated, galled the French on their approach; and when the ships grappled together, the example of the king and the nobility who were with him so animated the seamen and soldiers, that they maintained everywhere a superiority over the enemy. The Flemings observing the battle, hurried out of their ports, and brought

63 The French entirely defeated at sea.

France. brought a reinforcement to the English; which coming unexpectedly, had a greater effect than in proportion to its power and numbers. Two hundred and thirty ships were taken: and 30,000 Frenchmen were killed, with two of their admirals: the loss of the English was inconsiderable, compared to the greatness and importance of the victory. None of Philip's courtiers, it is said, dared to inform him of the event; till his fool or jester gave him a hint, by which he discovered the loss he had sustained.

After this great victory, Edward landed his forces and laid siege to Tournay. Philip marched to its relief with a very numerons army: but acted with so much caution, that Edward found himself in a manner blocked up in his camp: and the countess dowager of Hainault, sister to Philip, mother-in-law to Edward, and sister-in-law to Robert d'Artois, coming out of a convent, to which she had retired, interposed with so much spirit and address, that she engaged all parties to agree to a truce for a year, and might perhaps have brought about a peace if she had survived.

64 Edward invited into France a third time.

In 1341, however, Edward's ambition was once more excited by the invitation of the count de Mountfort, who had possessed himself of the province of Brittany, and applied to Edward to second his claims. An offer of this kind entirely coincided with Edward's most sanguine desires. He was happy in the promised assistance of Mountfort, an active and valiant prince, closely united to him by interest, and thus opening to him an entrance into the heart of France. These flattering prospects, however, were for a while damped by the imprisonment of Mountfort; whose aims being discovered, he was besieged in the city of Nantz and taken. But Jane of Flanders his wife soon made up for the loss of her husband. This lady courageously undertook to support the falling fortunes of her family. She assembled the inhabitants of Rennes, where she then resided; and carrying her infant son in her arms, deplored her misfortunes, and attempted to inspire the citizens with an affection for her cause. The inhabitants of Nantz instantly espoused her interests, and all the other fortresses of Brittany embraced the same resolution. The king of England was apprised of her efforts; and was entreated to send her succours with all possible expedition to the town of Hennebone, in which place she resolved to sustain the attacks of the enemy. Charles de Blois, Philip's general, anxious to make himself master of so important a fortress as Hennebone, and still more to take the countess a prisoner, sat down before the place with a large army, and conducted the siege with indefatigable industry. The defence was no less vigorous: several sallies were made by the garrison, in which the countess herself was still the most active, and led on the assault. Observing one day that their whole army had quitted the camp to join in a general storm, she sallied out by a postern at the head of 300 horse, set fire to the enemies tents and baggage, put their sutlers and servants to the sword, and occasioned such an alarm, that the French desisted from the assault, in order to cut off her communication with the town. Thus intercepted, she retired to Auray, where she continued five or six days; then returning at the head of 500 horse, she fought her way through one quarter of the French camp, and returned to her faithful citizens in triumph. But the besiegers had at length made several breaches in the walls; and it was apprehended that a general assault, which was hourly expected, would be fatal. A capitulation was therefore proposed, and a conference was already begun, when the countess, who had mounted on a high tower, and was looking towards the sea with great impatience, descried some ships at a distance. She immediately exclaimed that succours were arrived, and forbade any further capitulation. She was not disappointed in her wishes; the fleet she discerned carried a body of English gentlemen, with 6000 archers, whom Edward had prepared for the relief of Hennebone, but who had been long detained by contrary winds. They entered the harbour under the conduct of Sir Walter Manny, one of the most valiant commanders of his time. This relief served to keep up the declining spirits of the Bretons until the time appointed by the late truce with Edward was expired, on which he was at liberty to renew the war in greater form.

The succours under Sir Walter Manny were quickly followed by a more considerable reinforcement commanded by Robert of Artois, who made himself master of the city of Vannes soon after his arrival: but the French soon recovered the city, and Robert was compelled to relinquish his prize after receiving a mortal wound. Edward himself, eager to revenge the death of his ally, soon landed at Morbian near Vannes with an army of 12,000 men. With this small number he undertook at once the siege of Vannes, Nantz, and Rennes: but by dividing his forces, he failed in every enterprise, and gave an opportunity to John duke of Normandy, the king of France's eldest son, to invest him in his camp. In this situation his provisions soon began to fail; and Edward, notwithstanding all his valour, would have been obliged to surrender, had he not, by a train of artful negotiations, induced Philip to relinquish the advantage he had obtained, and consent to a truce of three years. This was accomplished by the mediation of the court of Rome; and the French monarch was soon made sensible of the partiality of that court, and the imprudence of the step he himself had taken. Edward soon found a pretence to renew the war, from the execution of some nobles of Brittany, who, he said, were partisans of Mountfort, and chose to look upon their punishment as an infraction of the treaty.

Philip now endeavoured to secure himself against the power of his rival by alliances, and by purchasing the city of Montpelier from the king of Majorca: but in the mean time, the English, under the command of the earl of Derby, had invaded Guienne, twice defeated the French army commanded by the count de Lisle, and made themselves masters of a great number of towns. Philip, by reason of the exhausted state of his treasury, was for some time incapable of making any opposition. To recruit his finances, he was obliged to lay a duty on salt; which gave such offence to his subjects as had almost excited a rebellion. When these discontents were assuaged, however, he soon raised an army of 100,000 men, whose courage was further raised by the presence of the dukes of Normandy and Burgundy. The English general was therefore compelled to stand upon the defensive. One fortress after another was surrendered to the French; till at length nothing appeared but the total extinction of the power of of England upon the continent. In this situation, Edward resolved to bring relief in person to his distressed subjects and allies; and accordingly embarked in 1346 at Southampton, on board a fleet of near 1000 sail, of all dimensions. He carried with him, besides all the chief nobility of England, his eldest son the prince of Wales (afterwards surnamed the *Black Prince*), a youth of about 15 years old, and already remarkable both for understanding and valour above his age. His army consisted of 4000 men at arms, 10,000 archers, 10,000 Welsh infantry, and 6000 Irish; all which he landed safely at La Hogue, a port in Normandy, which country he determined to make the seat of the war.

65 He lands with an army in Normandy.

The intelligence of Edward's landing, and the devastation caused by his troops, who dispersed themselves over the whole face of the country, soon spread universal consternation through the French court. The rich city of Caen was taken and plundered by the English without mercy; the villages and towns, even up to Paris, shared the same fate; and the French had no other resonrce but by breaking down their bridges, to attempt putting a stop to the invader's career. In the mean time, Philip was not idle in making preparations to repress the enemy. He had stationed one of his generals, Godemar de Faye, with an army on the opposite side of the river Somme, over which Edward was to pass; while he himself, at the head of 120,000 fighting men, advanced to give the English battle. Edward, thus unexpectedly exposed to the danger of being enclosed and starved in an enemy's country, published a reward to any that should bring him intelligence of a passage over the river Somme. This was discovered by a peasant of the country, named Gobin Agace: and Edward had just time to get his whole army over the river, when Philip appeared in his rear. Of the battle that ensued, in which the French were overthrown with great slaughter, an account is given under the article CRESSY.

66 Calais taken.

Edward next laid siege to Calais, which was then defended by John de Vienne, an experienced commander, and supplied with every thing necessary for defence. It was at length taken, after a twelvemonth's siege, the defendants having been reduced to the last extremity by famine and fatigue: for the consequences of which, see the article CALAIS.

From the very beginning of this unfortunate war, Philip had invariably showed himself desirous of peace, and the victory of Cressy rendered him still more so. Edward also, notwithstanding his successes, was unable to support the expences of the war any longer. The mediation of the court of Rome was therefore readily accepted, and a truce for three years concluded. At the same time, Philip met with some recompense for the losses he had sustained, by the acquisition of Dauphiny, which has ever since given the title of *Dauphin* to the eldest son of the king of France. It was obtained by the resignation of Hubert prince of Dauphiny; who, being disappointed in his hopes of marrying Joan, daughter of the duke of Bourbon, gave up his territories to Charles the grandson of Philip, who had married that lady; himself retiring into a convent. Soon after this event, the king himself, who had been some time a widower, was married to Blanch, the daughter of Philip count of Evreux, and Jane queen of Navarre; and his son John to the countess of Boulogne. But the happiness occasioned by these marriages was soon interrupted by the death of the king; who expired in the year 1350, the 57th of his age, and 23d of his reign.

67 Death of King Philip.

On the death of Philip his eldest son John took possession of the kingdom; but scarcely was he seated on the throne, when he disgusted his nobility by an unseasonable act of severity. Robert de Brienne, count of Eu and Guisnes, had been taken prisoner by the king of England at Caen; and under pretence of negotiating his ransom, had passed several times between France and England; but being accused of a treasonable correspondence with Edward, he was by order of his sovereign suddenly arrested, condemned, and beheaded, without any form of trial. At his death, it is said that he confessed his treasonable practices; but that has not been authenticated by any historian of credit. Having been constable of France, the sword, the badge of his office, was delivered to Charles de la Carda: but his fate was equally unfortunate with that of his predecessor, being soon after assassinated by Charles king of Navarre, surnamed *The wicked*. This prince, celebrated for his personal qualifications, but detested for his crimes, was the son-in-law of John himself. He had demanded the duchy of Angouleme of the king: but as the latter had thought proper to bestow it upon Carda, he had taken the effectual method of revenging himself, by assassinating his rival. John did not fail to show a proper resentment; but such was the weakness of his government, that the king of Navarre set him at defiance, and would not even condescend to the ceremony of asking pardon until John had sent him his second son as an hostage for his personal security. To these offences the king of Navarre added another still more atrocious, viz. that of aspiring to the crown of France itself; to which he pretended a right derived from his mother, being grandson by the female side to Louis the Boisterous. But his more immediate demands were the countries of Champagne and Brie. To obviate all difficulties on this head, however, John bestowed the duchy of Normandy on his eldest son Charles; and commanded him to seize the estates of the king of Navarre. On this the latter soon made his appearance at Paris; but John fonnd himself obliged to appease his murmurs at the expence of no less than 100,000 crowns.

68 Infamous conduct of the king of Navarre.

All this time the truce with England had been very ill observed on both sides; the French had possessed themselves of the port of St Jean d'Angeli; and the English had surprised the town of Guisnes. The rival houses of Mountfort and Blois still continued their animosities; while Edward continued to threaten war. The king of Navarre went on with his intrigues; and even the dauphin was drawn into a confederacy against his father. John, however, being informed of their machinations, found means to defeat them effectually. The dauphin was reclaimed by pointing out to him the impropriety of his conduct, and the disadvantage which must unavoidably accrue to himself from the connexions which he had formed. The king of Navarre was invited with his principal adherents, to an entertainment, where they were unexpectedly arrested: the former being sent prisoner to Chateau Gaillard, and several of the most obnoxious of the latter put to death. The rest of the conspirators, instead

69 He is taken and confined.

France. instead of being dismayed by this check, immediately showed themselves in open rebellion; and finding themselves unable, without farther assistance, to gain their point, they without delay invited over Edward from England.

70 France again invaded by Edward.

That warlike and enterprising monarch had never lost sight of the object he had originally embraced; and on the expiration of the truce had sent his son, the prince of Wales, from the colour of his armour surnamed the *Black Prince*, with a fleet towards the coast of France. Young Edward had with this fleet entered the mouth of the river Garonne, burnt the towns and villages of Languedoc, and retired with the plunder into the country of Guienne. Edward himself, who had likewise passed over to the continent, wasted the country as far as St Omer; but the French king, notwithstanding all these provocations, determined to avoid a battle, and therefore prohibited his general, the constable of Bourbon, from coming to an engagement, though his army was much superior to that of the prince of Wales. With the flower of his troops, however, he pursued Edward from St Omer to Hesdin, where he defied him to a pitched battle; but the latter, without minding his bravadoes, continued his march to Calais, from whence he embarked for England. After his departure, John called an assembly of the states at Paris, where he explained the distressed situation of his finances, and showed so fully the necessity of assisting him in the defence of the kingdom, that they consented to maintain an army of 30,000 men during the war. To supply the other exigencies of government, they revived the duty on salt, and added a variety of other imposts; but at the same time appointed a committee of their own number to take care that the money was solely appropriated to the public service.

The satisfaction which John received from these grants, and the suppression of some disturbances which happened about this time, was soon overcast by the news that the prince of Wales had marched with an army of 12,000 men from Bourdeaux: and, after ravaging the Agenois, Quercy, and the Limousin, had entered the province of Berry. The young warrior had penetrated into the heart of France with this trifling body of forces, in hopes of joining the duke of Lancaster in Guienne. But he soon found that his scheme was impracticable: the country before him was too well guarded to permit his advancing further; and all the bridges behind were broken down, which effectually barred a retreat. In this embarrassing situation, his perplexity was increased, by being informed, that the king of France was actually marching at the head of 60,000 men to intercept him. He at first thought of retreating: but soon finding it impossible, he determined calmly to wait the approach of the enemy; and, notwithstanding the disparity of forces, to commit all to the hazard of a battle.

Battle of Poictiers.

It was at a place called *Maupertuis*, near Poictiers, that both armies came in sight of each other. The French king might very easily have starved the English into any terms he thought proper to impose; but such was the impatient valour of the French nobility, and such their certainty of success, that it might have been equally fatal to attempt repressing their ardour to engage. In the mean time, while both armies were drawn out, and expecting the signal to begin, they were stopped by the appearance of the cardinal of Perigord, who attempted to be a mediator between them. However, John, who made himself sure of victory, would listen to no other terms than the restitution of Calais; with which the Black Prince refusing to comply, the onset was deferred till the next morning, for which both sides waited in anxious suspense.

During this interval, the young prince strengthened his post by new intrenchments; and placed 300 men in ambush, with as many archers, who were commanded to attack the enemy in flank during the heat of the engagement. Having taken these precautions, he ranged his army in three divisions; the van was commanded by the earl of Warwick, the rear by the earls of Salisbury and Suffolk, and the main body by himself. In like manner, the king of France arranged his forces in three divisions; the first commanded by the duke of Orleans; the second by the dauphin, attended by his younger brothers; while he himself led up the main body, seconded by his youngest and favourite son, then about 14 years of age. As the English were to be attacked only by marching up a long narrow lane, the French suffered greatly from their archers, who were posted on each side behind the hedges. Nor were they in a better situation upon emerging from this danger, being met by the Black Prince himself, at the head of a chosen body of troops, who made a furious onset upon their forces, already in great disorder. A dreadful overthrow ensued: those who were as yet in the lane recoiled upon their own forces; while the English troops who had been placed in ambush, took that opportunity to increase the confusion, and confirm the victory. The dauphin and the duke of Orleans were among the first that fled. The king of France himself made the utmost efforts to retrieve by his valour what his rashness had forfeited; but his single courage was unable to stop that consternation which had now become general through his army; and his cavalry soon flying, he found himself exposed to the enemy's fury. At length, spent with fatigue and despairing of success, he thought of yielding himself a prisoner; and frequently cried out, that he was ready to deliver himself to his cousin the prince of Wales. The honour of taking him, however, was reserved for a much more ignoble hand; he was seized by Dennis de Morbec, a knight of Arras, who had been obliged to fly his country for murder.

72 French defeated.

73 King John taken prisoner.

In April following, the prince conducted his royal prisoner through London, attended by an infinite concourse of people of all ranks and stations. His modesty upon this occasion was very remarkable: the king of France was clad in royal apparel, and mounted on a white steed distinguished by its size and beauty: while the prince himself rode by his side upon a mean little horse, and in very plain attire.

74 Miserable situation of France.

This dreadful defeat, which happened in the year 1356, almost entirely ruined the French affairs; and the miseries which ensued from this cause were greatly augmented by internal commotions. The dauphin, who had now assumed the government, was altogether unable to govern a turbulent and seditious people at such a crisis. An assembly of the states, which he called, took the opportunity to limit the power of the prince, impeach the former ministers, and demand the liberty

 liberty of the king of Navarre; the treasurer of the crown was murdered by one Marcel, a partizan of that worthless prince who had filled the city of Paris with confusion by his intrigues. The assassin whom Marcel employed was dragged, by order of the dauphin, from an altar where he had taken refuge, and instantly put to death. The bishop of Paris resented the indignity done to the church; and Marcel avenged the fate of his adherent, by murdering both the mareschals who had seized him in the presence of the dauphin; and so near him, that his clothes were stained with their blood. The prince indignantly asked him, if he was to be involved in the same destruction? when Marcel affected to provide for his safety by putting upon him a blue hood, the badge of the adherents of Navarre.

75 The king of Navarre escapes from prison.

The public disorders were now also augmented by the escape of the king of Navarre from confinement; and though the dauphin was even assured that he had administered a dose of poison to him, he was obliged still to pay him some appearance of regard. A scheme was even formed by the chiefs of the sedition to change the government, to vest all the power in the commons, and leave the king no more than an empty title; but though this was favourably received by the city of Paris, it was entirely rejected by the other cities of the kingdom. The dauphin was likewise recognized as regent by the states general, and the inhabitants of Picardy and Champagne took up arms in his cause.

76 Insurrections and tumults of the peasants.

In this disastrous state of affairs, the miseries of the people were heightened by a new and unexpected evil. The peasants, who had been all along oppressed by the nobles, were now treated in such a manner, that they rose in great numbers to revenge themselves; the castles of the nobility were rased to the ground, their wives and daughters ravished, and themselves put to the most cruel torments. At last they were obliged to arm in their own defence. The duke of Orleans cut off 10,000 of them in the neighbourhood of Paris; 12,000 were massacred by the king of Navarre; 9000, who had laid siege to the town of Meaux, where the dauphiness and three other ladies of the first rank resided, were routed and pursued with dreadful slaughter by an officer in the service of Edward. Amidst these confusions, Marcel, the seditious leader already mentioned, perished in a tumult of his own raising; and the most virtuous and prudent people of the nation supported the pretensions of the dauphin. His most dangerous enemy was the king of Navarre, who had allured to his standard numbers of those Norman and English adventurers who had followed Edward into France, and there been left to seek their fortunes; where they associated themselves under the name of the *Companions*.

77 Peace between the dauphin and king of Navarre.

By such a formidable competitor the dauphin was reduced almost to the last extremity, when his hopes were revived by an unexpected proposal from his rival, of peace upon equitable and moderate terms. Historians in general have ascribed this to the natural levity of the king of Navarre; but some have been of opinion that he acted from prudential motives, and that he justly supposed it would be more easy to deal with the dauphin who was his own kinsman, and humbled by so many misfortunes, than with a haughty and imperious conqueror like Edward.

On the expiration of the truce in 1359, Edward again set sail for France, and anchored before Calais with a fleet of 1100 sail, assumed the title of *King of France*, and augmented his army to 100,000 men.

78 A new invasion of France by Edward.

The dauphin, finding himself unable to withstand so great a power, was obliged to act on the defensive; choosing the city of Paris for his station, and allowing the English to ravage all the open country. Thus they were allowed to penetrate through Picardy into Champagne; but the city of Rheims, where Edward designed to have been crowned king of France, baffled their utmost efforts. From Champagne, therefore, which was already laid waste, the English monarch marched into Burgundy; pillaged Tonnere, Gaillon, and Avalon. Burgundy was saved by the payment of 100,000 merks, and a like sum was paid for Nivernois. At last, after a long and destructive march, Edward arrived at the gates of Paris; but the prudence of the dauphin and citizens of that metropolis had rendered it impregnable to the attacks of famine as well as the assaults of an army.

79 He concludes a peace.

Thus the war went on till the year 1360, when the king of England was inclined to peace, as is said, by a dreadful tempest, to which his army was exposed while encamped in the fields round Chartres. His conduct, however, may more reasonably be derived from other motives. Notwithstanding all the victories he had gained, the French nation showed not the least favour to his claim of succession; the king of Navarre was a dangerous rival, and the caution of the dauphin in avoiding an engagement deprived him of the advantages he might expect from his valour and military skill. Thus conferences for a peace were opened at Bretigny in the Chartraine; and it was at last concluded on the following conditions, viz. That King John should pay for his ransom, at different periods, three millions of crowns of gold (about a million and a half of our money): Edward should for ever renounce all claim to the kingdom of France; and should remain possessed of the territories of Poictou, Xaintonge, l'Agenois, Perigord, the Limousin, Quercy, Rouvergne, l'Angoumois, and other districts in that quarter, together with Calais, Guisnes, Montreuil, and the county of Ponthieu on the other side of France. Some other stipulations were made in favour of the allies of England, as a security for the execution of these conditions.

Upon John's return to his dominions, he found himself very ill able to ratify those terms of peace that had been just concluded. He was without finances, at the head of an exhausted state; his soldiers without discipline, and his peasants without subordination. These had risen in great numbers; and one of the chiefs of the banditti assumed the title of *The Friend of God and the terror of Man*. A citizen of Sens, named *John Gouge*, also got himself, by means of his robberies, to be acknowledged king; and he soon caused as many calamities by his devastations, as the real king had brought on by his misfortunes. Such was the state of that wretched kingdom upon the return of its captive monarch: and yet such was his absurdity, that he immediately prepared for a croisade into the Holy Land, before he was well replaced on the throne. Had his exhausted subjects been able to equip him for this chimerical project, it is probable, he would have gone through with it; but their miseries were such, that they were even too poor to pay his ransom. This was a breach of treaty that John would not submit to;

80 John, unable to pay his ransom, returns to England.

and he was heard to express himself in a very noble manner upon the occasion: "Though (says he) good faith should be banished from the rest of the earth, yet she ought still to retain her habitation in the breast of kings." In consequence of this declaration, he actually returned to England once more; and yielded himself a prisoner, since he could not be honourably free. It is said by some, that his passion for the countess of Salisbury was the real cause of his journey: but we want at this time the foundations for such an injurious report. He was lodged in the Savoy, the palace where he had resided during his captivity; and soon after he closed a long and unfortunate reign, by his death, which happened in the year 1384, about the 56th year of his age.

81 His, and is succeeded by Charles the Wise.

Charles, surnamed *the Wise*, succeeded his father on the throne of France; and this monarch, merely by the force of a finely conducted policy, and even though suffering some defeats, restored his country once more to tranquillity and power. He quelled and dissipated a set of banditti, who had associated themselves under the name of *Companions*, and who had long heen a terror to the peaceable inhabitants. He had them enrolled into a body, and led them into the kingdom of Castile against Peter, surnamed *the Cruel*, whom his subjects had dethroned, and who, by means of an alliance with the English, endeavoured to get himself reinstated upon the throne. In consequence of these alliances, the English and French again came to an engagement; their armies on the one side commanded by the Black Prince; on the other, by Henry of Transtamarre, and Bertrand du Guesclin, one of the most consummate generals and accomplished characters of the age in which he lived. However, the usual good fortune of the English prince prevailed; the French lost above 20,000 men, while only four knights and 40 private men on the side of the English were slain.

82 Bad success of the English.

Nevertheless, these victories were attended with very few good effects. The English, by their frequent levies, had been quite exhausted, and were unable to continue an army in the field. Charles, on the other hand, cautiously forebore coming to any decisive engagement; but was contented to let his enemies waste their strength in attempts to plunder a fortified country. When they were retired, he then was sure to sally forth, and possess himself of such places as they were not strong enough to defend. He first fell upon Ponthieu; the citizens of Abbeville opened their gates to him; those of St Valois, Rue, and Crotoy, imitated the example; and the whole country was in a little time reduced to total submission. The southern provinces were, in the same manner, invaded by his generals with equal success; while the Black Prince, destitute of supplies from England, and wasted by a cruel and consumptive disorder, was obliged to return to his native country, leaving his affairs in the south of France in a desperate condition.

In this exigence, the resentment of the king of England was excited to the utmost pitch; and he seemed resolved to take signal vengeance on his enemies of the continent. Bnt the fortunate occasion was now elapsed; and all his succeeding designs were marked with ill success. The earl of Pembroke and his whole army were intercepted at sea, and taken prisoners by Henry king of Castile. Sir Robert Knolles, one of his generals on the continent, at the head of 30,000 men, was defeated by Bertrand du Guesclin; while the duke of Lancaster, at the head of 25,000 men, had the mortification of seeing his troops diminished one half by flying parties, without ever coming to a battle.

At last, the English affairs were totally ruined by the death of the Black Prince and King Edward. On receiving this news, the armies of Charles attacked the English on all sides. One, under the command of the duke of Burgundy, entered Artois; another entered Auvergne, under the command of the duke of Berry; that which acted in Guienne was commanded by the duke of Anjou; and the forces in Bretagne were under the constable Guesclin: the king himself had a powerful body of troops, that he might be able to repair any accident which should happen through the chance of war. The constable joined the duke of Burgundy, who found it difficult to oppose Sir Thomas Felton and the seneschal of Bourdeaux. Soon after his arrival, the constable attacked and defeated them, making both the commanders prisoners of war. This victory was so well pnrsued, that, at the close of the campaign 1377, Bayonne and Bourdeaux, with the districts about them, and the fortress of Calais with its dependencies, were all the places left to England on the continent.

Thus Charles established once more the house of Valois on the throne of France, but did not long live to enjoy his good fortune. He died in the year 1379, at the age of 44, of the consequences of poison formerly given him by the king of Navarre, as has already been mentioned. The immediate operation of this poison had been suspended by the skill of a physician sent by the emperor Charles IV. He opened an issue in his arm, the running of which preserved his life; but the physician declared, that whenever it should dry up, the consequence would be fatal. Not long before his death, Charles had commenced a process against the king of Navarre for this crime. Several of the associates of the latter suffered on this occasion, and the king himself was deprived of his possessions in Normandy, as well as his lordship of Montpelier, which had been given him in lieu of the counties of Champagne and Brie, and the duchy of Burgundy which he had claimed. He did not long survive the death of the French monarch whom he destroyed. His death was singular and very terrible; for having been afflicted with the leprosy, he had been obliged to make use of some bandages dipped in sulphur, and afterwards steeped in brandy. These took fire by the carelessness of a page, and the unfortunate prince was burnt to death.

83 Death of Charles;

84 and of the king of Navarre.

85 Reign of Charles VI.

Charles V. was succeeded by his son Charles VI. surnamed the *Well-beloved*, who, at the time of his accession to the throne, was only 12 years of age. The duke of Anjou, eldest brother to the late king, had been appointed guardian during the minority of the prince; but he being totally unfit for the office, and distinguished only for his rapacity and ambition, readily resigned his charge to the dukes of Burgundy and Bourbon, the former uncle to the king by his father's side, the latter by his mother's. None of these tutors, however, proved faithful to the trust reposed in them. The duke of Anjou seized the plate and treasures of the late

late king, in order to support his ambitious enterprises. At that time Joan, infamous for her profligacy, reigned in Naples. She had appointed one Charles Durazzo, who was her relation, to succeed her in the throne; but the inhuman wretch murdered his benefactress, who with her last breath revoked her grant of the kingdom to him, and bestowed it upon the duke of Anjou. His influence at the French court enabled him to waste the treasures of the kingdom in support of his pretensions; though he proved ultimately unsuccessful, his forces being constantly defeated, and his designs frustrated by the superior skill of his adversary. The duke of Burgundy, instead of instructing his pupil in the ways of virtue, indulged him in every kind of vicious pleasure, hoping thereby to gain his favour afterwards. The citizens of Paris, oppressed by taxes, broke out into tumults, and were quelled with difficulty; while the mal-administration of Philip the duke of Burgundy soon involved the nation

86 Flanders invaded.

in hostilities with the Flemings. Philip invaded their country at the head of an army of 80,000 men, along with whom was the young king, accompanied by the principal nobility of France. The first operations of war were favourable to the Flemings; but they were at length totally defeated on the banks of the river Lis, where their leader, with 25,000 of his followers, perished. This victory was followed by the submission of the whole country; but the satisfaction of the king at this event was disturbed by new seditions and revolts in the city of Paris, and other great towns of the kingdom. His return, however, at the head of a victorious army, soon reduced them to their duty, and several of the revolted cities were severely punished; at the same time that the death of the duke of Anjou having freed him from the immediate dependence on his tutors, he assumed the reins of government into his own hands in the year 1384.

The genius which Charles began to display in his early years, raised the hopes of the nation; but these were soon overcast, and greater misfortunes than ever were now about to ensue. The young king, whose marriage began to be a subject of attention to the council, refused to comply with the forms in use among his predecessors, and insisted upon seeing the

87 Marries Isabella daughter to the duke of Bavaria.

person designed for his consort. An interview was accordingly contrived betwixt him and Isabella daughter to the duke of Bavaria; where he fell in love with that princess, and afterwards married her. His administration was for some time prudent and vigorous. He conciliated the affections of his people by restoring their privileges, punishing their oppressors, and relieving them from the taxes which had been imposed in his minority. He reduced the Flemings to submit to the authority of his uncle the duke of Burgundy; detached 15,000 archers and 1500 men at arms to assist the Scots in their incursions into England; and in 1385 fitted out a prodigious armament against England. A vast fleet was assembled in the harbour of Sluys, and a very numerous army in the neighbourhood. According to some writers, the armament consisted of 1200 ships, 20,000 foot differently armed, 20,000 cavalry, and 20,000 cross-bow-men. There was besides a vast wooden edifice or floating town, which was contrived for the protection of the soldiers when landed: but all these preparations were at last brought to nothing through the obstinacy of the duke of Berry; who, having been originally against this measure, carried on his part of the armament so slowly, that he did not arrive at Sluys till the middle of September, when the season was so far advanced, that no invasion was practicable. A storm that happened soon after, drove the greatest part of the fleet on shore, and beat the wooden edifice all to pieces; the remains of which the king bestowed on the duke of Burgundy, to whom he gave also the port of Sluys, which was then very commodious, and of the utmost importance.

The destruction of the French fleet was only a prelude to calamities of a more extraordinary nature. The Sieur de Craon, a profligate nobleman, had been intrusted by the court of France with a considerable sum of money for the support of the duke of Anjou, at the time he was reduced to distress by his Italian expedition. This money he had dissipated at Venice; but, by the credit of the duke of Orleans, the king's brother, he had obtained his pardon, and returned to court. Here he attempted to gratify his private resentment by the assassination of Oliver Clisson the constable, whom he suspected of having promoted his disgrace. This veteran hero was attacked, on his return from the hotel de St Pol, by a band of 20 ruffians, against whom he defended himself with wonderful intrepidity, when at last he fell, after receiving more than 50 wounds. Happily, however, he recovered notwithstanding his being mangled in this manner; while the assassin, to screen himself from vengeance, fled for protection to the duke of Brittany. The king demanded the assassin to be given up to him in chains; but the duke answered, that he knew nothing of him: to which the king giving no credit, marched with all his forces into his territories. When the army arrived

88 Is seized with lunatic fits.

at Mans, the king was seized with a slow fever; but could not be prevailed upon to rest or take physic. On the 5th of August 1391, having marched all day in the heat of the sun, a miserable, ragged, wild-looking fellow darted from behind a tree, and laying hold of the bridle of his horse, cried out "Stop! where are you going, king? You are betrayed:" and immediately withdrew again into the wood. The king passed on not a little disturbed: and soon after one of the pages, who rode behind and carried his lance, overcome with heat, fell asleep, and let it fall upon the helmet which was carried by the other. The king hearing the noise, looked about; and perceiving the page lifting the lance, killed him immediately: then riding furiously with his sword drawn, he struck on every side of him, and at every person, till he broke his sword: upon which one of his gentlemen leaped up behind him and held his arm. He fell soon after, and lay as if he had been dead; so that being taken up and bound in a waggon, he was carried back to Mans, where he lay two days in a lethargy, after which he came a little to himself, and expressed great concern at the blood he had shed in his delirium. The people, who had expressed the greatest concern for his distemper, were equally rejoiced at the news of his recovery; but unfortunately it was soon discovered, that he no longer possessed that strength of judgment and understanding for which he had formerly been remarkable. Hence a regency became indispensably necessary; and

and the competition for it brought to light the characters of the queen and duke of Orleans, which had not hitherto been displayed to public view. The former of these was a most beautiful and accomplished princess; but vindictive, violent, and intriguing: insensible to natural affection, but easily accessible to flattery, and ready to yield to every impulse of lawless passion. The duke of Orleans was equally remarkable for his personal accomplishments, and had married Valentina daughter of the duke of Milan; but his engagements with that princess did not prevent him from engaging in a number of licentious amours, and among the rest, as was supposed, with his sister-in-law Isabella. During the king's illness he openly aspired at the regency; but his pretensions were overruled by the states, the administration of affairs being for the present conferred on the duke of Burgundy. In a few months indeed the health and understanding of the king seemed to be sufficiently restored: but in the year 1393 it was again disturbed by an accident no less extraordinary than the former had been. An entertainment had been given in honour of the marriage of one of the queen's attendants. At this six masques entered the apartment, disguised like satyrs, in linen clothes covered with rosin, and while warm stuck over with down. These were the king and five of his lords. The duchess of Berri paid attention to the king, though she did not know him, and engaged in conversation with him. In the mean time the duke of Orleans, ignorant of the consequence, out of diversion ran a lighted torch against one of them. His whole dress was instantly in a flame, and the fire was from him communicated to all the rest. The masques, notwithstanding the dreadful situation they were in, called out, "Save the king; save the king!" on which the duchess of Berri, recollecting that it must be him with whom she had engaged in conversation, wrapped him in her cloak, and preserved him from further danger. Only one of the rest escaped by jumping into a cistern of water; the other four perished in the flames. The terror which the king underwent by this accident instantly occasioned a relapse; and he continued delirious at intervals as long as he lived. During this state of insanity he was untractable by every person except Valentina duchess of Orleans; who seemed to have as great an influence over him as her husband the duke had over the mind of the queen. So great was the power indeed which she had over the king in this deplorable state, that in those superstitious times it was supposed by many to be the effect of magic. Others, with more probability, ascribed it to her superior charms as a woman; and this idea instantly produced her a number of enemies among her own sex, the duchess of Burgundy particularly; and the quarrel between the two ladies soon extended itself to their husbands. Amidst their dissensions, however, they did not entirely neglect the administration of public affairs; they strove to conciliate the affection of the parliament by preserving the rights of the commons inviolate; and they endeavoured to check an inordinate passion for gaming which began to appear about this time, and to substitute manly and martial exercises in its place.

89 Disturbances about a regency.

90 An accident occasions a relapse in the king.

During the intervals of his reason, Charles frequently assumed the government into his own hands: and as the war still continued with England, though in a languid manner, the French monarch, in one of these lucid intervals, had an interview with Richard king of England, in order to put an end to hostilities, of which both were equally weary. Still, however, their claims were so difficult to be adjusted, that they could do no more than conclude a truce for 25 years; during which space it was hoped that a lasting peace might take place. Richard gave up Cherburg to Charles, and Brest to the duke of Brittany: a marriage was also concluded betwixt the king of England and Isabella the daughter of Charles, though the latter was then only seven years of age; but by reason of the tender age of the princess, this marriage was never consummated.

91 Interview betwixt the kings of France and England.

During this unfortunate reign, France was still farther weakened by the succours sent to the Hungarians against the Turks. On this fatal expedition upwards of 1000 of the bravest and most experienced knights were sent under the conduct of John count of Nevers, eldest son of the duke of Burgundy; the count of Eu, constable of France; John de Vienne, admiral of France; and the count of Marche, a prince of the blood royal; together with De Courcy, one of the best and most experienced captains in Christendom. The prudent counsels of this veteran, however, were not obeyed by the youthful warriors by whom he was accompanied. Attacking the enemy therefore rashly, and while heated with wine, they were all either killed or taken prisoners. Notwithstanding this disaster, however, assistance was sent in the year 1400 to Wenceslaus emperor of Germany; and the duke of Orleans, who commanded the army on this occasion, acquitted himself so well that he acquired the duchy of Luxemburg for himself, and left his ally satisfied: but while the friendship of France was thus courted by foreign powers, the kingdom itself was in the most miserable situation. The king's distemper seemed daily to gain ground; while the discordant interests of the contending parties kept the whole nation in a ferment. The most violent animosity took place betwixt the dukes of Orleans and Burgundy. The former, by means of his own interest with the queen, and the ascendency his duchess had over the king, for some time got the better of his rival, and was made lieutenant general and governor of the kingdom; but having presumed on his power to levy new imposts on the people, and oppressing also the churchmen, whom in that superstitious age he ought by all means to have let alone, he was deprived of his authority, and obliged to yield to the duke of Burgundy. For some time, however, these powerful rivals were kept within some bounds by the mediation of the duke of Bourbon, who seems to have been the only grandee who maintained a pure and unspotted character; but by his death in 1404, the unhappy nation was left totally exposed to their relentless fury. In 1405, the queen and duke of Orleans again seized the administration; but were soon deprived of it by the unanimous voice of the people. During this period Charles and his children were neglected and abandoned to distress; but they were relieved by the duke of Burgundy on his obtaining the regency; and Isabella, with the duke of Orleans, was obliged to retire from Milan. A sudden return of the king's reason and understanding for a much longer time than usual, now deprived both parties of their power; and the administration

92 Unhappy fate of the succours sent to the Hungarians.

93 Violent commotions in France.

France. nistration was vested in the queen and a council composed of princes of the blood.

The two rival dukes, thus prohibited from interfering in public affairs, exercised themselves in committing hostilities against the English, with whom the truce had been lately concluded. They were encouraged to this infraction of the treaty by the unsettled situation of the affairs of Henry IV.; but their attempts proving unsuccessful, the truce was renewed after obtaining restoration of the princess, who had been married to Richard II. as has been already mentioned. The failure of their enterprises produced a new scene of discord betwixt the dukes, who mutually threw the blame upon each other. By the entreaties of the duke of Berry they were apparently reconciled; but the duke of Burgundy pretended friendship only in order to take

94 Duke of Orleans assassinated.

the more signal vengeance. To this he was now further inflamed by jealousy. Having hired a band of ruffians to execute his bloody purpose, the duke was one evening attacked by eighteen of them while attended only by two pages. A Norman gentleman whom the duke had deprived of an employment, headed the assassins, and in person attacked the duke. At the first blow he cut off his hand, at the second he struck him from his mule, and at the third put an end to his life. His wife Valentina was so deeply affected with his death, that she died soon after. The duke of Burgundy escaped to Flanders; and the whole nation was rent into two factions, called the *Burgundians* and *Armagnacs*; the latter being the title of the party of the duke of Orleans, from Armagnac the father-in-law of that prince. A dreadful confusion ensued: the duke of Burgundy soon returned to France, and extorted a pardon from the unhappy king, who was now no longer able to resist him: and we may have some notion of the state of the kingdom in general from being told, that 2000 people perished in one tumult in the capital. The king himself was alternately the prisoner of each party, and alternately transferred the power from the one to the other as he happened to fall into their hands. This therefore was thought by Henry V. of England, a favourable opportunity to recover from France those grants that had been formerly given up by treaty. But previously, to give his intended expedition the appearance of justice, he sent over ambassadors to Paris, offering a perpetual peace and alliance, on condition of being put in possession of all those provinces which had been ravished from the English during some former reigns, and of espousing Catharine, the French king's daughter, in marriage, with a suitable dowry. Though the French court was at that time extremely averse to war, yet the exorbitance of these demands could not be complied with; and Henry very probably made them in hopes of a denial. He

95 Invasion by Henry V. of England.

therefore assembled a great fleet and army at Southampton; and having allured all the military men of the kingdom to attend him, from the hopes of conquest, he put to sea, and landed at Harfleur, at the head of an army of 6000 men-at-arms, and 24,000 foot, mostly archers.

His first operations were upon Harfleur: which being pressed hard, promised at a certain day to surrender unless relieved before that time. The day arriving, and the garrison, unmindful of their engagement, still resolving to defend the place, Henry ordered an assault to be made, took the town by storm, and put all the garrison to the sword. From thence the victor advanced farther into the country, which had been already rendered desolate by factions, and which he now totally laid waste. But although the enemy made a feeble resistance; yet the climate seemed to fight against the English; a contagious dysentery carrying off three parts of Henry's army. In this situation he had recourse to an expedient common enough in that barbarous age, to inspire his troops with confidence in their general. He challenged the dauphin, who commanded in the French army, to single combat, offering to stake his pretensions on the event. This challenge, as might naturally be expected, was rejected; and the French, though disagreeing internally, at last seemed to unite at the appearance of the common danger. A numerous army of 14,000 men-at-arms, and 40,000 foot, was by this time assembled under the command of Count Albert, and was now placed to intercept Henry's weakened forces on their return. The English monarch, when it was too late, began to repent of his rash inroad into a country where disease and a powerful army everywhere threatened destruction; he therefore thought of retiring into Calais. In this retreat, which was at once both painful and dangerous, Henry took every precaution to inspire his troops with patience and perseverance; and showed them in his own person the brightest example of fortitude and resignation. He was continually harassed on his march by flying parties of the enemy; and whenever he attempted to pass the river Somme, across which his march lay, he saw troops on the other side ready to oppose his passage. However, he was so fortunate as to seize by surprise a passage near St Quintin, which had not been sufficiently guarded; and there he safely carried over his army.

But the enemy was still resolved to intercept his retreat: and after he had passed the small river of Tertrois at Blangi, he was surprised to observe from the heights the whole French army drawn up in the plains of Agincourt; and so posted, that it was impossible for him to proceed on his march, without coming to an engagement. A battle accordingly took place, in which the English gained a victory, the most remarkable perhaps of any recorded in history; an account of which is given under the article AGINCOURT. 96 Battle of Agincourt.

This victory, gained on the 25th of October 1415, was however attended with no immediate effects. Henry still continued to retreat, after the battle of Agincourt, out of the kingdom; and carried his prisoners to Calais, and from thence to England. In 1417, he once more landed an army of 25,000 men in Normandy; and prepared to strike a decisive blow for the crown of France, to which the English monarchs had long made pretensions. That wretched country was now in a most deplorable situation. The whole kingdom appeared as one vast theatre of crimes, murder, injustice, and devastation. The duke of Orleans was assassinated by the duke of Burgundy; and the duke of Burgundy, in his turn, fell by the treachery of the dauphin. At the same time, the duke's son, desirous of revenging his father's death, entered into a secret treaty with the English; and a league was immediately concluded at Arras, between Henry and the young duke of Burgundy, in which the king promised 97 Henry lands again in Normandy.

France.

mised to revenge the murder of the late duke; and the son seemed to insist upon no further stipulations. Henry, therefore, proceeded in his conquests without much opposition from any quarter. Several towns and provinces submitted on his approach; the city of Rouen was besieged and taken: and he soon became master of Pontoise and Gisors. He even threatened Paris by the terror of his power, and obliged the court to remove to Troyes. It was at this city that the duke of Burgundy, who had taken upon him the protection of the French king, met Henry in order to ratify that treaty which was formerly begun, and by which the crown of France was to be transferred to a stranger. The imbecility into which Charles had fallen, made him passive in this remarkable treaty; and Henry dictated the terms throughout the whole negotiation. The principal articles of this treaty were, that Henry should espouse the princess Catharine; that King Charles should enjoy the title and dignity of king for life; but that Henry should be declared heir to the crown, and should be intrusted with the present administration of the government; that France and England should for ever be united under one king, but should still retain their respective laws and privileges; that Henry should unite his arms with those of King Charles and the duke of Burgundy, to depress and subdue the dauphin and his partisans.

98 Henry marries the princess Catharine.

It was not long after this treaty, that Henry married the princess Catharine; after which he carried his father-in-law to Paris, and took a formal possession of that capital. There he obtained from the estates of the kingdom a ratification of the late compact; and then turned his arms with success against the adherents of the dauphin; who, in the mean time, wandered about a stranger in his own patrimony, and to his enemies successes only opposed fruitless expostulations.

Henry's supplies were not provided in such plenty as to enable him to carry on the war without returning in person to prevail upon his parliament for fresh succours; and, upon his arrival in England, though he found his subjects highly pleased with the splendour of his conquests, yet they seemed somewhat doubtful as to the advantage of them. A treaty, which in its consequences was likely to transfer the seat of empire from England, was not much relished by the parliament. They therefore, upon various pretences, refused him a supply equal to his exigencies or his demands; but he was resolved on pursuing his schemes; and, joining to the supplies granted at home, the contributions levied on the conquered provinces, he was able once more to assemble an army of 28,000 men, and with these he landed safely at Calais.

In the mean time, the dauphin, a prince of great prudence and activity, omitted no opportunity of repairing his ruined situation, and to take the advantage of Henry's absence from France. He prevailed upon the regent of Scotland to send him a body of 8000 men from that kingdom; and with these, and some few forces of his own, he attacked the duke of Clarence, who commanded the troops in Henry's absence, and gained a complete victory.

This was the first action which turned the tide of success against the English. But it was of short duration: for Henry soon after appearing with a considerable army, the dauphin fled at his approach; while many of the places, which held out for the dauphin in the neighbourhood of Paris, surrendered to the conqueror. In this manner, while Henry was everywhere victorious, he fixed his residence at Paris; and while Charles had a small court, he was attended with a very magnificent one. On Whitsunday 1421, the two kings and their two queens with crowns on their heads dined together in public; Charles receiving apparent homage, but Henry commanding with absolute authority.

In the mean time, the dauphin was pursued beyond the Loire, and almost totally dispossessed of all the northern provinces. He was even pursued into the south, by the united arms of the English and Burgundians, and threatened with total destruction. In this exigence, he found it necessary to spin out the war, and to evade all hazardous actions with a rival who had been long accustomed to victory. His prudence was everywhere remarkable; and, after a train of long persecutions from fortune, he found her at length willing to declare in his favour, by the death of the king of England.

99 Death of Henry and Charles.

Charles VI. died a short time after; and Charles VII. succeeded his father to a nominal throne. Nothing could be more deplorable than the situation of that monarch on assuming his title to the crown. The English were masters of almost all France; and Henry VI. though yet but an infant, was solemnly invested with regal power by legates from Paris. The duke of Bedford was at the head of a numerous army, in the heart of the kingdom, ready to oppose every insurrection; while the duke of Burgundy, who had entered into a firm confederacy with him, still remained stedfast, and seconded his claims. Yet notwithstanding these favourable appearances, Charles found means to break the leagues formed against him, and to bring back his subjects to their natural interests and their duty.

100 Desperate situation of Charles VII.

However, his first attempts were totally destitute of success. Wherever he endeavoured to face the enemy he was overthrown, and he could scarcely rely on the friends next his person. His authority was insulted even by his own servants; advantage after advantage was gained against him; and a battle fought near Verneuil, in which he was totally defeated by the duke of Bedford, seemed to render his affairs altogether desperate. But from the impossibility of the English keeping the field without new supplies, Bedford was obliged to retire into England; and in the mean time, his vigilant enemy began to recover from his late consternation. Dumois, one of his generals, at the head of 1000 men, compelled the earl of Warwick to raise the siege of Montargis; and this advantage, slight as it was, began to make the French suppose that the English were not invincible.

101 The French affairs retrieved by the Maid of Orleans.

But they soon had still greater reason to triumph in their change of fortune, and a new revolution was produced by means apparently the most unlikely to be attended with success. In the village of Domremi, near Vaucouleurs, on the borders of Lorrain, there lived a country girl, about 27 years of age, called *Joan de Arc*. This girl had been a servant at a small inn; and in that humble station had submitted to those hardy employments which fit the body for the fatigues of war. She was of an irreproachable life, and had hitherto

therto testified none of those enterprising qualities which displayed themselves soon after. She contentedly fulfilled the duties of her situation, and was remarkable only for her modesty and love of religion. But the miseries of her country seemed to have been one of the greatest objects of her compassion and regard. Her mind, inflamed by these objects, and brooding with melancholy stedfastness upon them, began to feel several impulses, which she was willing to mistake for the inspirations of heaven. Convinced of the reality of her own admonitions, she had recourse to one Baudricourt, governor of Vaucouleurs, and informed him of her destination by heaven to free her native country of its fierce invaders. Baudricourt treated her at first with neglect: but her importunities at length prevailed; and willing to make a trial of her pretensions, he gave her some attendants, who conducted her to the court, which at that time resided at Chinon.

The French court were probably sensible of the weakness of her pretensions; but they were willing to make use of every artifice to support their declining fortunes. It was therefore given out, that Joan was actually inspired; that she had been able to discover the king among the number of his courtiers, although he had laid aside all the distinctions of his authority; that she had told him some secrets, which were only known to himself; and that she had demanded, and minutely described a sword in the church of St Catharine de Fierbois, which she had never seen. In this manner, the minds of the vulgar being prepared for her appearance, she was armed cap-a-pee, and shown in that martial dress to the people. She was then brought before the doctors of the university; and they, tinctured with the credulity of the times, or willing to second the imposture, declared that she had actually received her commision from above.

When the preparations for her mission were completely blazoned, the next aim was to send her against the enemy. The English were at that time besieging the city of Orleans, the last resource of Charles, and every thing promised them a speedy surrender. Joan undertook to raise the siege; and to render herself still more remarkable, girded herself with the miraculous sword, of which she before had such extraordinary notices. Thus equipped, she ordered all the soldiers to confess themselves before they set out; she displayed in her hand a consecrated banner, and assured the troops of certain success. Such confidence on her side soon raised the spirits of the French army; and even the English, who pretended to despise her efforts, felt themselves secretly influenced with the terrors of her mission. A supply of provisions was to be conveyed into the town; Joan, at the head of some French troops, covered the embarkation, and entered Orleans at the head of the convoy which she had safely protected. While she was leading her troops along, a dead silence and astonishment reigned among the English; and they regarded with religious awe that temerity, which they thought nothing but supernatural assistance could inspire. But they were soon roused from their state of amazement by a sally from the town; Joan led on the besieged, bearing the sacred standard in her hand, encouraging them with her words and actions, bringing them to the trenches, and overpowering the besiegers in their own redoubts. In the attack of one of the forts, she was wounded in the neck with an arrow; but instantly pulling out the weapon with her own hands, and getting the wound quickly dressed, she hastened back to head the troops, and to plant her victorious banner on the ramparts of the enemy. These successes continuing, the English found that it was impossible to resist troops animated by such superior energy; and Suffolk, who conducted the attack, thinking that it might prove extremely dangerous to remain any longer in the presence of such a courageous and victorious enemy, raised the siege, and retreated with all imaginable precaution.

From being attacked, the French now in turn became the aggressors. Charles formed a body of 6000 men, and sent them to besiege Jergeau, whither the English, commanded by the earl of Suffolk, had retired, with a detachment of his army. The city was taken; Suffolk yielded himself a prisoner; and Joan marched into the place in triumph at the head of the army. A battle was soon after fought near Patay, where the English were worsted, as before; and the generals Scales and Talbot were taken prisoners.

The raising of the siege of Orleans was one part of the Maid's promise to the king of France; the crowning him at Rheims was the other. She now declared that it was time to complete that ceremony; and Charles, in pursuance of her advice, set out for Rheims at the head of 12,000 men. The towns through which he passed opened their gates to receive him; and Rheims sent him a deputation, with its keys, upon his approach. The ceremony of his coronation was there performed with the utmost solemnity; and the *Maid of Orleans* (for so she was now called) seeing the completion of her mission, desired leave to retire, alleging that she had now accomplished the end of her calling. But her services had been so great, that the king could not think of parting with her; he pressed her to stay so earnestly, that she at length complied with his request.

A tide of successes followed the performance of this solemnity; Laon, Soissons, Chateau-Thierri, Provins, and many other fortresses in that neighbourhood, submitted to him on the first summons. On the other hand, the English, discomfited and dispirited, fled in every quarter; not knowing whether to ascribe their misfortunes to the power of sorcery or to a celestial influence; but equally terrified at either. They now found themselves deprived of the conquests they had gained, in the same manner as the French had formerly submitted to their power. Their own divisions, both abroad and at home, unfitted them entirely for carrying on the war; and the duke of Bedford, notwithstanding all his prudence, saw himself divested of his strong holds in the country, without being able to stop the enemy's progress. In order, therefore, to revive the declining state of his affairs, he resolved to have Henry crowned king at Paris, knowing that the natives would be allured to obedience by the splendour of the ceremony. In 1430, Henry was accordingly crowned, all the vassals that still continued under the English power swearing fealty and homage. But it was now too late for the ceremonies of a coronation to give a turn to the affairs of the English; the generality of the kingdom had declared against them, and the remainder

102
Henry VI of England crowned king of France.

France. remainder only waited a convenient opportunity to follow the example.

An accident ensued soon after, which, though it promised to promote the English cause in France, in the end served to render it odious, and conduced to the total evacuation of that country. The duke of Burgundy, at the head of a powerful army, had laid siege to Compeign; and the Maid of Orleans had thrown herself into the place, contrary to the wishes of the governor, who did not desire the company of one whose authority would be greater than his own. The garrison, however, were rejoiced at her appearance, and believed themselves invincible under her protection. But their joy was of short duration; for Joan having the day after her arrival headed a sally, and twice driven the enemy from their entrenchments, she was at last obliged to retire, placing herself in the rear, to protect the retreat of her forces. But in the end, attempting to follow her troops into the city, she found the gates shut, and the bridge drawn up by order of the governor, who is said to have long wished for an opportunity of delivering her up to the enemy.

103 Maid of Orleans taken prisoner.

Nothing could exceed the joy of the besiegers, in having taken a person who had been so long a terror to their arms. The service of Te Deum was publicly celebrated on this occasion; and it was hoped, that the capture of this extraordinary person would restore the English to their former victories and successes. The duke of Bedford was no sooner informed of her being taken, than he purchased her of the Count Vendome, who had made her his prisoner, and ordered her to be committed to close confinement. The credulity of both nations was at that time so great, that nothing was too absurd to gain belief that coincided with their passions. As Joan but a little before, from her successes, was regarded as a saint, she was now, upon her captivity, considered as a sorceress, forsaken by the demon who had granted her a fallacious and temporary assistance. Accordingly it was resolved in council to send her to Rouen to be tried for witchcraft: and the bishop of Beauvais, a man wholly devoted to the English interest, presented a petition against her for that purpose. The university of Paris was so mean as to join in the same request. Several prelates, among whom the cardinal of Winchester was the only Englishman, were appointed as her judges. They held their court at Rouen, where Henry then resided; and the Maid, clothed in her former military apparel, but loaded with irons, was produced before the tribunal. Her behaviour there no way disgraced her former gallantry; she betrayed neither weakness nor womanish submission, but appealed to God and the pope for the truth of her former revelations. In the issue, she was found guilty of heresy and witchcraft; and sentenced to be burnt alive, the common punishment for such offences.

But previous to the infliction of this dreadful sentence upon her, they were resolved to make her abjure her former errors; and at length so far prevailed upon her, by terror and rigorous treatment, that her spirits were entirely broken by the hardships she was obliged to suffer. Her former visionary dreams began to vanish, and a gloomy distrust to take place of her late inspirations. She publicly declared herself willing to recant, and promised never more to give way to the vain delusions which had hitherto misled her, and imposed on the people. This was what her oppressors desired; and willing to show some appearance of mercy, they changed her sentence into perpetual imprisonment, and to be fed during life on bread and water. But the rage of her enemies was not yet satiated. Suspecting that the female dress which she had consented to wear, was disagreeable to her, they purposely placed in her apartment a suit of men's apparel, and watched for the effect of their temptation upon her. Their cruel artifices prevailed. Joan, struck with the sight of a dress in which she had gained so much glory, immediately threw off her penitent robes, and put on the forbidden garment. Her enemies caught her equipped in this manner; and her imprudence was considered as a relapse into her former transgressions. No recantation would suffice, and no pardon would be granted. She was condemned to be burnt alive in the market-place of Rouen; and this infamous sentence was accordingly executed with most brutal severity.

104 and cruelly put to death.

One of the first misfortunes which the English felt after this punishment, was the defection of the duke of Burgundy; who had for some time seen the error of his conduct, and wished to break an unnatural connexion, that only served to involve his country in ruin. A treaty was therefore begun and concluded between him and Charles, in which the former agreed to assist him in driving the English out of France. This was a mortal blow to their cause; and such was its effects upon the populace of London when they were informed of it, that they killed several of the duke of Burgundy's subjects, who happened to be among them at the time. It might perhaps also have hastened the duke of Bedford's death, who died at Rouen a few days after the treaty was concluded; and the earl of Cambridge was appointed his successor to the regency of France.

105 Affairs of the English totally ruined.

From this period, the English affairs became totally irretrievable. The city of Paris returned once more to a sense of its duty. Lord Willoughby, who commanded it for the English, was contented to stipulate for the safe retreat of his troops to Normandy. Thus ground was continually, though slowly, gained by the French; and notwithstanding their fields were laid waste, and their towns depopulated, yet they found protection from the weakness and divisions of the English. At length both parties began to grow weary of a war, which, though carried on but feebly, was yet a burden greater than either could support. But the terms of peace insisted upon by both were so wide of each other, that no hopes of an accommodation could quickly be expected. A truce, therefore, for twenty-two months, was concluded in 1443, which left every thing on the present footing between the parties. No sooner was this agreed upon, than Charles employed himself with great industry and judgment in repairing those numberless ills to which his kingdom, from the continuance of wars both foreign and domestic, had so long been exposed. He established discipline among his troops, and justice among his governors. He revived agriculture, and repressed faction. Thus being prepared once more for taking the field, he took the first favourable occasion of breaking the truce; and Normandy was at the same time invaded by four

powerful

France.

powerful armies; one commanded by Charles himself, a second by the duke of Brittany, a third by the count of Alençon, and a fourth by the Count Dunois. Every place opened its gates almost as soon as the French appeared before them. Rouen was the only one that promised to hold out a siege; but the inhabitants clamoured so loud for a surrender, that the duke of Somerset, who commanded the garrison, was obliged to capitulate. The battle, or rather the skirmish, of Fourmingi, was the last stand which the English made in defence of their French dominions. However, they were put to the rout, and above a thousand were slain. All Normandy and Guienne, that had so long acknowledged subjection to England, were lost in the space of a year; and the English saw themselves entirely dispossessed of a country which for above three centuries they had considered as annexed to their native dominions. Calais alone remained of all their conquests: and this was but a small compensation for the blood and treasure which had been lavished in that country, and only served to gratify ambition with a transient applause.

Thus, in the year 1450, the power of the English in France was entirely destroyed: and Charles deservedly obtained the surname of *Victorious*, on account of the vigour he had shown in driving out the invaders of his country. His satisfaction, however, was now

106 Domestic misfortunes and death of Charles.

greatly diminished by domestic misfortunes. The dauphin, forgetting the allegiance and filial duty he owed to his father, had already impeded his conquests by his seditious intrigues. He had used every endeavour to thwart the designs of his ministers, and it was supposed that he had destroyed Agnes Soreille his father's favourite mistress by poison. He had married Charlotte daughter to the duke of Savoy; which Charles had resented by a declaration of war against the duke, but had been persuaded to recal it in order to prosecute the war against Guienne, which made part of the dominions of the English. At last, weary of the disobedience of his son, he commanded him to be arrested; but Louis, informed of his design, withdrew to Franche Comte, and afterwards to Brabant; of which the duke of Burgundy (at this time sovereign of the country) was no sooner apprised, than he ordered him to be supplied with every necessary, and treated with all imaginable respect. He refused to see him, however, until he should obtain the approbation of his father; on which Louis, having in vain attempted to draw the duke into a participation of his crimes, employed himself in sowing dissension betwixt his benefactor and his son the count of Charolois, at the very time that he himself was receiving a pension of 12,000 crowns annually from the father. Thus he at last destroyed the domestic peace of his benefactor, while his unnatural behaviour created continual suspicions in the mind of his father. Charles was repeatedly informed that his own domestics, along with his undutiful son, were in a conspiracy against his life. The miserable monarch, therefore, in continual fear of being poisoned, and having none in whom he could repose any confidence, obstinately refused for some days to take any nourishment; and when at last prevailed upon by the importunities of his attendants to do so, his stomach had become incapable of receiving food, so that he died for want of sustenance in the year 1461. His body, neglected by his unnatural son, was interred at the expence of Tannegui de Chastel, who had been his faithful companion.

107 Reign of Louis XI.

On the death of Charles, his son Louis succeeded to the throne, to which he had so long aspired. He was reckoned one of the greatest politicians that ever existed; though his character was not on that account the more amiable; on the contrary, there are few princes whose history appears in a more detestable light. So destitute was he of natural affection, that he did not even attempt to conceal his joy at his father's death. He pretended much friendship for the count of Charolois, son to the duke of Burgundy, on account of the protection he had received at his father's court; and even conferred upon him a pension of 12,000 crowns annually: but all this show of affection soon degenerated into a mortal aversion on both sides. Some differences which took place between the courts of France and Castile produced an interview betwixt the two monarchs, Louis, and Henry surnamed the *Impotent*. They met at Mauleon on the confines of Navarre: but their negotiations came to nothing, and they parted with a mutual contempt of each other; Henry despising the mean and sordid appearance of Louis, as he in his turn did the gaudy magnificence of Henry. In his negotiations with the duke of Burgundy, Louis proved more successful; persuading him to restore some towns on the river Somme, which had been ceded by Charles VII. and by the possession of which the duke was in effect master of Picardy. This cession was opposed by the count of Charolois; but Louis, by corrupting John de Croy the duke's minister, obtained his end; and for the sum of 400,000 crowns the cities were delivered to him. By this transaction he effectually ensured the hatred of Charolois: and even in that very transaction the duplicity of Louis was eminently displayed; for though he had agreed to retain in those towns the officers appointed by the duke, he was no sooner in possession of them than he displaced them all, and nominated others in their stead.

108 Formidable confederacy against Louis.

The duchy of Brittany was at this time governed by Francis, a weak but generous prince, and whose defect of capacity was supplied by the abilities of his ministers. Him Louis insulted in the most grievous manner; and as Francis found himself unable to oppose such a powerful adversary alone, he joined in a close alliance with the duke of Burgundy and the count of Charolois; the latter having been grievously offended with Louis, and even accused him of attempting his life. The conspiracy was joined by several of the principal French nobility, who had been oppressed by the king; and though the secret was confided to upwards of 500 persons, not one of them ever divulged it. Louis, finding matters become very critical, marched with an army towards the capital, which the count of Charolois already insulted. A battle ensued, in which both princes exerted themselves to the utmost, though their valour was but ill seconded by the bravery of their troops. About 1500 perished on each side; but the count of Charolois remained master of the field of battle. Louis, however, after this engagement, entered the capital: where he endeavoured, by every kind concession he could think of, to conciliate the affection of his subjects; in which he succeeded so well, that though the army of insurgents was

ance.

was soon augmented to more than 100,000 men, they were unable to make themselves masters of the city. 109 Peace concluded. At last a treaty was set on foot betwixt Louis and the count of Charolois; by which the latter obtained the towns which had been formerly ceded, with the the districts of Boulogne, Guisne, Peronne, Mondidior, and Roye, as a perpetual inheritance for himself. By granting favours to the other confederates, the league 110 Treachery of Louis. was broken; and the moment that Louis found himself freed from danger, he protested against the whole treaty in the presence of some confidential members of parliament, as contrary to the interest of the crown; and therefore waited the first favourable opportunity to crush one by one those who had been ready by their united efforts to destroy himself. The duke of Bourbon, one of the most able of the confederates, was gained over, by bestowing upon him in marriage, Jane the natural daughter of Louis himself, with the dowry of Usson in Auvergne; together with Moras, Beaurepaire, and Cormillon in Dauphiny; while, by the discontents betwixt the dukes of Brittany and Normandy, he was enabled to secure the neutrality of the former, and to recover from the latter some territories which he had unwillingly ceded to him.

In 1467, Philip duke of Burgundy, from his amiable qualities surnamed *The Good*, died, and left his dominions to his son Charles count of Charolois. That fiery and impetuous prince, jealous of the growing power of France, and an implacable enemy of Louis, had entered into a secret treaty with Francis; but Louis had driven the Bretons from the posts they occupied in Normandy before the duke of Burgundy could pass the Somme. The king, however, alarmed at the power of the confederates, concluded a peace with Brittany; and, confiding in his talents for negotiation, determined to have a personal interview with the duke of Burgundy.

111 Louis imprisoned by Charles. This memorable interview took place in the year 1468; and Peronne, a city of Picardy, but belonging to the duke of Burgundy, was appointed as the place of rendezvous. To this place the politic Louis repaired with a slender train, and attended only by Cardinal Balue, the duke of Bourbon, and the count de St Pol, constable of France; seemingly without reflecting that he was entering a hostile city, where he might be confined for any length of time, or treated at the pleasure of the duke, who was his mortal enemy. Indeed he had not long been in the place when he began to see the error of his conduct; and by the daily concourse of Burgundian lords and other persons of rank, who were his avowed enemies, he became alarmed for his personal safety. His fear now suggested to him a worse measure than even the former; and he requested apartments in the castle, where it was in the power of his rival in a moment to make him a close prisoner. This event accordingly took place, and that through the arts and machinations of Louis himself. His design had been from the beginning to keep the duke of Burgundy constantly employed in domestic wars. For this purpose he had, before his interview with Charles, excited the inhabitants of Liege, who were subject to the duke of Burgundy, to revolt. It is most probable, that he did not imagine the effects of this treachery would so soon begin to appear. At the very time, however, that Louis was in the castle of Peronne, the people of Liege revolted, seized the bishop and governor; and having massacred great numbers of the adherents of Charles, retired with the prisoners they had made to the capital. Charles was soon informed of this massacre, with the additional circumstance, that the ambassadors of Louis were seen animating the insurgents to their work of destruction. He then flew into a transport of rage; commanded the gates of the castle to be shut and strictly guarded; denouncing the severest vengeance on the perfidious monarch who had so often deceived him. Louis, however, though greatly, and no doubt very justly, alarmed, did not neglect to take the proper methods for securing himself. He distributed large sums of money among those officers to whom he imagined the duke was most inclined to pay any regard, and by splendid promises and presents endeavoured to allay the resentment of his other enemies. At last the resentment of Charles having subsided, he entered into a treaty with the king, and concluded it upon much the same terms as those which had been agreed upon before. His resentment, however, still manifested itself so far, that he insisted upon Louis being present at the punishment he inflicted upon the inhabitants of Liege for the massacre they had committed, and of which we have already taken notice. This was agreed to: the two princes formed the siege of the city in conjunction; and, notwithstanding the obstinate defence of the people, it was at last taken by storm, and the inhabitants massacred. It was not long, however, before the new alliance was dissolved. A confederacy against Louis, whom neither promises nor treaties could bind, was formed betwixt his own brother the duke of Normandy and the duke of Burgundy; but before their measures were ripe for execution, Louis had already commenced hostilities. The duke of Burgundy, as a peer of France, was summoned to parliament; and on his refusal, the constable St Pol made himself master of St Quintin. Several other cities were soon after reduced; and Baldwin, the natural brother of Charles, corrupted by Louis, deserted his cause; and the haughty spirit of the duke was thus at last obliged to condescend to solicit a peace. This, however, was of no long duration. Charles, encouraged by the success of Edward IV. of England his brother-in-law, began once more to league against Louis with the dukes of Brittany and of Guienne; the latter being the king's brother, formerly duke of Normandy, but who had exchanged that duchy for the territory of Guienne. But while the affairs of the confederates seemed to be in a prosperous way, their prospects were suddenly overcast by the death of the duke of Guienne, which was universally supposed to have been occasioned by poison, and Louis was as universally looked upon as the author. The abbot of St Joan d'Angeli was fixed upon as the immediate perpetrator of the deed; but on the day appointed for his trial he was found strangled in his cell; and this also was with great probability supposed to have been the deed of Louis, who after the death of his brother instantly seized on the territory of Guienne, and annexed it to the dominions of France.

France.

112 A treaty between Louis and Charles.

By this unheard-of conduct of the French monarch, Charles was exasperated to such a degree, that he vowed the most dreadful vengeance against the unhappy people

France.

people of France, and threatened to sacrifice to the memory of the duke of Guienne every one who now fell into his hands. The citizens of Nesle were massacred without distinction of sex or age; Beauvis resisted his attacks; after which Charles wreaked his fury on other places. Having entered the country of Caux, he reduced the cities of Eu and St Valery, burnt Longueville, and wasted the whole country as far as Rouen. Louis, on the other hand, steady and constant in his designs, determined to dissolve the league between the duke of Brittany and Edward IV. of England. Accordingly he encamped with his army on the frontiers of Brittany; while the duke, not meeting with the assistance promised by Edward, was obliged to consent to a truce for a year; and the duke of Burgundy himself was obliged to follow his example, having committed such devastations as deprived him of all means of subsistence in the country, so that he could neither advance nor retreat. In a very little time, however, he again began to conspire with the king of England against Louis, and a powerful invasion was determined upon. Edward was to cross the sea with an army of 10,000 men, while Charles assembled all his forces to join him. The former was also to set up a claim to the crown of France, and at least to obtain the provinces of Normandy and Guienne; the duke was to have Champagne with some adjacent districts; to free his dominions from homage; and neither party was to make peace without the consent of the other. It was supposed that the duke of Brittany would naturally accede to the confederacy; and the Count de St Pol, constable of France, had engaged to deliver up the town of St Quintin and others which he occupied on the river Somme. Louis, however, still had the good fortune to avoid the storm. Charles, instead of advancing to the assistance of Edward, who had entered France at the head of 15,000 archers and 1500 men at arms, laid siege to the city of Nuiz on the Rhine; while the constable St Pol, instead of delivering up the towns as he had promised, deceived his allies, and enabled Louis to dissolve a confederacy, which, had it been vigorously maintained, might have involved him in the greatest difficulties. To procure the departure of Edward, however, he was obliged to consent to a tribute of 75,000 crowns, as well as to settle on the king himself 50,000 crowns for life; betrothing also the dauphin to the eldest daughter of the king of England. The duke of Burgundy exclaimed loudly against this treaty: but Edward persisted in his resolution; and it was accordingly executed at a place called *Pecquigny*, near Amiens; but in such a manner as showed the little confidence the two sovereigns reposed in each other. A grated barrier was erected in the middle of the bridge of Pecquigny, between the barriers of which only a man's arm could pass: the two princes appeared on the opposite sides of it; and having conferred privately, and confirmed the treaty between them, parted with many protestations of friendship; in which, probably, neither party was very sincere. A power was reserved by Edward, for the duke of Burgundy to accede to the treaty: but the latter haughtily replied, that he was able to support himself without the assistance of England; and that he would make no peace with Louis till three months after the return of Edward to his own country. To this resolution he adhered: but no sooner was the term expired, than he concluded a truce with Louis for nine years. The stipulations publicly agreed upon betwixt these two princes consisted only in some articles for the mutual advantage of their subjects; but privately they had signed others of a different nature. The constable St Pol having rendered himself obnoxious to all parties by his complicated treachery, fled to Mons in Hainault; but the duke of Burgundy had already consented to deliver him up on condition of receiving his estates and moveables as the price of his treachery.

113 Furious invasion of France by Charles of Burgundy.

114 Invasion by Edward IV. of England.

115 Louis agrees to pay an annual pension to Edward.

Thus was Louis, without any other remarkable qualification than the mere arts of falsehood and duplicity, got rid of all his enemies except the duke of Burgundy, whose growing power rendered him a constant object of jealousy and terror. His own imprudence and rashness, however, soon proved his ruin. Having rashly engaged in a war with the Swiss, he was defeated in the first engagement with that martial nation, with the loss of his military chest and baggage, with his plate and jewels, supposed to be the richest in Europe. His disappointment on this occasion was so great, that he was seized with a severe sickness, from which he had hardly recovered when he resumed his mad scheme of conquering the Swiss. Another battle ensued; in which, after an obstinate dispute, Charles was defeated with the loss of 18,000 men, himself escaping with great difficulty. This disaster was followed by the defection of most of his allies; the duke of Lorrain recovered the city of Nancy and great part of his dominions which Charles had seized; while the latter, overwhelmed with shame and disappointment, spent his time in solitude and inactivity. From this he was at last roused by the misfortunes which fell upon him in such quick succession. He now invested the city of Nancy; and in this, as well as in every other instance, he acted against the advice of his best officers; and the consequences were still more fatal than before. The duke of Lorrain advanced with a strong body of Germans to the relief of the city, while Charles had scarcely 4000 men to oppose him. His troops were therefore easily defeated, and himself, notwithstanding the most heroic efforts of valour, hurried away in the crowd. The count de Campobasso, an Italian nobleman in whom he put a great deal of confidence, but who was in reality a traitor, had deserted with about 80 men in the beginning of the engagement. He left 12 or 15 men about the duke's person, with strict orders to assassinate him in the tumult; and this order they punctually complied with; the body of Charles being found two days after the battle pierced with three wounds.

116 Charles engages in a war with the Swiss.

117 He is assassinated.

The news of Charles's death was received with the most unfeigned joy by Louis, whose sole object now was to unite the territories of the duke of Burgundy to his own. This might be done in two ways; one by a match betwixt the dauphin and Mary the heiress of Burgundy; the other, by marrying her to the duke of Angoulême, a prince of the royal blood of France, and on whom Mary had shewn some inclination to bestow herself. The king, however, to whom duplicity and falsehood seem to have been absolutely necessary, chose a third method, more agreeable to his character. The match with the dauphin was attended with such circumstances

118 Conquers Burgundy by Louis.

France. circumstances as rendered it evidently impracticable. The disparity of age was very great, the dauphin being only eight years old, and the princess twenty: the Flemings were besides very much averse from submitting to a prince whose powerful resources would enable him to oppress their liberties: but notwithstanding these unsurmountable difficulties, Louis chose to insist upon the match, at the same time that he endeavoured to make himself master of her dominions by force of arms. He addresssd circular letters to the principal cities of Burgundy; representing that the duchy had been given by King John to the male heirs of his son Philip; and that now, when these were extinct by the death of Charles, the territory reverted of course to the crown. To render this argument more effectual, he corrupted the governors of some towns; seduced the inhabitants of others to rise against their governors; whilst he himself at the head of an army, prepared to enforce obedience from those who could not be worked upon by other methods. Thus the province of Burgundy was entirely reduced; but Flanders could not be brought under subjection either by fair means, force, or fraud. In his conduct for this purpose, indeed, Louis displayed the most detestable as well as the meanest treachery and falsehood. To render Mary odious to her subjects, he negotiated with her ministers, and prevailed upon them to disclose to him some of the most important state secrets; after which he communicated their letters to the states of Flanders. This double treachery, however, did not at present answer his purpose. The two ministers whom he had betrayed were indeed put to death without mercy, and that even in the presence of their sovereign: but Mary herself was thus induced to bestow herself upon the emperor Maximilian; and Louis had the mortification to find that all his arts had contributed only to aggrandise a rival power, whom he had already sufficient cause to dread. To remedy this oversight, he entered into an alliance with Edward IV. of England, whom he had inspired with a jealousy of his brother Clarence, in order to prevent a match betwixt that nobleman and the princess Mary, which had also been in agitation. Thus a peace was concluded between the two monarchs, to continue during the life of each, and a year after.

The marriage of Mary with Maximilian effectually secured the independence of Flanders; while the return of the prince of Orange to the party of that princess extended the flames of war once more to the cities of Burgundy. The French were on the point of being totally expelled from that country, when Maximilian unexpectedly made proposals of peace. A truce was on this concluded between the two princes, but without any term limited for its duration, or without any conditions stipulated in favour of the Burgundians; so that the whole country was quickly after reduced by Louis.

1[illegible]
Tyranny and cruelty of Louis.

The king now freed from the apprehensions of foreign enemies, turned his vindictive disposition against his own subjects; over whom, under pretence of former rebellions, he exercised the most insupportable tyranny. The principal victim to his sanguinary disposition on this occasion was James d'Armagnac duke of Nemours, one of the first noblemen in the kingdom, but who had formerly appeared a zealous confederate against him in the league in which Edward and Charles were concerned. The unfortunate nobleman, knowing that vengeance was determined against him, fled to a fortress named *Carlat*, situated among the mountains of Auvergne. Here he was besieged by the Seigneur de Beaujeu, who had married Anne the daughter of Louis. The place, however, was almost impregnable to any force; so that his enemies were obliged to make the most solemn promises of safety in order to induce him to surrender himself. By these he was at last persuaded to trust himself in the hands of the faithless tyrant: who no sooner had him in his power than he shut him up in the Bastile in an iron cage, and reprimanded the judges because they had released him from this close confinement during the time of his examination. The judges reluctantly condemned him to be beheaded: but the king's cruelty extended beyond the sentence: and he ordered the two young sons of the duke, though yet in early childhood, to be placed directly under the scaffold, that they might be covered with the blood of their father. Four thousand persons are supposed to have perished upon this occasion without any form or trial: and were it not for the concurrent testimony of the historians of that age, the inhumanities and barbarities of this monarch are scarce to be credited. By these he broke the spirits of the French nobility, and gradually extended the power of the crown beyond all bounds; so that at last it was limited only by the sovereign's pleasure. Amidst all the perfidy and cruelty, however, for which this monarch is so justly to be detested, we may on some occasions remark a kind of magnanimity and generosity which we cannot but applaud. An instance of this was his supporting the house of Medici against Pope Sextus, whom he obliged to desist from his attacks, and to recal his sentence which he had fulminated against them.

120
Burgundy unsuccessfully invaded by Maximilian.

In 1479, the emperor Maximilian, who had lightly abandoned the duchy of Burgundy, when he might have reduced it, now renewed his claims when it was no longer in his power to enforce them. After a variety of actions of lesser note, and the destruction of cities on both sides, a decisive battle was fought at Guinegate. Here the Flemings were routed; but as the French pursued with too great ardour, the infantry of the enemy rallied, and the battle was renewed with great slaughter on both sides. A more decisive advantage was afterwards gained by the capture of 80 Flemish vessels, which induced that commercial people to think of peace. In the meantime, however, Louis, after a life spent in continual deceit, hypocrisy, and cruelty, received warning of his approaching end by a fit of apoplexy with which he was seized in the year 1480. He lay speechless and motionless for two days; after which he recovered in some degree, but never completely regained his health and strength. His illness, however, neither prevented him from pursuing the schemes of his ambition, nor from using the same methods as before to attain them. He seized, without any pretence, the estates of the duke of Bourbon, the only nobleman in the kingdom whose power could give him any cause of suspicion; yet, notwithstanding his assiduity for the interest of the dauphin, he kept him a kind of prisoner in the castle of Amboise, permitting none but his own servants, or persons

France. sons of the meanest rank, to have access to him. He banished his own consort, the mother of the dauphin, to Savoy, and endeavoured to inspire the prince with aversion towards her. By the death of Charles, the titular king of Naples, and the last of the second house of Anjou, he became master of the county of Provence; but his satisfaction on this occasion was marred by a second stroke of apoplexy. Still, however, he revived, and, with his recovery, again began to pursue his ambitious intrigues. The death of Mary of Burgundy, who perished by a fall from her horse, inspired him with new views; and he betrothed his son to the infant daughter of the emperor. Thus he offended Edward IV. of England, whose eldest daughter Elizabeth had been previously contracted to the dauphin; and a war would have undoubtedly ensued, had it not been for the death of the king of England. This was followed in no long time after by that of

121 Death of Louis XI. Louis himself, who had in vain exhausted the skill of the physician, and wearied the clerical order with prayers and processions to avert the impending stroke. He expired in the year 1483, after a reign of 23 years; during which he was detested by his subjects, whom he had continually oppressed; and equally dreaded and hated by his neighbours, whom he had constantly deceived: notwithstanding which he obtained the title of *Most Christian* from his holiness, which his successors have ever after retained.

Notwithstanding the dark character of this prince, it is undoubtedly to be allowed, that he laid the foundations of the future greatness of France. By his arts he deprived the common people of their liberty, depressed the power of the nobility, established a standing army, and even induced the states to render many taxes perpetual, which formerly were only temporary, in order to support the army which was to keep themselves in slavery. From this time the people were accustomed to submit entirely to the voice of their sovereign as their only legislator; and being always obedient in matters of the greatest consequence, they cheerfully contributed whatever sums were required to fulfil the king's pleasure.

122 Reign of Charles VIII. Charles VIII. who succeeded his father Louis XI. in 1483, was only 14 years of age at the time of his father's death: but though he might, even at that age, have ascended the throne without any material violation of the laws of France, yet it was judged necessary to have a regent, on account of the king's delicacy of constitution and want of education. Three competitors appeared as candidates for this important trust, viz. John duke of Bourbon, a prince of the blood, and who had, till the age of 60, maintained the most unblemished character; Louis duke of Orleans, presumptive heir to the crown, but who from his being only 20 years old himself, seemed incapacitated on that account from undertaking such an important office: the third competitor was Anne, the eldest daughter of Louis, to whom the latter had in

123 Regency of the Lady Beaujeu. the last moments of his life committed the charge of the kingdom, with the title of governess. The claim of this lady was supported by the assembly of the states general at Tours; and though she was only entered into the 22d year of her age, it appears that the office could not have been more properly bestowed. Being married to Peter of Bourbon, sire of Beaujeu, her present title was *the Lady of Beaujeu*; but she appears to have acted entirely independent of her husband, who was but of a modera e capacity; and indeed had been recommended to her by Louis on account of his slender abilities, lest by any other match the house of Bourbon should be too much aggrandized. Her first step was to ingratiate herself with the people, by some popul r acts; among which one was to punish the instruments of her father's cruelties. One of these, named Oliver le Dian, who, from the station of a barber, had raised himself to the confidence and favour of the king, and had distinguished himself by the invention of new modes of torture, was publicly hanged. Another, named Jean Doyac, who by continual acts of violence and rapacity had oppressed the people, was condemned, after being whipped in all the open places or squares of Paris, to have one of his ears cut off, and his tongue pierced with a hot iron; after which he was conveyed to his native city of Montferrand, where he was a ain whipped, and his other ear cut off; after which his estates, as well as those of Oliver, were confiscat . Jacques Coitier, the physician of Louis, who had availed himself of the terror of death with which the king was strongly influenced, to extort great sums of money from him, was ordered to answer for the immense wealth he had acquired; but he averted the danger by paying a fine of 50,000 crowns.

Thus the lady de Beaujeu gained the affection of the people at large; and was equally successful in gaining over those who were averse to her government. The duke of Bourbon was made constable, an office which he had long desired; but the duke of Orleans behaved in such a manner as to exclude all hopes of favour. Incensed at the determination of a trifling dispute at tennis against him, by the lady Beaujeu, he exclaimed, that whoever had decided in that manner "was a liar if a man, or a strumpet if a woman." After this furious declaration he fled to the castle of Beaujency, where, however, he was soon forced to surrender. He then applied to Henry VII. of England, who had newly ascended the throne of England; but that prince, naturally slow and cautious, did not pay much attention to his proposals; on which he next made his application to the court of Britanny. Here he was received 124 Duke of Orleans flies to Britany.
with great marks of esteem, and began to entertain hopes of marrying the daughter of the duke; but being looked upon with a jealous eye by the nobility, they entered into secret negotiations with Anne, and even solicited her to invade the conntry. In these negotiations, however, they stipulated that only a certain number of troops should enter the province, and that no fortified place should remain in the hands of the French; which conditions were indeed agreed to by the regent, though she determined to keep them no longer than it answered her purpose. In pursuance of 125 That country invaded by the French.
this resolution, Brittany was invaded at once by four armies, each of them superior to the stipulated number, who quickly made themselves masters of the most important places in the country; while the troops of the duke retired in disgust, leaving them to pursue their conquests as they pleased. Finding at last, however, that the entire subjection of their country was determined upon, the nobility began to exert themselves in defence of it; and, inflamed by the enthusiasm of liberty

France.

ty, they raised an army of 60,000 men. By these the French were compelled to abandon the siege of Nantz; but this proved only a transient gleam of success. Anne persevered in her design of completing the conquest of the country, and the state of Europe at that time favoured the design. Of all the European states, England alone was then capable of affording any effectual assistance: and the slow caution of Henry prevented him from giving the assistance which for his own interest he ought to have done. Thus the Bretons were left to defend themselves the best way they could; and having ventured a battle, they were entirely defeated, and most of their leaders taken prisoners. A small body of English, under the command of Lord Woodville, who assisted them, were entirely cut in pieces. The duke soon after died by a fall from his horse, leaving his dominions to his daughter Anne, at that time only 13 years of age. A marriage was negotiated betwixt this princess and Maximilian king of the Romans, who had been married to Mary of Burgundy; but by reason of the poverty of that prince it was never completed. The lady Beaujeu, then finding that the absolute conquest of Brittany would still be a difficult matter, determined to conclude a marriage betwixt the young king of France and the duchess, though the former had already been married to Margaret of Austria, the daughter of Maximilian. This marriage indeed had not been consummated by reason of the tender age of the princess; but she had been sent to Paris for her education, and had for several years been treated as queen of France. In 1491, however, Margaret was sent back to her father: Anne of Brittany for a long time refused to violate the engagements into which she had entered; but at last, finding herself distressed on all sides, and incapable of resisting the numerous forces of France with which she was pressed, she reluctantly consented to the match, and the nuptials were celebrated the same year at Langeais in Touraine.

126
Marriage between the king of France and duchess of Brittany.

Maximilian, whose poverty had prevented him from giving any assistance to his bride, or even from coming to see her, enraged at the double disgrace he had suffered, began, when too late, to think of revenge. France was now threatened with an invasion from the united forces of Austria, Spain, and England. But this formidable confederacy was soon dissipated.—Henry, whose natural avarice had prevented him from giving the necessary assistance, was bought off with money: the immediate payment of 745,000 crowns, and the promise of 25,000 annually ever after, persuaded him to retire into his own country. Ferdinand king of Spain had the counties of Roussillon and Cerdagne restored to him; while Maximilian was gratified by the cession of part of Artois, which had been acquired by Louis XI.

127
His expedition into Italy, and surprising success.

The young king of France agreed to these terms the more readily, that he was impatient to undertake an expedition into Italy, in order to conquer the kingdom of Naples, to which he claimed a right. Most of his counsellors were against the expedition; but the king was inflexible, even though Ferdinand king of Naples offered to do homage for his kingdom, and pay him a tribute of 50,000 crowns a-year. He appointed Peter duke of Bourbon regent in his absence; after which he set out on his expedition with very few troops and very little money. By the way he fell ill of the smallpox, but in a short time recovered, and entering Italy with only 6000 horse and 12,000 foot, he was attended with the most surprising success, traversing the whole country in six weeks, and becoming master of the kingdom of Naples in less than a fortnight. Such extraordinary good fortune seemed miraculous; and he was reckoned an instrument raised up by God to destroy the execrable tyrants with which Italy was at that time infested. Had Charles made use of this prepossession in his favour, and acted up to the character generally given him, he might have raised his name as high as any hero of antiquity. His behaviour, however, was of a very different nature. He amused himself with feasts and shows; and leaving his power in the hands of favourites, they abandoned it to whoever would purchase titles, places, or authority, at the rates they imposed; and the whole force he proposed to leave in his new conquered dominions amounted to no more than 4000 men.

But while Charles was thus losing his time, a league was concluded against him at Venice; into which entered the pope, the emperor Maximilian, the archduke Philip, Ludovic Sforza, and the Venetians. The confederates assembled an army of 40,000 men, commanded by Francis marquis of Mantua; and they waited for the king in the valley of Fornova, in the duchy of Parma, into which he descended with 9000 men. On the 6th of July 1495 he attacked the allies; and, notwithstanding their great superiority, defeated them, with the loss of only 80 of his own men. Thus he got safe to France; but his Italian dominions were lost almost as soon as he departed. Some schemes were proposed for recovering these conquests; but they were never put in execution, and the king died of an apoplexy in 1498.

128
His death.

The premature death of this monarch in the 28th year of his age, was supposed to have been owing to his irregular life, and particularly his attachment to women; which had for some time impaired his health, and brought on evident symptoms of his approaching dissolution. At last he relinquished his irregularities, and retired with the queen to the castle of Ambloise. Here in passing through a low door he struck his head with violence against the top. No unfavourable symptom appeared at the time; but soon afterwards, as he conversed with his confessor, and avowed his design of observing the nuptial fidelity he owed to the queen, he suddenly fell backward in a fit of apoplexy. He recovered his voice three times, and uttered some expressions of devotion; but instantly relapsed, and in a short time expired, notwithstanding every assistance that could be given. He was greatly celebrated for his sweet temper and agreeable disposition, which procured him the surnames of the *Affable* and *Courteous*. Two of his domestics are said to have died of grief after his death, and his widow abandoned herself to the most pungent sorrow for *two days*.

By the death of Charles VIII. the throne of France passed from the direct line of the house of Valois, and Louis duke of Orleans succeeded to the throne. At the time of his accession he was in his 36th year, and had long been taught prudence in the school of adversity. During the administration of the lady Beaujeu, he had been, as we have already observed, constantly in disgrace; and after his connexions with the duke

duke of Brittany, had spent a very considerable time in prison; and though afterwards set at liberty by Charles, he had never possessed any share of that monarch's confidence or favour. Towards the conclusion of that reign, he fell under the displeasure of the queen; and had afterwards continued at his castle of Blois till he was called from thence to the possession of the kingdom. He had been married in early life, and against his will, to Jane the youngest daughter of Louis XI. a princess of an amiable disposition, but deformed in her person, and supposed to be incapable of bearing children. Afterwards he entertained thoughts of having his marriage dissolved, and was supposed to possess the affection of the duchess of Brittany, before she became queen of France. After the death of her husband, that princess retired to Brittany, where she pretended to assume an independent sovereignty; but Louis having got his marriage with Jane dissolved by Pope Alexander VI. quickly after made proposals to the queen-dowager, which on her part were accepted without hesitation; though it was stipulated, that if she should have two sons, the younger should inherit the duchy of Brittany.

As Louis, while duke of Orleans, had some pretensions to the kingdom of Naples, he instantly set about realizing them by conquest. On his accession, he found matters in that country much more favourable to his designs than formerly. The pope, Alexander VI. was very much in his interests, from the hopes of getting his son Cæsar Borgia provided for: he had conciliated the friendship of the Venetians by promising them a part of the Milanese; he concluded a truce with the archduke Philip; and renewed his alliances with the crowns of England, Scotland, and Denmark.

120 Expedition of Louis XII. into Italy.

He then entered Italy with an army of 20,000 men; and being assisted by the Venetians, quickly conquered one part of the duchy, while they conquered the other, the duke himself being obliged to fly with his family to Inspruck. He then attacked Ferdinand of Spain with three armies at once, two to act by land, and one by sea; but none of these performing any thing remarkable, he was obliged to evacuate the kingdom of Naples in 1504.

In 1506, the people of Genoa revolted; drove out the nobility; chose eight tribunes; and declared Paul Nuova, a silk dyer, their duke: after which they expelled the French governor, and reduced a great part of the Riviera. This occasioned Louis's return into Italy; where, in 1507, he obliged the Genoese to surrender at discretion: and, in 1508, entered into the league of Cambray, with the other princes who at that time wanted to reduce the overgrown power of the Venetians. Pope Julius II. who had been the first contriver of this league, very soon repented of it; and declared, that if the Venetians would restore the cities of Faenza and Rimini, which had been unjustly taken from him, he would be contented. This was refused; and in 1509, the forces of the republic received such an entire defeat from Louis, that they agreed to restore not only the two cities demanded by Pope Julius, but whatever else the allies required.

The pope now, instead of executing his treaties with his allies, made war on the king of France without the least provocation. Louis called an assembly of his clergy; where it was determined, that in some cases it was lawful to make war upon the pope; upon which the king declared war against him, and committed the care of his army to the Marshal de Trivulce. He soon obliged the pope to retire into Ravenna; and in 1511, Gaston de Foix, duke of Nemours, gained a great victory at Ravenna, but was himself killed in the engagement. After his death the army was disbanded for want of pay; and the French affairs in Italy, and everywhere else, fell into great confusion. They recovered the duchy of Milan, and lost it again in a few weeks. Henry VIII. of England invaded France, and took Terruenne and Tournay; and the Swiss invaded Burgundy with an army of 25,000 men. In this desperate situation of affairs the queen died, and Louis put an end to the opposition of his most dangerous enemies by negotiating marriages. To Ferdinand of Spain he offered his second daughter for either of his grandsons, Charles or Ferdinand; and to renounce, in favour of that marriage, his claims on Milan and Genoa. This proposal was accepted; and Louis himself married the princess Mary, sister to Henry VIII. of England. This marriage he did not long survive, but died on the 2d of January 1514; and was succeeded by Francis I. count of Angoulesme, and duke of Bretagne and Valois.

130 His marriage with the princess Mary of England, and death.

131 Francis I. invades Italy.

The new king was no sooner seated on the throne, than he resolved on an expedition into Italy. In this he was at first successful, defeating the Swiss at Marignon, and reducing the duchy of Milan. In 1518, the emperor Maximilian dying, Francis was very ambitious of being his successor, and thereby restoring to France such a splendid title, which had been so long lost. But Maximilian, before his death, had exerted himself so much in favour of Charles V. of Spain, that Francis found it impossible to succeed; and from that time an irreconcileable hatred took place between the two monarchs. In 1521, this ill will produced a war; which, however, might perhaps have been terminated, if Francis could have been prevailed upon to restore the town of Fontarabia, which had been taken by his admiral Bonivet: but this being refused, hostilities were renewed with greater vigour than ever; nor were they concluded till France was brought to the very brink of destruction. The war was continued with various success till the year 1524; when Francis having invaded Italy, and laid siege to Pavia, he was utterly defeated before that city, and taken prisoner on the 24th of February.

132 Defeated and taken prisoner.

This disaster threw the whole kingdom into the utmost confusion. The Flemish troops made continual inroads; many thousand boors assembled in Alsace, in order to make an invasion from that quarter; Henry VIII. had assembled a great army, and threatened the kingdom on that side also; and a party was formed in the kingdom, in order to dispossess the duchess of the regency, and confer it upon the duke de Vendosme. This prince, however, who, after the constable, was the head of the house of Bourbon, went on purpose to Lyons, where he assured the regent that he had no view but for her service, and that of his country; upon which he formed a council of the ablest men of the kingdom, and of this she made him president. The famous Andrew Doria sailed with the French galleys to take on board the remains of the French troops under the duke of Alva, whom he landed safely in France. Those who escaped out of the Milanese

France.

Milanese also made their way back again as well as they could. Henry VIII. under the influence of Cardinal Wolsey, resolved not to oppress the oppressed: he therefore assured the regent that she had nothing to fear from him; and at the same time advised her not to consent to any treaty by which France was to be dismembered. To the emperor, however, he used another language. He told him, that the time was now come when this puissant monarchy lay at their mercy; and therefore, that so favourable an opportunity should not be let slip: that, for his part, he should be content with Normandy, Guienne, and Gascony, and hoped the empire would make no scruple of owning him king of France: adding, that he expected the emperor would make a right use of his victory, by entering Guienne in person; in which case he was ready to bear half the expence of the war. He foresaw what fell out; the emperor was alarmed at these conditions, and did not care to have him for a neighbour; for which reason he agreed to a truce with the regent for six months. In Picardy the Flemings were repulsed; and the count de Guise, with the duke of Lorrain, had the good fortune, with a handful of troops, to defeat and cut to pieces the German peasants.

[1]33 Francis I. carried to Madrid, where he signs a disadvantageous treaty;

In the mean time, Francis was detained in captivity in Italy: but being wearied of his confinement in that country, and the princes of Italy beginning to cabal for his deliverance, he was carried to Madrid; where, on the 14th of January 1525, he signed a treaty, the principal articles of which were, That he should resign to the emperor the duchy of Burgundy in full sovereignty; that he should desist from the homage which the emperor owed him for Artois and Flanders; that he should renounce all claim to Naples, Milan, Asti, Tournay, Lisle, and Hesden, &c.; that he should persuade Henry d'Albert to resign the kingdom of Navarre to the emperor, or at least should give him no assistance; that within 40 days he should restore the duke of Bourbon and all his party to their estates; that he should pay the king of England 500,000 crowns which the emperor owed him; that when the emperor went to Italy to receive the Imperial crown, he should lend him 12 galleys, four large ships, and a land army, or instead of it 200,000 crowns.

All these articles the king of France promised on the word and honour of a prince to execute; or, in case of non-performance, to return prisoner into Spain. But, notwithstanding these professions, Francis had already protested before certain notaries and witnesses in whom he could trust, that the treaty he was about to sign was against his will, and therefore null and void. On the 21st of February, the emperor thought fit to release him from his prison, in which he had been closely confined ever since his arrival in Spain; and after receiving the strongest assurances from his own mouth, that he would literally fulfil the terms of the treaty, sent him under a strong guard to the frontiers, where he was exchanged for his two eldest sons, who were to remain as hostages for his fidelity.

and breaks it.

When the king returned to his dominions, his first care was to get himself absolved by the pope from the oaths he had taken; after which he entered into a league with the pontiff, the Venetians, the duke of Milan, and the king of England, for preserving the peace of Italy. In the month of June, he publicly received remonstrances from the states of Burgundy; in which they told him, without ceremony, that by the treaty of Madrid he had done what he had no right to do, in breach of the laws and his coronation oath; adding, that if he persisted in his resolution of throwing them under a foreign yoke, they must appeal to the general states of the kingdom. At these remonstrances the viceroy of Naples and the Spanish ministers were present. They perceived the end which the king aimed at, and therefore expostulated with him in pretty warm terms. At last the viceroy told him, that he had now nothing left but to keep his royal word in returning to the castle of Madrid, as his predecessor John had done in a like case. To this the king replied, that King John acted rightly; that he returned to a king who had treated him like a king; but that at Madrid he had received such usage as would have been unbecoming to a gentleman: that he had often declared to the emperor's ministers, that the terms they extorted from him were unjust and impracticable: but that he was still willing to do all that was fit and reasonable; and to ransom his sons at the rate of two millions of gold, in lieu of the duchy of Burgundy.

Hitherto the treaty for the tranquillity of Italy had been kept secret, in hopes that some mitigation of the treaty of Madrid would have been obtained; but now it was judged expedient to publish it, though the viceroy of Naples and the Spanish lords were still at the French court; and the emperor was to be admitted into it, provided he accepted the king's offer of two millions for the release of his children, and left the duke of Milan and other Italian princes in quiet possession of their dominions. It is the common misfortune of all leagues, that the powers who enter into them keep only their own particular interests in view, and thus defeat the general intention of the confederacy. This was the case here. The king's great point was to obtain his children upon the terms he had proposed; and he was desirous of knowing what hopes there were of that, before he acted against the monarch who had them in his power. Thus the duke of Milan and the pope were both sacrificed. The former was obliged to surrender to the duke of Bourbon, and the latter was surprised by the Colonnas; both of which disasters would have been prevented if the French succours had entered Italy in time. See ITALY.

According to an agreement which had been made between Francis and Henry, their ambassadors went into Spain, attended each of them by a herald, in order to summon the emperor to accept the terms which had been offered him; or, in case of refusal, to declare war. It seems the emperor's answer was foreseen in the court of France; and therefore the king had previously called together an assembly of the notables; that is, persons of the several ranks of his people in whom he could confide. To them he proposed the great question, Whether he was bound to perform the treaty of Madrid? or, Whether if he did not perform it, he was obliged in honour to return to Spain? To both these questions, the assembly answered in the negative: they said, that Burgundy was united to the crown of France, and that he could not separate it by his own authority; that his person also was the property of the public, of which therefore he could not dispose; but for the two millions, which they looked upon

France. upon as a just equivalent, they undertook that it should be raised for his service. When the ambassadors delivered their propositions, Charles treated the English herald with respect, and the French one with contempt; which produced a challenge from Francis to the emperor †. All differences, however, were at last

135 Treaty of Cambray. adjusted; and a treaty was concluded at Cambray, on the 5th of August 1528. By this treaty, instead of the possession, the emperor contented himself with reserving his right to the duchy of Burgundy, and the two millions of crowns already mentioned. Of these he was to receive 1,200,000 in ready money: the prince's lands in Flanders belonging to the house of Bourbon were to be delivered up; these were valued at 400,000 more: and the remaining 400,000 were to be paid by France in discharge of the emperor's debt to England. Francis was likewise to discharge the penalty of 500,000 crowns which the emperor had incurred, by not marrying his niece the princess Mary of England; and to release a rich *fleur-de-lis* which had been many years before pawned by the house of Burgundy for 50,000 crowns. The town and castle of Hesden were also yielded; together with the sovereignty of Flanders and Artois, and all the king's pretensions in Italy. As for the allies of France, they were abandoned to the emperor's mercy, without the least stipulation in their favour; and Francis himself protested against the validity of the treaty before he ratified it, as did also his attorney-general before he registered it in parliament; but both of them with the greatest secrecy imaginable.

† See *Duel*.

Nothing farther of much consequence happened during the remainder of the reign of Francis I. The war was soon renewed with Charles, who made an invasion

136 Francis dies and is succeeded by Henry II. into France, but with very bad success; nor was peace fully established but by the death of Francis, which happened on the 3d of March, 1547. He was succeeded by his son Henry II. who ascended the throne that very day on which he was 29 years of age. In the beginning of his reign, an insurrection happened in Guienne, owing to the oppressive conduct of the officers who levied the salt tax. The king despatched against the insurgents two bodies of troops; one commanded by the duke of Aumale son to the duke of Guise, the other by the constable. The first behaved with the greatest moderation, and brought back the people to their duty without making many examples: the other behaved with the utmost haughtiness and cruelty; and though the king afterwards remitted many of his punishments, yet from that time the constable became odious to the people, while the family of Guise were highly respected.

137 Henry persecutes the Protestants. In 1548, the king began to execute the edicts which had been made against the Protestants with the utmost severity; and, thinking even the clergy too mild in the prosecution of heresy, erected for that purpose a chamber composed of members of the parliament of Paris. At the queen's coronation, which happened this year, he caused a number of Protestants to be burned, and was himself present at the spectacle. He was, however, so much shocked, that he could never forget it; but complained, as long as he lived, that, at certain times, it appeared before his eyes, and troubled his understanding.

In 1549, a peace being concluded with England, the king purchased Boulogne from the latter, for the sum of 400,000 crowns; one half to be paid on the day of restitution, and the other a few months after. Scotland was included in the treaty, and the English restored some places they had taken there. This was the most advantageous peace that France had hitherto made with England; the vast arrears which were due to that crown being in effect remitted; and the pension, which looked so like tribute, not being mentioned, was in fact extinguished. The earl of Warwick himself, who had concluded the peace, was so sensible of the disgrace suffered by his nation, on this occasion, that he pretended to be sick, in order to avoid setting his hand to such a scandalous bargain. 138 Advantageous treaty with England.

This year, an edict was made to restrain the extravagant remittances which the clergy had been in use of making to the court of Rome, and for correcting some other abuses committed by the papal notaries. With this edict Pope Julius III. was highly displeased; and the following year (1550) war was declared by the king of France against the pope and the emperor. The pretence was, that Henry protected Octavio Farnese duke of Parma, whom the pope was desirous of depriving of his dominions. In this war the king was threatened with the censures of the church, more especially when it was known that he had entered into an alliance with the Turks, and a Turkish fleet entered the Mediterranean, where they threatened the isle of Gozo, and made descents upon Sicily. Henry, however, strongly denied any such connexion, and insisted that the emperor had given them sufficient provocation: but be that as it will, the emperor soon found himself in such danger from these new enemies, that he could not support the pope as he intended, who on that account was obliged to sue for peace. After this the king continued the war against the emperor with success; reducing the cities of Toul, Verdun, and Metz. He then entered the country of Alsace, and reduced all the fortresses between Hagenau and Wissenburg. He failed, however, in his attempt on Strasburg; and was soon after obliged by the German princes and the Swiss to desist from farther conquests on that side. This war continued with very little interruption, and as little success on the part of the French, till the year 1557, when a peace was concluded; and soon after, the king was killed at a tournament by one Count de Montgomery, who was reckoned one of the strongest knights in France, and who had done all he could to avoid this encounter with the king. 139 Henry's success against the emperor. 140 He is killed at a tournament.

The reign of his successor Francis II. was remarkable only for the persecution of the Protestants; which became so grievous, that they were obliged to take up arms in their own defence. This occasioned several civil wars, the first of which commenced in the reign of Charles IX. who succeeded to the throne in 1560. This first war continued till the year 1562, when a peace was concluded, by which the Protestants were to have a free pardon and liberty of conscience. In 1565, the war broke out anew, and was continued with very little interruption till 1569, when peace was again concluded upon very advantageous terms for the Protestants. After this King Charles, who had now taken the government into his hands, caressed the Protestants in an extraordinary manner. He invited to court 141 Civil wars with the Protestants.

court the admiral Coligni, who was the head of the Protestant party; and cajoled him so, that he was lulled into a perfect security, notwithstanding the many warnings given him by his friends, that the king's fair speeches were by no means to be trusted; but he had soon reason to repent his confidence. On the 22d of August 1571, as he was walking from the court to his lodgings, he received a shot from a window, which carried away the second finger of his right hand, and wounded him grievously in the left arm. This he himself ascribed to the malice of the duke of Guise, the head of the Catholic party. After dinner, however, the king went to pay him a visit, and amongst others made him this compliment: "You have received the wound, but it is I who suffer:" desiring at the same time that he would order his friends to quarter about his house, and promising to hinder the Catholics from entering that quarter after it was dark. This satisfied the admiral of the king's sincerity; and hindered him from complying with the desires of his friends, who would have carried him away, and who were strong enough to have forced a passage out of Paris if they had attempted it.

142 Dreadful massacre of the Protestants.

In the evening, the queen mother, Catharine de Medicis, held a cabinet council to fix the execution of the massacre of the Protestants, which had been long meditated. The persons of which this council was composed, were, Henry duke of Anjou, the king's brother; Gonzagua duke of Nevers; Henry of Angoulesme grand prior of France, and bastard brother of the king; and marshal de Tavannes; and Albert de Gondi, count de Retz: the direction of the whole was given to the duke of Guise, to whom the administration had been entirely confided during the former reign. The guards were appointed to be in arms, and the city officers were to dispose the militia to execute the king's orders, of which the signal was the ringing of a bell near the Louvre. Some say, that when the hour approached, which was that of midnight, the king grew undetermined: that he expressed his horror at shedding so much blood, especially considering that the people whom he was going to destroy were his subjects, who had come to the capital at his command, and in confidence of his word; and particularly the admiral, whom he had detained so lately by his caresses. The queen mother, however, reproached him with his cowardice, and represented to him the great danger he was in from the Protestants; which at last induced him to consent. According to others, however, the king himself urged on the massacre; and when it was proposed to him to take off only a few of the heads, he cried out, "If any are to die, let there not be one left to reproach me with breach of faith."

As soon as the signal was given, a body of Swiss troops of the Catholic religion, headed by the duke of Guise, the chevalier d'Angoulesme, accompanied by many persons of quality, attacked the admiral's house. Having forced open the doors. the foremost of the assasins rushed into the apartment; and one of them asked if he was Coligni? To this he answered that he was; adding, "Young man, respect these gray hairs:" to which the assasin replied by running him through the body with a sword. The duke of Guise and the chevalier growing impatient below stairs, cried out to know if the business was done; and being told that it was, commanded that the body should be thrown out at the window. As soon as it fell on the ground, the chevalier, or (as some say) the duke of Guise, wiping the blood off the face, kicked it with his foot. The body was then abandoned to the fury of the populous; who, after a series of indignities, dragged it to the common gallows, to which they chained it by the foot, the head being cut off and carried to the queen mother; who, it is said, caused it to be embalmed and sent to Rome. The king himself went to see the body hang upon the gibbet; where a fire being kindled under it, part was burnt, and the rest scorched. In the Louvre, the gentlemen belonging to the king of Navarre and the prince of Condé were murdered under the king's eye. Two of them, wounded and pursued by the assasins, fled into the bedchamber of the queen of Navarre and jumped upon her bed, beseeching her to save their lives; and as she went to ask this favour of the queen mother, two more, under the like circumstances rushed into the room, and threw themselves at her feet. The queen mother came to the window to enjoy these dreadful scenes; and the king, seeing the Protestants who lodged on the other side of the river, flying for their lives, called for his long gun, and fired upon them. In the space of three or four days, many thousands were destroyed in the city of Paris, by the most cruel deaths which malice itself could invent. Peter Ramus, professor of philosophy and mathematics, after being robbed of all he had, his belly being first ripped open, was thrown out of a window. This so much affected Denis Lambin, the king's professor, that, though a zealous Catholic, he died of terror. The first two days, the king denied it was done by his orders, and threw the whole blame on the house of Guise: but, on the 28th of August, he went to the parliament, avowed it, was complimented upon it, and directed a process against the admiral, by which he was stigmatized as a traitor. Two innocent gentlemen suffered as his accomplices in a pretended plot against the life of the king, in order to set the crown on the head of the prince of Condé. They were executed by torch light; and the king and the queen mother (with the king of Navarre and the prince of Condé by force) were spectators of this horrid deed; and they also assisted at the jubilee to thank God for the execution of such an infamous design.

The massacre was not confined to the city of Paris alone. On the eve of St Bartholomew, orders had been sent to the governors of provinces to fall upon the Protestants themselves, and to let loose the people upon them; and though an edict was published before the end of the week, assuring them of the king's protection, and that he by no means designed to exterminate them because of their religion, yet private orders were sent, of a nature directly contrary; in consequence of which, the massacre, or (as, in allusion to the Sicilian vespers†, it is now styled) the *Matins of Paris*, were repeated in Meaux, Orleans, Troyes, Angers, Thoulouse, Rouen, and Lyons; so that in the space of two months 30,000 Protestants were butchered. The next year Rochelle, the only strong fortress which the Protestants held in France, was besieged, but was not taken without the loss of 24,000 of the Catholics who besieged it. After this a pacification ensued on terms favourable

† See Sicily.

France. favourable to the Protestants, but to which they never trusted.

This year the duke of Anjou was elected king of Poland, and soon after set out to take possession of his new kingdom. The king accompanied him to the frontiers of the kingdom; but during the journey was seized with a slow fever, which from the beginning had a very dangerous appearance. He lingered for some time under the most terrible agonies both of body and mind; and at last died on the 30th of May 1572, having lived 24 years, and reigned 13. It is said, that after the dreadful massacre above mentioned, this prince had a fierceness in his looks, and a colour in his cheeks, which he never had before. He slept little, and never sound. He waked frequently in agonies, and had soft music to compose him again to rest.

143 Death of Charles IX.

144 Henry III.

During the first years of the reign of Henry III. who succeeded his brother Charles, the war with the Protestants was carried on with indifferent success on the part of the Catholics. In 1575, a peace was concluded, called by way of eminence the *Edict of Pacification*. It consisted of no fewer than 63 articles; the substance of which was, that liberty of conscience, and the public exercise of religion, were granted to the reformed, without any other restriction than that they should not preach within two leagues of Paris or any other part where the court was; party chambers erected in every parliament, to consist of equal numbers of Catholics and Protestants, before whom all judgments were to be tried; the judgments against the admiral, and, in general, all who had fallen in the war or been executed, were reversed; and eight cautionary towns were given to the Protestants.

145 Catholic league formed.

The edict gave occasion to the Guises to form an association, in defence, as was pretended, of the Catholic religion, afterwards known by the name of the *Catholic League*. In this league, though the king was mentioned with respect, he could not help seeing that it struck at the very root of his authority: for, as the Protestants had already their chiefs, so the Catholics were, for the future, to depend entirely upon the chief of the league; and were, by the very words of it, to execute whatever he commanded, for the good of the cause, against any, without exception of persons. The king, to avoid the bad effects of this, by the advice of his council declared himself head of the league; and of consequence recommenced the war against the Protestants, which was not extinguished as long as he lived.

The faction of the duke of Guise, in the mean time, took a resolution of supporting Charles cardinal of Bourbon, a weak old man, as presumptive heir of the crown. In 1584 they entered into a league with Spain, and took up arms against the king; and though peace was concluded the same year, yet in 1587 they again proceeded to such extremities, that the king was forced to fly from Paris. Another reconciliation was soon after effected; but it is generally believed that the king from this time resolved on the destruction of Guise. Accordingly, finding that this nobleman still behaved towards him with his usual insolence, the king caused him to be stabbed, as he was coming into his presence, by his guards, on the 23d of December 1587. The king himself did not long survive him; being stabbed by one James Clement, a Jacobine monk, on the first of August 1588. His wound at first was not thought mortal; but his frequent swooning quickly discovered his danger; and he died next morning, in the 39th year of his age, and 16th of his reign.

146 Duke of Guise murdered, and likewise the king.

Before the king's death, he nominated Henry Bourbon king of Navarre for his successor on the throne of France; but as he was a Protestant, or at least one who greatly favoured their cause, he was at first owned by very few except those of the Protestant party. He met with the most violent opposition from the members of the Catholic league; and was often reduced to such straits, that he went to people's houses under colour of visits, when in reality he had not a dinner in his own. By his activity and perseverance, however, he was at last acknowledged throughout the whole kingdom, to which his abjuration of the Protestant religion contributed not a little. As the king of Spain had laid claim to the crown of France, Henry no sooner found himself in a fair way of being firmly seated on the throne, than he formally declared war against that kingdom; in which he at last proved successful, and in 1597 entered upon the quiet possession of his kingdom.

147 Henry IV.

The king's first care was to put an end to the religious disputes which had so long distracted the kingdom. For this purpose he granted the famous edict, dated at Nantz, April 13. 1598. It re-established, in a most solid and effectual manner, all the favours that had ever been granted to the reformed by other princes; adding some which had not been thought of before, particularly the allowing them a free admission to all employments of trust, profit, and honour; the establishing chambers in which the members of the two religions were equal; and the permitting their children to be educated without constraint in any of the universities. Soon after, he concluded peace with Spain upon very advantageous terms. This gave him an opportunity of restoring order and justice throughout his dominions; of repairing all the ravages occasioned by the civil war; and abolishing all those innovations which had been made, either to the prejudice of the prerogatives of the crown or the welfare of the people. His schemes of reformation, indeed, he intended to have carried beyond the boundaries of France. If we may believe the duke of Sully, he had in view no less a design than the new-modelling of all Europe. He imagined that the European powers might be formed into a kind of Christian republic, by rendering them as nearly as possible of equal strength; and that this republic might be maintained in perpetual peace, by bringing all their differences to be decided before a senate of wise, disinterested, and able judges: and then he thought it would be no difficult matter to overturn the Ottoman empire. The number of these powers was to be 15; viz. the Papacy; the empire of Germany; France; Spain; Hungary; Great Britain; Bohemia; Lombardy; Poland; Sweden; Denmark; the republic of Venice; the States General; the Swiss Cantons; and the Italian commonwealth, which was to comprehend the states of Florence, Genoa, Lucca, Modena, Parma, Mantua, and Monaco. In order to render the states equal, the empire was to be given to the duke of Bavaria; the kingdom of Naples to the pope; that of Sicily

148 Edict of Nantz

149 The king proposes new-modelling the European powers.

Sicily to the Venetians; Milan to the duke of Savoy, who, by his acquisition, was to become king of Lombardy; the Austrian Low Countries were to be added to the Dutch republic; Franche Compte, Alsace, and the country of Trent, were to be given to the Swiss. With a view, is is now thought, of executing this grand project, but under pretence of reducing the exorbitant power of the house of Austria, Henry made immense preparations both by sea and land; but if he really had such a design, he was prevented by death from attempt-
150 He is murdered. ing to execute it. He was stabbed in his coach by one Ravilliac, on the 12th of May 1608.

On the death of Henry IV. the queen mother assumed the regency. Ravilliac was executed, after suffering horrid tortures. It is said that he made a confession, which was so written by the person who took it down, that not one word of it could ever be read, and thus his instigators and accomplices could never
151 Louis XIII. be discovered. The regency, during the minority of Louis XIII. was only remarkable for cabals and intrigues of the courtiers. In 1617, the king assumed the government himself, banished the queen mother to Blois, caused her favourite Marshal d'Ancre to be killed, and chose for his minister the famous Cardinal Richelieu. In 1620, a new war broke out between the Catholics and Protestants, which was carried on with the greatest fury on both sides; and we may judge of the spirit which actuated both parties by what happened at Negreplisse, a town in Quercy. This place was besieged by the king's troops, and it was resolved to make an example of the inhabitants. The latter, however, absolutely refused to surrender upon any terms. They defended themselves, therefore, most desperately; and the city being at last taken by storm, they were all massacred, without respect of rank, sex, or age, except ten men. When these were brought into the king's presence, he told them they did not deserve mercy: they answered, that they would not receive it; that the only favour they asked, was to be hanged on trees in their own gardens; which was granted, and the place reduced to ashes. Both parties soon became weary of such a destructive war; and a peace was concluded in 1621, by which the edict of Nantz was confirmed. This treaty, however, was of no long duration. A new war broke out which lasted till the year 1628, when the edict of Nantz was again confirmed; only the Protestants were deprived of all their cautionary towns, and consequently of the power of defending themselves in time to come. This put an end to the civil wars on account of religion in France. Historians say, that in these wars above a million of men lost their lives, that 150,000,000 livres were spent in carrying them on; and that 9 cities, 400 villages, 2000 churches, 2000 monasteries, and 10,000 houses, were burnt or otherwise destroyed during their continuance. The next year, the king was attacked with a slow fever which nothing could allay, an extreme depression of spirits, and prodigious swelling in his stomach and belly. The year after, however, he recovered, to the great disappointment of his mother, who had been in hopes of regaining her power. She was arrested; but found means to escape into Flanders, where she remained during the rest of his reign. Richelieu, by a masterly train of politics, though himself was next to an enthusiast for popery, supported the Protestants of Germany and Gustavus Adolphus against the house of Austria; and after quelling all the rebellions and conspiracies which had been formed against him in France, he died some months before Louis XIII. in 1643.

Louis XIV. surnamed *le Grand*, succeeded to the 152 Louis XIV.
throne when he was only five years of age. During his minority, the kingdom was torn in pieces under the administration of his mother Anne of Austria, by the factions of the great, and the divisions between the court and parliament, for the most trifling causes and upon the most despicable principles. The prince of Condé flamed like a blazing star; sometimes a patriot, sometimes a courtier, and sometimes a rebel. He was opposed by the celebrated Turenne, who from a Protestant had turned Papist. The nation of France was involved at once in civil and domestic wars; but the queen mother having made choice of Cardinal Mazarine for her first minister, he found means to turn the arms even of Cromwell against the Spaniards, and to divide the domestic enemies of the court so effectually among themselves, that when Louis assumed the reins of government into his own hands, he found himself the most absolute monarch that had ever sat upon the throne of France. He had the good fortune, on the death of Mazarine, to put the domestic administration of his affairs into the hands of Colbert, who formed new systems for the glory, commerce, and manufactures of France, all which he carried to a surprising height. The king himself ignorant and vain, was blind to every patriotic duty of a king, promoting the interests of his subjects only that they might the better answer the purposes of his greatness; and by his ambition he embroiled himself with all his neighbours, and wantonly rendered Germany a dismal scene of devastation. By his impolitic and unjust revocation of the edict of Nantz in the year 1685, with the dragooning * the Protestants that followed it, he obliged them to take shelter in England, Holland, and different parts of Germany, where they established the silk manufactories, to the great prejudice of their own country. He was so blinded by flattery, that he arrogated to himself the divine honours paid to the Pagan emperors of Rome. He made and broke treaties for his conveniency: and in the end he raised against himself a confederacy of almost all the other princes of Europe; at the head of which was King William III. of England. He was so well served, that he made head for some years against this alliance; and France seemed to have attained the highest pitch of military glory, under the conduct of those renowned generals Condé and Turenne. (See UNITED PROVINCES). At length, having provoked the English by his repeated infidelities, their arms under the duke of Marlborough, and those of the Austrians under Prince Eugene, rendered the latter part of Louis's life as miserable as the beginning of it was splendid. His reign, from the year 1702 to 1711, was one continued series of defeats and calamities; and he had the mortification of seeing those places taken from him, which, in the former part of his reign, were acquired at the expence of many thousand lives. (See BRITAIN, N° 342, &c.)—Just as he was reduced, old as he was, to the desperate resolution of collecting his people and dying at their head, he was saved by the English Tory ministry deserting

* See *Dragooning*.

France. serting the cause, withdrawing from their allies, and concluding the peace of Utrecht in 1713. See BRITAIN, N° 371, &c.

The last years of Louis XIV. were also embittered by domestic calamities; which, added to those he had already endured of a public nature, impressed him with a deep melancholy. He had been for some time afflicted with a fistula; which, though successfully cut, ever afterwards affected his health. The year before the peace, his only son, the duke of Burgundy, died, together with the duchess and their eldest son; and the only remaining child was left at the point of death. The king himself survived till the month of September 1715; but on the 14th of that month expired, leaving the kingdom to his great grandson Louis, then a minor.

153 Louis XV. 154 Administration of the duke of Orleans.

By the last will of Louis he had devolved the regency during the minority of the young king, upon a council, at the head of which was the duke of Orleans. That nobleman, however, disgusted with a disposition which gave him only a casting vote, appealed to the parliament of Paris, who set aside the will of the late king, and declared him sole regent. His first acts were extremely popular, and gave the most favourable ideas of his government and character. He restored to the parliament the right which had been taken from them of remonstrating against the edicts of the crown, and compelled those who had enriched themselves during the calamities of the former reign to restore their wealth. He also took every method to efface the calamities occasioned by the unsuccessful wars in which his predecessor had engaged; promoted commerce and agriculture; and, by a close alliance with Great Britain and the United Provinces, seemed to lay the foundation of a lasting tranquillity. This happy prospect, however, was soon overcast by the intrigues of Alberoni the Spanish minister, who had formed a design of recovering Sardinia from the emperor, Sicily from the duke of Savoy, and of establishing the Pretender on the throne of Britain. To accomplish these purposes, he negotiated with the Ottoman Porte, Peter the Great of Russia, and Charles XII. of Sweden; the Turks intending to resume the war against the emperor; the two latter to invade Great Britain. But as long as the duke of Orleans retained the administration of France, he found it impossible to bring his schemes to bear. To remove him, therefore, he fomented divisions in the kingdom. An insurrection took place in Brittany; and Alberoni sent small parties into the country in disguise, in order to support the insurgents, and even laid plots to seize the regent himself. All of a sudden, however, the Spanish minister found himself disappointed in every one of his schemes. His partizans in France were put to death; the king of Sweden was killed at Frederickshall in Norway; the Czar, intent on making new regulations, could not be persuaded to make war upon Britain; and the Turks refused to engage in a war with the emperor, from whom they had lately suffered so much. The cardinal, nevertheless, continued his intrigues; which quickly produced a war betwixt Spain on the one part, and France and Britain on the other. The Spaniards, unable to resist the union of two such formidable powers, were soon reduced to the necessity of suing for peace; and the terms were dictated by the regent of France; and of these the dismission of Alberoni the Spanish minister was one. A double marriage was now set on foot: the duke of Orleans gave his own daughter, Mademoiselle Montpensier, to Don Lewis prince of Asturias, while the infanta of Spain was betrothed to her cousin the king of France. From this time the house of Bourbon continued united; both princes being convinced, that it was their interest not to waste their strength in wars against each other.

155 Destruct. project of John Law.

The spirit of conquest having now in a great measure subsided, and that of commerce taken place throughout the world in general, France became the scene of as remarkable a project in the commercial way as ever was known in any country. One John Law, a Scotsman, who had been obliged to leave his own country, laid the plan of a company which might by its notes pay off the debt of the nation, and reimburse itself by the profits. Law had wandered through various parts of Europe, and had successively endeavoured to engross the attention of various courts. The proposal was made to Victor Amadeus king of Sicily; but he dismissed Law with a reply, that "he was not rich enough to ruin himself:" but in France it was looked upon in a more favourable light; the nation being at this time involved in a debt of 200 millions, and the regent, as well as the people in general, very fond of embarking in new schemes. The bank, thus established, proceeded at first with some degree of caution; but having by degrees extended their credit to more than 80 times their real stock, they soon became unable to answer the demands made upon them; so that the company was dissolved the very same year in which it had been instituted. The confusion into which the kingdom was throne by this fatal scheme, required the utmost exertions of the regent to put a stop to it; and scarcely was this accomplished when the king, in 1723, took the government into his own hands. The duke then became minister; but did not long enjoy this post. His irregularities had broken his constitution, and had brought on a number of maladies, under which he in a short time sunk, and was succeeded in his administration by the duke of Bourbon Condé. The king, as we have already remarked, had been married, when very young, to the infanta of Spain, though by reason of his tender years the marriage had never been completed. The princess, however, had been brought to Paris, and for some time treated as queen of France; but as Louis grew up, it was easy to see that he had contracted an inveterate hatred against the intended partner of his bed. The minister, therefore, at last consented that the princess should be sent back; an affront so much resented by the queen her mother, that it had almost produced a war betwixt the two nations.

156 The king takes the government into his own hands.

157 The infanta of Spain sent back.

The dissolution of the marriage of Louis was the last act of Condé's administration; and the procuring of a new match was the first act of his successor Cardinal Fleury. The princess pitched upon was the daughter of Stanislaus Lesczinski, king of Poland, who had been deposed by Charles XII. of Sweden. The princess was destitute of personal charms, but of an amiable disposition; and though it is probable that she never possessed the love of her husband, her excellent qualities could not but extort his esteem; and the birth

158 Marriage with the daughter of Stanislaus king of Poland.

France.

birth of a prince soon after their marriage removed all the fears of the people concerning the succession.

Cardinal Fleury continued the pacific schemes pursued by his predecessors; though they were somewhat interrupted by the war which took place in the year 1733. Notwithstanding the connexion betwixt that monarch and the French nation, however, Fleury was so parsimonious in his assistance, that only 1500 soldiers were sent to relieve Dantzic, where Stanislaus himself resided, and who at that time was besieged by the Russians. This pitiful reinforcement was soon overwhelmed by a multitude of Russians; and Stanislaus was at last obliged to renounce all thoughts of the crown of Poland, though he was permitted to retain the title of king: and that this title might not be merely nominal, the king of France consented to bestow upon him the duchies of Bar and Lorrain; so that, after the death of Stanislaus, these territories were indissolubly united to the dominions of France. Fleury steadily pursued his pacific plans, and the disputes between Spain and England in 1737 very little affected the peace of France; and it must be remembered to his praise, that instead of fomenting the quarrels betwixt the neighbouring potentates, he laboured incessantly to keep them at peace. He reconciled the Genoese and Corsicans, who were at war; and his mediation was accepted by the Ottoman Porte; who at that time carried on a successful war with the emperor of Germany, but made peace with him at the intercession of the cardinal. All his endeavours to preserve the general peace, however, proved at last ineffectual. The death of the emperor Charles VI. in 1740, the last prince of the house of Austria, set all Europe in a flame. The emperor's eldest daughter, Maria Theresa, claimed the Austrian succession, which comprehended the kingdoms of Hungary and Bohemia, the duchy of Silesia, Austrian Suabia, Upper and Lower Austria, Stiria, Carinthia, Carniola; the four forest towns; Burgaw; Brisgaw; the Low Countries; Friuli; Tyrol; the duchy of Milan; and the duchies of Parma and Placentia. Among the many competitors who pretended a right to share, or wholly to inherit, these extensive dominions, the king of France was one. But as he wished not to awaken the jealousy of the European princes by preferring directly his own pretensions, he chose rather to support those of Frederick III. who laid claim to the duchy of Silesia. This brought on the war of 1740; and of which an account is given under the articles BRITAIN and PRUSSIA. It was terminated in 1748 by the treaty of Aix-la-Chapelle; but to this Louis, who secretly meditated a severe vengeance against Britain, only consented, that he might have time to recruit his fleet, and put himself somewhat more upon an equality with this formidable power. But while he meditated great exploits of this kind, the internal tranquillity of the kingdom was disturbed by violent disputes betwixt the clergy and parliaments of France. In the reign of Louis XIV. there had been violent contests betwixt the Jansenists and Jesuits concerning free will and other obscure points of theology; and the opinions of the Jansenists had been declared heretical by the celebrated papal bull named *Unigenitus*; the reception of which was enforced by the king, in opposition to the parliaments, the archbishop of Paris, and the body of the people. The archbishop, with 15 other prelates, protested against it as an infringement of the rights of the Gallican church, of the laws of the realm, and an insult on the rights of the people themselves. The duke of Orleans favoured the bull by inducing the bishops to submit to it; but at the same time stopped a persecution which was going on against its opponents. Thus matters passed over till the conclusion of the peace; a short time after which, the jealousy of the clergy was awakened by an attempt of the minister of state to inquire into the wealth of individuals of their order. To prevent this, they revived the contest about the bull Unigenitus; and it was resolved, that confessional notes should be obtained of dying persons; that these notes should be signed by priests who maintained the authority of the bull; and that, without such notes, no person could obtain a viaticum, or extreme unction. On this occasion the new archbishop of Paris, and the parliament of that city, took opposite sides; the latter imprisoning such of the clergy as refused to administer the sacraments excepting in the circumstances above mentioned. Other parliaments followed the example of that of Paris; and a war was instantly kindled betwixt the civil and ecclesiastical departments of the state. In this dispute the king interfered, forbade the parliaments to take cognizance of ecclesiastical proceedings, and commanded them to suspend all prosecutions relative to the refusal of the sacraments: but instead of acquiescing, the parliaments presented new remonstrances, refused to attend any other business, and resolved that they could not obey this injunction without violating their duty as well as their oath. They cited the bishop of Orleans before their tribunal; and ordered all writings, in which its jurisdiction was disputed, to be burnt by the executioner. By the assistance of the military, they enforced the administration of the sacraments to the sick, and ceased to distribute that justice to the subject for which they had been originally instituted. The king, enraged at their obstinacy, arrested and imprisoned four of the members who had been most obstinate, and banished the remainder to Bourges, Poictiers, and Auvergne; while, to prevent any impediment from taking place in the administration of justice by their absence, he issued letters patent, by which a royal chamber for the prosecution of civil and criminal suits was instituted. The counsellers refused to plead before these new courts; and the king, finding at last that the whole nation was about to fall into a state of anarchy, thought proper to recal the parliament. The banished members entered Paris amidst the acclamations of the inhabitants; and the archbishop, who still continued to encourage the priests in refusing the sacraments, was banished to his seat at Conflans; the bishops of Orleans and Troyes were in like manner banished, and a calm for the present restored to the kingdom.

159 Disputes betwixt the parliaments and clergy.

160 Parliament of Paris banished.

161 New disputes betwixt the king and parliament.

The tranquillity thus established was of no long duration. In the year 1756, the parliaments again fell under the displeasure of their king by their imprudent persecution of those who adhered to the bull Unigenitus. They proceeded so far in this opposition as to refuse to register certain taxes absolutely necessary for the carrying on of the war. By this Louis was so provoked, that he suppressed the fourth and fifth chambers of inquests, the members of which had distinguished

France. guished themselves by their opposition to his will. He commanded the bull Unigenitus to be respected, and prohibited the secular judges from ordering the administration of the sacraments. On this 15 counsellors of the great chamber resigned their offices, and 124 members of the different parliaments followed their example; and the most grievous discontents took place throughout the kingdom. An attempt was made by a fanatic, named *Damien*, to assassinate him; and the king was actually wounded, though slightly, between the ribs, in the presence of his son and in the midst of his guards. The assassin was put to the most exquisite tortures; in the midst of which he persisted, in the most obstinate manner, to declare that he had no intention to kill the king; but that his design was only to wound him, that God might touch his heart, and incline him to restore peace to his dominions, &c. These expressions, which undoubtedly indicated insanity, had no effect on his merciless judges, who consigned him to one of the most horrid deaths the ingenuity or cruelty of man could invent. This attempt, however, seems to have had some effect upon the king; for he soon after banished the archbishop of Paris, who had been recalled, and once more accommodated matters with his parliament.

162 Family compact between France and Spain established.

The unfortunate event of the war of 1755 had brought the nation to the brink of ruin, when Louis implored the assistance of Spain; and on this occasion the celebrated *Family Compact* was signed; by which, with the single exception of the American trade, the subjects of France and Spain are naturalized in both kingdoms, and the enemy of the one sovereign is invariably to be looked upon as the enemy of the other. At that time, however, the assistance of Spain availed very little; both powers were reduced to the lowest ebb, and the arms of Britain were triumphant in every quarter of the globe. See the article BRITAIN.

The peace concluded at Paris in the year 1763, though it freed the nation from a most destructive and bloody war, did not restore its internal tranquillity. The parliament, eager to pursue the victory they had formerly gained over their religious enemies, now directed their efforts against the Jesuits, who had obtained and enforced the bull Unigenitus. That once powerful order, however, was now on the brink of destruction. A general detestation of its members had taken place throughout the whole world. A conspiracy formed by them against the king of Portugal, and from which he narrowly escaped, had roused the indignation of Europe, and this was still farther inflamed by some fraudulent practices of which they had been guilty in France. Le Valette, the chief of their missionaries at Martinico, had, ever since the peace of Aix-la-Chapelle, carried on a very extensive commerce, insomuch that he even aspired at monopolizing the whole West India trade when the war with Britain commenced in 1755. Leonay and Gouffre, merchants at Marseilles, in expectation of receiving merchandise to the value of two millions from him, had accepted of bills drawn by the Jesuits to the amount of a million and a half. Unhappily they were disappointed by the vast number of captures made by the British; in consequence of which they were obliged to apply to the Society of Jesuits at large: but they, either ignorant of their true interest, or too slow in giving assistance, suffered the merchants to stop payment; and thus not only to bring ruin upon themselves, but to involve, as is usual in such cases, a great many others in the same calamity. Their creditors demanded indemnification from the Society at large; and on their refusal to satisfy them, brought their cause before the parliament of Paris. That body, eager to revenge themselves on such powerful adversaries, carried on the most violent persecutions everywhere against them. In the course of these, the volume containing the constitution and government of the order itself was appealed to, and produced in open court. It then appeared, that the order of Jesuits formed a distinct body in the state, submitting implicitly to their chief, who alone was absolute over their lives and fortunes. It was likewise discovered that they had, after a former expulsion, been admitted into the kingdom upon conditions which they had never fulfilled; and to which their chief had obstinately refused to subscribe; consequently that their existence at that time in the nation was merely the effect of toleration. The event was, that the writings of the Jesuits were pronounced to contain doctrines subversive of all civil government, and injurious to the security of the sacred persons of sovereigns: the attempt of Damien against the king was attributed to them, and every thing seemed to prognosticate their speedy dissolution. In this critical moment, however, the king interfered, and by his royal mandate suspended all proceedings against them for a year; a plan of accommodation was drawn up, and submitted to the pope and general of the order: but the latter, by his ill-timed haughtiness, entirely overthrew the hope of reconciliation. The king withdrew his protection, and the parliament redoubled their efforts against them. The bulls, briefs, constitutions, and other regulations of the Society, were determined to be encroachments on authority, and abuses of government; the Society itself was finally dissolved, and its members declared incapable of holding any clerical or municipal offices; their colleges were seized; their effects confiscated, and the order annihilated ever since.

163 Expulsion of the Jesuits.

164 Contention betwixt the king and his parliament.

The parliament having gained this victory, next made an attempt to set bounds to the power of the king himself. They now refused to register an edict which Louis had issued for the continuance of some taxes which should have ended with the war, and likewise to conform to another by which the king was enabled to redeem his debts at an inadequate price. The court attempted to get the edicts registered by force, but the parliaments everywhere seemed inclined to resist to the last. In 1766, the parliament of Brittany refused the crown a gift of 700,000 livres; in consequence of which they were singled out to bear the weight of royal vengeance; but while matters were on the point of coming to extremities, the king thought proper to drop the process altogether, and to publish a general amnesty. The parliaments, however, now affected to despise the royal clemency; which exasperated the king to such a degree, that he ordered the counsellors of the parliament of Brittany (who had refused to resume the functions of which he deprived them) to be included in the list of those who were to be drafted for militia; and those upon whom the lot fell were immediately obliged to join their respective regiments;

France. ments; the rest being employed in forming the city guard. The parliament of Paris remonstrated so freely upon this conduct of the king, that they also fell under his censure; and Louis in the most explicit manner declared, that he would suffer no earthly power to interfere with his will; and the parliaments were for the present intimidated into submission.

The interval of domestic tranquillity which now took place, was employed by the king in humbling the pride of the pope, who refused to recal a brief he had published against the duke of Parma. On this the French monarch reclaimed the territories of Avignon and Venaissin; and while the pontiff denounced his unavailing censures against him, the marquis de Rochecouart, with a single regiment of soldiers, drove out the troops of the pope, and took possession of the territories in question.

165 [Is]land of [C]orsica [re]duced.

A more formidable opposition was made by the natives of the small island of Corsica; the sovereignty of which had been transferred to France by the Genoese, its former masters, on condition that Louis should reinstate them in the possession of the island of Caprala, which the Corsicans had lately reduced. These islanders defended themselves with the most desperate intrepidity; and it was not till after two campaigns, in which several thousands of the bravest troops of France were lost, that they could be brought under subjection.

166 [D]istressed [st]ate of the [na]tion.

The satisfaction which this unimportant conquest might afford to Louis, was clouded by the distress of the nation at large. The East India Company had totally failed, and most of the capital commercial houses in the kingdom were involved in the same calamity. The minister, the duc de Choiseuil, by one desperate stroke, reduced the interest of the funds to one half, and at the same time took away the benefit of the survivorship in the tontines, by which the national credit was greatly affected; the altercation betwixt the king and his parliaments revived, and the dissensions became worse than ever. The duc de Choiseuil attempted in vain to conciliate the differences; his efforts tended only to bring misfortunes upon himself, and in 1771 he was banished by the king, who suspected him of favouring the popular party too much; and this was soon after followed by the banishment of the whole parliament of Paris, and that by the banishment of a number of others; new parliaments being everywhere chosen in place of those who had been expelled. The people where by no means disposed to pay the same regard to these new parliaments that they had done to the old ones; but every appearance of opposition was at last silenced by the absolute authority of the king. In the midst of this plenitude of power, however, which he had so ardently desired, his health daily declined, and the end of his days was evidently at no great distance. As he had all along indulged himself in sensual pleasures to the greatest excess, so they now proved the immediate means of his destruction. His favourite mistress Madame de Pompadour, who for a long time governed him with an absolute sway, had long since been dead, and the king had for some time been equally enslaved by the charms of Madame du Barre. At last even her beauty proved insufficient to excite desire; and a succession of mistresses became necessary to rouse the languid appetites of the king. One of these, who was infected with the smallpox, communicated the disease to the king; who in a short time died of it, notwithstanding all the assistance that could be given him by the physicians. France.

167 Death of Louis XV.

168 Reign of Louis XVI.

The new king Louis XVI. grandson to the former, ascended the throne in the year 1774, in the 20th year of his age; and to secure himself against the disease which had proved fatal to his predecessor, submitted to inoculation, with several others of the royal family. Their quick and easy recovery contributed much to extend that practice throughout the kingdom, and to remove the prejudices which had been entertained against it.

The king had no sooner regained his health, than he applied himself diligently to extinguish the differences which had taken place betwixt his predecessor and the people. He removed those from their employments who had given cause of complaint by their arbitrary and oppressive conduct; and he conciliated the affection of his subjects by removing the new parliaments and recalling the old ones.

But though the prudence of Louis had suggested to him these compliances, he endeavoured still to preserve pure and entire the royal authority. He explained his intentions by a speech in the great chamber of parliament. "The step that he had taken to ensure the tranquillity and happiness of his subjects, ought not (he observed) to invalidate his own authority; and he hoped, from the zeal and attachment of the present assembly, an example of submission to the rest of his subjects. Their repeated resistance to the commands of his grandfather had compelled that monarch to maintain his prerogative by their banishment; and they were now recalled, in the expectation that they would quietly exercise their functions, and display their gratitude by their obedience." He concluded with declaring, "That it was his desire to bury in oblivion all past grievances; that he should ever behold with extreme disapprobation whatever might tend to create divisions and disturb the general tranquillity; and that his chancellor would read his ordinance to the assembly, from which they might be assured he would not suffer the smallest deviation to be made." That ordinance was conceived in the most explicit terms, and was immediately registered by the king's command. The articles of it limited within very narrow bounds the pretensions of the parliament of Paris: The members were forbidden to look upon themselves as one body with the other parliaments of the kingdom, or to take any step, or assume any title, that might tend towards or imply such an union: They were enjoined never to relinquish the administration of public justice, except in cases of absolute necessity, for which the first president was to be responsible to the king; and it was added, that on their disobedience the grand council might replace the parliament, without any new edict for the purpose. They were still, however, permitted to enjoy the right of remonstrating before the registering of any edicts or letters patent which they might conceive injurious to the welfare of the people, provided they preserved in their representations the respect due to the throne. But these remonstrances were not to be repeated; and the parliament, if they proved ineffectual, were to register the edict objected to within a month at farthest from the first day of its being

France.

being published. They were forbidden to issue any arrets which might excite trouble, or in any manner retard the execution of the king's ordinances; and they were assured by the king himself, at the conclusion of this code for their future conduct, that as long as they adhered to the bounds prescribed, they might depend upon his countenance and protection. In short, the terms on which Louis consented to re-establish the parliaments were such, that they were reduced to mere cyphers, and the word of the king still continued to be the only law in the kingdom. The archbishop of Paris, who had likewise presumed to raise some commotions with regard to the bull Unigenitus, was obliged to submit: and severely threatened if he should afterwards interfere in such a cause.

The final conquest of the Corsicans, who, provoked by the oppression of their governors, had once more attempted to regain their former liberty, was the first event of importance which took place after this restoration of tranquillity: but the kingdom was yet filled with disorder from other causes. A scarcity of corn
1775. happening to take place just at the time that some regulations had been made by M. Turgot the new financier, the populace rose in great bodies, and committed such outrages, that a military force became absolutely necessary to quell them; and it was not till upwards of 500 of these miserable wretches were destroyed that they could be reduced. The king, however, by his prudent and vigorous conduct on this occasion, soon put a stop to all riots, and eminently displayed his clemency as well as prudence in the methods he took for the restoration of the public tranquillity.

169 Humane edict in favour of deserters.

The humanity of Louis was next shown in an edict which he caused to be registered in parliament, sentencing the deserters from his army in future to work as slaves on the public roads, instead of punishing them as formerly with death; and with equal attention to the general welfare of his subjects, he seized the moment of peace to fulfil those promises of economy which on his

170 Suppression of the mousquetaires.

accession he had given to the people. Various regulations took place in consequence; particularly the suppression of the mousquetaires and some other corps, which being adapted more to the parade of guarding the royal person than any real military service, were supported at a great expence, without any adequate return of benefit to the state.

Particular attention was also paid to the state of the marine; and the appointment of M. de Sartine in 1776 to that department did honour to the penetration of the sovereign. That minister, fruitful in resources, and unwearied in his application, was incessantly engaged in augmenting the naval strength of his country; and the various preparations that filled the ports and docks created no small uneasiness to the British court.

The next appointment made by the king was equally happy, and in one respect singular and unprecedented. M. Turgot, though possessed of integrity and industry, had not been able to command the public confidence. On his retreat, M. Clugny, intendant general of Bourdeaux, had been elevated to the vacant post: but he dying in a very short space, M. Taboureau des Reaux was appointed his successor; and the king soon after associated with him in the management of the finances M. Neckar, by birth a Swiss, and by religion a Protestant. That gentleman, in the preceding reign, had been chosen to adjust some differences between the East India Company and the crown; and had discharged his trust in a manner which gained the approbation of both parties. Possessed of distinguished abilities, his appointment would have excited no surprise, had it not been contrary to the constant policy of France, which had carefully excluded the aliens of her country and faith from the controul of her revenue. It now stood forward as a new instance of enlargement of mind and liberality of sentiment; and will to posterity mark the prominent features of the reign of Louis XVI.

France.

171 Appointment of M. Neckar to the direction of the finances.

Although the French monarch was of a pacific disposition, and not destitute of generosity of sentiment; yet his own and the public exultation had been openly and constantly proportioned to the success of the Americans in their contest with Britain: the princes of the blood and the chief nobility were eager to embark in support of the cause of freedom; and the prudence of the king and his most confidential ministers alone restrained their ardour. The fatal events of the former war were still impressed on the mind of Louis; and he could not readily consent to expose his infant marine in a contest with a nation who had so frequently asserted the dominion of the seas, and so lately broken the united strength of the house of Bourbon. At the same time, he was sensible that the opportunity of humbling those haughty islanders, should not be entirely neglected, and that some advantages should be taken of the present commotions in America. Two agents from the United States, Silas Deane and Dr Benjamin Franklin, had successively arrived at Paris: and though all audience was denied them in a public capacity, still they were privately encouraged to hope that France only waited the proper opportunity to vindicate in arms the independence of America. In the mean while, the American cruisers were hospitably received into the French ports: artillery and all kinds of warlike stores were freely sold or liberally granted to the distress of the colonists; and French officers and engineers, with the connivance of government, entered into their service.

172 The French privately assist the Americans in their contest with Britain,

Some changes were about this time introduced into the different departments of state. The conduct of M. Neckar in the finances had been attended with universal approbation; and M. Taboureau des Reaux, his colleague, had resigned his situation, but still retained the dignity of counsellor of state. To afford full scope to the genius of M. Neckar, Louis determined no longer to clog him with an associate: but, with the title of Director General of the Finances, submitted to him the entire management of the funds and revenue of France. In the ensuing year, the count de St Germains, secretary at war, died; and the prince de Montbarey, who had already filled an inferior situation in that department, was now appointed to succeed him.

In the mean time, Louis's negotiations with foreign courts were not neglected. He concluded a new treaty of alliance with Switzerland; vigilantly observed the motions of the different princes of Germany on the death of the elector of Bavaria; and when closely questioned by the English ambassador, Lord Stormont, respecting the various warlike preparations which were diligently

France.

diligently continued through the kingdom, he replied, That at a time when the seas were covered with English fleets and American cruisers, and when such armies were sent to the New World as had never before appeared there, it became prudent for him also to arm for the security of the colonies and the protection of the commerce of France. The king was not ignorant at the same time, that the remonstrances of Great Britain, and the importunities of the agents of the United States, would soon compel him to adopt some decisive line of conduct. This was hastened by a new event disastrous to Britain; the failure of General Burgoyne's

173 at last openly acknowledge the independence of the United States.

expedition, and the capture of his army. The news of that event was received at Paris with unbounded exultation. M. Sartine, the marine superintendant, was eager to measure the naval strength of France with that of Great Britain; the queen, who had long seconded the applications of the American agents, now espoused their cause with fresh ardour; and the pacific inclinations of Louis being overborne by the suggestions of his ministers and the influence of the queen, it was at length determined openly to acknowledge the independence of the United States.

Dr Franklin and Silas Deane, who had hitherto acted as private agents, were now acknowledged as public ambassadors from those states to the court of Versailles; and a treaty of amity and commerce was signed between the two powers in the month of February 1778. The duke of Noailles, ambassador to the court of London, was in the month of March instructed to acquaint that court with the above treaty. At the same time he declared, that the contracting parties had paid great attention not to stipulate any exclusive advantages in favour of France, and that the United States had reserved the liberty of treating with every nation whatever on the same footing of equality and reciprocity. But this stipulation was treated by the British with contempt; and the recal of Lord Stormont, their ambassador at Versailles, was the signal for the commencement of hostilities.—The events produced by this war are related under the articles AMERICA, BRITAIN, and INDOSTAN. Here our chief business is with domestic transactions, the measures of the cabinet, and the internal economy of the state.

In the year 1780 new changes in the French ministry took place. M. Bertin had resigned the office of secretary of state; the prince de Montbarey had retired from the post of secretary at war, and was succeeded by the marquis de Segur. But the most important removal was that of M. Sartine, who had for

174 Removal of M. Sartine.

several years presided over the marine department, and whose unwearied application and ability had raised the naval power of France to a height that astonished Europe: but his colleagues in the cabinet loudly arraigned a profusion, which would have diverted into one channel the whole resources of the kingdom; and his retreat opened a road to the ambition of the marquis de Castries, who was appointed to supply his place.

This year, the king fixed on the anniversary of his birth day to render it memorable by a new instance of humanity: and he abolished for ever the inhuman custom of *putting the question*, as it was called, by torture; a custom which had been so established by the practice of ages, that it seemed to be an inseparable part of the constitution of the courts of justice in France. At the same time, to defray the charges of war, he continued to diminish his own expenditure; and sacrificing his magnificence to the ease of his subjects, dismissed at once above 400 officers belonging to his court.

175 Dismission of M. Neckar.

Unhappily, however, the popular discontents were excited next year by the dismission of their favourite minister, M. Neckar. He had conceived the arduous but popular project of supporting a war by loans without taxes; and the rigid economy which he had introduced into all the departments of the royal household, and the various resources that presented themselves to his fertile genius, had supported him amidst the difficulties that attended this system. But his austerity of temper had not rendered him equally acceptable to the sovereign and his subjects; and the repeated reforms he had recommended were represented as inconsistent with the dignity of the crown: he was therefore in 1781 dismissed from his office of comptroller-general; and M. Joli de Fleuri, counsellor of state, was appointed to that important department. The defeat of the count de Grasse happened next year, and impressed the kingdom with general grief and consternation. Immense preparations were, however, made for the operations of 1783; and in conjunction with the courts of Madrid and the Hague, Louis was determined this year to make the most powerful efforts to bring the war to a conclusion. But in the midst of these preparations, the voice of peace was again heard; and Louis was induced

176 Peace concluded.

to listen to the proffered mediation of the two first potentates in Europe, the emperor of Germany and the empress of Russia. The count de Vergennes, who still occupied the post of secretary of foreign affairs, was appointed to treat with Mr Fitzherbert the British minister at Brussels, but who had lately proceeded to Paris to conduct this important negotiation. The way was already smoothed for the restoration of public tranquillity, by provisional articles signed at the conclusion of the last year between the states of America and Great Britain, and which were to constitute a treaty of peace finally to be concluded when that between France and Great Britain took place. Preliminary articles were accordingly agreed upon and signed at Versailles: these were soon after succeeded by a definitive treaty; and France, throughout her extensive dominions, beheld peace once more established. Though the late war had been attended by the most brilliant success, and the independence of America seemed to strike deep at the source of her rival's power, yet France herself had not been entirely free from inconvenience. The retreat of M. Neckar, had, as we have already observed, diminished the public confidence; three different persons who had since transiently occupied his post, increased the jealousies of the people;

177 Of the Caisse d'Escompte.

and the failure of the celebrated Caisse d'Escompte completed the universal consternation.

That bank had been established in the year 1776. The plan of it was formed by a company of private adventurers, and its capital was fixed at 500,000l. sterling. The professed design of the Company was to discount bills at short dates, at the rate of four per cent. per annum: but as this interest could never be an equivalent for the capital sunk by the proprietors, they were intrusted with the additional power of issuing notes to the amount of their capital, which, as they were

France. were capable at any time of being converted into specie, might be often voluntarily taken by their customers from mere convenience. The reputation of the bank soon caused its stock to sell above par: and its credit was still at the highest, when to the astonishment of the nation it suddenly stopped payment on the 2d of October 1783. The cause assigned was an uncommon scarcity of specie: But the public suspected that the failure arose from a loan secretly made to government; and what confirmed the suspicion was, that government about the same time stopped payment of the bills drawn upon them by their army in America.

Whatever was the cause of this event, the king was prevailed on to extend his protection to the Company. By four successive edicts the banks in Paris were ordered to receive the notes of the Caisse d'Escompte as currency; and a lottery with a stock of one million sterling, redeemable in eight years, being established, the tickets were made purchasable in notes of the Caisse d'Escompte. By these expedients the public confidence in that bank was revived, its business increased, and its stock rose to above double the original subscription; the bills from America were at the same time put in a train of payment, and public credit was restored throughout the kingdom. Some compensation also for the expences that had been incurred during the late war, was drawn from a treaty with the United States of America. These engaged to reimburse France in the sum of 18 millions of livres, which had been advanced in the hour of their distress; and Louis consented to receive the money, as more convenient to the States, in the space of 12 years, by 12 equal and annual payments.

178 Treaty between France and Holland.

The general peace was soon after followed by a particular treaty between France and Holland, which was effected with great address by the Count de Vergennes. It included all the principles which can serve to cement in the closest union distinct nations under distinct governments; and by which they may mutually participate, in peace or in war, of good or of evil; and in all cases administer the most perfect aid, counsel, and succour to each other. It also prescribed, if their united good offices for the preservation of peace should prove ineffectual, the assistance they were to afford each other by sea and land. France was to furnish Holland with 10,000 effective infantry, 2000 cavalry, with 12 ships of the line and 6 frigates. Their high Mightinesses, on the other side, in case of a marine war, or that France should be attacked by sea, were to contribute to her defence six ships of the line and three frigates; and in case of an attack on the territory of France, the States General were to have the option of furnishing their land contingent either in money or troops, at the estimate of 5000 infantry and 1000 cavalry. Further, If the stipulated succours should be insufficient for the defence of the party attacked, or for procuring a proper peace, they engaged to assist each other with all their forces, if necessary; it being however agreed that the contingent of troops to be furnished by the States General should not exceed 20,000 infantry and 4000 cavalry. It was further added, that neither of the contracting powers should disarm, or make or receive proposals of peace or truce, without the consent of the other: they promised also not to contract any future alliance or engagement whatever, directly or indirectly, contrary to the present treaty; and on any treaties or negotiations being proposed which might prove detrimental to their joint interest, they pledged their faith to give notice to each other of such proposals as soon as made.

Thus was Holland now converted into the firm ally of that power against whose encroaching spirit she had formerly armed the most powerful kingdoms of Europe; while France having asserted the independence of America against Great Britain, and having converted an ancient and formidable foe into an useful friend, seemed to have attained an influence over the nations of the earth that she had never before been possessed of.

But however exalted her present situation might appear, the seeds of future commotion were already apparent to an attentive observer. The applause that had attended the parliament of Paris in their struggles with the late king might be considered as the first dawn of freedom; the language of that assembly had boldly inculcated to their countrymen their natural rights, and taught them to look with a less enraptured eye on the lustre that encompassed the throne. The war in America had contributed to enlarge the political ideas of the French: they had on that occasion stood forth as the champions of liberty, in opposition to regal power; and the officers, who had acted on that conspicuous theatre, accustomed to think and speak without restraint, on their return imparted to the provinces of France the flame of freedom which had been kindled in the wilds of America. From that moment the French, instead of silently acquiescing under the edicts of their sovereign, canvassed each action with bold and rigid impartiality; while the attachment of the army, which has ever been considered as the sole foundation of despotism, gave way to the noble enthusiasm of liberty.

179 Consequence to France from her interference between Britain and her colonies.

We have already noticed the public dissatisfaction that had attended the dismission of M. Neckar; his transient successor, M. de Fleury, had retired from the management of the finances in 1783, and the more transient administration of M. d'Ormesson had expired in the same year that gave it birth. On his retreat, M. de Calonne, who had successively filled with acknowledged reputation the office of intendant of Mentz, and afterwards of the provinces of Flanders and Artois, was nominated to the post of comptroller-general. This gentleman, flexible and insinuating, eloquent in conversation, and polished in his manners, fertile in resources and liberal in the disposal of the public money, soon rendered himself acceptable to the sovereign. But he did not enter upon this new and arduous station favoured by the breath of popularity: he was reported to be more able than consistent, and not to have tempered the ardour of his spirit by the severity of deep research; and the people, amidst repeated loans, regretted that severe simplicity which had characterized the administration of M. Neckar.

180 Appointment and measures of M. de Calonne.

It was the bold and judicious measures of Calonne, however, that restored credit to the Caisse d'Escompte, which had stopped payment a few weeks before his accession. His next measure, in 1784, the establishment of the Caisse d'Amortissement, or sinking fund, was entitled to a still higher degree of applause. The plan of that fund was simple and moderate: It was to pay annually by government, into the hands of a board set apart

France. apart for that purpose, the entire interest of the national debts, whether in stock or annuities, together with an additional sum of 120,000l. The annuities that would be extinguished every year were estimated at 50,000l.; and in that proportion, the sum set apart for the redemption of the national debt would annually increase. The operation of this new fund was limited to the term of 25 years; and during that term the annual receipt of the Caisse d' Amortissement is declared unalterable, and incapable of being diverted to any other object.

The principal measure of the next year was the establishment of a new East India Company, (the constitutions of which have been already detailed: see COMPANY);—a measure not equally commendable with the preceding, and which did not fail to excite violent complaints. The time, however, was now approaching, when the necessities of the state would compel him to measures still more unpopular, and destined to undergo a severer scrutiny. Although peace had been re-established throughout Europe for three years, yet the finances of France seemed scarce affected by this interval of tranquillity, and it was found requisite to close every year with a loan. The public expenditure of 1785 might probably seem to sanction this measure. It had been thought proper to fortify Cherbourg upon a large and magnificent scale; the claim of the emperor to the navigation of the Scheldt had obliged the French to increase their land forces, either to form a respectable neutrality, or to assist effectually their Dutch allies; and the marquis de Castries, fond of war, and profuse in his designs, had not suffered the navy, which M. Sartine had surrendered into his hands, to decline during the interval of peace. The treaty of commerce concluded in the year 1786 with Great Britain was a new source of discontent.—Though regarded by the English manufacturers as far from advantageous, it excited in France still louder murmurs. It was represented as likely to extinguish those infant establishments, which were yet unable to vie with the manufactures of England that had attained to maturity; and the market that it held out for the wines and oils of France was passed over in silence, while the distress of the artisan was painted in the most striking colours. But when the edict for registering the loan at the conclusion of the last year, and which amounted to the sum of three millions three hundred and thirty thousand pounds, was presented to the parliament of Paris, the murmurs of the people, through the remonstrances of that assembly, assumed a more legal and formidable aspect. The king, however, signified to the select deputation that were commissioned to convey to him their remonstrances, that he expected to be obeyed without further delay. The ceremony of the registering accordingly took place on the next day; but it was accompanied with a resolution, importing, "that public economy was the only genuine source of abundant revenue, the only means of providing for the necessities of the state, and restoring that credit which borrowing had reduced to the brink of ruin."

The king was no sooner informed of this step, than he commanded the attendance of the grand deputation of parliament; when he erazed from their records the resolution that had been adopted; and observed, that though it was his pleasure that the parliament should communicate, by its respectful representations, whatever might concern the good of the public, yet he never would allow them so far to abuse his clemency as to erect themselves into the censors of his government. At the same time, more strongly to mark his displeasure at their expostulations, he superseded one of their officers, who had appeared most active in forwarding the obnoxious resolution. France.

M. de Calonne, however, though gratified by the approbation of his sovereign, could not but feel himself deeply mortified by the opposition of the parliament. His attempts to conciliate that assembly had proved ineffectual: and he experienced their inflexible aversion at the critical juncture when their acquiescence might have proved of the most essential service. An anxious inquiry into the state of the public finances had convinced him that the expenditure by far exceeded the revenue. In this situation, to impose new taxes was impracticable; to continue the method of borrowing was ruinous; to have recourse only to economical reforms, would be found wholly inadequate; and he hesitated not to declare, that it would be impossible to place the finances on a solid basis, but by the reformation of whatever was vicious in the constitution of the state.

To give weight to this reform, M. de Calonne was sensible that something more was necessary than the royal authority; he perceived that the parliament was neither a fit instrument for introducing a new order into public affairs, nor would submit to be a passive machine for sanctioning the plans of a minister, even if those plans were the emanations of perfect wisdom. Though originally a body of lawyers, indebted for their appointments to the king, there was not an attribute of genuine legislative assembly but what they seemed desirous to engross to themselves; and they had been supported in their pretensions by the plaudits of the people, who were sensible that there was no other body in the nation that could plead their cause against royal or ministerial oppression. To suppress, therefore, the only power of controul that remained, and to render the government more arbitrary, was deemed too perilous a measure: yet to leave the parliament in the full possession of their influence, an influence that the minister was convinced would be exerted against him, was at once to render his whole system abortive.

In this dilemma, the only expedient that suggested itself was to have recourse to some other assembly, more dignified and solemn in its character, and which should in a greater degree consist of members from the various orders of the state and the different provinces of the kingdom. This promised to be a popular measure; it implied a deference to the people at large, and might be expected to prove highly acceptable. But the true and legitimate assembly of the nation, the States General, had not met since the year 1614; nor could the minister flatter himself with the hope of obtaining the royal assent to a meeting which a despotic sovereign could not but regard with secret jealousy. Another assembly had occasionally been substituted in the room of the States General: this was distinguished by the title of the *Notables*; and consisted of a num- 181 Assembly of the Notables.

ber

France.

ber of persons from all parts of the kingdom, chiefly selected from the higher orders of the state, and nominated by the king himself. This assembly had been convened by Henry IV. again by Louis XIII. and was now once more summoned by the authority of Louis XVI.

The writs for calling them together were dated on the 29th of December 1786; and they were addressed to seven princes of the blood, nine dukes and peers of France, eight field mareschals, twenty-two nobles, eight counsellors of state, four masters of requests, eleven archbishops, and bishops, thirty-seven of the heads of the law, twelve deputies of the *pays d'etats*, the lieutenant civil, and twenty-five magistrates of the different towns of the kingdom. The number of members was 144; and the 29th of January 1787 was the period appointed for their meeting.

Upon the arrival of the notables at Paris, however, the minister found himself yet unprepared to submit his system to their inspection, and postponed the opening of the council to the 7th of February. A second delay to the 14th of the same month was occasioned by the indisposition of M. de Calonne himself, and that of the count de Vergennes president of the council of finance and first secretary of state; and a third procrastination was the necessary result of the death of the count on the day previous to that fixed for the opening of the meeting. He was succeeded in the department of foreign affairs by the count de Montmorin, a nobleman of unblemished character. But his loss at this critical juncture was severely felt by M. de Calonne; he alone, of all the ministers, having entered with warmth and sincerity into the plans of the comptroller general. The chevalier de Miromesnil, keeper of the seals, was avowedly the rival and enemy of that statesman. The mareschal de Castries, secretary for the marine department, was personally attached to M. Neckar; and the baron de Breteuil, secretary for the household, was the creature of the queen, and deeply engaged in what was called the Austrian system.

182 Splendid project of M. de Calonne.

It was under these difficulties that M. de Calonne, on the 22d of February, first met the assembly of the notables, and opened his long-expected plan. He began by stating, that the public expenditure had for centuries past exceeded the revenue, and that a very considerable deficiency had of course existed; that the Missisippi scheme of 1720 had by no means, as might have been expected, restored the balance; and that under the economical administration of Cardinal Fleury the deficit still existed; that the progress of this derangement under the last reign had been extreme; the deficiency amounting to three millions sterling at the appointment of the Abbé Terray; who, however, reduced it to one million six hundred and seventy-five thousand pounds; it decreased a little under the short administrations that followed, but rose again in consequence of the war, under the administration of M. Neckar; and at his own accession to office, it was three millions three hundred and thirty thousand pounds.

In order to remedy this growing evil, M. Calonne recommended a territorial impost, in the nature of the English land tax, from which no rank or order of men were to be exempted; and an inquiry into the possessions of the clergy, which hitherto had been deemed sacred from their proportion of the public burdens: the various branches of internal taxation were also to undergo a strict examination; and a considerable resource was presented in mortgaging the demesne lands of the crown.

The very necessity for these reforms was combated with a degree of boldness and force of reasoning that could not fail of deeply impressing the assembly; and instead of meeting with a ready acquiescence, the comptroller general was now launched into the boundless ocean of political controversy. M. Neckar, previous to his retirement, had published his Compte rendu au Roy, in which France was represented as possessing a clear surplus of 425,000 pounds sterling: this performance had been read with avidity, and probably contributed to estrange from the author the royal countenance; but the credit of it was ably vindicated by M. de Brienne archbishop of Thoulouse.

183 Opposed by Mirabeau and the bishop of Thoulouse.

M. de Calonne met with a still more formidable adversary in the count de Mirabeau. This extraordinary man, restless in his disposition, licentious in his morals, but bold, penetrating, and enterprising, had occasionally visited every court in Europe. He had been admitted at one time to the confidence of the minister; and had been directed, though in no ostensible character, to observe at Berlin, the disposition of the successor of the great Frederick. In this capacity he was frequently exposed to neglect and disappointment; his letters were often left unanswered; disgust succeeded to admiration; and he who had entered the Prussian court the intimate friend, returned to Paris the avowed enemy, of M. de Calonne: While the archbishop arraigned the understanding, the count impeached the integrity, of the comptroller general.

The eloquence of M. de Calonne, however, might have successfully vindicated his system and reputation against the calculations of Brienne, and the invectives of Mirabeau; but he could not support himself against the influence of the three great bodies of the nation.

184 and by the principal nobility, clergy, and magistrates.

The ancient nobility and the clergy had ever been free from all public assessments; and had the evil gone no farther, it might have been still perhaps borne with patience; but through the shameful custom of selling patents of nobility, such crowds of new noblesse started up, that every province in the kingdom was filled with them. The first object with those who had acquired fortunes rapidly, was to purchase a patent; which, besides gratifying their vanity, afforded an exemption to them and their posterity from contributing proportionably to the exigencies of the state; the magistracies likewise throughout the kingdom enjoyed their share of the exemptions; so that the whole weight of the taxes fell on those who were least able to bear them.

The minister's design, then, of equalizing the public burdens, and by rendering the taxes general diminishing the load borne by the lower and most useful classes of people, though undoubtedly great and patriotic, at once united against him the nobility, the clergy, and the magistracy; and the event was such as might be expected: the intrigues of those three bodies raised against him so loud a clamour, that finding it impossible to stem the torrent, he not only resigned his place

place on the 12th of April, but soon after retired to England from the storm of persecution.

185 ...on ...ich M. Calonne ...gns.

In the midst of these transactions at home, Louis's attention was also called to the state of affairs in the republic of Holland, his new and close ally. The prince of Orange had been stripped of all authority by the aristocratic party; and, retiring from the Hague, maintained the shadow of a court at Nimeguen. His brother-in-law, however, the new king of Prussia, exerted his endeavours to promote the interests of the stadtholder; and, having offered, in concert with France, to undertake the arduous task of composing the differences which distracted the republic, the proposal was received with apparent cordiality by the court of Versailles. At the same time it could scarce be expected that France would become the instrument of restoring the prince of Orange to that share of power which he had before occupied, and thus abandon one of the longest and most favourite objects of her policy, the establishing a supreme and permanent controul in the affairs of Holland. In fact, the conditions which were framed by the Louvestein faction, as the basis of reconciliation, were such as plainly indicated their design to reduce the influence and authority of the stadtholder within very narrow limits. On his renouncing his right of filling up the occasional vacancies in the town senates, he was to be restored to the nominal office of captain general: but he was to be restrained from marching the troops into or out of any province, without leave from the respective provinces concerned; and he was also to subscribe to a resolution passed some time before by the senate of Amsterdam, that the command should at all times be revocable at the pleasure of the states. Had the prince acquiesced in these preliminaries, France would have completely attained the object of her long negotiations, and by means of the Louvestein faction have acquired the ascendency that she had repeatedly sought in the councils of Holland. But under the difficulties that surrounded him, the prince of Orange was admirably supported and assisted by the genius, the spirit, and the abilities of his consort: she firmly rejected every measure tending to abridge any rights that had been attached to the office of stadtholder; and M. de Rayneval, the French negotiator, having in vain endeavoured to overcome her resolution, broke off the correspondence between the Hague and Nimeguen, and returned to Paris about the middle of January 1787.

But the republican party were totally disappointed in their hopes from France. The court of Versailles had indeed long trusted to the natural strength of this party, and had been assiduous during the whole summer in endeavouring to second them by every species of succours that could be privately afforded. Crowds of French officers arrived daily in Holland; and either received commissions in the service of the states, or acted as volunteers in their troops. Several hundreds of tried and experienced soldiers were selected from different regiments; and being furnished with money for their journey, and assurances of future favour, were despatched in small parties to join the troops, and help to discipline the burghers and volunteers. A considerable corps of engineers were also directed to proceed silently and in disguise towards Amsterdam, and to assist in strengthening the works of that city. These aids, which might have proved effectual had the contest been confined to the states of Holland and the stadtholder, were overwhelmed in the rapid invasion of the Prussians; and the court of Berlin had taken its measures with so much celerity, and the situation of the republicans was already become so desperate, that it was doubtful whether their affairs could be restored by any assistance that France was capable of immediately administering. Yet on Great Britain fitting out a strong squadron of men of war at Portsmouth to give confidence to the operations of the king of Prussia, the court of Versailles also sent orders to equip 16 sail of the line at Brest, and recalled a small squadron which had been commissioned on a summer's cruise on the coast of Portugal. But in these preparations Louis seemed rather to regard his own dignity, than to be actuated by any hopes of effectually relieving his allies. All opposition in Holland might be already considered as extinguished. The states assembled at the Hague had officially notified to the court of Versailles, that the disputes between them and the stadtholder were now happily terminated; and as the circumstances which gave occasion for their application to that court no longer existed, so the succours which they had then requested would now be unnecessary.

Under these circumstances, France could only wish to extricate herself from her present difficulty with honour. She therefore readily listened to a memorial from the British minister at Paris: who proposed, in order to preserve the good understanding between the two crowns, that all warlike preparations should be discontinued, and that the navies of both kingdoms should be again reduced to the footing of a peace establishment. This was gladly acceded to by the court of Versailles; and that harmony which had been transiently interrupted between the two nations was restored.

188 Domestic concerns of France.

Though the French king could not but sensibly feel the mortification of thus relinquishing the ascendency which he had attained in the councils of Holland, the state of his own domestic concerns and the internal situation of his kingdom furnished matter for more serious reflection. The dismission of M. de Calonne had left France without a minister, and almost without a system; and though the king bore the opposition of the notables with admirable temper, yet the disappointment that he had experienced sunk deep into his mind. Without obtaining any relief for his most urgent necessities, he perceived too late that he had opened a path to the restoration of the ancient constitution of France, which had been undermined by the crafty Louis XI. and had been nearly extinguished by the daring and sanguinary counsels of Richelieu under Louis XIII. The notables had indeed demeaned themselves with respect and moderation, but at the same time they had not been deficient in firmness. The appointment of the archbishop of Thoulouse, the vigorous adversary of M. de Calonne, to the office of comptroller-general, probably contributed to preserve the appearance of good humour in that assembly; yet the

189 Assembly of the Notables dissolved.

France. the proposed territorial impost, or general land tax, which was an object so ardently coveted by the court, was rejected. Louis, therefore, deprived of any further hope of rendering the convention subservient to his embarrassments, determined to dissolve the assembly; which he accordingly did, with a very moderate and conciliatory speech to the members on their dismission.

190
Refusal of the parliament to register the new taxes.

Thus disappointed of the advantage which he had flattered himself he would have drawn from the acquiescence of the notables, the king was obliged now to recur to the usual mode of raising money by the royal edicts; among the measures proposed for which purpose were the doubling of the poll-tax, the re-establishment of the third twentieth, and a stamp duty. But the whole was strongly disapproved by the parliament of Paris; and that assembly, in the most positive terms, refused to register the edict. Louis was obliged to apply, as the last resort, to his absolute authority; and, by holding what is called *a bed of justice*, compelled them to enrol the impost.

The parliament, though defeated, were far from subdued; and on the day after the king had held his bed of justice, they entered a formal protest against the edict; declaring, "that it had been registered against their approbation and consent, by the king's express command; that it neither ought nor should have any force; and that the first person who should presume to attempt to carry it into execution, should be adjudged a traitor, and condemned to the galleys."—This spirited declaration left the king no other alternative, than either proceeding to extremities in support of his authority, or relinquishing for ever after the power of raising money upon any occasion without the consent of the parliament. Painful as every appearance of violence must have proved to the mild disposition of Louis, he could not consent to surrender, without a struggle, that authority which had been so long exercised by his predecessors. Since the commencement of the present discontents, the capital had been gradually filled with considerable bodies of troops; and about a week after the parliament had entered the protest, an officer of the French guards, with a party of soldiers, went at break of day to the house of each individual member, to signify to him the king's command, that he should immediately get into his carriage, and proceed to Troyes, a city of Champagne, about 70 miles from Paris, without writing or speaking to any person out of his own

191
The members banished.

house before his departure. These orders were served at the same instant; and before the citizens of Paris were acquainted with the transaction, their magistrates were already on the road to their place of banishment.

Previous to their removal, however, they had presented a remonstrance on the late measures of government, and the alarming state of public affairs. In stating their opinions on taxes, they declared, that neither the parliaments, nor any other authority, excepting that of the three estates of the kingdom collectively assembled, could warrant the laying of any permanent tax upon the people; and they strongly enforced the renewal of those national assemblies, which had rendered the reign of Charlemagne so great and illustrious.

This requisition of the parliaments to re-establish the national council, or states general, was the more honourable, as the former assemblies must have sunk under the influence of the latter, and returned to their original condition of mere registers and courts of law. The confidence and attachment of the people of consequence rose in proportion to this instance of disinterestedness; their murmurs were openly expressed in the streets of the capital, and the general dissatisfaction was augmented by the stop that was put to public business by the exile of the parliament.

The cabinet at the same time was apparently weak, disunited, and fluctuating: and continual changes took place in every department of the state. Louis, averse to rigorous counsels, wished to allay the growing discontent by every concession that was consistent with his dignity; but it was generally believed, that the queen strongly dissuaded him from any step that might tend to the diminution of the royal authority. The influence of that princess in the cabinet was undoubtedly great: but the popularity which once had accompanied her was no more; and some imputations of private levity, which had been rumoured through the capital, were far from rendering her acceptable to the majority of the people; while the Count d'Artois, the king's brother, who had expressed himself in the most unguarded terms against the conduct of parliament, stood exposed to all the consequences of popular hatred.

Nor was it only in the capital that the flame of liberty once more burst forth; it blazed with equal strength in the provincial parliaments. Among various instances of this nature, the parliament of Grenoble passed a decree against *lettres de cachet*, the most odious engine of arbitrary power; and declared the execution of them within their jurisdiction, by any person, and under whatever authority, to be a capital crime.

The king had endeavoured to soothe the Parisians by new regulations of economy, and by continual retrenchments in his household: but these instances of attention, which once would have been received with the loudest acclamations, were now disregarded under their affliction for the absence of their parliament. His majesty, therefore, in order to regain the affections of his subjects, consented to restore that assembly; abandoning at the same time the stamp duty, and the territorial impost, which had been the sources of dispute. 192 Recalled.

These measures were, however, insufficient to establish harmony between the court and the parliament. The necessities of the state still continued; nor could the deficiency of the revenue be supplied but by extraordinary resources, or a long course of rigid frugality. About the middle of November 1787, in a full meeting of the parliament, attended by all the princes of the blood and the peers of France, the king entered the assembly, and proposed two edicts for their approbation: one was for a new loan of 450 millions, near 19 millions sterling: the other was for the re-establishment of the Protestants in all their ancient civil rights; a measure which had long been warmly recommended by the parliament, and which was probably now introduced to procure a better reception to the loan.

On

On this occasion, the king delivered himself in a speech of uncommon length, filled with professions of regard for the people, but at the same time strongly expressive of the obedience he expected to his edicts. Louis probably imagined, that the dread of that banishment from which the members had been so lately recalled would have ensured the acquiescence of the assembly; but no sooner was permission announced for every member to deliver his sentiments, than he was convinced that their spirits remained totally unsubdued. An animated debate took place, and was continued for nine hours; when the king, wearied by perpetual
193 ...ose the ...t for a ...
opposition, and chagrined at some freedoms used in their debates, suddenly rose and commanded the edict to be registered without farther delay. This measure was most unexpectedly opposed by the duke of Orleans, first prince of the blood; who, considering it as an infringement of the rights of parliament, protested against the whole proceedings of the day as being thereby null and void. Though Louis could not conceal his astonishment and displeasure at this decisive step, he contented himself with repeating his orders; and immediately after, quitting the assembly, retired to Versailles. On the king's departure, the parliament confirmed the protest of the duke of Orleans; and declared, that as their deliberations had been interrupted, they considered the whole business of that day as of no effect.

It was not to be supposed that Louis would suffer so bold an attack on his power with impunity. Accordingly, a letter was next day delivered to the duke of Orleans, commanding him to retire to Villars Cotterel, one of his seats, about 15 leagues from Paris, and to receive no company there except his own family;
194 Duke of Orleans and two members banished.
at the same time, the Abbé Sabatiere and M. Freteau, both members of the parliament, and who had distinguished themselves in the debate, were seized under the authority of lettres de cachet, and conveyed, the first to the castle of Mont St Michael in Normandy, the last to a prison in Picardy.
195 Strong remonstrances of the parliament.
This act of despotism did not fail immediately to rouse the feelings of the parliament. On the following day they waited on the king, and expressed their astonishment and concern that a prince of the blood royal had been exiled, and two of their members imprisoned, for having declared in his presence what their duty and consciences dictated, and at a time when his majesty had announced that he came to take the sense of the assembly by a plurality of voices. The answer of the king was reserved, forbidding, and unsatisfactory; and tended to increase the resentment of the parliament. At the same time, it did not prevent them from attending to the exigencies of the state; and convinced of the emergency, they consented to register the loan for 450 millions of livres, which had been the source of this unfortunate difference. This concession contributed to soften the mind of the king, and the sentence of the two magistrates was in consequence changed from imprisonment to exile; M. Freteau being sent to one of his country seats, and the Abbé Sabatiere to a convent of Benedictines.

The parliament, however, was not to be soothed by that measure to give up the points against which they had originally remonstrated. In a petition conceived with freedom, and couched in the most animated language, they boldly reprobated the late acts of arbitrary violence, and demanded the entire liberation of the persons against whom they had been exerted. We have already noticed the fluctuating counsels of the court of Versailles; and that Louis, as often as he was left to pursue his own inclinations, adopted measures of reconciliation. On the present occasion, in 196 Duke of Orleans recalled.
the beginning of the year 1788, he recalled the duke of Orleans to court, who soon after obtained leave to retire to England; and he permitted the return of the Abbé Sabatiere and M. Freteau to the capital.

The parliament, however, had not confined their demands to the liberation of those gentlemen; but had also echoed the remonstrances of the parliament of Grenoble, and had loudly inveighed against the execution of *lettres de cachet*. These repeated remonstrances, mingled with personal reflections, seconded most probably the suggestions of the queen, and Louis was once more instigated to measures of severity. Mess. 197 New remonstrances.
d'Espremenil and Monsambert, whose bold and pointed harangues had pressed most closely on the royal dignity, were doomed to experience its immediate resentment. While a body of armed troops surrounded the hotel in which the parliament were convened, Colonel Degout entered the assembly, and secured the persons of the obnoxious members, who were instantly conducted to different prisons. This new instance of arbitrary violence occasioned a remonstrance from parliament, which in boldness far exceeded all the former representations of that assembly. They declared they were now more strongly confirmed, by every proceeding, of the entire innovation which was aimed at in the constitution. "But, Sire," added they, "the French nation will never adopt the despotic measures to which you are advised, and whose effects alarm the most faithful of your magistrates; we shall not repeat all the unfortunate circumstances which afflict us; we shall only represent to you with respectful firmness, that the fundamental laws of the kingdom *must* not be trampled upon, and that *your authority can only be esteemed so long as it is tempered with justice.*"

Language so pointed and decisive, and which assert- 198 Assembly of the Notables.
ed the controlling power of the laws above the regal authority, could not fail of seriously alarming the king; and with a view to diminish the influence of parliament, it was determined again to convene the notables. Accordingly, about the beginning of May, Louis appeared in that assembly: and after complaining of the excesses in which the parliament of Paris had indulged themselves, and which had drawn down his reluctant indignation on a few of the members, he declared his resolution, instead of annihilating them as a body, to recal them to their duty and obedience by a salutary reform. M. de la Moignon, as keeper of the seals, then explained his majesty's pleasure to establish a *cour plenier* or supreme assembly, to be composed of princes of the blood, peers of the realm, great officers of the crown, the clergy, mareschals of France, governors of provinces, knights of different orders, a deputation of one member from every parliament, and two members from the chambers of council, and to be summoned as often

France.

often as the public emergency, in the royal opinion, should render it requisite.

If the assembly of the notables listened in silent deference to the project of their sovereign, the parliament of Paris received it with every symptom of aversion.

199 Opposition to the king's proposals.

That body strongly protested against the establishment of any other tribunal; and declared their final resolution not to assist at any deliberations in the supreme assembly which his majesty prepared to institute. A more unexpected mortification occurred to the king in the opposition of several peers of the realm; these expressed their regret at beholding the fundamental principles of the constitution violated; and while they were lavish in the professions of attachment to the person of their sovereign, concluded with apologizing for not entering on those functions assigned them in the plenary court, as being inconsistent with the true interests of his majesty, which were inseparable from those of the nation.

The flame quickly spread throughout the more distant provinces; at Rennes in Brittany, and Grenoble in Dauphiné, the people broke out into acts of the most daring outrage. In the latter city several hundred of the inhabitants perished in a conflict with the military; they yet maintained their ground against the regulars; and the commanding officer, at the entreaties of the first president, readily withdrew his troops from a contest into which he had entered with reluctance. The different parliaments of the kingdom at the same time expressed their feelings in the most glowing language; and strongly urged the necessity of calling together the states general, the lawful council of the kingdom, as the only means of restoring the public tranquillity.

Louis now plainly, saw, that a compliance with the public wishes for the re-establishment of the states general was absolutely necessary, in order to avoid the calamities of a civil war, which impended upon his refusal. In that event he must have expected to have encountered the majority of the people, animated by the exhortations and example of their magistrates; the peers of the realm had expressed the strongest disapprobation of his measures; nor could he even depend any longer on the support of the princes of his blood: but what afforded most serious matter of alarm was the spirit lately displayed among the military, who, during the disturbances in the provinces, had reluctantly been brought to draw their swords against their countrymen, and many of whose officers so recently engaged in establishing the freedom of America, publicly declared their abhorrence of despotism.

It was, not, however, till after many a painful struggle that Louis could resolve to restore an assembly, whose influence must naturally overshadow that of the crown, and whose jurisdiction would confine within narrow limits the boundless power he had inherited from his predecessor. In the two preceding reigns the states general had been wholly discontinued; and though the queen regent, during the troubles which attended the minority of Louis XIV. frequently expressed her intention of calling them together, she was constantly dissuaded by the representations of Mazarin. It is probable that the present monarch still flattered himself with the hope of being able to allure the members of that assembly to the side of the court; and having employed them to establish some degree of regularity in the finances, and to curb the spirit of the parliament, that he would again have dismissed them to obscurity.

200 Arret for summoning the states general.

Under these impressions an arret was issued in August, fixing the meeting of the states general to the first of May in the ensuing year; and every step was taken to secure the favourable opinion of the public during the interval. New arrangements took place in the administration; and M. Neckar, whom the confidence of the people had long followed, was again introduced into the management of the finances; the torture, which by a former edict had been restricted in part, was now entirely abolished; every person accused was allowed the assistance of counsel, and permitted to avail himself of any point of law; and it was decreed, that in future sentence of death should not be passed on any person, unless the party accused should be pronounced guilty by a majority at least of three judges.

The time appointed for the convention of the states general was now approaching; and the means of assembling them formed a matter of difficult deliberation in the cabinet. The last meeting, in 1614, had been convened by application to the bailiwicks. But this mode was liable to several strong objections; the bailiwicks had been increased in number and jurisdiction, several provinces having since that period been united to France; and the numbers and quality of the members were no less an object of serious attention; it was not till the close of the year, therefore, that the proposal of M. Neckar was adopted, which fixed the number of deputies at 1000 and upwards, and ordained that the representatives of the third estate or commons should equal in number those of the nobility and clergy united.

The eyes of all Europe were now turned on the states general; but the moment of that assembly's meeting was far from auspicious: The minds of the French had long been agitated by various rumours; the unanimity that had been expected from the different orders of the states was extinguished by the jarring pretensions of each; and their mutual jealousies were attributed by the suspicions of the people to the intrigues of the court, who were supposed already to repent of the hasty assent which had been extorted. A dearth that pervaded the kingdom increased the general discontent; and the people, pressed by hunger, and inflamed by resentment, were ripe to revolt. The sovereign also, equally impatient of the obstacles he continually encountered, could not conceal his chagrin; while the influence of the queen in the cabinet was again established, and was attended by the immediate removal of M. Neckar. The dismission of that minister, so long the favourite of the public, was the signal of open insurrection; the Parisians assembled in myriads; the guards refused to oppose and stain their arms with the blood of their fellow citizens; the Count d'Artois and the most obnoxious of the nobility thought themselves happy in eluding by flight the fury of the insurgents; and in a moment a revolution was accomplished, the most remarkable perhaps of any recorded in history.

201 Insurrections and revolution.

But before we proceed in our narration, and detail the

the transactions which have marked the progress of this singular and terrible revolution, it may be worth while to take a short view of the internal situation of France previous to this period, and the more obvious political causes, the operation of which seems to have contributed to the production of this great event.

The moral history of man is always more important than the mere recital of any physical occurrences that may take place in his lot. It is not the fall of a mighty monarch and the dispersion of his family; it is not the convulsions of empires, and the oceans of human blood which have been shed, that render the French revolution peculiarly interesting. Such events, however deplorable, are far from being without example in the history of mankind. In the populous regions of the east, where superstition and slavery have always prevailed, they are regarded as forming a part of the ordinary course of human affairs; because an intrepid and skilful usurper finds it easy to intimidate or ensnare millions of weak and credulous men. In Europe the case is very different; no adventurer can advance far without encountering thousands as artful and as daring as himself. Events are not the result either of blind hazard or of individual skill; conspiracies or plots produce little effect. Like other arts, the art of government has been brought to much perfection; and an established constitution can only be shaken by the strong convulsion produced by national passions and efforts. The wonderful spectacle which we are now to contemplate, is that of a mild and polished people becoming in an instant sanguinary and fierce; a well established government, celebrated for its dexterity and skill, overturned almost without a struggle; a whole nation apparently uniting to destroy every institution which antiquity had hallowed or education taught them to respect; a superstitious people treating the religion of their fathers with contempt; a long-enslaved people, whose very chains had become dear to them, occupied in their public councils in the discussion of refined and even visionary schemes of freedom: in short, 25,000,000 of persons suddenly treading under foot every sentiment and every prejudice that they themselves had once regarded as sacred and venerable.

202
France formerly under a barbarous aristocracy.

Like the other nations of Europe, France was anciently governed by a barbarous aristocracy, whose different members were feebly united by the authority of a succession of kings destitute of power or influence. The nobles, within their own territories, enjoyed privileges entirely royal: they made peace and war; they coined money; they were judges in the last resort; their vassals were their slaves, whom they bought and sold along with the lands; the inhabitants of cities, although freemen, were depressed and poor, depending for protection upon some tyrannical baron in their neighbourhood. At length, however, by the progress of the arts, the cities rose into considerable importance, and their inhabitants, along with such freemen of low rank as resided in the country, were considered as entitled to a representation in the states-general of the kingdom, under the appellation of *tiers etat*, or *third estate;* the clergy and the nobles forming the two first estates. But the sovereign having speedily become despotic, the meetings of the states-general were laid aside. This absolute authority, on the part of the crown, was not acquired, as it was in England by the house of Tudor, by abolishing the pernicious privileges of the nobles and elevating the commons; but by skilful encroachments, by daring exertions of prerogative, and the use of a powerful military force. In France, therefore, the monarch was absolute, yet the nobles retained all their feudal privileges, and the ecclesiastical hierarchy did the same. The following was, in a few words, the state of that country during these two last centuries.

203
Was never reduced into one homogeneous mass.

The kingdom of France, previous to the revolution, was never reduced to one homogeneous mass. It consisted of a variety of separate provinces acquired by different means; some by marriage, some by legacy, and others by conquest. Each province retained its ancient laws and privileges, whether political or civil, as expressed in their capitularies or conditions by which they were originally acquired. In one part of his dominions the French monarch was a count, in another he was a duke, and in others he was a king; the only bond which united his vast empire being the strong military force by which it was overawed. Each province had its barriers; and the intercourse betwixt one province and another was often more restrained by local usages than the intercourse of either with a foreign country. Some of the provinces, such as Bretagne and Dauphiné, even retained the right of assembling periodically their provincial states; but these formed no barrier against the power of the court.

204
The clergy formed the first estate in the kingdom.

The clergy formed the first estate of the kingdom in point of precedence. They amounted to 130,000. The higher orders of them enjoyed immense revenues; but the *curés* or great body of acting clergy seldom possessed more than about 28l. sterling a-year, and their *vicaires* about half that sum. A few of their dignified clergy were men of great piety, who resided constantly in their dioceses, and attended to the duties of their office; but by far the greater number of them passed their lives at Paris and Versailles, immersed in all the intrigues and dissipation of a gay and corrupted court and capital. They were almost exclusively selected from among the younger branches of the families of the most powerful nobility, and accounted it a kind of dishonour to the order of bishops for any persons of low rank to be admitted into it. The lower clergy, on the contrary, were persons of mean birth, and had little chance of preferment. At the same time, we find several respectable exceptions to this last rule. The clergy, as a body, independent of the tithes, possessed a revenue arising from their property in land, amounting to four or five millions sterling annually; at the same time they were exempt from taxation. The crown had of late years attempted to break through this privilege. To avoid the danger, the clergy presented to the court a free gift of a sum of money somewhat short of a million sterling every five years.

205
The nobility the second.

The nobility was nominally the second order of the state, but it was in reality the first. The nobles amounted to no less than 200,000 in number. The title and rank descended to all the children of the family, but the property to the eldest alone: hence vast multitudes of them were dependent on the bounty of the court. They regarded the useful and commercial arts as dishonourable, and even the liberal professions of the law and physic as in a great measure beneath their dignity, dis-

daining

daining to intermarry with the families of their professors. The feudal system in its purity was extremely favourable to the production of respectable qualities in the minds of those who belonged to the order of the nobles; but the introduction of commerce has rendered its decline equally unfavourable to that class of men. Instead of the ancient patriarchal attachment between the feudal chieftain and his vassals, the nobility had become greedy landlords in the provinces, that they might appear in splendour at court and in the capital. There, lost in intrigue, sensuality, and vanity, their characters became frivolous and contemptible. Such of the French noblesse, however, as remained in the provinces, regarded with indignation this degradation of their order, and still retained a proud sense of honour and of courage, which has always rendered them respectable. The order of the nobles was exempted from the payment of taxes, although the property of some of them was immense. The estates of the prince of Condé, for example, were worth 200,000l. a-year, and those of the duke of Orleans nearly twice as much. The crown had indeed imposed some trifling taxes upon the noblesse, which, however, they in a great measure contrived to elude.

206 The parliament the third.

Next to the nobles, and as a privileged order possessing a secondary kind of nobility of their own, we may mention the parliaments. These were large bodies of men, in different provinces, appointed as courts of law for the administration of justice. In consequence of the corruption of the officers of state, the members purchased their places, which they held for life; but the son was usually preferred when he offered to purchase his father's place. In consequence of this last circumstance, the practising lawyers had little chance of ever becoming judges. Courts thus constituted, consisted of a motley mixture of old and young, learned and ignorant, men. Justice was ill administered. The judges allowed their votes in depending causes to be openly solicited by the parties or their friends. No wise man ever entered into a litigation against a member of one of these parliaments; no lawyer would undertake to plead his cause; it never came to a successful issue, and usually never came to any issue at all. After the states-general had fallen into disuse, the parliaments acquired a certain degree of political consequence, and formed the only check upon the absolute power of the crown. The laws, or royal edicts, before being put in force, were always sent to be registered in the books of the parliaments. Taking advantage of this, in favourable times and circumstances, they often delayed or refused to register the royal edicts, and presented remonstrances against them. This was done under a kind of legal fiction: for they pretended that the obnoxious edict being injurious to the public happiness, could not be the will of the king, but must either be a forgery or an imposition by the ministers. These objections were got the better of, either by a positive order from the king, or by his coming in person and ordering the edict to be registered. The parliaments, however, often carried their opposition very far, even to the ruin of themselves and their families as individuals. This rendered them extremely popular with the nation, and enabled them to embarrass a weak administration. After all, however, the opposition of the parliaments was so feeble, that it was never thought worth while to abolish them entirely till towards the end of the reign of Louis XV.; but they were restored as a popular measure, at the beginning of the reign of Louis XVI.

207 The commons the lowest order. Oppressive burdens of them.

The *tiers etat*, or commons, formed the lowest order of the state in France, and they were depressed and miserable in the extreme. To form a conception of their situation, it is necessary to observe that they bore the whole pecuniary burdens of the state: They alone were liable to taxation. An expensive and ambitious court; an army of 200,000 men in time of peace, and of twice that number in war; a considerable marine establishment, public roads and works, were all supported exclusively by the lowest of the people. To add to the evil, the revenues were ill collected. They were let out to farmers-general at a certain sum, over and above which they not only acquired immense fortunes to themselves, but were enabled to advance enormous presents to those favourites or mistresses of the king or the minister, by means of whom they procured their places. To raise all this money from the people, they were guilty of the cruellest oppression, having it in their power to obtain whatever revenue laws they pleased, and executing them in the severest manner. For this last purpose they kept in pay an army of clerks, subalterns, scouts, and spies, amounting to 80,000 men. These men were indeed detested by the king, whom they deceived and kept in poverty; by the people, whom they oppressed; and by the ancient nobility, as purse-proud upstarts. But the court of France could never contrive to manage without them. The peasants could be called out by the intendants of the provinces, in what they called *corvées*, to work upon the high roads for a certain number of days in the year, which was a source of severe oppression, as the intendant had the choice of the time and place of their employment, and was not bound to accept of any commutation in money. They were moreover subject to the nobles in a thousand ways. The nobles retained all their ancient manorial or patrimonial jurisdictions. The common people being anciently slaves, had obtained their freedom upon different conditions. In many places they and their posterity remained bound to pay a perpetual tribute to their feudal lords. Such tributes formed a considerable part of the revenue of many of the provincial nobles. No man could be an officer of the army, by a late regulation, who did not produce proofs of nobility for four generations. The parliaments, although originally of the *tiers etat*, attempted also to introduce a rule that none but the noblesse should be admitted into their order. In such a situation, it will not be accounted surprising that the common people of France were extremely superstitious and ignorant. They were, however, passionately devoted to their monarch, and whatever concerned him. In 1754, when Louis XV. was taken ill at Metz, the whole nation was truly in a kind of despair. The courier and his horse that brought the news of his recovery to Paris were both almost suffocated by the embraces of the people.

208 Despotic power of the king.

We have said that the French monarch was despotic. His power was supported by his army, and by a watchful police, having in pay an infinite host of spies and other servants. In France no man was safe. The secrets of private families were searched into. Nothing

was

was unknown to the jealous inquisition of the police. Men were seized by *lettres de cachet* when they least expected it, and their families had no means of discovering their fate. The sentence of a court of law against a nobleman was usually reversed by the minister. No book was published without the license of a censor-general appointed by the court, and the minister was accountable to none but the king. No account was given of the expenditure of the public money. Enormous gratifications and pensions were given as the reward of the most infamous services. The supreme power of the state was usually lodged with a favourite mistress, and she was sometimes a woman taken from public prostitution. This was not indeed the case under Louis XVI. but it was nevertheless one of the misfortunes of his life that he was far from being absolute in his own family. Still, however, with all its faults, the French court was the most splendid and polished in Europe. It was more the resort of men of talents and literature of every kind, and there they met with more ample protection, than anywhere else. The court was often jealous of their productions, but they met with the most distinguished attention from men of fortune and rank; insomuch that for a century past the French have given the law to Europe in all questions of taste, of literature, and of every polite accomplishment. The gay elegance that prevailed at court diffused itself through the nation; and amidst much internal misery, gave it to a foreigner the appearance of happiness, or at least of levity and vanity.

209 Splendour of the court &c.

210 Causes of the revolution.

Such as it was, this government had stood for ages, and might have continued, had not a concurrence of causes contributed to its overthrow. The inferior orders of clergy, excluded from all chance of preferment, regarded their superiors with jealousy and envy, and were ready to join the laity of their own rank in any popular commotion. The inferior provincial noblesse beheld with contempt and indignation the vices and the power of the courtiers, and the higher nobility wished to diminish the power of the crown. The practising lawyers, almost entirely excluded from the chance of becoming judges, wished eagerly for a change of affairs, not doubting that their talents and professional skill would render them necessary amidst any alterations that could occur. Accordingly, they were the first instruments in producing the revolution, and have been its most active supporters. The moneyed interest wished eagerly for the downfal of the ancient nobility. As for the great mass of the common people, they were too ignorant, too superstitiously attached to old establishments, and too much depressed, to have any conception of the nature of political liberty, or any hope of obtaining it. We have already stated the leading circumstances which led to the French revolution (see N° 184, &c.); but there were other circumstances which contributed in an equal degree both to its commencement and its progress.

For 40 years the principles of liberty had been disseminated with eagerness in France by some men of great talents, as Rousseau, Helvetius, and Raynal, to whom the celebrated Montesquieu had led the way. Besides these, there was in France a vast multitude of what were called *men of letters*, or persons who gave this account of the manner in which they spent their time. All these were deeply engaged on the side of some kind of political reform. The men of letters in Paris alone are said to have amounted to 20,000. One of the last acts of the administration of the archbishop of Thoulouse was, on the 5th July 1788, to publish a resolution of the king in council, inviting all his subjects to give him their advice with regard to the state of affairs. This was considered as a concession of an unlimited liberty of the press; and it is scarcely possible to form an idea of the infinite variety of political publications which from that period diffused among the people a dissatisfaction with the order of things in which they had hitherto lived.

The established religion of France had for some time past been gradually undermined. It had been solemnly assaulted by philosophers in various elaborate performances; and men of wit, among whom Voltaire took the lead, had attacked it with the dangerous weapon of ridicule. The Roman Catholic religion is much exposed in this respect, in consequence of the multitude of false miracles and legendary tales with which its history abounds. Without discriminating betwixt the respectable principles on which it rests, and the superstitious follies by which they had been defaced, the French nation learned to laugh at the whole, and rejected instead of reforming the religion of their fathers. Thus the first order in the state had already begun to be regarded as useless, and the minds of men were prepared for important changes.

The immense population of the city of Paris, amounting to upwards of 800,000 souls, rendered it an important engine in the hands of the conductors of the revolution. An overgrown capital has always proved dangerous to a government that is or attempts to be despotic, as appears from the history of ancient Babylon and Rome, as well as of modern Constantinople, of London under Charles I. and Paris under several of its kings.

We cannot here avoid mentioning a physical event, which assisted not a little in producing many of the convulsions attending the revolution, a general scarcity of grain, which occurred about that period. On Sunday the 13th of July 1788, about nine in the morning, without any eclipse, a dreadful darkness suddenly overspread several parts of France. It was the prelude of such a tempest as is unexampled in the temperate climates of Europe. Wind, rain, hail, and thunder, seemed to contend in impetuosity; but the hail was the great instrument of ruin. Instead of the rich prospects of an early autumn, the face of nature in the space of an hour presented the dreary aspect of universal winter. The soil was converted into a morass, the standing corn beaten into the quagmire, the vines broken to pieces, the fruit trees demolished, and unmelted hail lying in heaps like rocks of solid ice. Even the robust forest trees were unable to withstand the fury of the tempest. The hail was composed of enormous, solid, and angular pieces of ice, some of them weighing from eight to ten ounces. The country people, beaten down in the fields on their way to church, amidst this concussion of the elements, concluded that the last day was arrived; and scarcely attempting to extricate themselves, France. themselves, lay despairing and half suffocated amidst the water and the mud, expecting the immediate dissolution of all things. The storm was irregular in its devastations. While several rich districts were laid entirely waste, some intermediate portions of country were comparatively little injured. One of 60 square leagues had not a single ear of corn or fruit of any kind left. Of the 66 parishes in the district of Pontoise, 43 were entirely desolated, and of the remaining 23 some lost two-thirds and others half their harvest. The Isle of France, being the district in which Paris is situated, and the Orleannois, appear to have suffered chiefly. The damage there, upon a moderate estimate, amounted to 80,000,000 of livres, or between three and four millions sterling. Such a calamity must at any period have been severely felt; but occurring on the eve of a great political revolution, and amidst a general scarcity throughout Europe, it was peculiarly unfortunate, and gave more embarrassment to the government than perhaps any other event whatever. Numbers of families found it necessary to contract their mode of living for a time, and to dismiss their servants, who were thus left destitute of bread. Added to the public discontent and political dissensions, it produced such an effect upon the people in general, that the nation seemed to have changed its character; and instead of that levity by which it had ever been distinguished, a settled gloom now seemed fixed on every countenance.

211 Attempt to reduce the power of the crown in spring 1789.

The spring of the year 1789 was a period of much political anxiety in France. The superior orders wished to reduce the power of the crown, but were jealous of their own privileges, and determined to retain them; while the popular philosophers and others were endeavouring to render them odious, and to rouse the people to a love of freedom. Still, however, the great body of the common people remained careless spectators of the struggle, and unconscious of the approaching commotion. Such was their indifference, that few of them took the trouble even to attend and vote at the elections of the deputies to the states-general. In many places, where a thousand voters were expected, not fifty came forward; but such of them as did appear showed that a seed was sown which might one day rise into important fruits. In the instructions which they gave to their deputies, the British constitution was in general the model of what they wished their government to be. They demanded equal taxation, the abolition of *lettres de cachet* or arbitrary imprisonment, the responsibility of ministers, and the extinction of the feudal privileges of the nobles; but they wished that the whole three orders of the state should sit and vote in one house, well knowing that their nobility were not prepared to act the moderate part of a British house of lords. The nobles, on the contrary, although willing to renounce some of their pecuniary privileges, and to sacrifice the power of the crown, were most decisively resolved neither to surrender their feudal prerogatives nor the right of sitting in three separate assemblies; by means of which each of the orders could easily resist the encroachments of the other two. M. Neckar has been improperly censured for not deciding this last important question previous to the meeting of the states-general; but it must be observed, that the very purpose of calling that assembly was to overturn the unjust privileges of the higher orders through its medium, and without any direct interposition on the part of the ministers. Had the king positively decided in favour of three chambers, the nobles and the clergy would have retained all those ancient abuses established in their own favour, of which it was his wish to deprive them, and the crown and its prerogatives would have been the only objects of sacrifice. It was therefore thought safer to leave the *tiers etat* to fight its own battle; nor was it yet imagined that the commons of France, depressed and poor, and dispersed by situation over a multitude of provinces, could ever unite in enterprises dangerous to the sovereign.

212 States summoned to meet at Versailles.

The states had been summoned to meet at Versailles on the 27th of April, and most of the deputies arrived at that time; but the elections for the city of Paris not being concluded, the king deferred the commencement of their sessions till the 4th of May. During this period, the members, left in idleness, began to find out and form acquaintance with each other. Among others, a few members from Brittany (Bretagne) formed themselves into a club, into which they gradually admitted many other deputies that were found to be zealous for the popular cause, and also many persons who were not deputies. This society, thus originally established at Versailles, was called the *Comité Breton*; and was one day destined, under the appellation of the *Jacobin Club*, to give laws to France, and to diffuse terror and alarm throughout Europe. On the other side, the aristocratic party established conferences at the house of Madame Polignac, for the purpose, it is said, of uniting the nobles and the clergy.

213 A popular riot in the suburb of St Antoin.

An event occurred at this time which all parties ascribed to some malicious motive. In the populous suburb of St Antoine, a M. Reveillon carried on a great paper manufactory. A false report was spread that he intended to lower the wages of his workmen, and that he had declared bread was too good for them, and that they might subsist very well on potato-flour. A commotion was raised, he was burnt in effigy, and his house was thereafter burnt and pillaged by the mob, who were not dispersed till the military had been called in, and much carnage ensued. The popular party asserted that the commotion had been artfully excited by the party of the queen and the Count D'Artois, to afford a pretence for bringing great bodies of the military to the neighbourhood to overawe the states-general, or induce the king more decisively to resolve on assembling that body at Versailles, in preference to Paris, where they and the popular minister M. Neckar wished it to be held.

214 The States General commence business at Versailles.

On the 4th of May the states general assembled at Versailles. They commenced business by going in a solemn procession, preceded by the clergy, and followed by the king, according to ancient custom, to church, to perform an act of devotion. The nobles were arrayed in a splendid robe, and they and the higher clergy glittered in gold and jewels. The commons appeared in black, the dress belonging to the law. The assembly was thereafter opened by a short

short speech from the throne, in which the king congratulated himself on thus meeting his people assembled; alluded to the national debt, and the taxes, which were severely felt because unequally levied; he took notice of the general discontent and spirit of innovation which prevailed, but declared his confidence in the wisdom of the assembly for remedying every evil. "May an happy union (added he) reign in this assembly; and may this epocha become ever memorable for the happiness and prosperity of the country. It is the wish of my heart; it is the most ardent desire of my prayers; it is, in short, the price which I expect from the sincerity of my intentions and my love for my people."

M. Barretin, the keeper of the seals, next addressed the assembly in a congratulatory and uninteresting speech. He was followed by the popular minister M. Neckar, who spoke for three hours. Though much applauded on account of the clear financial details which his speech contained, he encountered a certain degree of censure from all parties, on account of the cautious ambiguity which he observed with regard to the future proceedings of the states-general.

215 Their debates and inactivity.

Next day the three orders assembled separately. The deputies of the *tiers etat* amounted to 600 in number, and those of the nobles and clergy to 300 each. During their first sittings much time was spent in unimportant debates about trifling points of form; but the first important question, that necessarily became the subject of their discussion, was the *verification of their powers*, or production of the commissions of the members, and investigation of their authenticity. The commons (*tiers etat*) laid hold of this as a pretext for opening the grand controversy, whether the states-general should sit in one or in three separate chambers? They sent a deputation inviting the nobles and the clergy to meet along with them in the common hall for the purpose of *verifying their powers* in one common assembly. In the chamber of the clergy 114 members voted for the performance of this ceremony in the general assembly; and 133 against it. But in the more haughty order of the nobles, the resolution for the verification in their own assembly was carried by a majority of 188 against 37. The commons paid no regard to this. They were conducted by bold and skilful leaders, who discerned the importance of the point in contest, and resolved not to abandon it. Aware of the exigencies of the state, they knew that the crown was nearly verging upon bankruptcy; and that such were the deficiencies of the revenue, that only a short delay was necessary to accomplish the absolute dissolution of the government. They suffered five weeks to pass away therefore in total inactivity. During this period proposals were made on the part of the ministry for a pacification between the three orders, and conferences were opened by commissioners from each. But no art could seduce the commons from their original purpose, or prevail with them to enter upon the business of the state.

216 Popularity of the Tiers Etat or commons.

The nation had expected much from the assembling of the states-general, and learnt the news of their inaction with no small degree of concern. The *tiers etat* was naturally popular, and the public censure could not readily devolve upon that favourite order. Moreover, from the first period of their assembling, the commons made every effort to augment their own natural popularity. They admitted all persons promiscuously into the galleries, and even into the body of their hall. No restraint was attempted to be laid upon the most vehement marks of popular applause or censure. Lists of the voters names were publicly taken and sent to Paris upon every remarkable occasion; and the members suddenly found themselves become, according to their political sentiments, the objects of general execration or applause. The new and bold notions of liberty that were daily advanced by the leaders of the *tiers etat* were received with acclamation by their hearers. The capital became interested in the issue of every debate; and the political fervor was eagerly imbibed by the nation with that vivacity which is so peculiar to the French. The commons accused the nobles of obstinately impeding the business of the state, by refusing to verify their powers in one common assembly. The accusation was swallowed by the multitude, who saw not, or were unwilling to see, that the attack was made by their own favourite order. In the mean time the nobles became rapidly more and more unpopular. Their persons were insulted, new publications daily came forth, and were greedily bought up, which reviled their whole order, and represented them as an useless or pernicious body of men, whose existence ought not to be tolerated in a free state. Whoever adhered to them was branded with the odious appellation of *Aristocrat*. The clergy, from the influence of the parish *curés* or parsons, seemed ready to desert their cause. They were even opposed by a minority of their own body, which derived lustre from having at its head the duke of Orleans the first prince of the blood. Still, however, the majority of the nobles remained firm; well aware, that if they once consented to sit in the same assembly, and to vote promiscuously, with the ambitious and more numerous body of the commons, their whole order, and all its splendid privileges must speedily be overthrown.

217 Taking advantage of this popularity, they seize the legislative authority;

The leaders of the commons saw the change that was taking place in the minds of men; and they at length regarded the period as arrived when they ought to emerge from their inactivity, and execute the daring project of seizing the legislative authority in their country. They declared that the representatives of the nobles and the clergy were only the deputies of particular incorporations whom they would allow to sit and vote along with themselves; but who had no title in a collective capacity to act as the legislators of France. For conducting business with more facility, they appointed 20 committees. In consequence of a proposal by the Abbe Sieyes, a final message was sent to the privileged orders, requiring their attendance as individuals, and intimating that the commons, as the deputies of 96 out of every hundred of their countrymen, were about to assume the exclusive power of legislation. None of the nobles obeyed this summons; but three curés, Messrs Cesve, Ballard, and Jallot, presented their commissions, and were received with loud acclamations. They were next day followed by five more, among whom were Messrs Gregoire, Dillon, and Bodineau. After some debate concerning the appellation which they ought to assume, the commons, with such

France. 1789. such of the clergy as had joined them, solemnly voted themselves the sovereign legislators of their country, under the name of the *National Assembly*. The result of the vote was no sooner declared, than the hall resounded with shouts from the immense concourse of spectators, of "Vive le roi et vive l'assemblée nationale," *Long live the king and the national assembly*. M. Bailly was chosen president for four days only, Messrs Camus and Pison de Galand secretaries, and the assembly proceeded to business.

218 And assert their own sovereignty.

Its first acts were decisively expressive of its own sovereignty. All taxes imposed without the consent of the representatives of the people were declared to be null and void; but a temporary sanction was given to the present taxes, although illegal, till the dissolution of the assembly, and no longer. It was added, that "as soon as, in concert with his majesty, the assembly should be able to fix the principles of national regeneration, it would take into consideration the *national debt*, placing, from the present moment, the creditors of the state under the safeguard and honour of the French nation."

219 Majority of the clergy unite with them.

The popular cause now gained ground so fast, that on the 19th of June a majority of the clergy voted for the verification of their powers in common with the national assembly, and they resolved to unite with them on the following day.

220 Fears of the nobles.

Affairs were now come to a crisis, and the nobles perceived that they must instantly make a decisive stand, or yield up their cause as finally lost. Such was their alarm, that M. d'Espremenil proposed, at one of the sittings of their order, to address the king, intreating him to dissolve the states-general. Hitherto that prince had gone along with M. Neckar in favouring the popular cause in opposition to the aristocracy. But every art was now used to alarm his mind upon the subject of the late assumptions of power on the part of the commons, and these arts were at length successful. Repeated councils were held; M. Neckar was absent attending a dying sister, and the king was prevailed upon to act agreeably to the advice of the leaders of the nobles. But the first measure which they adopted was so ill conducted as to afford little prospect of final success to their cause. On the 20th of June, when the president and members were about to enter as usual into their own hall, they found it unexpectedly surrounded by a detachment of the guards, who refused them admission, while the heralds at the same time proclaimed a royal session. Alarmed by this unforeseen event, the meaning of which they knew not, but apprehending that an immediate dissolution of the assembly was designed, they instantly retired to a neighbouring tennis court, where, in the vehemence of their enthusiasm, they took a solemn oath "never to separate till the constitution of their country should be completed."

221 Royal session proclaimed.

On the 22d a new proclamation intimated that the royal session was deferred till the following day. It was now found that the assembly had been excluded from their hall merely because the workmen were occupied in preparing it for the intended solemnity. This information was ill calculated to excite favourable expectations of the measures about to be adopted at a royal session, ushered in by such circumstances of marked disrespect for the representatives of the people. The assembly, after wandering about in search of a place of meeting, at length entered the church of St Louis, and were immediately joined by the majority of the clergy, with their president, the archbishop of Vienne, at their head. Two nobles of Dauphiné, the marquis de Blaçon and the count d'Agoult, presented their commissions at the same time. Encouraged by these events, and by the applauses of surrounding multitudes, the assembly now expected with firmness the measures about to be adopted.

France. 1789. 222 The Assembly meets in the church of St Louis.

223 Discourse of the king.

The royal session was held in the most splendid form, but altogether in the style of the ancient despotism. Soldiers surrounded the hall. The two superior orders were seated, while the representatives of the people, left standing a full hour in the rain, were in no humour, when at last admitted, to receive with much complacency the commands of their sovereign. The king read a discourse, in which he declared null and void the resolutions of the 17th, but at the same time presented the plan of a constitution for France. It contained many good and patriotic principles, but preserved the distinction of orders, and the exercise of *letters de cachet*; it said nothing about any active share in the legislative power to be possessed by the states-general, and was silent both about the responsibility of ministers and the liberty of the press. The king concluded by commanding the deputies immediately to retire, and to assemble again on the following day. He then withdrew, and was followed by all the nobles and a part of the clergy. The commons remained in gloomy silence on their seats. It was interrupted by the grand master of the ceremonies, who reminded the president of the intentions of the king. Instantly the vehement count de Mirabeau, starting from his seat, exclaimed with indignation, "The commons of France have determined to debate. We have heard the intentions that have been suggested to the king; and you, who cannot be his agent with the states-general, you who have here neither seat nor voice, nor a right to speak, are not the person to remind us of his speech. Go tell your master that we are here by the power of the people, and that nothing shall expel us but the bayonet." The applause of the assembly seconded the enthusiasm of the orator, and the master of the ceremonies withdrew in silence.

224 Ill received by the commons.

225 Debates after the king's departure.

M. Camus then rose; and in a violent speech indignantly stigmatized the royal session by the obnoxious appellation of a *bed of justice*; he concluded by moving that the assembly should declare their unqualified adherence to their former decrees. This motion was followed by another, pronouncing the persons of the deputies inviolable. Both were supported by Messrs Petion, Barnave, Glaizen, the Abbes Gregoire, Sieyes, and many others, and were unanimously decreed. The assembly, therefore, continued their sittings in the usual form. On the following day the majority of the clergy attended as members; and on the 25th the duke of Orleans, along with 49 of the deputies belonging to the order of nobles, joined them also. The remaining nobles, as well as the small minority of the clergy, now found themselves awkwardly situated. Whether on this account, or because their leaders had by this time formed a plan for carrying their point not by peaceable means but by the aid of a military force, the king, on the 27th, invited by a pressing letter both orders to to join the commons. This request was immediately complied with, although many of the nobility disapproved of the measure.

226 Alarming situation of France at this period.

The situation of France was now become truly alarming. When the king retired from the assembly after the royal session, he was followed by more than 6000 citizens, from whom loud clamours and every mark of disapprobation broke forth. All Versailles was speedily in an uproar. M. Neckar had repeatedly solicited his dismission, and the report of this had increased the popular clamour. The court was in consternation. The king probably discovered, with no great satisfaction, that his minister was more popular than himself. At six o'clock in the evening the queen sent for M. Neckar. When he returned from the palace, he assured the crowd that waited for him that he would not abandon them; upon which they retired satisfied. At the same time the news of the royal session had thrown the city of Paris into violent agitation. The peace of that capital was at this time deranged by a variety of causes. A dreadful famine raged through the land, which in a great city is usually most severely felt. This prepared the minds of men for receiving unfavourable impressions of their political state. Every effort was moreover made to disorganize the government, and pro-

227 Numerous seditious publications.

duce a dislike to the ancient order of things. The press poured forth innumerable publications, filled with new and seducing, though generally impracticable, theories of liberty. These were distributed *gratis* among the bulk of the people of Paris, and dispersed in the same manner through the provinces. Philip duke of Orleans) presumptive heir to the crown, failing the children and brothers of the king) is with good reason believed to have supplied this expence out of his more than royal revenues. In the gardens of the Palais Royal at Paris, which belonged to him, an immense multitude was daily assembled, listening from morning to night to orators who descanted upon the most violent subjects of popular politics. Many of these orators were suspected to be in his pay. It was even believed that his money found its way into the pockets of some of the most distinguished leaders in the national assembly.

228 Seduction of the military.

But the government was, if possible, still more dangerously assaulted by the methods now generally used to seduce the military. Every officer of the French army belonged to the order of the nobles; and from that quarter, therefore, it might have been imagined that there was little danger. But this very circumstance became the means of disorganizing that great engine of despotism. As the soldiers could not avoid imbibing some of the new opinions, their own officers became the first objects of their jealousy; especially in consequence of that impolitic edict of Louis XVI. which required every officer to produce proofs of four degrees of nobility; and thus insulted, by avowedly excluding the private men from promotion. Perhaps with a view to what might happen, the instructions to the deputies of the *tiers etat* had recommended an increase of the pay of the soldiers. And now at Paris every art was used to gain them to the popular cause. They were conducted to the Palais Royal, and were there caressed and flattered by the populace, while they listened to the popular harangues. These arts were successful. On the 23d of June they first refused to fire on the mob in a riot. Some of them were on the 30th reported to be in confinement for this offence; a crowd instantly collected, and rescued them, the dragoons that were brought to suppress the tumult grounding their arms. A deputation of the citizens solicited of the assembly the pardon of the prisoners. The assembly applied to the king, who pardoned them accordingly.

229 The military called out.

All these events, together with the tumultuous state of the capital, which was daily increasing, made it necessary for the king to call out the military force to restore, if possible, the public peace. That his intentions were pure, the then state of affairs will permit no man but a democrat to doubt; but the aristocracy, with the Count d'Artois at their head, were bringing forward other measures, which ultimately contributed to the ruin of themselves, the king, and the kingdom. Crowds of soldiers were collected from all parts of the kingdom around Paris and Versailles. It was observed that these consisted chiefly of foreign mercenaries. Camps were traced out. Marshal Broglio, a tried veteran, was sent for and placed at the head of the army. The king was supposed to have entirely yielded to new counsels, and every thing bore the appearance of a desperate effort to restore the energy of the ancient government. This is the most important period of the French revolution; yet the specific designs of the leading actors have never been clearly understood. It was rumoured at the time, that Paris was to be subdued by a siege and bombardment; that the assembly was to be dissolved, and its leaders put to death. These are incredible exaggerations; but the crisis of French liberty was universally regarded as at hand, and also the existence of the national assembly as an independent body; or at least upon any other footing than that proposed by the king on the 23d of June.

230 The assembly address the king to remove them, which is refused.

An able and eloquent address to the king against the assemblage of foreign troops in their neighbourhood was brought forward by Mirabeau, and voted by the assembly. The king properly replied, that the state of the capital was the cause of assembling the troops, and offered to transfer the states-general to Noyons or Soissons. "We will neither remove (exclaimed Mirabeau) to Noyons or to Soissons; we will not place ourselves between two hostile armies, that which is besieging Paris, and that which may fall upon us through Flanders or Alsace; we have not asked permission to run away from the troops; we have desired that the troops should be removed from the capital."

Thirty-five thousand men were now stationed in the neighbourhood of Paris and Versailles. The posts were occupied which commanded the city, and camps were marked out for a greater force. The Count d'Artois and his party regarded their plans as ripe for execution; and M. Neckar received a letter from the king, requiring him to quit the kingdom in 24 hours. That popular minister took the route of Brussels on the following day, when his departure was made public. In his dismission the popular, or, as it was now called, the *democratic* party, thought they saw the resolution adopted to accomplish their ruin. The assembly again addressed the throne; they requested anew the removal of the troops, offering to be responsible for the public peace, and to proceed in a body to Paris to encoun-

231 They again address the king;

ter

ter personally every danger that might occur. But they were coolly told, that the king was the best judge of the mode of employing the troops, and that the presence of the assembly was necessary at Versailles.

232 *and are again refused.*

From a sovereign who doubtless recollected the proceedings of the long parliament of England, a different reply could not in reason be expected.

233 *Decree of the assembly in consequence.*

On receiving it, however, it was instantly decreed, on the motion of the marquis de la Fayette, that the late ministry had *carried with them* the confidence of the assembly; that the troops *ought* to be *removed*; that the ministry are and shall be responsible to the people for their conduct; that the assembly persisted in all its former decrees; and that as it had taken the public debt under the protection of the nation, no power in France was entitled to pronounce the infamous word *bankruptcy*.

234 *Consternation in Paris on Neckar's retreat.*

The city of Paris was thrown into deep consternation by the news of M. Neckar's retreat. His bust and that of the duke d'Orleans were dressed in mourning, and carried through the streets. The royal Allemand, a German regiment, broke in pieces the busts, and dispersed the populace.

235 *Cruelty of the Prince De Lambesq.*

The prince de Lambesq, grand ecuyer of France, was ordered to advance with his regiment of cavalry, and take post at the Thuilleries. Being a man of a violent temper, and enraged by the appearances of disapprobation which were visible around him, he furiously cut down with his sword a poor old man who was walking peaceably in the gardens. The consequences of this act of inhumanity were such as might have been expected; a shout of execration instantly arose; the cry *to arms* was heard; the military were assaulted on all sides; the French guards joined their countrymen, and compelled the Germans, overpowered by numbers, and unsupported by the rest of the army, to retire.

236 *Terror in the city universal.*

All order was now at an end, and as night approached an universal terror diffused itself through the city. Bands of robbers were collecting; and from them or from the foreign soldiery a general pillage was expected. The night passed away in consternation and tumult. It was found in the morning that the hospital of St Lazare was already plundered. The alarm bells were rung; the citizens assembled at the Hotel de Ville, and adopted a proposal that was there made, of enrolling themselves as a militia for general defence, under the appellation of the *national guard*. This day and the succeeding night were spent in tolerable quietness, without any attempt on the part of the army. On the morning of the memorable 14th of July, it was discovered that the troops encamped in the Champs Elisees had moved off, and an immediate assault was expected. The national guard now amounted to 150,000 men; but they were in general destitute of arms. They had assumed a green cockade; but on recollecting that this was the livery of the Count d'Artois, they adopted one of red, blue, and white. M. de la Salle was named commander in chief, officers were chosen, and detachments sent round in quest of arms. In the Hotel des Invalides upwards of 30,000 stand of arms were found, along with 20 pieces of cannon; a variety of weapons was also procured from the *garde meuble de la couronne*, and from the shops of armourers, cutlers, &c.

The celebrated fortress of the Bastile was an object of much jealousy to the Parisians. At 11 o'clock in the morning, M. de la Rosiere, at the head of a numerous deputation, waited upon M. de Launay the governor, who promised, along with the officers of his garrison, that they would not fire upon the city unless they should be attacked.

237 *The Bastile attacked;*

But a report was soon spread through Paris, that M. de Launay had, in a short time thereafter, admitted into the fortress a multitude of persons, and then treacherously massacred them. The cause of this piece of perfidy has never been explained. The fact itself has been denied; but it was attested at the time by the duke of Dorset, the British ambassador at the court of France. The effect of the report was, that a sudden resolution was adopted of assaulting the Bastile; an immense and furious multitude rushed into its outer, and soon forced their way into its inner courts, where they received and returned a severe fire for the space of an hour. The French guards, who were now embodied into the national guard, conducted the attack with skill and coolness; they dragged three waggons loaded with straw to the foot of the walls, and there set them on fire; the smoke of these broke the aim of the garrison, while it gave no disturbance to the more distant assailants. The besieging multitude pressed the attack with incredible obstinacy and vigour for the space of four hours; the garrison was in confusion; the officers served the cannon in person, and fired their muskets in the ranks; the governor, in despair, thrice attempted to blow up the fortress.

238 *and surrendered unconditionally.*

A capitulation, when at last sought, was refused to the garrison, and an unconditional surrender took place. The governor, and M. de Losme Salbrai his major, a gentleman of distinguished humanity and honour, became victims of popular fury in spite of every effort that could be made for their protection; but the French guards succeeded in procuring the safety of the garrison. Only seven prisoners were found in the Bastile. A guard was placed in it, and the keys were sent to the celebrated M. Brissot de Warville, who a few years before had inhabited one of its caverns.

The remaining part of this eventful day was spent at Paris in a mixture of triumph and alarm. In the pocket of the governor of the Bastile a letter was found, encouraging him to resistance by the promise of speedy succours, written by M. de Flesselles, the prevot des marchands, or chief city magistrate, who had pretended to be a most zealous patriot. This piece of treachery was punished by instant death; and his bloody head was carried through the city on a pole, along with that of M. de Launay. At the approach of night a body of troops advanced towards the city, at the Barriere d'Enfer. The new national guard hurried thither, preceded by a train of artillery, and the troops withdrew upon the first fire: barricadoes were everywhere formed, the alarm-bells were rung, and a general illumination continued during the whole of this night of confusion.

239 *A new ministry appointed.*

In the mean time, it was obvious that the new ministry were entering upon a difficult scene of action, where one false step might lead to ruin, and where their own plan of conduct ought to be maturely digested. Marshal Broglio was made minister of war, the baron de Breteuil president of finance, M. de la Galeziere comptroller-general, M. de la Porte intendant of the war department, and M. Foulon intendant of the navy;

ance. 789. 240 ir situa- diffi- , and r con- bad.

navy; but these were only meant to act as official men, under the Count d'Artois, and the other leaders of the aristocracy. To these leaders there did not even remain a choice of difficulties; no resource was left but that of overawing by military power the national assembly and the capital, and of risking the desperate measure of a national bankruptcy, which the court had not formerly dared to encounter, and to avoid which it had convoked the states-general. No trace remains, however, of any attempts to put this criminal, but last resource, in execution. The evening after the departure of M. Neckar was spent by the court of Versailles in feasting and joy, as if a victory had been gained. The courtiers of both sexes went round among the soldiery, striving to secure their fidelity by caresses, largesses, and every species of flattering attention. The ministry not only failed to support the Prince de Lambesq in the post which he had been sent to occupy, but they suffered the whole of the 13th to pass in indecision, while the capital was in a state of rebellion, while an army was formally mustering within its walls, and the names of the principal nobility were put up in lists of proscriptions. They received the news of the capture of the Bastile with confusion and dismay, which were increased, if possible, by information given by Marshal Broglio, that the troops refused to act against Paris or the national assembly. In this perplexity they adopted the miserable device of concealing from the king the state of public affairs; and that unfortunate prince was thus perhaps the only person out of millions around him who remained ignorant of the convulsions in which his country was involved.

At length, at midnight, the duke de Liancourt forced his way into the king's apartment, and told him of the revolt of his capital, of his army, and of the surrender of the fortress of the Bastile. The Count d'Artois, who was present, still attempted to retain the monarch under his fatal delusion; but the duke de Liancourt turning round, exclaimed, "As for you, Sir, your life can only be saved by instant flight; I have seen with horror your name in the bloody list of the proscribed." Accordingly the count, with the members of his short-lived administration and their adherents, fled to the frontiers. And thus an emigration commenced, the source of that terrible contest which has covered Europe with bloodshed and mourning. This ministry had, no doubt, many difficulties to contend against; but an accurate attention to their conduct excites a suspicion which, while it exculpates them from many intended crimes that have been laid to their charge, at the same time does little honour to their talents. It is this, that they had come into office without having formed any clear plan of conduct; that they were men acting without decision and at random, and consequently became the sport of those events which they wanted skill and vigour to direct or controul. By their introduction into office, and their misconduct while in it, the royal authority fell prostrate before the popular party in the national assembly. The nobles and the clergy still remained, but confounded in one assembly with the more numerous order of the *tiers etat;* and no longer rallying round a throne that was too feeble to afford protection, they soon yielded to that fierce and levelling spirit of democracy that now rose around them.

France 1789. 241 The king goes to the assembly.

But the person of the monarch was still beloved.—Early next morning the king went to the assembly, but with none of the usual solemnities. He "regretted the commotions of the capital, disavowed any knowledge of an intention against the persons of the deputies, and intimated that he had commanded the removal of the troops." A deep and expressive silence prevailed for a few moments; this was succeeded by vehement and universal shouts of applause. The king rose to depart, and instantly the whole assembly crowded around, and attended him to his palace. The queen appeared at a balcony with the dauphin in her arms; the music played the pathetic air of *Où peut on être mieux qu'au sein de sa famille.* The enthusiasm of loyalty communicated itself to the surrounding multitudes, and nothing was heard but acclamations of joy.

242 And next day visits the city of Paris in person;

On the following day, the king declared his resolution to visit the city of Paris in person. Accordingly that prince, who never wanted personal courage, however deficient he might be in political stedfastness, set out, attended by some members of the assembly and by the militia of Versailles. He was met by the celebrated M. de la Fayette, at the head of a body of the national guard, of which he had now been chosen commander in chief. M. Bailly, in whose person the ancient office of mayor of Paris had been revived, received the king at the gates, and delivered to him the keys. All this while no shout was heard from the crowd of innumerable spectators but that of *Vive la nation.* The king advanced to the Hotel de Ville, where the new cockade was presented to him, which he put on, and presented himself with it at the window. At the sight of this badge of patriotism an universal shout of *Vive le Roi* burst forth from every quarter; and he returned to Versailles amidst general triumph and applause.

243 in which much confusion still prevailed.

Much confusion still prevailed in the capital; but there was more appearance of regularity than could have been expected at the conclusion of such important events. This arose from a casual concurrence of circumstances. To conduct with ease the elections to the states general, Paris had been divided into 60 districts, each of which had a separate place of meeting. The people did not elect the members to the states-general; but they chose delegates, who under the name of electors, voted for the members. At the commencement of the disturbances, the electors, at the request of their fellow-citizens, assumed a temporary authority; of which however they were soon weary, and as soon as possible procured the public election of 120 persons as municipal officers for the government of the city. The citizens having got the habit of assembling in their districts, grew fond of it: they assembled frequently, made rules for their own government, and sent commissioners to communicate with other districts. The tumultuous nature of these meetings, and the vehemence of debate which prevailed in them, will best be conceived from the ludicrous contrivance of one of their presidents, who stationed a drummer at the back of his chair, and when the confusion and noise became altogether ungovernable, gave the signal for beating the drum, which speedily overpowered every other noise. These meetings, however, gradually ripened into clubs, in which much dexterity and intrigue were exerted.

The whole of the late ministry escaped excepting M. Foulon,

France. 1789.

Foulon. His character, it may well be imagined, was extremely unpopular; for he is said to have asserted, that he would "make the people of Paris eat hay."

244 Fate of M. Foulon, and Berthier.

He had retired to the country, but was seized by his own vassals, and brought to Paris with a bundle of hay tied on his back. In spite of every effort made by M. M. Bailly and Fayette to procure him a fair trial at least, he was carried to the *Place de Greve*, and hanged at a lamp-iron by the enraged multitude. His son-in-law, M. Berthier, attempting to defend himself against a similar fate, fell, covered with wounds. Their heads were carried round on poles; and thus the populace became habituated to the sight of blood and murder: they were even taught by popular songs to glory in such actions, and particularly by the well known song *Ca-ira*.

245 Consequences of M. Neckar's return.

In consequence of an invitation from the king, M. Neckar returned to France. He was received by the assembly with great applause, and in Paris with infinite solemnity and triumph. He here, however, committed a political error that made some noise. In deploring the late excesses and murders, and taking notice of the arrest of M. Bezenval, an officer of the Swiss guards, he requested of the electors at the Hotel de Ville, in a solemn harangue, that the past should be forgotten; that proscriptions should cease, and a general amnesty be proclaimed. In a moment of enthusiasm this was agreed to, and the electors decreed what unquestionably exceeded their powers. The districts of Paris were instantly in commotion; the electors alarmed, declared that they only meant that "henceforth the people would punish no man but according to law;" and at the same time, to prove that they themselves were free from ambition, they formally renounced all their own powers. The assembly took up the question. Lally Tolendal, Mounier, Clermont Tonnerre, Garat junior, and others, declared that no person ought to be arrested without a formal accusation; while Mirabeau, Robespierre, Barnave, and Gleizen, alleged, on the contrary, that the people were entitled to lay hold of any man who had publicly appeared at the head of their enemies. The debate ended, by admitting the explanation of the electors, and by a declaration that it was the duty of the assembly to see justice executed in all cases.

246 The commotions, &c. of the capital reach to the provinces.

The commotions and enthusiasm of the capital were speedily communicated to the provinces. In every quarter the people seized upon all the arms that could be found, and the military uniformly refused to act against them. Many acts of outrage were committed in Brittany, at Strasburg, in the Lyonnois, and elsewhere, in which the nobility were the sufferers. The mischiefs that occurred were usually magnified at a distance; but that very circumstance was an additional evil. For example: It was stated in the National Assembly that M. de Mesmay, lord of Quincey, invited a number of patriots, among whom were the officers of a neighbouring garrison, to a splendid entertainment at his house, to celebrate the happy union of the three orders: That in the midst of the feast the master of the house contrived to withdraw unnoticed, and to set fire to a train previously laid, which communicated with a quantity of gunpowder in the cellars, in consequence of which, the whole company, by a sudden explosion, were blown into the air. It was found on inquiry, that there was not one word of truth in the whole story. But before this inquiry could be made, all France had resounded with accounts of the pretended bloody tragedy; and the whole nobility of the kingdom suffered in a less or greater degree, from the prejudices excited by this unhappy report, the origin of which has never been well explained. It would be vain to state all the idle rumours to which at this time the blind credulity of the multitude gave currency. At one time, the aristocrats were cutting down the green corn; at another time they were burying flour in common sewers, or casting loaves into the Seine. One report was no sooner proved to be false than another arose, and the whole nation was agitated by suspicion and alarm. The National Assembly were engaged in framing their celebrated declaration of the rights of man, which was to form the basis of the new constitution, when the alarming accounts received from all quarters, of the state of anarchy into which the kingdom was falling, obliged them suddenly to turn their attention to objects of practical necessity. The privileged orders found themselves become the objects of universal jealousy and hatred; and that something must instantly be done to save their families and property, which were menaced on every side with persecution and pillage. Regarding the popular torrent as now become irresistible, to save something they resolved to sacrifice a part.

247 Viscount Noailles and Duke d'Aguillon propose that

On the afternoon sitting of the 4th of August, the Viscount de Noailles, seconded by the Duke d'Aguillon, opened one of the most important scenes in the French Revolution, or in the history of any country. These noblemen stated, that the true cause of the commotions which convulsed the kingdom existed in the misery of the people, who groaned under the double oppression of public contributions and of feudal services. "For three months (said M. de Noailles) the people have beheld us engaged in verbal disputes, while their own attention and their wishes are directed only to things. What is the consequence? They are armed to reclaim their rights, and they see no prospect of obtaining them but by force." He therefore proposed to do justice, as the shortest way of restoring tranquillity, and

248 the taxes should be in proportion to the wealth of the contributors.

for that purpose to decree, that henceforth every tax should be imposed in proportion to the wealth of the contributors, and that no order of the state should be exempted from the payment of public burdens; that feudal claims should be redeemed at a fair valuation; but that such claims as consisted of personal services on the part of the vassal should be abolished without compensation, as contrary to the imprescriptible rights of man. The extensive possessions of the noblemen who made these proposals added much lustre to the disinterested sacrifice which they afforded. Their speeches were received with the most enthusiastic applauses by the Assembly and the galleries, and their proposals were decreed by acclamation without a vote. No nation is so much led by the influence of sudden emotions as the French. The patriotic contagion now spread fast through every breast, and a contest of generosity ensued. The hereditary jurisdictions possessed by the nobles within their own territories were next sacrificed. All places and pensions granted by the court were suppressed, unless granted as the reward of merit or of actual services.

249 The game laws, &c. abolished.

The game laws, which condemned the husbandman, under severe penalties, to leave his proper-

ty

rance. 1789.

ty a prey to infinite multitudes of animals reserved for pastime, had always been numbered among the severe grievances of the French peasantry. These were therefore renounced, along with the exclusive rights of rabbit warrens, fisheries, and dovecots. The sale of offices was abolished, and the fees exacted from the poor, together with the privilege of holding a plurality of livings, were relinquished by the clergy. The deputies of the *Pais d'Etat*, or privileged provinces, with the deputies of Dauphiné at their head, next came forward, and offered a surrender of their ancient privileges, requesting that the kingdom might no longer remain parcelled out among Dauphinois, Bretons, Provençaux, &c. but that they should all form one great mass of French citizens. They were followed by the representatives of Paris, Marseilles, Lyons, Bourdeaux, Strasbourg, &c. who requested leave to renounce all their separate privileges as incorporations, for the sake of placing every man and every village in the nation upon a footing of equality. Thus the assembly proceeded, till every member had exhausted his imagination upon the subject of reform. To close the whole, the Duc de Liancourt proposed that a solemn *Te Deum* should be performed, that a medal should be struck in commemoration of the events of that night; and that the title of RESTORER OF GALLIC LIBERTY should be bestowed upon the reigning monarch. A deputation was accordingly appointed to wait upon the king, respectfully to inform him of the decrees.

250 ny an- nt privi- es are untarily render-

251 Tithes and revenues of the clergy taken away.

Several succeeding days were necessary to form into laws the decrees of the 4th August, and committees were appointed to make out reports for that purpose. One of these reports having included the tithes and revenues of the clergy among the abuses that were to be done away, and having proposed in lieu of them to grant a certain stipend to the different ministers of religion to be payable by the nation, the clergy attempted to make a stand in defence of their property, and violent debates ensued. In these they were ably supported by the Abbe Sieyes: but as the clergy had formerly deserted the nobles, so they were now in their turn abandoned to their fate by the hereditary aristocracy. The popular party had long regarded the wealth of the church as an easy resource for supplying the wants of the state.— Never was there a more complete proof of the influence of opinion over the affairs of men. The Catholic clergy of France, though possessed of more property than they enjoyed at the time when princes took up arms or laid them down at their command, now found so few defenders, that they were terrified into a voluntary surrender of all that they and their predecessors had possessed for ages. In their overthrow, they scarcely enjoyed even the barren honour of having fallen the last of those privileged orders that so long had ruled over this ancient kingdom. They and the nobles, and the king, still possessed their former titles and nominal dignity; but all of them were now subdued, and at the mercy of the commons of France, who speedily dismissed them at their pleasure.

252 A new ministry appointed.

As a short season of tranquillity in the Court and the National Assembly succeeded these great popular sacrifices, the king laid hold of it as a fit opportunity for the appointment of a new ministry. They consisted of the archbishop of Vienne, the archbishop of Bourdeaux, M. Neckar, the Count de St Priest, Count de Montmorin, the Count de la Luzerne, and the Count de la Tour du Pin Paulin. M. Neckar, as minister of finance, having stated the distressed situation of the revenue, presented the plan of a loan of thirty millions of livres. But M. Mirabeau, from a spirit of rivalship, as it would seem, to M. Neckar, prevailed with the assembly to alter and to narrow the conditions of it in such a degree that very few subscribers were found, and the loan could not be filled up. This failure involved the assembly in a considerable degree of unpopularity: in consequence of which they allowed M. Neckar to prescribe his own terms for the purpose of obtaining a loan of eighty millions. But the happy instant of public confidence had been allowed to pass away, and this loan was never more than half filled up. Recourse was next had to patriotic contributions; and great numbers of gold rings, silver buckles, and pieces of plate, were presented to the assembly. The royal family themselves sent their plate to the mint, either to give countenance to these donations, or, as M. Neckar has since asserted, through absolute necessity, for the purpose of supporting themselves and their family. The confusion into which the nation had been thrown by the late events had produced a suspension of the payment of all taxes. There existed, in fact, no efficient government; and if society escaped entire dissolution, it was merely in consequence of those habits of order which are produced by a state of long continued civilization. The business of government could not be transacted without money, and many vain efforts were made by the ministry to procure it. At length M. Neckar was driven to the desperate resource of proposing a *compulsory loan*, or that every individual possessed of property should advance to the state a sum equal to one-fourth of his annual income. This bold proposition was supported by Mirabeau, and adopted by the assembly; but it does not appear to have ever been effectually executed.

France. 1789.

253 Who find great difficulty in raising money.

254 Discussion on the *Rights of Man*,

In the mean time, the assembly was busily occupied in framing the celebrated declaration of the *Rights of Man*, which was afterwards prefixed to the new constitution. This was followed by the discussion of a point of much delicacy and difficulty; viz. What share of legislative authority the king ought to possess under the new constitution: whether an absolute negative or *veto*, a suspensive *veto*, or no *veto* at all? This question operated like a touchstone for trying the sentiments of every person; and the assembly, consisting of 1200 men, was now seen to arrange itself into two violent contending factions. The debates were vehement and tumultuous, and continued for many days. As the assembly sat in public, and as multitudes of people of all descriptions were admitted into the galleries, and even into the body of the hall among the members, many indecent scenes took place in consequence of the interference of the spectators to applaud or censure the sentiments which were delivered. Thus the public at large became speedily interested in the discussion; the city of Paris took a side in opposition to the *veto*, and the whole empire was thrown into agitation by new and speculative questions. The distinguished place which France holds among the nations of Europe rendered these singular events and discussions the object of universal attention. The contagious love of novelty spread rapidly abroad, and gave rise to that well-founded jealousy on the part of the monarchs of Europe, which was

255 and the king's *veto*.

was speedily to burst forth in a bloody tempest.—In the present case, the people of Paris became most eagerly interested. Rumours of plots were spread through the country, and a new storm was obviously gathering, when the question was thus got quit of. M. Mounier remarked, that the executive power could possess no negative against the decrees of the present assembly, which had been nominated by the nation with supreme powers for the express purpose of framing a constitution, which was to remain binding over all orders of men in the state; and with regard to future legislatures, the king declared by a message, that he wished to possess no more than a *suspensive veto*. It is remarkable that the popular Mirabeau concluded a speech in favour of the absolute *veto* of the crown with these words, "That it would be better to live in Constantinople, than in France, if laws could be made without the royal sanction." This political adventurer is, however, accused of having taken care to circulate in Paris a report that he had opposed the *veto* with all his influence; and to give credit to the story, he is said to have quitted the assembly just before the division, that his vote might not appear on record against it.

256 Discussion about the legislative body, whether it ought to consist of one or two chambers.

The month of August was spent in the debates about the *veto*; and in the beginning of September a new constitutional question was presented to the assembly by one of its numerous committees. This was, Whether the legislative body, ought to consist of one or of two chambers? Mounier, Lally Tollendal, Clermont Tonnerre, and others, who were zealous lovers of freedom upon what were then accounted moderate principles, supported eagerly the idea of establishing two independent chambers in imitation of the British constitution; but they were deserted both by the democratic and aristocratic parties. The first of these regarded an upper house or senate as a refuge for the old aristocracy, or as the cradle of a new one; while the higher nobles and clergy feared lest such an arrangement might prevent the future re-establishment of the ancient division into three orders. Of 1000 members who voted, only 89 supported the proposal for dividing the legislature into two chambers.

257 The royal sanction granted to the decrees of the 4th August, &c.

Soon after this the king gave his sanction to the important decrees of the 4th of August, but not without some hesitation, and expressing doubts of the wisdom of some of them in a letter to the assembly. At the same time the *inviolability* of the person of the monarch was decreed, the indivisibility of the throne, and its hereditary descent from male to male in the reigning family. But we shall not here attempt to enter into a detail of the various articles of the new constitution as connected with the circumstances under which they became the subject of debate. We shall only state those more remarkable circumstances which tend to ascertain the peculiar changes which the sentiments of the nation underwent in the progress of a revolution the most remarkable that occurs in human history.

258 State of parties in Paris.

In consequence of the debates upon the questions of the *veto* and the two chambers, the minds of parties had become much irritated. Paris wore the same threatening aspect that it had done in the months of June and of July preceding; and every thing seemed tending towards an important crisis. The aristocratic party accused their antagonists of a design to excite new insurrections; and the charge was retorted, by circulating a report that a plot for conveying the king to Metz was already ripe for execution.

259 Conseque ces of th mutual j lousies.

From the period of the defection of the French guards, who were now in the pay of the capital, the protection of the royal family had been entrusted to the militia or national guard of Versailles, together with the regiment of the *gardes du corps*, which was composed entirely of gentlemen. Upon the circulation of the report of the intended flight of the king, the French guards began to wish to be restored to their ancient employment of attending his person, for the purpose of preventing any attempt of this nature. This idea was eagerly cherished by the capital; and, in spite of every effort used by M. de la Fayette, the obvious appearance of approaching disturbances could not be prevented. The popular party saw the advantages which they would derive from placing the assembly and the king in the midst of that turbulent metropolis which had given birth to the revolution, and upon the attachment of which they could most securely depend. Every encouragement was therefore given by the most active leaders of what was now called the *Democratic* party to the project of establishing the court at Paris. The ministry were under no small degree of alarm; and the count d' Estaing, who commanded the national guard of Versailles, requested the aid of an additional regiment. The regiment of Flanders was accordingly sent for: its arrival caused no small degree of anxiety; and every effort was instantly made to gain over both officers and soldiers to the popular cause.

On the first of October the gardes du corps, probably for the purpose of ingratiating themselves with the newly arrived regiment, and perhaps to attach them more steadily to the royal cause, invited the officers of the regiment of Flanders to a public entertainment. Several officers of the national guard, and others of the military were invited. The entertainment was given in the opera house adjoining to the palace; several loyal toasts were drank: but it is asserted, that when the favourite popular toast *The Nation* was given, it was rejected by the gardes du corps. In ordinary cases, such a trifling circumstance as this, or even any other of the transactions of a night of festivity, would justly be regarded as unworthy of notice in recording the more remarkable events in the history of a great nation; but such was now the singular state of affairs, that the most trivial occurrences were instrumental, by their combination, in the production of important consequences. The queen, having seen from a window of the palace the gaiety which prevailed among the military, prevailed with the king, who was just returned from hunting, to visit them along with herself and the dauphin. Their sudden appearance in the saloon kindled in an instant the ancient enthusiasm of French loyalty. The grenadiers of the regiment of Flanders along with the Swiss chasseurs, had been admitted to the dessert; and they, as well as their officers, drank the health of the King, Queen, and Dauphin, with their swords drawn. The royal family having bowed with politeness to the company, retired. Of all nations, the French are most liable to the influence of sudden impressions: the music played the favourite air, *O, Ricard! O mon Roi! l'univers t'abandonne*, "O Richard! O my king! the world abandons thee." In the eagerness of loyalty

loyalty, the national cockade, which had been adopted by some of the gardes du corps, was thrown aside, and white cockades were supplied as quickly as they could be made by the ladies of the court.

When these events were next day reported at Paris, accompanied by a multitude of exaggerations, they gave rise to the most violent alarm. The capital was at that time suffering all the horrors of famine; and in such a situation, the news of a feast which others have enjoyed, seldom gives much pleasure to hungry men. To the former report of an intended flight on the part of the royal family, it was now added, that a counter revolution was speedily to be attempted by force of arms; and that the present scarcity was artificially created by the court for the purpose of reducing the people to submission. Their aristocratic antagonists have since asserted, that the famine was indeed artificial; but that it was created by a portion of the violent party in the national assembly, which was then denominated the *Cabal*, whose object was to excite commotions as the means of procuring an opportunity of setting the duke of Orleans at the head of the state, either as regent, or in some other form. To this last party Mirabeau is said to have belonged.

For four days no notice was taken in the assembly of what had passed at the entertainment given by the gardes du corps. On the 5th of October M. Petion mentioned it for the first time, and a violent debate ensued; during which Mirabeau rose and exclaimed, "Declare that the king's person *alone* is sacred, and I myself will bring forward an impeachment;" thereby alluding to the conduct of the queen. While this de-

260 A multitude of women of the lowest rank march to Versailles.

bate was proceeding at Versailles, the city of Paris was in commotion. A vast multitude of women of the lowest rank, with some men in women's clothes, had assembled at the *Hotel de Ville*, and were calling aloud for arms and bread. They resolved to proceed instantly to Versailles to demand bread from the king and from the national assembly. La Fayette opposed them in vain; for his own soldiers refused to turn their bayonets against the women. Upon this one Stanislaus Maillard, who had distinguished himself at the taking of the Bastile, offered himself as a leader to the insurgents. He had the address to prevail with them to lay aside such arms as they had procured; and he set out for Versailles about noon with as much order among his followers as could well be expected from such an assemblage. Either because the passion for going to Versailles had suddenly become too infectious to be resisted, or because the multitude already gone thither was now accounted dangerous, the mayor and municipality of Paris thought fit to give orders to La Fayette instantly to set out for that place at the head of the national guard.

In the mean time, Maillard approached Versailles with his tumultuous troop; he arranged them in three divisions, and persuaded them to behave with tolerable decency. The king was hunting in the woods of Mendon when he was informed of the arrival of a most formidable band of women calling aloud for bread. "Alas! (replied he) if I had it, I should not wait to

261 and send a deputation to the assembly.

be asked." Maillard entered the assembly accompanied by a deputation of his followers to state the object of their journey. The assembly, to pacify them, sent a deputation of their own number along with them to lay their complaints before the king. His majesty received the whole with great politeness, and readily agreed to go into any measures for the supply of the capital that could be suggested. The report of this behaviour had such an effect upon the multitude collected around the palace, that they began to disperse; but they were speedily succeeded by another crowd not less numerous. A sudden resolution of flight seems now to have been proposed by the court; for the king's carriages were brought to the gate of the palace which communicates with the orangery: but the national guard of Versailles refused to allow them to pass, and the king himself refused to remove, or to allow any blood to be shed in his cause.

262 La Fayette with his army reaches Versailles at night.

La Fayette with his army at length arrived about 10 o'clock at night, and found the assembly in a very unpleasant situation. Their hall and galleries were crowded by the Parisian fish-women and others of the mob, who, at every instant, interrupted the debates. La Fayette waited upon the king, and informed him of the proceedings of the day, planted guards in every quarter; and after a scanty banquet had been procured for the multitude, he prevailed with the assembly to close their sitting for the night. In this last part of his conduct M. la Fayette has been much censured, and probably not without reason; for it could scarcely be expected that such a night would be spent in peace by the immense assemblage of turbulent characters that

263 Desperate attempt on the queen.

were now brought together. All was quiet, however, till about six in the morning of the 6th, when a great number of women and desperate persons rushed forward to the palace, and attempted to force their way into it. Two of the gardes du corps were killed; the crowd ascended the stair leading to the queen's apartment, but were bravely resisted by M. Miemandre a sentinel, who gave the alarm, and defended his post till he fell covered with wounds, of which, however, he afterwards fortunately recovered. The ruffians, reeking with his blood, rushed into the chamber of the queen, and pierced with bayonets and poniards the bed whence this persecuted woman had but just time to fly almost naked, and, through ways unknown to the murderers, had escaped to seek refuge at the feet of the king, who was already alarmed, and had gone to seek her.

264 The royal family saved by Fayette.

The tumult became more violent every moment, and sudden death seemed to threaten the royal family; but La Fayette was by this time at the head of his troops, whom he beseeched earnestly to save the gardes du corps from massacre. In this he was successful; some that had been taken prisoners were surrounded by the grenadiers of the French guards, who protected them, and the retreat of the whole corps was easily secured. The crowd was speedily driven from the different quarters of the palace, which they were already beginning to pillage; and the royal family ventured to show themselves at a balcony. A few voices now exclaimed, *Le Roi à Paris*, "the King to Paris." The shout became general; and the king, after consulting with La Fayette, declared that he had no objection to take up his residence at Paris, provided he was accompanied by the queen and his children. When the proposal was reported to the assembly, the popular leaders expressed much satisfaction. They ordered a deputation of 100 members to attend the king thither; they voted the national assembly inseparable from the king. His majesty set

France 1789.

265 Are carried prisoners to Paris. set out at two o'clock a prisoner in the custody of the mob. Two gentlemen were selected from his body guard, and, with all the parade of an execution, beheaded in the court of his palace. Their heads were stuck upon spears, and led the procession; whilst the royal captives who followed in the train, and beheld this spectacle, were conducted so slowly, that a short journey of twelve miles was protracted to six hours. The king, the queen, and their children, were lodged in the old palace of the Louvre, while Monsieur went to reside at the Luxemburg. The city was illuminated, and the evening spent in triumph by the Parisians.

266 Triumph of the popular party. The removal of the king to Paris was regarded as a triumph by the popular party. The higher order of nobles considered it as completely ruinous to their hopes; and even many men of talents, such as Mounier and Lally Tollendal, whom we cannot avoid regarding as friends to the popular cause in its outset, now regarded every prospect of attaining a happy constitutional freedom as at an end, as the national representatives must be for ever exposed to the insults, and overawed by the influence of a turbulent capital. Many members of the assembly took refuge in foreign countries, and used every effort to excite the other nations of Europe to hostility against France. As the duke of Orleans had been regarded as a chief agent in promoting the late disturbances, the marquis de la Fayette waited upon him, and insisted upon his leaving the kingdom for a time. The duke was overawed, and, on pretence of public business, went to England, where he remained for several months.

267 The assembly holds its first session at Paris. On the 19th of October, the National Assembly held its first session in Paris. The king was closely guarded in his own palace; and no apparent opposition now stood in the way to prevent the popular party from giving to their country such a constitution as they might judge expedient. Much, however, was yet to be done, and many difficulties remained, resulting from the habits of men educated under a very different order of things. Two days after the assembly came to Paris, a baker was publicly executed by the mob, upon a false accusation of having concealed a quantity of bread.—While the assembly was at a distance, events of this nature had been little attended to, and the leading party avoided attempting to check these ebullitions of popular violence, from which they had derived so much advantage; but that party was now all powerful, and so flagrant an offence committed against the law was regarded as an insult upon the sovereignty of the National Assembly. Two leaders of the mob were therefore tried and publicly executed, and a severe law was passed, of the nature of the British riot act, authorising the magistrates to act by military force against any multitude of persons that should refuse to disperse. Thus the peace of the capital was secured for several months; but in the country at large no small degree of anxiety and trouble still subsisted. The same suspicious temper which had prevailed at Paris agitated the provinces with the dread of plots and monopolies of grain. Add to this, that the noblesse in the country were by no means satisfied with the liberality with which their representatives had on the 4th of August voted away their privileges and their property. This produced violent jealousies between the peasants and their lords, and gradually conveyed to every corner of the kingdom the political ferment which had commenced at Paris.

268 The kingdom divided into 83 departments. The National Assembly being now, however, in tolerable security, proceeded in the arduous attempt of forming a free constitution for the great empire of France. The Abbe Sieyes presented a plan for dividing the kingdom into 83 *departments*, of about 324 square leagues, and each department into several *districts*, and each district was subdivided into *cantons* of four square leagues in extent. Thus the whole of the ancient divisions of the kingdom into governments, generalities, and bailiwicks, was in an instant obliterated. An attempt was also made to simplify in an equal degree the relative situation of individuals in civil life, by a decree which put an end to all distinction of orders and immunities, so far as any privileges whatever was concerned. At the same time, a bold and most important measure was adopted, which has since proved the organ of those terrible efforts which France has

269 The church lands confiscated. been enabled to make against the rest of Europe. This was the confiscation of the whole of the lands belonging to the church, for the purpose of supplying the exigencies of the state. In this transaction, all regard to justice was thrown aside. The lands of the church were as certainly the property of the then possessors of them as any entailed estate among us is the property of him who occupies it. The state may have had a right to appropriate to itself the church lands upon the death of the incumbents; but it might with equal justice, and perhaps greater propriety, have seized the enormous revenues of the duke of Orleans, as have confiscated a single acre belonging to the most useless abbot without his own consent. This nefarious measure was proposed by the bishop of Autun, M. Talleyrand Perigord, a man of no religion, who had been promoted to the bench in a most irregular manner to serve this very purpose. The mode in which this property was to be expended was by issuing assignments (*assignats*) upon it; which assignments were to be received by the state for the payment of taxes, or for the purchase of church lands when set up to sale. A provision was at the same time made for the national clergy, who were for the future to be paid by the state. On the day following that on which this important measure was adopted, a decree was passed, suspending the parliaments of the kingdom from the exercise of their functions.

270 Fruitless attempt of the parliament. Decrees, in which the interests of so vast a multitude of individuals were involved, could not be carried into effect without much murmuring and opposition. The parliaments, in particular, began to exert themselves with vigour, and, by protests and other publications, attempted to invalidate the decrees of the assembly as illegal; but these privileged bodies, who had often been accustomed to contend with some success against the despotic administration of their country, and on that account had been for ages the objects of public applause, now found themselves utterly forsaken, and unable to resist the mandate of a popular assembly. After a few fruitless struggles, they were all of them under the necessity of submitting to their fate.

271 Municipalities established. Nothing remarkable now occurred for some time.—The assembly proceeded to organize the kingdom by the establishment of municipalities, and by reforming the jurisprudence of the country. It is to be observed, however, that when the parliament of Paris was abolished,

France. 1790.

lished, the Chatelet, being the second court in that city, was retained for the purpose of trying those persons who had become most obnoxious by their attachment to the royal cause. This court had the spirit to acquit the Baron de Bezenval, Marshal Broglio, and the Prince de Lambesq. But having incurred much popular odium on this account, they were guilty of the unworthy meanness of condemning to death the Marquis de Favres, for a pretended conspiracy (of which no tolerable proof was ever brought) to massacre La Fayette, Bailly, and Neckar, and to convey the king to Peronne.

1790. During the whole of this winter the king had been very strictly watched by numerous guards placed round his palace, insomuch that the other nations of Europe considered him as in a state of captivity. To do away this impression, if possible, and to make their king appear a voluntary agent in the measures that had lately been adopted, was now regarded as a matter of some importance. Every effort was therefore made to prevail with him to come to the assembly suddenly, and, as it were, of his own voluntary motion, there to declare his adherence to the measures which had lately been adopted. For some time he resisted this proposal; but at length, on the 4th of February, he did suddenly appear in the national assembly, where he complained of the attempts that had been made to shake the new constitution. He declared his wish "that it should be universally known that the monarch and the representatives of the nation were united, and their wishes were the same; that he would defend the constitutional liberty of the state; that, in conjunction with the queen, he would early form the sentiments of his son for that new order of things which the circumstances of the empire had introduced." This declaration dispirited the aristocratic party in no small degree, and increased that unhappy tendency of looking for aid from foreign countries which they had always been too apt to indulge.

272 Monasteries suppressed, and their lands confiscated.

On the 13th of February, monastic establishments were suppressed, and their lands confiscated; but the present friars and nuns were allowed pensions for their subsistence, and to continue the observance of their monastic vows, if they thought fit. We may observe here, that, in consequence of the evacuation of the monasteries, it is probable that about this time the *Breton* committee began to assume the appellation of the *Jacobin Club*, from the hall belonging to the Jacobin friars at Paris, in which their meetings were now held.

March 13th 273 The Red Book or list of pensions and donations, published.

An event occurred at this time which tended in no small degree to increase the odium under which the old government already laboured. This was the publication of the *Red Book*, or list of pensions and donations granted by the crown. In consequence of the most pressing instances, it had been communicated by M. Neckar to a committee of the assembly, after many entreaties, and the most solemn promises of secrecy. It afforded, however, too striking an advantage to the popular party not to be made use of, and in a few days M. Neckar, to his no small surprise, saw this register publicly sold by every bookseller in Paris. He ought not, indeed, to have been surprised; and the giving up of this list is one of the many proofs which the transactions of that period afford of his great unfitness for the office which he held. With much indignation, however, he demanded why the committee had published it without the permission of the assembly or the king? But he was told by the committee, that "as to the assembly, they were sure of its approbation; and as to the king, they were not his representatives." To give an idea of the effect of this publication, it is only necessary to remark, that, under the short administration of M. Calonne, the two brothers of the king had received from the public treasury, independent of their legitimate income, nearly two millions sterling, and that 600,000l. had been granted to an individual, because he was the husband of Madame de Polignac. M. Neckar's opposition to this publication tended in no small degree to injure his popularity, and the rest of the ministry began to lose the confidence of the public. Indeed, at this time, fertile causes of alarm prevailed on all sides. The clergy were attempting to revive in the provinces the ancient animosities between the Roman Catholics and the Protestants, ascribing the late decrees of the assembly to the latter. The German princes who possessed property in the north of France were complaining loudly of the violation of their rights by the abolition of the feudal system, although the national assembly had voted to them a compensation. The most melancholy intelligence was received from their colonies in the West Indies. In regulating these, the assembly had not recognized the right of the free negroes to enjoy the same privileges with other citizens; at the same time, they did not go the length of denying these privileges. This uncertain conduct produced infinite calamities. The whites contended with those commonly called *people of colour*. These again sometimes stood in opposition to the free negroes, or to the slaves; and hence it sometimes happened that no less than three hostile assemblies were held at the same time in the same colony, which made war upon each other with the most inveterate fury. Each party found protectors in the national assembly of the parent state. Those who favoured or opposed the existence of distinctions at home, in general followed out the same principle with regard to the colonies.

274 Effect of its publication.

275 Numerous sources of alarm.

276 Debate on the royal power to declare peace and war.

On the 14th of May, M. de Montmorency communicated to the national assembly the preparations for war in which England and Spain were engaged. This brought forward the constitutional question, "Who ought to possess the power of declaring peace and war? The Count Clermont Tonnerre, Messrs de Serent, Virieu, and Dupont, supported the royal prerogative; while on the other side, the exclusive right of the legislative body to exercise this important prerogative was supported by Messrs d'Aiguillon, Garat, jun. Freteau, Jellot, Charles Lambeth, Sillery, Petion, Robespierre, &c. M. Petion proposed a decree "that the French nation renounced for ever all idea of conquest, and confined itself entirely to defensive war;" which was passed with universal acclamation. The Count de Mirabeau at length successfully proposed that peace and war should be declared by the king and the legislative body in conjunction; and the decree that was passed on the subject is a strange farrago of contradictions and absurdities. It enjoined the king to "guard the state from external attacks." But how could this be done without repelling any attack that might be made upon it? This, however, he could not do, without previously informing the national assembly; and if that body chanced not

France. 1790.

not to be sitting at the time, he was bound to let the enemy advance without opposition, till he had convened his orators, dispersed over 20,000 square leagues, and listened to their metaphysical quibbles in Paris.

277 Farce acted in the assembly by a Prussian refugee, &c.

On the 16th June, a very singular farce was acted in the assembly. A Prussian refugee, who called himself Anacharsis Clouts, and who was struggling hard to bring himself into public notice, on an evening sitting (which, it is to be observed, was generally ill attended by the persons of the highest rank), introduced to the assembly a number of persons dressed in the different habits of all the different countries that could be thought of. In a formal harangue, he told the assembly that he was come, as the *orator of the human race*, at the head of the representatives of all nations, to congratulate them upon the formation of their new constitution. He was answered by the president with abnndance of solemnity, and retired with his motley groupe. This fantastical piece of folly, which in any other country than France would scarcely, perhaps, have excited a smile, was treated by the assembly in a serious light. Alexander Lambeth proposed, that the figures of different nations exhibited in chains at the feet of Louis XIV. should be destroyed as an insult upon mankind.

278 Abolition of hereditary titles.

M. Lambel, a lawyer, at this moment proposed the *abolition of all hereditary titles*. He was supported by La Fayette, St Fargeau, and the Viscount de Noailles. The decree was passed, along with another suppressing all armorial bearings. It is our intention at present rather to state facts than to hazard any political opinion concerning the wisdom or folly of the transactions which we record. It may here, however, be remarked, that no part of the proceedings of the French national assembly was received by persons of rank upon the continent of Europe with so much indignation as this. —The feudal system had been overturned, and the property of the church wrested from it, with little comparative notice; but when those nominal distinctions were attacked which antiquity had sanctioned, and personal vanity rendered dear, the surrounding nations were instantly alarmed, and beheld with terror the levelling precedent. We may likewise add, that no part of their proceedings was more inimical to rational and practical freedom. To preserve a perfect equality of ranks is impossible. In a commercial nation, industry will procure wealth, and wealth will every where procure dependents. Now nothing more contributes to keep within some tolerable bounds the insolence of newly acquired wealth, than the rank attached to birth and nobility, which time and prejudice have conspired to make respectable. It is not a little remarkable, that of all the king's ministers, Neckar alone, a plebeian, a republican, born and bred in a democracy, advised his majesty to refuse his assent to this foolish decree, as a violent but useless encroachment upon the prejudices of a powerful order of the state.

279 Proposal to commemorate the taking of the Bastile.

In the mean time, the capital was entirely engrossed by hurry and bustle. M. Bailly had proposed a plan for commemorating the anniversary of the taking of the Bastile. It was adopted, because it flattered the vanity of the people, by presenting them with a splendid spectacle in commemoration of their own exertions. —The army had been much disorganized; and it was resolved to attempt to unite all its branches, as well as the whole departments of the state, in one common attachment to the new order of things, by collecting into one place deputations, for the purpose of swearing fidelity to the new constitution.

France. 1790.

280 Ceremony of the confederation.

In the middle of the Champ de Mars an altar was erected, at which the civic oath, as it was called, was to be taken. Around the altar an amphitheatre was thrown up capable of containing 400,000 spectators: 2000 workmen were employed in this operation; and the people of Paris fearing lest the plan might not be completed, assisted in the labour. All ranks of persons, the nobles, clergy, and even ladies, with the eagerness for novelty so peculiar to that people, united their efforts. Crowds of foreigners as well as natives hurried to the capital to be present at this solemnity, which was called the *Confederation*. The long-expected 14th of July at length arrived. At six o'clock in the morning the procession was arranged on the Boulevards, and consisted of the electors of the city of Paris, the representatives of the commons, the administrators of the municipality, a battalion of children, with a standard, inscribed "The hopes of the nation;" deputies from the troops of France wherever quartered, and of every order, along with deputies from all the departments; to these were added immense detachments of the military, and of the national guards, along with an almost infinite multitude of drums, trumpets, and musical instruments. The procession was extremely splendid, as every district had its peculiar decorations. The national assembly passed through a grand triumphal arch, and the king and queen, attended by the foreign ministers, were placed in a superb box. After a solemn invocation to God, the king approached the altar, and, amidst the deepest silence, took the following oath: "I the king of the French do swear to the nation, that I will employ the whole power delegated to me by the constitutional law of the state, to maintain the constitution, and enforce the execution of the law." The president of the national assembly then went up to the altar, and took the civic oath, "I swear to be faithful to the nation, the law, and the king; and to maintain with all my powers the constitution decreed by the national assembly, and accepted by the king." Every member of the assembly standing up, said, "That I swear." La Fayette then advancing, took the oath for himself; the other deputies of the national guards pronouncing after him, "That I swear;" and these words were solemnly pronounced by every individual of this immense assembly. *Te Deum* was then sung. The performance was sublime beyond the powers of description. Never perhaps before was there such an orchestra, or such an audience: their numbers baffled the eye to reckon, and their shouts in full chorus rent the skies. It is impossible to enumerate all the means which were employed to add splendor to this day. It ended with a general illumination, and no accident disturbed the public tranquillity.

281 The soldiers at Nancy disgusted, & the consequences.

The assembly now proceeded in the formation of the constitution with considerable tranquillity; which, however, was disturbed by an unhappy event at Nancy. Most of the officers of the army were unfriendly to the late revolution, and every means had been employed by them to disgust the soldiers with it. At Nancy, in particular, necessaries had been denied them, and their pay was kept back, under pretence that this was the will of the national assembly. Driven to despair, the regiments in garrison threw off their allegiance, and demanded

France. 1790.

manded loudly the regimental accounts. They seized at the same time the military chest, and sent a deputation to state their case at Paris to the national assembly. But the officers were before-hand, and prepossessed the minister of war against them; upon whose representation a decree was passed, authorising the commander in chief of the province, M. Bouillé, to reduce the insurgents by force. This was no sooner known, than the national guard of Nancy assembled, and sent a deputation to give a fair statement of facts. But Bouillé, without waiting the result of an explanation, hastened to Nancy at the head of all the troops he could suddenly collect; and having fallen upon the regiments of Chateauvieux and Mestre de Camp, after putting an immense multitude to the sword, he took 400 prisoners.

The king's regiment was prevented from acting against Bouillé by the intrepidity of a young officer of the name of *Dessiles*, who, however, died of the wounds which he received on the occasion. The news of these events filled Paris with indignation. The assembly afterwards reversed its own decrees against the insurgents at Nancy. Public honours were decreed to the memory of Dessiles; but Bouillé could not be punished, because he had only acted in obedience to authority.

282 M. Neckar resigns, and leaves the kingdom without being regretted.

M. Neckar's popularity had been gradually declining, as he was unwilling to go all the lengths that the ruling party wished. He gave in his resignation on the 4th of September, and speedily thereafter left the kingdom. He was regretted by no party. He was regarded, on the one side, as having conducted the kingdom to its ruin, by the concessions which he originally advised the king to make in favour of the *tiers etat;* while he was despised by the opposite party as a lukewarm politician, of narrow views, and a feeble mind. He departed, however, with the unblemished reputation of strict integrity. M. Neckar does not seem to have penetrated deeply into the characters of men, or to have had any conception of the effects of that terrible and restless energy which is called forth in a nation which attempts to make important changes in its ancient manners and government. Having no conception of the important era which was about to open upon that country of which he was the minister, he was far from being qualified to direct or controul it amidst the convulsions which it was destined to encounter. Unable to brook the loss of his popularity, he peevishly retired to Swisserland, where he published a work, which shews to the conviction of every unprejudiced reader the integrity of the French king, and the wicked projects of the leading democrats, whom he himself had armed with power.

283 Attempts to reorganize the navy.

The remaining part of this year was occupied in attempts to introduce some degree of subordination into the navy of France, which had been much disorganized, and in farther regulating the affairs of the clergy. It was now declared, that such clergymen as should not take the following oath, which had been prescribed some months before, should be considered as ejected from their benefices: "To watch carefully over the faithful in the parish or diocese which was entrusted to his care; to be faithful to the nation, the law, and the king; and to maintain to the utmost of his power the new constitution of France, and particularly the decrees relative to the civil constitution of the clergy." This decree rendered the situation of conscientious men extremely perplexing; especially as the pope testified in marked terms his disapprobation of the oath. The people were reduced to the dilemma of choosing between their new political and their old religious prejudices, and the result was extremely unfavourable to the interest of religion.

France. 1791.

284 Hostile appearances in Germany, &c.

The assembly commenced the new year with a decree, announcing the termination of its session, which was to take place as soon as it should have finished the discussion of a list of constitutional articles. In the mean time, on the side of Germany, Spain, Italy, and Savoy, hostile appearances began to be exhibited, and bodies of troops advanced around the French frontier. The emperor Leopold was, however, too cautious to announce his intentions; and the king soon communicated a letter from him, containing protestations of amicable dispositions, but adding, that "the innovations occasioned by the decrees of the 4th of August ought to be done away." The king treated this merely as an official measure on the part of the emperor, that he might not appear to renounce the claims of certain German princes connected with Lorrain and Alsace. But the assembly expressed some alarm, and voted an augmentation of the national force. About this period several new efforts were made by the disaffected clergy in various parts of the kingdom to excite disturbances, which it is unnecessary to mention in detail.

285 Departure of the king's aunts from Paris.

On the 20th of February the public attention was roused by a circumstance that in any other state of affairs would have been accounted unimportant. The king announced to the assembly, that his aunts, the daughters of Louis XV. had that morning left Paris; but as he did not apprehend that the existing laws laid them under any restraint in this respect, he had not opposed their departure. After some debate, the assembly agreed that the king had judged well; and these princesses were left to pursue their journey to Rome, which they reached after some delays occasioned by the jealousy of certain municipalities through which they passed. Thus the kingdom was gradually deserted by every branch of the royal family, excepting the king and his eldest brother Monsieur. The assembly, however, continued its labours with considerable quietness.

286 Death of Mirabeau.

In the end of the month of March died the celebrated M. de Mirabeau, at the age of 42 years; a man whose integrity has for many good reasons been much suspected, but whose political address and intrepidity, and whose splendid powers of eloquence, have been seldom equalled. He received from his countrymen at his death marks of respect unparalleled in modern history. During his short illness, his door was besieged by anxious citizens. A mourning of eight days was decreed by the assembly, and also a grand procession, which was attended by all the public functionaries. He was the first who was interred in the new magnificent Pantheon, consecrated to the reception of the remains of illustrious men. But his ashes were afterwards removed, in consequence of very clear proofs that he had not been incorruptible by money.

287 An emigrant army assembled on the borders of Alsace.

During the whole of this spring, much fear was entertained that some attempts at a counter revolution were about to be made. The emigrant army assembled on the borders of Alsace was reviewed by the prince of Condé. Their uniform was black, faced with yellow, with

France. 1791.

with a death's head, surrounded by a laurel wreath, on one cuff, and a sword on another; with the motto, "Conquer or die." The king was also surrounded by crowds of nonjuring priests and other disaffected persons. Thus, that popular jealousy which in every period of the revolution has strikingly marked the French character, was kept on the alarm. On the 18th of April, therefore, when the royal family was preparing to go to St Cloud to pass some days, a report was instantly spread that the king was about to fly from the country. The carriages were immediately surrounded by people. La Fayette drew out the national guard, but they refused to act. "We know (exclaimed they) that we are violating the laws, but the safety of our country is the first law." The king instantly went to the assembly, and with much spirit complained of the insult. He was answered respectfully by the president, and continued his journey. As the royal family had enjoyed a considerable degree of freedom for some time past, which was demonstrated by the unsuccessful opposition made to this journey—the present opportunity was embraced for intimating to foreign courts his acceptance of the constitution; and all obnoxious persons were dismissed from about his person. The breach of discipline on the part of the national guard on this occasion was so much resented by La Fayette, that he resigned his command. Paris was thrown into consternation; and it was not till after the most universal solicitation that he was prevailed upon to resume his office.

288 Jealousy of the people and military lest the king and his family should emigrate.

289 Behaviour of Bouillé on the frontiers.

About this time M. de Bouillé, to whom the protection of the frontiers was entrusted, was employing, as it is now said, every means in his power to render the country defenceless. The garrisons were left unprovided; disunion was spread among the national troops; they were removed from the frontiers, and their place was occupied by foreigners, wherever it could be done. The emigrants abroad, and their friends at home, were lying in wait for an opportunity of revolt;—when suddenly, on the 21st of June, it was announced from the Thuilleries, that the king, the queen, the dauphin, with monsieur and madame, had quitted the palace and the capital, without leaving any information of their intention or their route. The emotion excited by this news among the multitude was a mixture of consternation and rage. The national assembly, however, acted with much coolness. They instantly took upon themselves the government, and decreed their sittings permanent. They sent messengers, at the same time, in all directions, to attempt to lay hold of the fugitives. These had taken different routes. Monsieur and madame arrived safely at Brussels on the 23d. The king, queen, and their children, when they came to a considerable distance from the capital, were furnished by Bouillé with a guard of dragoons, under pretence of protecting treasure for the pay of the troops. At the distance of 156 miles, and when only a few leagues from the frontiers, they were arrested at St Menehould by the postmaster, M. Drouet, formerly a dragoon in the regiment of Condé. At half past seven o'clock in the evening the carriages stopt to change horses at his house; he thought he recollected the queen, and imagined that the king's face resembled the impressions stamped upon assignats. The escort of dragoons increased the suspicion. He suffered them to depart at 11 o'clock without notice; but taking a companion with him, he went by a shorter road to Varennes, With the assistance of the postmaster there he gave the alarm, and overturned a carriage on the bridge, which detained the royal travellers till the national guard of the place had assembled, and the arrest was effected without bloodshed. They were brought back to Paris by a deputation from the assembly. At his departure, the king had imprudently left beyond him a memorial, in which he declared, that he never had thought any sacrifice too great for the restoration of order; but that the destruction of the kingdom, and the triumph of anarchy, being the only reward of all his efforts, he thought it necessary to depart from it. He then takes a review of the faults of the new constitution, the grievances he has suffered; and protests against every thing that he had been compelled to do during his captivity.

290 The king, queen, and royal family, leave Paris.

291 Monsieur and madame arrive at Brussels.

292 The king and queen arrested at Varennes.

Different parties were very differently affected by this ill-conducted and unfortunate flight of the king. A small republican party had already begun to appear, and during the king's absence, attempts were made to induce the puplic at large to consider the royal authority as no necessary part of a free constitution. But the minds of men were by no means prepared for the reception of this new doctrine. The idea, however, having been thus publicly proposed, left some impressions, which in time contributed to give rise to important events. By far the greater number of leading men, however, were at present convinced, that it was impossible to conduct a great empire like France, well and prosperously, without the assistance of an hereditary chief. They therefore determined to pass over the affair with as much silence as possible, and to hasten the period when their new constitution should be complete. But there is reason to believe, that this journey was at the long-run highly instrumental in producing very fatal effects to the personal safety of the monarch.

293 Consequences of this unfortunate flight.

His flight seemed a signal for emigration. Many of the aristocratic party sent in resignations of their seats in the national assembly. Troops were levied on the frontiers in the king's name; who took care, however, to disavow any connection with such a procedure. Bouillé emigrated, and afterwards sent to the assembly a furious threatening letter: "You shall answer (says he) for the lives of the king and of the queen to all the monarchs of the universe. Touch but a single hair of their heads, and not one stone shall be left upon another in Paris. I know the roads. I will conduct the foreign armies. This letter is but the forerunner of the manifesto of the sovereigns of Europe."

A considerable calm throughout France followed these events, and it might be regarded as in a state of tranquillity. It contained, indeed, parties entertaining much animosity against each other, and many citizens had withdrawn to foreign countries; but the peace was not broken, and moderate men hoped that much prosperity would follow from the late agitations. But this calm was delusive; and in the midst of it those projects were formed which were afterwards to prove so fatal to the peace of France and of Europe. Towards the close of this summer, a convention took place at Pilnitz in Saxony between the emperor Leopold and the king of Prussia. Its object was not known at the time, but it gradually came into view, and is now by many understood

294 Treaty of Pilnitz.

stood to have been intended for the purpose of concluding a league for the invasion of France, the new-modelling of its government, and the partition of some of its fairest provinces. The following paper has been repeatedly published as the copy of a treaty concluded and signed at Pavia, and is generally understood to have been identical with, and therefore known by, the name of the *Treaty of Pilnitz.* We are far from vouching for its authenticity. It may have been fabricated by the French assembly, to unite all parties in the nation against the foreign powers which threatened to invade them. But in stating the events of this revolution, it is perhaps still more necessary, for the purpose of rendering the actions of men comprehensible, to give an account of what was at the time *believed* to have occurred, than it now is to ascertain what was actually true.

Partition Treaty between the Courts in Concert, concluded and signed at Pavia, in the month of July 1791.

His majesty the emperor will take all that Louis XIV. conquered in the Austrian Netherlands, will give them to his serene highness the elector Palatine; so that these new possessions, added to the Palatinate, may hereafter have the name of *Austrasia.*

His majesty will preserve for ever the property and possession of Bavaria, to make in future an indivisible mass with the domains and hereditary possessions of the house of Austria.

Her serene highness the archduchess Maria Christina shall be, conjointly with his serene highness her nephew the archduke Charles, put into hereditary possession of the duchy of Lorraine.

Alsace shall be restored to the empire; and the bishop of Strasbourg, as well as the chapter, shall recover their ancient privileges, and the ecclesiastical sovereigns of Germany shall do the same.

If the Swiss Cantons consent to accede to the coalition, it may be proposed to them to annex to the Helvetic league the bishopric of Porentrui, the defiles of Franche Comte, and even those of Tyrol, with the neighbouring bailiwicks, as well as the territory of Versoy, which intersects the Pays de Vaud.

Should his majesty the king of Sardinia subscribe to the coalition, La Bresse, Le Bugey, and the Pays de Gex, usurped by France from Savoy, shall be restored to him.

In case his Sardinian majesty can make a grand diversion, he shall be suffered to take Dauphiné, to belong to him for ever as the nearest descendant of the ancient dauphins.

His majesty the king of Spain shall have Roussillon and Bearn, with the island of Corsica; and he shall have the French part of the island of St Domingo.

Her majesty the empress of all the Russias shall take upon herself the invasion of Poland, and at the same time retain Kaminiech, with that part of Podolia which borders on Moldavia.

His majesty the emperor shall oblige the Porte to give up Chocsim, as well as the small forts of Servia, and those on the river Lurna.

His majesty the king of Prussia, by means of the above-mentioned invasion of the empress of all the Russias into Poland, shall make an acquisition of Thorn and Dantzic, and there unite the Palatinate on the east to the confines of Silesia.

His majesty the king of Prussia shall besides acquire Lusace; and his serene highness the elector of Saxony shall in exchange receive the rest of Poland and occupy the throne as hereditary sovereign.

His majesty the present king of Poland shall abdicate the throne on receiving a suitable annuity.

His royal highness the elector of Saxony shall give his daughter in marriage to his serene highness the youngest son of his royal highness the grand duke of all the Russias, who will be the father of the race of the hereditary kings of Poland and Lithuania. (Signed) LEOPOLD. PRINCE NASSAU. COUNT FLORIDA BLANCA. BISCHOFFSWERDER.

295 The new constitution concluded by the assembly.

In the mean time, the national assembly was hastening fast to the completion of the new constitution. It was finished on the 3d of September, and presented to the king. It begins with the following declaration of the rights of a man and a citizen: and thereafter follow the different branches; the chief of which are here translated.

I. All men are born, and remain, free and equal in rights: social distinctions cannot be founded but on common utility.

II. The end of all political associations is the preservation of the natural and imprescriptible rights of man: these rights are liberty, property, security, and resistance against oppression.

III. The principle of *sovereignty* resides essentially in the nation: *no body* of *men*, no *individual*, can exercise an authority that does not emanate expressly from that source.

IV. *Liberty* consists in the power of doing every thing except that which is hurtful to another: hence the exercise of the natural rights of every man has no other bounds than those that are necessary to ensure to the other members of society the enjoyment of the same rights: those bounds can be determined by the law only.

V. The law has a right to forbid those actions alone that are hurtful to society. Whatever is not forbidden by the law, cannot be hindered; and no person can be constrained to do that which the law ordaineth not.

VI. The law is the expression of the general will: all the citizens have a right to concur personally, or by their representatives, to the formation of the law: it ought to be the same for all, whether it protect, or whether it punish. All citizens being equal in the eye of the law, are equally admissible to dignities, places, and public offices, according to their capacity, and without any other distinction but that of their virtue and their talents.

VII. No man can be accused, arrested, or detained, except in cases determined by the law, and according to the forms which the law hath prescribed. Those who solicit, dispatch, execute, or cause to be executed, arbitrary orders, ought to be punished; but every citizen that is summoned or seized in virtue of the law, ought to obey instantly—he becomes culpable by resistance.

VIII. The law ought to establish such punishments only as are strictly and evidently necessary; and no person can be punished but in virtue of a law established and promulgated prior to the offence, and legally applied.

IX. Every man being presumed innocent till such time as he has been declared guilty, if it shall be deemed absolutely necessary to arrest a man, every kind of rigour employed, not necessary to secure his person, ought to be severely repressed by the law.

X. No person shall be molested for his opinions, even such as are religious, provided that the manifestation of those opinions does not disturb the public order established by the law.

XI. The free communication of thought, and of opinion, is one of the most precious rights of man. Every citizen, therefore, may freely speak, write, and publish, his sentiments; subject, however, to answer for the abuse of that liberty, in cases determined by the law.

XII. The guarantee of the Rights of Man and Citizens, involves a necessity of *public force:* this force is then instituted for the advantage of all, and not for the particular utility of those to whom it is confided.

XIII. For the maintenance of public force, and for the expences of administration, a common contribution is indispensably necessary: this contribution should be equally divided amongst all the citizens, in proportion to their abilities.

XIV. Every citizen has a right, by himself, or by his representatives, to decide concerning the necessity of the public contribution; to consent to it freely; to look after the employment of it; to determine the quantity, the distribution, the collection, and duration.

XV. The society has a right to demand from every public agent an account of his administration.

XVI. Every society, in which the guarantee of rights is not assured, nor the separation of powers determined, has *no constitution.*

XVII. Property being a right inviolable and sacred, no person can be deprived of it, except when the public necessity, legally ascertained, shall evidently require it, and on condition of a just and previous indemnification.

The constitution guarantees, as natural and civil rights,

1. That all citizens are admissible to places and employments without any distinction, but that of ability and virtue.

2. That all contributions shall be divided equally among all the citizens, in proportion to their means.

3. That the same crimes shall be subject to the same punishments, without any distinction of persons.

The constitution in like manner guarantees, as natural and civil rights,

Liberty to all men of going, staying, or departing, without being arrested, or detained, but according to the forms prescribed by the constitution.

Liberty to all men of speaking, writing, printing, and "publishing their thoughts, without having their writings subjected to any examination or inspection before publication;" and of exercising the religious worship to which they are attached.

Liberty to all citizens of assembling peaceably, and without arms, complying with the laws of police.

Liberty of addressing to all constitutional authorities petitions individually signed.

The constitution guarantees the inviolability of property, or a just and previous indemnity for that of which public necessity, legally proved, shall require the sacrifice.

A public instruction shall be created and organized, common to all citizens, gratuitous with regard to those parts of tuition indispensable for all men, and of which the establishment shall be gradually distributed in a proportion combined with the division of the kingdom.

"The kingdom is one and indivisible;" its territory for administration, is distributed into 83 departments, each department into districts, each district into cantons.

Those are French citizens,

Who are born in France, of a French father.

Who having been born in France of a foreign father, have fixed their residence in the kingdom.

Who having been born in a foreign country, of a French father, have returned to settle in France, and have taken the civic oath:

In fine, who having been born in a foreign country, being descended in whatever degree from a Frenchman or Frenchwoman, who have left their country from religious motives, come to reside in France, and take the civic oath.

The right of French citizenship is lost,

1st, By naturalization in a foreign country;

2dly, By being condemned to penalties which involve the civic degradation, provided the person condemned be not reinstated;

3dly, By a sentence of contumacy, provided the sentence be not annulled;

4thly, By initiation into any foreign order or body which supposes either proofs of nobility "or distinctions of birth, or requires religious vows."

"The law considers marriage only as a civil contract."

The sovereignty is one, indivisible, "inalienable, and imprescriptible," and it belongs to the nation: no section of the people, or individual, can arrogate the exercise of it.

The nation, from which alone flow all powers, cannot exercise them but by delegation.

The French constitution is representative: the representatives are the legislative body and the king.

The National Assembly, forming the legislative body, is permanent, and consists of one chamber only.

It shall be formed by new elections every two years.

The legislative body cannot be dissolved by the king.

The number of representatives to the legislative body shall be 745, on account of the 83 departments of which the kingdom is composed; and independent of those that may be granted to the colonies.

The representatives shall be distributed among the departmen s, according to the three proportions of land, of population, and of the contribution direct.

Of the 745 representatives 247 are attached to the land. Of these each department shall nominate three, except the department of Paris, which shall nominate only one.

Two hundred and forty-nine representatives are attached to the population. The total mass of the active population of the kingdom is divided into 249 parts, and each department nominates as many of the deputies as it contains parts of the population.

Two hundred and forty-nine representatives are attached to the contribution direct. The sum total of the direct contribution of the kingdom is likewise divided into 249 parts; and each department nominates as many deputies as it pays parts of the contribution.

In

In order to form a legislative national assembly, the active citizens shall convene, in primary assemblies, every two years in the cities and cantons.

"The primary assemblies shall meet of full right on the first Sunday of March, if not convoked sooner by the public officers appointed to do so by the law."

To be an active citizen, it is necessary,

To be a Frenchman, or to have become a Frenchman;

To have attained 25 years complete;

To have resided in the city or the canton from the time determined by the law;

To pay in any part of the kingdom a direct contribution, at least equal to the value of three days labour, and to produce the acquittance;

Not to be in a menial capacity, namely, that of a servant receiving wages;

To be inscribed in the municipality of the place of his residence in the list of the national guards;

To have taken the civic oath.

The primary assemblies shall name electors in the proportion of the number of active citizens residing in the city or canton.

There shall be named one elector to the assembly, or not, according as there shall happen to be present 100 active citizens.

There shall be named two, when there shall be present from 151 to 250, and so on in this proportion.

The electors named in each department shall convene, in order to choose the number of representatives, whose nomination shall belong to their department, and a number of substitutes equal to the third of the representatives.

"The assemblies shall be held of full right on the last Sunday of March, if they have not been before convoked by the public officers appointed to do so by law."

All active citizens, whatever be their state, profession, or contribution, may be chosen representatives of the nation.

Excepting, nevertheless, the ministers and other agents of the executive power, &c.

The members of the legislative body may be re-elected to a subsequent legislature, but not till after an interval of one legislature.

No active citizen can enter or vote in an assembly if he is armed.

The representatives shall meet on the first Monday of May, in the place of the sittings of the last legislature.

The royalty is indivisible, and delegated hereditarily to the race on the throne from male to male, by order of primogeniture, to the perpetual exclusion of women and their descendants.

Nothing is prejudged on the effect of renunciations in the race on the throne.

The person of the king is inviolable and sacred; his only title is king of the French.

If the king put himself at the head of an army, and direct the forces of it against the nation, or if he do not oppose, by a formal act, any such enterprise undertaken in his name, he shall be held to have abdicated.

If the king having gone out of the kingdom, do not return to it, after an invitation by the legislative body, within the space which shall be fixed by the proclamation, "and which cannot be less than two months," he shall be held to have abdicated the royalty.

After abdication, express or legal, the king shall be in the class of citizens, and may be accused and tried like them, for acts posterior to his abdication.

The nation makes provision for the splendour of the throne by a civil list, of which the legislative body shall fix the sum at the commencement of each reign, for the whole duration of that reign.

The king is a minor till the age of 18 complete; and during his minority there shall be a regent of the kingdom.

The regency belongs to the relation of the king, next in degree according to the order of succession to the throne, who has attained the age of 25; provided he be a Frenchman resident in the kingdom, and not presumptive heir to any other crown, and having previously taken the civic oath.

The presumptive heir shall bear the name of *Prince Royal.*

"The members of the king's family called to the eventual succession of the throne, shall add the denomination of *French Prince* to the name which shall be given them in the civil act proving their birth; and this name can neither be patronymic nor formed of any of the qualifications abolished by the present constitution.

"The denomination of *prince* cannot be given to any individual, and shall not carry with it any privilege or exception to the common right of all French citizens."

To the king alone belong the choice and dismission of ministers.

"The members of the present national assembly, and of the subsequent legislatures, the members of the tribunal of appeal, and those who shall be of the high jury, cannot be advanced to the ministry, cannot receive any place, gift, pension, allowance, or commission of the executive power or its agents during the continuance of their functions, or during two years after ceasing to exercise them: the same shall be observed respecting those who shall only be inscribed on the list of high jurors as long as their inscription shall continue."

No order of the king can be executed if it be not signed by him, and countersigned by the minister or comptroller of the department.

In no case can the written or verbal order of a king shelter a minister from responsibility.

The constitution delegates exclusively to the legislative body the powers and functions following:

To propose and decree laws—The king can only invite the legislative body to take an object into consideration;

To fix the public expences;

To establish the public contributions, to determine the nature of them, the amount of each sort, the duration, and mode of collection, &c.

War cannot be resolved on but by a decree of the national assembly, passed on the formal and necessary proposition of the king, and sanctioned by him.

During the whole course of war, the legislative body may require the king to negotiate peace; and the king is bound to yield to this requisition.

It belongs to the legislative body to ratify treaties of peace,

peace, alliance, and commerce; and no treaty shall have effect but by this ratification.

The deliberations of the legislative body shall be public, and the minutes of the sittings shall be printed.

The legislative body may, however, on any occasion, form itself into a general committee.

The plan of a decree shall be read thrice, at three intervals, the shortest of which cannot be less than eight days.

The decrees of the legislative body are presented to the king, who may refuse them his consent.

In case of a refusal of the royal consent, that refusal is only suspensive.—When the two following legislatures shall successively present the same decree in the same terms on which it was originally conceived, the king shall be deemed to have given his sanction.

The king is bound to express his consent or refusal to each decree within two months after its presentation.

No decree to which the king has refused his consent can be again presented to him by the same legislature.

The supreme executive power resides exclusively in the hands of the king.

The king is the supreme head of the land and sea forces.

The king names ambassadors, and the other agents of political negotiations.

He bestows the command of armies and fleets, and the ranks of marshal of France and admiral:

He names two-thirds of the rear-admirals, one-half of the lieutenant generals, camp-marshals, captains of ships, and colonels of the national gendarmerie:

He names a third of the colonels and lieutenant-colonels, and a sixth of the lieutenants of ships:

He appoints in the civil administration of the marine, the directors, the comptrollers, the treasurers of the arsenals, the masters of the works, the under masters of civil buildings, half of the masters of administration, and the under masters of construction.

He appoints the commissaries of the tribunals:

He appoints the superintendants in chief of the management of contributions indirect, "and the administration of national domains:"

He superintends the coinage of money, and appoints officers entrusted with this superintendance in the general commission and the mints.

The effigy of the king is struck on all the coinage of the kingdom.

There is in each department a superior administration, and in each district a subordinate administration.

The administrators are specially charged with distributing the contributions direct, and with superintending the money arising from the contributions and the public revenues in their territory.

The king has the right of annulling such acts of the administrators of department as are contrary to the law or the orders transmitted to them.

He may, in case of obstinate disobedience, or of their endangering, by their acts, the safety or peace of the public, suspend them from their functions.

The king alone can interfere in foreign political connections.

Every declaration of war shall be made in these terms: *By the king of the French in the name of the nation.*

The judicial power can in no case be exercised either by the legislative body or the king.

Justice shall be gratuitously rendered by judges chosen from time to time by the people, and instituted by letters patent of the king, who cannot refuse them.

"The public accuser shall be nominated by the people."

"The right of citizens to determine disputes definitively by arbitration, cannot receive any infringement from the acts of the legislative power."

In criminal matters, no citizens can be judged except on an accusation received by jurors, or decreed by the legislative body in the case in which it belongs to it to prosecute the accusation.

After the accusation shall be admitted, the fact shall be examined, and declared by the jurors.

The person accused shall have the privilege of challenging 20, "without assigning any reason."

The jurors who declare the fact shall not be fewer than 12.

The application of the law shall be made by the judges.

The process shall be public; "and the person accused cannot be denied the aid of counsel."

No man acquitted by a legal jury can be apprehended or accused on account of the same fact.

For the whole kingdom there shall be one tribunal of appeal, established near the legislative body.

A high national court, composed of members of the tribunal of appeal and high jurors, shall take cognizance of the crimes of ministers, and the principal agents of the executive power; and of crimes which attack the general safety of the state, when the legislative body shall pass a decree of accusation.

It shall not assemble but on the proclamation of the legislative body; "and at the distance of 30,000 toises at least from the place of meeting of the legislative body."

The national guards do not form a military body, or an institution in the state; they are the citizens themselves called to assist the public force.

Officers are chosen for a time, and cannot again be chosen till after a certain interval of service as privates.

None shall command the national guard of more than one district.

All the parts of the public force employed for the safety of the state from foreign enemies are under the command of the king.

Public contributions shall be debated and fixed every year by the legislative body, and cannot continue in force longer than the last day of the following session, if they are not expressly renewed.

"Detailed accounts of the expence of the ministerial departments, signed and certified by the ministers or comptrollers-general, shall be printed and published at the commencement of the sessions of each legislature.

"The same shall be done with the statements of the receipt of the different taxes, and all the public revenues."

The French nation renounces the undertaking of any war with a view of making conquests, and will never employ its forces against the liberty of any people.

The constituting national assembly declares, "That the

the nation has the imprescriptible right of changing its constitution; and nevertheless considering that it is more conformable to the national interest to employ only by means provided in the constitution itself, the right of reforming those articles of it, of which experience shall have shown the inconveniences, decrees, that the proceeding by an assembly of revision shall be regulated in the form following:

"When three successive legislatures shall have expressed an uniform wish for the change of any constitutional article, the revision demanded shall take place.

"The next legislature, and the following, cannot propose the reform of any constitutional article.

"The fourth legislature, augmented with 249 members, chosen in each department, by doubling the ordinary number which it furnishes in proportion to its population, shall form the assembly of revision."

The French colonies and possessions in Asia, Africa, and America, "though they form part of the French empire," are not included in the present constitution.

With respect to the laws made by the national assembly which are not included in the act of constitution, and those anterior laws which it has not altered, they shall be observed, so long as they shall not be revoked or modified by the legislative power.

296 Is accepted by the king.

On the 13th of September the king announced, by a letter to the president of the assembly, his acceptance of the constitution. This event was ordered to be notified to all the foreign courts, and the assembly decreed a general amnesty with respect to the events of the revolution. On the following day the king repaired in person to the national assembly; and being conducted to a chair of state prepared for him at the side of the president, he signed the constitutional act, and took an oath of fidelity to it. He then withdrew, and was attended back to the Thuilleries by the whole

297 The assembly dissolved.

assembly, with the president at their head. On the 30th of September, this national assembly, which has since been known by the name of the *Constituent Assembly*, dissolved itself, and gave place to the succeeding *Legislative National Assembly*, which had been elected according to the rules prescribed by the new constitution.

298 Character and labours of the constituent assembly.

On the character and the labours of the *Constituent Assembly*, we shall only remark, that it contained many men of talents, and, in all probability, a considerable number of men of integrity. Towards the close of its session, it assumed a very striking character of moderation, and appears to have been completely monarchical, although its jealousy of the ancient aristocracy prevented it from sufficiently guarding the throne against popular violence: for a very striking defect in the new constitution soon appeared. The king possessed a *veto*, or negative, upon the resolutions of the legislative body: but this negative he was bound to exercise in *person*, without responsibility, and without the intervention of his ministers. He had no senate, or upper chamber, to stand between him and popular violence; and there was something apparently absurd in setting the vote of an individual in opposition to the collective wisdom and will of a whole nation. In consequence of this, he was reduced to the hard alternative of yielding to every vote of the national assembly, or of exposing himself personally to public odium.

The new assembly was opened by the king on the 7th of October, with much apparent union on all sides. His speech, recommending unanimity and confidence between the legislative and executive powers, was received with unbounded applause. The character of the men who composed the new national assembly was unauspicious to the Court. At the commencement of the revolution, the great body of the people at a distance from the capital were little interested in those projects of freedom which occupied the more enlightened or more turbulent inhabitants of Paris. They had gradually, however, been roused from their lethargy. The variety of powers conferred by the new constitution upon the people at large, and the multiplicity of offices of which it gave them the patronage, had kindled in the minds of men a love of dominion, and a wish to interfere in public affairs. This attached them to the new order of things. The love of power, which is the least disguised passion in the human heart, and equally strong in the breast of the meanest and of the highest of mankind, was thus, under the name of liberty, become a leading passion throughout this wide empire. They who flattered it most, and were most loud in praise of the rights of the people, became speedily the favourites of the public. The consequence of this was, that the new national assembly was chiefly composed of country gentlemen, of principles highly democratic, or of men of letters who had published popular books, or conducted periodical publications. The members of the constituent assembly had been excluded by their own decree from holding seats in the new legislature.—The members of the latter, therefore, had little regard for a constitution which they themselves had not framed, and which was not protected by the venerable sanction of antiquity.

299 The new assembly opened by the king. Character of the members.

When this assembly first met, it showed a very trifling attention to formalities, and a peevish jealousy of the ministers of the crown. In the mean time, the treaty of Pilnitz, already mentioned, began to be rumoured abroad, and France was thrown into a state of anxious jealousy for the safety of its newly-acquired liberties. Although the Prussians and Germans (the elector of Mentz alone excepted) all continued to temporize, the northern powers, Sweden and Russia, entered into strict engagements to restore the old despotism of France. On the 9th of November, a decree was passed, that the emigrants, who, after the first of January next, should be found assembled, as at present, in a hostile manner, beyond the frontiers, should be considered as guilty of a conspiracy, and suffer death; that the French princes, and public functionaries, who should not return before that period, should be punishable in the same manner, and their property forfeited during their own lives. On the 10th, a series of severe decrees was also passed against such of the ejected clergy as still refused to take the civic oath. To both these decrees the king opposed his *veto*, or negative.—The moderate party, who were attached to the constitution, rejoiced at this as a proof of the freedom of their sovereign. But, on the other side, it excited a most violent clamour, and became the means of exciting new suspicions of the wishes of the court. At this time answers were received from the different foreign courts to the notification sent them of the king's acceptance of the new constitution. These were generally conceived in a stile of caution, and avoided giving

300 Their jealousy of the ministers of the crown.

301 Pacific answers are received from foreign powers.

open

France. 1791.

open offence. The emperor even prohibited all assemblages of emigrants within his states; and the king intimated to the assembly that he had declared to the elector of Treves, that unless the emigrants should cease before the 15th of January to make hostile preparations within his territories, he would be considered as the enemy of France. All this, however, did not preserve the court from suspicion; for although the different foreign courts had openly declared pacific intentions, yet the French emigrants boldly asserted that all Europe was actually arming in their favour. Accordingly they ceased not to solicit their equals in rank, who still remained within the country, to leave it to join with them in what they called the *royal cause.*—The unhappy Louis, placed between a republican party that was gradually gathering strength, and an aristocratical party that was rousing Europe to arms against a nation of which he was the constitutional chief, and a combination of princes justly suspected of wishing to seize upon a part of his dominions, stood in a situation which would have perplexed the most skilful statesman; and it is no proof of incapacity that he fell a sacrifice to circumstances which might have overwhelmed any known measure of human ingenuity. Addresses were crowding into the assembly, disapproving the conduct of the court. M. Montmorin resigned; M. Delessart succeeded him; and M. Cahier de Gerville became minister of the interior. M. du Portail resigned also, and M. Narbonne succeeded him as minister of war. In the month of November, M. Bailly's mayoralty terminated; and the once popular La Fayette appeared as a candidate to succeed him. But he was successfully opposed by M. Petion, a violent Jacobin, and a declared republican, who was elected mayor of Paris by a great majority.

302 But the court is still suspected.

303 The ministry changed.

304 The Feuillans established to oppose the Jacobin club.

At this period the moderate men, who were friends of the constitution, attempted to counteract the influence of the Jacobin club by the establishment of a similar one. It derived its name from the vacant convent of the *Feuillans*, in which it assembled. The most active members of the Constitutent Assembly belonged to it, such as M. M. D'Andre, Barnave, the Lameths, Du Port, Rabaud, Sieyes, Chapelier, Thouret, Labord, Taleyrand, Montesquieu, Beaumetz, &c. The Jacobins contrived to excite a riot at the place of their meeting, which was in the vicinity of the hall of the National Assembly. This afforded a pretext for applying to the assembly for the removal of the new club. The assembly showed their disposition, by complying with this request.

305 State of France in the end of 1791 and beginning of 1792.

At the end of this year, the kingdom of France was by no means prosperous. The public revenue had fallen far short of the expenditure. The emigrant nobility had carried out of the kingdom the greater part of the current coin; and a variety of manufacturers, who depended upon their ostentatious luxury, were reduced to much distress. The dispositions of foreign courts appeared very doubtful. The new year, however, opened with delusive prospects of tranquillity.—The German princes appeared satisfied with the mode of compensation which the French had offered for the loss of their possessions in Alsace and Lorraine. The prince of Lowestein accepted of an indemnification.—The princes of Hohenlohé and Salm-Salm declared themselves ready to treat upon the same terms. Prince Maximilian, and the dukes of Wirtemberg and Deux-Ponts, freely negotiated. It is unnecessary to state in detail the subterfuges employed, in the mean time, by the crafty Leopold, for amusing the French with the appearances of peace. M. Delessart, minister for foreign affairs, fell a sacrifice to them, and probably to the undecided character of Louis. He was accused by M. Brissot of not having given timely notice to the National Assembly of the dispositions of foreign powers, and of not pressing proper measures for securing the honour and safety of the nation. A decree of accusation passed against him in his absence. He was apprehended, tried by the high national court at Orleans, and executed in consequence of its sentence.

306 The death of the emperor and murder of the king of Sweden.

The sudden death of Leopold on the first of March gave rise to a transient hope that peace might still be preserved. A suspicion of poison fell upon the French, but it was removed by the detail of his disease that was speedily published. On the 16th of the same month, the king of Sweden was wounded by a nobleman of the name of Ankerstrom, and died on the 29th. This enterprising prince had overturned the constitution of his own country, and he had formed the project of conducting in person his troops to the frontiers of France, and of commanding or accompanying the combined armies of Europe in their attempt to avenge the cause of insulted royalty. It was in a great measure to counteract this scheme that he was assassinated.

307 The emperor's successor openly avows warlike intentions.

The sudden fall, however, of these two enemies rather accelerated than retarded the meditated hostilities. The young king of Hungary, who succeeded to the empire, made no secret either of his own intentions or of the existence of a *concert of Princes* against France. M. Dumourier was now at the head of the war-office, M. Roland was minister of the interior, and M. Claviere minister of finance. The Jacobins were all-powerful. The court gave way to the torrent. The property of the emigrants was confiscated, reserving the rights of creditors. The Imperial minister, Prince Kaunitz, demanded three things of France; 1st, The restitution of their feudal rights to the German princes; 2dly, To restore Avignon to the Pope, the inhabitants of which had some time before thrown off their allegiance, and prevailed with the constituent assembly to receive their country as a part of France; and lastly, Prince Kaunitz demanded, that "the neighbouring powers should have no reason for apprehension from the present weakness of the internal government of France." On receiving these demands, the king proposed a declaration of war, which was decreed by the National Assembly on the 20th of April, against *the king of Hungary and Bohemia.*

308 And the Austrian Netherlands are unsuccessfully attacked by the French.

The French immediately began the war, by attacking in three different columns the Austrian Netherlands. M. Theobald Dillon advanced from Lisle to Tournay, where he found a strong body of Austrians ready to receive him. The national troops, unaccustomed to sustain the fire of regular soldiers, were instantly thrown into confusion, and fled even to the gates of Lisle. The cry of *treason* resounded on all sides; and their commander, an experienced and faithful officer, was murdered by his own soldiers and the mob. A second division of 10,000 men, under Lieutenant-General Biron, took possession of Quiverain on the 29th, and marched towards Mons. General Biron was here attacked by the

the Austrians, whom he repulsed. Hearing, however, of the defeat of Dillon, he retreated. A third party advanced to Furnes, but afterwards withdrew. La Fayette at the same time advanced towards Bouvines, half way to Namur, from which he afterwards retreated. The whole of these expeditions were ill contrived, in as much as they divided the French undisciplined troops, and exposed them in small bodies to the attack of veteran forces. The Austrians were some time before they attempted to retaliate. At length, however, on the 11th of June, they attacked M. Gouvion, who commanded the advanced guard of La Fayette's army near Maubeuge. M. Gouvion was killed by a rolling bullet; but La Fayette himself having come up, the Austrians abandoned the field.

309 The parties in Paris this period, and the consequences.

In the mean time, matters were hastening in Paris towards a violent crisis. Two parties, both of which were hostile to the present constitution, had gradually been formed in the state. The one wished to give more effectual support to the royal authority, by establishsng a *senate* or *two chambers*, to prevent the king's vote from being the sole check upon popular enthusiasm. The other party wished to set aside royalty altogether, and to hazard the bold experiment of converting France into a republic. These last were supported by the Jacobin club, which had now contrived to concentrate in itself an immense mass of influence. Innumerable popular societies were established in every town and village throughout the provinces. With these a regular correspondence was kept up by writing and by emissaries. Thus schemes and notions were instantaneously propagated through a great empire, and all the violent spirits which it contained were enabled to act in concert: But the more immediate engine of the republican party consisted of the immense population of the metropolis, whom they now endeavoured to keep in constant alarm. For this purpose they alleged, that an *Austrian Committee*, that is to say, a conspiracy in favour of the enemies of the country, existed among the friends of the court. M. M. Gensonne and Brissot even offered in the assembly to prove the existence of this pretended Austrian committee. A report was next circulated, that the king intended to abscond from the capital on the 23d of May. His majesty publicly contradicted these accusations as calumnies, but they made no small impression upon the minds of the public. New decrees were now made against the refractory clergy, but these his majesty refused to sanction. A proposal was also made and decreed in the assembly to form a camp of 20,000 men under the walls of Paris, and that for this levy every canton in the kingdom should contribute one horseman and four infantry. The national guard of Paris disliked the proposal, and the king gave to it his negative. Indeed at this time the king seems to have come to a resolution of standing out against the Jacobin party, to which he had for some time yielded. The ministry were therefore dismissed, excepting M. Dumourier, and others were appointed in their stead. By this event Dumourier lost the confidence of the Jacobin club. He saw his error, resigned his office, and joined the army. In the mean time a decree had been passed, authorising the manufactory of pikes for the purpose of arming cheaply the lower class of citizens. All means were used to render the king odious by inflammatory writings and harangues; and in both of these the noted incendiary Marat took the lead.

310 An armed mob marches through the assembly, &c.

On the 20th of Jnne, M. Roederer, the procureur general syndic informed the national assembly, that, contrary to law, formidable bodies of armed men were preparing to present petitions to the king, and to the national assembly. A part of them speedily appeared with St Huruge and Santerre a brewer at their head. They marched through the hall in a procession that lasted two hours, at four o'clock in the afternoon, to the number of about 40,000. They surrounded the Thuilleries. The gates were thrown open; and on an attempt to break the door of the apartment where the king then was, he ordered them to be admitted. His sister the princess Elizabeth never departed from his side during four or five hours that he was surrounded by the multitude, and compelled to listen to every indignity. All this while Petion, the mayor of Paris, was unaccountably absent. He at length, however, arrived, and also a deputation from the assembly. The queen, with her children and the princess de Lamballe, were in the mean time in the council-chamber, where, though protected from violence, they were yet exposed to much insult. At last, in consequence of the approach of evening, and of the entreaties of Petion, the multitude gradually dispersed.

311 The more respectable inhabitants are ashamed of such conduct.

The indignities suffered on this day by the royal family were in some respects not unfavourable to their cause. A great nnmber of the most respectable inhabitants of the capital were ashamed of such proceedings. They complained of them severely in a petition to the assembly, and addresses to the same purpose were received from several departments. The directory of the department of Paris, at the head of which were M. Rochefoucault and M. Talleyrand, published a declaration disapproving of the conduct of the mayor, and of M. Manuel the procureur of the commune, whom they afterwards suspended from their offices, although they were speedily restored by a decree of the assembly. At the same time, La Fayette leaving his army suddenly, appeared on the 26th at the bar of the national assembly. He declared that he came to express the indignation which the whole army felt on account of the events of the 20th: he called upon the assembly to punish the promoters of these events, and to dissolve the factious clubs. The sudden appearance of La Fayette threw the Jacobins into consternation, and from that period they never ceased to calumniate him.

312 The king of Prussia marches against France.

On the 1st of July, on the motion of M. Jean de Brie, the assembly ordered a proclamation to be made, that *the country was in danger*. On the 6th, the king gave intimation that the king of Prussia was marching with 52,000 men to co-operate against France. The French arms were at this time somewhat successful in the Austrian Netherlands; but the cabinet speedily thought it necessary to order the armies to retreat: a measure which was afterwards publicly censured by Marshal Luckner.

313 Moderate speech of the bishop of Lyons.

On the 7th, a singular scene occurred in the national assembly. At the instant that M. Brissot was about to commence an oration, M. Lammourette bishop of Lyons requested to be heard for a few minutes. He expatiated on the necessity of union among the members of the assembly, and of sacrificing their passions and prejudices

France. 1792.

judices on the altar of their country. He concluded an animated address with these words, "Let all who hold in equal detestation a republic and two chambers, and who wish to maintain the constitution as it is, rise!" The words were scarcely pronounced when the whole assembly started from their seats. Men of all parties solemnly embraced each other, and protested their adherence to the constitution. A deputation announced this happy event to the king; who immediately came and congratulated them in a short speech, which was received with infinite applause. The only good effect, however, produced by this temporary agreement was, that the festival of the 14th of July, which was celebrated with the usual magnificence, passed over in tranquillity.

314 Manifesto of the duke of Brunswick.

On the 25th of July, the duke of Brunswick issued at Coblentz his celebrated manifesto. It declared the purpose of the intended invasion of France to be the restoration of the French king to full authority. It declared the national guard of France responsible for the preservation of tranquillity; and threatened with the punishment of death, as rebels to their king, these who should appear in arms against the allied powers. All men holding offices, civil or military, were threatened in the same manner, as well as the inhabitants of all cities. The city of Paris in particular, and the national assembly, were declared responsible for every insult which might be offered to the royal family. It was declared, that if they were not immediately placed in safety, the allies were resolved to inflict "on those who should deserve it, the most exemplary and ever memorable avenging punishments, by giving up the city of Paris to military execution, and exposing it to total destruction; and the rebels who should be guilty of illegal resistance should suffer the punishments which they should have deserved."

315 Injurious to Louis.

This sanguinary and imprudent manifesto operated as a warrant for the destruction of the unfortunate Louis XVI. It left no middle party in the nation. All who wished to preserve freedom in any form, and all who loved the independence of their country, were instantly united. At the same time, the reproaches cast on the king by the Jacobins now gained universal credit. The kings of Prussia and of Hungary told the French nation, that their monarch was secretly hostile to the constitution; and the restoration of him and his family to despotic power was made the sole pretence for a bloody and dangerous war.

316 But advantageous to the republican party, who resolve to depose him.

The republican party saw the advantage which they had now gained, and resolved upon the deposition of the king. The chief engine which they meant to employ in this service consisted of about 1500 men, who had come to Paris at the period of the confederation on the 14th of July, and therefore called *fœderés*, and who were also sometimes denominated *Marseillois*, from the place from which the greater number of them came. Next to these, dependence was placed in the populace of the suburbs of the capital. The designs of the republicans were not unknown to the court, and both parties were forming plans of operation. It is said that the royal party intended that the king and his family should suddenly leave the capital, and proceed to as great a distance as the constitution permitted. The republicans are said to have intended to seize the person of the king, and to confine him in the castle of Vincennes till a national convention should decide upon his fate. Both allegations are probably true. Every motive which can influence the mind of man must have induced Louis to wish to be at a distance from the factious and sanguinary capital. And the subsequent conduct of the republicans authorize us to believe them capable of the worst crime that was laid to their charge.

317 La Fay[ette] accused and acquitted.

Various charges had been brought forward in the assembly against La Fayette, and the 8th of August was appointed for their discussion. In the mean time, on the 3d of August, Petion the mayor, at the head of a deputation from the section of Paris, appeared at the bar, and in a solemn speech demanded the deposition of the king. The discussion of the accusation against La Fayette was considered as a trial of strength between the parties: he was acquitted, however, by a majority of nearly 200; and the republican party, despairing of carrying their point by a vote of the national assembly, resolved to have recourse to insurrection and force.

31[8] Horrid [plot] of the [re]publica[ns].

On the evening of the 9th of August, about 1500 gentlemen, officers of the army, and others, repaired to the palace, resolved to protect the royal family or to die in their defence: added to these were 700 Swiss guards, with a body of cavalry amounting to about 1000. Mandat, the commander of the national guards, a man who was firmly attached to the constitution, had procured 2400 of that body and 12 pieces of cannon. With such a force, it has been generally thought that, by vigorous and steady councils, the palace, which is a kind of castle, might have been successfully defended; and what is now called a revolution might have borne the name of a rebellion. Meanwhile the assembly declared its sittings permanent. Petion was at the palace late on the evening of the 9th. Some apprehensions were entertained, or pretended to be entertained, for his safety (for the whole of this business was, on the part of the republicans, the most infernal plot), and a deputation from the assembly brought him away. At midnight the tocsin or alarm bell was sounded, and the drums beat to arms through the city. At this instant a number of the most active leaders of the republican party assembled, and elected a new common council or *commune*. The persons thus irregularly chosen instantly took possession of the common hall, and drove out the lawful members; who, with that weakness with which men are apt to shrink from stations of responsibility in perilous times, readily gave place to the usurpers. The new commune sent repeated messages to M. Mandat, requiring his attendance upon important business. He was occupied in arranging the troops in the best order around the palace; but suspecting nothing, he went to the common hall, and was there astonished to find a different assembly from what he expected. He was abruptly accused of a plot to massacre the people, and ordered to prison; but as he descended the stairs, he was shot with a pistol, and Santerre was appointed in his stead to command the national guard.

On this eventful night no person in the palace went to bed. About six o'clock in the morning of the 10th the king descended into the gardens to review the troops. He was received with shouts of *Vive le roi*, excepting from the artillery, who shouted *Vive le nation*. The king returned to the palace, and the multitude continued to collect. The national guard seemed undetermined about what they were to do, as they assembled in divisions near the palace; and had a steady resistance

sistance been made from within, it is probable they would have joined the royal party. But towards eight o'clock M. Roederer procured admittance to the palace, and told the king that armed multitudes were assembling in hostile array around the Thuilleries; that the national guard was not to be depended upon; and that, in case of resistance, the whole royal family would most certainly be massacred. He therefore advised the king to seek protection in the hall of the national assembly. With this advice the king, with his usual facility of temper, was ready to comply; but the queen opposed with vehemence the humiliating proposal. Becoming gradually, however, alarmed for the safety of her children, she gave her consent; and the king and queen, the princess Elizabeth, with the prince and princess royal, went on foot to the hall of the assembly. "I am come hither (said his majesty) to prevent a great crime. Among you, gentlemen, I believe myself in safety." By an article of the constitution the assembly could not deliberate in presence of the king. The royal family were, therefore, placed in a narrow box separated from the hall by a railing, where they remained for 14 hours without any place to which they could retire for refreshment, excepting a very small closet adjoining. Here they sat listening to debates, in which the royal character and office were treated with every mark of insult.

When the king left the palace of the Thuilleries, he unfortunately forgot to order it to be immediately surrendered. He recollected this as soon as he reached the assembly, and sent orders for this purpose; but it was now too late. The insurgents amounted to about 20,000 effective men. They were drawn up in tolerable order by Westerman a Prussian, and had about 30 pieces of cannon along with them. The gentlemen within the palace, who had assembled to protect the king's person, were now dispirited, and knew not what part to act. The commander of the Swiss, M. Affry, was absent, and the captains knew not what to do; and the national guard had no leader in consequence of the death of Mandat. About nine o'clock the outer gates were forced open; and the insurgents formed their line in front of the palace. A bloody combat commenced chiefly between the Marseillois and the Swiss. After a brave resistance of about an hour, the Swiss were overpowered by numbers, and gave way. All of them that could be found in the palace were massacred; some even while imploring quarter on their knees. Others escaped into the city, and were protected by individuals. Of this brave regiment, however, only 200 survived; but every human being, even the lowest servants found in the palace, were put to death. The Swiss taken prisoners in various quarters were conducted to the door of the assembly, and taken by a decree under the protection of the state. But the sanguinary multitude insisted upon putting them to instant death; and the assembly would, in all probability, have been unable to protect them, had not the Marseillois interfered in their favour.

The suspension of the royal authority was now decreed, and the nation was invited to elect a *Convention* to determine the nature of its future government. On this uncommon occasion all Frenchmen of 21 years of age were declared capable of electing, and of being elected, deputies to the new national convention. Commissioners, were, in the mean time, sent on the same evening to give to the armies a false and favourable account of these transactions. The royal family were sent to the old palace of the Temple in the midst of the city, to remain there under a strict guard; and all persons of rank who had been attached to them were seized and committed to the different prisons.

322 Bloody temper of the people of Paris, &c.

To give an idea of the temper of the people of Paris at this time, it is proper to remark, that at the same instant when the multitude with a bloody fury was massacring the menial servants in the palace, and could scarcely be restrained from offering violence to the Swiss who were made prisoners, they would suffer no act of pillage to pass unpunished. Several attempts of this kind were accordingly followed by the instant death of the criminals. The plate, the jewels, and money found in the Thuilleries were brought to the national assembly, and thrown down in the hall. One man, whose dress and appearance bespoke extreme poverty, cast upon the table an hat full of gold. But the minds of these men were elevated by enthusiasm; and they conceived themselves at this moment the champions of freedom, and objects of terror to the kings of the earth.

323 Critical situation of the whole kingdom.

In the mean time, the situation of France was extremely critical, and it appeared very doubtful if the new convention would ever be suffered to assemble. La Fayette had accidentally got speedy notice of the events of the 10th of August. He advised the magistrates of the town of Sedan to imprison the commissioners from the national assembly when they should arrive there; which was accordingly done. He, at the same time, published an address to his army, calling upon them to support the king and the constitution; but finding that they were not to be depended upon, on the 19th of August he left the camp in the night, accompanied only by his staff and a few servants. They took the route of Rochefort in Liege, which was a neutral country; but were met by a party of the enemy, who took them prisoners, and La Fayette was detained for several years in Prussian and Austrian dungeons. The severe treatment of this man was probably a considerable error in policy on the part of the allies. His fidelity to his king is very generally admitted; though some have entertained strong suspicions of his having acted a very base part to that unfortunate monarch; and in the British house of commons he has been called an abandoned ruffian. The expression is certainly too strong. His errors seem to have been those of the head rather than of the heart; and at all events, he should have been protected by the allies, if for no other reason than to encourage subsequent desertions among the officers of the republican army.

324 La Fayette withdraws from the army.—His fate and character.

To return from this digression. The commissioners were soon set at liberty at Sedan, and received with applause by the army of La Fayette. General Arthur Dillon at first entered into the sentiments of La Fayette; but the politic Dumourier diverted him from his purpose, and by this means regained his credit with the Jacobins, and was appointed commander in chief. The other generals, Biron, Montesquieu, Kellerman, and Custine, made no opposition to the will of the national assembly.

Meanwhile, the combined armies of Austria and Prussia had entered France. The duke of Brunswick's army

France. 1792.

325 The combined armies enter France in great force.

army was above 50,000 strong. General Clairfait had joined him with 15,000 Austrians, and a considerable body of Hessians, along with 20,000 French emigrants; amounting in all to 90,000 men. To oppose these, Dumourier had only 17,000 men collected near the point from which the enemy were approaching in Luxembourg. The French emigrants had given the duke of Brunswick such an account of the distracted state of their own country, and of the pretended disaffection of all orders of men towards the ruling faction in Paris, that no resistance of any importance was expected. When the combined troops, consisting either of steady Austrian or Hungarian battalions, or of those well disciplined Prussians which the great Frederick had inured to the best military discipline, were reviewed in Germany before setting out on their march, it is said that the spectators, among whom the French cause was not unpopular, beheld them with anxiety and regret, and pitied the unhappy country against which this irresistible force was directed. The soldiers and their officers regarded themselves as departing for a hunting match, or an excursion of pleasure; and many of the usual accommodations of an army were ill attended to, such as hospitals, &c. The beginning of their progress into France justified these expectations. Longwy surrendered after a siege of 15 hours, although well fortified, possessed of a garrison of 3500 men, and defended by 71 pieces of cannon. The news of this event irritated the assembly so much, that they decreed, that, when retaken, the houses of the citizens should be razed to the ground; and, distrustful of the officers of the army, they decreed that the municipal officers of a town should hereafter have power to controul the deliberation of the council of war. Verdun was next summoned; and here the municipality compelled the governor M. Beaurepaire to surrender. That officer, disappointed and enraged, shot himself dead with a pistol in presence of the council, and on the 2d of September the Prussian troops entered the town.

326 Alarm at Paris on account of their success.

The news of this second capture, and of the approach of the Prussians, spread an instant alarm through Paris. It was proposed to raise a volunteer army, which should set out immediately to meet the enemy. The common council, which was now led by Robespierre, Danton, Marat, and others of the most sanguinary character, ordered the alarm-guns to be fired, and the populace to be summoned to meet in the Champ de Mars to enroll themselves to march against the enemy. The people assembled, and either in consequence of a premeditated plan, or, which is not very probable, of an instantaneous movement, a number of voices exclaimed, that "the domestic foes of the nation ought to be destroyed before its foreign enemies were attacked."

327 Horrid massacres.

Parties of armed men proceeded without delay to the prisons where the non-juring clergy, the Swiss officers, and those confined since the 10th of August on account of practices against the state, were detained in custody. They took out the prisoners one by one, gave them a kind of mock trial before a jury of themselves, acquitted some few, and murdered the rest. Among these last was the princess de Lamballe. She was taken from her bed before this bloody tribunal, and massacred; her head was carried by the populace to the Temple, to be seen by the queen, whose friend she was. These massacres lasted for two days, and upwards of 1000 persons were put to death. There is scarce any thing in history that can be represented parallel to them; they were committed, it is said, by less than 300 men, in the midst of an immense city, which heard of them with horror, and in the vicinity of the national assembly, which, by going in a body, could have put an end to them. But such was the confusion and dismay of these two disgraceful days, that no man dared to stir from his own house; and every one believed that the whole city, excepting his own street, was engaged in massacre and bloodshed. The national guard were all ready at their respective posts, but no man directed them to act: and there is too much reason to suspect that Santerre and the chiefs of the commune connived, at least, at the transaction.

32[8] State o[f] the Fr[ench] army, [as] conduc[ted by] Dumou[rier].

In the mean time, General Dumourier was taking the best measures to protract the march of the enemy till the army of Kellerman, consisting of 20,000 men, could join him from Lorraine, and that of Bournonville from Flanders, amounting to 13,000; together with whatever new levies Luckner might be able to send him from Chalons. The forest of Argonne extends from north to south upwards of 40 miles; it lay directly in the route of the duke of Brunswick, who must either force his way across it, or make a circuit of 40 miles by the pass of Grandpre on the north, or by Barleduc on the south. The pass that lay directly in his route was that of Biesme. After surveying Dillon's position here, he left a party of 20,000 men to watch it; and with the main body of his army took the circuitous route by Grandpre on the north. Here Dumourier waited to receive him, and was attacked on the 12th and 13th without success: but on the 14th, the attack of the Prussians was irresistible, and Dumourier retreating, gave up the pass. On his march he was so violently pressed by the advanced cavalry of the Prussians, that his army, at one time, was seized with a panic, and fled before 1500 men; who, if they had pushed their advantage, might have dispersed it. On the 15th, however, Dumourier encamped at St Menehould, and began to fortify it. Bournonville's army joined Dumourier on the 17th. The duke of Brunswick formed a plan of attacking Kellerman before his junction could be completed. That general arrived on the 19th within a mile of Dumourier's camp; the projected attack took place; the Prussians manœuvred with their usual coolness and address; they attempted to surround Kellerman's army, but this could not be accomplished. The French troops preserved excellent order, while the national vivacity was constantly showing itself in their shouts and patriotic songs: 400 French were killed, and 500 wounded; the loss of the Prussians was much greater: and, in the face of the enemy, Kellerman joined Dumourier at the end of the engagement without opposition. At the time that the attack was made on the army of Kellerman, an attempt was made to force Dillon's camp at Biesme by the 20,000 men that had been left in its vicinity, but without success; and this large detachment was thus prevented from crossing the forest of Argonne and joining the duke of Brunswick. It is to be observed, that in these engagements the French owed their superiority chiefly to the excellence of their artillery; a circumstance which served to convince their enemies that they had

32[9] The Pr[us]sians ob[lige] him to [re]treat, b[ut] do not [fol]low up their a[d]vantag[e].

France. 1792.

332 The Prussians distressed by sickness and famine.

had to contend with regular military bodies, and not with undisciplined multitudes, as they expected.

The duke of Brunswick encamped his army at La Lun, near the camp of Dumourier. And here the Prussians began to be in extreme distress both from sickness and famine. No temptation could induce the inhabitants of the country to carry provisions to the hostile camp, while at the same time the French army was abundantly supplied.

Bournonville, with a body of 4000 men, intercepted several droves of cattle and other convoys of provisions destined for the Prussians. The rain fell in torrents, and the roads were uncommonly deep. Exposed to the cold, the moisture, and want of provisions, the Prussians rashly ate great quantities of the grapes of Champagne. The consequence of this was, that an epidemical distemper commenced and spread through the army to such an extent, that 10,000 men at one time were unfit for duty. The duke of Brunswick, however, still commanded a force much more numerous than that of Dumourier; and he has been much censured for not attacking his camp, and forcing him to engage. It has been said that the veteran and numerous force which he commanded would have marched to certain victory against the raw troops that opposed them; that, having defeated Dumourier's army, there was nothing to oppose their march to Paris. But the duke of Brunswick had entered France upon the supposition, that in its present distracted state no regular army could be brought into the field against him, and that the people at large were hostile to the ruling faction. The contrary of all this had turned out to be true. He found himself in the midst of an hostile people, and opposed by skilful military chiefs. A defeat in such a situation would have brought certain ruin to his army; and even the loss sustained in the acquisition of a victory might have proved equally fatal. The remains of the French army would not fail to hang upon his rear; and from the disposition of the people it appeared impossible to ascertain to what amount that army might be suddenly increased. After proposing a truce, therefore, which lasted eight days, he commenced his retreat towards Grandpré, and no advantage was gained over him in the course of it. Verdun was retaken by the French on the 12th of October, and Longwy on the 18th; the siege of Thionville was at the same time raised. That small, but strong fortress, under the command of General Felix Wimpfen, had held in check an army of 15,000 men.

333 Lisle summoned and vigorously besieged by the Austrians, but in vain.

While the Prussians were advancing from the north-east, the Austrians under the duke of Saxe Teschen laid siege to Lisle. The council-general of the commune answered the summons of the besiegers thus: "We have just renewed our oath to be faithful to the nation, and to maintain liberty and equality, or to die at our post. We will not perjure ourselves." Such was the cant of these men, who had already perjured themselves by contributing to overturn the constitution which they had repeatedly sworn to defend. The Austrian batteries began to play upon the town on the 29th, and were chiefly directed against that quarter which was inhabited by the lower class of citizens, for the purpose of making them mutinous and seditious. This procedure was ill judged. The lower classes of mankind are always much accustomed to hardships, and they go farthest in support of any enthusiastic principle they have been persuaded to adopt. Accordingly, though a great part of the city was reduced to a heap of ruins, the citizens of Lisle became daily more obstinate. They received each other into the houses that were still standing, and every vault and cellar was occupied. Although upwards of 30,000 red-hot balls and 6000 bombs were thrown into the city, besides the efforts made by an immense battering train of artillery, yet the loss both to the garrison and people did not exceed 500 persons, most of whom were women and children. After a fortnight of fruitless labour, the Austrians raised the siege.

334 War declared against the king of Sardinia, Savoy taken, &c.

War had been declared against the king of Sardinia on account of the threatening appearances exhibited in that quarter. On the 20th of September General Montesquieu entered the territories of Savoy, and was received at Chambery and throughout the whole country with marks of unbounded welcome. On the 29th General Anselm, with another body of troops, took possession of Nice and the country around it. On the 30th General Custine advanced to Spires, when he found the Austrians drawn up in order of battle. He attacked and drove them through the city, taking 3000 of them prisoners. The capture of Worms succeeded that of Spires; Mentz surrendered by capitulation; and Francfort fell into the hands of the French on the 23d. Out of this last place, however, they were afterwards driven on the 2d of December.

335 The national convention assembled,

On the 20th of September the French *National Convention* assembled. It was found to contain men of all characters, orders, and ranks. Many distinguished members of the *Constituting* Assembly were elected into it, and also several that had belonged to the *Legislative* Assembly; even foreigners were invited to become French legislators. The famous Thomas Paine and Dr Priestley of England were elected by certain departments; but the latter declined accepting. Clouts, a Prussian, whom we formerly noticed as bringing a deputation to the bar of the constituent assembly, consisting of persons representing all the nations of the earth, was also chosen. The general aspect of the new convention showed that the republican party had acquired a decided superiority. On the first day of meeting M. Collot d'Herbois, who had formerly been an actor, ascended the tribune, and proposed *the eternal abolition of royalty in France*. The question was carried by acclamation, and the house adjourned. Messages were sent to all parts of the country to intimate the decree, and by the influence of the Jacobins they were everywhere received with applause. It was next day decreed, that all public acts should be dated by the year of the French republic; and all citizens were declared eligible to all the vacant offices and places. The rage of republicanism soon went so far, that the ordinary titles of Monsieur and Madame were abolished, and the appellation of *Citizen* substituted in their stead, as more suitable to the principles of liberty and equality.— It may be remarked, that in this last trifling circumstance an attachment to the form of speech to which they had been accustomed appears even in its abolition: For, although the Roman orators addressed their countrymen when assembled by the honourable appellation of *Citizens*, yet they never, in accosting an individual, called him Citizen Cato, or Citizen Cæsar, according to the mode now adopted in France.

336 and decrees the eternal abolition of royalty in France.

It

France. 1792.

357 Two opposite factions in the convention.

It was soon discovered that the leading republicans had divided into two opposite factions. The one of these was called *Girondists*, because Vergniaud, Gensonné, Gaudet, and some others of its leaders, were members from the department of La Gironde. The celebrated Condorcet belonged to this party; and they were sometimes denominated *Brissotines*, from M. Brissot de Warville their principal leader. They supported the ministry now in office, at the head of which was Roland; and the majority of the convention was obviously attached to them. In opposition to these was the smaller party of the *Mountain*: so called from its members usually sitting in the convention on the upper seats of the hall. They were men possessed of less personal respectability, and fewer literary accomplishments, but of daring and sanguinary characters, whom the revolution had brought into public notice. At the head of this party were Danton and Robespierre; and subordinate to these were Couthon, Bazire, Thuriot, Merlin de Thionville, St André, Camille Demoulins, Chabot, Collot D'Herbois, Sergent, Legendre, Fabre d'Eglantine, Panis, and Marat.

These two parties shewed the diversity of their characters in the manner in which they treated the massacres of the 2d and 3d of September. The Brissotines, with the majority of the convention, wished to bring the murderers to trial; but the question was always eluded by the other party, with the assistance of the Jacobin club and of the populace.

338 Decree against the emigrants, &c.

On the 9th of October it was decreed, that all emigrants, when taken, should suffer death; and on the 15th of November, in consequence of an insurrection in the duchy of Deux Ponts, and an application on the part of the insurgents to the convention for aid, the following decree was passed: "The national convention declare, in the name of the French nation, that they will grant fraternity and assistance to all those people who wish to procure liberty; and they charge the executive power to send orders to the generals to give assistance to such people as have suffered, or are now suffering, in the cause of liberty." Of this decree foreign nations, with great reason, complained much, as will shortly appear.

339 Battle of Jemappe, and surrender of the Austrian Netherlands.

To return to the military affairs of the new republic. On the 12th of October General Dumourier came to Paris, and was speedily sent to commence a winter campaign in the Netherlands. He suddenly attacked the Austrians at the village of Bossu, and drove them from their ground. On the 5th of November he came in sight of the enemy upon the heights of *Jemappe*. Three rows of fortifications arose above each other, defended by 100 pieces of cannon. Their right was covered by the village and a river, and their left by thick woods. The French were by their own account 30,000, whilst others, with great probability of truth, compute them at double that number, and the number of the Austrians was at least 20,000. At seven in the morning of the following day a heavy cannonade commenced on both sides, and at noon a close attack was determined on by the French, whose right wing was commanded by Generals Bournonville and Dampierre, and the centre by Generals Egalité (son to the duke of Orleans who had assumed that name), Stetenboffe, Desporets, and Drouet. The music played the popular march of the Marsellois, and the soldiers rushed on with enthusiasm, shouting "Vive la nation." The engagement was warm and bloody; the French were twice repulsed; but their impetuosity was at last irresistible, and about two o'clock the enemy fled from their last entrenchments. The loss on both sides was very great, that of the Austrians amounting to 4000. This victory was decisive of the fate of the Netherlands. Mons and Brussels surrendered to Dumourier; Tournay, Malines, Ghent, and Antwerp, were taken possession of by General Labourdonnaye; Louvaine and Namur were taken by General Valence; and the whole Austsian Netherlands, Luxembourg only excepted, fell into the hands of the French: Liege was taken on the 28th of November after a successful engagement, in which the Austrians lost 500 or 600 men and an immense train of artillery.

France. 1792.

340 Violent contests between the Girondists and the Mountain.

France was now in a situation not unusual in the history of those nations that either are free, or are attempting to become so; successful in all quarters abroad, but distracted by factions at home. The two parties in the convention were engaged in a struggle, which daily became more implacable. The party called the *Mountain* did not hesitate about the nature of the means they were to employ to bring about the ruin of their antagonists. They are even suspected of having, through the medium of Pache the war-minister, retarded the supply of the armies, to render the ruling party odious by want of success. They were for some time, however, unfortunate in this respect; and the daily news of victories supported with the public the credit of the Girondists. A new subject was therefore fallen upon, which was the question, how the dethroned king was to be disposed of? The moderate party wished to save him; and this was a sufficient reason for their antagonists to resolve upon his ruin. A committee was appointed to give in a report upon his conduct. A variety of accusations were brought against him; and the convention infamously resolved to act the part of accusers and of judges.

341 The king brought to trial.

It was on the 11th of December when the ill-fated monarch was ordered to the bar of the convention: the act of accusation was read, and the king was summoned by the president, Barrere, to answer to each separate charge.

Pres. "Louis, the French nation accuses you of having committed a multitude of crimes to establish your tyranny, in destroying her freedom. You, on the 20th of June 1789, attempted the sovereignty of the people, by suspending the assemblies of their representatives, and expelling them with violence from the places of their sittings. This is proved in the process verbal entered at the Tennis-court of Versailles by the members of the constituent assembly. On the 23d of June you wanted to dictate laws to the nation; you surrounded their representatives with troops; you presented to them two royal declarations, subversive of all liberty, and ordered them to separate. Your own declarations, and the minutes of the assembly, prove these attempts. What have you to answer?"

Louis. "No laws were then existing to prevent me from it."

Pres. "You ordered an army to march against the citizens of Paris. Your satellites have shed the blood of several of them, and you would not remove this army till the taking of the Bastile and a general insurrection announced to you that the people were victorious. The speeches

speeches you made on the 9th, 12th, and 14th of July to the deputations of the constituent assembly, shew what were your intentions; and the massacres of the Thuilleries rise in evidence against you.—What have you to answer?"

Louis. "I was master at that time to order the troops to march; but I never had an intention of shedding blood."

Pres. "After these events, and in spite of the promises which you made on the 15th in the constituent assembly, and on the 17th in the town-house of Paris, you have persisted in your projects against national liberty. You long eluded the execution of the decrees of the 11th of August, respecting the abolition of personal servitude, the feudal government, and tythes: you long refused acknowledging the rights of man: you doubled the number of the life-guards, and called the regiment of Flanders to Versailles: you permitted, in orgies held before your eyes, the national cockade to be trampled under foot, the white cockade to be hoisted, and the nation to be slandered. At last, you rendered necessary a fresh insurrection, occasioned the death of several citizens, and did not change your language till after your guards had been defeated, when you renewed your perfidious promises. The proofs of these facts are in your observations of the 18th of September, in the decrees of the 11th of August, in the minutes of the constituent assembly, in the events of Versailles of the 5th and 6th of October, and in the conversation, you had on the same day with a deputation of the constituent assembly, when you told them you would enlighten yourself with their councils, and never recede from them.—What have you to answer?"

Louis. "I have made the observations which I thought just on the two first heads. As to the cockade, it is false; it did not happen in my presence."

Pres. "You took an oath at the federation of the 14th of July, which you did not keep. You soon tried to corrupt the public opinion, with the assistance of Talon who acted in Paris, and Mirabeau who was to have excited counter-revolutionary movements in the provinces.—What have you to answer?"

Louis. "I do not know what happened at that time; but the whole is anterior to my acceptance of the constitution."

Pres. "You lavished millions of money to effect this corruption, and you would even use popularity as a means of enslaving the people. These facts are the result of a memorial of Talon, on which you have made your marginal comments in your own hand-writing, and of a letter which Laporte wrote to you on the 19th of April; in which, recapitulating a conversation he had with Rivarol, he told you, that the millions which you had been prevailed upon to throw away had been productive of nothing. For a long time you had meditated on a plan of escape. A memorial was delivered to you on the 28th of February, which pointed out the means for you to effect it; you approve of it by marginal notes.—What have you to answer?"

Louis. "I felt no greater pleasure than that of relieving the needy: this proves no design."

Pres. "On the 28th a great number of the nobles and military came into your apartments in the castle of the Thuilleries to favour that escape; you wanted to quit Paris on the 10th of April to go to St Cloud.—What have you to answer?"

Louis. "This accusation is absurd."

Pres. "But the resistance of the citizens made you sensible that their distrust was great; you endeavoured to discard it by communicating to the constituent assembly a letter, which you addressed to the agents of the nation near foreign powers, to announce to them that you had freely accepted the constitutional articles, which had been presented to you; and, notwithstanding, on the 21st you took flight with a false passport. You left behind a protest against these self-same constitutional articles; you ordered the ministers to sign none of the acts issued by the national assembly; and you forbade the minister of justice to deliver up the seals of state. The public money was lavished to insure the success of this treachery, and the public force was to protect it, under the orders of Bouillé, who shortly before had been charged with the massacre of Nancy, and to whom you wrote on this head, "to take care of his popularity, because it would be of service to you." These facts are proved by the memorial of the 23d of February, with marginal comments in your own hand-writing; by your declaration of the 20th of June, wholly in your own hand-writing; by your letter of the 4th of September 1790 to Bouillé; and by a note of the latter, in which he gives you an account of the use he made of 993,000 livres, given by you, and employed partly in trepanning the troops who were to escort you.—What have you to answer?"

Louis. "I have no knowledge whatever of the memorial of the 23d of February. As to what relates to my journey to Varennes, I appeal to my declaration to the commissaries of the constituent assembly at that period."

Pres. "After your detention at Varennes, the exercise of the executive power was for a moment suspended in your hands, and you again formed a conspiracy. On the 17th of July the blood of citizens was shed in the Champ de Mars. A letter, in your own hand-writing, written in 1790 to La Fayette, proves that a criminal coalition subsisted between you and La Fayette, to which Mirabeau acceded. The revision began under these cruel auspices; all kinds of corruptions were made use of. You have paid for libels, pamphlets, and news-papers, designed to corrupt the public opinion, to discredit the assignats, and to support the cause of the emigrants. The registers of Septeuil shew what immense sums have been made use of in these liberticide manœuvres.—What have you to answer?"

Louis. "What happened on the 17th of July has nothing at all to do with me. I know nothing of it."

Pres. "You seemed to accept the constitution on the 14th of September; your speeches announced an intention of supporting it, and you were busy in overturning it, even before it was completed. A convention was entered into at Pilnitz on the 24th of July, between Leopold of Austria and Frederic-William of Brandenburgh, who pledged themselves to re-erect in France the throne of absolute monarchy, and you were silent upon this convention till the moment when it was known by all Europe.—What have you to answer?"

Louis. "I made it known as soon as it came to my knowledge; besides, every thing that refers to this subject concerns the minister."

 Pres.

France. 1792.

Pres. "Arles had hoisted the standard of rebellion; you favoured it by sending three civil commissaries, who made it their business not to repress the counter-revolutionists, but to justify their proceedings.—What have you to answer?"

Louis. "The instructions which were given to the commissaries must prove what was their mission; and I knew none of them when the ministers proposed them to me."

Pres. "Avignon, and the county of Venaissin, had been united with France; you caused the decree to be executed; but a month after that time civil war desolated that country. The commissaries you sent thither helped to ravage it.—What have you to answer?"

Louis. "I do not remember what delay has been caused in the execution of the decree; besides, this occurrence has no personal reference to me; it only concerns those that have been sent, not those who sent them."

Pres. "Nimes, Montauban, Mende, Jales, felt great shocks during the first days of freedom. You did nothing to stifle those germens of counter-revolution till the moment when Saillant's conspiracy became manifestly notorious.—What have you to answer?"

Louis. "I gave, in this respect, all the orders which were proposed to me by the ministers."

Pres. "You sent 22 battalions against the Marseillois, who marched to reduce the counter-revolutionists of Arles.—What have you to answer.?"

Louis. "I ought to have the pieces referring to this matter, to give a just answer."

Pres. "You gave the southern command to Witgenstein, who wrote to you on the 21st of April 1792, after he had been recalled: 'A few instants more, and I shall call around the throne of your majesty thousands of French, who are again become worthy of the wishes you form for their happiness.'—What have you to answer?"

Louis. "This letter is dated since his recall; he has not been employed since. I do not recollect this letter."

Pres. "You paid your late life-guards at Coblentz; the registers of Septeuil attest this; and general orders signed by you prove that you sent considerable remittances to Bouillé, Rochefort, Vauguyon, Choiseul, Beaupre, Hamilton, and the wife of Polignac.—What have you to answer?"

Louis. "When I first learned that my life-guards assembled beyond the Rhine, I stopped their pay: as to the rest, I do not remember."

Pres. "Your brothers, enemies to the state, caused the emigrants to rally under their banners: they raised regiments, took up loans, and concluded alliances in your name: you did not disclaim them; but at the moment when you were fully certain that you could no longer cross their projects, your intelligence with them by a note, written by Louis Stanislaus Xavier, signed by your two brothers, was conceived in these words:

'I wrote to you, but it was by post, and I could say nothing. We are two here, who make but one; one in sentiments, one in principles, one in zeal of serving you. We keep silence; because, were we to break it too soon, it would injure you: but we shall speak as soon as we shall be certain of general support, and that moment is near. If we are spoken to on the part of those people, we shall hear nothing; but if on your part, we shall listen: we shall pursue our road straight. It is therefore desired that you will enable us to say something. Do not stand on ceremonies. Be easy about your safety: we only exist to serve you; we are eagerly occupied with this point, and all goes on well; even our enemies feel themselves too much interested in your preservation to commit an useless crime which would terminate in their own destruction.

'L. S. Xavier and
'Charles Philippe'.

"What have you to answer?"

Louis. "I disowned all the proceedings of my brothers, according as the constitution prescribed me to do, and from the moment they came to my knowledge. Of this note I know nothing."

Pres. "The soldiers of the line, who were to be put on the war establishment, consisted but of 100,000 men at the end of December, you therefore neglected to provide for the safety of the state from abroad. Narbonne required a levy of 50,000 men, but he stopped the recruiting at 26,000, in giving assurances that all was ready; yet there was no truth in these assurances. Servan proposed after him to form a camp of 20,000 men near Paris; it was decreed by the legislative assembly; you refused your sanction.—What have you to answer?"

Louis. "I had given to the ministers all the orders for expediting the augmentation of the army: in the month of December last, the returns were laid before the assembly. If they deceived themselves, it is not my fault."

Pres. "A flight of patriotism made the citizens repair to Paris from all quarters. You issued a proclamation, tending to stop their march; at the same time our camps were without soldiers. Dumourier, the successor of Servan, declared that the nation had neither arms, ammunition, nor provisions, and that the posts were left defenceless. You waited to be urged by a request made to the minister Lajard, when the legislative assembly wished to point out the means of providing for the external safety of the state, by proposing the levy of 42 battalions. You gave commission to the commanders of the troops to disband the army, to force whole regiments to desert, and to make them pass the Rhine, to put them at the disposal of your brothers, and of Leopold of Austria, with whom you had intelligence. This fact is proved by the letter of Toulougeon, governor of Franche Comté.—What have you to answer?"

Louis. "I know nothing of this circumstance; there is not a word of truth in this charge."

Pres. "You charged your diplomatic agent, to favour this coalition of foreign powers and your brothers against France, and especially to cement the peace between Turkey and Austria, and to procure thereby a larger number of troops against France from the latter. A letter of Choiseul-Gouffier, ambassador at Constantinople, verifies the fact.—What have you to answer?"

Louis. "M. Choiseul did not speak the truth: no such thing has ever been."

Pres. "The Prussians advanced against our frontiers: your minister was summoned on the 8th of July to give an account of the state of our political relations with

with Prussia; you answered, on the 10th, that 50,000 Prussians were marching against us, and that you gave notice to the legislative body of the formal acts of the pending hostilities, in conformity to the constitution.—What have you to answer?"

Louis. "It was only at that period I had knowledge of it: all the correspondence passed with the ministers."

Pres. "You entrusted Dabancourt, the nephew of Calonne, with the department of war; and such has been the success of your conspiracy, that the posts of Longwy and Verdun were surrendered to the enemy at the moment of their appearance.—What have you to answer?"

Louis. "I did not know that Dabancourt was M. Calonne's nephew. I have not divested the posts. I would not have permitted myself such a thing. I know nothing of it, if it has been so."

Pres. "You have destroyed our navy—a vast number of officers belonging to that corps had emigrated; there scarcely remained any to do duty in the harbours; meanwhile Bertrand was granting passports every day; and when the legislative body represented to you his criminal conduct on the 8th of March, you answered, that you were satisfied with his services.—What have you to answer?"

Louis. "I have done all I could to retain the officers. As to M. Bertrand, since the legislative assembly presented no complaint against him that might have put him in a state of accusation, I did not think proper to turn him out of office.

Pres. "You have favoured the maintenance of absolute government in the colonies; your agents fomented troubles and counter-revolutions throughout them, which took place at the same epoch, when it was to have been brought about in France, which indicates plainly that your hand laid this plot.—What have you to answer?"

Louis. "If there are any of my agents in the colonies, they have not spoken the truth: I had nothing to do with what you have just mentioned."

Pres. "The interior of the state was convulsed by fanatics; you avowed yourself their protector, in manifesting your evident intention of recovering by them your ancient power.—What have you to answer?"

Louis. "I cannot answer to this; I know nothing of such a project."

Pres. "The legislative body had passed a decree on the 29th of January against the factious priests; you suspended its execution.—What have you to answer?"

Louis. "The constitution reserved to me the free right to refuse my sanction of the decrees."

Pres. "The troubles had increased; the minister declared, that he knew no means in the laws extant to arraign the guilty. The legislative body enacted a fresh decree, which you likewise suspended. What have you to say to this?"

[Louis replied in the same manner as in the preceding charge.]

Pres. "The uncitizen-like conduct of the guards whom the constitution had granted you, had rendered it necessary to disband them. The day after, you sent them a letter expressive of your satisfaction, and continued their pay. This fact is proved by the treasurer of the civil list.—What have you to answer?"

Louis. "I only continued them in pay till fresh ones could be raised, according to the tenor of the decree."

Pres. "You kept near your person the Swiss guards: the constitution forbade you this, and the legislative assembly had expressly ordained their departure.—What have you to answer?"

Louis. "I have executed all the decrees that have been enacted in this respect.

Pres. "You had private companies at Paris, charged to operate movements useful to your projects of a counter-revolution. Dangremont and Gilles were two of your agents, who had salaries from the civil list. The receipts of Gilles, who was ordered to raise a company of 60 men, shall be presented to you.—What have you to answer?"

Louis. "I have no knowledge whatever of the projects laid to their charge: the idea of a counter-revolution never entered into my mind."

Pres. "You wished to suborn, with considerable sums, several members of the legislative and constituent assemblies. Letters from St Leon and others evince the reality of these deeds.—What have you to answer?"

Louis. "Several persons presented themselves with similar decrees, but I have waved them."

Pres. "Who are they that presented you with those projects?"

Louis. "The plans were so vague that I do not recollect them now."

Pres. "Who are those to whom you gave money?"

Louis. "I gave money to nobody."

Pres. "You suffered the French name to be reviled in Germany, Italy, and Spain, since you omitted to demand satisfaction for the bad treatment which the French suffered in those countries.—What have you to answer?"

Louis. "The diplomatical correspondence will prove the contrary; besides, this was a concern of the ministers."

Pres. "You reviewed the Swiss on the 10th of August at five o'clock in the morning; and the Swiss were the first who fired upon the citizens."

Louis. "I went on that day to review all the troops that were assembled about me; the constituted authorities were with me, the department, the mayor, the municipality; I had even invited thither a deputation of the National Assembly, and I afterwards repaired into the midst of them with my family."

Pres. "Why did you draw troops to the castle?"

Louis. "All the constituted authorities saw that the castle was threatened; and as I was a constituted authority, I had a right to defend myself."

Pres. "Why did you summon the mayor of Paris on the night between the 9th and 10th of August to the castle?"

Louis. "On account of the reports that were circulated."

Pres. "You have caused the blood of the French to be shed."

Louis. "No, Sir, not I."

Pres. "You authorized Septeuil to carry on a considerable

France. 1792.

considerable trade in corn, sugar, and coffee, at Hamburg. This fact is proved by a letter of Septeuil."

Louis. "I know nothing of what you say."

Pres. "Why did you affix a *veto* on the decree which ordained the formation of a camp of 20,000 men?"

Louis. "The constitution left to me the free right of refusing my sanction of the decrees; and even from that period I had demanded the assemblage of a camp at Soissons."

President, addressing the convention. "The questions are done with." (To Louis)—"Louis, is there any thing that you wish to add?"

Louis. "I request a communication of the charges which I have heard, and of the pieces relating thereto, and the liberty of choosing counsel for my defence."

Valazé, who sat near the bar, presented and read to Louis Capet the pieces, viz. The memoir of Laporte and Mirabeau, and some other, containing plans of a counter-revolution.

Louis. "I disown them."

Valazé next presented several other papers, on which the act of accusation was founded, and asked the king if he recognized them. These papers were the following.

Valazé. "Letter of Louis Capet, dated June 29th 1790, settling his connexions with Mirabeau and La Fayette to effect a revolution in the constitution."

Louis. "I reserve to myself to answer the contents"—(Valazé read the letter.)—"It is only a plan, in which there is no question about a counter-revolution; the letter was not to have been sent."

Valazé. "Letter of Louis Capet, of the 22d of April, relative to conversations about the Jacobins, about the president of the committee of finances, and the committee of domains; it is dated by the hand of Louis Capet."

Louis. "I disown it."

Valazé. "Letter of Laporte, of Thursday morning, March 3d, marked in the margin in the hand-writing of Louis Capet with March 3d 1791, implying a pretended rupture between Mirabeau and the Jacobins."

Louis. "I disown it."

Valazé. "Letter of Laporte without date, in his hand-writing, but marked in the margin by the hand of Louis Capet, containing particulars respecting the last moments of Mirabeau, and expressing the care that had been taken to conceal from the knowledge of men some papers of great concern which had been deposited with Mirabeau."

Louis. "I disown it as well as the rest."

Valazé. "Plan of a constitution, or revision of the constitution, signed la Fayette, addressed to Louis Capet, April 6th 1790, marked in the margin with a line in his own hand-writing."

Louis. "These things have been blotted out by the constitution."

Valazé. "Do you know this writing?"

Louis. "I do not."

Valazé. "Your marginal comments?"

Louis. "I do not."

Valazé. "Letter of Laporte of the 19th of April, marked in the margin by Louis Capet April 19. 1791, mentioning a conversation with Rivarol."

Louis. "I disown it."

Valazé. "Letter of Laporte, marked April 16. 1791, in which it seems complaints are made of Mirabeau, the abbé Perigord, André, and Beaumetz, who do not seem to acknowledge sacrifices made for their sake."

Louis. "I disown it likewise."

Valazé. "Letter of Laporte of the 23d of February 1791, marked and dated in the hand-writing of Louis Capet; a memorial annexed to it, respecting the means of his gaining popularity."

Louis. "I know neither of these pieces."

Valazé. "Several pieces without signature, found in the castle of the Thuilleries, in the gap which was shut in the walls of the palace, relating to the expences to gain that popularity."

President. "Previous to an examination on this subject, I wish to ask a preliminary question: Have you caused a press with an iron door to be constructed in the castle of the Thuilleries, and had you your papers locked up in that press?"

Louis. "I have no knowledge of it whatever."

Valazé. "Here is a day-book written by Louis Capet himself, containing the pensions he has granted out of his coffer from 1776 till 1792, in which are observed some douceurs granted to Acloque."

Louis. "This I own, but it consists of charitable donations which I have made."

Valazé. "Different lists of sums paid to the Scotch companies of Noailles, Gramont, Montmorency, and Luxembourg, on the 9th of July 1791."

Louis. "This is prior to the epoch when I forbade them to be paid."

Pres. "Louis, where had you deposited those pieces which you own?"

Louis. "With my treasurer."

Valazé. "Do you know these pension-lists of the life-guards, the one hundred Swiss, and the king's guards for 1792?"

Louis. "I do not."

Valazé. "Several pieces relative to the conspiracy of the camp of Jales, the original of which are deposited among the records of the department of L'Ardêche."

Louis. "I have not the smallest knowledge of them."

Valazé. "Letter of Bouillé, dated Mentz, bearing an account of 993,000 livres received of Louis Capet."

Louis. "I disown it."

Valazé. "An order for payment of 168,000 livres, signed Louis, indorsed Le Bonneirs, with a letter and billet of the same."

Louis. "I disown it."

Valazé. "Two pieces relative to a present made to the wife of Polignac, and to Lavauguyon and Choiseul."

Louis. "I disown them as well as the others."

Valazé. "Here is a note signed by the two brothers of the late king, mentioned in the declaratory act."

Louis. "I know nothing of it."

Valazé. "Here are pieces relating to the affair of Choiseul Gouffier at Constantinople."

Louis. "I have no knowledge of them."

Valazé.

Valazé. "Here is a letter of the late king to the bishop of Clermont, with the answer of the latter, of the 16th of April 1791."

Louis. "I disown it."

President. "Do you not acknowledge your writing and your signet?"

Louis. "I do not."

President. "The seal bears the arms of France."

Louis. "Several persons made use of that seal."

Valazé. "Do you acknowledge this list of sums paid to Gilles?"

Louis. "I do not."

Valazé. "Here is a memorandum for indemnifying the civil list for the military pensions; a letter of Dufresne St Leon, which relates to it."

Louis. "I know none of those pieces."

343 is allowed to nominate his own counsel;

When the whole had been investigated in this manner, the president, addressing the king, said, "I have no other questions to propose—have you any thing more to add in your defence?"—"I desire to have a copy of the accusation (replied the king), and of the papers on which it is founded. I also desire to have a counsel of my own nomination." Barrere informed him, that his two first requests were already decreed, and that the determination respecting the other would be made known to him in due time.

It would have been an excess of cruelty to refuse a request so reasonable in itself; it was therefore decreed that counsel should be allowed to the king, and his choice fell upon M. M. Tronchet, Lamoignon, Malesherbes, and Deseze; he had previously applied to M. Target, who excused himself on account of his age and infirmity. On the 26th of December, the king appeared for the last time at the bar of the convention; and M. Deseze read a defence which the counsel had prepared, and which was equally admired for the solidity of the argument and the beauty of the composition.

When the defence was finished, the king arose, and holding a paper in his hand, pronounced in a calm manner, and with a firm voice, what follows: "Citizens, you have heard my defence; I now speak to you, perhaps for the last time, and declare that my counsel have asserted nothing to you but the truth; my conscience reproaches me with nothing. I never was afraid of having my conduct investigated; but I observed with great uneasiness, that I was accused of giving orders for shedding the blood of the people on the 10th of August. The proofs I have given through my whole life of a contrary disposition, I hoped would have saved me from such an imputation, which I now solemnly declare is entirely groundless."

but is condemned to death by a small majority.

The discussion was fatally closed on the 16th of January. After a sitting of near 34 hours, the punishment of death was awarded by a small majority of the convention, and several of these differed in opinion from the rest, respecting the time when it should be inflicted; some contending that it should not be put in execution till after the end of the war, while others proposed to take the sense of the people, by referring the sentence to the primary assemblies.

M. Deseze then solemnly invoked the assembly in the name of his colleagues, to consider by what a small majority the punishment of death was pronounced against the dethroned monarch. "Do not afflict France (added this eloquent advocate) by a judgment that will appear terrible to her, when *five* voices only were presumed sufficient to carry it." He appealed to eternal justice, and sacred humanity, to induce the convention to refer their sentence to the tribunal of the people. "You have either forgotten or destroyed (said the celebrated M. Tronchet) the lenity which the law allows to criminals, of requiring at least *two-thirds* of the voices to constitute a definitive judgment."

The sentence was ordered to be executed in twenty-four hours.

344 And executed.

The king and his family had been for some time kept separate from each other; but he was now allowed to see them, and to choose an ecclesiastic to attend him. The meeting, and, above all, the separation from his family, was tender in the extreme. On Monday the 21st January, at eight o'clock in the morning, the unfortunate monarch was summoned to his fate. He ascended the scaffold with a firm air and step. Raising his voice, he said, "Frenchmen, I die innocent; I pardon all my enemies; and may France"—at this instant the inhuman Santerre ordered the drums to beat, and the executioners to perform their office. When they offered to bind his hands, he started back as if about to resist; but recollected himself in a moment, and submitted. When the instrument of death descended, the priest exclaimed, "Son of St Louis, ascend to heaven." The bleeding head was held up, and a few of the populace shouted *Vive la Republique*. His body was interred in a grave that was filled up with quicklime, and a guard placed around till it should be consumed.

345 Character of this unfortunate monarch.

Thus fell Louis XVI. He possessed from nature a good understanding, which, however, was blunted by the early indulgences of a court. He had a strong sense of justice, and his humanity was perhaps extreme. One defect rendered his virtues of little value, which was the possession of an irresolute and unsteady character. Unambitious, and easily advised, he was without difficulty induced to change his purposes, especially by his queen, whose connexion with the house of Austria had always tended to render his counsels unpopular. Whether he was or was not connected with the foreign invaders of his country, posterity must decide; but all men of sense and moderation must be convinced that he was murdered by a band of ruffians. Indeed a sentence so infamous, and in all respects unjust, is not to be found in the records of history. The greater part of the charges brought against him were trifling. Those which seem to be of importance relate to conduct authorized by the constitution under which he acted; and that constitution declared his person inviolable. The severest punishment that he could incur by law, was not death, but deposition; and there is no doubt, that in putting him to death the French nation broke the social compact which their representatives made with him. In a political view, this tragical event was injurious to the republican cause throughout Europe. No man out of France ventured to justify it; and in all countries it excited the most violent indignation against the rulers of the new republic.

346 Rupture with Great Britain.

New enemies were now hastening to join the general league against France. We do not mean here to enter into a detail of the political struggles that occurred in any other country, than that in the narrative of whose revolution we are now engaged. It will therefore only be necessary to remark in general, that the British government at this time thought itself endangered by the propagation of those speculative opinions which had

overturned

France. 1793.

overturned the French monarchy. Almost all the men of property in the kingdom concurred with the ministry in thinking a war with France necessary for the purpose of securing the constitution at home. After the 10th of August the British minister had been recalled; but the new republic still suffered the former ambassador from France, M. Chauvelin, to remain in England.

347 Grounds of the quarrel on the part of Great Britain.

The ostensible grounds of quarrel on the part of Great Britain were chiefly two; the decree of the 15th of November 1792, by which it was truly observed that encouragement to rebellion was held out to the subjects of every state, and that war was thereby waged against every established government. Of this decree the French executive council gave explanations, denying the fairness of the interpretation put upon it, and alleging, that the intention of the convention was only to give aid to such countries as *had already* acquired their freedom, and by a declaration of the general will requested aid for its preservation. But this explanation cannot be admitted. The decree expressly says, that the French nation will *grant assistance to all who wish to procure liberty;* and when it is considered what their notions of liberty are, it cannot be doubted but that their intention was to excite rebellion in foreign nations. The second point of dispute referred to the opening of the Scheldt. This river runs from Brabant through the Dutch territory to the sea. The Dutch had shut up the mouth of it, and prevented any maritime commerce from being carried on by the people of Brabant by means of the river. To render themselves popular in Brabant, the French had declared that they would open the navigation of the Scheldt. But Great Britain had some time before bound herself by treaty with the Dutch to assist them in obstructing this navigation, and now declared to the French, that the project of opening the Scheldt must be renounced if peace with Great Britain was to remain. The French alleged, that by the law of nations navigable rivers ought to be open to all who reside on their banks; but that the point was of no importance either to France or England, and even of very little importance to Holland; that if the people of Brabant themselves chose to give it up, they would make no objection. It has been thought remarkable, that the Dutch gave themselves no trouble about the matter. They did not ask the assistance of England; and with that coolness which is peculiar to their character, the merchants individually declared, that if the Scheldt was opened, they could manage their commerce as well at Antwerp as at Amsterdam. But in all this there is nothing strange. Among the Dutch were many republicans, who wished for the downfal of the stadtholder. These rejoiced at every thing which distressed him, or had a tendency to render his office useless in the eyes of the people. Others, who thought differently, were afraid to speak their sentiments, as Dumourier was in their neighbourhood with a victorious army. The result of the whole was, that M. Chauvelin was commanded by the British government to leave this country. The

348 War declared against the king of England, and stadtholder of Holland.

French executive council gave powers to another minister, M. Maret, to negotiate, and requested a passport for him; but he was not suffered to land. The haughty republicans having thus far humbled themselves before the British government, at last, on the 1st of February 1793, on the motion of Brissot, the national convention decreed, among other articles, that "George king of England had never ceased since the revolution of the 10th of August 1792 from giving to the French nation proofs of his attachment to the concert of crowned heads; that he had drawn into the same lake the stadtholder of the United Provinces; that, contrary to the treaty of 1783, the English ministry had granted protection to the emigrants and others who have openly appeared in arms against France; that they have committed an outrage against the French republic, by ordering the ambassador of France to quit Great Britain; that the English have stopped divers boats and vessels laden with corn for France, whilst, at the same time, contrary to the treaty of 1786, they continue the exportation of it to other foreign countries; that to thwart more efficaciously the commercial transactions of the republic with England, they have by an act of parliament prohibited the circulation of assignats. The convention therefore *declare,* that in consequence of these acts of hostility and aggression, the French republic is at war with the king of England and the stadtholder of the United Provinces.

The absurdity of pretending that any treaty with France made in 1783 could be violated by protecting the emigrants who fled from the fury of the convention, must be obvious to every reader. The convention was itself a rebellious usurpation of the government with which such a treaty was made. The prohibition of assignats was certainly contrary to no law, and was sanctioned by every motive of expediency, unless the convention could prove that all nations were bound by the law of nature to risk their own credit upon the credit of the French republic.

349 And against Spain.

About a fortnight after this absurd declaration against Britain, war was likewise declared against Spain; and in the course of the summer France was at war with all Europe, excepting only Swisserland, Sweden, Denmark, and Turkey.

350 Progress of Dumourier.

In the mean time General Dumourier, who was proceeding agreeable to his orders, made an attack upon Holland; but in doing this he dispersed his troops in such a manner as to expose them much to any attack on the side of Germany. He commanded General Miranda to invest Maestricht, while he advanced to block up Breda and Bergen-op-Zoom. The first of these places, viz. Breda, surrendered on the 24th of February; Klundert was taken on the 26th; Gertruydenberg on the 4th of March. But here the triumphs of Dumourier ended. The sieges of Williamstad and Bergen-op-Zoom were vigorously but unsuccessfully pressed.

351 He is defeated.

On the 1st of March General Clairfait having passed the Roer, attacked the French posts, and compelled them to retreat with the loss of 2000 men.

The following day the archduke attacked them anew with considerable success. On the 3d the French were driven from Aix-la-Chapelle, with the loss of 4000 men killed and 1600 taken prisoners.

The siege of Maestricht was now raised, and the French retreated to Tongres, where they were also attacked, and forced to retreat to St Tron. Dumourier here joined them, but did not bring his army along with him from the attack upon Holland. After some skirmishes, a general engagement took place at Neerwinden. It was fought on the part of the French with great obstinacy; but they were at length overpowered by the number of their enemies, and perhaps also by the treachery of their commander. This defeat was fatal. The French lost 3000 men, and 6000 immediately

ance.

joins allies;

immediately deserted and went home to France. Dumourier continued to retreat, and on the 22d he was again attacked near Louvain. He now, through the medium of Colonel Mack, came to an agreement with the Imperialists that his retreat should not be seriously interrupted. It was now fully agreed between him and the Imperialists, that while the latter took possession of Condé and Valenciennes, he should march to Paris, dissolve the convention, and place the son of the late king upon the throne.

The rapid retreat and successive defeats of General Dumourier rendered his conduct suspicious. Commissioners were sent from the executive power for the purpose of discovering his designs. They dissembled, and pretended to communicate to him a scheme of a counter-revolution. He confessed his intention of dissolving the convention and the Jacobin club by force, which he said would not exist three weeks longer, and of restoring monarchy. On the report of these commissioners the convention sent Bournonville the minister of war to supersede and arrest Dumourier, along with Camus, Blancal, La Marque, and Quinette, as commissioners. The attempt on the part of these men was at least hazardous, to say no more of it; and the result was, that on the first of April Dumourier sent them prisoners to

53
bu is army fuse to with him

General Clairfait's head-quarters at Tournay as hostages for the safety of the royal family. He next attempted to seduce his army from their fidelity to the convention; but he speedily found that he had much mistaken the character of his troops. Upon the report that their general was to be carried as a criminal to Paris, they were seized with sudden indignation; but when they found that an attempt was making to prevail with them to turn their arms against their country, their

4
Proclamation of the Imperial commander in chief.

sentiments altered. On the 5th of April, two proclamations were issued; one by General Dumourier, and the other by the prince of Saxe Cobonrg, declaring that their only purpose was to restore the constitution of 1789, 1790, and 1791. Prince Cobourg announced that the allied powers wished merely to co-operate with General Dumourier in giving to France her constitutional king and the constitution she had formed for herself, declaring, on his word of honour, that he came not to the French territory for the purpose of making conquests. On the same day Dumourier went to the advanced guard of his own camp at Maulde. He there learned that the corps of artillery had risen upon their general, and were marching to Valenciennes; and he soon found that the whole army had determined to stand by their country. Seven hundred cavalry and 800 infantry was the whole amount of those that deserted with Dumourier to the Austrians, and many of them afterwards returned.

State of France at this period.

By the defection of Dumourier, however, the whole army of the north was dissolved, and in part disbanded, in presence of a numerous, well disciplined, and victorious enemy. The Prussians were at the same time advancing on the Rhine with an immense force, and about to commence the siege of Mentz. In the interior of the republic more serious evils if possible were arising. In the departments of La Vendée and La Loire, or the provinces of Brittany and Poitou, immense multitudes of emigrants and other royalists had gradually assembled in the course of the winter. They professed to act in the name of Monsieur, as regent of France. About the middle of March they advanced against Nantz to the amount of 40,000. In the beginning of April they defeated the republicans in two pitched battles, and possessed themselves of 50 leagues of country. They even threatened by their own efforts to shake the new republic to its foundation. On the 8th of April a congress of the combined powers assembled at Antwerp. It was attended by the prince of Orange and his two sons, with his excellency Vander Spiegel, on the part of Holland; by the duke of York and Lord Auckland on the part of Great Britain; by the prince of Saxe Cobourg, Counts Metternich, Starenberg, and Mercy Dargenteau, with the Prussian, Spanish, and Neapolitan envoys. It was here determined to commence active operations against France. The prince of Cobourg's proclamation was recalled, and a scheme of conquest announced.

France.
1793.

356
Congress of the combined powers.

357
The republican army again assembled.

Commissioners from the convention now set up the standard of the republic anew, and the scattered battalions flocked around it. General Dampierre was appointed commander, and on the 13th he was able to resist a general attack upon his advanced posts. On the 14th, his advanced guard yielded to superior numbers, but on the 15th was victorious in a long and well-fought battle. On the 23d, the Austrians were again repulsed, and on the 1st of May General Dampierre was himself repulsed in an attack upon the enemy. On the 8th, another engagement took place, in which the French general was killed by a cannon ball. On the 23d, a very determined attack was made by the allies upon the French fortified camp of Famars, which covered the town of Valenciennes. The French were overcome, and in the night abandoned their camp. In consequence of this the allies were enabled to commence the siege of Valenciennes; for Condé had been blockaded from the first of April.

358
Revolt of Paoli.

About the same time General Custine on the Rhine made a violent but unsuccessful attack upon the Prussians, in consequence of which they were soon enabled to lay siege to Mentz. The Corsican general Paoli revolted at this period; and the new republic, assaulted from without by the whole strength of Europe, was undermined by treachery and faction within.

359
State of parties in France, and the revolutionary tribunal established.

While the country was in a state verging upon utter ruin, parties in the convention were gradually waxing more fierce in their animosity; and regardless of what was passing at a distance, they seemed only anxious for the extermination of each other. In the month of March, the celebrated *Revolutionary Tribunal* was established for the purpose of trying crimes committed against the state; and the Girondist party, the mildness of whose administration had contributed not a little to increase the evils of their country, began to see the necessity of adopting measures of seversity. But the public calamities, which now rapidly followed each other in succession, were ascribed by their countrymen to their imbecility or perfidy. This gave to the party of the *Mountain* a fatal advantage. On the 15th of April the communes of the 48 sections of Paris presented a petition, requiring that the chiefs of the Girondists therein named should be impeached and expelled from the convention. This was followed up on the 1st of May by another petition from the suburb of St Antoine. The Girondist party in the mean time impeached Marat, but he was acquitted by the jury at his trial. The

France. 1793.

Mountain, by the assistance of the Jacobin club, had now acquired a complete ascendancy over the city of Paris. The Girondists or Brissotines proposed therefore to remove the convention from the capital; and to prevent this, the *Mountain* resolved to make the same use of the people of the capital against the Girondist party that they had formerly done against the monarch on the 10th of August. It is unnecessary to state in detail all the tumults that occurred either in Paris or in the convention during the remaining part of the month of May. On the 31st, at four o'clock in the morning, the tocsin was sounded, the generale was beat, and the alarm guns fired. All was commotion and terror. The citizens flew to arms, and assembled round the convention. Some deputations demanded a decree of accusation against 35 of its members. The day, however, was spent without decision. On the afternoon of the 1st of June an armed force made the same demand. On the 2d of June this was repeated, the tocsin again sounded, and an hundred pieces of cannon surrounded the national hall. At last Barrere mounted the tribune. He was considered as a moderate man, and respected by both parties; but now he artfully deserted the Girondists. He invited the denounced members voluntarily to resign their character of representatives. Some of them complied, and the president attempted to dissolve the sitting; but the members were now imprisoned in their own hall. Henriot, commander of the armed force, compelled them to remain; and the obnoxious deputies, amounting to upwards of 90 in number, were put under arrest, and a decree of denunciation against them signed.

360 The Mountain party get the upper hand.

It is obvious, that on this occasion the liberties of France were trodden under foot. The minority of the national representatives, by the assistance of an armed force raised in the capital, compelled the majority to submit to their measures, and took the leading members prisoners. Thus the city of Paris assumed to itself the whole powers of the French republic; and the nation was no longer governed by representatives freely chosen, but by a minority of their members, whose sentiments the city of Paris and the Jacobin club had thought fit to approve of. Human history is a mass of contradictions. The *Mountain* party came into power by preaching liberty, and by violating its fundamental principles. How far the plea of political necessity may excuse their conduct, we shall not venture to decide explicitly. Certain it is, however, that they soon commenced, both at home and abroad, a career of the most terrible energy that is to be found in the annals of nations.

361 Several cities and departments revolt in consequence.

The first result of their victory in the capital was calamitous to the republic at large. Brissot and some other deputies escaped, and endeavoured to kindle the flames of civil war. In general, however, the influence of the Jacobin club, and of its various branches, was such, that the north of France adhered to the convention as it stood; but the southern departments were speedily in a state of rebellion. The department of Lyons declared the *Mountain* party outlawed. Marseilles and Toulon followed the example of Lyons, and entered into a confederacy, which has since been known by the appellation of *Fœderalism*. The departments of La Gironde and Calvades broke out into open revolt. In short, the whole of France was in a state of violent convulsion. Still, however, the enthusiastic garrisons of Mentz and Valenciennes protected it against the immediate entrance of a foreign force, and allowed leisure for one of its internal factions to gain an ascendancy, and thereafter to protect its independence. In the mean time, the political enthusiasm of all orders of persons was such, that even the female sex did not escape its contagion. A young woman of the name of Charlotte Cordé, in the beginning of July, came from the department of Calvades to devote her life for what she thought the cause of freedom and of her country. She requested an interview with *Marat*, the most obnoxious of the Mountain party. Having obtained it, and conversed with him calmly for some time, she suddenly plunged a dagger in his breast, and walked carelessly out of the house. She was immediately seized and condemned. At the place of execution she behaved with infinite constancy, shouting *Vive la Republique*. The remains of Marat were interred with great splendour, and the convention attended his funeral. His party perhaps derived advantage from the manner of his death, as it seemed to fasten the odious charge of assassination upon their antagonists, and gave them the appearance of suffering in the cause of liberty. The truth is, that assassination was sanctioned by both parties under pretence of defending the liberties of the republic.

Marat... dered ... woman

The re... lican ... stitution ... nished ... the M... tain.

One of the first acts of the Mountain junto after their triumph was to finish the republican constitution. Previous to their fall, the Girondists had brought forward the plan of a constitution, chiefly the work of Condorcet; but it was never sanctioned by the convention, and was too intricate to be practically useful. The new constitution now framed, which was afterwards sanctioned by the nation, but was never put in practice, abolished the former mode of electing the representatives of the people through the medium of *electoral* assemblies, and appointed them to be chosen immediately by the *primary* assemblies, which were to consist of from 200 to 600 citizens, each man voting by ballot or open vote at his option. There was one deputy for every 40,000 individuals, and population was the sole basis of representation. The elections were to take place every year on the 1st of May. Electoral assemblies were, however, retained for one purpose. Every 200 citizens in the primary assemblies named one elector; and an assembly of all the electors of the department was afterwards held, which elected candidates for the *executive council*, or ministry of the republic. The legislative body chose out of all this list of candidates the members of the executive council. One half of this council was renewed by each legislature in the last month of the session. Every law, after being passed by the legislative body, was sent to the department. If in more than half of the departments the tenth of the primary assemblies of each did not object to it, it became effectual. Trial by jury was established. National conventions might be called for altering the constitution, and were to be called, if required by the tenth of the primary assemblies of each department in a majority of the departments.

The publication of this constitution procured no small degree of applause to the convention and the Mountain party. The rapidity with which it was formed (being only a fortnight) seemed to cast a just reproach upon the slowness of their antagonists, and it was regarded as a proof of their being decidedly serious

rious in the cause of republicanism. No regard, however, was paid to it by the convention, which declared itself permanent, nor indeed did it seem possible to carry it into execution.

364
...of ...dé and ...encien-...

We have mentioned that Condé was invested from the beginning of April. It did not yield till the 10th of July, when the garrison was so much reduced by famine and disease, that out of 4000 men, of which it originally consisted, only 1500 were fit for service. The eyes of all Europe were in the mean time fixed upon the siege of Valenciennes. Colonel Moncrieff had contended, that batteries ought immediately to be placed under the walls, without approaching it by regular parallels; but the imperial engineer Mr Ferraris asserted, that the work of the great Vauban must be treated with more respect; and his opinion was adopted by the council of war. The trenches were opened on the 14th of June. Few sallies were attempted by the garrison, on account of the smallness of their number. The inhabitants at first wished to surrender; but the violence of the bombardment prevented their assembling or giving much trouble on that head to General Ferrand the governor. Much of the labour of the siege consisted of mines and countermines. Some of these having been successfully sprung by the allies, the town was surrendered on the 27th of July by capitulation to the duke of York, who took possession of it in behalf of the emperor of Germany. The siege of Mentz was at the same time going on. It suffered much from famine. At last, after an unsuccessful attempt by the French army on the Rhine for its relief, it surrendered on the 22d of July.

...5
Th...llied pow...s divid...as to the...u-tur...ro-cee...gs.

At the termination of the siege of Valenciennes it would appear that the allied powers were at a loss how to proceed next. The Austrian commanders are said to have presented two plans: The first was to penetrate to Paris by the assistance of the rivers which fall into the Seine; the other was to take advantage of the consternation occasioned by the surrender of Valenciennes, and with 50,000 light troops to penetrate suddenly to Paris, while a debarkation should be made on the coast of Brittany to assist the royalists. The proposal of the British ministry was, however, adopted, which was, to divide the grand army, and to attack West Flanders, beginning with the siege of Dunkirk. This determination proved ruinous to the allies. The French found means to vanquish in detail that army, which they could not encounter when united.

...6
Unfo...u-nate...onse-quen...s of the ...ision of th... force...

It has been said that the duke of York was in secret correspondence with Omeron the governor of Dunkirk; but the latter was removed before any advantage could be taken of his treachery. On the 24th of August the duke of York attacked and drove the French outposts into the town, after an action in which the Austrian general Dalton was killed. A naval armament was expected from Great Britain to co-operate in the siege, but it did not arrive. In the mean time, a strong republican force menaced the covering army of the allies, which was commanded by General Freytag. He was soon attacked and totally routed. The siege was raised. The British lost their heavy cannon and baggage, with several thousand men; and the convention, believing that their general Houchard could have cut off the duke of York's retreat, tried and executed him for this neglect of duty.

Prince Cobourg and General Clairfait in the mean time unsuccessfully attempted to besiege Cambray and Bouchain. Quesnoy was, however, taken by General Clairfait on the 11th of September; and here finally terminated for the present campaign the success of the allies in the Netherlands.

A considerable part of the French army of the north took a strong position near Maubeuge, where they were blockaded by Prince Cobourg: but upon the 15th and 16th of October he was repeatedly attacked by the French troops under General Jourdan, who succeeded Houchard. The French had now recovered their vigour. They brought into the field a formidable train of artillery, in which were many 24 pounders. Commissioners from the convention harangued the soldiers, threatened the fearful, and applauded the brave. Crowds of women, without confusion, went through the ranks, distributing spirituous liquors in abundance, and carrying off the wounded. The attacks were repeated and terrible on both sides; but the Austrians had considerably the disadvantage, and Prince Cobourg retired during the night. The French now menaced maritime Flanders. They took Furnes and besieged Nieuport. A detachment of British troops ready to sail to the West Indies were hastily sent to Ostend, and prevented for the present the farther progress of the French.

Such was the multiplicity of the events that now occurred in France, that it is difficult to state the outlines of them with any tolerable perspicuity. We have already mentioned the extensive dissensions that occurred throughout the republic in consequence of the triumph of the Mountain party on the 31st of May. The department of Calvades was first in arms against the convention, under the command of General Felix Wimpfen; but before the end of July the insurrection was quieted, after a few slight skirmishes. But the fœderalism of the cities of Marseilles, Lyons, and Toulon, still remained. Lyons was attacked on the 8th of August by the conventional troops. Several actions followed, which were attended with great loss both on the part of the assailants and of the besieged. The city was reduced almost to ruins; but it held out during the whole month of September. The besieging general Kellerman was removed from his command, on account of his supposed inactivity; and the city surrendered on the 8th of October to General Doppet, a man who had lately been a physician. Such was the rage of party zeal at this time, that the walls and public buildings of Lyons were ordered to be destroyed, and its name changed to that of *Ville Affranchie*. Many hundreds of its citizens were dragged to the scaffold on account of their alleged treasonable resistance to the convention. The victorious party, wearied by the slow operation of the *guillotine*, at last destroyed their prisoners in multitudes, by firing grape-shot upon them. Such indeed was the unrelenting character of the Mountain at this time, not only here but through the whole republic, that they themselves pretended not to excuse it, but declared that terror was with them *the order of the day*.

367
Lyons besieged by the conventional troops, and taken.

368
Unrelenting character of the conquerors.

In the end of July General Cartaux was sent against Marseilles. In the beginning of August he gained some successes over the advanced fœderalist troops. On the 24th he took the town of Aix, and the Marseillois submitted.

369
The Marseillois obliged to submit.

France. 1793.

submitted. But the leading people of the important town and harbour of Toulon entered into a negotiation, and submitted to the British admiral Lord Hood, under condition that he should preserve as a deposit the town and shipping for Louis XVII. and under the stipulation that he should assist in restoring the constitution of 1789. The siege of Toulon was commenced by General Cartaux in the beginning of September. It continued without much vigour during that and the whole of the succeeding month. Neapolitan, Spanish, and English troops, were brought by sea to assist in its defence. In the beginning of November, General Cartaux was removed to the command of the army in Italy, and General Dugommier succeeded him. General O'Hara arrived with reinforcements from Gibraltar, and took upon him the command of the town, under a commission from his Britannic majesty. On the 30th of November, the garrison made a powerful sally to destroy some batteries that were erecting upon heights which commanded the city. The French were surprised, and the allies succeeded completely in their object; but, elated by the facility of their conquest, the allied troops rushed forward in pursuit of the flying enemy, contrary to their orders, and were unexpectedly met by a strong French force that was drawn out to protect the fugitives. General O'Hara now came from the city to endeavour to bring off his troops with regularity. He was wounded in the arm and taken prisoner. The total loss of the allies in this affair was estimated at nearly one thousand men. The French had now mustered in full force around Toulon, and prepared for the attack. It was begun on the 19th of December in the morning, and was chiefly directed against Fort Mulgrave, defended by the British. This fort was protected by an entrenched camp, 13 pieces of cannon, 36 and 24 pounders, &c. 5 mortars, and 3000 troops. Such was the ardour of assault, that it was carried in an hour, and the whole garrison was destroyed or taken. The allies now found it impossible to defend the place; and in the course of the day embarked their troops, after having set on fire the arsenal and ships. A scene of confusion here ensued, such as has not been known in the history of modern wars. Crowds of people of every rank, age, and sex, hurried on board the ships, to avoid the vengeance of their enraged countrymen. Some of the inhabitants began to fire upon their late allies; others in despair were seen plunging into the sea, making a vain effort to reach the ships; or putting an end at once to their own existence upon the shore. Thirty-one ships of the line were found by the British at Toulon; thirteen were left behind; ten were burnt; four had been previously sent to the French ports of Brest and Rochefort, with 5000 republicans who could not be trusted; and Great Britain finally obtained by this expedition only three ships of the line and five frigates.

370 Toulon conditionally submits to Lord Hood,

371 who is at length obliged to evacuate it.

On the side of Spain the war produced nothing of importance; and in the mountainous country of Piedmont it went on slowly. Nice and Chamberry were still retained by the French; but more terrible scenes were acting in other quarters. In La Vendée a most bloody war was persisted in by the royalists. In that quarter of the country the language of the rest of France is little understood. The people were superstitious, and had acquired little idea of the new opinions that had lately been propagated in the rest of the empire. They were chiefly headed by priests, and regarded their cause as a religious one. Their mode of warfare usually was, to go on in their ordinary occupations as peaceable citizens, and suddenly to assemble in immense bands, insomuch that at one time they were said to amount to 150,000 men. They besieged Nantz and the city of Orleans, and even Paris itself was not thought altogether safe from their enterprises. The war was inconceivably bloody. Neither party gave quarter; and La Vendee proved a dreadful drain to the population of France. On the 28th of June, the conventional general Biron drove the royalists from Lucon; and Nantz was relieved by General Beysser. After some success, General Westerman was surprised by them, and compelled to retreat to Parthenay. In the beginning of August the royalists were defeated by General Rossignol; but on the 10th of that month, under Charette their commander in chief, they again attacked Nantz, but suffered a repulse. It would be tedious to give a minute detail of this obscure but cruel war. The royalists were often defeated and seemingly dispersed, but as often arose in crowds around the astonished republicans. At last, however, about the middle of October, they were completely defeated, driven from La Vendee, and forced to divide into separate bodies. One of these threw itself into the island of Noirmoutier, where they were subdued; another took the road of Maine and Brittany, where they struggled for some time against their enemies, and were at last cut to pieces or dispersed.

372 Proceedings of the royalists in La Vendee.

The royalists had long expected assistance from England; and an armament under the earl of Moira was actually fitted out for that service, but it did not arrive till too late, and returned home without attempting a landing. The Mountain party always disgraced their successes by dreadful cruelties. Humanity is shocked, and history would almost cease to obtain credit, were we to state in detail the unrelenting cruelties which were exercised against the unfortunate royalists, chiefly by Carrier, a deputy from the convention, sent into this quarter with unlimited powers. Multitudes of prisoners were crowded on board vessels in the Loire, after which the vessels were sunk. No age or sex was spared; and these executions were performed with every circumstance of wanton barbarity and insult.

373 Horrid cruelty of the Mountain party.

On the side of the Rhine a great variety of events occurred during the months of August and September. Several engagements at first took place, in which the French were, upon the whole, successful. In September, however, Landau was invested by the combined powers; and it was resolved to make every possible effort to drive the French from the strong lines of Weissembourg, on the river Lauter. On the 13th of October, the Austrian general Wurmser made a grand attack upon these lines. The French say that their generals betrayed them, and suffered the lines to be taken almost without resistance. The general of the allies confessed that the lines might have held out for several days. The French retreated to Hagenau, from which they were driven on the 18th; and suffered two other defeats on the 25th and 27th. Some of the principal citizens of Strasbourg now sent a private deputation to General Wurmser, offering to surrender the town, to be preserved as a deposit to be restored to Louis

374 Progress of the allies on the Rhine.

Louis XVII. General Wurmser refused to accept of it upon these terms, insisting upon an absolute surrender to his Imperial Majesty. In consequence of the delay occasioned by disagreement, the negotiation was discovered, and the citizens of Strasbourg engaged in the plot were seized by St Just and Lebas, commissioners from the convention, and brought to the scaffold. Prodigious efforts were now made by the French to recover their ground in this quarter. General Irembert was shot at the head of the army on the 9th of November, upon a charge, probably ill-founded, of treachery in the affair of the lines of Weissembourg. On the 14th, however, Fort Louis was taken by the allies, not without suspicion of treachery in the governor. But here the success of General Wurmser might be said to terminate. On the 21st the republican army drove back the Austrians, and penetrated almost to Hagenau. An army from the Moselle now advanced to co-operate with the army of the Rhine. On the 17th the Prussians were defeated near Sarbruck. Next day their camp at Bliescastel was stormed, and the French advanced to Deux Ponts. On the 29th and 30th the French were repulsed with great loss in two violent attacks made on the duke of Brunswick near Lautern. But it now appeared that the French had come into the field with a determination to conquer whatever it might cost. Every day was a day of battle, and torrents of blood were shed on both sides. The allies had the advantage of possessing the ground, which, in that quarter, at such a late season of the year, is very strong on account of its inequalities and morasses. In military skill, the French officers and those of the allies were perhaps nearly equal; but the French army was by far the most numerous; and although not a match in point of discipline, yet it derived no small superiority from the enthusiasm with which the troops were animated. On the 8th of December, under the command of General Pichegru, the French carried the redoubts which covered Hagenau by means of the bayonet.

375 The French at length successful in this quarter.

This modern instrument of destruction, against which no defensive weapon is employed, is always most successful in the hands of the most intrepid; and it was now a dreadful engine in the hands of French enthusiasm.—The finest troops that ever Europe produced were unable to withstand the fury of the republicans, which seemed only to increase in proportion to the multitude of companions that they lost. On the 22d the allies were driven with immense slaughter from Hagenau, notwithstanding the immense works they had thrown up for their defence. The entrenchments on the heights of Reishoffen, Jaudershoffen, &c. were considered as more impregnable than those of Jemappe. They were stormed by the army of the Moselle and the Rhine, under Generals Hoche and Pichegru. On the 23d and 24th, the allies were pursued to the heights of Wrotte. On the 26th, the entrenchments there were forced by the bayonet, after a desperate conflict. On the 27th, the republican army arrived at Weissembourg in triumph. General Wurmser retreated across the Rhine, and the duke of Brunswick hastily fell back to cover Mentz. The blockade of Landau, which had lasted four months, was raised. Fort Louis was evacuated by the allies, and Kaiserslatern, Germersheim, and Spires, submitted to the French.—During this last month of the year 1793, the loss of men on both sides in this quarter was immense, and unexampled in the history of modern war. It is even said that it might amount to more than 70,000 or 80,000 men.

376 Violent efforts of the Mountain party.

Thus far we have attended to the military affairs of the republic for some time past. Very violent efforts were in the mean time made at Paris by the new administration, established under the auspices of the Jacobin club, and of the party called the *Mountain*. The new republican constitution had been presented to the people in the primary assemblies, and accepted. The business, therefore, for which the convention was called together, that of forming a constitution for France, was at an end; and it was proposed that they should dissolve themselves, and order a new legislative body to assemble, according to the rules prescribed by that constitution. This, was, no doubt, the regular mode of procedure; but the ruling party considered it as hazardous to convene a new assembly, possessing only limited powers, in the present distracted state of the country. It was indeed obvious, that France at this time stood in need of a dictatorship, or of a government possessed of more absolute authority than can be enjoyed by one that acts, or even pretends to act, upon the moderate principles of freedom. It was therefore determined that the convention should remain undissolved till the end of the war; and that a *revolutionary* government, to be conducted by its members, should be established, with uncontrouled powers. Committees of its own body were selected for the purpose of conducting every department of business. The chief of these committees was called the *committee of public safety*. It superintended all the rest, and gave to the administration of France all the secrecy and dispatch which have been accounted peculiar to a military government, together with a combination of skill and energy hitherto unknown among mankind. A correspondence was kept up with the all Jacobin clubs throughout the kingdom. Commissioners from the convention were sent into all quarters, with unlimited authority over every order of persons. Thus a government possessed of infinite vigilance, and more absolute and tyrranical than that of any single despot, was established; and the whole transactions and resources of the state were known to the rulers. On the 23d of August, Barrere, in name of the committee of public safety, procured the celebrated decree to be passed for placing the whole French nation in a *state of requisition* for the public service. "From this moment (says the decree) till that when all enemies shall have been driven from the territory of the republic, all Frenchmen shall be in permanent readiness for the service of the army. The young men shall march to the combat; the married men shall forge arms, and transport the provisions; the women shall make tents and clothes, and attend in the hospitals; the children shall make lint of old linen; the old men shall cause themselves to be carried to the public squares, to excite the courage of the warriors, to preach hatred against the enemies of the republic; the cellars shall be washed to procure saltpetre; the saddle-horses shall be given up to complete the cavalry; the unmarried citizens, from the age of 18 to 25, shall march first, and none shall send a substitute; every battalion shall have a banner, with this inscription, *The French nation risen against tyrants*." The decree also regulates the mode of organizing this mass. A decree more tyrannical

377 France decreed to be in a state of requisition.

France. 1793.

rannical than this was never made by an eastern despot; and when it was first published, foreigners were at a loss whether to regard it as a sublime effort of a powerful government, or as a wild project which could produce nothing but confusion. The effects of it, however, have been truly terrible. We have already mentioned some of them in the bloody contest which occurred upon the Rhine, and Europe was soon destined to bear witness to still more extraordinary events.

378 General Custine tried and executed.

In the end of July, General Custine was brought to trial, and executed, in consequence of a variety of accusations of infidelity to his trust and disrespect to the convention. The queen was next brought to trial before the revolutionary tribunal, on the 15th of October.

379 Murder of the queen.

The charges against her were very various; but the chief tendency of them was to prove that she had always been hostile to the revolution, and had excited all the efforts that had been made by the court against it. On the 16th of October, this beautiful woman, whom fortune once placed so high, ended her days on a scaffold, after a mock trial, in which no regard was paid either to justice or decency. She behaved with much dignity and composure, and appeared deeply impressed with a sense of religion.

380 Execution of the heads of the Girondist party,

The members of the convention who had been at the head of the Girondist party, and had either been detained in prison since the 31st of May, or seized in the departments to which they had retired, were afterwards brought to trial. On the 30th of October, 21 of them were executed, viz. Brissot, Vergniaud, Gensonné, Duprat, Lehardi, Ducos, Fonfrede, Boilcau, Gardien, Duchatel, Sillery, Fauchet, Dufriche, Duperret, La Source, Carra, Beauvais, Mainville, Antiboul, Vigée, and Lacaze. Seventy-one were still detained in confinement.

381 and of the duke of Orleans.

The duke of Orleans was afterwards condemned, on a charge of having aspired to the sovereignty from the beginning of the revolution. His execution gave satisfaction to all parties. His vote for the punishment of death upon the trial of the late king had done him little honour even in the opinion of the Mountain, and had rendered him odious to all the rest of mankind.

382 Executions become prodigiously common.

The execution of persons of all ranks, particularly of priests and nobles, became now so common, that it would be in vain to attempt to give any detail of them. Every person brought before the revolutionary tribunal was condemned as a matter of course. The Jacobins seemed insatiable in their thirst after blood, and the people at large appeared to regard their conduct with unaccountable indifference.

383 A new table of weights and measures established.

When the human mind is once roused, its activity extends to every object. At this time a new table of weights and measures was established by the convention, in which the decimal arithmetic alone is employed. The court of Spain had the liberality, notwithstanding the war, to suffer M. Mechain to proceed in his operations for measuring a degree of the meridian in that country. He carried on his series of triangles from Barcelona to Perpignan; and from this place the mensuration was continued to Paris. M. de Lambre, and his pupil M. la Francois, also measured a degree of latitude in the vicinity of the metropolis. In all, 12 degrees of the meridian were measured; of which the mean is 57027 toises, and by this the universal standard of measure is calculated. M. M. de Borda and Cassini determined the length of a pendulum that swings seconds, *in vacuo*, and in a mean temperature at Paris, to be 3 feet and 8.06 lines. M. M. Lavoisier and Hauy found that a cubic foot of distilled water at the freezing point weighs *in vacuo* 70 pounds and 60 gros French weight. We shall insert a table of the measures and weights now established.

LONG MEASURE.

Metres.		*French Toises.*
10,000,000	= a quadrant of the meridian, which is the principle on which the new measure is founded	5132430
100,000	= an hundredth part of a quadrant, or decimal degree of the meridian	51324
1000	= a *milliare*, or mile	513

.00001	= *centigravet*	0	0	0	0.18841

A piece of silver coin weighing a *centigrave*, and a *franc* of silver, according to the former standard, will be worth 40 sols $10\frac{2}{3}$ deniers. The *milliare*, or thousand *metres*, is substituted for the mile; and the *are* for the arpent in land-measure. The latter two are to each other as 49 to 25. The astronomical circles with which M. M. de Borda and Cassini made the observations, are divided according to this plan. The quadrant contains 100 degrees, and each degree 100 minutes. Hence the minute of a great circle on our globe is equal to a *milliare*, or new French mile. If, for the reduction of this measure, we estimate the Paris toise, according to the comparison made with the standard kept in the Royal Society of London, at 6.3925 English feet, the *milliare* or minute will be equal to 1093.633 yards, and the *metre* 3.270899 feet.

384 A new kalendar formed. At the same period a new kalendar was formed.—By it the year is made to begin with the autumnal equinox, and is divided into 12 months. These are called Vindemiaire, Brumaire, Frimaire, Nivose, Ventose, Pluviose, Germinal, Floreal, Prairial, Messidor, Thermidor, and Fructidor. The months consist of 30 days each, and are divided into three decades. The days of each decade are known by the names of Primidi, Duodi, Tridi, &c. to Decadi; and the day of rest is appointed for every tenth day, instead of the seventh. The day (which begins at midnight) is distributed into ten parts, and these are decimally divided and subdivided. Five supernumerary days are added every year after the 30th of Fructidor. To these is given the absurd appellation of *Sans Culotides*, a word borrowed from a term of reproach (*sans culotte*), which had often been bestowed on the republican party from the meanness of their rank and fortune; but which that party now attempted to render honourable and popular. The childish folly of this innovation has struck every person with surprise, as it can serve no good purpose whatever. It is a wonderful instance of the waywardness of the human mind, which can occupy itself one moment with deeds of savage barbarity, and the next with a matter so unimportant as the artificial division of time.

385 Decay of religion. The religion of France had been gradually losing its influence; and on the 7th of November, Gobet, bishop of Paris, along with a great multitude of other ecclesiastics, came into the hall of the convention, and solemnly resigned their functions and renounced the Christian religion. All the clergymen, whether Protestant or Catholic, that were members of the convention, followed this example, excepting only Gregoire, whom we formerly mentioned as having been one of the first priests that joined the *Tiers Etat* after the meeting of the States General. He had the courage to profess himself a Christian, although he said that the emoluments of his bishopric were at the service of the republic. With the acclamations of the convention, it was decreed that the only French deities hereafter should be Liberty, Equality, Reason, &c. and they would seem to have consecrated these as a kind of new objects of worship.—What political purpose the leaders in the convention intended to serve by this proceeding does not clearly appear; unless, perhaps, their object was to render the French manners and modes of thinking so completely new, that it should never be in their power to return to the state from which they had just emerged, or to unite in intercourse with the other nations of Europe. The populace, however, could not at once relinquish entirely the religion of their fathers. The commune of Paris ordered the churches to be shut up, but the convention found it necessary to annul this order; and Robespierre gained no small degree of popularity by supporting the liberty of religious worship on this occasion. Hebert and Fabre d'Eglantine, who led the opposite party, hastened their own fall by this ill-judged contempt of popular opinion.

For, now that the republic saw itself successful in all quarters, when the Mountain party and the Jacobins had no rival at home, and accounted themselves in no immediate danger from abroad, they began to split into factions, and the fiercest jealousies arose. The Jacobin club was the usual place in which their contests were carried on; and at this time Robespierre acted the part of a mediator between all parties. He attempted with great art to turn their attention from private animosities to public affairs. He spread a report that an invasion of Great Britain was speedily to take place. He therefore proposed that the Jacobin club should set themselves to work to discover the vulnerable parts of the British constitution and government. They did so: They made speeches, and wrote essays without number. And in this way was the most fierce and turbulent band of men that ever perhaps existed in any country occupied and amused for a very considerable time. What is no less singular, a great number of British subjects favoured the plans of these reforming Atheists, and, under the specious appellation of the *Friends of the People*, acted in concert with the French Jacobins. 386 Quarrels between the Mountain and Jacobins.

The winter passed away in tolerable quietness, and no military enterprise was undertaken either by the allies or by the French. On the 1st of February, Barrere asserted in the convention that the confederate powers were willing *provisionally* to acknowledge the French republic, to consent to a cessation of hostilities for two years, at the end of which a lasting peace should be ratified by the French people. But this proposal the convention declared itself determined to reject, as affording to the other nations of Europe the means of undermining their new government. 387 A provisional acknowledgement of the republic by the allies rejected by the convention. In the mean time, the revolutionary government was gradually becoming more vigorous. Thirty committees of the convention managed the whole business of the state, without sharing much of the direct executive government, which rested in the committee of public safety. These different committees were engaged in the utmost variety of objects. The ruling party had no competitors for power. Without confusion or opposition, therefore, the most extensive plans were rapidly carried into effect. The convention was little more than a court in which every project was solemnly registered. In the same session 30 decrees would sometimes be passed upon objects the most widely different. 388 Vigorous state of the revolutionary government. The finances were under one committee, at the head of which was Cambon.—This committee found resources for the most lavish expenditure. The assignats were received as money throughout the state; and thus a paper mill was said to have become more valuable than a mine of gold. Their credit was supported by an arbitrary law regulating the *maximum* or highest price of provisions, and by the immense mass of wealth which had come into the hands of the convention by seizing the church lands, and by confiscating 389 Management of the finances and other resources of the nation.

France. 1794. confiscating the property of royalists, emigrants, and persons condemned by the revolutionary tribunal. So unequally had property been divided under the ancient government, that by means of these confiscations about seven-tenths of the national territory was supposed to be in the hands of the public. To this was added the plunder of the churches, consisting of gold and silver saints, and utensils employed in divine worship, along with other articles of less value; among which may be mentioned the innumerable church bells, which were regarded as sufficient for the manufacture of 15,000 pieces of cannon. These resources formed a mass of property such as never was possessed by any government.

Other committees were engaged in very different objects. Highways were constructed, and canals planned and cut throughout the country. Immense manufactories of arms were everywhere established. At Paris alone 1100 muskets were daily fabricated, and 100 pieces of cannon cast every month. Public schools were assiduously instituted, and the French language taught in its purity from the Pyrenees to the Rhine. The French convention possessed immense resources, and they did not hesitate to lavish them upon their schemes. Every science and every art was called upon for aid, and the most accomplished men in every profession were employed in giving splendour to their country. The chemists, in particular, gave essential aid by the facility with which they supplied materials for the manufacture of gun-powder; and in return for their services, Lavoisier, the greatest of them, suffered death by a most iniquitous sentence. Not fewer than 200 new dramatic performances were produced in less than two years; the object of which was to attach the people to the present order of things. The vigour with which the committees of subsistence exerted themselves is particularly to be remarked. As all Europe was at war with France, and as England, Holland, and Spain, the three maritime powers, were engaged in the contest, it had been thought not impossible to reduce France to great distress by famine, especially as it was imagined that the country had not resources to supply its immense population. But the present leaders of that country acted with the policy of a besieged garrison. They seized upon the whole provisions of the country, and carried them to public granaries. They registered the cattle, and made their owners responsible for them.—They provided the armies abundantly, and, as the people were accurately numbered, they dealt out in every district, on stated occasions, what was absolutely necessary for subsistence, and no more. To all this the people submitted; and, indeed, throughout the whole of the mixed scenes of this revolution, the calm judgment of the historian is not a little perplexed. We cannot avoid admiring the patience with which the people at large endured every hardship that was represented as necessary to the common cause, and the enthusiastic energy with which they lavished their blood in defence of the independence of their country. At the same time we must regard with indignation and disgust the worthless intrigues by means of which the sanguinary factions in the convention and the capital alternately massacred each other.

390 Dissensions of the Jacobins increase.

During the winter the dissensions of the Jacobins still increased. They were divided into two clubs, of which the new one assembled at a hall which once belonged to the Cordeliers. The leaders of it were Hebert, Ronsin, Vincent, and others; but the old society retained its ascendency, and Robespierre was now decidedly its leader. This extraordinary man had gradually accumulated in his own person the confidence of the people and the direction of the government. As the committees were above the convention, which was become little more than a silent court of record, so the committee of public safety was above the other committees. Robespierre was the leader of this ruling committee. Barrere, St Just, Couthon, and others of its members, only acted a secondary part. They laboured in the business of the state, but the radical power was with Robespierre. He surrounded the members of the convention with spies. He was jealous and implacable, and set no bounds to the shedding of blood. On the 25th of March he brought to trial the following active Jacobins, who were condemned and executed on the following day: Hebert, Ronsin, Momoro, Vincent, Du Croquet, Koch, Col. Laumur, M. M. Bourgeois, Mazuel, La Boureau, Ancard, Le Clerc, Proly, Dessieux, Anacharsis Cloots, Pereira, Florent, Armand, Descombles, and Dubuisson. Not satisfied with this, on the 2d of April he brought to trial nine of those who had once been his most vigorous associates, Danton, Fabre d'Eglantine, Bazire, Chabot, Philippeaux, Camille Desmoulins, Lacroix, Delaunay d'Angers, Herault de Sechelles, who, along with Westerman, were executed on the evening of the 5th.

391 Preparations for the campaign of 1794, and plan of the allies.

Still, however, the preparations for the ensuing campaign were proceeding with unabated vigour. The committee for military affairs, at the head of which were Carnot, La Fitte, d'Anissi, and others, was busy in arranging along the frontiers the immense force which the requisition had called forth. Plans of attack and defence were made out by this committee; and when approved by the committee of public safety they were sent to the generals to be executed. On the other side, the allies were making powerful preparations for another attempt to subjugate France. The emperor himself took the field at the head of the armies in the Netherlands. The plan of the campaign is said to have been formed by the Austrian colonel Mack. West Flanders was to be protected by a strong body of men; the main army was to penetrate to Landrecies, and getting within the line of French frontier towns, it was to cut them off from the interior by covering the country from Maubeuge to the sea. The plan was *bold*. It belongs to military men to judge whether this was not its only merit. When attempting to put it into execution, the allies must have been ill informed of the immense force which the French were collecting against them. Even the town of Lisle alone, which was capable of containing a numerous army within its walls, and which was to be left in their rear, should have seemed an insurmountable objection to the plan.

392 State of the allied armies.

On the 16th of April the Austrian, British, and Dutch armies assembled on the heights above Cateau, and were reviewed by the emperor. On the following day they advanced in eight colums against the French, drove in their whole posts, and penetrated beyond Landrecies; which place the French attempted to relieve, but without success. The allied army now amounted to 187,000 men, who were disposed in the following manner; 15,000 Dutch and 15,000 Austrians, under the prince of Orange and General Latour, formed the siege

siege of Landrecies; 15,000 British, and 15,000 Austrians, commanded by the duke of York and General Otto, encamped towards Cambray. The emperor and the prince of Saxe-Cobourg, at the head of 60,000 Austrians, were advanced as far as Guise; 12,000 Hessians and Austrians under General Worms were stationed near Douay and Bouchain; Count Kaunitz with 15,000 Austrians defended the Sambre and the quarter near Maubeuge; and lastly, General Clairfait, with 40,000 Austrians and Hanoverians, protected Flanders from Tournay to the sea; 60,000 Prussians, for whom a subsidy had been paid by Great Britain, were expected in addition to these, but they never arrived.

The French now commenced their active operations. On the morning of the 26th of April they attacked the duke of York near Cateau in great force. After a severe conflict they were repulsed, and their general Chapuy was taken prisoner. At the same time they attacked the troops under his Imperial majesty, but were there also repulsed in a similar manner; losing in all 57 pieces of cannon. On the same day, however, General Pichegru advanced from Lisle, attacked and defeated General Clairfait, took 32 pieces of cannon; and, in the course of a few days, made himself master

393 Fall of Landrecies.

of Vervic, Menin, and Courtray. On the 29th of April, the garrison of Landrecies surrendered to the allies. When this event was known in the convention, it excited a considerable degree of alarm. It was, however, the last effectual piece of success enjoyed by the allies during this disastrous campaign. General Clairfait was again completely defeated by Pichegru in a general engagement; and it was found necessary to send the duke of York to his assistance. This movement was no doubt unavoidable; but the effect of it was, that it split down the allied army into a variety of portions, capable of carrying on a desultory warfare, but unfit for the vigorous objects of conquest. On the 10th of May the duke of York was attacked near Tournay by a body of the enemy, whom he repulsed; but he was unable to join Clairfait, upon whose de-

394 Success of Pichegru in West Flanders.

struction the French were chiefly bent: for at the same time that the duke of York was occupied by the attack upon himself, Pichegru fell upon Clairfait with such irresistible impetuosity, that he was compelled to retreat in confusion, and a part of his army appears to have fled to the neighbourhood of Bruges. While Pichegru was thus advancing successfully in West Flanders, General Jourdan advanced in East Flanders from Maubeuge, crossed the Sambre, and forced General Kaunitz to retreat. On the 18th, however, General Kaunitz succeeded in repulsing the enemy in his turn, and they re-crossed the Sambre with considerable loss.

The allies now found that no progress could be made in France while General Pichegru was advancing successfully and occupying West Flanders in their rear. The emperor, therefore, withdrew the greater part of his army to the neighbourhood of Tournay, and resolved to make a grand effort to cut off the communication between Courtray and Lisle, thus to prevent completely the retreat of Pichegru. On the night of the 16th, the army moved forwards in five columns for this purpose. Clairfait was at the same time directed to cross the Lys, to effect a general junction, if possible, and complete the plan. The attempt during that evening seemed to promise success; but, in the course of next day, the division under the duke of York was overpowered by numbers and defeated. The progress of the rest of the columns was stopped, and Clairfait completely defeated. In the confusion of the day, when attempting to rally the different parts of the division which he commanded, the duke of York was separated from his own troops by a party of the enemy's cavalry, and only escaped being made prisoner by the swiftness of his horse. The plan of the allies being thus frustrated, their army withdrew to the neighbourhood of Tournay.

Pichegru speedily attempted to retaliate against the allies. On the 22d of May he brought down at daybreak his whole force against them. The attack was commenced by a heavy fire of artillery, and all the advanced posts were forced. The engagement soon became general; the attacks were repeatedly renewed on both sides; the whole day was spent in a succession of obstinate battles. All that military skill could do was performed on both sides. The French and the allied soldiers fought with equal courage and equal discipline. At nine o'clock in the evening the French at last reluctantly withdrew from the attack. The day on which a vanquished enemy flies from the field is not always that on which the victory is won. In this engagement the French were unsuccessful in their immediate object; but the weight of their fire, their steady discipline, and their violent obstinacy of attack, raised their military character high in the estimation of the officers and soldiers of the allied army. It was soon perceived, that in addition to these they possessed other advantages. Their numbers were immense; they implicitly obeyed their generals; who, being men newly raised from the rank of subalterns, as implicitly submitted to the directions of the committee of public safety. A combination of efforts was thus produced, whose operation was not retarded by divided counsels. On the other side the numbers of the allies were daily declining; their leaders were independent princes or powerful men, whose sentiments and interests were often very hostile to each other, and their exertions were consequently disunited.

On the 24th the French again crossed the Sambre, but were driven back with much loss. On the 27th an attempt was made to besiege Charleroi, but the prince of Orange on the 3d of June compelled them to raise the siege. On the 12th a similar attempt was

made, and they were again repulsed. In West Flan- 395 He lays siege to Ypres, and

ders, however, Pichegru was sufficiently strong to commence the siege of Ypres. He was soon attacked by General Clairfait for the purpose of relieving it, but without success. Ypres was garrisoned by 7000 men; reinforcements were therefore daily sent from the grand army to Clairfait for the purpose of relieving it. It is unnecessary to mention the bloody contests in which that unfortunate general was daily engaged with the French. It is sufficient to say, that they were uniformly unsuccessful, and were the means of wasting,

in a great degree, the armies of the allies. Ypres held 396 takes it.

out till the 17th of June, when it capitulated: and such was the discipline of the French army at this time, that no notice could be obtained, for several days, of that event. But in consequence of this and of other events, the duke of York found it necessary to retreat to Oudenarde; for Jourdan, after storming the Austrian camp of

France. 1794.

of Betignies, now advanced with such strength upon Charleroi in the east that its immediate fall was feared. As this would have enabled the two French armies to encircle the whole of Flanders, the prince of Cobourg advanced to its relief. Charleroi surrendered at discretion on the 25th. This circumstance was not known by the prince of Cobourg when he advanced on the 26th to attack in their entrenchments the army that covered the siege near Fleurus: but the covering army being by this time reinforced by the accession of the besieging army, the allies were repulsed. Jourdan then drew his men out of their entrenchments; and, in his turn, attacked the Austrians. He was three times repulsed, but was at last successful: the loss of the vanquished army is said to have been prodigious; but no regular accounts of it have been published. The French unquestionably exaggerated their own success, when they said that it amounted to 15,000 men.

397 Charleroi surrendered, and the Austrians defeated.

398 Further successes of the French in Flanders.

The allies now retreated in all quarters. Nieuport, Ostend, and Bruges, were taken; and Tournay, Mons, Oudenarde, and Brussels, opened their gates. At this last place, the French armies of East and West Flanders united. Landrecies, Valenciennes, Conde, and Quesnoi, were fruitlessly left with garrisons in them. The allied troops, evacuating Namur, formed a line from Antwerp to Liege to protect the country behind. The French advanced in full force, and attacked General Clairfait, cut to pieces half the troops that now remained under him, and broke the line. The allies retreated before them. The duke of York was joined by some troops under the earl of Moira that with much difficulty had made their way to him from Ostend; and with these and the Dutch troops he retired to the neighbourhood of Bergen-op-zoom and Breda for the protection of Holland. The prince of Cobourg evacuated Liege, crossed the Maese, and placed a garrison in Maestricht. He soon, however, sent back a part of his troops to the neighbourhood of Tongres; for here, to the astonishment of all Europe, the French armies made a voluntary pause in their career of victory, and ceased to pursue their retiring foes. Sluys in Dutch Flanders was the only foreign post that they continued to attack, and it surrendered after a siege of 21 days.

399 And on the Rhine.

On the Rhine the war was equally successful on the part of the French. On the 12th, 13th, and 14th of July, repeated battles were fought; in which the French enjoyed their usual success. They had numerous armies in every quarter. Their mode of fighting was to make full preparation for accomplishing their object, and to fight in great bodies day after day till it was obtained. The Palatinate was then overrun, and Treves taken, by General Michaud. Flanders and the Palatinate have always been accounted the granaries of Germany; and both of them, at the commencement of the harvest, now fell into the hands of the French.

400 Corsica subdued by Great Britain.

During the course of this summer Corsica was subdued by Great Britain; and the whole of the French West India islands, excepting a part of Gaudaloupe, yielded to the British troops under the command of Sir Charles Grey and Sir John Jarvis. On the 1st of June the British fleet, under the command of Earl Howe, gained a most splendid victory over the French fleet to the westward of Ushant. The French committee of safety were known to have purchased in America immense quantities of grain and other stores. These were embarked on board 160 sail of merchantmen, convoyed by six sail of the line. Lord Howe sailed to intercept this valuable convoy. The French fleet sailed at the same time to protect it. On the morning of the 28th of May the fleets came in sight of each other. The British admiral had previously dispatched six ships of the line under Admiral Montague to intercept the French convoy, while he should engage and detain the grand fleet. The French dispatched eight sail to defeat this attempt. In the course of the 29th Lord Howe got to windward of the French fleet. His force was 25, and theirs was 26, sail of the line. The following day he bore down upon them, and broke their line. The engagement was one of the severest ever fought. The French admiral, in less than an hour after the close action commenced in the centre, crowded off with 12 of his ships. The British fleet was so much disabled, or separated, that several of the French dismantled ships got away under sails raised on the stump of their foremasts. Seven sail of the line, however, remained in possession of the British, and two were unquestionably sunk. In the mean time, Admiral Montague fell in with the French convoy, but it was now guarded by 14 sail of the line. As he could not encounter such a force, he returned home, and it was safely conveyed into port. Thus, by one of those contradictions which so often occur in human affairs, the British fleet was victorious, and the French were left in some measure masters of the sea. As this engagement however testified that the British seamen had not lost their ancient superiority on their own element, the nation regarded the present victory as a pledge of its independence, and very general rejoicings took place in consequence of it.

France. 1794.

401 Splendid victory of the British fleet under Lord Howe.

402 The hor[rid] executio[ns] at Paris continue.

In the mean time, the revolutionary system of government in the hands of committees of the convention at Paris, and of committees of the popular societies throughout the country, was arrived at its highest perfection, and proceeded without opposition in its severe and sanguinary measures.

On the 10th of May Madame Elizabeth, sister of the late king, was sacrificed by it, in consequence of a decree of the revolutionary tribunal. Multitudes of others of every rank and sex were daily sacrificed in a similar manner; the rich in particular were the great objects of persecution, because the confiscation of their property added to the strength of the ruling powers. But neither were the poor safe from the bloody vigilance of this new and singular government. By the different executions Robespierre had contrived to destroy every avowed rival. All the constituted authorities consisted wholly of persons nominated with his approbation; and as the committees which conducted the business of the state were at his disposal, his will was irresistible throughout the republic. He met with no opposition in the convention; for that body was no longer the turbulent popular assembly which it had once appeared; it was little more than a name employed to give some sort of respectability to such schemes as were proposed to it.

403 Immense power of Robespierre.

404 Verging to ruin.

Amidst this accumulation, however, of seemingly irresistible authority, Robespierre was at the brink of ruin. The whole of the old Girondist party was indeed subdued and silent; but many members of the convention still remained attached to it. The party of the Mountain, France. 1794. Mountain, by means of whom Robespierre had risen to power, with little satisfaction now found themselves not only disregarded, but ready at every instant to fall a sacrifice to that system of terror which they had contributed to erect. Even the Jacobins themselves, though neither timid nor cautious in the shedding of blood, began to murmur when they saw that awful privilege confined exclusively within a few hands, or rather monopolized by an individual. In this state things remained for some time; and it appeared how possible it is for an individual to govern a great nation, even while the whole of that nation is hostile to his power. The banishment or imprisonment of all foreigners, which had long been rigorously practised, prevents us from possessing much accurate information concerning the internal state of France at this period; but it is certain that one circumstance in particular tended much to accelerate the fall of Robespierre. He had procured a decree to be passed, authorizing the committee of public safety to imprison at its pleasure, and bring to trial, any member of the convention. All the individuals of that body found themselves placed by this decree in the hands of a man whose severe and suspicious temper they well knew. Still, however, they were so much surrounded by spies, that it was difficult to form a party or plan of operations; even the majority of the committee of public safety were among the number of the discontented, but they

405
Particulars of his fall.

dared not to withstand their chief. At last, on the 25th of July, the convention began to give signs of agitation. It was understood, that in the course of a few days Robespierre would sacrifice a number of the members to his suspicions. On the following day the sitting of the convention was still more tempestuous. In a long speech Robespierre defended his own conduct against those who had reproached him with aspiring to the dictatorship of France. He attacked the party whom he styled *Moderates*, as wishing to overturn the revolutionary government, and to restore the feeble system of the Brissotines. The result of a long debate was, that Robespierre was apparently victorious, and his speech was ordered to be printed. On the 27th the convention appeared ripe for a change: St Just, a member of the committee of public safety, in attempting to defend Robespierre, was repeatedly interrupted; and Billaud Varennes stood forward, and enumerated the crimes, and proclaimed the tyranny, of Robespierre. The speech was received with bursts of applause. Robespierre in vain attempted to defend himself; he was silenced by shouts of execration from every part of the hall. Tallien seconded the former speaker in his accusation. The sitting was declared permanent, and a decree of arrest was passed against Robespierre and a younger brother of his, along with St Just, Couthon, and Lebas. These men left the convention, and found security in the hall of the commune of Paris; where the municipal officers agreed to protect and stand by them. The tocsin was sounded; the armed force was under their command; an insurrection was therefore attempted against the convention: but the sections of Paris refused their support. Very few of the troops could be collected, and these were not firm; the late tyranny had become odious. The hall of the commune was therefore speedily surrounded; and about three o'clock in the morning of the 28th Robespierre and his associates were made prisoners. They had been outlawed by the convention on account of their resistance. They were not therefore tried, unless for the purpose of identifying their persons; and, in the course of that day, they were executed; 60 of the municipal officers were also executed for joining in the rebellion; and in this way a storm passed over, which at one time threatened to involve the French capital in ruin, and filled all Europe with astonishment. Thus also terminated the career of the most extraordinary man that the French revolution had brought forward. His talents were undoubtedly considerable, and his ambition knew no bounds, bidding defiance to the ordinary feelings of humanity. Had Dumourier possessed his coolness and caution, or had he possessed the military talents of Dumourier, the convention would certainly have been overturned, and we should have seen a second Cromwell on the throne of his murdered sovereign.

406
The system of terror gives place to that of moderatism.

After the fall of Robespierre, the convention exhibited no small change of appearance. Instead of that silence which formerly prevailed, all was bustle and noise; all accused each other. There was no longer any leader, and there was no formed party. The former system of terror was declared to be at an end, and a new system of *moderatism* succeeded. This was carried to as great a height as the system of terror had formerly been; and all means were taken to render popular the fall of their late tyrant. The committees were organized anew, and their members ordered to be frequently changed. The correspondence between the affiliated Jacobin clubs was prohibited, and at last the Jacobin club itself was abolished. This last event was accomplished with ease; and that society which had been the great engine of the revolution, was itself without resistance overturned. Seventy-one deputies of the Girondist party, who had been imprisoned since the 31st of May 1793, were set at liberty. The name of Lyons was restored to it. Some of the agents of Robespierre were punished, particularly the infamous Carrier, whose cruelties in La Vendée we formerly mentioned. Still, however, the convention appeared so little united and so little decided with regard to objects of the first importance, that in all probability they would not have conducted the important struggle against the nations of Europe with more success than the Girondist party had formerly done, if the revolutionary government and the late system of terror had not already accumulated in their hands such vast resources, and traced out such a plan of procedure, as rendered it an easy matter to preserve their numerous armies in the train of success to which they were now habituated.

407
The French towns strongly garrisoned by the allies surrender without resistance.

The allies in their retreat had left strong garrisons in the French towns which had surrendered to them. These were Condé, Valenciennes, Quesnoi, and Landrecies. They now surrendered to the republican armies with so little resistance, that the conduct of the emperor began to be considered as ambiguous, and he was suspected of having entered into some kind of compromise with the French. This idea proved erroneous; and as soon as the army which had besieged these towns was able to join the grand army under Pichegru and Jourdan, the operations of the campaign were resumed after a suspension of almost two months. The French army divided itself into two bodies. One of these under Jourdan advanced against General Clairfait, who had succeeded the prince of Cobourg in the command in

France 1794.

408 Further successes of the French.

in the neighbourhood of Maestricht. On the 15th of September the French attacked the whole Austrian posts in an extent of five leagues from Liege to Maestricht. On that and the following day the losses were nearly equal. On the 17th the French with 50 pieces of cannon attacked General Kray in his entrenched camp before Maestricht. M. de Kray was already retiring when General Clairfait arrived with a strong reinforcement, and after a severe combat the French were once more compelled to retire. On the 18th the French renewed the attack with tenfold fury upon every part of the Austrian line, and the whole was compelled to fly to the neighbourhood of Aix-la-Chapelle. General Clairfait now chose a strong position on the banks of the Roer, where he even declared it to be his wish that he might be attacked. But by this time the spirit of his army was humbled, desertions became numerous, and the want of discipline was extreme. On the first of October the French crossed the Maese and the Roer, and attacked the whole Austrian posts from Ruremond down to Juliers. After a bloody engagement, the brave and active, though unfortnnate, General Clairfait was compelled hastily to cross the Rhine, with the loss of 10 or 12,000 men. The French general did not attempt to cross that river, but one detachment of his army took possession of Coblentz, while others laid close siege to Venlo and Maestricht, which soon surrendered.

409 And their progress in the conquest of Holland.

The division of the French army, in the mean time, under General Pichegru, came down upon Holland, and attacked the allied army under the duke of York between Bois-le-duc and Grave. They forced the advanced post of Boxtel. Lieutenant-general Abercromby was sent to attempt to recover this post on the 15th of September, but he found the French in such force that he was obliged to retreat. Indeed the French were discovered to be no less than 80,000 strong in that neighbourhood. The duke of York was unable to contend against a force so superior, and retired across the Maese with the loss of somewhat less than 1500 men. Pichegru immediately laid siege to Bois-le-duc. On the 30th of September, Crevecœur was taken, and Bois-le-duc surrendered in 10 days thereafter. In it 408 French emigrants were taken prisoners; and these, as well as 760 that had been taken at Nieuport, 500 at Sluys, and 1100 at Valenciennes, were all put to death, agreeable to the rigorous law formerly made by the convention. The French now followed the duke of York across the Maese. Upon this the greater part of the allied army under his royal highness crossed the Rhine and took post at Arnheim. The remaining part of the army followed soon after, and Nimeguen was occupied by the French on the 6th of November. The duke of Brunswick was at this time requested to take the command of the allied army, to protect Holland, if possible. He came to Arnheim for that purpose; but after examining the state of things there, he declined the undertaking. The allied troops had now so often fled before their victorious and almost innumerable enemies, they had so often been in want of every necessary, and had been received so ill by the inhabitants of the countries through which they passed, among whom the French cause was extremely popular, that they had lost that regularity of conduct and discipline which alone can afford a secure prospect of success in military affairs.

410 Conduct, discipline, and state of the French armies.

The French, on the contrary, well received, abounding in every thing, and proud of fighting in a popular cause, now acted with much order, and submitted to the strictest discipline. In addition to all these advantages, the French leaders had the dexterity to persuade the world that new and unknown arts were employed to give aid to their cause. At this period the *telegraph* was first used for conveying intelligence from the frontiers to the capital, and from the capital to the frontiers. (See Telegraph). Balloons were also used by the French during this campaign to procure knowledge of the position of the enemy. An engineer ascended with the balloon, which was suffered to rise to a great height, but prevented from flying away by a long cord. He made plans of the enemy's encampment; and during an attack he sent down notice of every hostile movement. In the affairs of men, and more especially in military transactions, opinion is of more importance than reality. The French soldiers confided in their own officers as men possessed of a kind of omniscience, while the allied troops, no doubt, beheld with anxiety a new contrivance employed against them, whose importance wonld be readily magnified by credulity and ignorance. With all these advantages, however, after the capture of Nimeguen, they once more made a halt in their career, and abstained from the attack of Holland, which now seemed almost prostrate before them.

411 Their successes in Spain.

While these events occurred in the north, the French arms were scarcely less successful on the side of Spain. In the Western Pyrenees, Fon-Bellegarde was taken; in the Western Pyrenees, Fontarabia surrendered, and also St Sebastian; the whole kingdom of Spain seemed panic struck. That feeble government, with an almost impregnable frontier, and the most powerful fortresses, could make little resistance; and the difficult natnre of their country was their only protection. The history of this war is only a history of victories on the part of the French. In the Eastern Pyrenees, on the 17th November, the French general Dugommier was killed in an engagement, in which his army was successful. On the 20th of that month the French again attacked the Spaniards, and routed them by means of the bayonet, without firing a single musket-shot. Tents, baggage, and cannon, for an army of 50,000 men, fell into the hands of the conquerors, along with a great part of the province of Navarre. Towards the end of the year, an army of 40,000 Spaniards, entrenched behind 80 redoubts, the labour of six months, suffered themselves to be completely routed; their general Count de la Union was found dead on the field of battle, and the whole Spanish artillery was taken. In three days thereafter, the fort Fernando de Figuieres, containing a garrison of 9107 men, surrendered, although it mounted 171 pieces of cannon, and possessed abundance of provisions. The French continued their conquests; Rosas was taken, and the whole province of Catalonia was left at the mercy of the invaders.

412 The conquest of Holland completed.

The successes of this wonderful campaign were not yet terminated; and the last part of them is perhaps the most important, although no great effort was necessary to its execution. The winter now set in with uncommon severity. For some years past the seasons of Europe had been uncommonly mild; there had been little frost in winter, and no intense heat in summer. But during the late season the weather had long been remarkably ance. 95.

markably dry till the latter part of harvest, when there fell a considerable, though by no means unusual, quantity of rain. Towards the end of December a severe frost bound up the whole of the rivers and lakes of Holland. The Waal was frozen over in the beginning of January; a circumstance which had not occurred for 14 years past. Taking advantage of this, the French crossed that river, and with little opposition seized the important pass of Bommell, which at other seasons is so strong by its inundations. The allied army had been joined by 17,000 Austrians, and had received orders to defend Holland to the last. They did so, and were successful in repulsing the French for some days between the Waal and the Leck; but the republican army, amounting to 70,000 men, having at last advanced in full force, the allied troops were compelled to retire across the Yssel into Westphalia. In the course of their march through this desert country, in the midst of severe frost and a deep snow, they are said to have suffered incredible hardships, and to have lost a very great number of men. The French, in the mean time, advanced rapidly across the country to the Zuyder sea, to prevent the inhabitants from flying, and carrying off their property. On the 16th of January 1795, a party of horse, without resistance, took possession of Amsterdam. The other towns surrendered at discretion. In consequence of an order from the states general, the strong fortresses of Bergen-op-zoom, Williamstadt, Breda, &c. opened their gates to the French. The fleet and the shipping were fixed by the intense frost in their stations, and fell a prey to the enemy; who thus, with a little effort, made a complete conquest of this populous and once powerful country. The French were well received by the people at large. The power of the stadtholder had been supported among them merely by the influence of Prussia and England. Through hatred to this office, which had now become odious chiefly to the mercantile aristocracy of Holland, they were little attached to their allies, and gave them, during the present war, as little support as possible. The stadtholder and his family now fled to England. The French declared, that they did not mean to make subjects but allies of the Dutch, and invited them to call together popular assemblies for settling their own government, under the protection of the French republic.

Thus terminated a campaign, the most astonishing, perhaps, that has been known in the history of mankind. In the course of it, even before the conquest of Holland, the French had taken 2000 pieces of cannon and 60,000 prisoners. After that event, the conquered territories added to them a population of nearly 14 millions of people. Luxembourg and Mentz were the only places on this side of the Rhine that resisted them. The former was closely blockaded, for the purpose of compelling it to surrender; the latter was several times assaulted, but successfully held out.

3 The et of Rati n esolution eace

At this period Europe seemed to be weary of such a bloody contest, and the Diet of Ratisbon intimated its resolution to adopt such measures as might tend to bring about a general pacification. A treaty was concluded between the grand duke of Tuscany and France. The convention declared their readiness to treat for peace with any of the powers of Europe upon honourable terms. Great Britain and Austria, however, seemed to be persuaded, that an honourable and permanent peace could not be obtained with France, while her government was subject to such perpetual changes. For instance, such was the enmity of the Mountain party against the Gironde, that any treaty entered into by the latter would have been trampled upon by the former: and such, it was observed, might continue to be the aspect of affairs in that distracted country for an indefinite length of time.

France. 1795.

414 A new constitution.

As the constitution which had been framed in the year 1793, during the tyrannical dominion of Robespierre, was justly deemed impracticable, a committee was appointed to frame one entirely new. It was composed of Sieyes, Cambaceres, Merlin of Douay, Thibaudau, Mathieu, Le Sage of Eure and Loire, and Latouche. On the report of Cambaceres, the 19th of April, that the committee thought that a commission should be appointed for this important business, a number of qualified persons were accordingly chosen, while all citizens were invited to communicate their sentiments upon the subject, and the committee was to give orders for the best plans to be published. The feelings of the nation at large received additional gratification from the conduct of the convention towards Fonquier Tainville the president, and 15 judges and jurors, of the revolutionary tribunal. They were fully convicted on the 8th of May, and executed on the 9th, launched into eternity amidst the just execrations of a vast multitude of spectators.

415 Insurrection of the Jacobins.

Although the Jacobins were defeated on the 1st and 2d of April, they did not consider themselves as entirely subdued. They were plotting a more extensive insurrection, which was not to be confined to the capital, and fixed on the 20th of May as the period of revolt. On the morning of that day, the tocsin was accordingly sounded, and drums beat to arms in the suburb of St Antoine, in which the Jacobins had always enjoyed the greatest influence. Upon this the convention met; and although the insurrection was far from being a secret, the committee of public safety did not appear to have taken any measures to prevent it. It was only at the moment when the insurgents were approaching that General Hoche was appointed to the command of the armed force, and sent to collect the military and citizens for the protection of the convention. The hall was presently surrounded, the guards were overpowered, and the mob forced their way into the midst of the assembly. The multitudes of women who met upon this occasion shouted for bread, and the constitution of 1793. Vernier the president, a man far advanced in years, quitted the chair to Boissy d'Anglas, who kept it with commendable fortitude during the remainder of the day. The mob had cockades with this inscription upon them, "Bread, and the constitution of 1793." One of the party attached to the convention imprudently tore off the hat of one of the insurgents whom the multitude attacked with swords; and as he fled towards the chair of the president, he was killed by a musket shot. The majority of the members gradually retired from this scene of lawless intrusion, and left the multitude masters of the hall. Four of the members who remained espoused the cause of the insurgents, whose triumph, however, was of very short continuance. A large body of the military and the peaceable citizens vanquished them in the evening, the powers of the majority were restored, and the four deputies

France. 1795. puties who espoused the cause of the mob were arrested.

416 Mean compliance of the convention. It would appear that the convention and the citizens of Paris now believed their triumph to be complete, as no measures were adopted by them sufficient to prevent the repetition of a similar outrage. The Jacobins, however, were not yet determined to view their cause as desperate, for next day they collected in the suburbs, and in the afternoon made a second attempt. The Carousal was taken by them without opposition, when they pointed some pieces of cannon against the hall of the convention, the members of which being wholly unprotected, endeavoured to gain over the mob by flattery,—by promising them bread, and the constitution of 1793, or whatever else they thought proper to demand; and the president even gave the deputation the fraternal embrace. On the 23d, the citizens assembled, and went to the Thuilleries to defend the convention from insult and violence. The military collected in considerable force; and the convention was at length encouraged to act on the offensive. It was decreed that if the suburb of St Antoine did not immediately surrender its arms and cannon, with the murderer of Ferrand, it would be declared in a state of rebellion. The generals of the convention received orders to reduce it by force; and the insurgents finding themselves unequal to the conflict, were forced by the inhabitants to make an unconditional surrender, to preserve their property from the depredations of the military. The soldiers found among the prisoners were put to death, on which occasion six of the members were tried and condemned by a military commission. Three of them were guilty of suicide, and the other three were publicly executed.

417 Defeat of the Jacobins. In the southern parts of France, the Jacobins were equally turbulent as their brethren in Paris, and formed an insurrection at Toulon on the 20th of May, seizing on the gates, upon which they planted cannon; they set at liberty such of their associates as had been incarcerated, and detained the fleet which was about to put to sea. From Toulon they proceeded to Marseilles, at which time they were 3000 strong, and had 12 pieces of cannon. On their march they were opposed by Generals Charton and Pactod, by whom they were defeated, 300 of them being sent prisoners to Marseilles, and Toulon was liberated.

418 Hope to be successful. The Mountain party, who were anxious to revive the terrific reign and measures of Robespierre, were now very much reduced, and exposed in many places to violent persecution. Associations were formed for the purpose of avenging the crimes they committed during the continuance of their power. When we reflect on the character of Robespierre's government and what all ranks of men suffered under it, we must consider it truly astonishing that any number of men should hazard their lives in attempting its restoration. The party was of course gradually abandoned by its adherents on the fall of its tyrant, and it sunk in the estimation of every one who examined it with attention. Still, however, a small party remained, the members of which were men of superior activity and enterprise. They consisted of ferocious republicans, who thought they beheld the revival of royalty and aristocracy in every attempt to establish a mild, sober, and regular government Yet, amidst the universal odium cast upon them, the Jacobins expected to rise once more into power; but what is most singular, the revival of their strength is to be dated from their unsuccessful insurrection just now mentioned. Their want of popularity began to affect the convention, as the people remembered how tamely that body submitted to the tyranny of Robespierre, of whose power the majority of the members had been the servile instruments. The press, therefore, being now free, the most hideous picture of their conduct was held up to the public. The greater part of them now began to repent of their victory over the Jacobins, as they foresaw that the consequences in the end might prove fatal to themselves.

On the 23d of June, Boissy d'Anglas presented the report of the committee relative to the plan of a new constitution. It was, like its predecessors, prefaced with a declaration of the rights of man, consisting besides of 14 chapters on the following subjects:—the extent of the republican territories, the political state of citizens, primary assemblies, electoral assemblies, the legislature, the judicial authority, the public force, public instruction, the finances, foreign treaties, the mode of revising the constitution, and an act that no rank or superiority should exist among citizens, but what might arise from the exercise of public functions. 419 New constitution.

The legislature was composed of two assemblies, the council of the Ancients, consisting of 250 members, as none but married men and widowers turned of 40 could be chosen members of it; the other council consisted of 500 members, and enjoyed the exclusive privilege of proposing the laws, while the council of Ancients might reject or oppose, without having power to alter the decrees. The executive power was intrusted to five persons who were to be 40 years of age at least, and to be denominated the *Executive Directory*. The two councils had the power of electing its members, the council of five hundred proposing 10 times as many candidates as could be chosen, and the council of two hundred and fifty selected the five members from among these 50 candidates. One member of the directory was to go annually out of office, by which they were all changed in the course of five years. In enacting laws the directory had no vote, being appointed purely to superintend the execution of them, regulated the coining of money, and had the disposal of the armed force. The treaties made by the directory with foreign courts were not binding without the sanction of the legislature, and war could not be made without a decree of the two assemblies. The whole articles of the new constitution underwent a separate discussion, when they were to be transmitted to the primary assemblies for their approbation. Prior to this event, however, it was agreed on by a majority of the convention, in order to avert the danger which now threatened themselves, from the loss of public favour, that at the approaching general election, the electors should be bound to return two-thirds of the present members, and if this failed, that the convention themselves might fill up the vacancies. These decrees accompanied the constitution; but at Paris the idea of re-electing two-thirds of the old members was rejected with contempt, and the absurdity of it pointed out with every expression of acrimony. 420 made up of two assemblies.

The convention, in the mean time, did not fail to publish the approbation of the decrees by the primary assemblies, as well as of the constitution, although it is certain 421 Freedom abridged by the convention.

certain that vast numbers had confounded the two together, and given their approbation accordingly. Such was the rage of many against the convention in consequence of the decrees already mentioned, that it was even proposed to try the whole members before a new revolutionary tribunal, and punish each in proportion to his crimes. The sections remonstrated against the decrees to the convention, and the more eager they appeared in the business, the more persuaded was the convention of its own imminent danger. Every remonstrance, however, was disregarded, and the contending parties formed the resolution of settling it by force of arms. About 100 electors of Paris met in the hall of the theatre in the suburb of St Germain before the day of meeting which had been appointed by the convention, and having chosen De Nivernois for their president, began their debates, absurdly concluding that the sovereignty was vested in the hands of the electors, after these had been chosen by the primary sections. A body of troops was sent to dissolve them as an illegal assembly, which was accomplished without any difficulty, the citizens not having been unanimous in their sentiments respecting it.

22 Ja bins co ed by the nven- tio

This, however, did not prevent the sections from presuming that by steady perseverance they would be finally victorious, having always found that the party favoured by the co-operation of the Parisian populace, had carried their point ever since the commencement of the revolution. The armed force with which the convention was surrounded gave the people very little alarm, as they endeavoured to persuade themselves that the military could never be brought to act against the citizens. As the members of the convention also appeared to suspect their fidelity, they applied for assistance to those very Jacobins whom they had humbled on the 24th of May. If the sections of Paris detested the members for their connexion with the atrocities of Robespierre, the Jacobins admired them from this very circumstance; a set of restless, bloody men, who were never satisfied with wars abroad nor revolutions at home. Hundreds of them were released from prison, and put in a state of requisition for assisting the legislative body.

3 Stru le betw n the nven- tion d Par ans.

The sections of Paris having beheld the convention surrounded by men who had justly obtained the appellations of *terrorists* and *men of blood*, they exhibited a desire of engaging them which was altogether unbounded. Their leader designed to make the members prisoners, till they could be conveniently brought to trial, and in the interim conduct public affairs by committees of the sections, till a new legislative body could be chosen. General Miranda was to have the command of the armed force after the overthrow of the convention, but as it was still problematical which party would be triumphant, he retired to the country till the event should declare it, resolving to have the reward of a conquest to which he was to contribute nothing. The superior officers of the convention were unfaithful, yet the subalterns and soldiers might have continued firm, to which they would, no doubt, be strongly exhorted by their Jacobin auxiliaries. What was greatly in favour of the convention was, that the first moments of enthusiasm were permitted to pass away, after which the sections exhibited a conduct both undecided and weak.

424 Barras appointed to the chief command of the national troops.

Barras was appointed on the 4th of October by the convention to the command of the troops, Generals Menon, Raffet and some others, having been dismissed from office. Barras called in the aid of the most able officers, among whom we find Brune and Bonaparte, and made speedy preparations for a vigorous defence. Troops with cannon were placed in every avenue leading to the Thuilleries, and masked batteries were placed in situations of a more retired nature, if any of these should happen to be forced. The precaution was also taken of transporting the provisions and military stores to St Cloud, if the convention should be obliged to retreat from Paris. On the 5th of October both parties continued on the defensive for several hours, but about three o'clock in the afternoon, overtures were made by the general of the insurgents, Danican, in which he declared that the intention of the citizens was for peace, only they apprehended a massacre was to be begun by the armed terrorists surrounding the convention, and that if these were removed they would return to their duty; but it was resolved to try the issue of the dispute at the point of the sword, as the Jacobin party in the convention were now more fully persuaded of ultimate success. On this occasion the armed Jacobins without are generally understood to have been the first aggressors. The citizens on the south side of the river made an effort to reach the convention by the Quay de Voltaire, but were completely prevented by the cannon of the convention, while the conflict was extremely obstinate on the other side of the river, near the convention. After an engagement of four hours continuance, the sections were repulsed, and driven to the post of St Roche, which being also taken after an obstinate resistance, the insurgents fled to their head quarters at the section of Pelletier; but the troops of the convention were, about midnight, in possession of the whole city.

425 The violent Jacobins again take the lead.

The victors attributed this insurrection to the influence of the royalists; and whether they were right in their judgment or not, it is certain that the cause of royalty was now become less odious to the people in general than the bloody extravagance of republicanism; but the mob in fact seemed to have looked no farther than the disarming of the Jacobins, and obtaining new representatives. The attempt failed, and the Mountain were again at the head of the state. The sittings of the convention were terminated on the 27th of October, and was succeeded by the new legislature in terms of the constitution. Among its last decrees, was one granting a general amnesty for all crimes and proceedings of a revolutionary nature, but the emigrants, transported priests, and every one concerned in the last insurrection, were excluded from the benefit of it. The agents of Robespierre in Paris and the departments were liberated from prison, and promoted to lucrative offices under the new government.

426 Measures of the new legislature.

The next step of the new legislature was to divide itself into two councils, and proceed to the election of an executive directory. The council of five hundred was bound to present to the other council 50 candidates, of which a list was accordingly made out, consisting of no more than five whom they wished to be chosen, the other 45 consisting of obscure persons, farmers and peasants, which left no more power to the council of ancients than the form of an election, which must

France. 1795. must fall on Sieyes, Barras, Rewbell, La Reveillere Lepaux, and Letourneur de la Manche, none of the rest being qualified for the office. The intriguing Sieyes, however, did not deem it prudent to venture on the possession of power; and on his declining to accept of this new dignity, Carnot was appointed in his stead. The form of government now established did not promise to be productive of much happiness or tranquillity, as the most important offices in the state were filled by men whom the people could not endure. The members too of the executive directory, except only Reveillere Lepaux, had always been connected with the Mountain party, and they employed the Jacobins in almost every official department, which could not fail to render the government peculiarly obnoxious. It was feared that a directory chosen by the Jacobins, and new legislators appointed by the people, might one day be the means of totally subverting the constitution, which actually took place.

427 Treaty of peace with Prussia.

On the 10th of April a treaty of peace with the king of Prussia was presented to the convention, in order to be ratified. By virtue of this treaty, it was agreed that the republican troops should be immediately withdrawn from the territories of Prussia on the right bank of the Rhine, having power to retain, till a general peace, the teritories which France then possessed on the left bank of that river. There was to be a mutual exchange of prisoners of war, and the intercourse between the two countries was to be placed in its former situation. Measures were also adopted to shift the theatre of hostilities from the northern parts of Germany. At the same time the king of Sweden acknowledged the French republic, whose ambassador was received at Paris with great solemnity. Another treaty was concluded with Prussia in the month of May, which had a special reference to the line of neutrality. The cantons of Switzerland followed the example of the king of Sweden, and a treaty of peace was concluded at Basle on the 22d of July, between the republic and the court of Spain, in consequence of which France gave up all the conquests she had made in that country, and the original frontier was restored; in return for which the republic received all the Spanish part of St Domingo. In this treaty the Dutch republic was included, and the mediation of the king of Spain, in favour of Portugal and the Italian princes, was accepted by France.

428 Death of Louis XVII.

On the 9th of June, the dauphin, the heir to the throne of the unfortunate Louis XVI. and his only son, died in the prison of the Temple, where he was confined with his sister since the death of the king. Some think that his death was the consequence of disease, although it is much more probable that he was poisoned, since there is no crime in the annals of human depravity which the French rulers would have trembled to perpetrate, of which the numerous murders already detailed afford indubitable evidence. His death, however, interested the French nation so deeply in favour of his barbarously used family, that the convention found it prudent to liberate the princess. The committee of public safety proposed to the emperor to give her up in exchange for the commissioners whom Dumourier had sent prisoners to the Anstrians, together with Semonville and Marat, who were seized on their way to Turkey as envoys extraordinary from the French republic. The proposal was agreed to, and the exchange took place at Basle in Switzerland.

429 Britain superior by sea.

If Britain was unfortunate in her affairs on the continent, she still retained her superiority on the watery element. A fleet under Admiral Hotham engaged a French fleet on the 14th of March, and took two sail of the line, the Ca Ira and Censeur; but this was nearly counterbalanced by the loss of the Berwick and Illustrious. Three French ships of the line were captured by Lord Bridport on the 23d of June, in an attack on the enemy's fleet off Port L'Orient, the rest of the fleet effecting its escape. As Britain thus evinced upon all occasions her superiority by sea, advantage was taken of this circumstance to send assistance to the royalists in the western departments, which unfortunately for them came too late, for the convention had offered them a treaty, which was accepted and signed at Nantz on the 3d of March, on the one part by deputies from the convention, and on the other by Charette, Sapineau, and other chiefs of the insurgents of La Vendée, and by Cormartin, as representatives of the party called *Chouans* or *night owls*. Stofflet submitted to the republic on the 20th of April. The countenance given by Britain to the royalists made them disregard these treaties. The troops sent to their aid were composed of emigrants in the pay of Great Britain, and a number of prisoners who agreed to join the royal cause. Puisaye commanded this motley army, and Count de Sombreuil afterwards joined him with an inconsiderable reinforcement. This expedition arrived in the bay of Quiberon on the 25th of June. Arms were put into the hands of the inhabitants of the country, but it was soon found that they could not be of much advantage to regular troops. A resolution was therefore adopted to withdraw the emigrant army within the peninsula of Quiberon, the fort of which name was taken on the 3d of July, the garrison of which consisted of about 600 men, and was afterwards occupied by the emigrants. All the posts without the peninsula were carried by an army under General Hoche, the emigrants and Chouans escaping into the boats of the British fleet, or flying for protection under the cannon of Quiberon fort. The republicans then began to erect formidable works on the heights of St Barbe, which commanded the entrance of the peninsula. To prevent these operations, a sally on the 7th was made from the fort, but without effect, and another with still greater force had no better success. The whole forces in the peninsula amounted, including Chouans, to about 12,000 men, 5000 of whom were sent to make an attack on the heights of St Barbe, where the republicans were entrenched in three camps, two of which were taken without difficulty; but as the emigrants rushed forward to attack the third, a masked battery was opened upon them with grape shot, in consequence of which a dreadful slaughter ensued, and very few of the emigrants would have effected their escape, had not the fire from the British ships compelled the republicans to abandon the pursuit.

430 Failure of the Quiberon expedition.

It was now evident that a complete and ultimate failure would be the fate of this expedition, and desertion among the emigrants became very frequent, especially those who had been liberated from prison on condition of serving against the republic. The weather was very tempestuous on the evening of the 20th, which induced the emigrants to indulge in a fatal security. The troops of of the republic were conducted in silence along an unguarded quarter of the shore, and surprised one of the posts, where they found the artillerymen asleep. They extinguished the lanthorn which was intended to give the British fleet the alarm, and seized on their matches. Some of the emigrants threw down their arms and joined the republicans, while others maintained an obstinate contest before they surrendered. Count de Sombreuil was taken and put to death, together with the bishop of Dol and his clergy, none being spared but such as pretended that their appearing against the republicans was purely owing to compulsion.

31 Continental affairs.

But to return to the affairs on the continent. The fort of Luxembourg surrendered on the 7th of June, after having been besieged since the preceding campaign, which put the French in possession of the whole left bank of the Rhine, Mentz only excepted, because the Austrians could conveniently supply it with every necessary from the opposite bank of the river. The republicans therefore determined to cross the river, to invest it on every side; but for some time the attempt was delayed, till the result of the Quiberon expedition should be fully known. The passage of the Rhine at Dusseldorf was effected by General Jourdan in the month of August, as commander of what was denominated the army of the Sambre and Meuse. Having driven three Austrian posts before him, he crossed the Maine, and invested Mentz and Cassel, and Pichegru at the same time took possession of Manheim, having crossed the river near that city with the army of the Rhine and Moselle. A strong detachment of this army having driven Marshal Wurmser from an important post, began to plunder, and consequently run into confusion, of which the Austrians took a proper advantage, returned to the charge, and the republicans were vanquished. Jourdan was pursued by Clairfait to Dusseldorf, where the former general made a stand, and Pichegru recrossed the Rhine near Manheim, leaving a garrison in that city of 8000 men, which, after a vigorous siege, surrendered to the Austrians; and the republicans were driven from the vicinity of Mentz. Little more was either lost or won by the contending parties at this time, and they mutually agreed to an armistice of three months.

4.. Treaty with German princes.

The landgrave of Hesse Cassel entered into a treaty of peace with France on the 28th of August, which was agreed to, on condition that he would furnish Britain with no more troops during the war. Peace upon similar terms was granted to the elector of Hanover: and the duke of Wirtemberg and some other princes of the German empire began to treat; but the negotiations were broken off in consequence of the reverse of fortune which the French now experienced.

4.. Absurd conduct of the directory,

The directory, however, still resolved to prosecute the war with vigour, and therefore made vast preparations during the winter for another campaign. The Mountain party being again possessed of power, soon began to discover their restless, turbulent disposition, which could not long submit peaceably to any government whatever, and became disgusted with that very directory which they themselves had established. They were perpetually disturbing the public tranquillity. The people of Paris, after the 5th of October, durst not openly avow their abhorrence of the Jacobins, but it was understood that their wearing green cravats was a token of contempt. This piece of dress was prohibited by the directory as a mark of attachment to royalty. Of this they were soon ashamed, and recalled their edict in a few weeks. In the southern parts of France, the present authority of the Jacobins produced very serious effects. Freron, by whom they had been abandoned after the death of Robespierre, returned to their cause before the 5th of October, and was sent to Toulon with full powers of administration. He dismissed the municipality which had been chosen by the people, restored the Jacobin clubs, and every person whom he suspected he caused to be imprisoned. The directory was alarmed at the numerous complaints which were made from every quarter against the conduct of those turbulent and bloody men, and resolved to obtain the confidence and affections of the people by deserting them entirely. Freron was recalled from Toulon, and more moderate men were made choice of to succeed the restless, sanguinary Jacobins.

434 which takes measures against the Jacobins.

The directory also made a public declaration that its confidence had been abused. The police minister was charged with the removal from Paris of the members of former revolutionary tribunals, and such as were active leaders of the Jacobins. Ten thousand men, called the *legion of police*, who acted against the Parisians on the 5th of October, and were decidedly the favourers of the Jacobins, received orders from the directory and legislative body to join the armies on the frontiers, which orders they refused to obey, but were compelled to submit by the interference of other troops brought from a distant quarter to provide against that event. This led the violent Jacobins to concert a plan for the ruin of the directory and the majority of the councils, who had now abandoned them. But as they were a considerable time in being ready for action, their designs were discovered and completely defeated. The guards were increased on the 10th of May, and bodies of cavalry were stationed round the Luxembourg and Thuilleries. The council of five hundred was informed by the directory, that a terrible plot was ready to burst forth on the ensuing morning. The conspirators, at the ringing of the morning bell, were to proceed in small parties of three or four men each, to the houses of those persons whom they had singled out for destruction. Having murdered these, they were then to unite in one body against the directory, whose guard they conceived themselves qualified to vanquish. The Jacobins in the mean time had nominated a new directory and legislature, from among the most turbulent and abandoned of their own persuasion. Some of the leaders of this conspiracy were arrested, among whom was Drouet the postmaster of Varennes, who stopped the unfortunate Louis on his way to the frontiers, and with him ten others, who were condemned at Vendome, but Drouet made his escape.

435 Moderate party.

These defeats which the Jacobins experienced, and the disgrace into which they were again brought, determined the moderate party in the two councils to attempt to procure the repeal of the concluding decrees of the convention, which had granted them an amnesty, and confirmed the laws against emigrants, excluding their friends from succeeding them. A number of days were employed in the discussion of these topics, but the moderate party gained nothing in favour of the emigrants, and nothing against the Jacobins but this, that such as owed their preservation to the amnesty, should

France. 1796. should not be deemed competent to hold any public office.

436 Deplorable state of the finances. Another matter of no less a serious nature now called for the attention of the republican government, which was the deplorable state of the finances. While the tyrannical usurpation of Robespierre continued, terror supported the credit of the assignats, which joined to the sale of the church lands, and the property of the emigrants, furnished ample resources in the mean time; and no provision was at all thought of for future exigencies. If money was wanted, more assignats were fabricated, and no enquiry was made concerning the public expenditure, as no taxes were demanded from the people. The directory complained to the councils of the great distress under which they laboured, and of the want of sufficient funds to meet the unavoidable expences of the ensuing campaign. A law was in consequence passed on the 25th of March, giving authority to dispose of the remainder of the church lands at the value formerly fixed on them, which was 22 years purchase. A new paper currency, termed *mandats*, was to be received in payment, but government had now lost its credit. These rapidly lost a great part of their value, which increased the demand for national property; and to prevent this, the legislature decreed that one-fourth of every purchase should be paid in cash, which prevented the sale of the national property, and the circulation of *mandats*.

437 National institute established. During their preparations for the approaching campaign, the directory attempted to render themselves popular at home, by the establishment of the *National Institute*, or society of men of letters under the protection of government. Every man of erudition who had escaped the bloody persecution of the Mountain party, was invited to be a member. It was opened on the 4th of April, in the hall of the Louvre, when the ambassadors of Spain, Prussia, Sweden, Denmark, Holland, America, Tuscany, Genoa, and Geneva, were present, and the members of the directory in their robes of state. The president expressed the determination of the executive power to afford every encouragement to the improvement of literature and the arts; and the president of the institute replied that it was the determination of the members to endeavour to give lustre to the republican government by the exercise of their talents, and by publications. The speeches were enthusiastically applauded by 1500 spectators, and the general expectation was, that France was now to enter on a career of glory and prosperity wholly unprecedented.

438 Proposal of peace by Britain. About this time an approach towards a negotiation with France was made on the part of Great Britain, by Mr Wickham, ambassador to the Swiss Cantons; and on the 8th of March, a note was communicated to M. Barthelemy, ambassador from the French republic. It was asked, whether France would be willing to send ministers to a congress to negotiate peace with his Britannic majesty and his allies? Whether France would be inclined to communicate the general grounds on which she would be willing to conclude peace, that his majesty and his allies might consider them in concert? Lastly, whether France would desire to communicate any other mode of accomplishing a peace? Whatever answer should be returned was to be transmitted to the British court; but it was at the same time declared that Mr Wickham had no authority to discuss these subjects. An answer was returned on the 26th of the same month, by Barthelemy in the name of the directory, complaining of the insincerity of the British court, as its ambassador had no authority to negotiate, and that the proposal of a congress made negotiation endless. It stated the wish of the directory to obtain peace, but that no portion of territory would be relinquished, which formed part of the republic by the constitutional decree. To this note no reply was made; but it was complained of to the foreign ministers resident at the court of London, and considered as leaving Britain no other alternative than the prosecution of the war, at once both just and necessary.

439 Royalists in the west subdued. During the winter season, the directory found means to reduce the western departments to proper subjection. The expedition from England had tempted the royalists once more to try their fortune in the field of battle; but after a number of defeats, their leaders Charette and Stofflet were apprehended, and put to death on the 29th of March, which tended to suppress the insurgents in every quarter. Domestic enemies being thus subdued, the republican government was enabled to make the more vigorous exertions on the frontiers. Their military force was divided into three armies; the army of the Sambre and Meuse under Jourdan was principally stationed about Dusseldorf and Coblentz; the army of the Rhine and Moselle, commanded by the celebrated General Moreau, stationed on the Upper Rhine, and from Landau to Treves; and the third army occupied the Italian coast from Nice towards Genoa, the command of which was bestowed on Bonaparte, a native of Corsica, and one of the most extraordinary men that ever lived in any country, as our readers will perceive in the sequel.

440 Bonaparte takes the command of the army of Italy. The army of Italy about this time was 56,000 strong, which Bonaparte, at his arrival, found very ill equipped, and in a state of mutiny for want of pay and necessaries. Wishing them to prepare for immediate action, he addressed them in the following manner: "If we are to be vanquished, we have already too much, and if we conquer, we shall want nothing." He was anticipated by the enemy. The Austrians employed in the defence of Italy under Beaulieu were more numerous than the army of Bonaparte, to which were added 60,000 regular troops belonging to his Sardinian majesty, the militia of the country, and about 2500 Neapolitan cavalry. On the 9th of April the campaign was opened by General Beaulieu, who attacked a post called *Voltri*, in the possession of the republicans, six leagues from Genoa. They defended themselves till the evening, after which they retreated to Savona. Next day Beaulieu succeeded in all his attempts, till he reached Montenotte, the last republican entrenchment, which contained 1500 men. Rampon, their commander, prevailed with them in a moment of enthusiasm, to swear that they would not surrender, in consequence of which they succeeded in arresting the progress of the Austrian general for the remaining part of the day. The right wing of the French army was, during the night, stationed in the rear of the redoubt of Montenotte, under La Harpe, while Bonaparte, Massena, Berthier and Salicetti, advanced by Altara, to take the enemy on their flank and rear. Powerful reinforcements were in the mean time sent to Beaulieu, who, on the morning of the 11th, again made an attack on La Harpe; but the approach of Massena soon made the Austrians and Sardinians

France. 1796.

nians give way on all sides. Two of their generals were wounded, 2500 were made prisoners, and the republicans pursued them beyond Cairo, which, on the following day, fell into their hands.

441 Defiles of Millesimo forced by Angereau.

General Angereau, on the 13th, forced the defiles of Millesimo: and by a rapid movement General Provera was surrounded at the head of 1500 grenadiers; but instead of surrendering, this brave officer forced his way through the enemy, and entrenched himself in the ruins of an old castle at the top of the hill. Angereau, with his artillery, endeavoured to dislodge him; after which he arranged his troops into four columns, and made an attempt to carry Provera's entrenchments by storm, which proved unsuccessful, but the French had two generals killed, and Joubert was wounded. The adverse armies faced each other on the 14th, while a division was left to continue the blockade of Provera. The Austrians made an unsuccessful attack on the republican centre, while Massena turned the left flank of their left wing in the vicinity of Dego, and La Harpe turned the right flank of the same wing. One column kept in check the centre of the Austrians, another attacked the flank of their left wing, and a third column gained its rear. The republicans took 8000 prisoners, and General Provera at last surrendered.

442 Dego retaken by Bonaparte.

General Beaulieu, after he was defeated at Millesimo, made an effort similar to those which have been frequently found to change the fortune of war. With 7000 of his best troops he made an attack upon the village of Dego, where the republicans after their success were indulging in security. He made himself master of the village, and the troops having rallied under Massena, that general employed the greater part of the day in his efforts to retake it. The republicans were three times repulsed, but Bonaparte having arrived in the evening with reinforcements, the post was retaken, and 1400 men were made prisoners. Bonaparte was now, by design, between the Austrian and Sardinian armies, his right wing being secured by the village of Dego against the efforts of Beaulieu, while he could act against the Piedmontese troops with the greater part of his force. Angereau powerfully seconded his exertions, who had opened a communication with the Tanaro, where Serrurier was approaching the town of Ceva, in the vicinity of which there was a Piedmontese entrenched camp of 8000 men. The redoubts covering this camp were, on the 16th, attacked by General Angereau, capturing the greater part of them, on which the Piedmontese evacuated Ceva during the night, and, on the 17th, Serrurier entered it in triumph. Count Colli repulsed Serrurier on the 20th; but Bonaparte, on the 22d, defeated him at Mondovi. The flying army endeavoured to make a stand at Fossano, its wings being at Coni and Cherasci, which latter place was taken by Massena on the 25th, when Fossano was taken by Serrurier, and Alba by Angereau.

443 Armistice with Sardinia.

Prior to these movements, an armistice was requested by Count Colli on the 23d, which General Bonaparte granted, on condition that the fortresses of Coni, Ceva, and Tortona, should be given up to him, with their magazines and artillery, and that he should have permission to cross the Po at Valentia. The armistice was signed on the 29th of April, and a definitive treaty was concluded at Paris on the 17th of May. The conditions, in so far as they concerned his Sardinian majesty, were unquestionably humiliating. The duchy of Savoy was given up to France for ever, as were also the counties of Nice, Jende, and Bretueil. An amnesty was granted to all his subjects who were persecuted for political opinions, and he agreed that the French troops should have free access to Italy through his territory. He was to erect no fortresses on the side of France, to demolish those of Brunette and Susa, and confess that his conduct to the last republican ambassador had been disrespectful.

444 A formal treaty.

The republican army, in the mean time, advanced towards the Po; but Beaulieu was deceived respecting one article of the armistice, which granted permission to Bonaparte to cross that river at Valentia. Concluding that the republican chief seriously intended to cross at this place, he made every possible preparation to oppose him, while Bonaparte hastily penetrated into Lombardy, and on the 7th of May, was 60 miles down the river to Placentia before the enemy could obtain information of his route. He passed the river without difficulty. Six thousand infantry and 2000 cavalry were dispatched by Beaulieu to oppose the passage of Bonaparte across the river when it was too late, by whom they were met and defeated on the following day, at the village of Fombio. As 5000 more advanced to the assistance of these, they were repulsed by La Harpe, at which time that officer was killed. An armistice was granted by General Bonaparte on the 9th to the duke of Parma, on condition that he paid 2,000,000 of French money, and delivered 10,000 quintals of wheat, 5000 quintals of oats, and 2000 oxen for the use of the army. He likewise agreed to give up 20 of his best paintings, to be made choice of by the republicans. This last measure was strongly objected to by several men of literature and artists as soon as it was known; but the directory disregarded every remonstrance, and gave orders for similar stipulations to be inserted in every subsequent treaty.

445 Victory of Lodi.

As General Beaulieu was forced to abandon the Po, he crossed the Adda at Lodi, Pizzighitine, and Cremona, leaving some troops to defend the approaches to Lodi, which were attacked by the advanced guard of the republicans on the 10th, who drove them into the town, and pursued them so rapidly, that there was no time left to break down the bridge over the Adda. Here the Austrians defended the passage with 30 pieces of cannon, and the republican officers, after holding a consultation, were of opinion that the bridge could not be forced. Bonaparte, however, having demanded of his grenadiers whether they were willing to make the attempt, they commended the proposal, on which he formed them into a close column, when they availed themselves of the darkness occasioned by the smoke of the enemy's artillery, and reached the middle of the bridge unperceived, where 700 of them perished by the Austrian cannon: but a number of republican officers flew to the head of the column, urged on the brave soldiers, broke into the Austrian ranks, and made them fly in all directions.

446 And consequences of it.

It appears that nothing more was expected from the campaign of Bonaparte in Italy, than to induce the different princes and states to abandon the coalition against France, which every one of them assisted either with troops, or with money and provisions. He made himself master of Ferarra, Bologna, and Urbino, granting

X 2 to

France. 1796.

to his Holiness and the duke of Modena an armistice on the usual terms, we mean large contributions, paintings, and curiosities. The Neapolitan cabinet was so terrified in consequence of his march into the Roman territory, that it requested a peace; and Bonaparte agreed to an armistice without any of the humiliating conditions demanded from the other states of Italy. He next proceeded to Leghorn, in the neutral state of Tuscany, in order to drive out the English, and confiscate their property. In this manner did he finish the task assigned him, before the commencement of the campaign on the Rhine. It is true that Mantua was still in possession of the Imperial troops; but it was in a state of siege, and the rest of Italy was submissive to the French republic.

447 Success of the French in Germany.

With a view to lessen the exertions of the republicans in Italy, the contest in Germany was renewed by the Austrians. General Jourdan was of consequence informed, that the armistice would terminate, and the war be renewed, on the 31st of May. Jourdan at this time had to contend with General Wartensleben, while the archduke was at the head of the army in the Hundsruck, to oppose General Moreau on the Upper Rhine. A singular stratagem distinguished the commencement of the campaign on the part of the French, with a view to decoy the whole of the Austrian forces to the Lower Rhine, that an opportunity might thus be afforded to General Moreau of suddenly entering Swabia, and carrying the war to the hereditary territories of Austria. Jourdan began to make vigorous exertions, and Moreau remained inactive. The lines of Dusseldorf were left on the 31st of May by the left wing of Jourdan's army, under the command of General Kleber, who defeated the Austrians in marching towards the Sieg. Advancing with his centre and right wing, Jourdan forced the Austrian posts on the Nahe, effected the passage of the Rhine, blockaded Ehrenbreitstein, and hastened forward as if he designed to form the siege of Mentz. These movements brought the archduke into the perilous situation of having Moreau in his front, and Jourdan in his rear. He therefore crossed the river in haste, leaving the fortresses of Mentz and Manheim to retard the progress of Moreau. The archduke attacked the advanced guard of General Jourdan, which, after an obstinate and bloody conflict, he forced to retire. Jourdan, upon this retired to his former positions; and Kleber, on the 20th, entered the lines of Dusseldorf, from which he had taken his departure.

448 Defeat of the archduke Charles.

The archduke had no sooner withdrawn from the Palatinate to force Jourdan down the Rhine, than Moreau marched speedily towards Strasburgh, by which the hostile armies seemed as fast as possible to be flying from each other. The passage of the river opposite to Kehl was effected by Moreau on the 24th of June, which was attended with considerable difficulty, a sudden swell having prevented the Austrians from being taken by surprise, which appears to have been the primary intention of the republican commander. The entrenchments on the islands occupied by troops, were instantly carried at the point of the bayonet, and 2600 republicans effected a landing on the opposite shore, where they were exposed to the Austrian cannon from the camp of Wilstedt, and to the cannon of the fort; still, however, they maintained their ground, and likewise acted on the offensive, till the boats returned with reinforcements, when the fort and redoubts were carried by storm, and the Austrians retreated towards Offenburgh.

449 Austrians defeated by Moreau.

In consequence of the archduke's departure to the Lower Rhine in pursuit of General Jourdan, and the detachments sent to Italy to check the victorious career of Bonaparte, General Moreau was in a situation for entering Swabia with a superior force. On the 26th of June he succeeded in compelling the Austrians to abandon their camp at Wilstedt, and next day proceeded with his army in three columns, against another body of 15,000 men before Offenburgh. A detachment from General Wurmser was sent to their assistance, but these were defeated on their march by two republican columns, and Offenburgh was evacuated during the night. The mountain of Knubis was seized on the 2d of July by a body of French under General Laroche. This is the loftiest point in that ridge of mountains denominated the *Black Forest*. The Austrians were next day driven from the pass of Friedenstadt, after an obstinate resistance, by which their communication with the emigrants under the Prince of Condé was entirely cut off. The Austrians were attacked at Rastadt on the 8th by the left wing of the republican army, commanded by the gallant General Dessaix, and, after a most obstinate resistance, were obliged to retreat to Ettingen.

450 The French enter Frankfort.

The archduke now arrived with his army on the Lower Rhine, leaving Wartensleben to check the progress of General Jourdan, who began to act upon the offensive as soon as the archduke departed. General Kleber, as before, set off from the lines of Dusseldorf, and the centre and right wing crossed the Rhine in the vicinity of Coblentz. The French forced the posts of Ukareth and Altenkirchen, and the whole army under General Jourdan crossed the Lahn on the 9th of July, and next day Wartensleben was defeated with great slaughter, and the loss of 500 men taken prisoners; and the republicans entered Frankfort on the 12th. The two imperial armies were now not far from each other, being in the centre between those of Moreau and Jourdan. Had the archduke found it practicable to resist for a little one of these two armies of the French by a detachment, while he rushed upon the other with the main body of his army, it is not improbable that an end might thus have been put to any further invasion of the Germanic empire; but the activity of the republican officers was not so easily checked, nor could their progress be arrested by any partial exertions. His last resource, therefore, was to give battle to Moreau, which was most obstinately fought on both sides. The French, in their endeavours to force the heights of Rollensolhe, were four times repulsed, and, after a most terrible slaughter, they carried the field at the point of the bayonet.

451 The archduke retreats through Swabia.

In consequence of the loss they sustained at the battle of Ettingen, the two imperial armies retired eastward, the archduke retreating through Swabia towards Ulm, where he had magazines. At every post of any strength he made a stand, in order to obstruct General Moreau's progress as much as possible. Wartensleben, in his retreat through Franconia, made a similar opposition to the march of Jourdan. The archduke was forced by Moreau to cross the Neckar, and afterwards the Danube, by which means the whole circle of Swabia was in the rear of the republicans. Wartensleben was forced to to retreat through Aschaffenbourg, Wartsburg, Schweinfurt; and was obliged to cross the Rednitz, in order to shun the army of Jourdan, which was pressing on his rear. Jourdan continued to advance, till his right wing, commanded by General Bernadotte, was posted at Neumarck, his advanced posts at Teining, and the main body of the army pursued Wartensleben beyond the Nab, having arrived at Amberg on the 22d of August.

452 Great alarm in Germany. The three republican armies commanded by Moreau, Bonaparte, and Jourdan, were possessed of the whole country from the frontiers of Bohemia to the Adriatic, excepting only a part of the mountains of Tyrol, which caused an alarm through the whole of Germany. The payment of 4,000,000 of French money procured a peace for the duke of Wirtemberg; and the circle of Swabia obtained it, on condition of paying 12,000,000 of livres, and delivering 8400 horses, 5000 oxen, 100,000 quintals of wheat, 50,000 quintals of rye, 100,000 sacks of oats, 100,000 pairs of shoes, and a large quantity of hay. Peace was granted to the margrave of Baden upon similar terms. Negotiations were also entered into by the elector of Bavaria and the circle of Franconia, having offered large sums in order to procure it. Even the diet of Ratisbon sent a deputation to the republican generals to treat for a neutrality. Spain made a treaty with France, both offensive and defensive, and war was in consequence soon after declared against Great Britain.

453 The house of Austria in danger. Bonaparte was detained still in Italy, whereas had it been in his power to cross the Tyrol at Inspruck, and reach the Danube, it is more than probable that the emperor of Germany would have been obliged to accept of a peace upon any terms which the conquerors thought proper to propose. He was now abandoned by every member of the coalition, Britain alone excepted, whose pecuniary aid enabled him to extricate himself from the dangers which surrounded him. A command of money raised one army after another to check the career of Bonaparte in Italy, while his German armies were recruited by extensive levies, and mercenary troops belonging to the states which had made peace with France.

454 Able conduct of the archduke. The archduke Charles having received strong reinforcements, came to the resolution of opposing Moreau at Umersheim. A desperate battle was of consequence fought, of 17 hours continuance, when one of the wings of the Austrian army succeeded in gaining about four leagues of territory in the rear of the republican army; but as the archduke was informed that Wartensleben could not maintain his ground against the efforts of General Jourdan, he deemed it prudent to retreat, and adopt new measures. On the 17th of August, he left General La Tour to be a check upon Moreau, and crossing the Danube at Ingolstadt, he marched to the relief of General Wartensleben, and with united forces determined to fall upon Jourdan. On the 23d he made an attack upon Bernadotte at Teining, whom he compelled to retreat towards Nuremberg. The archduke was now on the right of Jourdan, and Wartensleben was in front of him, which induced the French commander to retreat on the 24th. Such was the state of the French finances at the beginning of this campaign, that the armies of Jourdan and Moreau were under the necessity of plundering wherever they came, to supply their immediate wants. This was particularly the case with Jourdan's army, which, when it began to retreat, suffered almost as much from the exasperated inhabitants as from the opposing army. The archduke and Wartensleben having united their forces, the former was enabled to dispatch General Nauendorf with reinforcements to La Tour, to keep Moreau in check, while he continued his pursuit of Jourdan towards Wartzburg, where the French made a stand, and a severe engagement took place on the 3d of September. In this, General Jourdan was the greatest sufferer, and he continued his retreat during the night. Having crossed the Lahn, he made a feeble resistance, and marched along the banks of the Rhine, till his army, on the 17th, arrived at Coblentz and Dusseldorf, from which it had formerly departed.

The army of Moreau was now in a situation extremely perilous, yet he maintained his position till the 17th of September, the very day on which Jourdan reached Dusseldorf; but he was obviously in a wavering condition as to his future movements, and one of the greatest generals Europe ever beheld was now at a loss what step to take. He made an unsuccessful effort to draw the archduke from the pursuit of Jourdan. Many attacks were made upon him, but without effect; and the Austrian generals gave way to him wherever he turned. But finding that the retreat of Jourdan was irretrievable, and that General Bonaparte was still detained in Italy, he finally resolved to retreat. To prepare for this arduous undertaking, he had crossed the Lech, which he suddenly repassed, as if fully determined to penetrate farther into Austria, and compelled La Tour to fall back to Lansberg. Having thus obtained a free passage for his future movements, he began his ever memorable and unexampled retreat, passing between the Danube at Ulm and the lake of Constance, while La Tour continued pressing upon his rear. The passes of the Black Forest were occupied by numerous bodies of Austrians and armed peasantry, while his right flank was harassed by Generals Nauendorf and Petrasch, at the head of 24,000 men. He turned once more upon La Tour with terrible impetuosity, defeated him, and took 5000 prisoners, whom he was able to carry to France. He after this continued his retreat, checking Nauendorf and Petrasch with the right wing of his army under General Dessaix, and the rest of the army cleared the passages in front, till he reached the Valley of Hell, a narrow defile extending for some leagues between lofty mountains, and in particular parts of it not more than a few fathoms broad. This passage was forced by the centre of his army in a mass, and the wings opposed the enemy under Nauendorf and La Tour. After this dreadful effort, he arrived at Fribourg on the 13th of October. The archduke, on his arrival from the pursuit of Jourdan, forced him to abandon his positions on the Swabian side of the Rhine, Kehl excepted, and a temporary fortification at Huningen, called a bridge-head.

455 Moreau's situation highly critical.

456 His unparalleled retreat.

As the French frontier at this time was in a defenceless situation, the Imperial troops took advantage of it to cross the Rhine at Manheim, and march in different detachments to Weissemburg, Seltz, Hagenau, and nearly to the very gates of Strasburgh, levying contributions, and demanding hostages wherever they came. When these detachments were recalled, the 457 French frontier at this time defenceless.

archduke

France. 1796. archduke formed the resolution of terminating the campaign by the reduction of Kehl and the fortification at Huningen, which he found to be no easy task. At both these places a communication was open with the French side of the river, and the divisions of General Moreau's army did duty at them alternately. Much of the winter was spent by the Austrians in endeavouring either to carry them by storm, or to reduce them in consequence of a regular siege. The French at last agreed to evacuate Kehl on the 10th of January, and the fortification at Huningen was surrendered in the month of February.

458 Bonaparte victorious in Italy.

Although the republicans in Germany experienced very considerable reverses of fortune, as we have just now seen, yet Bonaparte in Italy continued victorious. Having laid all Italy under contribution, he enjoyed the means of preserving a secure and steady discipline over a well paid army. The mode of fighting which he adopted in all desperate cases, was that of the close column; the favourite method of Epaminondas and Gustavus Adolphus. The style, too, in which he addressed his army before any great action, was well adapted to inspire them with enthusiasm. His speech to his army when he first entered Lombardy, deserves to be remembered. "Soldiers, you have rushed like a torrent from the summit of the Appenines, you have driven back and dispersed all who opposed your march. Your fathers, your mothers, your wives, your sisters, your sweethearts, rejoice in your success, and boast with pride of being related to you. But remains there nothing more for you to effect? Shall posterity reproach us with having found a Capua in Lombardy? But I already see you rushing to arms; an unmanly repose fatigues you, and the days lost to glory are lost to your felicity. But let the people be tranquil; we are the friends of all nations, and more particularly of the descendants of the Brutuses, the Scipios, and the illustrious personages whom we have chosen as models. To restore the capitol, to replace with honour the statues of the heroes who rendered it renowned, and to rouse the Roman people, become torpid by so many ages of slavery, such will be the fruit of your victories; they will form an epoch to posterity, and you will have the immortal glory of renovating the fairest portion of Europe. The French nation, free and respected by all the world, will give to Europe a glorious peace. You will then return to your homes, and your fellow-citizens, who, when pointing to you, will say, "He was of the army of Italy."

459 Siege of Mantua.

Bonaparte took up the first part of the month of July in commencing a regular siege against Mantua, expecting to be master of that city towards the end of the month. In this, however, he proved too sanguine, for the military efforts of Austria were very great, and the pecuniary aid of Britain was not refused. Twenty thousand troops were sent from the Rhine, besides vast numbers from different quarters, so that he was obliged to raise the siege, and provide for his own safety in the best manner he could. Massena was driven from his post at La Corona on the 29th of July, while 15,000 Austrians drove the republicans from Salo, and next from Brescia, with the whole of the stores and magazines belonging to the army of General Bonaparte. The Imperial troops, however, committed a fatal blunder in their plan of operations, by dividing into two parts an army which, when united, was a match for the enemy, and placing Bonaparte between them. Of this blunder the republican chief was fully aware, and did not fail to take advantage of it. He unexpectedly raised the siege of Mantua, and leaving a small body of troops to check the Austrians, he marched rapidly westward and retook Brescia, with the magazines and hospitals, on the 1st of August. As he had the mass of his army with him, he exceeded his enemies in numbers wherever he attacked them. Forming a large body of his troops into close columns, the Austrians extended their line with the view of surrounding him, being not yet acquainted with his manner of fighting, by which means he penetrated their line in all directions, and threw them into the greatest confusion. He made 4000 prisoners, and took 20 pieces of cannon. A division of them finding Salo in possession of the republicans, wandered about in search of a road, by which to make their escape, when they summoned Lonado to surrender, believing that the bulk of the French army had gone in search of Wurmser to give him battle. This was indeed the case; but Bonaparte was in Lonado with no more than 1200 men. Although this event no doubt gave him much uneasiness, yet with great presence of mind he threatened to destroy their whole division for insulting the French army, by summouing its commander in chief to surrender. The Austrian officers believed that the whole army was in the place, so that by this singular stratagem 4000 men were induced to throw down their arms.

460 Defeat of Wurmser.

Marshal Wurmser was attacked by Bonaparte on the 5th and 6th, and driven from Peschiera and the river Mincio. The Austrians were obliged to quit Verona on the 7th, and again to betake themselves to the mountains of Tyrol; losing in a contest of six days upwards of 20,000 men, but fortunately three-fourths of them were prisoners. The siege of Mantua was again begun by the French, whose works the enemy had destroyed in their absence, and taken 140 pieces of cannon into the city which they had left behind. By this loss, the French could not undertake a regular siege, and General Wurmser was in a condition to attempt the relief of it by the beginning of September. Bonaparte having been apprised of his approach, left troops behind him to carry on the blockade, while he directed his march northward with the main body of his army, drove the Austrians from St Marco and Roveredo to the pass of Calliano, where they made a stand. Here an engagement ensued, in which the Austrians lost 6000 men taken prisoners, and the French entered Trent in triumph. Instead of retiring from the hero who had vanquished him, Wurmser threw himself into Bassano, upon the flank and rear of Bonaparte, and then marched with rapidity towards Mantua. He endeavoured to make a stand at Bassano, but was defeated with the loss of 5000 men taken prisoners. He crossed the Adige at Porto Legnago, and entered Mantua with no more than 8500 men, infantry and cavalry. Great as this veteran's loss was, it had the effect of detaining Bonaparte in Italy, to watch the numerous garrison of Mantua. He expected that its numbers would very soon reduce it by famine to the necessity of capitulating, but in this he found himself disappointed, as the flesh of the 4500 horses which Wurmser carried into it, afforded subsistence to the troops for a long time.

Such

61 Revolt of Corsica from Britain.

Such was the fame of Bonaparte as a general, on account of the victories he obtained over the Austrians, that his countrymen, the Corsicans, discovered an inclination to throw off the British yoke, and be united to France. They became of course, so mutinous, that the viceroy deemed it necessary to evacuate the island, the submission of Italy to the republic having greatly diminished its value. The imperial subjects of Italy, together with the inhabitants of Bologna, Ferrara, and Modena, now began to form themselves into republics, under the patronage of General Bonaparte; they sent deputies to the convention, raised troops, and abolished all orders of nobility.

62 The Austrians partial successful.

The emperor soon after endeavoured to relieve Mantua, by sending another army into Italy, under the command of General Alvinzi, who having crossed the Piava, was met by the republicans, and compelled to repass the river. Davidovich with his division having driven the French down the Adige towards Verona, General Bonaparte found it necessary to concentrate his forces. He therefore left General Vaubois as a check to the progress of Davidovich, and marched in person against General Alvinzi, and was met by the Austrians at the village of Arcole. As this village could not be turned speedily, on account of a canal, the French were obliged to attempt the passage of a narrow bridge in the face of the Austrian fire. Their officers rushed to the head of the column which had undertaken it, but in vain endeavoured to rally them. Angereau advanced to the end of the bridge with a standard; but he was followed by none, when the commander in chief hastened to the bridge and exclaimed, Grenadiers, follow your general! They followed till within 30 yards of the bridge, when they were intimadated by the tremendous fire of the Austrians, and Bonaparte judged it proper to fall back. In the evening General Guieux took the village at the head of 2000 men, but again left the Austrians in possession of it. On the 16th of November a desperate engagement took place in the vicinity of Arcole; and next day the Austrians pressing on the centre of the republican army, were unexpectedly taken on their flank by the left wing of the enemy, which was lying in ambuscade. Bonaparte sent a party of horse and 25 trumpeters round to the rear of the Austrians, who concluded from the terrible noise, that they were surrounded, and fled on all sides in the utmost confusion.

Having driven Alvinzi across the Brenta, Bonaparte returned; the positions of Rivoli and La Corona were resumed, and Davidovich driven back into Tyrol. General Wurmser still defended Mantua during the remaining part of the year; so that nothing farther may be said to have been gained by so many victories, but to consider Bonaparte as their only invincible commander.

46 Negotiations between Britain and France.

During these transactions in the field of battle, Great Britain made a laudable effort to negociate with France. Passports were obtained from the directory, and Lord Malmesbury set out as ambassador to Paris. He began the negotiation with De la Croiz, the minister for foreign affairs; but his lordship soon found that the directory had no serious intention of concluding a treaty with Britain. While the British ministry, as individuals, did not approve of a peace at that time, yet officially they considered it as proper, if it could be obtained upon honourable terms. It was proposed by Lord Malmesbury, that the principle of mutual restitutions should be agreed upon as the basis of the treaty, and the directory wished that the objects should be specified. Lord Malmesbury therefore said, that the French should give up the Austrian Netherlands, for which Britain would give up the foreign settlements belonging to the republic. Many of the Dutch possessions abroad were also to be relinquished, on condition that the authority of the stadtholder should be acknowledged. He was next required to give in the ultimatum of his conditions in 24 hours; and on complaining of this demand, he was informed on the 19th of December, that the directory would agree to no conditions repugnant to the French constitution; and he was informed that his farther residence was unnecessary.

464 Cape of Good Hope taken by the British.

During this year Great Britain maintained her accustomed superiority at sea. The Cape of Good Hope was taken by Admiral Elphinstone on the 16th of September 1795, which the Dutch were extremely anxious to recover, for which purpose they advanced money to the French to fit out a squadron to combine with them in an attempt to reduce it. Seven ships of war were sent to retake the Cape, under the command of Admiral Lucas, but having been caught between two fires, he could not effect his escape, and therefore he surrendered to the British admiral without firing a gun.

465 The French make an unsuccessful attempt on Ireland.

Although Britain was superior by sea, yet an invasion of Ireland was attempted by the French in the end of 1796; but as folly seemed to have concerted the plan, it was of consequence abortive. The whole was committed to one man, General Hoche, without any second to occupy his place in the event of an accident. The disaffected party in Ireland had received no information of their approach, and the fleet was sent towards a part of the country where the people were not very much disposed to receive them. In this expedition 18 sail of the line, 13 frigates, 12 sloops, and transports with 25,000 men, were employed. It was detained for some time when ready for sailing, in consequence of a mutiny. Hoche set sail on the 10th of December, but in working out of Brest, a ship of the line was lost, and some more of them considerably damaged. The frigate which had on board the commander in chief was separated from the fleet by a gale of wind, in consequence of which, when most of the fleet arrived at Bantry Bay, they were without instructions how to proceed. The officers and troops wished to land, but Admiral Bouvet refused to comply. After remaining for some days on the coast, he sailed for France, and reached Brest with part of the fleet on the 31st. General Hoche reached Bantry Bay when it was too late, and consequently could not land. One ship of the line and two frigates foundered at sea, a frigate was captured by the British, and a ship of the line was run ashore, to prevent her from being taken.

466 Advantages gained by the Austrians.

In the beginning of the year 1797, the archduke Charles was still employed in his endeavours to reduce Kehl, and the fortifications opposite to Huningen, Moreau being still his antagonist. General Hoche was appointed to succeed Jourdan on the Rhine, and Bonaparte was still engaged in the siege of Mantua, while powerful efforts were making to recruit the army of Alvinzi. The youth of Vienna were requested to grant their assistance, when 6000 of them volunteered their services

France. 1797. services for Italy. General Alvinzi's army was now 50,000 strong, with which he continued to alarm the republicans in all directions, in order to conceal from them the plan of his future operations. Bonaparte was still at Bologna, to prevent the escape of General Wurmser by that quarter, which he understood, by an intercepted letter, was his design. Having been informed of the approach of the Austrian army, he hastened to Mantua, and from that city to Verona, where the centre of his line was opposed to Alvinzi; but as the Austrians continued to attack all quarters at once, he could not penetrate the design of their commander. On the 14th of January the movements of the enemy became more serious on the lower part of his line near Porto Legnago; but in the evening being informed that the upper extremity of it under Joubert, had been attacked by vastly superior numbers, there he concluded that the Austrians were in greatest force. Still the Austrians persisted in the absurd plan of dividing their army—an absurdity which melancholy experience had not taught them to correct. Ten thousand troops, including the Vienna volunteers, received orders to proceed to Mantua by Porto Legnago, at the lower end of the republican line, while Alvinzi in person advanced against Joubert, who was forced to retreat, and was reduced to such a situation, that the capture of his whole division on the following day (the 14th) seemed highly probable.

467 They are defeated. Bonaparte having received information respecting the state of affairs, left Verona on the 13th, having ordered Massena to follow him with the centre to Rivoli as fast as possible. On the 14th, at the break of day, the division of Joubert made an attack on the Austrians, at which they were very much surprised, not knowing that Bonaparte had arrived with reinforcements. The superior numbers of the Austrians defeated all the endeavours of the French troops to turn their divisions; and the two wings of the republican army were driven back upon the centre in considerable confusion. Alvinzi engaged the centre, which with difficulty maintained its ground; and the Austrian wings advancing on both sides, entirely surrounded the French. The victory seemed already won, and it is even reported that General Alvinzi sent a courier to Vienna, to announce the approaching capture of Bonaparte and all his army. There can be no doubt that the republican chief was now greatly alarmed, yet he still considered it in his power to make a last effort. Forming three strong columns, he dispatched them against the right wing of the Austrians, which they penetrated at various points, and made it fly in such confusion, that, having met a party of republicans which had not arrived in time to join the army, 4000 Austrians laid down their arms, and surrendered themselves prisoners of war. Bonaparte apprehending that this part of his line was no longer in danger, left Joubert to prosecute the victory, and went to oppose the march of Provera. A party under General Murat having continued their march all the night of the 14th after the battle, seized on Montebaldo in the rear of the position at Corona, to which part of the Austrians retreated, while Joubert on the following morning attacked them in front. Being thus surrounded, they were thrown into confusion, 6000 of them were taken prisoners. and numbers perished in attempting to cross the Adige.

During this bloody conflict on the upper part of the river, General Provera forced his passage across the lower part of it near Porto Legnago, and obliged the republican general Guieux to retreat to Ronco. As Provera was marching rapidly to Mantua, General Angereau came up with his rear, and made 2000 prisoners; but the Austrian general reached the neighbourhood of that city on the 15th, which was blockaded at St George and La Favourite. He summoned the republican commander here to surrender, but he having refused to comply, Provera endeavoured, without success, to carry it by assault. He next made an attack upon La Favourite, and was seconded by Wurmser with the troops in the garrison, who had perceived his arrival; but as Bonaparte had arrived with reinforcements, General Wurmser was defeated, and Provera being surrounded by the French, surrendered himself and his troops as prisoners of war. In consequence of these engagements at Rivoli and Mantua, the Austrians lost 23,000 men taken prisoners, and 60 pieces of cannon. The surrender of Mantua was now inevitable, on account of absolute famine, and therefore it capitulated on the 2d of February. That Bonaparte might allow the French emigrants to escape, he allowed General Wurmser to select and take out of the garrison 700 men who were not to be examined, nor viewed as prisoners of war, and the general himself was to depart unconditionally. 468 Surrender of Mantua.

469 The pope's forces subdued. The most active and vigorous preparations were making by the emperor and the French, for recommencing their bloody contest on the German frontiers, and therefore it was of importance for Bonaparte to leave Italy in his rear in a state of tranquillity. He sent General Victor on the 1st of February, together with the *Lombard legion*, to enter the papal territories; and after the surrender of Mantua, General Bonaparte followed in person. The Lombard legion, after storming the entrenchments of the Pope's troops, made 1000 of them prisoners, and took all their cannon. General Colli had carried away most of the treasure from the chapel at Loretto; but the republicans still found articles of gold and silver worth a million of livres, and the image of the virgin was sent to Paris as a curiosity. At Tolentino the republican chief was met by a messenger from the pope with an overture of peace, and a treaty was concluded on the 19th. The pope promised to pay 15,000,000 of livres, and to deliver 800 cavalry horses, with a like number of draught horses and oxen. He also agreed to pay 300,000 livres to the family of the French ambassador Basseville, whom the rabble had murdered at Rome, and to make an apology by his minister at Paris for that event.

470 Reinforcements sent to Bonaparte. The French having been so unfortunate in their invasion of Germany by the way of Swabia and Franconia, now determined to make their principal attempt from Italy under the command of General Bonaparte. Vast bodies of troops were therefore detached by the directory from those who had served under Moreau, and sent as secretly as possible towards Italy by the way of Savoy. The impending danger was however perceived by the court of Vienna, and therefore gave the command on the side of Italy to the archduke Charles, he being the only Austrian who had hitherto been successful against the republicans. The war was now about to be carried into new territories, where a foe

foe had scarcely ever been seen by the house of Austria. It was necessary that Bonaparte should once more force his way over the Alps, that immense chain of mountains which rises in the neighbourhood of Toulon, and stretching northward, obtains the names of Piedmont and Savoy. It then takes an easterly direction, forming the countries of Switzerland, Tyrol, Carinthia, and Carniola. The three last of these passing along the Adriatic, constitute the frontier, in this quarter, of the hereditary states of Austria. The fertile and level country, which belonged to Venice, lies between the mountains and the sea. It is crossed by many streams which are increased by the melting snows of the Alps, and whose peculiar characteristic is this, that they are greatest in summer, and least in winter.

471 Error of the court of Vienna.

The archduke, instead of making a stand in the defiles of the mountains, was sent into the plain to guard the passages of the rivers; a very important blunder which entered into the plan of defence adopted by the council of war at Vienna.

472 Progress of Bonaparte's army.

While Bonaparte continued to advance to the territories of the pope, the arrangement of the Austrian army was going forward along the eastern bank of the Piava. The republicans were on the opposite side, and Bonaparte, after quitting the papal territories, hastened to join them. Having effected the passage of the Piava on the 12th of March, the Austrians retired, skirmishing for some days, till they crossed the Tagliamento, where they halted with their whole force. The republican army reached, on the 17th, Valvesone, on the opposite side of the river, which after some hesitation they determined to cross. The stream having been diminished by the frost, the French crossed it in columns at different points. Joubert with the left wing received orders to pass along the valley of the river Drave, beyond the highest chain of the *Noric Alps*. Massena, at the head of the centre division, passed into the defiles of these mountains, and the right division, commanded by Bonaparte, marched along the coast of the Adriatic.

473 Surrender of Gradisca.

On the 19th, the town of Gradisca, on the river Lisonza, surrendered to the right wing of the army; and its garrison, consisting of 3000 men, were made prisoners. The same division entered Goritz on the 21st, where it found the principal magazines and hospitals belonging to the Austrians. Trieste was taken on the 23d, and materials worth 2,000,000 of livres were sent off by the French from the quicksilver mines of Ydria. On the 24th a large body of Austrians was confined by Massena, and a part of the right wing commanded by General Guieux; but they having procured reinforcements from the archduke, engaged the French next day, and were defeated, having lost 5000 prisoners and 400 baggage waggons. Equal success attended the left wing under Joubert, Baraguay D' Hilliers, and Delmas. Four thousand Austrians were taken on the banks of the Lavis, and they were defeated at Clauzen, with the loss of 1500 prisoners. This division then directed its march eastward, along the valley of the Drave, towards Clagenfurt, the metropolis of Carinthia, where it was met by General Massena, that officer having obliged the archduke to evacuate his head-quarters, and proceed nearer to the capital of the empire, which now began to be in danger. In 15 days General Bonaparte took 20,000 prisoners, and effected the passage of the Alps, after which there was no place of sufficient strength to arrest his progress to Vienna. Yet it must be confessed that his own situation was not free from danger, and therefore he prudently embraced this moment of unprecedented success to make overtures of peace. He wrote to the archduke on the 31st of March, deprecating the continuance of the war, and entreating him to use his influence for putting a period to its ravages. This prince evasively replied, that it did not belong to him to investigate the principles on which the war was carried on, and that he had no power to negotiate.

474 Partial success of the Austrians.

The Austrians raised the peasantry in the Tyrol, to harass the rear of the French army, by which they gained some advantages under General Laudohn, and drove out the republican troops which had been left at Botzen and Brixen. The people of the Venetian states acted a similar part against the troops left in them, and with the assistance of 10 Sclavonian regiments, they murdered every Frenchman they could find, not sparing even the sick in the hospitals, of whom 500 were massacred at Verona. The Austrians attempted to surround the invading army; but Bonaparte knew that the embarrassment of the court of Vienna was at least equal to his own. He was at the head of 95,000 men, hitherto irresistible; and the Austrians could not but know that to surround his army was not to vanquish it, on which account he persisted in advancing. On the 2d of April, after a bloody conflict, he forced the strong defiles between Freisach and Newmark, making 600 prisoners. His advanced guard reached Hunsmark on the 4th, where they again defeated the Austrians, which induced the cabinet of Austria to treat for peace, there being no place where the army of the archduke could make a stand, till it came to the mountains in the neighbourhood of Vienna. Bellegarde and Morveld requested a suspension of hostilities from Bonaparte, while care was taken to remove the public treasure and effects into Hungary. The French commander consented, on condition of getting possession of Gratz and Leoben, about 50 miles from Vienna. This was on the 7th of April, and the armistice, which was to expire on the 13th, was afterwards renewed for a longer period. A preliminary treaty followed this on the 19th, by which the French were to retain the Austrian Netherlands, and the republic of Lombardy should be called the Cisalpine republic, comprehending the Milanese, Mantua, Modena, Ferrara, and Bologna. Bonaparte consented to return to Italy, if his army should be supplied with provisions during its march, and all farther disputes were to be settled by a definitive treaty of peace. He brought an accusation against the Venetian government for conniving at the murder of the French during his absence, and having possessed himself of the city and territories, he dissolved that ancient aristocracy.

475 Peace concluded between France and Austria.

During the approach of Bonaparte towards Vienna, the republican armies on the Rhine were pressing on the Austrians, that they might not have it in their power to send reinforcements against him. An armistice was offered by the Austrians, but since the French required Ehrenbreitstein as a compensation, both parties resolved to prosecute the war. The left wing of the army of General Hoche proceeded from Dusseldorf, while the centre and right wing crossed the river near Coblentz. On the 18th of April a fierce contest took place between

France. 1797. tween the hostile armies near the Lahn, in which the Austrians lost 4000 taken prisoners. General Moreau having forced the passage of the Upper Rhine near Strasburg, attacked and carried the village of Diersheim. Next day the conflict was renewed with such vigour on the part of the republicans, that the fort of Kehl was taken, and 5000 Austrians were made prisoners. They were next pursued towards the Danube, when all military operations were instantly suspended by messengers dispatched through Germany from the archduke and Bonaparte, with the joyful news that peace was concluded. On the arrival of these messengers, the army of General Hoche was making a desperate attack upon Francfort on the Maine, which General Warnecht was employing every effort to protect. Both armies suddenly received the news, the hostile troops threw down their arms, and congratulated each other on the happy event.

476 Changes in the directory.

A contest of an alarming nature was now fast approaching between the legislative and executive branches of the French government. A third part of the legislative body was now to be changed. On the 19th of May, Letourneur went out of the directory by lot; on the 20th, the new third took their seats, and on the 21st Barthelemy was chosen a member of the directory in the room of Letourneur. Pichegru, Jourdan, and Willot, were among the members of the new third, so that a decided majority of both councils was of the moderate party; and two members of the directory, Carnot and Barthelemy, were understood to be men of the same description. Every measure was adopted which tended to render the Mountain party odious, or embarrass the directory.

477 New plan of finanee;

Gilbert Desmolicres, on the 14th of June, brought up a report from a committee on the state of the finances, in which he inveighed against the prodigality and profusion of the directory and its agents in the strongest language. A new plan of finance was proposed by the same committee on the 18th, which went to take from the directory the administration of the public money. On the preceding day Camille Jourdan presented a report of great length on the subject of religion, wherein he insisted on the impropriety of forbidding its ceremonies to be publicly displayed, and the iniquitous nature of that persecution which its ministers had suffered, because they could not take the oaths prescribed by the legislature. The council of five hundred decreed, on the 15th of July, that all the laws against refractory priests should be repealed; and on the following day a decree requiring from them an oath of fidelity to the constitution, was carried by a majority of no more than six members. Emery, a new member, proposed the repeal of those laws by which the property of emigrants had been confiscated, and that their relations should be considered as competent to succeed them. Such as had fled into foreign countries from Toulon and other parts of the nation, received encouragement to return home, and allowed to cherish the expectation that their names would be expunged from the list of emigrants.

478 and lenient measures in favour of the priests.

479 The royalists assume fresh courage.

The discussion which these topics underwent made the directory and the councils professed enemies to each other. The latter wished the former to be changed before the expiration of the legal time, and the directory wished to deprive many new members of their seats who had been elected by the people. As Barras was rather the most odious member of the directory, an effort was made to deprive him of his seat, under the pretence that he was less than the legal age of 40; but his colleagues maintained that he was born in the year 1755, and it seems no proof of the contrary could be produced. Still the directory did not want a number of adherents. The resolution of the councils in favour of the priests had the appearance of a counter-revolution, which induced the royalists to resume conrage, and journals were rapidly published in defence of their cause. The councils received information on the 20th of July, that a division of the army under General Hoche was within a few leagues of Paris, while the constitution declared that the directory incurred the penalty of ten years imprisonment, if it brought any troops nearer the residence of the legislative body than twelve leagues without its consent. An explanation was demanded, when the directory declared their ignorance of the march, having been undertaken without any orders from them, and purely owing to a mistake of the officer by whom it was conducted: bnt the councils paid little regard to such an allegation. The mutinous suburb of St Antoine adhered to the majority of the directory, which encouraged them so much, that they lost no time in proceeding to action. General Angereau had been sent for from Italy, under the pretext of delivering to the directory some standards taken from the enemy. The Thuilleries was surrounded by Angereau on the morning of the 4th, with a division of the troops, when the guard of the councils refused to act against them, and Ramel their commander was made prisoner. On entering the hall, he found Pichegru and twelve more of the chiefs of the opposite faction, whom he immediately sent prisoners to the Temple. Carnot made his escape on the preceding evening, but Barthelemy remained and was put under arrest. When several members of the councils came to the hall at the usual hour, they were astonished to find that seals had been put upon the doors, and that they could not find admittance. They were ordered to go to the surgeons hall, where the directory, it was said, had appointed them to meet. Of both councils not more than 120 members assembled, who sent to obtain from the directory an account of the late proceedings. They were given to understand that what had been done was absolutely necessary for the salvation of the republic, congratulating the duped councils *on their escape* from the machinations of the royalists. According to the report of Boullay de la Meurth, a vast royalist conspiracy, the centre of which was in the bosom of the councils, was endeavouring to subvert the constitution, but that the indefatigable diligence and activity of the directory had defeated all their attempts! It was proposed to transport the conspirators without a trial, and the councils were so completely imposed upon as to vote the transportation of 53 of their own members, and twelve other persons, among which number were included the directors Carnot and Barthelemy.

During the whole of these transactions the city of Paris remained in a state of tranquillity. Its unfortunate struggle on the 5th of October had so completely subdued the ardour of the inhabitants, that they allowed the national representation to be violated with impunity, and liberty to be trampled under foot, without a single exertion in its defence. The directory excused

France. 1797.

cused their conduct to the nation under pretence of the existence of a royalist conspiracy. General Pichegru, it was said, had offered to join the emigrants under the prince of Condé, and the Austrians commanded by General Wurmser, and with this aggregate force to march directly to Paris, for the re-establishment of royalty. There are certain circumstances which lead us to suspect that this was a fabrication: for at the time when this supposed correspondence became public, it was denied to be genuine; and Moreau, who was implicated in this conspiracy, was afterwards employed in the service of the republic, to whose military skill and fidelity the French rulers seemed willing to commit the salvation of the country.

480 Treaty of Campo Formio.

The directory was now very powerful, but its members soon became giddy from the elevated nature of their situation, and seemed to act under the dangerous conviction, that there was nothing in which they might not venture to engage, whatever might be the rapacity or ambition attached to it. While contending with the councils, they prolonged the negotiations with Lord Malmesbury, acting in a similar manner respecting those which had been entered into between Bonaparte and the imperial ambassadors at Campo Formio. Great Britain offered to make peace with France, if permitted to retain possession of the Cape of Good Hope, together with the Spanish island of Trinidad. The negotiations with the emperor were speedily terminated, and on the 17th of October a definitive treaty was signed at Campo Formio. The Netherlands were given up to the republic, the Milanese to the Cisalpine republic, and his territories in the Brisgaw to the duke of Modena, to compensate for the loss of his duchy in Italy. It was likewise agreed by the emperor that the French should possess the Venetian islands in the Levant, namely Corfu, Zante, Cephalonia, Santa Maura, Cerigo and others. The emperor was to have the city of Venice with its remaining territory, from the extremity of Dalmatia, as far as the Adige and the lake Garda. The Austrians accordingly left the Rhine, by which means the republicans were enabled to surround Mentz and Ehrenbreitstein, the former of which was captured in a short time, but the latter required a very tedious blockade before it would surrender. Venice was at the same time entered by the Austrians, the French having left it, and Bonaparte, when about to march out of Italy, left 23,000 men to garrison Mantua, Brescia, Milan, and some other places, and to preserve this new republic in a state of dependence upon France.

It is said that the directory about this time endeavoured to force America to purchase a forbearance from war by a large sum of money, together with a private present of 50,000l. to the members of the directory. The last part of this charge was denied by the minister Talleyrand, but the general impression it produced could not be effaced, and the directory was thus very much injured in the estimation of such countries as were otherwise disposed to view it in a very favourable light. To lessen its reputation still more, it caused the councils to pass two laws, by which all neutral ships on their way to Britain, or returning from it, should be liable to be seized. This, however, produced an effect very different from that which was intended; for having put all the trade of the western world into the power of the British, they enriched the very people whom they were meant to ruin. Britain at this time held the empire of the seas in such an eminent, and perhaps we may add, unprecedented degree, that the republican fleets lay blockaded in their own ports during the greater part of the year.

France. 1798.

481 A body of French troops land in Wales.

The expedition against Ireland having completely failed, the directory was at a loss how to dispose of the galley slaves who had made a part of Hoche's army destined against Ireland. It would have been cruel to remand them back to punishment; the troops would not serve with them in the army, and by the new laws of France they could not receive a pardon, neither was it prudent to give so many criminals liberty. Thus perplexed, the directory at last determined to send them over to England. They were landed from two frigates and some small vessels on the coast of Wales, with muskets and ammunition, but destitute of artillery. On the evening of the day on which they landed (23d of February), they were made prisoners of war by a party of militia, yeomanry, cavalry, colliers and others, under the command of Lord Cawdor.

482 Defeat of a Spanish fleet by Sir John Jervis.

Although the navy of France continued in port, and therefore out of danger, for the remainder of this year, yet the Dutch and Spanish allies of that country sustained very serious losses by sea. A Spanish fleet of 27 sail of the line, opposed to a British fleet of only 15 sail, under the gallant admiral Sir John Jervis, was completely defeated on the 14th of February, off Cape St Vincent. The British admiral passed twice through the enemy's line, and cut off part of their fleet from the rest. Four ships were taken, and the admiral's own ship made her escape with considerable difficulty. This fleet was on its way to Brest in order to effect a junction with the French fleet, but Jervis's victory rendered this object unattainable. In consequence of this memorable victory, Sir John was created earl St Vincent, and had an annuity of 2000l. settled upon him, receiving at the same time the thanks of both houses of parliament.

483 A Dutch fleet defeated by Admiral Duncan off Camperdown.

The Dutch, if possible, were still more unfortunate, Admiral Duncan having blocked up the Texel where their fleet lay, during the whole summer, with the assistance of which it appears that the French meant to try the fate of another attack upon Ireland. A resolution having at length been adopted of risking an engagement with the British at sea, De Winter received positive orders to sail, a step against which he remonstrated, but without effect. Admiral Duncan was at this time refitting at Yarmouth, but on receiving intelligence of the sailing of the Dutch fleet, he set out in search of, and came up with it on the 11th of October, consisting of a force rather inferior to his own fleet, which amounted to 16 sail of the line and three frigates. The British admiral run his fleet immediately through the Dutch line, commencing the attack between them and their own coast, about nine miles from Camperdown. As the Dutch are desperate fighters by sea, our readers will naturally conclude that this was a sanguinary conflict. It lasted for three hours, at which time the greater part of the Dutch fleet had struck; but owing to the shallowness of the water on the coast they could not all be seized. Eight ships of the line, two of 56 and one of 44 guns, were taken, besides a frigate afterwards lost near the coast of Britain. Admiral De Winter was captured with his ship, and

France. 1798.

Vice-admiral Rentjies. Admiral Duncan received honours similar to those which were bestowed upon Earl St Vincent, and an annuity to the same amount.

484 Great disturbances at Rome.

After the ratification of the treaty with the emperor at Campo Formio, Joseph Bonaparte, one of the brothers of the general, was sent to the city of Rome as plenipotentiary from the French republic. The pope having now no expectation of foreign assistance, submitted to every demand for the reduction of his troops, and for emancipating every person confined in prison on account of their political sentiments. On the 26th of December 1797, three men waited upon the ambassador, and requested the co-operation of France in bringing about a revolution which a party at Rome was anxious to establish. He rejected the proposal, and did every thing in his power to dissuade them from it; but he neglected to communicate the intelligence to the papal government, which was certainly his duty. He went to the secretary of state on the 28th, and shewed him a list of persons under his protection who had a legal authority to wear the French cockade, and consented at the same time that all others wearing it should be punished. He offered to give up six of the insurgents who had taken refuge in the palace. In the evening of the 28th a more serious tumult happened in the courts and vicinity of the French ambassador's palace, with which the pope, it is believed, was not personally acquainted; but the governor of the city endeavoured to disperse the insurgents by parties of cavalry and infantry. General Duphot, in attempting to make the military desist from firing upon the insurgents, was shot by a petty officer belonging to the troops of his holiness. The ambassador and his other friends now made their escape to the palace through a bye-way. The Spanish ambassador having been informed of this event, sent to the secretary of state, and protested against such a daring violation of the privileges of plenipotentiaries. The palace of the French ambassador was still surrounded by the military, when at last he demanded passports to enable him to leave the territories of the pope, which were soon granted, and accompanied by many protestations of the innocence of government, and its sorrow that such an unfortunate event should have taken place.

485 The continental powers decline assisting the pope.

Joseph Bonaparte went to Florence and from thence to Paris. The protection of Vienna, Spain, Naples, and Tuscany, was earnestly solicited by the pope, but they all seemed disposed to keep at a distance from his misfortunes. General Berthier experienced little or no opposition on his march to Rome, where he subverted the dominion of the pope, and proclaimed the sovereignty of the Roman people, with too many marks of wanton, unprovoked insult. The tree of liberty was planted on the very day on which the anniversary of the pope's election to the sovereignty was celebrated; intended, no doubt, to make him feel still greater mortification. While in the Sistine chapel, receiving the congratulations of the cardinals, the commissioner general, and Cervoni, who commanded the troops within the city, during this ceremony entered the chapel, and announced to the sovereign pontiff on his throne, that his reign was at an end. He was removed to the territory of Tuscany, where he dwelt in great obscurity, till his enemies being in their turn driven from Rome, were pleased to remove him farther from the capital, to terminate his existence beyond the Alps.

The greatest curiosities found in Rome were conveyed to Paris, and sold by public auction, the directory having sacrificed national vanity at the shrine of avarice. Passports were offered to the natives of countries at war with France, if they inclined to become purchasers.

486 Conquest of Switzerland resolved on by the French.

But scenes of a different and sanguinary nature were in the mean time exhibited in Switzerland, a country which had preserved its neutrality during the conflict of France with the combined powers, thus defending the weakest part of her frontiers; and as a grateful return for past favours, it was now determined to subjugate Switzerland. About the end of the year 1797, an insurrection broke out in the Pays de Vaud, subject to the canton of Berne, which made the government perceive its critical situation, and issue a proclamation on the 5th of January 1798, requiring the people of the Pays de Vaud to appear in arms, renew their oath of allegiance, and reform every existing abuse. A commission of the senate at Berne was empowered to examine every complaint, and redress every grievance; but their motions were considered as too tardy by popular impatience, and the insurgents endeavoured to become masters of the strong places. Troops were sent against them by the government of Berne, but General Weiss acted with hesitation, if not even with treachery, and a body of republicans appeared under General Menard, who sent an aid-de-camp and two hussars to General Weiss. As the messengers returned, one of the hussars was killed, most probably by accident, but it was instantly magnified into a horrid breach of the law of nations. The French, therefore, continued to advance, and were masters of the whole Pays de Vaud by the end of January. The government of Berne prepared for war, while it at the same time used every effort in order to maintain peace. A truce was entered into with General Brune, the successor of Menard, and those who killed the hussar were delivered up. An army of 20,000 men was collected, the command of which was given to M. d'Erlach, once a field marshal in the service of France. But there was a prevailing disaffection in his army, and the people were far from being united among themselves. With this circumstance the French were well acquainted, and therefore they demanded a total change of government. As M. d'Erlach was apprehensive of a still greater defection in his army, he requested permission to put an end to the armistice. The French now refused to negotiate, and General Schawenberg on the 2d of March took possession of Soleure at the head of 13,000 men. Brune afterwards made himself master of Friburg, and forced the Swiss army to retreat. The government of Berne being now greatly alarmed, decreed the *landsthurm*, or rising of the people in a mass, which their ancient customs justified in the time of necessity. The people assembled, dissolved the government, and offered to dismiss the army, if the republican troops would retire. This offer was rejected, without admitting a French garrison into Berne, and therefore they continued to advance. About 6000 from the army of M. d'Erlach had deserted, leaving him at the head of no more than 14,000 men; and although the rising had abundantly supplied him with numbers, yet he had not time sufficient to get them properly arranged. He was attacked on the 5th of March, and driven from Newenbeg and Favenbrun,

Favenbrun, but having rallied his troops, he made a stand for some time at Uteren. The conflict was renewed at Grauholtz, from whence they were driven four miles nearer the capital. Being completely defeated, they murdered many of their officers in a fit of despair, among whom was their commander in chief. Berne capitulated to the French, which induced the more wealthy and populous states to follow the example; but the poorer cantons made a dreadful effort to preserve their small possessions, and the independence of their country. They compelled Schawenberg to retire with the loss of 3000 men, but were at last totally vanquished by the superior skill and numbers of the republican army. The public magazines were plundered, and a new constitution was forced upon them after the model of France.

If the directory made no scruple to violate the independence of other nations, it was very reasonable to conclude that they would pay little regard to the liberties of their countrymen at home. A third of the legislature was changed in the month of April; one member of the directory went out by ballot, and Treilhard was chosen to succeed him. Nothing was left unattempted by the directory to influence the election in favour of their friends, but their success was not great. They complained to the council of five hundred on the 2d of May; they complained of plots of royaltsts, by which it was said that elections had been made to fall on men who were inimical to the interest of the republic. It was proposed on the 7th by the committee who reported on the message of the directory, that many electoral assemblies should be annulled; but General Jourdan opposed this plan as incompatible with the freedom of election, and as proceeding upon the supposition of conspiracies which had no existence.

7 The extravagant Egyptian project by the directory.

We are now to be presented with the most extravagant project which perhaps the directory ever attempted to execute;—to send a formidable army to take possession of Egypt, and from thence to proceed by the Red sea to the East Indies, to take possession of the British settlements in that quarter of the globe. After peace was proclaimed between France and Germany, the directory made no secret of their determination to invade Great Britain. Whether this project was of Bonaparte's own devising, or intended as a snare in order to get rid of him and his victorious army, seems to be a matter which our readers must be left to determine for themselves. It might not be his project, and he might accept the command of the army of Egypt from this conviction, that he would be safer abroad in the most perilous undertaking, than be exposed at home to the malice of a government become jealous of his reputation, and which was far from being scrupulous of its conduct.

The meditated attack upon Egypt was certainly conducted with such a degree of secrecy as was calculated to mislead. Prodigious stories were circulated concerning rafts of timber, by means of which the *army of England*, as it was called, was to be conveyed over to Britain; and to give the greater probability to this report, General Bonaparte, the commander in chief, made a journey to the western coast. The fleet was getting ready in the harbour of Toulon, and troops were collected in its vicinity. But Bonaparte embarked with 40,000 of his veteran troops, and on the 9th of June reached the island of Malta. He quarrelled with the grand master, because he would not permit so large a fleet to water all at once in his ports. The French commander landed his troops in different places, and attempted to make himself master of the island. It is said that many of the knights belonged to the illuminati, and were therefore ready to betray their government. After a very feeble opposition the grand-master capitulated, and thus gave up in a few days a fortress which, it is said, might have held out for weeks against all the troops of the French republic. Bonaparte left in the island a garrison of 4000 men, and sailed for Alexandria on the 21st.

488 Admiral Nelson goes in search of Bonaparte.

Rear-admiral Nelson having distinguished himself in a very eminent degree, while in the station of commodore under Lord St Vincent, was sent in pursuit of Bonaparte. Being wholly ignorant of the destination of the French, he sailed for Naples, where he obtained information of the attack upon Malta, to which accordingly he steered his course. On his arrival, however, he found that Bonaparte was gone; but conjecturing that he had sailed for Alexandria, he immediately prepared to follow him. The French commander, instead of keeping a direct course towards that city, stood along the Grecian coast, till he made the easternmost point of the island of Candia. Then steering to the southward, he so protracted his voyage, that he did not reach the Egyptian coast till Admiral Nelson had left it. Having landed his troops he took the city of Alexandria by storm on the 5th of July. It was desperately defended by the inhabitants, but without military skill. The republican transports were drawn up within the inner harbour of Alexandria, and the ships of war cast anchor along the shore of the bay of Aboukir. The republican army marched on towards the Nile, and in proceeding along the banks of that river, they suffered much from the intense heat of the climate. They soon came to action with the Mamelukes, or military rulers of the country; but the small degree of skill possessed by these barbarians, was by no means a match for European tactics. Cairo surrendered on the 23d, and two days after, another battle was fought, in which the inhabitants were defeated. They made a last effort on the 26th, near the celebrated pyramids, when 2000 of them were killed, 400 camels with baggage were taken, and 50 pieces of cannon.

489 Tyranny and duplicity of Bonaparte.

Having proceeded thus far in his conquest of Egypt, Bonaparte framed for it a provisional government, and issued proclamations in the Arabian language, protesting that the French were friendly to the religion of Mahomet, owned the authority of the grand signior, and were only come to inflict punishment on the Mamelukes for doing so much injury to their trade with Egypt. Thus far the good fortune of Bonaparte seemed still to attend him; but on the 1st of August the fleet under Admiral Nelson appeared off the mouth of the Nile, who having discovered the position of the French fleet, prepared to attack it. In point of numbers the two fleets were upon a level, but as to weight of metal the French fleet was the stronger of the two. Admiral Nelson, by running some of his ships between the enemy and the land, surrounded one part of the fleet, while the rest were thus rendered entirely useless. The Culloden ran aground while this plan was carrying into effect; an advantage upon the whole, as it pointed out to the rest where the danger lay concealed. This memorable

France. 1798. morable action commenced with the setting of the sun, and continued, with occasional intervals, till the break of day. Nine sail of the line belonging to the French were taken; a ship of the line was burnt by her own commander, and the admiral's flag ship, L'Orient, was blown up during the action, few of her crew, consisting of 1000 men, having escaped destruction. Two ships of the line and two frigates were saved by flight, but afterwards captured.

490 Battle of the Nile.

If we confine ourselves to modern times, it will be difficult to point out any naval engagement productive of more interesting effects than this. The military exertions of France had by degrees destroyed the combination which the princes of Europe formed against her. The victories of Bonaparte had humbled the pride of Austria; the continent looked with dismay towards the new republic, and when the directory seized on Rome and Switzerland, no power ventured to interpose in their behalf. The aspect of affairs, however, had now undergone an almost total revolution. The once triumphant Bonaparte was shut up in a barbarous country, from which the fleets of Britain might prevent his return. Proposals were made by Great Britain to the northern powers, for the recommencement of hostilities against France, as it was not conceived possible that she could make such resistance as formerly. The states of Italy, too, determined to make a bold effort for the recovery of their independence. The court of Naples rejoiced at the destruction of the French fleet, and the king himself went to meet Admiral Nelson on his return from the Nile.

491 General Humbert invades Ireland.

It is well known that the French had long promised encouragement to the Irish rebels; but as their expectations were not gratified in time, they broke out into open rebellion without the promised assistance; and when the spirit of rebellion was almost wholly subdued, the directory attempted to land troops in small divisions, such as that under General Humbert on the 22d of August, consisting only of 1100 men, who landed at Killala. Yet this force, small as it was, would have proved formidable but a month before. They were joined by a party of the most desperate of the rebels in the vicinity, and defeated General Lake at the head of a superior force, taking from him six pieces of cannon. Their next step was to march in different directions to announce the arrival of the republicans, and maintained their ground for three weeks. This able general receiving no reinforcements from France, finding the rebellion in a great measure crushed, and being informed that General Cornwallis was about to surround him with 25,000 men, he laid down his arms to a British column, four days after he had dismissed his Irish associates, that they might provide for their own safety. Active measures were now taken by the directory to send troops to Ireland when too late, as the vigilance of British cruizers defeated all their endeavours. La Hoche, a ship of 84 guns, and four frigates, were captured by Sir John Borlase Warren on the 12th of October, in attempting to reach Ireland with 3000 men. On the 20th another frigate was taken, destined for the same country, which induced the directory to abandon the attempt as altogether desperate.

492 Imprudent conduct of the king of Naples.

The victory obtained by Admiral Nelson at the mouth of the Nile, made the king of Naples act the very imprudent part of preparing to commence hostilities against France. Without even waiting till the Austrians should commence the attack on the republican troops in the Roman territory, he procured General Mack to assume the command of his army. He began the war without any foreign aid, except the British fleet, and thus brought upon himself the vengeance of the French republic. The directory had no idea that he would adopt such conduct, and of consequence when General Mack appeared at the head of 45,000 men, the troops of France in that quarter were unable to contend with him. General Championet having justly complained of the attack made upon his posts, circumstanced as he was, he received for answer from the hostile commander, that his majesty had resolved to take possession of the Roman territory, and advised the French to retire quietly into the Cisalpine states, maintaining that their entrance into Tuscany would be considered as a declaration of war. Championet accordingly evacuated Rome, as he had no force against such a formidable army. He left a garrison in the castle of St Angelo, and concentrated what troops he could collect in the northern parts of the Roman state. General Mack entered the city of Rome without opposition in the end of November.

493 The French declare war against Naples and Sardinia.

These transactions having been known at Paris, war was immediately declared against their Neapolitan and Sardinian majesties, the latter of whom had committed no act of hostility against the French; but he was accused of disaffection to the republic, a charge which could scarcely fail to be true. He found himself placed in a very humiliating situation since the first entrance of Bonaparte into Italy, his strongest fortresses being in possession of the French, who levied on him what contributions they thought proper, and even placed a garrison in his metropolis. Being unable to go to war, he made a voluntary surrender of his continental dominions, and agreed to retire to the island of Sardinia.

A period was soon put to the dispute with Naples. As the French retreated, the country people gave them much trouble and uneasiness, and the Neapolitan troops scarcely observed the modern rules of war respecting such as they had taken prisoners. When General Bouchard, by orders from General Mack, commanded the castle of St Angelo to surrender, he maintained that he would view the prisoners in the light of hostages for the conduct of the garrison, and that a man should be put to death for every gun fired from the castle. It is scarcely to be imagined that the Neapolitan officers would have expressed themselves in such a shocking manner, if they had not calculated on the vigorous cooperation of the Austrian forces, in which, however, they were very much deceived. The consequence was, that the territory of Naples very soon fell into the hands of the French. Either the terror of the republican name was so great in Italy, or the cowardice of the Neapolitan troops, that they were defeated by one-fourth of their own numbers, at Terni, Porto Fermo, Civita Castellana, Otricoli, and Calvi. As the army of General Mack was gradually reduced to 12,000 men, in consequence of desertion and frequent defeats, he advised the king of Naples and his family to take refuge on board the British fleet, which was then lying at Leghorn. This advice was adopted, and they reached Palermo in Sicily on the 27th of December, in Admiral Nelson's ship. General Mack having requested an armistice,

mistice, it was refused by the French commander. Being driven from Capua, the only remaining post of any consequence in the territory of Naples, and being in the greatest danger from the disaffection of his troops, he surrendered himself and the officers of his staff to the republican general. The governor of Naples offered a contribution of money if the French troops would not enter that city, which was agreed to, and they remained at Capua. General Serrurier, at the head of a French column, drove the Neapolitans out of Leghorn, and took possession of that place.

494 Desperate conduct of the Lazzaroni.

Such is the mildness of the climate in the southern parts of Italy, that the people can subsist with fewer efforts of industry than in almost any other country of Europe. This naturally begets an indolent disposition, which is cherished by a number of charitable institutions originating from the Catholic religion. In Naples there had long been a body of men called Lazzaroni, or beggars, amounting to the astonishing sum total of near 40,000, who entirely subsisted on charity. They frequently threatened the state if they did not receive an immediate supply of their wants, which procured them very liberal contributions. Having been informed that the French, wherever they came, destroyed all monasteries and other sources of charity, they determined to oppose them to the utmost of their power, and appear the advocates for royal government. In the beginning of January 1799, they exhibited marks of discontent, and at last broke out into an open insurrection. They appointed Prince Militorni their commander in chief, who made many fruitless efforts to restrain their violence and love of plunder. They declared war against the French, forced the prisons open, and murdered all who had been incarcerated for disaffection to the kingly government. Their ravages now became so dreadful and boundless, that Prince Militorni abandoned them, set out to Capua, and requested Championet to take possession of the city, in order to rescue it from utter destruction. It was agreed that a column of French troops should take a circuitous route, and enter the city from the opposite quarter. Before this plan could be carried into execution, two thirds of the Lazzaroni marched out on the 19th and 20th of January, with the daring resolution to attack the French in the fortifications of Capua. Multitudes of them perished by the French artillery; and in order to favour the capture of Naples by the party sent on that expedition, Championet made no sally out upon them, but continued on the defensive. The Lazzaroni being informed on the 21st that a French column had marched for Naples, returned to the city; and although Championet closely pursued them, they arrived in time to barricade the streets, and prepare for the defence of different quarters. A terrible conflict now commenced, which lasted from the morning of the 22d to the evening of the 23d of January. Having been driven from street to street, they finally rallied at one of the gates of the city, where they were almost totally cut off. It is certainly a reproach to the Neapolitan government, not to have been able to give a better direction to the undaunted courage of such men.

495 The directory becomes unpopular.

We may view this triumph as the last which the directory enjoyed, for the consequences of their past conduct were now rapidly gathering around them. They were with the greatest justice unpopular at home, both from their mode of conducting public affairs, and their repeated violations of the constitution of their country. Their profusion was unlimited, as well as the exorbitant demands which they made upon conquered countries. Championet was so ashamed of them, that in Italy he endeavoured to restrain them, in consequence of which he was deprived of his command, and thrown into prison; Scherer, the war minister, being appointed his successor. Under him the rapacity of the government agents, and the embezzlement of the public stores, were carried as high as possible. Yet France still continued to be dreaded by foreign nations, to whom the true state of internal affairs was but obscurely known. An army of 45,000 Russians had arrived to the assistance of Austria, yet that cabinet was at a loss whether to declare war or not. Britain solicited the aid of Prussia, with an offer of large subsidies; but Sieyes, the plenipotentiary at Berlin, artfully contrived to defeat the negotiation, and counteract the unpopularity of his country in Germany, by giving to the world the secret convention of Campo Formio. This determined the greater number of the German princes to maintain their neutrality under the guardianship of Prussia.

A note was presented to the congress at Rastadt on the 2d of January by the French plenipotentiaries resident there, intimating, that if the entrance of Russian troops into Germany was not prevented, it would be considered as tantamount to a declaration of war. To this no satisfactory answer was returned. The strong fortress of Ehrenbreitstein surrendered on the 26th of that month, after being blockaded since the treaty of Campo Formio. This possession, together with Mentz and Dusseldorf, made the French a very powerful enemy on the Rhine. Switzerland also belonged to them, and all the fortified places of Italy, on which account they were qualified to commence active operations. At this period Jourdan commanded on the Upper Rhine from Mentz to Huningen; the eastern frontier of Switzerland was occupied by General Massena; Scherer had the chief command in Italy; Moreau acted under him, and Macdonald commanded the troops in the territory of Rome and Naples. Yet all these armies so scattered, did not exceed 170,000 men, a force greatly inferior to that of Austria, altogether independent of the Russian army. The directory, however, trusting to the unity of its own plans, the wavering politics of the court of Vienna, and the slow movements of the imperial armies, was anxious to renew the war, a declaration of which against the emperor of Germany and the grand duke of Tuscany, was made on the 13th of March.

496 War declared against the emperor and grand duke of Tuscany.

Jourdan had actually crossed the Rhine at Strasburg on the 1st of that month, and occupied many strong positions in Swabia. Manheim was taken, and General Bernadotte summoned Philipsburg to surrender, while General St Cyr entered Stutgard. In order to oppose the march of this army, the archduke Charles crossed the Lech on the 4th of March; Massena marched into the territory of the Grisons, and surprising a strong body of Austrians, made the whole of them prisoners, together with their general, and the whole of his staff, in consequence of which the country of the Grisons was reduced.

The republican plan of procedure was not completed without the junction of Massena's and Jourdan's armies, to accomplish which it was necessary to carry the important

portant post of Feldkirch, which was held by General Hotze. Defeated in his first attempt, Massena renewed the attack five times with fresh forces, but the determined bravery of the Austrians rendered them ineffectual. But as the French were in possession of the Grisons, the invasion of the Engadine was facilitated, where the Austrians being too weak to resist, retreated into the Tyrol, and were pursued by the republicans, who forced some of the defiles, and extended their inroads as far as Glurentz and Nauders.

The vanguard of the principal Austrian army pushed on to meet the French. It was attacked by Jourdan on the 20th of March, by whom the outposts were driven in; but the centre of his army was attacked on the following day, and forced to retire to Stockach during the night. The archduke encamped before Stockach on the 24th, and the republicans attacked him on the following day. His right wing under General Meerfeldt was their main object, which they succeeded in driving into a wood between Liptingen and Stockach. Meerfeldt renewed the conflict without success. The left wing having maintained its ground, sent reinforcements to General Meerfeldt, who in his turn obliged the French to retire. The French, however, made 4000 prisoners during the various movements of the day. Yet their loss was so great, and the Austrian force so vastly superior to their own, that General Jourdan durst not hazard another engagement. He retreated on the following day, and feeling that he was not a match for the enemy, he sent a part of his army to recover Kehl and Strasburg. and marched with the remainder towards Switzerland. By this event General Massena, who was forcing his way to the Tyrol and Engadine, was obliged to return to the protection of Switzerland. He was appointed to the chief command in this quarter, and Jourdan was removed.

497 Success of the Austrians in Italy.

The Austrians were no less successful in Italy, notwithstanding they were attacked by the French before the termination of the armistice. General Kray obtained a complete victory over them at Legnago, and forced them to flee for protection under the walls of Mantua. On the 15th of April they were again attacked by the Austrians at Memiruolo, and again forced to retreat after an obstinate resistance. The loss sustained by the French in these different engagements was unquestionably great, but we should apprehend that the account which states it at 30,000 men in killed, wounded, and prisoners, must surely be exaggerated, But the Austrians may be said to have purchased these victories at a dear rate. Scherer at first gained some advantages over them, but he had not skill to improve them, else they would have unquestionably given a new turn to the aspect of affairs. The Austrian posts were forced by a division of his army on the 26th of March, and 4000 prisoners taken; but on the other division being repulsed, he withdrew his troops, and thus relinquished the advantages he had obtained. On the 5th of April the division under Moreau performed wonders, and took 3000 prisoners; but by the unskilful measures of Scherer he was not supported, and the triumph of the Austrians was of course complete.

498 The Russians and imperialists united under Suwarrow.

Prior to this period, a body of Russians joined the imperialists, and the command of this combined army was given to Field-marshal Suwarrow Rimniski, who advanced towards the Adda on the 24th of April; and after carrying the outposts of General Moreau, Suwarrow determined to attack him in his entrenchments. He maintained the appearance of attack along the whole line of Moreau, while he secretly threw a bridge over among the rocks at the upper part of the river, where such a thing had been considered as impossible. By means of this bridge a part of the combined army next morning turned the republican fortifications, and attacked their flank and rear, while the rest of the army forced the passage of the river at different points. The French fought with their usual intrepidity, but were soon driven from all their positions, and forced to retreat to Pavia, with the loss of 6000 men killed, 5000 made prisoners, including four generals, and 80 pieces of cannon.

General Moreau now established the poor remains of his army, amounting to 12,000 man, upon the Po, between Alessandria and Valentia. He forced, on the 11th of May, a body of Austrians, to retreat, and took a number of them prisoners. On the 12th, about 7000 Russians crossed the Po at Basignano, and marched on towards Pecetto, when Moreau fell upon them with fury; and they refusing to lay down their arms, about 2000 of them were drowned in repassing the river, and a few were taken prisoners. On the advance of Suwarrow, General Moreau was under the necessity of retiring to occupy the Bochetta, as well as other passes which lead to the territory of Genoa, when the combined army began the sieges of the fortified places in Italy then occupied by the French. Bellegarde drove the French from the Engadine; Massena was obliged to retire to the vicinity of Zurich, he was so pressed by the archduke; and nearly the whole of Piedmont had risen against the republicans. They received no reinforcements from the interior of France, and their officers were obliged to act on the defensive, to defend the frontiers as long as possible. In one instance only they had the power of making offensive war, and it was certainly done with great vigour. General Macdonald had still a considerable army in the southern parts of Italy, in the territories of Naples and Rome. The combined powers had made no effort to cut off his retreat, convinced, perhaps, that this could scarcely be accomplished in the mountainous countries of Tuscany and Genoa. Knowing his situation to be secure, he was in no hurry to remove, although nearly the whole country between him and France was occupied by the combined army. His army amounted to about 30,000 men, and he received orders from the directory to leave the territories of Rome and Naples, and unite, if possible, with the army of Moreau. From the situation of the allies, however, he resolved to hazard an action by himself. With Moreau he had concerted a plan for dividing their enemies, and vanquishing them in detail, as Bonaparte had so often done in Italy before. Macdonald alone was in a situation for striking an important blow, yet it was necessary for Moreau to draw upon himself as many of the Austro-Russian forces as possible, that the remainder might be more completely exposed to the attack of Macdonald.

499 Artful stratagem of Moreau.

Moreau availed himself of the circumstance of the French and Spanish fleets being in the vicinity of Genoa, to spread a report that they had brought him a very powerful reinforcement, intending thereby to withdraw the attention of Suwarrow from Macdonald. The

Russian

France. 1799.

Russian general was at Turin, his advanced posts at Susa, Pignerol, and the Col d'Assiette, while General Hohenzollern was stationed at Modena with a considerable force, and General Ott at Reggio with 10,000 men. General Macdonald began his operations on the 12th of June, when his advanced divisions attacked and defeated Hohenzollern, taking 2000 of his men prisoners. General Ott was attacked at the same time, and being compelled to retreat, the French made their entry into Parma on the 14th. He was again attacked on the 17th, and forced to retire towards Giovanni, where the progress of General Macdonald was arrested.

498 The French defeated by Suwarrow.

Suwarrow having received information of his approach, and of his successes, left Turin on the 15th of June, at the head of 20,000 men, and came up with Macdonald on the banks of the Tidone. The centre and right wing of Suwarrow's army were commanded by Rosenberg and Foerster, the Austrian general Melas commanded the left wing; Prince Procration was at the head of the advanced guard, and Prince Lichtenstein of the reserve. An action immediately commenced, which was fought with desperate fury on both sides for three successive days, when victory declared in favour of Suwarrow. Driven from Tidone to the Trebbia, the French were finally vanquished on the 19th, after a greater slaughter on both sides than the oldest officer present recollected to have witnessed. Victory remained doubtful, till General Kray arrived with large reinforcements from the army besieging Mantua, and, in direct contempt of his orders, decided the fate of the day.

The republicans retreated during the night, and the next day they were pursued by the army of Suwarrow in two columns. Seldom could the French be overtaken in a march, but the army of Suwarrow accomplished this, when he surrounded the rear-guard of the fugitives, and obliged them to lay down their arms. The rest of the army defended themselves in the passes of the Appenines and territory of Genoa, after losing, it is said, no fewer than 17,000 in killed, wounded, and prisoners. Moreau, in the mean time, gave battle to the Austrians under Bellegarde, and though far superior to him in numbers, they were totally defeated. This temporary advantage, however, availed little, in consequence of the rapid return of Suwarrow from the pursuit of Macdonald. The fortresses in Italy surrendered in close succession, and it appeared as if the combined powers would soon be able to enter the territory of France.

499

The affairs of the republic became equally critical in Palestine. After having defeated the Mamelukes, made himself master of Alexandria and Cairo, and avowed himself a Mahometan in Egypt, Bonaparte led an army into Palestine, to take possession of Jerusalem, and by rebuilding the temple, and restoring the Jews, to give the lie to the prophecies of the Christian religion. At the head of 10,000 men, with officers eminently skilled in the art of war, he reached the town of Acre on the sea-coast, 28 miles south of Tyre, and 37 north of Jerusalem. He laid siege to this town in due form, which was but indifferently fortified, and defended by a small garrison of Mussulmans, which the governor would have unconditionally surrendered, had he not been advised to make a vigorous resistance by an English naval officer. Sir Sidney Smith having received the command of the garrison, detained Bonaparte before Acre 69 days, although the number of the allies by whom it was defended did not exceed 2000 men. The French commander made eleven attempts to carry it by assault, all of which proved unsuccessful. He was at last obliged to raise the siege, after he had lost eight of his generals, 85 inferior officers, and almost one half of his army. His unsuccessful attempt upon Acre must indeed appear important, especially to Britain, if it be true that the Druses, to the number of 60,000 men, had promised to join him on the reduction of that town. Had this junction been effected, it is believed that Constantinople would have become their prey, which was first to have been plundered, and then reduced to ashes.

500 The directory sinks into contempt.

While France experienced such reverses abroad, she was much disturbed also by internal commotions, and the directory found itself in a very critical situation. New elections were still unfriendly to their interest; and they could no longer secure a majority in the councils, they were sunk into such contempt. When they sought money, they obtained reproaches on account of their own profusion, and the agents they employed. Insurrections in the west and south were formed by the friends of royalty, and these were with difficulty subdued, on account of the absence of the military. In the midst of all these difficulties, the occurrence of one event seemed to promise the directory the return of their former influence. On the 28th of April, the French plenipotentiaries received orders to quit Rastadt in 24 hours. Having demanded a passport from Colonel Barbasey, they received for answer that none could grant it but the commander in chief. They at last began their journey, the three ministers, Bonnier, Roberjot, and Jean Debry, were in separate carriages, Roberjot having his wife, and Jean Debry his wife and daughters along with him, attended by the ministers of the Cisalpine republic. At a short distance from Rastadt they were met by 50 Austrian hussars, who stopped the carriage of Jean Debry, and demanded his name. Of this he informed them, adding that he was a French minister returning to France. He was immediately torn from his carriage, desperately wounded with sabres, and thrown into a ditch for dead. Bonnier and Roberjot were murdered on the spot. When the ruffians departed, and the carriages returned to Rastadt, Jean Debry wandered all night in the woods, and next day returned to Rastadt. He demanded the restitution of the papers which the *hired* assassins had carried off when they plundered the carriages, but they were refused. Rastadt and its vicinity was occupied by French troops during the long sitting of congress, of which the Austrians had obtained possession but a few days before. The discipline, therefore, of the Austrian army was severely reproached by this event; but it is probable that more than the want of subordination was at the bottom of a crime so atrocious, unprecedented, and totally repugnant to the laws of nations. It is true, the archduke lost no time to declare his utter ignorance of the matter in a letter to Massena; but this was far from giving satisfaction to the French directory. In a message to the councils on the

501 Murder of the French ambassadors at Rastadt.

the 5th of May, they made it the premeditated act of the Austrian government, to insult France by the murder of her ambassadors.

502 Sieyes chosen a member of the directory.

A violent opposition to the directory commenced by the introduction of the new third of this year. Sieyes, who was ambassador at Berlin, and had possessed considerable influence over all parties, was elected a member of the directory. This station, we have already seen, he refused to occupy at the first establishment of the constitution, and therefore his acceptance of it at such a critical juncture, excited great surprise. Treilhard was removed from the directory, as it was said that he had held an office in the state within less than a year previous to his election. Merlin and Reveillere were under the necessity of resigning, to avoid an impeachment which was threatened to be brought against them; but Barras still retained his station. Moulins, Gohier, and Ducos, men who were but very little known, and far from being leaders of the contending parties, were chosen members of the directory. The public spirit was attempted to be revived by the establishment of clubs, a liberty of which the restless Jacobins first took advantage. They soon proposed violent measures, and began to denounce the members and the conduct of government. But their intemperance having justly alarmed the directory, they obtained permission from the councils to suppress their meetings, before they had time to corrupt the public mind.

503 General Joubert is killed, and the French retreat under Moreau.

The directory now employed every effort to augment the armies which had lately suffered such dreadful diminutions. In the beginning of August their army in Italy amounted to 45,000 men, of which General Joubert had the chief command. Turin, Alessandria, Milan, Peschiera, and Ferrara, were captured by the allies with astonishing rapidity. Turin sustained a bombardment of only three days, Alessandria held out seven, and Mantua only fourteen, in which last place there were 13,000, who were dismissed on their parole. The combined powers next laid siege to Tortona, and General Joubert resolved on its relief, which object he expected to accomplish before the arrival of Kray with assistance to Suwarrow. The whole of the Austrian posts were driven in by the republicans on the 13th of August, who took possession of Novi. On the 15th they were attacked by Suwarrow, who by this time had received troops from Mantua under General Kray. The right wing was commanded by this officer, its left by Melas, and its centre by Prince Procration and Suwarrow in person. The engagement commenced about five o'clock in the morning, soon after which, while General Joubert was urging his troops forward to charge with the bayonet, he received a musket shot in his body, and falling from his horse, he immediately expired. Moreau assumed the command, and after a bloody conflict, the allied army gave way in all directions. The Russians in particular suffered severely, from the obstinate manner in which they fought. The French line was attacked at three in the afternoon, but remained unbroken; and the whole would have terminated in the defeat of the allies, if General Melas had not turned the right flank of the republican line; and following up his advantages, he got possession of Novi, when the French army began to retreat under the command of General Moreau.

The Austrians say that the French upon this occasion lost 4000 men killed, and the same number taken prisoners, confessing that their own loss was equal to this; but the loss of the Russians was never published. We have reason to believe that it was the greatest of the whole, since they will rather stand and be cut to pieces than think of retreating. The French lost all hope of being able to defend Genoa, and therefore prepared to evacuate that city and territory. It was now the apprehension of the directory that the south of France would immediately be invaded, but in this they were happily deceived. The conquered army was astonished to find itself unmolested after so signal a defeat, and in a few days ventured to send back parties to reconnoitre the movements of the allies. Championet, the successor of Joubert, was amazed to find that they had rather retreated than advanced, on which account he resumed the positions held by his army before the battle of Novi.

504 Suwarrow marches to the relief of Switzerland.

So far from prosecuting the advantages they had obtained in Italy, Suwarrow was persuaded to abandon that country with his Russian troops, and march to the deliverance of Switzerland from the yoke of France. The army of Massena in this quarter amounted to 70,000 men in the month of August, which not only prevented the archduke from pursuing his advantages, but the French even threatened to endanger his position. Massena's right wing under General Lecourbe had carried Mount St Gothard, the great pass leading from the eastern parts of Switzerland into Italy. Suwarrow's expectations were no doubt high, having never yet been vanquished, and being called upon to undertake an enterprise in which the Austrians had hitherto failed, even under their most fortunate general. When he was ready to march, the Austrian commander in Italy refused to give him mules for transporting his baggage. This officer had recourse to a most pitiful falsehood, when he asserted that he would be furnished with a competent number at Bellinzone, where Suwarrow could find none. Having no other alternative, he dismounted the cavalry, and made use of their horses to drag along the baggage. In spite of these obstacles, however, he arrived, by forced marches, on the frontiers of Switzerland on the day which he and the archduke had fixed upon.

Either supposing that it would demean a prince of the house of Austria to serve under a Russian general, or not being daring enough to require the most experienced general in Europe to receive orders from so young a man as the archduke, that prince was sent into Swabia to attack a small body of republicans. He took with him 48,000, some say 60,000 men, although 20,000 would have been more than sufficient for the accomplishment of such an undertaking. It is not an easy matter to conceive upon what principle the council of war at Vienna could imagine, that such an able officer as Massena would continue inactive at the head of an army almost the double of that which was sent to oppose him. The archduke marched against the French in Swabia, who resisted him as much as the small number of their troops would permit; but they were gradually driven towards the Rhine. To carry on the deception, they made a serious stand in the vicinity of Manheim, where they lost 1800 men, and which the Austrians entered, seemingly determined to cross the Rhine.

Switzerland in the mean time was completely exposed

France. 1799.

posed to the army of Massena. The right wing of the combined army in this country was commanded by General Hotze; the centre, composed of the newly arrived Russians, was headed by Korsakof; and the left wing by General Nauendorf. As soon as Massena understood that the archduke had entered Manheim, and that Suwarrow was approaching to Switzerland by the way of St Gothard, he began his movements. St Gothard was defended by Lecourbe, and in the mean time Massena determined to anticipate the arrival of Suwarrow. Having drawn the attention of the Russians to another quarter on the 24th of September, by a false attack, he suddenly crossed the Limmat, three leagues from Zurich. Some of the French troops engaged the Austrians, but the principal part of the army marched against the Russians. General Hotze fell in the beginning of the action, and Petrasch who succeeded him shunned a total defeat, by retiring in the night with the loss of 4000 men. The Russians fought with very singular obstinacy, being in a mountainous country to which they were strangers, and fighting against the most able commanders in Europe. It was in vain, however, to attempt putting them to flight, for even when surrounded they would not lay down their arms, but stood to be slaughtered on the spot. The Austrians having retreated on the 25th, the Russians on the 28th followed their example, retreating under General Korsakof in good order, and with the loss of 3000 men, which was not very great, considering his perilous situation.

505 Suwarrow disgusted with the conduct of Austria.

During these transactions, General Suwarrow was proceeding by the way of Italy with an army of 18,000, but others say no more than 15,000 men. He carried the pass of St Gothard, and descended into the valley of Urseren, driving Lecourbe before him with great slaughter, and advanced as far as Altorf. He next day reached the canton of Glaris, and made 1000 of the French prisoners, and General Linken defeated another corps of 1300 men. Massena now turned upon Suwarrow, and by surrounding him on all sides, expected to take him and the grand duke Constantine prisoners. Suwarrow defended himself in a very masterly manner, and there being only one pass in the mountains unoccupied by the republicans, the aged hero discovered it, and by this he effected his escape, but lost his cannon and baggage among the dreadful precipices with which that country abounds. He made his way through the Grison country, and arrived at Coire with about 6000 men. Suwarrow felt truly indignant when he found in what manner affairs had been conducted, the perilous situation in which the Russians had been left by the archduke, and the destruction which of consequence they had met with. He considered himself and his men as treacherously betrayed, complained bitterly of the commander of the allies in Switzerland, and publicly charging the council of Vienna with selfishness and injustice, refused to co-operate farther with the Austrian army. He transmitted an account of the whole in a letter to Petersburgh, and withdrew his forces to the vicinity of Augsburg to wait for further orders from his court.

506 Britain prepares to invade Holland.

Great Britain in the mean time made active preparations to invade Holland, with an army of 40,000 men, composed of British troops and auxiliaries from Russia. The first division under General Sir Ralph Abercromby sailed in the month of August, protected by a fleet under Admiral Duncan. Bad weather prevented any attempt to land the troops till the 27th, on the morning of which day the debarkation was effected on the shore of Helder Point without oppostion. They were not expected to land in North Holland, on which account the troops in that neighbourhood were few. But before the British troops had proceeded far on their march, they had to contend with a considerable body of infantry, cavalry, and artillery, hastily collected from the adjacent towns. The Dutch fought with great obstinacy, but became fatigued by the steady opposition of their antagonists, and fell back about two leagues. They evacuated the fort of Helder in the night, and it was taken possession of by the British on the morning of the 28th. Admiral Mitchell now enterεd the Zuyder sea with a detachment of the British fleet, in order to give battle to the Dutch under Admiral Story. Instead of retiring to the shallow water with which that sea abounds, he unaccountably surrendered his whole fleet on the 30th of August without firing a gun, pretending that from the mutinous disposition of his seamen, he could not prevail upon them to fight.

507 Which is ill conducted.

If this had terminated the expedition, it would have been extremely fortunate, as establishing the power of the British fleet without a rival. But this victory, if it can be so called, was followed up by an endeavour to restore the authority of the stadtholder, and the ancient government of the United Provinces. As no more than the first division had arrived, the terror of an invading foe began to be dissipated, the enemies of the new government were disheartened, and time was allowed to prepare for defence. But these were not the only errors chargeable on the expedition. The British troops landed in the very worst place they could possibly have chosen, not only as it is everywhere intersected by ditches and canals, but it abounded more than any other part of Holland, with persons disaffected to the person and government of the stadtholder. In a word, this unfortunate expedition was undertaken towards the approach of the rainy season, when a campaign in Holland is next to impossible. When it was first spoken of, even the French directory hesitated to undertake the defence of that country; but when the time and place of landing came to be known, they were soon determined, being almost certain of success. General Brune was accordingly sent with what troops could be speedily collected, in order to co-operate with General Daendals.

General Abercromby in the mean time could only act on the defensive, as no reinforcement had arrived. The enemy was encouraged by his want of activity, and ventured to attack him on the 10th of September. Two Dutch columns, and one of republicans, advanced upon him, but were repulsed in every direction, and forced to retreat to Alkmaer. Additional troops arrived on the 13th, under his royal highness the duke of York, who assumed the chief command. On the arrival of the Russians, offensive operations were immediately resolved on, and the army advanced on the 19th. The left wing under General Abercromby marched along the shore of the Zuyder sea to attack Hoorne; Generals Dundas and Pultney commanded the centre columns, and the Russians were led on by their own general D'Herman. Owing to some misunderstanding, the Russians advanced to attack the enemy

 about

France. 1799.

about three o'clock in the morning, which was some hours before the rest of the army began its march. Their first efforts were crowned with success, and they made themselves masters of the village of Bergen; but as they pressed too eagerly forward without the co-operation of the other columns, the enemy nearly surrounded them. Their general was made prisoner; and notwithstanding the British troops came up in time to secure their retreat, they lost upwards of 3000 men. This defeat of the right wing made the commander in chief recal his troops from their advanced positions, notwithstanding General Abercromby was master of Hoorne and its garrison, and General Pultney had carried by assault the chief position of the Dutch army.

Such was the severity of the weather, that no fresh attack was made till the 2d of October, on which day a desperate action commenced between the British, and the united Dutch and French troops, at 6 o'clock in the morning, which did not terminate till the same hour at night when the British gained possession of Alkmaer and the neighbouring villages. This engagement having been chiefly carried on among the sand hills near the ocean, the fatigue which the troops endured, prevented them from gaining any great advantage over the fugitives, who took a position between Baverwycke and Wyck-op-zee, where the duke of York again attacked them on the 6th, and kept possession of the field after a very sanguinary contest. This, however, was the last success gained by the invading army. The duke of York finding that he could make no farther progress, the enemy having been so rapidly reinforced, the difficulties presented by the face of the country and the badness of the weather also conspiring against him, retired to Schager Brug, where he waited for orders from England relative to his return home. Being in the mean time closely pressed by the enemy, his embarkation must have been accomplished with great danger, had he not entered into a convention with the Dutch and French, that his retreat should not be molested farther, in return for which he promised not to injure the country by demolishing any of the dykes which defended it from the sea, and that Great Britain would restore to France and Holland 8000 prisoners taken before the present campaign.

The affairs of the French republic now began, in consequence of these events, to wear a more favourable aspect. It is true, Championet was defeated in Italy in all his efforts against the Austrians, and Ancona surrendered on the 13th November to General Frolich; but the French were still masters of the Genoese territory, Switzerland and Holland, and the new combination formed against them seemed about to be dissolved. Prussia withdrew at an early period, and still preserved a neutrality; and from existing circumstances it was natural to conclude, that the emperor of Russia would also desert the cause of the allies.

508 The Turks defeated by Bonaparte near the Pyramids.

An event took place about this time which presented the revolution of France in a light never before seen. Our readers will recollect that General Bonaparte was obliged to retreat from Acre with great loss, after a siege of 69 days. At this time he received information that a Turkish army was about to invade Egypt by sea, and therefore he returned across the desert of Arabia by the way of Suez, and arrived in the vicinity of the Pyramids on the 11th of July, when an army of 18,000 Turks landed at Aboukir, which they carried by assault, and put the garrison to death, consisting of 500 men. Bonaparte marched down the country against them on the 15th, and ten days after came in sight of them at six o'clock in the morning. Their troops were divided into two parts, encamped on the opposite sides of a delightful plain. The cavalry of Bonaparte advanced with rapidity into the centre of the Turkish army, cutting off the communication between its different parts. Struck with terror, the Turks endeavoured to gain their ships, when the whole of them perished in the sea. The left division made a more obstinate resistance, but it was at length defeated. About the end of September the news of this victory reached France, which recalled the memory of Bonaparte's conquests, as forming a striking contrast to the reverses experienced by the republic after that period. The directory received a dispatch from him on the 10th of October, which was read to the councils; and on the 14th a message announced the arrival of Bonaparte in France, together with his principal officers. He was received at Paris with marks of distinction, although none could tell why he had left his army and returned home. At this time the parties in the government were equally balanced; and the assistance of Bonaparte was requested by both. The Jacobins were superior in the council of five hundred, and the Moderates in that of the Ancients. It was understood that Sieyes was attached to the latter party, on which account the Jacobins had made many unsuccessful efforts to dismiss him from his office. Intriguing as the Jacobins were, they were fairly outwitted by Sieyes, who had a plot ripe for execution, to overwhelm them in a moment. On the morning of the 9th of November, one of the committees of the council of Ancients gave in a report, that the country was in danger, proposing the sitting of the legislature to be adjourned to St Cloud, about six miles from Paris. The council of five hundred having no legal right to question the authority of this decree, and as the ruling party was clearly taken unawares, the members gave their silent consent, and both councils met at the place appointed on the 10th of November.

509 Who returns to France—subverts the directorial government.

The council of five hundred received a letter from Lagarde, secretary to the directory, informing them that four of its members had resigned their offices, and that Barras was a prisoner by order of Bonaparte, whom the council of Ancients had appointed commander of their guard. In the midst of their deliberations, General Bonaparte entered the hall, accompanied by about 20 officers and grenadiers. He proceeded towards the chair where his brother Lucien sat as president, when great tumult ensued, and the epithets of a Cromwell, a Cæsar, and a usurper, were conferred upon him. The members pressed forward upon him, and Arena a Corsican endeavoured to dispatch him with a dagger; but he was rescued by his military attendants. A party of armed men entered the hall, and carried off the president, when in a violent debate which ensued, it was proposed that Bonaparte should be declared an outlaw. Military music was soon heard approaching; a body of armed troops entered the hall, and the members were obliged to disperse. The council of Ancients set aside the constitution, and passed a number of decrees. The directory was abolished, and an executive commission substituted in its place, consisting of Bonaparte, Sieyes, and

and Roger Ducos, under the denomination of consuls. The sittings were adjourned till the 20th of February 1800, and two committees, consisting of 21 members, chosen from both councils, to act as interim legislators. The greater part of the members composing the council of five hundred returned to Paris, having been expelled from the hall by the military, while part of them continued, and sanctioned all the decrees of the council of ancients. On the 17th of November the consuls decreed the transportation of a great number of Jacobins to Guiana, and cast a number of them into prison; but these decrees were soon after reversed, and every thing assumed an air of tranquillity.

The expedition to Egypt was in the mean time unsuccessful in every one of its objects. Tippoo Sultan, son and successor to the celebrated Hyder Ally, sovereign of the Mysore country, had, in the year 1792, been under the necessity of concluding a treaty of peace with Lord Cornwallis under the walls of Seringapatam, in which he resigned a portion of his territory to the invaders, and agreed to pay a very considerable sum of money. He was likewise obliged to deliver up two of his sons as hostages for the punctual performance of every thing stipulated. A war which terminated in this manner could not reasonably be expected to become the basis of much cordiality. He was indeed obliged to submit, but he only waited for a favourable opportunity to recover what he had lost, and to accomplish, if possible, the total expulsion of the British from India, which with him was a favourite object, as it had always been with his father. The ascendancy of Britain, however, was now so great, chiefly owing to the exertions of Warren Hastings, Esq. that Tippoo clearly perceived the impossibility of shaking it, without the assistance of an army from Europe. To no country but France could he look for an adequate force; but the foreign and domestic wars arising from the revolution, had prevented the rulers of that nation from attending to the interests of distant regions. In 1797, Tippoo determined to renew his intercourse with France by means of the islands of the Mauritius and Bourbon. One Ripaud, formerly a lieutenant in the French navy, who had resided for some time at Seringapatam, persuaded Tippoo that the French had a considerable force at the Mauritius, which with little difficulty might be sent to his assistance. Ripaud being sent to confer with the French upon the subject, he and two ministers from Tippoo were joyfully received by Malartic the governor, and vessels were sent to France to acquaint the directory with their proposals.

Ta[...]o-tion of Tippoo Saib watched by Brit[...].

The governor Malartic in the mean time, either from gross ignorance, from treachery, or a wish to involve Tippoo Sultan in a quarrel with Britain, adopted a measure which ultimately defeated the plans, and brought about the ruin of that prince. On the 30th of January 1798, he published a proclamation, containing the whole of Tippoo's confidential proposals, inviting all citizens of France to espouse his cause. Copies of this proclamation soon found their way into most quarters of the world. Accordingly the governor-general of India, received orders to watch the motions of Tippoo, and even hostilely attack him if it could not be prudently avoided. The Indian government, however, had, before this, been apprised of the impending danger, and had made preparations for war without loss of time.

But Tippoo did not place his sole dependence on assistance from France. He invited one Zemaun Shah from the north-west, whose kingdom was composed of provinces taken from Persia and India, to make an attack upon the British and their allies. In hopes of direct aid from France, which Tippoo expected in consequence of Bonaparte's invasion of Egypt, and the important service which he looked for from the exertions of Zemaun Shah, he remained quiet, and endeavoured to temporise with the British. Military preparations on the part of the British being in a considerable degree of forwardness, Lord Mornington, the governor-general, informed Tippoo that he was not ignorant of his hostile designs, and of his connection with France, proposing, however, to send an ambassador for the purpose of bringing about a reconciliation. This was not answered till the 18th of December, although written by his lordship on the 8th of the preceding month. Tippoo simply denied the charge, and refused to admit the ambassador. Unwilling to sport with human blood, his lordship on the 9th of January 1799, again intreated Tippoo to receive the ambassador, to which no answer was returned during a whole month, during which interval 5000 men arrived from England, and General Harris received orders to advance at the head of the Madras army against the kingdom of Mysore. This seemed to bring Tippoo a little more to reason, who now offered to receive the ambassador, on condition he should come without any attendance; but as this was not deemed a satisfactory concession, the army continued to advance. An army from Bombay was also approaching on the opposite side of his dominions, which encountered part of Tippoo's forces, and defeated them; General Harris defeating the remainder of them on the 27th of March, who on the 7th of April sat down before Seringapatam. This officer received a letter from Tippoo on the 9th, in which he mentioned his adherence to treaties, and wished to be informed as to the cause of the war. The only answer he received was a reference to Lord Mornington's letters. He made another attempt on the 20th, and General Harris informed him that he had already been made acquainted with the only conditions which could or would be granted. The half of his dominions was to be surrendered, large sums of money were expected from him; he was to admit an ambassador to his court, to disclaim all connection with the French, and grant hostages for the faithful observance of every stipulation.

511
Proposals of Tippoo rejected.

Tippoo wrote a letter to General Harris on the 28th, desiring leave to treat by ambassadors, which was refused him, as he was in possession of the *sine qua non* of the British government. It was believed that the besieging army would have been obliged to retreat, had it been possible for Seringapatam to hold out only a fortnight longer. On the last day of April the besiegers began to batter the walls of the city, and they got possession of it on the 4th of May. Tippoo hastened from his palace to the attack, when given to understand that a breach was made in the walls, where he fell undistinguished in the general conflict. His treasures and the plunder of the city were immense, with which the besieging army was enriched, after deducting a certain proportion for the British government and the East India Company. His subjects immediately surrendered, and

France, 1799.

and that part of the country which formed the ancient kingdom of Mysore, was conferred on a descendant of the former race of its kings, and the remaining territories were divided among the British and their allies. The family of Tippoo were either taken or made a voluntary surrender, being removed from that part of the country, and allowed a decent annuity.

Zemaun Shah in the mean time invaded the country from the north-west, advancing to the vicinity of Delhi, and spreading terror and desolation wherever he came. Satisfied with plunder, however, he soon withdrew his forces; and the French army being detained in Egypt by a war with the Turks, as well as the want of shipping at Suez, Tippoo had to contend singly against the united forces of Britain and her allies in those eastern regions.

512 A consular government established in France.

The plan of a new constitntion was presented to the public by the consuls in the month of December 1799. According to this plan, 80 men, who had the power of nominating their own successors, and were called the conservative senate, had likewise authority to elect the whole of the legislators and executive rulers of the state, while none of these offices could be held by themselves. One man, called the *chief consul*, possessed the sovereign authority, held his power for ten years, and was competent to be re-elected. Other two consuls were to assist in his deliberations, but had no power to controul his will. The legislative power was divided into two assemblies; the tribunate, composed of 100 members, and the conservative senate of 300. When the chief consul thought proper to propose a law, the tribunate might debate upon it, without having authority to vote either for or against it, while the members of the senate might vote, but were not enabled to debate. The consuls and the members of the legislative body, as well as of the conservative senate, were not responsible for their conduct, but ministers of state employed by them were understood to be accountable. The committees which framed the constitution, nominated the persons who were to execute the functions of government. Bonaparte was appointed chief consul, and Cambaceres and Lebrun second and third consuls. Sieyes, as formerly, declined taking any active part in the administration of public affairs, and he received, as a gratuity for his services, an estate belonging to the nation, called *Crosne*, in the department of the Seine and Oisne.

513 Bonaparte proposes to treat with Britain.

Bonaparte had not long been in possession of the reins of government, till he sent overtures for negotiating peace with the allied powers at war with France; but it is to be presumed that he did not wish for a general peace. Separate proposals were made to the different belligerent powers, no doubt with a view to dissolve the coalition; but the decrees of the convention, which declared war against all the powers of Europe, were not repealed by him. He departed from the forms sanctioned by the custom of nations in carrying on diplomatic correspondence, but addressed a letter directly to his Britannic majesty, the substance of which was contained in two questions; "whether the war, which had, for eight years, ravaged the four quarters of the globe, was to be eternal?" and "whether there were no means for Britain and France of coming to a good understanding?" Satisfactory, and we think, unanswerable replies, were made to these questions by the British ministry, who dwelt much, and very justly, on the bad faith of revolutionary rulers, and the instability of the governments of France since the subversion of monarchy. The overture transmitted to Vienna was of a similar nature, and it experienced similar treatment; but the emperor of Russia abandoned the coalition, probably on account of the shameful manner in which Suwarrow had been treated, while carrying on the war in Italy and Switzerland.

France 1800.

Bonaparte on the 7th of March sent a message to the legislative body, containing his own ideas of the conduct and designs of the British cabinet, and assuring them that he would invoke peace in the midst of battles and triumphs, and swear to fight only for the happiness of France and the repose of the world. This message was followed by two decrees; the one calling, in the name of honour, upon every soldier absent on leave from the armies of Italy and the Rhine, to join them before the 5th of April; and the other appointing a fresh army of reserve of 60,000 men to be assembled at Dijon, under the immediate command of the first consul.

About this time the belligerent powers were nearly ready for opening the campaign in Italy and on the Rhine. The Genoese republic was the only territory of any importance in Italy, which remained in the hands of the French, but the army by which they defended it was very much reduced since the preceding year, and might be considered as in a state of mutiny, from the want of pay, clothes and provisions. The Austrians eagerly wished to obtain possession of Genoa and all its dependencies, in which they could not fail to be seconded by the Genoese themselves, as they looked upon the republicans to be the destroyers of their commerce. Massena received the command of the army in Genoa, with extraordinary powers, and evinced himself to be a general of consummate abilities. Carrying a reinforcement of troops with him from Lyons and Marseilles, and reducing to order and obedience, by a judicious distribution of rewards and punishments, all whom he found ready to desert their standards, he soon found himself at the head of a force sufficient to check the progress of the Austrians, and keep the Genoese in subjection. After a number of battles had been fought, he was obliged to retire into the city, where he must soon have been compelled to surrender by famine, if General Melas had immediately blockaded it.

51[illegible] A Brit[illegible] fleet ap[illegible] pears [illegible] Genoa.

The appearance of the British fleet on the 5th of April, was the concerted signal for Melas to make an attack upon Genoa, the communication between which and France was thus cut off. Prior to the arrival of Lord Keith, a quantity of wheat and other provisions had been thrown into the city, by which means the army and the inhabitants were rescued from the consequences of immediate famine. The surrounding country was soon vanquished by the Austrians; but as the gallant Massena still lived in the expectation of supplies from France, he obstinately refused to surrender the city. General Melas having nothing to apprehend from this army blocked up in Genoa, left General Ott to continue the blockade, and went with his own forces against Sauchet, who commanded another division of the French army.

A decisive battle was fought between Ceva and St Lorenzo, ance. 300.

Lorenzo, on the 7th of May, in which the republicans experienced a total defeat, having lost 1200 prisoners, and 19 pieces of cannon. This soon obliged General Sauchet to abandon his strong position of Col di Tenda, where he left behind him four pieces of cannon and 200 prisoners; and marching on towards Nice, the Austrians drove him from one post to another, till he was finally obliged to take refuge behind the Var; by which movements General Melas became master of the whole department of the Maritime Alps. But the campaign on the Rhine did not open in such a favourable manner to the Austrians. The court of Vienna directed the archduke Charles to resign the command of the army to General Kray, who distinguished himself in such an eminent manner in Italy, during the campaign of 1799. Of his military talents there could be only one opinion, and his integrity and zeal had been sufficiently tried; but he had the misfortune not to be so *noble* as some of the other generals! It is truly ridiculous to behold men contending about trifles, when engaged in matters of such vast importance as the salvation of their country. During the most propitious days of Rome, her greatest generals were plebeians.

15 The French d..ated n.. Lo..

16 M..au refus.. to act as ..ected by ..uapa..

It could not be reasonably expected that such a discordant army, commanded by an able officer who had the misfortune not to be a *nobleman*, would ever be able to make head against the veterans of France, led on by such an extraordinary general as Moreau. The Hungarian troops, finding themselves ready to be sacrificed to the party dissensions of their officers, would not fight against the enemy. The council of war at Vienna had sent General Kray instructions at the opening of the campaign, how he was to dispose of his forces, and having no general under him to support his own opinion, he was under the painful necessity of obeying his instructions, whether he could approve of them or not. Instructions of a similar nature had been transmitted to Moreau by the chief consul, but he indignantly refused to fight under such restraints. He was no doubt conscious that his own knowledge of the military art was at least equal to that of Bonaparte, while he was infinitely better acquainted with the country, and therefore he sent a courier to Paris to acquaint the consul, that if the orders sent him were to be rigidly obeyed, he would feel it his duty to resign his command, and accept of an inferior station. He accompanied his resignation with a plan of the campaign which he had framed for himself, the propriety of which instantly struck the chief consul, and therefore he was ordered to carry on the war, according to his own judgement.

And ..ere..re ..eft ..his ..wn ..ge- ment.

General Moreau being thus wisely left to adopt and execute his own measures, crossed the Rhine, and drove the Austrians from one post to another, till Kray, finding it impracticable to adopt offensive measures with a rebellious army, with disaffected officers to command them, resolved to maintain his position at Ulm, and wait for assistance from Vienna. He was defeated at Stockach, Eugen, and Moskirch, although he exhibited fully the talents of an able general; but what talents were able to counteract the pernicious consequences of treachery? At one time, when 7000 men received orders to advance, they instantly threw down their arms. Kray too plainly perceiving that it was absolutely in vain to attempt any thing of an offensive nature, entrenched himself strongly at Ulm, commanding both sides of the Danube, which makes it a place of great importance. Moreau perceiving his intentions, resolved to try the passage of the Danube, and force him to a general engagement, by cutting him off from his magazines at Donawert. For this purpose he gave orders to Lecourbe with one of the wings of his army, to take possession of a bridge between Donawert and Dillingen, which was not effected without considerable difficulty. The Austrians having perceived, when too late, that their all was in danger, disputed every inch of ground with the French commander. Between the time of marching to, and of crossing the Danube, Kray sent reinforcements to the left bank to oppose the passage, in consequence of which a battle was fought at Hochstet, in the vicinity of Blenheim, where victory again declared for the French, who made 4000 of the enemy prisoners, independent of the killed and wounded lost by the Austrians, of which we have seen no estimate.

France. 1800.

General Kray, sensible that his situation was perilous, left a strong garrison at Ulm, and marched against the enemy, attacking them at Newburg, which both sides conducted with determined bravery; but the Austrians, after a long contest, fell back on Ingolstadt. It may not improperly be said, that this battle decided the fate of Germany. The electorate of Bavaria was now in the possession of the French, with other territories of less extent; and as they approached the hereditary dominions of the emperor, men of republican sentiments behaved with such effrontery, as to convince the court, that no dependence could be reasonably placed on armies composed of such men. The imperial family, and the British ambassador, were openly insulted in the theatre, and the cry of *peace, peace*, was vociferated from different quarters.

The ill success of General Kray alone could not excite such a spirit, because at this time the affairs of Germany were even in a more deplorable state in Italy than upon the Danube. When the campaign opened on the Rhine, the army of reserve under the command of Bonaparte, which was formed at Dijon, began its march. When the French government declared that this army was above 50,000 strong, and receiving daily reinforcements, few could be found who were disposed to give any credit to the report. Such as were friendly to the cause of the allies, were unwilling to allow the French government so much vigour, while it was industriously circulated by the Jacobins of Germany, that it could not amount to more than 6000 men. The first consul set out from Paris on the 5th of May, to take the command of an army, the strength and destination of which had given rise to so many conjectures, and on receiving the troops cantoned at Dijon, he proceeded towards Genoa. Having been a short time in the Pays de Vaud, he joined the army of reserve at the foot of St Bernard, of which he immediately assumed the command. It is certain that a very insignificant force would have been able to arrest the progress of Bonaparte while ascending the mountain; but either General Melas had heard nothing of its being in motion, or he had implicitly believed the report of the Jacobins. In consequence of this ignorance or credulity, the army of reserve encountered no opposition till it reached the town of Aost, of which the first consul very soon

518 The French army at Dijon unexpectedly marches for Italy.

France. 1800. soon gained possession. Having, with the most astonishing perseverance, passed the fort of Bard, he proceeded on his march down the valley of Aost with little opposition, till he arrived at the town of Yorea, where the Austrians were assembled in force, but were obliged to give way before the impetuosity of the republicans, and post themselves on the heights of Romano behind the Chinsella. It was of vast importance as commanding the passage of the river, and was occupied by 4000 cavalry, 5000 infantry, and a few pieces of cannon. It was taken on the 26th of May, and the fort of Brunette soon after, in consequence of which the road to Turin was now open. While the republicans were effecting a passage over St Bernard, the chief part of the Austrians under Melas were employed in the celebration of their victory over them at Nice, little suspecting how soon they were to experience a sad reverse of fortune, and that the victors would very soon be vanquished. General Melas, at length roused from his dream of security, marched towards Turin with all possible speed, in order to defend the Po, and prevent the invaders from arriving at Vienna. He naturally concluded that Turin would be the first important point of attack made by the French, but in this he was deceived; for while he prepared to dispute the passage of the Po with the republicans, Bonaparte suddenly turned to the left, and entered Milan on the 2d of June.

The army of Bonaparte was very numerous, but he wanted magazines, artillery, and stores of every kind; but understanding that Pavia was the great depot of the Austrian army, he sent his advanced guard against it under General Lannes, who made an easy conquest of it, and found in it more than 200 pieces of cannon, 8000 muskets, 2000 barrels of gunpowder, and a prodigious quantity of all sorts of provisions. Another of the chief consul's generals crossed the Po at Stradella; and having cut off the communication between General Melas and the country of Piedmont, gained possession of the Austrian magazines at Piacenza, Cremona, and a number of other places on the banks of the river.

519 Massena in a critical situation at Genoa.

About this time it was that Bonaparte became acquainted with the fate of Genoa, by means of intercepted letters. Massena did every thing in the power of bravery and perseverance to keep possession of the city; but after he had witnessed 15,000 of the inhabitants perish with hunger, he surrendered to the British and Austrian commanders on the 5th of June, and obtained very favourable terms, when we consider that it was impossible for him to hold out any longer. The right wing of his army, consisting of 8110 men, was permitted to march into France by the way of Nice, and the rest were to be conveyed by sea to Antibes, at the expence of Britain; no man was to be deemed responsible for having held any public office under the government of the Ligurian republic; and all officers taken prisoners since the commencement of the campaign, were allowed to return to France on their parole, not to serve till they should be regularly exchanged. By the fall of Genoa, the Austrian army which besieged it was at liberty to co-operate with the commander-in-chief; and, accordingly, General Ott marched at the head of thirty battalions to check the progress of the French army in Piedmont. On the 9th of June he was met by Generals Lannes and Victor at Montebello, where a battle was fought with great fury on both sides, when the French were victorious, and General Ott retreated with great loss. Melas being unable to arrest the progress of the republicans by detachments of his army, collected his whole force between Alessandria and Tortona, that he might be able to open a way for himself to the Austrians on the Mincio, if he should find it impossible to crush the enemy. The consequence of this step was the ever memorable battle of Marengo, fought on the 14th of June, which has been variously described. The French accounts represented the army of General Melas as more numerous than that of the chief consul, to whose superior conduct and bravery alone the French were indebted for success. Others have believed that the superiority was on the side of the republicans, and think they can discover as much from comparing together the different bulletins of the army of reserve. On this point we pretend not to decide, only it is certain that the Austrians were victorious for nine hours, and the fate of that battle appears to have been decided by the masterly conduct of General Desaix, who died on the field. One false movement, made by General Melas, which enfeebled his centre, afforded the gallant Desaix an opportunity of making a vigorous charge with a body of cavalry that had hitherto been unemployed. General Zach, a man worn out with age and fatigue, when about to take the command of the army from Melas, fell into the hands of the enemy, who remained masters of the field of battle.

520 Great loss of the Austrians at the battle of Marengo.

The Austrians lost in this engagement above 9000 men, and the French upwards of 12,000, according to their own account. Enraged that the victory should be thus snatched from them, the Austrians were eager to renew the combat on the following day; but General Melas deemed it prudent to check the ardour of his troops, and concluded a capitulation, said by some to be unparalleled in the annals of war. He may have signed such a capitulation in consequence of instructions from the council of war at Vienna, or the fortresses given up by him may have been destitute of provisions. If we admit the first supposition, it follows that the council of war were determined enemies to the cause of the combined powers; and if we go upon the second, Melas himself was perhaps the most improvident commander that ever was charged with the defence of a country. The whole of Piedmont and Genoa were given up to the French, and an armistice was concluded, to last till the court of Vienna had time to return its opinion.

General Kray in Italy was anxious to avail himself of this armistice, to arrest the progress of Moreau's army: but that able general would not listen to any overtures upon the subject, till he should receive instructions from Paris. Count St Julien arrived with proposals of peace from the Imperial cabinet, in consequence of which the armistice was concluded in Germany and Italy, the posts then occupied by the respective armies being considered as constituting the line of demarcation. In opposition to the spirit of their stipulations with General Melas, the French reinforced their army in Italy, levied immense contributions, and raised troops in different states declared by themselves to be independent.

521 Great distress of the French troops in Egypt.

While France was everywhere victorious in Europe, her troops in Africa were subjected to hardships and disgrace. Their being abandoned by their chief made them

ance.
1800.

them complain bitterly; and Kleber is said to have declared, that the same *universe* should not contain him and Bonaparte. He continued the negotiations begun by General Bonaparte with the grand visier for evacuating Egypt, between whom a convention was concluded on the 24th of January 1800, to which Sir Sidney Smith agreed on the part of Great Britain. By virtue of this convention, the republican army, its baggage and effects, were to be collected at Alexandria, Rosetta, and Aboukir, to be conveyed to France in vessels belonging to the republic, and such as might be furnished for that purpose by the Sublime Porte. It would seem that nothing could have happened more injurious to the interest of the allies than the evacuation of Egypt upon such terms, since the consul would thus have been furnished with nearly 18,000 troops, which might have been advantageously employed, either in Italy or on the Rhine. It is strange how this important circumstance did not occur to Sir Sidney Smith, and no less so, how he took upon him the office of plenipotentiary. Mr Dundas clearly proved in the house of commons, that he exceeded any power with which he could reasonably conceive himself vested, that being lodged with Lord Elgin at Constantinople.

22
Ge ral
Kl r as-
sas ated.

In the latter end of the year 1799, the British ministry had reason to believe that a negotiation would take place between the grand visier and General Kleber, respecting the evacuation of Egypt by the troops of the latter; and as such an event was much to be desired, Lord Keith received orders to accede to it, on condition that General Kleber and his army should be detained as prisoners of war, instead of being sent back to France. This was bitterly complained of in France, and numbers even in England exclaimed against it as a flagrant breach of faith, while General Kleber himself did not consider it in such a light, although the only person who had reason to do so, could he have done it with fairness. On the 20th of March he attacked the Turks in the vicinity of Cairo, who fled before him in all directions, and left more than 8000 men dead and wounded on the field of battle. By this conquest Cairo was restored to the French, which in terms of the convention they had abandoned. Kleber again proposed to evacuate Egypt, on the terms agreed to by the grand visier and Sir Sidney Smith, and Lord Keith being ordered to agree to them by the cabinet of St James's, a suspension of hostilities took place, and the Turks were ready to be delivered from enemies whom they were not able to expel, when General Kleber was suddenly assasinated.

3
Of ich

sus ted.

Both parties had reason to regret this event, as General Kleber appears to have been, not only the most honourable, but by far the ablest commander of the republicans, in that quarter of the globe. It is not certainly known by whom he was murdered, nor who were the contrivers of such a plot; but at Constantinople his successor Menou was strongly suspected. We must confess that he was not friendly to Kleber; but on the other hand we do not find General Reynier, in his "State of Egypt," insinuate any thing of this natnre against Menou, although he treats his conduct and abilities with some degree of contempt; and we are informed that the assassin himself, previous to his execution, solemnly acquitted Menou from being in the least acquainted with the plot.

France.
1801.

524
General Abercromby sails for Egypt.

As Menou refused to leave Egypt by capitulation, the British government formed the resolution of driving him out of it by force. Sir James Pulteney received the command of 12,000 men, to act in the Mediterranean in such a manner as might most effectually annoy the enemy; a plan which was disconcerted by the issue of the battle of Marengo. He was superseded by Sir Ralph Abercromby, who carried reinforcements along with him, together with a train of artillery from Gibraltar. He touched at Minorca and Malta, from whence he steered his course for the coast of Egypt, which he reached on the 1st of March 1801, and anchored next day in the bay of Aboukir; but the weather prevented him from attempting to land till the 7th of that month, at 10 o'clock in the forenoon. The first division effected a landing in the face of the French, to the amount of 4000 men, whose position was so very advantageous, that an eye witness thought they might have resisted the world; yet 2000 British troops drove them from it with the loss of some field pieces, and the disembarkation was continued during that and the following day.

525
The French conquered by the British near Alexandria, and General Abercromby mortally wounded.

The whole army of General Abercromby moved forward on the 12th, and coming in sight of the main body of the French, gave them battle on the 13th. The conflict was obstinate on both sides, and their loss very considerable, but victory in the end declared for the British. This advantage was followed up with vigour, and on the 21st a more interesting battle was fought with similar success, about four miles from the city of Alexandria. Sometimes the French had the advantage, and sometimes the British, but the latter were finally victorious. General Abercromby, that he might not damp the ardour of his troops, concealed for two hours the anguish of a mortal wound he received in this action:—a degree of magnanimity which has very seldom been equalled, and we believe never was surpassed. The loss of the British on this occasion was estimated at 1500, and that of the French at 4000 men.

526
The Northern Confederacy.

As it may be said that the fate of Egypt was decided in a great measure by these two battles, we beg leave to call the attention of our readers to affairs of great importance which about this time took place in Europe. The powers of the north, envious of the superiority of Britain by sea, and acting under the influence of the capricious Paul, were resolved to revive the armed neutrality of Catharine II. during the continuance of the American war, and claimed a right of trading to the ports of France, without being subjected to have their vessels searched. The ministry of Great Britain were determined to break such a confederacy; but to the astonishment of the nation they resigned at this period. Different causes have been assigned for an event which was so unexpected; but the ostensible reason was a difference in the cabinet relative to catholic emancipation. After the union of Ireland with Britain, it seems pretty clear that the minister did propose this subject in the cabinet; but his majesty, from a sacred regard to his coronation oath, put his negative upon it, in consequence of which Mr Pitt and his friends gave in their resignation. In general they were succeeded by men who had countenanced their administration during the war. Mr Addington was appointed first lord of the treasury, and chancellor of the exchequer;

527
A change of ministry takes place in Britain.

France 1801.

chequer; Lord Eldon, lord high chancellor; the earl of St Vincent, first lord of the admiralty; Lord Hawkesbury and Pelham, secretaries of state, and the honourable Colonel Yorke, secretary at war. The former ministry was dissolved on the 11th of February; but owing to the indisposition of his majesty, none of the new ministry entered upon office before the middle of March, during which eventful interval Mr Pitt and his associates had the chief management of public affairs. The new ministry entered upon office by solemnly pledging themselves to the nation, that they would employ their united efforts in procuring a safe and honourable peace with France, while they never lost sight for a moment of the warlike plans of those who had preceded them.

About this time the most hostile measures were adopted by the powers composing the northern confederacy. The free city of Hamburgh was taken by a Danish army under Charles prince of Hesse, in order to injure the commerce of Great Britain; and the king of Prussia sent a numerous army into the electorate of Hanover. To punish this unaccountable conduct, and dissolve the northern confederacy, a fleet of 17 sail of the line, four frigates, four sloops, and some bomb vessels, was fitted out in the ports of Britain, which sailed from Yarmouth on the 12th of March, under the command of Admiral Sir Hyde Parker, Lord Nelson, and Rear-admiral Graves, and having passed the Sound, appeared before Copenhagen on the 30th of the same month. The Danes did not appear in the smallest degree agitated, for it was impossible to molest either the fleet or the city, without passing through a channel so extremely intricate, that it was once believed hardly safe to attempt it with a single ship, and without any enemy to oppose. This channel was sounded by Lord Nelson, who undertook to conduct a large division of the fleet through it, requesting from Sir Hyde Parker the command of it, which was accordingly given him, and Rear-Admiral Graves was his second in command.

528 The Danes vanquished by Lord Nelson at Copenhagen.

As the largest ships drew too much water for being employed in such a hazardous attempt, his lordship selected 12 of from 74 to 50 guns, together with four frigates, four sloops, two fire-ships, and seven bombs. A most prodigious force was opposed to this, consisting of six sail of the line, 11 floating batteries, each mounting from 26 twenty-four pounders to 18 eighteen pounders, one bomb-ship, and a number of schooners. These were supported by the Crown islands, mounting 88 pieces of cannon; by four sail of the line, moored in the mouth of the harbour, and by a few batteries on the island of Amak. Lord Nelson attacked this tremendous force on the 2d of April, and silenced the firing of the batteries after an obstinate and bloody action which lasted four hours, taking, burning, and sinking about 17 sail, including seven sail of the line. In killed and wounded the British lost 943 men, while that of the Danes must have been at least double the number. A suspension of hostilities was the immediate consequence of this brilliant victory, and a treaty of armed neutrality to last for 14 weeks.

529 Who sails from thence to Carlscrona.

After repairing the ships that were damaged upon this occasion, the British fleet sailed for Carlscrona, and appeared before it on the 19th of April. The governor here was immediately informed by the British admiral of what had happened at Copenhagen, requesting his Swedish majesty to give an explicit answer whether he meant to adhere to, or abandon the confederacy. The reply was very ambiguous; but having received the news of the sudden death of the emperor Paul, on the 23d of March, and Lord Nelson, now commander in chief, writing in a more peremptory tone than the officer whom he had superseded, the court of Stockholm deemed it prudent to follow the example of that of Copenhagen. Alexander, the son and successor of Paul, possessed of more honour and justice than his father, restored all the British property which he had confiscated, relinquished his absurd claim to the island of Malta, and agreed that neutral vessels should be searched, when bound for any one country at war with another, which proved the grave of the northern confederacy.

When the armistice was signed between the Austrian and French generals in the year 1800, the troops of the latter were in possession of Germany almost to the banks of the Inn, and of Italy to the frontiers of Venice; but the spirit of the emperor was yet unsubdued, and he would not abandon his allies by a confirmation of the preliminaries of peace which Count St Julian had agreed to at Paris, as he exceeded the powers with which he was entrusted. Kray having retired from service, the archduke John succeeded him, with whom the emperor in person repaired to the army; but they soon found it impracticable to act an offensive part against General Moreau, and therefore another armistice, comprehending Italy, was agreed to. The emperor wished to include Britain in any treaty with France, but as Bonaparte would admit no plenipotentiary from that country without the benefit of a naval armistice, which it was truly absurd to expect, General Moreau received orders to go on with his military operations.

53[illegible] The A[illegible] trians tally r[illegible] at Ho[illegible] linden.

The army of Austria was now given to the command of generals whose very names were almost unknown beyond the confines of their own country, and who evinced themselves but very little acquainted with the military art. As Moreau was pondering on the plan of his winter campaign, the right wing of his army was attacked by the Austrians with such vigour, as had nearly reduced him to the necessity of acting on the defensive; and had General Klenau known how to make a temperate use of his victory on this occasion, the ruin of the French commander would have been inevitable. The case was otherwise. Elated with his success, he unaccountably abandoned his position on the Inn, and engaging his cautious and able antagonist at the village of Hohenlinden, was totally routed, with the loss of 80 pieces of cannon, 200 caissons, and 10,000 prisoners, independent of a prodigious number left dead on the field.

General Moreau allowing the enemy no time to rally, proceeded directly towards the Inn, crossing it on the 9th of December, 1800, and driving his enemies before him, struck the court of Vienna with consternation and dismay. Prince Charles was recalled to the command of the army, but after many fruitless efforts to retrieve its lost honour, he proposed an armistice on the 27th of December, which was granted by the French commander, on condition that it should be be immediately followed by a definitive treaty. If the archduke could have had any dependence on his army, although very much weakened, this armistice, in all probability, would not have taken place, for the position of Moreau was perilous in the extreme. In the very heart of Austria, he had behind him on his right, about 30,000 men in the Tyrol, with upwards of 50,000 on his left. But Austrian valour was now almost extinguished by so many sad reverses of fortune, and Austrian officers were not true to their trust.

531 T[rea]ty of L[une]ville.

This armistice was followed by a treaty of peace signed at Luneville on the 9th of February 1801, between the emperor for himself and the Germanic body, and the first consul of the French republic, in the name of the people of France. By it the emperor ceded the Brisgau to the duke of Modena, for the territories lost by that prince in Italy, and bound himself to find indemnities in the Germanic empire for all those princes whom the fate of war had deprived of their dominions. The grand duke of Tuscany was to renounce his dukedom for ever, with its dependencies in the isle of Elba, to the infant duke of Parma, for which the empire was to furnish him with an adequate indemnification.

On the 28th of March a treaty of peace was concluded between the French republic and the king of the Two Sicilies, by which his majesty obliged himself to shut all the ports of Naples and Sicily against ships of every description belonging either to the British or the Turks, till these powers should conclude a treaty with the French republic, and till Britain and the northern powers should come to a good understanding. He renounced for ever Porto Longano in the isle of Elba, his states in Tuscany, and the principality of Piombino, to be disposed of in such a manner as the French republic might think proper.

[5]32 Br[itai]n deser[ted] by al[mo]st all Eu[rop]e.

Great Britain had now none to assist her in the contest with France, but the Turks in Egypt and the Portuguese in Europe, powers which rather diminished than increased her strength, by dividing it. The Spaniards had made an attack upon Portugal at the desire of France, conquering some of its provinces; but a treaty of peace was concluded between them on the 6th of June, by which the king of Spain restored all his conquests except the fortress of Olivenza, and the prince regent of Portugal and Algarva promised to shut the ports of his whole territories against the ships of Great Britain, and to make indemnification to his Catholic majesty for all losses and damages sustained by his subjects during the war.

[5]33 Bo[na]parte thr[eat]ens to i[nv]ade Bri[tai]n.

When the chief consul had made peace with all his other enemies, he threatened Great Britain with an immediate invasion, which gave great uneasiness at first to a considerable part of the nation, but it gradually subsided. In order to diminish this alarm, Lord Nelson was sent to destroy the shipping and harbour of Boulogne. His success in this undertaking fell short of the expectations which many had formed; but he made such an impression on the enemy on the 4th of August, as evinced that Britain could annoy the coast of France with greater facility, than France could molest that of Britain. It was also highly satisfactory to find that the spirit of the British navy was not exclusively attached to the hero of the Nile; for Rear-admiral Saumarez having, in the month of July, come up with a combined squadron of French and Spanish ships of war bound for Cadiz, much superior to his own, he scrupled not to give them battle, the consequence of which was, that one of them was captured, and two more were burnt.

534 Britain attempts to treat with France.

Attempts were again made by Britain during the summer of 1801, to negotiate with France. The first consul could not but see, from the total dissolution of the northern confederacy, that it was impossible for him to ruin the British commerce, and consequently that all the treaties he had made for the purpose of excluding our ships from neutral ports would signify nothing. He seemed determined, however, to keep possession of Egypt; and Britain, on the other hand, was as fully resolved to wrest it from him. On this account the negotiations were protracted, till the conquest of that country was known at London and Paris.

535 Rosetta, Cairo, and Alexandria, taken by the British.

When Sir Ralph Abercromby died, General Hutchinson succeeded to the command of the British forces in Egypt, who was probably acquainted with the plan of his much lamented predecessor, as one spirit seemed to actuate both. Rosetta soon surrendered, which was followed by the conquest of Cairo; and Menou having accepted of similar terms for Alexandria, the whole of Egypt fell into the hands of the allies, and the republican troops and baggage were conveyed to the nearest French ports in the Mediterranean, in ships furnished them by the allies. After these events, the negotiations between Britain and France went on more agreeably; and, on the 1st of October, the preliminaries of peace were signed at London by Lord Hawkesbury on the part of his Britannic majesty, and M. Otto on that of the French republic. By it Great Britain engaged to give up all the conquests made during the continuance of the war, excepting the islands of Ceylon and Trinidad. France was to restore nothing. The Cape of Good Hope was to be free to all the contracting parties; the island of Malta was to be given to the knights of the order of St John of Jerusalem; Egypt was to be given to the Ottoman Porte; Portugal was to be maintained in its integrity, except what was ceded to the king of Spain by the prince regent; Naples and the Roman states were to be evacuated by the French, Porto Ferrajo by the British, with all the ports and islands occupied by them in the Mediterranean; and plenipotentiaries were appointed to meet at Amiens, for the purpose of drawing up and signing the definitive treaty. This was concluded on the 22d of March 1802, in consequence of which the French republic was acknowledged by the whole of Europe.

536 Peace concluded at Amiens between Britain and France.

The restoration of peace, after so long and sanguinary a contest, gave the highest satisfaction to all ranks and denominations of men, with the exception, perhaps, of a few interested individuals; and it was certainly as honourable to Britain as could be well expected from the nature of the war. It was celebrated at Paris, in the cathedral of Notre Dame, with great pomp and magnificence. The celebration of the re-establishment of the Catholic religion in France, to which the majority of the people were warmly attached, gave additional importance to the scene in that country, and the measure evinced the most consummate political wisdom on the part of Bonaparte, whose popularity in consequence of it was very much increased. We shall now notice a few of

France. 1802. of the leading articles in the celebrated *Concordat*, or convention concluded between Bonaparte and the pope, by which the Catholic faith was again established in that country, dated 10th September 1801, and a few of the regulations established for the government of the Protestant churches.

By the regulations established for the government of the Catholic church, it is settled that no bull, rescript, decree, provision, or any thing in the place of a provision, or, in short, any other dispatch from the court of Rome, even though it should relate to individuals only, shall be received, published, printed, or otherwise put in force, without the authority of the government, and that no individual, assuming the character of nuncio, legate, vicar, or apostolic commissary, or whatever other appellation he may assume, shall be allowed to exercise his functions in France, but with the consent of the government, and in a manner conformable to the liberties of the Gallican church. The decrees of foreign synods, or even of general councils, are not to be published in France before the government shall have examined their form, their conformity to the laws, rights, and privileges of the French republic, and whatever might in their publication have a tendency to alter or to affect public tranquillity. No national or metropolitan council, no diocesan synod, no deliberative assembly, is allowed to be held without the express permission of government.

The archbishops consecrate and instal their suffragans, and watch over the maintenance of doctrine and discipline in the dioceses dependent on their see. No person can be named a bishop who is not a Frenchman, and at least thirty years of age. He must undergo an examination respecting his tenets, by a bishop and two priests commissioned by the chief consul. He nominates and instals the *curés;* who are not however to make public their appointment, till their nomination has been agreed to by the chief consul. The bishops are bound to reside in their dioceses, and are not at liberty to quit them without the permission of the chief consul.

The curés are to perform no ecclesiastical functions before they have taken, in the presence of the prefect, the oath prescribed by the convention entered into between the government and the holy see. They are bound to reside in their respective parishes; and they are directly subject to the bishops in the exercise of their functions. The vicars, and the assistants performing their duties, are under the superintendence and direction of the curés. They must be approved by the bishop, and are liable to be recalled by his authority. No priest can quit his diocese to serve in another without the permission of his bishop.

The archbishops and bishops who wish to exercise the power which is given them, by establishing chapters, are allowed to make no appointment without having previously obtained the authority of the government, not only for the establishment itself, but for the number and choice of the ecclesiastics by whom they are to be formed.

All ecclesiastics are required to dress according to the French fashion, and in black. The bishops add to this costume the pastoral cross, and violet stockings. Domestic chapels and oratories, for the accommodation of individuals, are not to be established without the express permission of the government, granted on the application of the bishop.

The bishop is to concert with the prefect the means of calling the faithful to religious worship by public bells, which are to be rung on no other occasion, without the permission of the local police. The curés in the ordinary exercise of their parochial duties pray for, and cause prayers to be offered up in behalf of the prosperity of the French republic, and the safety of the French consuls.

Article 58 fixes that there shall be in France 10 archbishops and 50 bishops; and article 60. fixes that there shall be at least one parish within the jurisdiction of a justice of peace, and as many subsidiary places of worship as circumstances may require.

The salary of the archbishops is to be 15,000 francs (about 625l. sterling), and that of the bishops 10,000 francs (about 420l. sterling). The curés are divided into two classes. The salary of the curés of the first class is to be 1500 francs (about 62l. sterling); that of the second class is to be 1000 francs (about 42l. sterling.) The pensions they enjoy according to the regulations of the constituent asembly shall be deducted from their salaries. But the general councils of the larger communes are empowered to grant them an augmentation of salary, such as circumstances may require.

The principal articles relating to the Protestant religion are as follows:

No individual is allowed to officiate, as a minister of religion, who is not by birth a Frenchman; and neither the Protestant churches nor their ministers are permitted to have any connexion with a foreign power or authority. The pastors or ministers pray for the prosperity of the French republic and the safety of the consuls. No doctrinal decision or formality, under the title of a *confession*, or under any other title, is to be published or become a subject of instruction before its publication has been authorised by the government; and no change can take place in the forms of their discipline without the same authority. The council of the state takes cognizance of all the plans formed by their ministers, and of all the dissensions which may arise among them. To the support of pastors of consistorial churches, the property of these churches is to applied, as well as the obligations established by usage and by positive regulations; and they are on the same footing as the Catholics in regard to the liberty of endowments, and the nature of the property which can be the object of them.

Two academies or seminaries are appointed in the east of France for the instruction of the ministers of the confession of Augsburg; and one at Geneva for the instruction of the ministers of the reformed churches. The professors in all these academies or seminaries shall be nominated by the chief consul. No person can be elected a minister or pastor of any of these churches, who has not studied during a fixed period in one of the seminaries appointed for ministers of this persuasion, and who cannot produce a certificate in due form of his capacity and regular conduct during the continuance of his studies.

WHEN Bonaparte was elected first consul for ten years,

years, he was deemed competent to be re-elected for the same length of time; but he was afterwards chosen for life, with the strange power conferred upon him of nominating his successor, or, in other words, of governing beyond the grave, than which nothing can be conceived more ridiculous or unjust. Having advanced with such rapidity in the acquisition of power and authority, it was extremely natural to conclude, that the ambition of Bonaparte was not satiated, but that he would afterwards claim to himself, and influence an infatuated people to sanction, still higher degrees of dignity and grandeur. A book was accordingly published, either with his permission, or by his express command, pointing out the propriety and expediency of creating him *First Emperor of the Gauls!* At a subsequent period of the history contained in this article we shall see this extravagant proposition actually carried into effect, and Napoleon I. adorned with imperial honours. This verifies what Dumourier asserted concerning the French, at a time when such an event was highly improbable; "that a king they would have."

537 Bonaparte chosen consul for life.

538 The extent of his power.

In the capacity of first consul, his power was similar to that of his Britannic majesty, in respect of criminals under sentence of death, that he could grant them at his pleasure a plenary pardon, and admit them to return again to the bosom of society; but his executive authority in almost every other case was dangerously greater, as there was in fact no other power in the state which could possibly controul him. While his authority was established thus firmly within his own dominions, he endeavoured to increase his influence over the rest of Europe, by forming an alliance with the court of Petersburgh. At first it was believed to be purely of a commercial nature, but the active part taken by both in dismembering the Germanic body, clearly evinced that such an alliance was of a more interesting nature, notwithstanding the ostensible reason for such conduct was the indemnification of the sufferers during the war.

It will perhaps be admitted, that the state of France, after the dreadful convulsions occasioned by the revolution, required an executive government of considerable promptitude and vigour; yet it was surely possible, and it was no less a sacred duty binding upon him, to consult, in particular circumstances, the happiness and prosperity of the people much more than he did, without endangering in the smallest degree the stability of his government. The French people should not have been deprived of the many blessings resulting from a representative government; and if not ripe for it then, it should have been conferred upon them at a subsequent period. If the hero of Marengo was afraid of facing a free parliament, he thus pronounced himself a tyrant, and if unable to moderate its deliberations, very deficient in political knowledge. He might find it expedient, for instance, to impose some restraints on the licentiousness of the press; but totally to annihilate its liberty was as unjust as it was impolitic. He should have recollected a saying of an historian and philosopher, "that a whisper may circulate as rapidly as a pamphlet."

Towards the termination of the year 1802, Bonaparte was very active in his visitation of the sea-port towns, where the most fulsome addresses were presented to him which were ever given to any mortal being. Various conjectures were formed as to the probable design of such visits. It was thought by some that he intended to conciliate the affections of the people, especially the military and the constituted authorities; others imagined that it was to make himself acquainted with the true state of public opinion; while a third class conjectured that it was with a view to increase the navy of France, and acquire an intimate knowledge of the different parts of the coast. Whatever his object was, it is more than probable that it was directed to one point, and that his complicated movements were purposely intended to mislead those who felt an interest in watching him. It is true, he made no secret of his determination to invade Great Britain; but we should greatly diminish that knowledge which he must unquestionably possess, were we to conclude that he ever seriously believed in the practicability of such an undertaking.

His abilities as a soldier will be disputed by no man, for when viewed only in this light, he is unquestionably *great;* but it would be a most unpardonable breach of truth to call him an able politician. While he promised to restore the commerce of France, it continued to languish, more perhaps after the restoration of peace, than during the continuance of the war. This seems to be a subject fairly beyond his comprehension. Numbers in France drew a great part of their subsistence from the expenditure of such persons from the British dominions, as were disposed, after the return of peace, to pay a visit to the metropolis of the Gallic empire. But while we thus freely animadvert on the conduct of the first consul, and point out his errors or faults without any reserve, we wish not to conceal a single circumstance which redounds to his honour. When Cambaceres, the bishop of Caen, made application to the prefect of Rouen to have the Protestant churches forcibly shut; as soon as the request of the bishop was known to Bonaparte, he sent for the second consul, and told him, that if the bishop had not been *his* brother, he would have struck him off the list. Such a reply was certainly worthy of a great man.

539 Character of Bonaparte.

On the 21st of February 1803, a view of the state of France was laid before the legislative body and the tribunate, containing a comprehensive view of the relations of the republic, both with respect to colonies and foreign states; but the most important part of it had a reference to Britain, which was charged with acting improperly in retaining troops in Malta and Egypt, after the signing of the definitive treaty. It divided the inhabitants of it into two parties, representing the one as having sworn implacable enmity to France, and the other as anxious to maintain the relations of peace and amity, concluding with singular bravado, "whatever may be the success of intrigue at London, it will never force other nations into new leagues; and the French government asserts, with just pride, that England alone cannot now contend with France."

540 Hostile preparations of France.

It now began to be manifest, that the blessings of peace were not to be long enjoyed. The extensive warlike preparations going forward about this time in the ports of France and Holland, roused the jealousy of the British ministry; for although the ostensible reason was to reduce the revolted colonies to obedience, they could not help apprehending that much more was comprehended in such extensive armaments. We shall still be more inclined to adopt this opinion, if we advert to the following

France. 1803. lowing circumstance. When Bonaparte, on the 13th of March, found Lord Whitworth and M. de Marcoff standing together, he addressed them in these words: "We have fought for fifteen years, and it seems there is a storm gathering at London, which may produce another war of fifteen years more.—The king of England has said, in his message to the parliament, that France had prepared offensive armaments; he has been mistaken; there is not in the ports of France any considerable force, they having all set out for St Domingo. He said there existed some differences between the two cabinets; I do not know of any. It is true that his majesty has engaged by treaty that England should evacuate Malta. It is possible to kill the French people, but not to intimidate them." At the conclusion of the drawing-room, it is said that Bonaparte addressed the British envoy thus, when near the door: "The duchess of Dorset has passed the most unpleasant season at Paris; I most ardently wish she may pass the pleasant one also; but if it is true that we are to have war, the responsibility, both in the sight of God and man, will be on those who shall refuse to execute the treaty."

Much about the same time a paper was inserted in the *Hamburgh Correspondenten*, containing much violent declamation against Great Britain, and believed by many to have been the production of Bonaparte. If our information be correct, the French minister requested, and obtained permission, from the magistrates of that city to make it thus public. Some alterations were made on the manuscript, which having given offence to the republican ambassador, it was, on the 30th of March, inserted without any alterations or supposed amendments. It contains many rancorous expressions against Great Britain, while part of it seems to be a designed apology for the insulting conversation which took place at Madame Bonaparte's drawing room already mentioned. It contains some reflections also on the freedom of discussion indulged in the British newspapers relative to the affairs of France, a circumstance far beneath the notice of the first consul, who, in this particular, did not advert to the freedom of the British press.

In the interior parts of France, the most active preparations for war continued to be made, and at the seaports, the different commanders received orders to put the navy as fast as possible on a respectable footing. Vast bodies of the military received orders to leave the Netherlands, and march towards the frontiers of the Batavian republic, while the ships destined for the Newfoundland fishery were laid under an embargo.

541 Disputes concerning Malta.

As the island of Malta was, by the treaty of Amiens, to be surrendered to the knights of the order of St John of Jerusalem, upon certain conditions, De Thomasi, the new grand master, sent M. de Bussy his lieutenant in the month of January, with full powers to demand possession of the island; to which the governor Sir Alexander Jonathan Ball, replied, that as some of the powers who had, by the 10th article of the treaty of Amiens, been invited to guarantee the independence of Malta, had not as yet agreed to that measure, he could not terminate the government of his Britannic majesty without farther instructions.

As the long and tedious correspondence carried on between Great Britain and France, by means of Lord Whitworth and M. de Talleyrand, which was laid before both houses of parliament on the 18th of May 1803, did not terminate in such a manner as the lovers of peace most ardently wished, a fresh rupture between the two countries seemed unavoidable. Officers were sent to reside in the principal sea-ports of Great Britain, vested with the character of commercial agents, but they were in fact detected in sounding the harbours, and in drawing plans of the ports; a glaring proof that some desperate blow was meditated against this country.

542 Hostilities re-commence between Britain and France.

In spite of the efforts of the British ministry to prevent a rupture, hostilities actually commenced on the 16th of May, and letters of marque were issued against the French republic. The ultimatum of Britain was conceived in these terms: "that the French government should not oppose the cession of the island of Lampedosa to his Britannic majesty; that the French forces should evacuate the Batavian and the Swiss territory; that a suitable provision should be made for the king of Sardinia; and, by a secret article, that Britain should be permitted to retain possession of Malta for ten years." Our readers will no doubt immediately conclude, that this was rejected; but France still made some feeble endeavours to negotiate, which appearing to the cabinet of St James's to be a pretext only to gain time, the war was considered as actually recommenced. All subjects belonging to Britain who were now found in France and Holland were arrested and detained; an event which was speedily followed by the march of a republican army towards Osnaburgh and Hanover, the former of which was taken possession of by General Mortier on the 26th of May, after which he took the town of Bentheim, and the Hanoverian garrison were made prisoners of war. Osnaburgh was abandoned by the Hanoverians on the 28th, and two days after the French got possession of Quackenbrook. His royal highness the duke of Cambridge was determined to stand or fall with the electorate; but as he was at the head of no more than a handful of troops compared with the army of Mortier, the regency urged him to retire from the command, as the probability of success was entirely against him. The duke, therefore, returned to Bremen, and reached Yarmouth on the 13th of June, along with Prince William of Gloucester.

Much about this period, General Mortier was waited upon by deputies from the regency, both of a civil and military nature, who begged that he would suspend his march, and proposed a capitulation. By this the Hanoverian troops were permitted to surrender on their parole, and agreed not to take up arms against France during the continuance of the war. Sums were to be raised for maintaining the republican army, while private property was to be held sacred.

If this promise, however, was really made, it does not appear that it was considered as binding, for it has been said that more flagrant acts of cruelty and injustice were scarcely ever perpetrated by people professing to be civilized. The following, we are told, is part of the information upon this subject communicated by private letters. "In the city of Hanover, and even in the public streets, women of the highest rank have been violated by the lowest of the brutal soldiery, in the presence of their husbands and fathers, and subjected at the same time to such additional and undescribable outrages, as the brutal

2

tal fury of the violators, inflamed by drunkenness, could contrive. Nor have we heard that the philosophers of Goettingen, the enthusiasts of equality and perfectibility, have been at all better treated." We suspect that this picture is too highly coloured; yet, if a thousandth part of the narration be true, of which we have only selected a specimen, we must allow it to be an indelible stigma on the French nation.

Bo parte labo s to rui ritish erce.

It had always been a favourite object with Bonaparte, to do as much injury as possible to the commerce of Great Britain, and therefore he now determined to shut against this country the ports of the Weser and the Elbe; and also insisted on the ports of Denmark being shut against vessels belonging to Britain, proposing to plant a French garrison in the city of Copenhagen, while the other powers of Europe seemed to behold his conduct with indifference or stupefaction. The French having put themselves in possession of the exclusive navigation of the Elbe, Great Britain determined to blockade it with ships of war, as a report then prevailed that Bonaparte would make use of that port for the purpose of invading Scotland. In this view of the matter, the conduct of Britain was highly commendable.

About this time the French army in St Domingo was in a most melancholy condition, as appeared from the information contained in some intercepted letters. Although about 10,000 men reached the island, in three months after General Rochambeau's arrival, when they were landed in the different ports, scarcely any traces of a reinforcement could be perceived, so much had his army suffered. The atrocities of the troops in their turn were also said to be great, and complaints made to the commanding officers were answered with threats. It appears that Rochambeau was obliged to have recourse to absolute falsehood, in order to keep up the spirits of his troops, and allay their discontent; giving out, what he knew could not be the case, that a reinforcement of 20,000 men was daily expected.

Brit put in a te of de ce.

In the mean time, the ministry of Great Britain used every effort to place the country in a secure and respectable state of defence, should the insatiable ambition of Bonaparte lead him to a serious attempt to invade it. The intelligent part of the people indeed believed that he never seriously intended to hazard the consequences of what he threatened, yet it was certainly prudent to prepare for the worst. The troops of the line were industriously and successfully recruited, the militia were called out and kept in actual service, and an army of reserve was raised with the utmost expedition. Having almost 500,000 troops of different species, Britain had no just reason to apprehend an invasion, being able to accomplish the destruction of the boldest invader. These troops were encamped along the coast, garrison towns were properly supplied with men, the greatest force was concentrated wherever the probability of a landing was strongest, and care was taken of the health of the military, as well as the appointment of the ablest generals to command them. Provisions, ammunition, and stores, were collected in abundance. As it was natural to conclude that London would be the great object with an invading army, the utmost attention was paid to the defence of those parts of the coast which are most adjacent to it.

Similar efforts were made to annoy the enemy by sea, and render their designs wholly abortive. To Lord Keith and Admiral Montagu was entrusted the command of the channel fleet; and an attempt was made at Granville to disconcert the preparations of France, by a detachment of ships under the command of Sir James Saumarez, which was so far attended with success as to intimidate the inhabitants, damage a number of houses, and destroy some boats in the harbour. Similar attacks upon Calais and Boulogne also tended to convince the French residing on the coast that they were far from being secure, although total destruction was not the consequence of such exertions. Lord Nelson then guarded the Italian seas, and Sir Edward Pellew and Sir Robert Calder were stationed off Ferrol.

545 Cruelties of the French towards the Hanoverians.

In the mean time the republican army in Hanover continued to oppress the inhabitants, and to devour the resources of that electorate. The Dutch were made to suffer almost as much from their new allies and pretended friends, as the inhabitants of a conquered country. They were dragged into a war, of which they certainly wished to be the unconcerned spectators, compelled to raise and maintain a large body of native troops, to receive garrisons into all their strong towns, to give up their sea-ports to the French, and expose their whole country as a scene of passage and encampment to the armies of the republic. Their trade was ruined, and their ports blocked up by the British at sea, on account of their alliance with France. The inhabitants of the Belgic provinces belonging to France were also severe sufferers by the levies of conscripts, the interruption which their trade and manufactures met with from the war, and the rigour by which they were governed. It was reported that the first consul had 300,000 effective men in readiness along the coast and the places adjacent, and that 2800 men were incessantly employed, augmenting and repairing the fortifications at Boulogne.

546 The British coasts are fortified.

During the month of November 1803, the sea-coasts of Great Britain and Ireland received fresh additions of strength, that if ever troops from France should dare to attempt a landing, they might be assured of meeting with a warm reception. The garrison of Plymouth was augmented to 13,700 landmen, besides 1500 seamen and marines. A battery was erected at Paul Point, for the defence of the Humber, and two others were to be built opposite to it in Lincolnshire. Exertions equally spirited were continued by sea. Sir Sidney Smith cruised off the Texel, and drove on shore on the coast of Holland, 12 armed ships of the enemy, three of which were captured. During the month of February 1804, the French and Dutch ports continued to be blockaded by the British navy with the utmost vigilance, a measure which the tempestuous nature of the weather frequently rendered hazardous. The preparations for an invasion of this country were still continued on the part of France, but no force of any consequence found it practicable to put to sea, owing to the vigilance of our cruisers. A number of gun-boats were taken at different times off Boulogne, and different other parts of the French and Dutch coasts, which might have convinced the people of these countries of the absurdity of expecting to accomplish any thing decisive against Britain by such inadequate means.

A plan was suggested for filling up the ports of the enemy with stones and the hulks of old vessels, so as to render it difficult, if not wholly impracticable, either for ships or small craft to make their way out of

them.

France.
1804.

them. The idea seems to have been taken from a fact well known, that harbours have been often ruined by the tides and currents of the sea, the deposition of sand from rivers, earthquakes, and other accidents; and therefore it was concluded that similar effects might be produced by artificial means. The accomplishment of such an object, if it were practicable, would be an ample compensation for the greatest expence.

It was the opinion of the discerning part of mankind long before it happened, that the ambition of Bonaparte would not always remain satisfied with the dignity of first consul, even for life; for although he could receive no fresh additions to his power and influence, yet there was reason to believe that the sound of such titles as have always been deemed higher and more dignified still, would be too fascinating for him to resist. Accordingly, on the 25th of April 1804, the following decree was issued by the tribunate of France.

"The tribunate, considering that at the breaking out of the revolution, when the national will had an opportunity of manifesting itself with the greatest freedom, the general wish was declared for the individual unity of the supreme power, and for the hereditary succession of that power:

"That the family of the Bourbons, having by their conduct rendered the hereditary government odious to the people, forced them to lose sight of its advantages, and drove the nation to seek for a happier destiny in a democratical form of government:

"That France having made a trial of different forms of government, experienced from these trials only the miseries of anarchy:

"That the state was in the greatest peril, when Bonaparte, brought back by providence, suddenly appeared for its salvation:

"That the consulship for life, and the power granted to the first consul of appointing his successor, are not adequate to the prevention of intrigues at home or abroad, which could not fail to be formed during the vacancy of the supreme power:

"That in declaring that magistracy hereditary, conformity is observed at once to the example of all great states, ancient or modern, and the first wish of the nation, expressed in 1789:

"That, enlightened and supported by this experience, the nation now returns to this wish more strongly than ever, and expresses it on all sides:

"That when France demands for her security an hereditary chief, her gratitude and affection call on Bonaparte:

"That France may expect from the family of Bonaparte, more than from any other, the maintenance of the rights and liberty of the people:

"That there is no title more suitable to the glory of Bonaparte, and to the dignity of the supreme chief of the French nation, than the title of emperor.

"The tribunate have come to the following vote:

"That Napoleon Bonaparte, the first consul, be proclaimed emperor of the French, and in that capacity be invested with the government of the French republic:

"That the title of emperor and the imperial power be made hereditary in his family in the male line, according to the order of primogeniture."

The foregoing decree having been put to the vote, it was carried by acclamation, with the single exception of the only member (Carnot) who delivered his sentiments against its adoption.

The senate presented an address to the first consul, in which they took great pains to convince him that the safety of France, and the happiness of Europe, depended entirely upon his acceptance of the title of Emperor of the French, and upon its being made hereditary in his illustrious family. The different divisions of the army of course sent addresses to the first consul, intreating him to condescend to become emperor of France.

Bonaparte requested them, in his answer, "to make known to him the whole of their thoughts." The senate then desired him to take the imperial and hereditary dignity. Bonaparte consented.

An address was presented by the senate to the first consul, in which they employed many arguments to convince him (they might have spared themselves the trouble) that the preservation of France, and the repose of all Europe turned on his acceptance of the dignified title of the emperor of the French, which right to be hereditary in his august family. The different divisions of the army hoped also that he would be graciously pleased to *condescend* (what an instance of humility!) to become emperor of France. Whether or not it may excite the astonishment of our readers, we can assure them upon the most undoubted authority, that he was so *humble* as to accept of it, and the following is his address to the conservative senate.

"Senators,

"Your address of the 6th last Germinal has never ceased to be present to my thoughts. It has been the object of my most constant meditation.

"You have judged the hereditary power of the supreme magistracy necessary, in order to shelter the French people completely from the plots of our enemies, and from the agitations which arise from rival ambitions. It even appears to you, that many of our institutions ought to be improved, in order to secure for ever the triumph of equality and public liberty, and present to the nation and to the government the double guarantee they are in want of.

"In proportion as I fix my attention upon these great objects, I am still more convinced of the verity of those sentiments which I have expressed to you, and I feel more and more, that in a circumstance as new as it is important, the counsels of your wisdom and experience were necessary to enable me to fix my ideas.

"I request you then to make known to me the whole of your thoughts.

"The French people can add nothing to the honour and glory with which it has surrounded me; but the most sacred duty for me, as it is the dearest to my heart, *is to secure to its latest posterity* those advantages which it has acquired by a revolution that has cost it so much, particularly by the sacrifice of those millions of brave citizens who have died in defence of their rights. Fifteen years have past, since, by a spontaneous movement you ran to arms, you acquired liberty, equality, and glory. These first blessings of nations are now secured to you for ever, are sheltered from every tempest, they are preserved to you and your children; institutions conceived and begun in the midst of the storms of interior and exterior wars, developed with constancy, are just terminated in the noise of the attempts and plots of our

our most mortal enemies, by the adoption of every thing which the experience of centuries and of nations has demonstrated as proper to guarantee the rights which the nation had judged necessary for its dignity, its liberty, and its happiness."

The new emperor was allowed to adopt the children or grand-children of his brothers, if arrived at the age of 18 years complete, and he without legitimate children of his own; but this privilege cannot be enjoyed by his successors. Failing both legitimate and adopted heirs, the crown shall be enjoyed by Joseph Bonaparte and his descendants; and failing Joseph and his descendants, it shall devolve on Louis Bonaparte and his descendants, &c. If a successor cannot be found in any of these channels, a *Senatus consultum*, proposed to the senate by the dignities (we presume it should have been dignitaries) of the empire, and submitted for the acceptance of the people, shall nominate an emperor. It was also decreed that the members of the imperial family should be called French princes, and the eldest son of the family, the imperial prince. Amongst other things it was enacted, that every emperor, two years after he comes to the throne, shall swear to maintain the integrity of the territory of the French republic! We have mentioned this last circumstance, wholly for this reason, that *the emperor of a republic* is no doubt a rarity to the greater part of our readers.

Tria[l] of state pri-soners in France.

The trial of the state prisoners commenced at Paris on the 29th of May 1804. They were charged with conspiring against the life and government of Bonaparte; but how great was our astonishment to find the justly celebrated General Moreau included in the number! Envy and jealousy of Bonaparte can alone have implicated this great man in such a charge, as he was heard to say on the arrival of the new emperor from Egypt;—"this is the man who is necessary to save France." Georges with 11 of his associates, were condemned and executed on the 25th of June; the gallant Moreau and four more, were sentenced to suffer two years imprisonment, and about 18 were acquitted. Some of those who were condemned were afterwards pardoned by imperial clemency, moved by the fascinating charms of female eloquence and female tears. The sentence of imprisonment against Moreau was commuted to banishment for life to the United States of America.

5[49] Coronation of Bonaparte.

The coronation of Bonaparte took place in the month of December 1804, which was accompanied on the part of the people by such demonstrations of apparent satisfaction as evinced the degraded state of the public mind in that unfortunate country. After receiving a number of the most fulsome speeches, filled entirely with bombast and falsehood, his imperial majesty delivered the following address. "I ascend the throne, to which the unanimous wishes of the senate, the people, and the army have called me, with a heart penetrated with the great *destinies* of that people, whom, from the midst of camps, I first saluted with the name of Great. From my youth, my thoughts have been solely fixed upon them (so it appears); and I must add here, that my pleasures and my pains are derived entirely from the happiness or misery of my people. My descendants shall long preserve this throne (a very bold prediction). In the field they will be the first soldiers of the army, sacrificing their lives for the defence of their country. As magistrates they will never forget, that contempt of the laws, and the confusion of social order, are only the result of the imbecility and uncertainty of princes. You, senators, whose counsels and support have never failed me in the most difficult circumstances, your spirit will be handed down to your successors. Be ever the prop and first counsellors of that throne, so necessary to the welfare of this vast empire."

550 Who writes a letter to his Britannic majesty on the subject of peace.

On the 4th of February 1805, a letter written by Bonaparte to his Britannic majesty on the subject of peace, was laid before the legislative body by the counsellors of state, in which he observed that providence, the senate, the people, and the army, had called him to the throne of France. He admitted that the two countries, over which they presided as the chief magistrates, might contend against each other for ages, but denied that it was for the interest of either to continue the contest. He requested his Britannic majesty not to deny himself the inexpressible felicity of giving peace to the world; for should the present moment be lost, he did not see how all his efforts would be able to terminate the war, which he considered as without any object or presumable result. He concluded with observing, that reason is sufficiently powerful to discover means of reconciling every thing, when the wish of reconciliation exists on both sides. On the 16th of the same month, a very splendid entertainment was given to the emperor and empress by the city of Paris.

551 The memorable battle of Trafalgar, in which Lord Nelson fell.

Never was any naval victory more glorious or decisive than that which was gained by the British under Vice-admiral Lord Nelson over the combined fleets of France and Spain, off Cape Trafalgar, on the 21st October 1805. The British commander in chief gave the signal for bearing up in two columns as they formed in the order of sailing, a mode of attack which had been previously ordered by his lordship, to prevent the delay and inconveniency of forming the line of battle in the manner usually adopted. The fleet of the enemy consisted of 33 ships, under the command of the French admiral Villeneuve. The Spanish division under Admiral Gravina, formed the line of battle with great coolness and skill, the heads of the ships being turned to the northward. The manner of attack was uncommon, and the formation of their line was consequently new. Few signals were necessary from the commander of the British fleet, because the flag officers and captains were made previously acquainted with the admiral's whole plan. The weather column was led by the commander in chief, on board the Victory, and Lord Collingwood in the Royal Sovereign took charge of the leeward division. The leading ships of the British columns breaking through the enemy's line, was the signal for commencing hostilities, which began about 12 o'clock. The ships of the enemy were fought in such a manner as did the highest honour to the officers by whom they were commanded, but they opposed a force which was not to be vanquished. About 3 o'clock in the afternoon the enemy's line gave way, many of their ships having struck their colours. Admiral Gravina then steered for Cadiz; and 19 sail of the line, of which two were first rates, fell into the hands of the victors, and three flag-

552 Germany is overrun by Bonaparte.

flag-officers, Villeneuve, Don Ignatia Maria d'Aliva, and Don Baltazar Hidalgo Cisneros, were made prisoners.

About the same time that the British navy acquired the most signal victory over the combined fleets of France and Spain, the emperor Napoleon was carrying his victorious arms through the heart of Germany, and forcing the emperor of that country to abandon his metropolis. He left Paris on the 24th of September 1805, to join the grand army, and reached Strasburg on the 26th, accompanied by the empress. Here he issued a manifesto to his army, in which he mentioned the commencement of the war of what he termed the *third coalition*, which he said was created and maintained by the gold and hatred of England. He declared he would fight till he had secured the independence of the Germanic body, and never again make peace without sufficient security of its continuance. He crossed the Rhine at Kehl on the 1st of October, and on the evening of the same day arrived at Ettlingen, where the elector of Baden was presented to him, along with his two sons. On the 2d he went to Stutgard, where the elector (now king) of Wirtemberg received him in the most magnificent manner, and the city was illuminated. The king of Wirtemberg agreed to furnish 6000 men for the assistance of France, and the elector of Baden 4000.

The French armies on the coast reached the banks of the Rhine in the month of September, and crossed that river on the 25th. General Bernadotte reached Franconia on the 23d, where he was joined by the Bavarian army of 20,000 infantry and cavalry; by the army of Holland under Marmont, and the Batavian division. This army of Bernadotte, about 40,000 strong, constituted the fifth division of the grand or imperial French army. It is remarkable that these three great men, Jourdan, Lecourbe, and Macdonald, were not employed; the reason assigned for which measure is, that Bonaparte suspected them of disloyalty ever since the condemnation of that singular officer Moreau. Bernadotte marched directly for the Danube on the 2d of October, and took a position at Ingolstadt. The rapidity with which the French forces moved seems to have disconcerted the Austrian commander completely, as no movements were made to oppose their progress.

Hostilities commenced on the 7th, when the Austrians were defeated with the loss of many killed, wounded, and prisoners, in attempting to oppose the passage of General Vandamme across the bridge of Donawert. Field-marshal Auffenberg, while on his march to Ulm, was completely surrounded by the French, and obliged to surrender. It is said that the Austrians here lost two colonels, five majors, 60 officers, and 4000 men made prisoners. Memmingen surrendered on the 14th to Marshal Soult, after which he marched on to Biberach, in order to cut off the retreat of the Austrians by that road. Marshal Ney crossed the Danube, and made an attack upon Elchingen a little above Ulm. The Austrians made a sortie, but were driven back to their entrenchments before Ulm, with the loss, it is said, of 3000 men taken prisoners; and at Langenau their loss amounted to the same number, in an action with Prince Murat, who commanded the cavalry. This officer again brought them to action on the 17th, when their loss was computed at 1000 men, and next day General Werneck's division was obliged to capitulate. From Albeck to Nuremberg, Murat is said to have got possession of 1500 waggons and 16,000 prisoners; but Prince Ferdinand effected his escape.

Ulm surrendered by capitulation on the 17th, and this unaccountable step was taken by General Mack, because Berthier assured him that the Austrians were on the other side of the Inn; that Lannes was in pursuit of Prince Ferdinand; that Werneck had capitulated, and that it was impossible for any succours to reach Ulm. After the surrender of this place, the Austrian generals who were made prisoners, were sent under an escort through Bavaria to Vienna, and Mack was entrusted with some proposals to the emperor of Germany.

On the 28th of October a spirited proclamation was issued by the emperor at Vienna, declaring that the views of Austria and Russia were extremely moderate, and execrating the designs and views of Bonaparte. Every division of the French army, except that under General Ney, crossed the river Inn on the 1st of November. Bonaparte himself was with the right wing at Saltsburg; and the centre, commanded by Prince Murat, marched towards Lintz with uncommon rapidity. The Austro-Russian army retreated to Maelk (50 miles from Vienna) as the enemy advanced. The Austrians and Russians made no stand between the Ens and Vienna, which latter place the French entered on the 12th of October. Bonaparte arrived on the 13th, and took up his quarters in the palace of Schoenbrun, about two miles from the city of Vienna. The French troops conducted themselves with the utmost propriety and decorum, which prevented any disturbance from taking place in the metropolis.

On the 27th November, as Bonaparte perceived the dreadful carnage which was inevitable from the conflict of two such prodigious armies as that of the allies and his own, was extremely anxious to spare the effusion of human blood, and for this purpose he proposed an armistice, which was rejected with disdain. It was not long before Bonaparte discovered that the allies were acting from presumption, want of consideration, and imprudence, of which circumstance he was but too well qualified to take advantage. At sunrise the battle commenced, and a tremendous cannonade took place along the whole line. It is almost needless to remark, that 200 pieces of cannon and 200,000 men made a most tremendous noise. In less than an hour the whole left wing of the allies was cut off, their right being by that time at Austerlitz, the head quarters of the Russian and Austrian emperors. From the heights of this place the emperors witnessed the total defeat of the Russians by the French guard. The loss sustained by the allies during the whole of this battle was estimated at 150 pieces of cannon, with 45 stand of colours, and 18,000 Russians, and 600 Austrians were left dead on the field. On the 5th of December an interview took place between the emperors of Austria and France, which lasted for two hours. An armistice was mutually agreed to, which was to serve as the basis of a definitive treaty. The emperor of Russia was comprehended in this armistice, on condition of marching home his army

France. 1806.

army in such a manner as the emperor Napoleon might think proper to prescribe. By virtue of the treaty of peace, the French agreed to evacuate Brunn on the 4th of January, Vienna on the 10th, and the whole Austrian states in six weeks after the signing of the treaty, except such as were ceded to Italy and Bavaria.

From the humbled situation of the emperor of Germany after the memorable battle of Austerlitz, it was natural to expect that he would feel it his interest to make peace with the French emperor, and accordingly the treaty of Presburg was signed and ratified on the 26th and 27th of November, 1805. By this treaty, Austria gave up the Venetian territories both in Italy and Dalmatia, with the islands in the Adriatic. She acknowledged Napoleon as emperor of the French and king of Italy, and acknowledged also the new royal titles of the princes of Bavaria and Wirtemberg.

A fleet which escaped from Brest in the end of 1805, had the bad fortune which usually attended the French maritime expeditions. It consisted of eleven sail of the line and some frigates; and a part of it under Admiral Le Seigle, after disembarking some troops and ammunition at St Domingo, was destroyed or taken by Admiral Sir J. Duckworth in Ocoa bay. The other division of the fleet under Admiral Villaumez, which was destined for the Cape of Good Hope, having learned the capture of that colony, sailed first to Brazil, and afterwards to the West Indies, and the coast of North America, where some of the vessels were shipwrecked, others taken by the British; and of the whole eleven sail of the line, the Castor only, with Jerome Bonaparte on board, returned to France. About the same time the Marengo and Bellepoule French ships of war, which had committed great depredations in the East Indies, were taken by Sir J. B. Warren near the Mauritius.

In August 1805, an expedition, consisting of about 5000 land troops, with a proportional naval force, under Sir David Baird and Sir Home Popham, sailed from England for the Cape of Good Hope, and disembarked in Saldanha bay on the 4th January 1806. The army having advanced, defeated the Dutch force on the 8th, and shortly after terms of capitulation were proposed by General Jansens. This important settlement with all its dependencies was given up to the British, and the Dutch army was sent to Holland at the expence of the British government.

The reduction of the Cape was followed by another expedition, the first result of which produced an extraordinary sensation in Great Britain. Sir Home Popham had formerly been entrusted with some schemes formed by the British government against the Spanish possessions in South America, but which had subsequently been abandoned. Thinking, however, that success would cover the crime of disobedience, and perhaps stimulated by the prospect of private gain, he carried away the whole naval force from the Cape, and persuaded Sir David Baird to supply him with a small body of troops. He sailed to the Rio Plata, and disembarked his small army of 1600 men, about 12 miles from Buenos Ayres on the 25th June 1806. The Spanish regular troops being all at Monte Video and Maldonado, the town was defended only by the militia, who retired and left it open to the British almost without the least shew of resistance. The news of the capture of the place, accompanied by a very exaggerated account of the advantages of the colony as a market for British manufactures, spread the most extravagant joy through Great Britain, and led to a multitude of ruinous mercantile speculations. The Spaniards had been surprised rather than conquered. Seeing the small amount of the British force, they drew a body of troops from Monte Video, armed the country population, and assisted by a conspiracy within the town, they attacked the British on the 12th August, compelled them to surrender, and marched them up the country as prisoners. Another army, however, arrived under Generals Whitlocke, Crawford, and Sir S. Achmuty, in June 1807. Monte Video was taken by storm, with the loss of 600 men in killed and wounded on the part of the British. On the 5th July, an attack was made on Buenos Ayres; but the Spaniards had fortified their houses, broken up the streets, and made their defences so strong, that after a bloody and obstinate conflict in the town, the British general found it necessary to enter into terms with the enemy in order to effect his retreat; and thus an expedition, undertaken foolishly and without authority, cost Britain a vast sum of money, and some thousand lives, and brought disgrace on her arms, while it was the means of tempting thousands of her citizens into ruinous mercantile speculations. We return now to events more immediately belonging to the history of France.

The king of Naples, who had agreed by a treaty with France to observe a strict neutrality during the Austrian campaign, had inconsiderately allowed a body of Russian and English troops to land at Naples. Bonaparte immediately availed himself of this circumstance, by issuing a decree from Vienna, "declaring that the king of Naples had ceased to reign." A French army under Joseph Bonaparte immediately advanced into Calabria, and the Neapolitan government gave up the country without resistance. The fortress of Gaeta alone held out for a short time, and the peasantry of Calabria carried on a desultory warfare of little importance. A British force from Sicily under General Stewart landed in the gulf of St Eufemia, on the 1st July 1806, advanced to Maida, where it met the French army of General Regnier, nearly twice as numerous. A battle ensued, in which the French received a signal defeat, with the loss of 700 men killed, and two or three thousand wounded or prisoners. As the Neapolitans, however, were not excited to any new exertions by this event, the British army returned shortly after to Sicily, and the French occupied the whole country.

The emperor Napoleon now prepared to consolidate the great accession of power and territory he had obtained by new arrangements. Hanover, which the French had occupied, was given up to Prussia, who surrendered to France certain districts in return. Prussia followed up this measure, by excluding British vessels from her ports in the Baltic; and the British ministry retaliated by blockading the mouths of the Ems, Weser, and other rivers flowing through Prussia. Joseph Bonaparte was raised to the throne of Naples; the Venetian territories were added to the kingdom of Italy, the succession to which, in failure of heirs from Napoleon, was settled on Prince Eugene Beauharnois.

France. 1806. Holland, to bring her system into a correspondence with that of France, received a king in the person of Louis Bonaparte; and Murat received the principalities of Cleves and Berg. To crown this series of changes, the old constitution of the German empire was dissolved, and by an act of 12th July 1806, nearly all the smaller German powers were united into a body, denominated the Confederation of the Rhine, of which Napolean was created the head, with the title of *protector*. This confederation furnished the French emperor with a large auxiliary force of good troops, and was a formidable instrument in his hands in all his future plans of aggrandisement. It was finally dissolved in 1813; but the principles upon which it was founded have been embodied with little alteration in the new Germanic constitution. (See CONFEDERATION of the RHINE, in the SUPPLEMENT.)

556 Battle of Jena. The king of Prussia soon found that his co-operation in Bonaparte's plans would not secure him from spoliation or degradation, when it suited the views of the latter to humble him. The Prussian army and population too resented the indignities to which their king had submitted; and the latter, after making great sacrifices to maintain peace, found himself hurried into a war by circumstances which made no change in his relations with France. The bad faith of France, indeed afforded him just grounds of war; but of that bad faith he was well apprised before he entered into his engagements. With an ill-advised precipitancy, his preparations disclosed his hostile intentions before means had been taken to insure the support of Russia in sufficient time. Napoleon, who was never behind his opponents on such occasions, immediately assembled a formidable army, and advanced into Germany. Some actions of little importance brought the armies in presence of each other at Jena in Saxony, on the 13th October 1806. The battle commenced at day-light next morning between the armies, estimated at 130,000 men each. After a struggle of two hours the first advantage was gained by Marshal Soult on the French right; but this was by no means decisive. The Prussians, thrown partially into disorder, formed anew and fought bravely; but while the combat continued in suspense, Murat, who commanded the reserve, made a sudden and vigorous charge with the whole forces under his command, and overthrew the Prussians entirely. Never was a victory more complete. The Prussians, according to the French account, lost 20,000 killed, from 30,000 to 40,000 prisoners, besides 300 pieces of cannon, and immense magazines of military stores and provisions. The duke of Brunswick, and General Ruchel were among the killed. Such was the panic produced by this disaster, that most of the Prussian garrison towns, though well prepared for a siege, surrendered without attempting resistance. Erfurth with a garrison of 14,000 men, Magdeburg with 22,000, Stettin with 6000, Hameln, with 9000, Spandau and other fortresses, were reduced almost without bloodshed. Blucher alone distinguished himself by an obstinate but unsuccessful resistance. The French passed through Leipsic, and reached Berlin in a few days. A single victory gave them almost complete possession of the Prussian monarchy. The unfortunate king retired to Konigsberg, where he collected the wrecks of his army, scarcely amounting to 50,000 men, in order to await the arrival of his Russian allies. Bonaparte in the mean time organized a provisional government for Prussia; occupied Hamburgh, Lubeck, and other ports; and, irritated at the real or pretended abuse of the right of blockade by the British, he issued his celebrated Berlin decree, declaring the British islands in a state of blockade. The great extent of sea coast which he now commanded, enabled him to exclude the manufactures and merchandise of Great Britain from the continent much more effectually than he had ever done before; and though this decree was at first regarded as an impotent and ridiculous threat, the event shewed that it was the means of inflicting a serious wound on the commerce of Britain.

An ineffectual attempt was made by the king of Prussia to negociate; but the terms offered by the conqueror were so humiliating, that he preferred trying the chances of war with the aid of his Russian allies. About the end of November a division of the French army reached Warsaw, and re-established a bridge which the Russians had destroyed. The other corps arrived in succession, and crossed the Vistula. The Russian army was now collected in the part of Poland, immediately eastward of that river, and hostilities commenced. After some actions of less importance, a pretty severe engagement took place at Pultusk, in which the Russians were worsted, though they made a most determined resistance. The depth of winter now suspended hostilities for a short time. A part of the population of Silesia, excited by a proclamation of the king of Prussia's, had risen in arms; but they were defeated by a French force under Jerome Bonaparte, and after a short struggle, nearly all the fortresses in the province surrendered to the enemy. Early in February 1807, the contending armies, strengthened by reinforcements, recommenced hostilities. On the 7th and 8th was fought the battle of Eylau, one of the most obstinately contested engagements in modern times. The issue was in favour of the French, who remained masters of the field of battle; but it was by no means a decisive victory; and though the loss on each side was estimated at 30,000 in killed, wounded, and prisoners, no consequence of any importance resulted from it. During the pause which followed this bloody contest, the French pushed vigorously the siege of Dantzic; and that fortress was at last surrendered to them on the 21st May, after a brave defence by General Kalkreuth, and after repeated attempts by the allies to throw succours into it had failed.

The combined Russian and Prussian armies having collected their various corps, began a series of attacks on the French on the 5th of June, and continued them to the 12th, in all of which, however, they failed, and generally with great loss. On the 14th was fought the battle of Friedland. It commenced at five in the morning, and continned till seven at night; and though the Russians fought with determined courage, and succeeded at some points, the ignorance of their commanders, and the superior tactics and skill of the French, gave the latter a most decisive victory. The Russians lost altogether in the ten days, from the 5th to the 14th, forty thousand men, and twenty-seven generals. After the defeat they abandoned Koningsberg, crossed the Niemen, and continued their retreat eastward. Napoleon arrived at Tilsit on the 19th, and two days after this

this an armistice was agreed upon. On the 25th the emperors of Russia and France met on a raft constructed on the Niemen, and conferred together for two hours. Entertainments, reviews, and fetes followed, with all the external demonstrations of friendship and harmony. The peace of Tilsit, signed on the 9th July, deprived Prussia of all her territories on the left of the Elbe, and of all her recent acquisitions in Poland: Dantzic was created an independent town; East Friesland was added to Holland; the ceded Prussian territories in Germany were erected into the kingdom of Westphalia, the sovereignty of which was bestowed on Jerome Bonaparte; and the emperor Alexander agreed to recognize the titles of this new prince, of the kings of Holland and Naples, and of the new kings belonging to the Rhenish confederation. But what was most disgraceful to the Russian emperor, he obtained for himself the cession of a district of Polish Prussia from his distressed and humbled ally, to redress whose wrongs he pretended to take up arms. By a secret article Russia ceded the Ionian islands to France, and engaged to enforce the French continental system by excluding British vessels from her ports. In short, never had France acquired before in one campaign such extraordinary advantages.

Negociations for peace had been opened in February 1806 between the governments of France and Britain. The French ministers, however, shifted their ground again and again, eluded all direct and intelligible propositions, and seemed so anxious to separate the claims and interests of Britain from those of her ally Russia, that after some months spent in discussion, no progress was made, and all hopes of peace were abandoned. Mr Fox died during the discussions, but it is not probable that the prolongation of his life would have given a different termination to the negociations. Shortly after the treaty of Tilsit, Russia offered her mediation towards effecting a peace between England and France, but the offer was couched in terms so offensive to the British government, that it was promptly declined. In this state of things the ill-considered expedition to Copenhagen was undertaken, and furnished the Russian emperor with a most plausible pretext for those hostile measures to which he was already disposed. He was no sooner apprised of the seizure of the Danish fleet, than he dismissed the British ambassador, and published his resolution to put an end to all commercial intercourse with England, and to revive the principle of the armed neutrality. This was received and replied to as a declaration of war by the British government. The British property in Russia was forthwith confiscated, and the most vigorous measures were adopted to exclude our manufactures. The great extent of coast which Bonaparte now commanded, enabled him to make his edicts against our commerce operate with signal effect, and the pressure became very severe upon the cotton manufacturers and the West India planters. Parliament appointed a committee to investigate the subject, but, as might be expected, no means could be devised to afford any effectual relief. The orders in council issued by the British government, January and November 1807, were found to inflame the evil they were designed to cure.

On Bonaparte's return from the north after such splendid conquests, congratulations from public bodies and public functionaries flowed in upon him in uninterrupted succession: the powers of language were exhausted to find expressions, and history was ransacked to find comparisons, to set forth the glory and grandeur of his achievements. Now was the moment for his ambition to pause from schemes of conquest, and for giving his cares to those measures of internal improvement, which he declared should henceforth occupy his attention. But with such means of conquest in his hands, new enterprises were sure to tempt his ambition. Portugal had hitherto been suffered to enjoy a neutrality which had been denied to stronger states. Her trade with Britain, however, was now become an inexpiable crime; and as she refused to adopt the continental system, which would have involved her in war with her ancient ally Great Britain, her subjugation was resolved on. The government, fully apprised of the intentions of France, prepared a fleet, and on the approach of General Junot with a French army, the prince regent and court set sail for Brazil. As the means of the country were inadequate to a war with so powerful an enemy, no resistance was made; and so rapid was the approach of the enemy, that before the fleet had got out of the Tagus on the 29th November 1807, the French army was seen upon the heights.

557 Invasion of Spain.

Napoleon was now about to enter on another enterprise, more daring in its nature than any he had hitherto engaged in; and as the event shewed, more difficult and hazardous in its execution. The imbecile and disorganized government of Spain had hitherto been a passive instrument in his hands, by which he had held at his disposal the resources of the country, such as they were. But as he had already given kings to Holland and Belgium, he was tempted to think that Spain would consent with the same facility to see the drowsy and useless figures which misgoverned her thrust aside, and replaced by a branch of the imperial family. To pave the way for the meditated change, 16,000 Spanish troops, the flower of the army, were drawn away to Germany to act as auxiliaries to the French. And under the pretext of securing possession of Portugal, bodies of French troops, to the number of 70,000, were introduced into the north of Spain, and placed in the fortresses which commanded the roads into the country. When things were thus prepared, a plot was got up or discovered for killing the old king, in which his son Ferdinand was implicated; and afterwards the court was persuaded to embrace the absurd resolution of emigrating to Mexico. The discovery of this intention led to a popular tumult. The king intimidated, dismissed his minister Godoy, and resigned the crown in favour of his son Ferdinand. Murat was no sooner informed of these transactions than he advanced with the French army towards Madrid, and getting possession of the person of the deposed king, the latter declared that his resignation was compulsory. Ferdinand alarmed by the approach of the French, and the declaration of his father, was prevailed upon in an evil hour to submit his claims to Napoleon, and to repair to Bayonne to receive his award. When the two princes were thus within the power of Napoleon, a resignation of the crown was extorted from both, from the father on the 5th, and from the son on the 10th of May 1808, after which the royal prisoners were marched into the interior of France.

Murat

Murat in the mean time advanced to Madrid, and obtained possession of the city, but the spirit of the Spaniards was roused by the indignities offered to their king. The populace, unaided by the authorities, boldly attacked the French and drove them out with great loss on the 2d of May; but the latter returning in greater force, repossessed themselves of the town, and put to death above a hundred of the inhabitants in cold blood as conspirators. The supreme junta, entrusted by Ferdinand with the government, basely repressed the rising spirit of the people; and the holy inquisition did not scruple to lend its aid to a treacherous enemy, and to issue a circular enjoining submission to the French, accusing the people of faction and insubordination, and laying the guilt of the recent bloodshed upon them. When the news of the resignation arrived, it produced a universal burst of indignation. The spirit of resistance spread from province to province: Juntas were formed, among which that of Seville peculiarly distinguished itself by its activity and wisdom. Muskets and amunition were dispatched from Britain; all the unmarried men from 18 to 45 were summoned to arms, and a correspondence was established among the patriots in the different quarters of the country. The first measures of the Spaniards were eminently successful. Five French ships of the line lying in Cadiz were forced to surrender after three days cannonading. General Dupont, who had been dispatched too late to take possession of that port, attacked a superior force of Spaniards at Baylen, but was repulsed with such loss that he was not able to effect his retreat, and surrendered his army of 14,000 men prisoners. In the north Palafox defended Saragossa with astonishing courage and perseverance. The French were defeated with great loss in two attacks upon Valencia; and Joseph Bonaparte, after coming to Madrid with the title of king, backed by the nobles and the inquisition, and with a new constitution in his pocket, was compelled to measure back his steps on the 27th July. Thus, within less than three months Spain was almost cleared of its enemies by the valour and patriotism of its population.

These unexpected reverses had in no respect shaken Bonaparte's purpose. A new levy of 160,000 men was ordered in France; and large reinforcements were poured into Spain. Napoleon, after holding a meeting with Alexander at Erfurth, and receiving additional assurances of his support, joined his army in Spain, which had occupied the line of the Ebro for some months. By a series of persevering attacks, the three principal Spanish armies under Castanos, Blake, and Count Belvedere, were broken, and in a great measure dispersed; and on the 4th December Napoleon entered Madrid, after battering it for two days.

A British army of 30,000 men under Sir Arthur Wellesley landed in Portugal in July to assist the Portuguese, who had begun to rise in arms, in expelling their invaders. Junot advanced from Lisbon to meet them, and on the 21st of August was fought the battle of Vimiera, which ended in the defeat of the French. By the convention of Cintra which followed this battle, the British generals agreed to transport the French army to France; and much dissatisfaction was excited in England when it was found that so decisive a victory had not enabled the British commanders to dictate more humiliating terms. The generals were called home to be tried; and Sir John Moore was appointed to command the army. An additional force under Sir David Baird landed at Corunna, and the two armies advancing into Spain joined at Valladolid. Notwithstanding the flattering promises of support they received from the supreme junta, not a single regiment of Spaniards joined them; and the commanders having at length learned that Bonaparte was advancing upon them with a force of 70,000 men, they found it indispensable to retreat. As it was now the depth of winter, the retreat was attended with great loss and incredible hardships to the troops. The army reached Corunna on the 12th January 1809, and on the 15th was attacked by the French under Soult. They were repulsed at all points, but the death of General Sir John Moore, who fell early in the engagement, damped the joy of the victors. He was buried the next morning on the ramparts of Corunna. The loss of the British was about 700 in killed and wounded; that of the French about 2000. The British army embarked next day, and returned to England.

The occupation of so large a portion of the French force in Spain seemed to present a favourable opportunity to Austria for recovering some of her losses. She had been silently, but diligently, increasing and improving her military establishment, and re-organizing her finances. Bonaparte, who kept an eye on her proceedings, endeavoured to intimidate her; but failing in this object, he prepared for war. He called up the contingents of the Rhenish confederation, and with these, added to some large bodies of French troops, advanced into Bavaria. He attacked and defeated the Austrians at Ebensberg on the 20th, and at Eckmuhl on the 22d April, in which two battles the Austrians lost 40,000 men. These successes laid open the whole of Austria to him, and he reached Vienna on the 10th May, which was surrendered after a trifling resistance. The archduke Charles retired to Hungary, and took up a position near Presburg; and on the 21st and 22d was fought the battle of Aspern, one of the most bloody and obstinately contested engagements which has occurred in modern times. The Austrians were the assailants; and though they did not succeed in their object of driving the French across the Danube, it is yet clear that the latter suffered the greater loss, and had no victory to boast of. Not less than 30,000 men were killed or wounded on each side. The situation of Napoleon had never before been so critical. During the month of June he was assiduously employed in collecting troops. On the 6th July, having completed his preparations, he attacked the Austrians at Wagram, and by superiority of skill, more than numbers, gained a decisive victory. The loss of the Austrians, according to the French accounts, amounted to 40,000 killed and wounded, and 20,000 prisoners. Another defeat at Znaim entirely ruined their hopes; and they now sought peace on the conqueror's terms. The treaty of Presburg, which was not definitely arranged till October, subjected Austria to less considerable sacrifices than had been expected. To France she gave up Fiume and Trieste, with the whole northern shores of the Adriatic; to Bavaria certain districts between the Alps and the Danube, with the Tyrol; to Saxony she ceded the western part of Galicia, and to Russia the district of Tarnopol on the east of that province. In the Tyrol, and in the north-west of Germany, a desultory war was carried on against the French for a short time; but the resistance in both cases proved unavailing.

Bonaparte, in the course of this campaign, had annexed the papal territories to the French empire, by a decree dated from Vienna. Parma, Placentia, and Tuscany, had been added some time before.

Soon after the breaking out of the war between France and Austria, the British ministers collected a large force, naval and military, for an expedition, the object of which was kept a profound secret. It sailed from the Downs on the 29th July, and on the 1st August, Flushing, in the island of Walcheren, was invested. The place held out till the 14th, when the garrison of 4000 men surrendered prisoners of war. Antwerp was the main object of the expedition; but the British commander, the earl of Chatham, had neglected to seize some forts which would have facilitated his approach to the place; the French had employed the time lost in the siege of Flushing in strengthening the defences; and the capture of that great naval depot was now judged to be impracticable. The expedition then returned to England, to the great disappointment of the nation, who anticipated some more important result than the occupation of a useless sandy island, from an expedition consisting of 40,000 chosen troops, and 35 sail of the line. The public mortification was increased in the sequel. The ministers resolved to keep possession of Walcheren, apparently for no other reason than that they were ashamed to renounce what had cost them so dear. A pestilential fever, the annual and regular scourge of the place, which broke out among the troops, destroyed or disabled nearly all who remained in it, and ultimately rendered it indispensable to abandon the island.

In the month of April, this year, a most gallant and daring attack was made by Lord Cochrane on the French fleet in Basque roads, by which six ships of the line were driven on shore and rendered useless, and three others, besides frigates, were burnt.

After the expulsion of the British from the peninsula, the Spanish armies were attacked by the French, and defeated in various engagements; but the patriotism of the people soon filled up the ranks again, and kept a respectable force on foot. Saragossa was besieged a second time, and defended with incredible valour and perseverance, till it was reduced to a mass of ruins, and 30,000 of its inhabitants had perished by the sword and disease. Another British army, which had been recently landed in Portugal under Sir Arthur Wellesley, marched into Spain, and joined the Spanish force under General Cuesta. The two armies advanced towards Madrid, and at Talavera were attacked by the French under Marshal Victor. The battle continued two days, and terminated in the repulse of the French, who retired in good order. The loss of the latter was estimated at 10,000 men; that of the British and Spaniards at 7000. The rapid advance, however, of Soult and Ney from the south compelled the British general to measure back his steps to Badajoz, and no advantage was reaped from the victory. From the middle of summer to the end of the year a number of actions were fought between the French and Spaniards, in which the former were generally successful, though they sometimes experienced reverses. The battles of Ocana and Alba were peculiarly disastrous to the Spaniards, and broke their confidence so completely, that for a considerable time after they offered little resistance to their enemy, who possessed himself of Seville, and all the most considerable places in the south except Cadiz.

Massena arrived in Spain in the spring of 1810 with large reinforcements, and assumed the command of the French army destined to act against Portugal. After taking Ciudad Rodrigo and Almeida, he advanced to Busaco, and attacked the British in their strong position there, but was defeated with great loss. The pass by the northern edge of the Sierra, however, being left open by accident, he proceeded through it to Coimbra, and thence to Torres Vedras, where finding the British army posted in an impregnable position, he retired a short distance, and took up his quarters at Santarem. Here he remained from the 15th November to the 5th of March, when he returned to Spain, continually harassed in his retreat by the British.

In the course of this year, the islands of Guadaloupe in the West Indies, and of Mauritius and Bourbon in the Indian ocean, were taken from the French by the British with little loss.

The peace of Presburg had put it in Bonaparte's power to accomplish an object, on which it is probable his thoughts had long been bent. Possessing a power surpassing that of any sovereign in Europe, he was anxious to ally himself by marriage with some of those royal families, who could add the lustre of ancient renown to the titles which the sword had given him. His marriage with the archduchess Maria Louisa took place in March 1810. It was followed by splendid fetes, and multitudes of addresses, couched in the most sickening style of hyperbolical flattery. As if this new alliance had made him more regardless of public opinion, he, about the same time, issued several decrees of a most arbitrary nature, of which one authorized the detention of all such persons as the government might suspect, without bringing them to trial; another ordered the names of all servants, male or female, employed in families, to be registered at the police, obviously for the purpose of perfecting the system of espionage previously established; and several others subjected the press to a rigid censorship, and limited the number of printers and booksellers. His brother Louis, king of Holland, being found too humane for the rigorous system he had adopted, was set aside; and that unhappy country, as well as Bremen, Hamburg, and Lubeck, with the intermediate sea coast, were added to the French empire. He was now in fact at the acme of his power. Within the empire, if he did not enjoy the love of his subjects, he had dazzled their judgments by his exploits, and commanded their admiration. The conscription furnished him with an inexhaustible supply of soldiers. His revenues were equal to his expenditure; and a crowd of tributary kings and princes, who owed their dignities to him, enabled him to command the resources of all the adjacent countries. Of the only two princes on the continent capable of disturbing his security, the one was his firm supporter, and in some measure the participator in his crimes; the other was closely connected with him by family ties. The countries directly under

France. 1811. under his authority were now a half larger than old France, and contained *forty-four millions* of inhabitants; but including the dominions of his tributary princes, namely, Naples, Lombardy, and the confederation of the Rhine, he ruled over an extent of territory embracing 490,000 square English miles, and containing *seventy millions* of inhabitants. This is exclusive of Spain and Prussia. So great an extent of dominion had never been held by one man in modern times; and yet, with all its appearances of stability and overwhelming power, the causes were already in operation which worked its overthrow.

During 1811 the war was carried on with undiminished activity on both sides in the Spanish peninsula. A division of the British army having laid siege to Badajoz, Soult advanced to relieve it, and attacked Marshal Beresford at Albuera. The battle was remarkably obstinate and bloody, but the French general did not drive the British from their post, though he did not sustain a defeat. The siege, however, was raised, though only for a short time. Another battle, equally obstinate and bloody, was fought between some divisions of the British and French armies at Fuentes d'Honor, which ended in the repulse of the French. Another glorious but unprofitable victory was gained by General Graham at Barrosa, in March. On this occasion, the jealousy or cowardice of the Spanish general, La Pena, alone prevented the total destruction of the French army. Badajoz and Ciudad Rodrigo were taken by the British, the latter by a very bold and gallant attack. To balance these successes, however, the French took Tarragona, Murviedro, Figueras, and Valencia; but none of them without considerable resistance. A series of defeats had at length taught the Spaniards the imprudence of meeting the French armies in the field. They now confined themselves much more to desultory hostilities, the surprising of posts, the harassing of foraging parties, the intercepting of supplies and dispatches. The small corps who carried on this species of warfare had the name of *guerillas;* and a new race of leaders sprung up among them, who attained great distinction by their courage and enterprise. Of these Sanchez, Porlier, Mina, and Martin were the most celebrated.

After the reduction of Badajoz and Ciudad Rodrigo, the British army moved northward; and on the 22d July 1812, was fought the celebrated battle of Salamanca, in which the French, under Marshal Marmont, were defeated with the loss of about 13,000 men, of whom 7000 were made prisoners. This splendid victory was immediately followed by the evacuation of Madrid by Joseph Bonaparte; and shortly after Soult raised the siege of Cadiz, and retired northward. Lord Wellington pressed on the broken French army for some time, but failed in his attempt to take Burgos from the want of heavy artillery. The French, however, having soon concentrated their different armies, were again in a condition to advance. They compelled the British commander to raise the siege of Burgos, and about the end of October again occupied Madrid. The retreat of the British was attended with much loss, chiefly in consequence of the state of the weather and the roads.

553 War with Russia. At the peace of Tilsit, the emperor Alexander had agreed to adopt the continental system, by excluding British manufactures and produce from his ports. He persevered in this course till the complaints of his nobles induced him to relax the prohibition, and to permit British goods to be imported in limited quantities under licence. This concession, which had been wrung from him by necessity, was highly resented by Napoleon, who seized the duchy of Oldenburg, belonging to the emperor's brother-in-law, and presented menacing remonstrances to the Russian monarch. Alexander, though really anxious for peace, could not revoke the concession, and nothing less would satisfy his ally. Both sides then prepared for war. Bonaparte collected the troops of Westphalia, of the Rhenish confederation, and of Italy; and with these, joined to a large body of French stationed in Prussia, he took the field. This army was computed to amount to 360,000 men; and certainly surpassed in numbers, discipline, and in the skill of the commanders, any that Europe had ever witnessed. The Russians had been equally diligent in preparing for hostilities; but as a great part of their troops were new levies, it was part of their plan not to hazard a general action at first, but to train their men to military habits by the defence of posts, and by partial engagements. Napoleon left Paris in May 1812, and reached the banks of the Niemen 22d June. A continued series of small engagements followed, in which the French, though they generally saw their enemies retreat, had little advantage to boast of. The Russians, though inferior to their enemies in discipline and equipments, constantly displayed a desperate courage. In every contest, small or great, the victors purchased their success extremely dear, and few prisoners were taken on either side. The first general battle was fought under the walls of Smolensko on the 17th August, and terminated in the defeat of the Russians, and capture of the town, which was on fire in many places when the victors entered it. Had Napoleon now stopped in his career, and employed the winter in organizing Poland, of which he had complete possession, he might, in the ensuing spring, have resumed his operations under the most favourable auspices, and in all probability have dictated a peace under the walls of Petersburg. But a fatality hurried him on, against the advice, it is said, of his ablest generals. He followed his enemy boldly into the centre of Russia, undismayed by the approach of winter. The sanguinary battle of Borodino, in which the Russians were compelled to retire, rather than defeated, opened his way to Moscow, which he entered on the 15th September. But what was his surprise to find that the Russians had set fire to their ancient capital. The flames burst out in a hundred places after the French entered the town; and four-fifths of the houses were destroyed. The conqueror now saw the dangers of his situation; and after waiting some time in the hope of receiving a submissive application for peace from the Russians, he at length condescended to offer them terms. His proposals were indignantly rejected. Mortified by this circumstance, he reluctantly left Moscow on the 16th October. We forbear to give the details of the disastrous retreat which ensued. Suffice it to say, that the vengeance of an exasperated enemy tracked his footsteps, and left him not a moment's respite. The country in his rear had been occupied, and his exhausted and dispirited army had to dispute every height and every pass. Those whom the sword spared, the

the rigour of the climate destroyed; and of the fine army of 360,000 men, with which he entered Russia, scarcely 50,000 returned to Poland. At the end of the year the wrecks of the army reached Marienwarder in Prussia.

Napoleon had left the army in Poland, and travelling rapidly with a small escort, he arrived in Paris before the end of the year. In his address to the legislative body, he admitted that a heavy calamity had befallen the army, to repair which, great sacrifices would be necessary. A pompous exposition was then made of the resources of the country, and of the improvement which had taken place in it since the revolution. On the 11th January 1813, a *senatus consultum* was issued, decreeing a levy of 350,000 men; and so perfect was the system of the conscription, that in a few weeks this enormous levy was raised, and after a short drilling, the men were marched off to Germany, in separate bodies. Napoleon before leaving Paris, effected a reconciliation with Pope Pius VII. by restoring his temporal possessions; and he at the same time nominated the empress regent during his absence. He joined the army on the Elbe about the middle of April.

The emperor Alexander was determined to follow up his successes with the utmost vigour. New and extensive levies were made throughout his empire, and he endeavoured at the same time, to engage the kings of Sweden and Prussia in the war. As Denmark continued to adhere to the French cause, the bait held out to the Swedish crown prince, was the conquest of Norway, in which Alexander engaged to assist him. The king of Prussia had so often suffered from the overwhelming power of France, that his fears held him long in suspense, and he was at last only driven into an alliance with Alexander, by the impatience of his subjects to deliver themselves from the French yoke. At length both he and the Swedish crown prince engaged cordially in the cause. Austria for the present professed neutrality; but Napoleon was aware that no reliance could be placed on her, and that any fresh disaster might tempt her to become his enemy, notwithstanding the family alliance. She had recruited her army, and put herself in a condition to derive advantage from any circumstances which might occur.

Campaign of 1813.

The campaign was opened in April. The French army assembled on the Elbe amounted to 170,000 men, but with a very small proportion of veteran troops. The Russian, Prussian, and Swedish forces were estimated at 200,000. After some fighting, of less consequence, the two armies met on the field of Lutzen, on the 2d of May. A line of five or six villages occupied by the French were attacked, taken and retaken several times, till night put an end to the combat. The allies retired next day, but were not molested in their retreat by the French, though the latter claimed the victory. In the French official dispatch to the empress, it was affirmed that this action, like a clap of thunder, had dissipated the chimerical hopes of those who calculated on the destruction of the French empire. The allies, however, were not disheartened. They received considerable reinforcements soon after, and again resolved to abide the combat. The battle of Bautzen fought the 20th and 21st May, was as severe and bloody as that of Lutzen, but the advantage which the French obtained was rather more decisive. Austria, who had, as already mentioned, greatly increased her military force, now interposed her mediation. She felt herself in a condition which enabled her to interfere with effect, and she had an obvious interest in preventing Napoleon from again attaining that baleful ascendency under which she had suffered so much. Napoleon was sensible that notwithstanding the advantages he had gained in Germany, the state of his affairs in Spain rendered his situation precarious. The mediation of Austria was accepted by both parties, and an armistice concluded on the 4th June. A congress was formed at Prague; but the negociations, which were continued till the 10th August, served only to show how irreconcilable the objects of the contending parties were. In the course of the discussions, Austria went more and more into the views of the allies. She proposed that the duchy of Warsaw should be suppressed, the Prussian fortresses occupied by the French given up, the Illyrian provinces restored to her, and the confederation of the Rhine dissolved. These terms were rejected by Bonaparte, who endeavoured, but in vain, to bribe Austria to co-operate with him, by offering her a large section of the Prussian monarchy. At length all prospect of pacification disappeared. Austria joined herself to the allies, and both parties appealed once more to the sword.

While the armistice lasted, Prussia had made great exertions to recruit her armies. The king made a strong appeal to the people, promised them a representative constitution, and called upon them to deliver their country from a foreign and hateful yoke. The call was obeyed with unprecedented zeal. Vast numbers presented themselves spontaneously to be enrolled; a large militia force was organized, as a support to the regular army; carts and horses were voluntarily supplied by the peasantry; and the women furnished clothes and flannels for the use of the soldiers. In short, the whole of Prussia resembled a camp.

The first considerable action after the campaign recommenced, was fought at Jauer in Silesia, where the French, under Marshal Macdonald, were defeated with great loss by Blucher. This was followed by the battle of Dresden, fought on the 26th, 27th, and 28th August, in which the allies were repulsed with the loss of 20,000 or 30,000 men, and the celebrated General Moreau was mortally wounded. The entire destruction of Vandamme's corps shortly after in Bohemia, was, however, a compensation for this disaster. The Austrians in the mean time, had formed a junction with the allies, who were farther strengthened by the arrival of a corps of 40,000 Russians under General Beningsen. The Westphalians, released from the presence of the French, by the irruption of a body of Russians, declared against the French; and at the same time the Bavarians made a treaty with Austria, and joined the allies. Napolean now found his situation more critical than ever. He was greatly outnumbered by his enemies, his allies were daily deserting his standard, his troops were inexperienced and dispirited, and he was at a distance from France in the midst of a hostile population. From that fatal confidence which he had displayed in his Russian campaign, he did not attempt a retreat while such a measure was practicable. The allies pushed bodies of troops forward on both

France. 1813. both flanks, till his communication with the Rhine was intercepted, and his position almost surrounded. Napoleon now prepared for the combat, which he saw was unavoidable, by concentrating his troops, and strengthening the weak points of his position with field-works. The decisive battle of Leipsic, the greatest and most eventful in modern times, was fought on the 16th, 17th, and 18th October. On the 16th, the advantage at the close of the day was rather on the side of the French: the 17th was spent chiefly in preparations for renewing the engagement. Even on the 18th, the success of the allies was not so complete, that it would have been ruinous to Napoleon's army, had the bridge between Leipsic and Lindenau not been destroyed prematurely, and exposed the divisions of Macdonald and Poniatowsky to destruction. The loss of the French was estimated at 60,000 men, in killed, wounded, and prisoners, and 500 pieces of cannon. Their route to the Rhine was strewed with baggage, artillery, and every species of military wreck. At Hanau they encountered the Bavarian general Wrede, with 35,000 men, but he was not able to stop their march. The remnant of the army crossed the Rhine at Mentz, on the 7th November.

Bonaparte after his first reverses in Russia had weakened his armies in Spain, by drawing troops from that country to Germany. The British and Spanish generals now prepared to avail themselves of this advantage. The French withdrew from Madrid in the end of May, and appeared at first disposed to defend the line of the Ebro. But this intention was soon abandoned, and they continued to retire northward. At Vittoria the British general attacked them on the 20th June, and gained a brilliant victory. A second victory in the heart of the Pyrenees enabled Lord Wellington to lay siege to Pampeluna and St Sebastian, both of which were reduced. The war was now carried into France, and after five days fighting, the strong lines which the French had formed in the neighbourhood of Bayonne were forced, and the British and Spanish armies advanced to the Adour.

The supports of Napoleon's power now crumbled down on all sides. The Confederation of the Rhine was entirely dissolved immediately after the battle of Leipsic, and the whole of the German auxiliaries were from that moment lost to the French cause. In his efforts to collect an army, Napoleon had withdrawn almost all the French troops from Holland. The Dutch, who had suffered severely from his anticommercial principles, gladly seized the opportunity to shake off the yoke. A conspiracy was formed at the Hague and in Amsterdam; the Dutch military joined the people; and Holland recovered her independence almost without a struggle. On the 30th November the prince of Orange arrived from England, and was greeted with the liveliest acclamations of the people.

Preparatory to entering France, the allied sovereigns issued a proclamation from Frankfort (1st December), in which they declared to the French nation, that they had no plans of conquest in view; that they wished France to be great, happy, and free; and that it was solely against the ambition of Napoleon, who held all the neighbouring states in slavery, that they made war. The French emperor called for a new levy of 300,000 men, and by his own authority increased the existing taxes. The legislative body was convoked, and for the first time ventured to speak another language than that of adulation. A deputation of its members drew up a report (28th December), in which they stated the necessity of uniting the nation to the throne, by an open renunciation of projects of aggrandisement, and by maintaining the entire and constant execution of the laws which guarantee liberty, and the free exercise of political privileges. These they considered as the only means of giving energy to the French in their own defence. Napoleon resented the freedom of this statement with the insolence which unbridled power had taught him. He taxed the members of the committee with faction and treason; and without regard to their remonstrances, took measures for recruiting his armies, and raising the nation *en masse*. But the people, worn out with his endless demands, answered his call to arms with much less zeal than was evinced by the Prussians in a similar case.

The allies passed the Rhine on the 1st January 1814, and spread themselves over the Netherlands and Alsace, without experiencing much resistance. They wisely pressed on, without losing time in besieging fortresses. A last and fruitless effort was made to negociate, but without suspending hostilities. Commissioners met at Chatillon on the Seine. The basis proposed by the allies was, that France should be reduced within the limits she occupied in 1792; and that Antwerp, and certain other strong places, should be put immediately into their hands, till the treaty was completed. The French ministers shifted their grounds as the fortunes of their master fluctuated, during the course of hostilities, till the negociations were closed on the 18th March. It would be tedious to recount the various movements and battles of the different armies, which were now pressing towards Paris as a common centre, and against which Napoleon made head with a very inferior force. It is admitted that he never displayed greater ability than in this short campaign; and that the French troops, though consisting in a great measure of raw levies, never fought with greater intrepidity. No exertions, however, could now avail against the overwhelming force of the allies under Prince Schwartzenburg. Laon, Rheims, Troyes, Montmiral, Arcis, places within seventy or eighty miles of Paris, were the scenes of sanguinary contests, in which the French often succeeded; but still the loss generally operated more severely upon their small force, than upon the larger masses of the allies. It was on the 22d March that Napoleon made a movement, which suddenly changed the state of the war. Placed between two armies of a hundred thousand men each, with a force not exceeding sixty thousand, he attempted by a desperate effort at Arcis, to disable or defeat one of his antagonists; but failing in his design, and despairing of forcing the position of the Austro-Russian army, he ventured on the daring project of retiring to Vitry, where he was interposed between the two hostile armies, but where he was in no condition to prevent their approach to the capital, if they chose to follow that course. He calculated that Prince Schwartzenburg would not advance to Paris, while he hung on his rear; but that on the contrary, he would be followed by the Austrian general, who would thus be drawn away from the capital, without the expence of a battle. The result, however, disappointed ance. 814. pointed his calculations. Blucher and Schwartzenburg pushed rapidly forward, leaving a corps to observe Napoleon's motions, and on the 28th March reached the neighbourhood of Paris. The French emperor saw his error when too late, and in the first moment of despair, addressed a letter to his father-in-law at Dijon, entreating him to interpose to secure the throne to his daughter's child. But his application was fruitless. On the 29th several of the villages on the north of the capital were taken after a brave defence; and on the 30th the allies drove the French within the barriers, when Marshal Marmont seeing farther resistance to be hopeless, proposed a capitulation, which was signed at two in the morning on the 31st March. The allied sovereigns with their troops entered Paris the same day. The inhabitants were assured by proclamations, that they came not as conquerors, but as friends and deliverers; that private property and rights should be religiously respected, and no insult offered to the national feelings. In such circumstances, it was not wonderful that a people so susceptible of sudden emotions as the French, relieved by this liberal conduct from the most appalling apprehensions, should welcome the allied princes with unbounded acclamations. As they passed into the city through the suburb of St Martin, shouts of *long live Alexander, long live Frederic William, long live our Deliverers*, were heard on all sides. The Parisians were divided into three parties. The most considerable party in point of numbers was chiefly anxious about the establishment of a free constitution; another party was attached to the existing order of things, and wished to secure the crown to Bonaparte's son; the third and smallest party consisted of Royalists, and desired merely the restoration of the Bourbons. The allies naturally wished to favour the last party; but as Alexander professed his readiness to allow the French to form a constitution for themselves, and to make what conditions they pleased with their prince, the liberal party, with a few exceptions, declared for the Bourbons. The senate assembled, with Talleyrand at its head, decreed on the 2d April, that Napoleon by his various acts of ambition and tyranny had forfeited the throne. A plan of a constitution was immediately afterwards drawn up, and unanimously adopted by that body, under which it was carried, that the crown should be offered to Louis, brother of the late king. By this instrument, the supreme authority was vested in the king, the senate, and legislative body; the king was to possess an absolute *veto;* the senate was to consist of not less than 150, nor more than 200 members, whose dignities were hereditary; the legislative body was to be elected immediately by the electoral bodies, for a period of five years. The existing nobility were to preserve their titles, and the old nobles to resume theirs. The freedom of the press was guaranteed. While these great changes were taking place in Paris, Napoleon remained at Fontainebleau, from which he sent Marshals Ney and Macdonald to negociate with the allies, and to endeavour to secure the succession to his son. The restoration of the Bourbons, however, had already been determined on; and the result of the negociation was, that Napoleon was allowed to retire to the isle of Elba, with a pension of two millions of francs per annum (80,000l.); one million more were assigned to the ex-empress Josephine; two millions and a half to the other branches of the imperial family; and the sovereignty of Parma, Placentia, and Guastalla, was given to the empress Maria Louisa, and to her son in succession. Napoleon was permitted also to take with him to Elba, 400 volunteers as a guard,

France. 1814.

While the allies were thus bringing the war to a happy termination in the north of France, Lord Wellington was advancing with uninterrupted success in the south. His lordship passed the Adour, as soon as the cessation of the rains rendered the roads passable, and on the 27th February attacked Soult in his strong position at Orthes. The French army, though much inferior in numbers to the allies, made a most determined resistance, but was at length driven back with the loss of seven thousand men. This victory opened the city of Bourdeaux to the conquerors, where the white flag was immediately displayed, amidst shouts of *long live the Bourbons.* Soult retired slowly towards Thoulouse, under the walls of which he took up a very strong position. He was here again attacked by the allied British and Spanish armies on the 10th April. The French commander availed himself of the advantages of his situation with consummate skill, and baffled his antagonists for many hours; but he was at last overpowered, and compelled to retire, leaving the city to be occupied by the victors. The loss of the British and Spaniards in this battle which terminated the war, amounted to five thousand men: that of the French has not been mentioned, but must of course have been greater. Next day intelligence of the capitulation of Paris arrived, and immediately led to the suspension of hostilities.

562 Restoration of the Bourbons.

Louis left his residence in England, and arrived at Paris on the 3d May, where he was welcomed with the tumultuous acclamations of the populace. The negociations now proceeded rapidly, and the peace of Paris was signed on the 30th May. The limits of France were re-established as they existed on the 1st January 1792, except that some small additions were made for the sake of rounding the frontier. She received back all her colonies except Tobago, St Lucia, the Mauritius and its dependencies, and the part she possessed of St Domingo. The allies discharged her of all pecuniary claims, or claims for compensation, except those of private individuals; and she was allowed to retain the works of art collected in the Louvre from the spoils of Italy and Germany. Considering how wantonly the victors had been provoked, and how much they had suffered from the restless aggressions of Napoleon's government, it must be admitted that the terms they dictated to France were extremely liberal, and that they made a very temperate use of their power.

Louis thus found himself reinstated on the throne of his ancestors without any effort of his own. Though his situation presented considerable difficulties, they were such as prudence and liberal conduct on his part would have surmounted. As his policy was necessarily pacific, he could not hope to detach the affections of the army from the celebrated commander who had been so long their idol. But in these circumstances, it was so much the more incumbent on him to attach the nation firmly to his cause; to unite their interest with his own, by establishing liberal institutions, and by showing the people that their only security for the blessings of

France. 1814. of unshackled industry, the upright administration of justice, and a really free government, depended the stability of his throne. The great changes which had taken place in the state of property in France had created an interest adverse to his family; and the enjoyment of liberty was the only bribe by which Louis could hope to reconcile this hostile interest to his authority. Unfortunately it was found that the schooling of adversity had produced no beneficial effect on the Bourbon dynasty. The very first acts of Louis betrayed arbitrary principles. He rejected the constitution framed by the senate, and ratified by a large portion of the legislative body, and promulgated another by his own authority, less liberal in its character, and rendered the more offensive because it asserted the supreme and uncontrouled power of the crown, though it admitted the propriety of regulating its exercise according to circumstances. He assumed the title of Louis XVIII. and dated the year of his accession as the 19th of his reign, thus declaring all the acts of the preceding period rebellious and illegal. His new ministers, chiefly emigrants, evinced a restless and violent spirit. Though subjected to the forms of a representative government, they did not hesitate to avow the principles of absolute monarchy in their speeches; and some of them were so imprudent, as to give no very obscure hints that a time might soon come when the property of emigrants would be reclaimed. The freedom of the press, so pompously announced by the charter, was violated by the establishment of a rigorous censorship; and to show that this was not meant to be a temporary measure, it was professedly founded on the rash and impetuous disposition of the French people. The situation of the finances, it was declared, would not admit of the abolition of the *droits reunis*, which had been promised. The conscription, though nominally laid aside, was re-established before any relief was experienced from its abolition. In short, the French soon found or conceived, that the return of the Bourbons brought no alleviation of their grievances. The peace which attended their restoration was considered as stamped with national ignominy; they were viewed as having all the arbitrary principles of Napoleon, without any pretensions to his talents or his renown. They were dreaded as the friends and patrons of feudal rights, and as the enemies of those revolutionary interests which comprehended so great a portion of the population. The public discontents arising out of this state of things, would not have shaken their power had they been secure of the attachment of the army; but possessing neither the confidence of the soldiers nor the people, the indiscreet and violent measures they adopted continually increased the perils that surrounded them. All that has transpired since 1815, has tended to show more and more clearly that the subversion of their power was not the consequence of any conspiracy, but was simply the effect of the attachment of the military to their old commander, and of the indifference or hostility of the great bulk of the population.

The constitution or charter granted by Louis, vested the elective franchise in persons of thirty years of age, and paying 300 francs (12l.) direct taxes. This law, which is still in force, restricts the right of voting to about 110,000 persons in the whole of France. The individual eligible as a representative must be forty years of age, and belong to the class which pays 1000 francs (40l.) direct taxes. The chamber of peers consists of persons holding their dignities either for life or hereditarily. This court, named by the king, and whose deliberations are secret, takes cognizance of crimes of high treason, and all attempts against the state. In both chambers the king has the initiation of all laws. It is unnecessary to dwell upon the principles of such a constitution. A body better contrived than the chamber of peers for destroying individuals obnoxious to the government could not easily be conceived. The intention of confining the choice of deputies to persons above forty, is partly no doubt to limit the number who are eligible, but still more to fill the chamber with individuals born before the revolution, and therefore more probably attached to the old *regime*. The object in making the qualification of electors so high, is obviously to confine the franchise to so small a number of persons, that the government by its money and patronage may be able to corrupt them, and thus in effect name the deputies itself. As it turned out, however, that the French ministers were not so dexterous in the trade of corruption as some of their neighbours, and that the national voice still made itself heard through this very imperfect instrument, a great change was made in its composition in 1820. The power of returning nearly two-fifths of the members is now vested in about 20,000 persons; and by gaining one half of these, and a small proportion of the rest, perhaps in all about 25,000 or 30,000 individuals, the government can secure a decided majority of its own creatures in the chamber. With a revenue of thirty millions sterling a-year, and such a multitude of places, titles, and distinctions to bestow, it can never be difficult for the ministry to accomplish this object. It is a mockery to give the name of a chamber of representatives to such a body which represents not the sense of the people, but the will of the court. It is a convenient instrument of taxation and coercion, a mask which conceals the harsh features of despotism without restraining its malignant spirit. It is necessarily doomed by the vices of its constitution to be the enemy —not the friend of popular rights, the champion of prerogative, the protector and promoter of the corruption and profusion by which it is nourished. We now return from this digression to our narrative.

France. 1814. Napoleon landed in Elba on the 4th May. For some time his active mind seemed to be entirely occupied with the embellishment of his capital and with various rural pursuits. He conversed freely with the British and Austrian commissioners, and with strangers of all nations, about the scenes and events of his past life, and seemed perfectly reconciled to his situation. But after some months residence he suddenly assumed more retired habits. He abandoned his usual pursuits, rarely received visitors, and when seen appeared absorbed in thought. He was in fact now maturing a project for recovering the French throne. He kept up a correspondence with various individuals in France who were disgusted with the conduct of the Bourbons; and it was most probably the numerous and increasing symptoms of discontent in that country which induced him to embark in the daring enterprise. He secretly augmented his military force, and collected a number

number of small craft; and the execution of his design is said to have been hastened by the intelligence he received that the allied princes at Vienna had it in contemplation to transport him to St Helena. At length, on the 26th February 1815, he left Porto Ferrajo with 900 men, on board of seven vessels, of which one was armed. With this handful of men he was now about to invade a powerful kingdom, defended by an army of 200,000 soldiers. A landing was effected on the 1st March, near Antibes. For five days he received no support, and his situation appeared extremely critical; but a force of 6000 men sent from Grenoble to arrest his progress having joined him, and the garrison of that city having immediately after declared in his favour, his difficulties were in a moment at an end. From this period every regiment sent against him served to swell his army. The people, even those who had insulted him during his journey to Elba, moved by novelty, or disappointed in the conduct of the Bourbons, strewed his path with flowers, and received him as a deliverer with joyful acclamations. In short, his journey to Paris was a continued triumphal procession. He reached that capital on the 20th March, in the evening, and, without shedding one drop of blood, reascended the throne from which he had been driven eleven months before. Louis had left Paris at one o'clock the same morning, accompanied by a few emigrants, without the body of the people testifying the least concern for his misfortunes, or the least regret at his departure. He retired to Ghent in the Netherlands.

Though the whole of France submitted almost instantaneously to Napoleon, he was well aware that vast exertions would be required to establish his power. The great princes assembled at the congress of Vienna, no sooner learned that he had landed in France, than they issued a proclamation, placing him "without the pale of civil and social relations," and declaring their determination to maintain the dispositions of the treaty of Paris at all hazards. Sensible of the difficulties of his situation, he now endeavoured to unite the national feeling to his cause by a liberal system of government. A new *constitutional act* was promulgated, establishing a hereditary chamber of peers, and settling a plan of representation, which, though not entirely unobjectionable, was infinitely preferable to any that had been in operation since the dissolution of the republican government. The two chambers, when they afterwards met, evinced a spirit of independence to which France had been a stranger for 15 years. The censorship was abolished by an imperial decree, and every thing was done to give a popular character to the acts of the government. Deputations called from the electoral colleges, met at Paris, and an assembly, to which the ancient name of a *Champ de Mai* was given, swore to maintain the constitution. Bonaparte had been all the time sedulously employed in strengthening his army. It was desirable to act before his enemies could concentrate their vast resources; and as soon therefore as his preparations were tolerably advanced, he hastened to the Netherlands. Both the Prussians and British were taken by surprise. The former were attacked and repulsed near Charleroi with considerable loss on the 15th. On the 16th were fought the battles of Quatre Bras and Ligny, in which the Prussians again suffered severely; but the small body of British engaged maintained their ground by astonishing efforts of heroism. Napoleon had now accomplished one object; he had separated the main body of the Prussians from their allies; and the 17th was spent in preparations for a conflict with the British on the following day. The duke of Wellington had taken up a station in a position chosen by himself in the neighbourhood of Waterloo. Here he awaited the attack of the French, which commenced at mid-day on the 18th. It is impossible to do justice within our present limits to this memorable battle. Both generals exerted themselves to the utmost; and never did two armies second the skill of their commanders by a more devoted courage. The immoveable firmness of the British troops, defied the tactics, the enthusiasm, and the desperation of their enemies; and on the arrival of the Prussians at sunset, the French, worn out by incessant but fruitless efforts, were at length overthrown with unexampled carnage, and the entire loss of their artillery and baggage. The victory was so decisive, that the flight was a complete route, the beaten army seemed totally dissolved, and scarcely a semblance of resistance was offered. The total loss of the French in this battle was never accurately ascertained, but has been estimated at 40,000 men in killed, wounded, and prisoners, out of an army of 80,000. Napoleon arrived at Paris on the 20th, and finding that he was now considered as the only obstacle to peace, he resigned the imperial crown in favour of his son. The two chambers conducted themselves with great firmness and wisdom in this trying conjuncture. They formed a provisional government, sent commissioners to treat with the allies for peace, made preparations for defending Paris, and found themselves so warmly seconded by the national spirit of the people and the army, that probably nothing but the extreme difficulties of their situation, from the sudden approach of an overwhelming force, prevented a general rising of the nation to defend its independence. When the cannon were roaring within hearing of the citizens, and a hostile army threatened them with the most fearful calamities, not a single voice was raised in the chamber in favour of the Bourbons. The representatives continued to meet till the 8th July, when the allied troops being in possession of Paris in virtue of a capitulation, the doors of the chamber were shut, and the deputies excluded by an armed force. The allies now acted with less reserve than in the former year. They avowed their determination to replace Louis on the throne by force; and in this measure the British minister concurred, in opposition to the most obvious sense of the treaty between the allied powers of 25th March, and subsequent declarations, which however were found to be nicely adapted to cover such a design by a happy equivocation in their terms (D). In every town which the allies entered they proclaimed Louis XVIII.;

165
French finally defeated at Waterloo.

(D) "In this war they do not desire to interfere with any legitimate right of the French people. They have no design to oppose the claim of that nation to choose their own form of government, or intention to trench in any respect upon their independence as a great and free people. However general the feelings of the sovereigns may

France. 1815. XVIII.; and he returned to Paris with their baggage, and surrounded with their bayonets, on the 8th of July. Negociations for peace now commenced, and were prolonged to the 20th November, when the second treaty of Paris was concluded. The terms of this treaty were more humiliating to the vanquished party than those of 1814. Some small portions of territory were detached from France. The works of art collected in the Louvre from Italy and Germany, which she had been allowed to retain by the treaty of 1814, were restored to their original owners. France was to pay to the allies seven hundred millions of francs, as an indemnity for the expence of the campaign, and to provide for 150,000 of the allied troops, who were stationed on her northern frontier under the duke of Wellington, to keep down any renewed attempts at revolution. These troops were only removed in 1818.

563 Bonaparte surrenders himself to the British. The ex-emperor after the resignation of his authority, proceeded to Rochfort, with the view of sailing to America. But finding all chance of escape precluded by the vigilance of the British squadron, he left the port in a small vessel, and surrendered himself a prisoner to Captain Maitland of the Bellerophon, on the 15th July. After being exhibited in Torbay for some days to wondering crowds, he was removed to St Helena, where he has since continued, and is likely during the remainder of his life to continue to live—a monument of the mutability of fortune, and the instability of earthly grandeur.

Shortly after the king was re-established, he dissolved the chamber of deputies, and convoked a new chamber; having previously caused his prefects fill up the vacancies in the electoral colleges, which should have been filled up by the primary assembly; in other words, having nominated a great proportion of the electors. By this infamous juggle, the chamber was filled with a set of furious ultra-royalists, who outdid the king himself in a zeal for prerogative, and disgraced the name of representatives by clamouring for the restoration of absolute power. A violent reaction naturally followed; the press was again subjected to a censorship; the protestants in the south were harassed and persecuted; their houses were burned, and 240 murdered in cold blood. Louis, who soon became sensible that the ultra zeal of the deputies was multiplying his dangers, prudently dissolved the chamber again in 1816, and convoked another, in which a more moderate spirit prevailed. Since this period the only changes of importance which have taken place in France are those made in the charter, of which some account has already been given.

566 Climate of France. In a country so extensive as that of France, it is not to be expected that the climate should be invariably the same; but it is certainly clearer and more salubrious upon the whole than that of Britain, and it is admirably adapted to the cultivation of the vine, without which many parts of it would perhaps continue in a state of nature. The country presents to the eye a level appearance in general; but several mountains are met with in the southern parts of it, such, for example, as Auvergne, Languedoc, Dauphiné, and Provence. Some reckon the Limousin the most beautiful province in France, although many parts of it besides this exhibit a charming diversity of hills and valleys, and some of the rivers, but the Seine in particular, often assume a picturesque appearance. It cannot be said that agriculture has attained to the perfection which it has done in Britain; yet in different provinces the cultivation of the ground seems to keep pace with its fertility, and the husbandmen of others display a degree of industry which is deserving of commendation. As a striking proof of this, many mountains of the Cevennes, only remarkable for their sterility, have been rendered extremely fertile by the indefatigable exertions of industry.

The most remarkable rivers of France are commonly reckoned four in number, the Seine, Loire, Rhone, and the Garonne, although there are many others of inferior note. The Seine is universally allowed to be a beautiful river, which takes its rise in the department of Cote d'Or, and, after traversing a country of about 250 miles in extent, falls into the English channel at Havre de Grace. The source of the Loire is in Mont Gerbier, in what was formerly called Languedoc, and after running about 500 miles, empties itself into the sea beyond Nantes. The Rhone rises from the Glacier of Furea, and the Garonne in the vale of Arau in the Pyrenees. The inferior rivers are the Saone, Dordogne, and a number of lesser streams which form a junction with the Loire.

There are numerous mountains in France, but there are none which are of a great height. The chain of the Vosges, in the east, about twenty or thirty miles from the Rhine, has an elevation not exceeding 4600 feet. Those of Brittany consist chiefly if not wholly of granite, but there is nothing remarkable in their elevation. France is divided from Switzerland by Mont Jura; but the principal chain of mountains is that denominated Cevennes, running from north to south, and sending out ramifications from east to west. Some naturalists are of opinion, that certain volcanic appearances may be traced among the mountains in the departments of Cantal and the Upper Loire; but the basaltic columns of which they chiefly consist, either do not favour this conjecture, or leave the truth of it extremely problematical. The loftiest mountains in France are those called Monts d'Or, which constitute the centre, of which Puy de Sansi forms the chief elevation, its height being computed at 6300 feet above the level of the sea. This mountain is covered a great part of the year with snow, and from its sides issues the river Dordogne.

The Pyrenees have been known and celebrated in history since the time of Herodotus, and may with equal propriety be considered as belonging either to France or Spain; although they have been more ably and minutely described by the learned of the former country. Shells and skeletons of animals have been found among the Pyrenees, which may afford matter for ample discussion to the admirers of nature's productions. Marine productions

---

may be in favour of the restoration of the king, they no otherwise seek to influence the proceedings of the French, in the choice of this or any other dynasty or form of government, than may be essential to the safety or permanent tranquillity of Europe." *Lord Clancarty's Despatch, dated Vienna, 6th May 1815.*

productions have been discovered on the top of Mont Perdu, which it is extremely difficult to ascend, because, in many places, it is almost perpendicular for nearly 900 feet; and near the summit there is a lake about 9000 feet above the level of the sea.

There are many forests in France, and of considerable extent, to the growth of which it becomes of importance to attend, as the chief fuel which the inhabitants can command is wood. The largest forests are those of Orleans and Ardennes, but our limits forbid us to give an ennmeration of the rest, which could answer no important purpose.

Of the botanical state of this country nothing can be advanced with certainty; for although its prodnctions of this nature may be said to have been examined around Paris, Lyons, and Montpelier, with considerable accuracy, yet mnch is still wanting to furnish any thing like a complete history of its vegetables. We have no certain accounts of what are purely indigenous or what are exotic, although the former must be more abundant in France than in any other European country.

The horses of this country are certainly inferior to those of Britain; and in former times its monarchs were drawn by oxen to the national assemblies. Their cattle are of a beautiful cream colour, but their sheep are much inferior to the English, owing, perhaps, to their wretchedly ill management, their meat being straw during the winter season instead of green food. France in some places is infested by the wild boar and the wolf, while the ibex and chamois inhabit the Pyrenees and the Alps.

At one period there were gold mines in the southern parts of France, and particles of that precious metal are still to be found in some of the rivulets. There are mines of silver in Alsace, and mines of copper in the departments of the Alps. The duchy of Deux Ponts contains mines of mercury; antimony is found in Ardeche; and abundance of iron, the most extensively useful of all the metals, is met with in the northern departments, for the working of which there were computed to be 2000 furnaces employed in the year 1798. 572 Minerals.

The population of France was estimated at 26,363,000 in 1791. In 1817 it amounted to 29,327,000. Our readers will find a pretty accurate account of it by inspecting the following table, which exhibits the number contained in each department, according to the division adopted since the revolution. 573 Population.

Ancient Provinces.	*Departments.*	*Population.*	*Chief Towns.*
Flandre Françoise.	Nord.	899,890	Douai.

574 Religion, &c.

The established religion is that of the church of Rome, but entirely independent of the Holy see; and the revenues of the clergy are not so extensive as to render them formidable to the preservation of the state. Of its political constitution, as that is an ignis fatuus which eludes all description, little need be said.

Army.

Subsequent to the revolution, it was perhaps impossible to give a just account of the strength of the French army, for both themselves and their enemies made it more numerous than it really was, although both parties must have been actuated by very different motives. The numerous defeats which the allies experienced, rendered it necessary to speak of their antagonists as a never-

France. never-to-be-diminished swarm of men, and the French no doubt gave exaggerated reports of their own actual strength, in order to intimidate the allies. In the time of the old government, the army amounted to 170,000 infantry, 44,000 cavalry, and 11,000 artillery; and perhaps at no period of the revolution did it ever exceed 600,000 men, although it has been often magnified to
576 Navy. the prodigious total of a million. Since the restoration of the Bourbons, the army has been about 140,000, the annual expence of which is abont six millions sterling.

The naval power of France was once formidable even to Britain: but the decided superiority in this respect has been invariably possessed by the latter country ever since the battle of La Hogue.

577 Revenue. The revenue of France, immediately before the revolution, has been estimated at twenty-two millions sterling. The amount during Bonaparte's reign, it is believed, was never honestly stated. In 1820, it was estimated at thirty millions. The public debt, funded and unfunded, in 1814, was one hundred and twenty-three millions, and the interest seven millions.

578 Learning. With respect to literature, France certainly holds a distinguished place among the nations of Europe; and if the palm has been adjuged to Italy and Britain by some authors, in point of bold invention and profound philosophical speculations, French authors are to be met with in great abundance who have done honour to human nature by their polite learning, and elegant as well as useful science. Altogether independent of a Corneille, a Racine, a Crebillon, a Moliere, or a Voltaire, this country has, at a more modern period, produced many distinguished writers in literature and philosophy, whose productions will continue to be read and admired, so long as men retain a sense of the value and importance of the sciences they respectively illustrate.

At one period there were no fewer than 21 universities in France, of which the Sorbonne at Paris was reputed the most celebrated, the fame of which drew numbers of students from distant countries. There were about 39 academies and literary societies, which produced many elegant and valuable dissertations on the different sciences, which have been long known to, and justly esteemed by, the learned world.

579 Cities &c. The cities of France are very numerous, and many of them make a most conspicuous figure. Paris, which is still the metropolis, has been sometimes reckoned a third smaller than London, and its population stated at 713,000 souls. It has often been considered as superior to London in point of magnificence, but it is undoubtedly inferior both in regard to convenience and cleanliness, the streets in general having very poor accommodations for passengers on foot;—a defect for which no elegance or magnificence can fully compensate. The next to Paris in importance, is the city of Lyons, the population of which is computed at 101,000: the desolation which it suffered during the tremendous reign of Jacobin fury it has since recovered. The abolition of monarchy was the innocent cause of much injury to its trade, which consisted chiefly in the manufacture of such splendid articles as were consumed by the court.

Next to Lyons we may mention Marseilles and Bourdeaux, of which the former contains 100,000 people, the latter 92,000. The port of the former city is perhaps the best, as well as the most frequented, of any in the Mediterranean. Lisle and Valenciennes are both strongly fortified cities, the former of which has a population of about 60,000. It surrendered to the combined powers in the year 1793, but the French retook it in the following year. The remaining cities, of which we can only give a bare enumeration, are Amiens, Rouen, Brest, Nantes, Orleans, Nancy, Metz, Strasbourg, Toulouse, Montpelier, &c. none of them having a population under 30,000 souls, many of them carrying on an extensive trade, and all of them abounding with elegant buildings.

Many exertions have been made at different periods, 580 Canals. to improve the inland navigation of France. The great Henry IV. began the celebrated canal of Burgundy, which was finished by Louis XIII. and by which a communication is opened between the rivers Loire and Seine. It consists of 42 locks, and is of singular importance to the commerce of the western provinces. The canal of Picardy reaches from the river Somme to the Oise, taking its rise from St Quintin, and affording an intercourse to the provinces lying on the north-east. But the greatest and most expensive work of this nature in France, which was begun and finished by Louis XIV. is the canal of Languedoc, which was completed in 15 years. It is 144 feet broad, six feet deep, and about 180 miles long; and it cost upwards of half a million sterling.

The total amount of the exports of France in the 581 Trade. year 1784, exclusive of the provinces of Lorraine and Alsace, and the trade with the West Indies which has been since carried on, was 307,151,700 livres, and her imports 271,365,000. The exports in 1789 were estimated at 613,000,000 livres, and the imports at 448,000,000. Since the restoration of the Bourbons, in 1818, the exports have been stated in the French journals at 15,400,000l. sterling. See the article FRANCE, in the SUPPLEMENT, in which a full view is given of the statistics of the country.

France, Francfort. *Isle of FRANCE*, a late province of France, but now divided into five departments, and so called, because it was formerly bounded by the rivers Seine, Marne, Oise, Aisne, and Ourque. It comprehends, besides Paris, the Beauvoisis, the Valois, the county of Senlis, the Vexin, and Hurepois, the Gatinois, the Multien, the Goele, and the Mantois. Paris is the capital.

FRANCFORT *on the MAINE*, an imperial and hanseatic town of Franconia in Germany, where the emperors were formerly elected. It is a handsome, strong, rich place, and has a great deal of commerce. Here the golden bull is preserved, which is the original of the fundamental laws of the empire. It is seated in a fine fertile plain; and well fortified with a double ditch, bastions, redoubts, and ravelins. The streets are remarkably wide, and the houses handsomely built.

Since 1815 it has been the permanent seat of the German diet. The number of inhabitants is 41,000; and it is one of the four towns which still retain their privileges. It was taken in October 1792, by the French, who were dispossessed of it by the Prussians in December following; it was again taken by the French in July 1796, but they evacuated it to the Austrians in September following. The suburb is called *Saxonhausen*, and joined to the town by a stone bridge built over the Maine. E. Long. 8. 37. N. Lat. 50. 7.

Francfort on the Oder, a rich and handsome town of Germany, in the middle marche of Brandenburgh, formerly imperial, but now subject to the king of Prussia. It is remarkable for three great fairs, and a celebrated university; and was taken by the French in 1806. It lies about 45 miles south-east of Berlin, and 72 south of Stetin. E. Long. 14. 45. N. Lat. 52. 22.

FRANCHE-COMPTE, a late province of France, bounded on the south and west by Champagne and Burgundy; on the north by Lorrain; and to the east by the earldom of Mumplegard, and Switzerland. It is in length from north to south about 30 leagues; in breadth about 20. It is partly flat and partly hilly. The flat country is fruitful in grain, wine, hemp, and pasture; and the hilly country abounds in cattle, producing also some wine and corn, copper, lead, iron, and silver ores, mineral waters, and quarries of stone, marble, and alabaster. It now forms the three departments of Doubs, Jura, and Upper Saone.

FRANCHISE, in *Law*. *Franchise* and *liberty* are used as synonymous terms; and their definition is, "a royal privilege, or branch of the king's prerogative, subsisting in the hands of a subject." Being therefore derived from the crown, they must arise from the king's grant; or in some cases may be held by prescription, which, as has been frequently said, presupposes a grant. The kinds of them are various, and almost infinite. We shall here briefly touch upon some of the principal, premising only, that they may be vested in either natural persons or bodies politic; in one man, or in many: but the same identical franchise, that has before been granted to one, cannot be bestowed on another, for that would prejudice the former grant.

To be a county palatine, is a franchise vested in a number of persons. It is likewise a franchise for a number of persons to be incorporated and subsist as a body politic; with a power to maintain perpetual succession, and do other corporate acts: and each individual member of such corporation is also said to have a franchise or freedom. Other franchises are, to hold a court leet; to have a manor or lordship; or, at least, to have a lordship paramount; to have waifs, wrecks, estrays, treasure-trove, royal fish, forfeitures, and deodands; to have a court of one's own, or liberty of holding pleas and trying causes; to have the cognizance of pleas; which is still a greater liberty, being an exclusive right, so that no other court shall try causes arising within that jurisdiction: to have a bailiwick, or liberty exempt from the sheriff of the county; wherein the grantee only, and his officers, are to execute all process: to have a fair or market; with the right of taking toll, either there or at any other public places, as at bridges, wharfs, or the like: which tolls must have a reasonable cause of commencement (as in consideration of repairs, or the like), else the franchise is illegal and void: or lastly, to have a forest, chase, park, warren, or fishery, endowed with privileges of royalty. See Chase, Forest, &c.

Franchise is also used for an asylum or sanctuary, where people are secure of their persons, &c. Churches and monasteries in Spain are franchises for criminals; so were they anciently in England, till they were abused to such a degree that there was a necessity for abolishing the custom. One of the most remarkable capitulars made by Charlemagne in his palace of Heristal, in 779, was that relating to the franchises of churches. The right of franchise was held so sacred, that even the less religious kings observed it to a degree of scrupulousness; but to such excess in time was it carried, that Charlemagne resolved to reduce it. Accordingly he forbade any provision being carried to criminals retired into churches for refuge.

Franchise of Quarters, is a certain space or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire cannot be arrested or seized by the sbirri or serjeants, nor prosecuted at law. The people of Rome look on this as an old usurpation and a scandalous privilege, which ambassadors, out of a jealousy of their power, carried to a great length in the 15th century, by enlarging insensibly the dependencies of their palaces or houses, within which the right of franchise was anciently confined. Several of the popes, Julius III. Pius XIV. Gregory XIII. and Sixtus V. published bulls and ordinances against this abuse; which had rescued so considerable a part of the city from their authority, and rendered it a retreat for the most abandoned persons. At length Innocent XI. expressly refused to receive any more ambassadors but such as would make a formal renunciation of the franchise of quarters.

FRANCIS I. king of France, the rival of the emperor Charles V. and the restorer of learning and politeness in France. See (*History of*) France.

Francis, *Philip*, a very ingenious writer, of Irish extraction, if not born in that kingdom. His father was a dignified clergyman in Ireland, being dean of some cathedral; and our author, his son, was also bred to the church, and had a doctor's degree conferred on him. He was more distinguished as a translator than as an original writer. His versions of Horace and Demosthenes have been justly valued: the former is accompanied with notes, and is perhaps as complete and useful a work of its kind as hath yet appeared. He was also a considerable political writer; and in the beginning of the present reign is supposed to have been employed by the government: for which service he was promoted to the rectory of Barrow in Suffolk, and to the chaplainship of Chelsea hospital. He was also the author of two tragedies, Eugenia and Constantia; but as a dramatic writer, not very successful. He died at Bath in March 1773; leaving a son, who was then one of the supreme council at Bengal.

FRANCISCANS, in *Ecclesiastical History*, are religious of the order of St Francis, founded by him in the year 1209. Francis was the son of a merchant of Assisi, in the province of Umbria, who, having led a dissolute life, was reclaimed by a fit of sickness, and afterwards fell into an extravagant kind of devotion, that

that looked less like religion than alienation of mind. Soon after this, viz. in the year 1208, hearing the passage repeated, Mat. x. 9. 10. in which Christ addresses his apostles, *Provide neither gold, nor silver*, &c. he was led to consider a voluntary and absolute poverty as the essence of the gospel, and to prescribe this poverty as a sacred rule both to himself and to the few that followed him. This new society, which appeared to Innocent III. extremely adapted to the present state of the church, and proper to restore its declining credit, was solemnly approved and confirmed by Honorius III. in 1223, and had made considerable progress before the death of its founder in 1226. Francis, through an excessive humility, would not suffer the monks of his order to be called *fratres*, i. e. brethren or friars, but *fraterculi*, i. e. little brethren, or friars-minor, by which denomination they still continue to be distinguished. They are also called *gray friars*, on account of the colour of their clothing, and *cordeliers*, &c. The Franciscans and Dominicans were zealous and active friends to the papal hierarchy, and, in return, were distinguished by peculiar privileges and honourable employments. The Franciscans, in particular, were invested with the treasure of ample and extensive indulgences; the distribution of which was committed to them by the popes, as a means of subsistence, and a rich indemnification for their voluntary poverty. In consequence of this grant, the rule of the founder, which absolutely prohibited both personal and collective property, so that neither the individual nor the community were to possess either fund, revenue, or any worldly goods, was considered as too strict and severe, and dispensed with soon after his death. In 1231, Gregory IX. published an interpretation of this rule, mitigating its rigour; which was farther confirmed by Innocent IV. in 1245, and by Alexander IV. in 1247. These milder operations were zealously opposed by a branch of the Franciscans called the *spiritual;* and their complaints were regarded by Nicholas III. who, in 1279, published a famous constitution, confirming the rule of St Francis, and containing an elaborate explication of the maxims it recommended, and the duties it prescribed. In 1287, Matthew of Aqua Sparta, being elected general of the order, discouraged the ancient discipline of the Franciscans, and indulged his monks in abandoning even the appearance of poverty; and this conduct inflamed the indignation of the spiritual or austerer Franciscans; so that from the year 1290 seditions and schisms arose in an order that had been so famous for its pretended disinterestedness and humility. Such was the enthusiastic frenzy of the Franciscans, that they impiously maintained that the founder of their order was a second Christ, in all respects similar to the first; and that their institution and discipline were the true gospel of Jesus. Accordingly, Albizi, a Franciscan of Pisa, published a book in 1383, with the applause of his order, entitled, The book of the Conformities of St Francis with Jesus Christ. In the beginning of this century, the whole Franciscan order was divided into two parties; the one embracing the severe discipline and absolute poverty of St Francis, were called *spirituals;* and the other, who insisted on mitigating the austere injunctions of their founder, were denominated *brethren of the community*. These wore long, loose, and good habits, with large hoods; the former were clad in a strait, coarse, and short dress, pretending that this dress was enjoined by St Francis, and that no power on earth had a right to alter it. Neither the moderation of Clement V. nor the violence of John XXII. could appease the tumult occasioned by these two parties; however, their rage subsided from the year 1329. In 1368 these two parties were formed into two large bodies, comprehending the whole Franciscan order, which subsist to this day; viz. the *conventual brethren*, and the *brethren of the observance* or *observation*, from whom sprung the capuchins and recollects. The general opinion is, that the Franciscans came into England in the year 1224, and had their first house at Canterbury, and their second at London; but there is no certain account of their being here till King Henry VII. built two or three houses for them. At the dissolution of the monasteries, the conventual Franciscans had about 55 houses, which were under seven custodies or wardenships; viz. those of London, York, Cambridge, Bristol, Oxford, Newcastle, and Worcester.

FRANCOIS, or FRANCAIS, *Port Des*, the name of a bay or harbour discovered by Peyrouse on the north-west coast of America, is situated in N. Lat. 58. 37. and in Long. 139. 50. W. from Paris. This harbour was from three to four leagues deep: he entered it with his two frigates in July 1786, and came to an anchor in an island near the middle of it, in 20 fathoms water, with a muddy bottom. The bottom of the bay, he observes, is one of the most extraordinary places in the world; the water is so deep that it could not be fathomed, and surrounded by peaked mountains of a great height, covered with snow, without vegetation, and seemingly condemned by nature to perpetual sterility. He never saw the surface of the water ruffled with the smallest breath of air, or in the least disturbed but by the falling of enormous pieces of ice, which continually detach themselves from five different glaciers. The air was so calm, and the silence so profound, that the voice of a man might be heard at the distance of half a league, as well as the noise of sea-birds which hatch their eggs in the cavities of the rocks.

He found the variation of the compass to be 28° E. and the dip of the needle 74°. At full and change of the moon, when it is high water at one o'clock, the sea rose seven feet and a half. The current of the channel at the entrance of the harbour, during the sea breeze, came in like a rapid river, so that it must be impracticable to take the channel when the winds blow violently from the southward; and indeed the currents at all times render the entrance difficult. This harbour possesses many advantages, but it is also subject to several inconveniences. It seems not to be convenient for ships to anchor, which are employed in trafficking in skins, because such ships ought to enter many bays, making in each a short stay, since the whole stock of the Indians is very soon disposed of; but it seems to be a very commodious place for the establishment of a factory, and this commercial settlement, it is suggested, should be made on Cenotaph island, a name given to an island in the middle of the harbour, from the monument erected on it to the memory of some of the crew of Peyrouse's ships, which were lost in the channel. This island is about a league in circumference, abounds with wood and water, and seems capable of cultivation. The quantity

tity of otter skins far exceeded any thing which Peyrouse had observed in any other part of America.

The climate of this coast, according to Peyrouse, seemed much milder than that of Hudson's Bay. For three or four months of the year vegetation was very vigorous; there was found abundance of celery, endive, lupin, and yarrow, with most of the plants which are common in the meadows and mountains of France. Gooseberries, raspberries, and strawberries, were also common in the woods; poplars, willows, hornbeam, and pines, some of which measured six feet in diameter, and 140 feet high, fit for masts of the largest ships. The river seemed to be filled with trout and salmon, and different kinds of fish were found in the bay itself. The variety of birds was not great; but bears, martens, and squirrels, were frequent in the woods. The inhabitants are said to be considerably different from the Californians, being taller, stouter, of a more agreeable figure, having greater vivacity of expression, and a greater share of courage and sense. Their colour is olive, and the hair in general is neither so coarse nor black as that of the South Americans. It is supposed that they are worshippers of the sun, for they were frequently observed addressing themselves in their prayers to this planet; but neither temple nor priest, nor trace of public worship, was seen. It is said that they burn their dead.

FRANCONIA, a circle of Germany, bounded on the north by the circle of Upper Saxony, on the east by that of Bavaria, on the south by that of Swabia, and on the west by the circles of the Rhine. The middle is fertile in corn, wine, and fruits, but the borders are full of woods and barren mountains.

This country was overrun by the French republicans in the summer of 1796; but in September the Austrians compelled them to retreat. The Franks, who conquered France, came from this province, and gave their name to this kingdom.

FRANGULA. See RHAMNUS, BOTANY *Index*.

FRANK LANGUAGE, *Lingua Franca*, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts of and ports of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

FRANK, or *Franc*, an ancient coin, either of gold or silver, struck and current in France. The value of the gold frank was something more than that of the gold crown: this coin has been long out of use, though the name is still retained as the name of a money of account: in which sense it is equivalent to the livre, or 20 sols.

FRANK, or *Franc*, meaning literally *free* from charges and impositions, or exempt from public taxes, has various significations in the ancient English customs.

FRANK-Almoigne, (*libera eleemosyna*), or "free alms;" a tenure of a spiritual nature, whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and their successors for ever. The service which they were bound to render for these lands was not certainly defined: but only in general to pray for the souls of the donor and his heirs, dead or alive; and therefore they did no fealty (which is incident to all other services but this), because this divine service was of a higher and more exalted nature. This is the tenure by which almost all the ancient monasteries and religious houses held their lands; and by which the parochial clergy, and very many ecclesiastical and eleemosynary foundations, hold them at this day; the nature of the service being upon the Reformation altered, and made conformable to the purer doctrines of the church of England. It was an old Saxon tenure; and continued under the Norman revolution, through the great respect that was shown to religion and religious men in ancient times. This is also the reason that tenants in frank almoigne were discharged of all other services except the *trinoda necessitas*, of repairing the highways, building castles, and repelling invasions; just as the Druids, among the ancient Britons, had *omnium rerum immunitatem*. And even at present, this is a tenure of a very different nature from all others; being not in the least feodal, but merely spiritual. For, if the service be neglected, the law gives no remedy by distress, or otherwise, to the lord of whom the lands are holden; but merely a complaint to the ordinary or visitor to correct it.

FRANK-Chase is defined to be a liberty of free chase, whereby persons that have lands within the compass of the same, are prohibited to cut down any wood, &c. out of the view of the forester.

FRANK-Fee, signifies the same thing as holding lands and tenements in fee-simple; that is, to any person and his heirs, and not by such service as is required by ancient demesne, but is pleaded at common law. See FEE.

FRANK-Law, a word applied to the free and common law of the land, or the benefit a person has by it.

He that for any offence loseth this frank-law incurs these inconveniences, viz. He may not be permitted to serve on juries, nor used as an evidence to the truth; and if he has any thing to do in the king's court, he must not approach it in person, but appoint his attorney; his lands, goods, and chattels, shall be seized into the king's hands; and his lands be estreated, his trees rooted up, and his body committed to custody.

FRANK-Marriage, in *Law*, is where tenements are given by one man to another, together with a wife, who is the daughter or cousin to the donor, to hold in frank-marriage. By such gift, though nothing but the word *frank-marriage* is expressed, the donees shall have the tenements to them, and the heirs of their two bodies begotten; that is, they are tenants in special tail. For this one word, *frank marriage*, denotes *ex vi termini*, not only an inheritance, like the word *frank-almoigne*, but likewise limits that inheritance; supplying, not only words of descent, but of procreation also. Such donees in frank-marriage are liable to no service but fealty: for a rent reserved therein is void until the fourth degree of consanguinity be past between the issues of the donor and donee.

FRANK-Pledge, in *Law*, signifies a pledge or surety for the behaviour of freemen.

According to the ancient custom of England, for the preservation of the public peace, every freeborn man, at the age of fourteen, except religious persons, clerks, knights, and their eldest sons, was obliged to give security for his truth and behaviour towards the king and his subjects, or else be imprisoned. Accordingly, a certain number of neighbours became interchangeably bound

bound for each other, to see each person of their pledge forthcoming at all times, or to answer for the offence of any one gone away: so that whenever any person offended, it was presently inquired in what pledge he was, and there the persons bound either produced the offender in 31 days, or made satisfaction for his offence.

Frank-Tenement. See Tenure.

FRANKED letters. The privilege of letters coming free of postage to and from members of parliament was claimed by the house of commons in 1660, when the first legal settlement of the present post office was made; but afterwards dropped, upon a private assurance from the crown, that this privilege should be allowed the members. And accordingly a warrant was constantly issued to the postmaster general, directing the allowance thereof to the extent of two ounces in weight: till at length it was expressly confirmed by 4 Geo. III. c. 24. which adds many new regulations, rendered necessary by the great abuses which had crept into the practice of franking; whereby the annual amount of franked letters had increased from 23,600l. in the year 1715, to 170,700l. in the year 1763. Further regulations have since taken place; in particular, franks must be dated (the month written at length), and put into the office the same day; notwithstanding which, the revenue still loses by this privilege a very considerable annual sum.

FRANKEN, Franciscus, commonly called *Old Frank*, a famous Flemish painter, supposed to have been born about the year 1544; but though his works are well known, very few of the circumstances of his life have been transmitted to posterity. This master painted historical subjects from the Old and New Testaments; and was remarkable for introducing a great number of figures into his compositions, which he had the address to group very distinctly. Vandyck often commended his works, and thought them worthy of a place in any collection.

Franken, *Franciscus*, distinguished by the name of *Young Frank*, was the son of the former, born in the year 1580. He was instructed by his father; whose style he adopted so closely, that their works are frequently mistaken. When he found himself sufficiently skilled at home, he travelled into Italy for improvement in colouring; and, on his return, his works were much coveted. The most capital performances of this painter are, a scriptural performance in the church of Notre Dame at Antwerp; and an excellent picture, in a small size, of Solomon's idolatry. Young Frank died in 1642.

FRANKENDAL, a strong town of Germany, in the dominions of the Elector Palatine, situated near the Rhine, about seven miles south of Worms. It was taken by the Spaniards in 1623, by the Swedes in 1632, burnt by the French in 1688, and finally taken by the allies in the year 1794. E. Long. 8. 29. N. Lat. 49. 25.

FRANKENIA, a genus of plants belonging to the hexandria class; and in the natural method ranking under the 17th order, *Calycanthemæ*. See Botany *Index*.

FRANKFORT, the name of several townships in different places of North America; such as Frankfort, a township in Hancock, and district of Maine, with a few houses regularly built. It contains 891 inhabitants, and lies about 238 miles north-east of Boston. Frankfort, a thriving village in Philadelphia; the name of another in Hampshire, of one in Virginia, and the name of the metropolis of Kentucky.

FRANKINCENSE. See Incense.

FRANKLIN, Thomas, D. D. chaplain in ordinary to his majesty, was born in London about the year 1720, and was the son of Richard Franklin, well known as the printer of an anti-ministerial paper called *The Craftsman*; in conducting which he received great assistance from Lord Bolingbroke, Mr Pulteney, and other excellent writers, who then opposed Sir Robert Walpole's measures. By the advice of the second of these gentlemen, young Franklin was devoted to the church, with a promise of being provided for by the patriot; who afterwards forgot his undertaking, and then entirely neglected him. He was educated at Westminster school; from whence he went to the university of Cambridge, where he became fellow of Trinity college, and was some time Greek professor. In December 1758, he was instituted vicar of Ware and Thundridge; which, with the lectureship of St Paul, Covent Garden, and a chapel in Queen street, were all the preferments he held till he obtained the rectory of Brasted in Kent. This gentleman was possessed of no inconsiderable share of learning and poetical abilities, and was long a favourite in the literary world. His translations of Phalareus, Sophocles, and Lucian, equally evince his learning and his genius, as they are not more distinguished for fidelity in the version, than congeniality with the spirit of the admirable originals. Dr Franklin, like Mr Foote, suffered a translation from the French to be printed in his name; but the Orestes and Electra are supposed to be all that were really by him. It was a translation of Voltaire's works, to which also Dr Smollett's name appears. His own dramatic compositions, of which the principal are the tragedies of The Earl of Warwick and Matilda, are universally known, and deservedly esteemed by the public. He died in March 1784.

Franklin, *Benjamin*, a philosopher and a statesman of considerable eminence, was born in the year 1706, at Boston in New England. His family derived their origin from Ecton in Northamptonshire, where his ancestors had an inconsiderable freehold for many generations. The persecution of the non-conformists in the reign of Charles II. induced his father to take refuge in New England; and in the city of Boston he followed the occupation of a soap-boiler and tallow-chandler. Franklin drew up a history of his own life from his nativity to the 25th year of his age; but as at that period he had made no very conspicuous figure in the world, it is to be lamented that we have not the assistance of his own pen to the meridian of his career. This defect we have endeavoured to supply in the subsequent narrative from the most authentic materials, avoiding as much as possible the exaggerated panegyric of friends, and the unmerited detraction of enemies.

Our author, from his very infancy, discovered the strongest propensity towards literary pursuits, which determined his father to qualify him for the ministry; but he was thwarted in his designs by a numerous and increasing family, Franklin. family, and therefore Benjamin was taken from school at ten years of age, to take part in the drudgery of his father's trade. This greatly mortified the aspiring mind of young Franklin, who wished to prefer a seafaring life to such an employment; but from this he was dissuaded by the influence of his father, who was a man of some knowledge, and possessed a solid understanding. He made it his chief aim to inspire his children with the love of knowledge and the principles of moral rectitude. He had few books; yet from among these Benjamin selected a number of voyages and travels, as well as different histories, a species of reading for which he had a strong predilection. By going through a course of controversial divinity in this unaided manner, he greatly strengthened his argumentative powers, which was most probably all he had in view. Defoe upon Projects, according to his own account, made such impressions upon his mind as in a great measure directed the subsequent events of his life.

He was now chosen to an employment which accorded much better with the natural bent of his mind than the business of his father's shop. A brother of his own had a printing-office in Boston, to whom Benjamin was bound apprentice at 12 years of age. With the mechanical part of the business he was soon acquainted; and the opportunities thus afforded him of procuring new books to read, were eagerly seized, and the greater part of the night frequently spent in the perusal of them. He soon became anxious to imitate the works which he most admired, and his first attempts were of a poetical nature. He composed and printed ballads, which were well received by those who love such a species of reading; yet his father had the address to convince him that nature never designed him for a poet. He therefore turned his whole attention to the cultivation of prose composition, in which he succeeded infinitely better; and he thus became superior to his brethren of the press, and raised himself to stations of public importance. As his passion for reading and writing was very strong, so he became in a short time a powerful disputant, which was strengthened by his intimacy with a young man of a similar disposition. He perused, with uncommon attention, a translation of Xenophon's Memorabilia, which enabled him either to confute or confound an adversary by a number of questions. It is also certain that he became a sceptic as to the religion in which he had been educated, and propagated his unbelief with zeal and assiduity. The fatal consequences which this produced on the deportment of some of his intimate companions, at length happily convinced him that it is extremely dangerous to destroy the salutary influence of religion, without being able to substitute any thing in its place of equal importance and efficacy. He seems, however, to have continued a sceptic in his own mind, yet he still retained a love for moral rectitude, which led him to adopt honourable means in the prosecution of valuable ends. Much to his honour be it spoken, he acquired, at a very early period of life, that triumph over his sensual appetites, which is so essentially necessary to a life of dignity, usefulness, and virtue. Having read Tyron's recommendation of a vegetable diet, at 16 years of age, he abandoned the use of animal food; and on offering to his brother to support himself on half the money which was paid for his board, he was allowed to adopt his own plan, by which means he was enabled to save a considerable sum for the purchase of books. Although he relaxed considerably as to a vegetable diet, yet he thus acquired the habit of being satisfied with little, and a contempt of the gratifications of the palate was frequently of singular advantage to him through the whole of life.

When his brother began a newspaper, Benjamin sent a number of pieces on various topics to be inserted, which met with the approbation of the most competent judges;—a satisfaction he enjoyed without being known, as they were all anonymous. His brother treated him with the harshness of a master, which he bore with the utmost impatience, as the public had already pronounced him to be possessed of merit. The states of America having prohibited James Franklin from publishing this paper, on account of some political offence, the name of Benjamin was employed as publisher, in consequence of which he procured his indentures, although he agreed privately with his brother to serve out his time. But as he did not deem this agreement obligatory, he went to New York by sea, and from that place to Philadelphia, in the seventeenth year of his age. He himself acknowledges this to have been a fault, and therefore has averted that censure which he would otherwise have deserved. At Philadelphia he engaged with a printer of the name of Keimer, whose affairs he soon placed on a more respectable footing; and here also he became acquainted with several young men of a literary turn of mind, by whose company his taste for knowledge was greatly improved.

He soon after became acquainted with Sir William Keith the governor of that province, who powerfully recommended it to him to commence business on his own account, and promised to give him all the encouragement in his power. Encouraged by this gentleman to adopt such a plan, he set out for Boston on a visit to his parents, in order to proeure from them some pecuniary aid; but a welcome reception was all he could obtain. Having returned to Philadelphia, Sir William generously offered to take the whole burden upon himself, and advised Franklin to make a voyage to England, in order to procure every thing necessary for a printing-office. He set sail in the year 1725, and took with him his intimate companion Ralph, whose name has been rendered memorable by being celebrated in the Dunciad. Unfortunately for Franklin, Sir William Keith, on whose letters of recommendation and credit he entirely relied, basely deceived him, and he was obliged to work as a journeyman in London for his immediate subsistence. His friend Ralph could only live by his head, and his income of consequence was extremely circumscribed, as well as precarious, which made him a heavy burden on the pocket of Benjamin. In that dissolute metropolis the one forgot his wife and child in America, and the other the solemn promises of fidelity which he had made to a Miss Read, prior to his departure;—another step of his conduct which he himself severely censures. By a dissertation on liberty and necessity, pleasure and pain, he acquired considerable reputation, and it was the means of introducing him to the celebrated Dr Mandeville, author of the Fable of the Bees. In the second printing-office in which he worked, he laboured incessantly to convince his fellow workmen that a pint of porter does not contain half

Franklin.

half so much nourishment as a penny roll, for which he obtained the ludicrous epithet of the *American aquatic*; yet he was finally enabled to make many converts to his doctrine;—a proof that he possessed strong persuasive powers, when we consider the deep-rooted attachment of those with whom he had to treat to their favourite libation.

After eighteen months residence in London, he returned to Philadelphia in the year 1726, and became clerk to a Mr Denham, a man of respectability, who had opened a warehouse in that city. He soon became acquainted with the principles of commerce, and led a very happy life in this new situation, till the connection was dissolved by the death of Mr Denham, which happened the following year. This again obliged him to become journeyman printer, and he was afterwards overseer in the office of Keimer, whom we have already mentioned. Here he acquired great esteem, and at length conceived the idea of setting up for himself, which he accomplished by entering into partnership with one Meredith, a fellow workman, whose father was in circumstances to enable him to advance them some money. His industry was habitual, but the idea that he was now working for himself, gave it additional energy. He was chiefly instrumental in the institution of a club which went by the name of the *junto*, and which was highly conducive to the intellectual improvement of its members. Before the admission of a candidate, the following questions were put to him. "Do you sincerely declare that you love mankind in general, of what profession or religion soever? Do you think any person ought to be harmed in his body, name, or goods, for mere speculative opinions, or his external way of worship? Do you love truth for truth's sake; and will you endeavour impartially to find and receive it yourself, and communicate it to others?" Franklin and his copartner began a newspaper, which the labours and talents of the former brought into repute, and by them the votes and laws of the assembly came afterwards to be printed. The partnership being dissolved by the departure of Meredith, Franklin, by the generous aid of friends, was enabled to take the whole business upon himself, to which he added the business of a stationer. When the increase of paper money engaged the attention of the American government, Franklin wrote an anonymous pamphlet in defence of the measure, by which he acquired considerable reputation, the countenance of men in power, and it placed his prosperity on a permanent basis. About this time he kept up a criminal correspondence with different females, chiefly owing, perhaps, to the disappointment he met with in the first object of his love, Miss Read, who by this time was married to another in consequence of his neglect. But we forget the faults of the man in the ingenuous confession of the penitent. A report prevailing that Miss Read's husband was married to another woman, he retired to the West Indies, where he died, and Franklin married the object of his first love in the month of September 1736, being then about 24 years of age. She proved a valuable wife, and in every sense of the word, an "help meet for him."

To him we are to ascribe the establishment of a public library at Philadelphia, which he accomplished in the year 1731, and had the satisfaction of seeing it arrive at that flourishing condition which it has long since attained. His "Poor Richard's Almanac," was begun in 1732, and became remarkable for the many prudential maxims with which it abounded; and the proverbial manner in which they were expressed made them take fast hold of the memory. His political career commenced in 1736, when he was chosen clerk to the general assembly of Pennsylvania, to which he was re-elected for several years, and at last became a representative. In 1737, he was made postmaster of Philadelphia, and in the subsequent year he greatly improved the police of the city, by the formation of a fire-company, and afterwards an insurance-company against losses by fire. In the war with France, which broke out in 1744, when the best means of defending the province against the inroads of the enemy, and when the militia bill was thrown aside from its being obnoxious to the people, Franklin suggested the idea of a voluntary association for their mutual defence, which was instantly signed by 1200 persons, and 10,000 subscriptions were obtained in a short time by circulating it through the province. By this and similar means America had an opportunity of ascertaining her own strength, and how to make use of it with advantage in cases of emergency.

About this time he began his interesting experiments on electricity, by the result of which he justly acquired a distinguished reputation. The library society of Philadelphia having received from Mr Peter Collinson in the year 1745, an account of the facts respecting electricity which at that time engrossed the attention of philosophers in Europe, Franklin set about studying the subject with the greatest assiduity. He gave the account of his researches, the title of "New experiments and observations on electricity, made at Philadelphia in America," and addressed to Mr Collinson in the form of letters, bearing date from 1747 to 1754. They were everywhere read with avidity, and universally admired; Dr Priestley speaks of them in the following terms. "It is not easy to say whether we are most pleased with the simplicity and perspicuity with which the author proposes every hypothesis of his own, or the noble frankness with which he relates his mistakes, when they were corrected by subsequent experiments." Not to swell this article with a detailed account of all his discoveries on this subject, we shall content ourselves with mentioning that most interesting of the whole, his grand discovery that lightning and electric fire are identically the same. This identity had begun to be suspected, and experiments had been made in France to ascertain the fact; but it was reserved to Franklin to demonstrate this fact by his own experiments. He obtained his first decisive proof of this in the month of June 1752, by setting up a silken kite into the air with a point of iron, and a key fastened to the end of the hempen string by which he held it. In this manner he drew down from a thunder cloud a sufficient quantity of electric fire to emit sensible sparks from the key. By means of an insulated iron rod which he fixed upon his house, he drew down the lightning, and was thus furnished with an opportunity of discovering whether it was positive or negative. As he firmly believed that philosophical discoveries were only valuable in so far as they could be productive of benefit to man, he made them subservient to the protection of buildings from the effects

Franklin.

effects of lightning, which are truly alarming in North America. He applied physics to the purposes of common life, and in 1745 invented his Pennsylvania fireplaces, in which the qualities of an open grate were combined with that of a stove.

He turned his attention very much to the subject of politics, which was extremely natural for a man of a public spirit living under a popular government. He was chosen a representative of the city of Philadelphia for the provincial assembly in 1747. At this time a contest subsisted between the assembly and the proprietaries, as to the claim of the latter to be exempted from public burdens. Franklin took the popular side of the question, by which he acquired great influence, and was regarded as the head of the opposition. This was not the offspring of eloquence, for he seldom spoke, and never in the form of an harangue; but his pointed observations, his unadorned good sense, frequently destroyed the effect of the most elaborate orations.

He drew up the plan of an academy to be founded at Philadelphia, from a conviction that education in a free state is of the utmost importance. It was carried into effect in the year 1750, by virtue of a subscription, to which the proprietors afterwards liberally contributed. He discharged the duties of his office as postmaster of Philadelphia with so much punctuality, that he was appointed deputy postmaster general for the British colonies in 1753, and the revenue was soon bettered by his unwearied exertions. A plan for conciliating the Indians, and forming an alliance with them, was drawn up by Franklin in 1754, to which the commissioners at Albany agreed, and a copy of it was transmitted to the British privy council. It is a singular circumstance, that this plan was rejected by the assemblies as giving too much power to the crown, while the British ministry declared that it gave too much influence to the representatives of the people. In the year 1757, Franklin set sail for London, as agent for Pennsylvania, the assembly of that province being involved in disputes with the proprietary. It was agreed on by the privy council, that landholders should pay their share of the public burdens, on condition Franklin would engage that they should be fairly proportioned. He continued at the British court as agent for his province, and acquired so great reputation, that the same trust was reposed in him for Massachusets, Maryland, and Georgia. His merit as a philosopher was now justly appreciated in Europe, and he was made a fellow of the Royal Society of London. The degree of L. L. D. was also conferred upon him at St Andrew's, Edinburgh, and Oxford.

In the year 1762 he returned to America, where he received the thanks of the assembly of Pennsylvania, and a handsome recompense in money for his important services. When the stamp act occasioned so much disturbance in America, Dr Franklin was summoned to the bar of the house of commons, to give evidence respecting the dispositions of the people, whether he thought they could be induced to submit to it; and the energy and clearness of his representations were instrumental in procuring the repeal of that obnoxious measure.

On the commencement of hostilities between Great Britain and the colonies in 1775, he returned to America, and was chosen a delegate to congress by the legislature of Pennsylvania. In 1776 he treated with Lord Howe on the subject of a reconciliation, and in one of his letters expressed in strong terms the temper of the British nation, to which he imputed the fatal extremity then arrived. When the question of independence came to be discussed, he was decidedly in favour of the measure, and was highly instrumental in bringing over the public mind to the same opinion. When a negotiation with France was opened, Dr Franklin was chosen one of the personages to reside at that court. His political abilities eminently qualified him for such a station, and his character as a philosopher gained him great esteem in a country where knowledge is revered. He brought about a treaty with France of an offensive and defensive nature in 1778, the immediate consequence of which was a war with Britain. He was one of those who signed the provisional treaty the year following. Prior to his leaving Europe he concluded a treaty with Sweden and Prussia. He was recalled from that active station in 1785, which he had filled with so much ability, and chosen president of the supreme executive council. He was chosen president of a society for alleviating the miseries of prisons, and abolishing slavery. His increasing infirmities made him withdraw from all public business in 1788; and on April the 17th 1790, he terminated his active and useful life, in the 85th year of his age.

Perhaps no man ever exceeded Dr Franklin in that solid practical wisdom which consists in pursuing valuable ends by the most appropriate means. His cool temper and sound judgment secured him from erroneous expectations. He saw things in their true light, and predicted consequences with nearly a prophetic spirit. He said of himself "I have always set a greater value on the character of a *doer of good*, than any other kind of reputation." In 1779, his "Political, Miscellaneous, and Philosophical pieces," were published in 4to and 8vo. His essays, humorous, moral, and literary, were published after his death, in two small volumes.

He was by no means inattentive to his own interest, of which his rapid advancement in life furnishes an ample proof; yet he never neglected the interest of society, or the good of mankind in general. The delicate situations in which he frequently stood, unavoidably exposed him to the censure of his enemies; yet his general conduct has long ago received the approbation of his countrymen, by whom he was considered as the best and most valuable of citizens. When we view him as a philosopher, we must ascribe his chief merit to his electrical discoveries, yet on many other topics, such as meteorology and mechanics, he evinced himself a man of considerable penetration. As a political writer, his great merit is clearness, energy, and simplicity; and as a miscellaneous author he possesses a fund of humour which cannot fail to be at once both entertaining and impressive.

Franklin, the name of several counties in America, such as Franklin county in Pennsylvania, computed to contain 800 square miles, or 512,000 acres. It contains 11 townships, and 15,655 inhabitants. Franklin, a county in Kentucky; the name of one in Halifax, of one in Virginia, and of another in Georgia, which contains 1041 inhabitants, including 156 slaves. It is also the name of a township in Massachusets; of one in Pennsylvania, another in New York, and of another in Connecticut,

Connecticut, as well as of a small isle at the mouth of St George's river.

FRANKS, FRANCS, FRANKIS, or FRANQUIS, a name which the Turks, Arabs, Greeks, &c. give to all the people of the western parts of Europe. The appellation is commonly supposed to have had its rise in Asia, at the time of the croisades; when the French made the most considerable figure among the croissees: from which time the Turks, Saracens, Greeks, Abyssinians, &c. used it as a common term for all the Christians of Europe; and called Europe itself *Frankistan*. The Arabs and Mahometans, says M. d'Herbelot, apply the term *Franks* not only to the French (to whom the name originally belonged), but also to the Latins and Europeans in general.

But F. Goar, in his notes on Condinus, cap. 5. n. 43. furnishes another origin of the appellation *Franks*, of greater antiquity than the former. He observes, that the Greeks at first confined the name to the *Franci*, i. e. the German nations, who had settled themselves in France or Gaul; but afterwards they gave the same name to the Apulians and Calabrians, after they had been conquered by the Normans; and at length the name was farther extended to all the Latins.

In this sense is the word used by several Greek writers; as Comnenus, &c. who to distinguish the French, call them the *western Franks*. Du Cange adds, that about the time of Charlemagne they distinguished eastern France, western France, Latin or Roman France, and German France, which was the ancient France, afterwards called *Franconia*.

FRASCATI, or FRESCATI. See FRESCATI.

FRASERSBURGH, a small sea-port town in the county of Aberdeen, situated on the point of land called *Kinnaird's Head*, which is the southern extremity of the Murray frith. It has a small but excellent harbour, made and kept up at a considerable expence by the proprietor and the town, and well adapted for building small vessels. According to the tide, there are from 11 to 15 feet water within the harbour, and 20 feet immediately without at spring tides: without is a tolerable road for shipping, in a bay nearly a league in length and half a league in breadth, with good anchorage in a sandy bottom. Vessels of about 200 tons burden can enter the harbour. Frasersburgh contained 2271 inhabitants in 1811, and is well situated for trade with the east coast of Europe. The only manufacture carried on in Frasersburgh is in linen yarn, of which there is annually exported to the amount of 3000l. or 4000l.

FRATERNAL, something belonging to the relation of brother.

FRATERNAL Affection is the love and attachment subsisting among, or due to one another by, children of the same family.

Though all mankind sprung from the same head, are bound to cultivate a mutual good will to each other; yet this duty is not so obvious and striking as that which is incumbent on those who belong to the same family. Nothing can approach nearer to self love than fraternal affection: and there is but a short remove from our own concerns and happiness, to theirs who come from the same stock, and are partakers of the same blood. Nothing, therefore, can be more horrible than discord and animosity among members so allied; and nothing so beautiful as harmony and love.

This relation is formed by nature, not by choice; and though it has many things in common with, yet it is prior to, the obligations of friendship: consequently nature and reason dictate that there should be a peculiar affection between brethren. We are not obliged, however, to make a brother or sister an intimate or bosom friend in preference to one who is not akin. Diversity of temper, and want of suitable qualifications, may render it unsafe and improper. But where friendship and fraternity meet in the same persons, such a conjunction adds a lustre to the relation.

Among brethren, a hearty benevolence, an ardent concern for each others welfare, a readiness to serve and promote it, are the peculiar offices of this relation; and though friends are to have their share, yet the claim of kindred is first and ordinarily strongest. "Necessaria præsidia vitæ debentur iis maxime (says Cicero), quos ante dixi, (i. e. propinquis): vita autem, victusque communis, concilia, sermones, &c. in amicitiis vigent maxime," *De Officiis*.

FRATERNITY, BROTHERHOOD, the relation or union of brothers, friends, partners, associates, &c.

FRATERNITY, in a civil sense, is used for a guild, association, or society of persons, united into a body, for some common interest or advantage. See COMPANY and GUILD.

FRATERNITY, in the Roman Catholic countries, signifies a society for the improvement of devotion. Of these there are several sorts; as, 1. The fraternity of the rosary, founded by St Dominic. It is divided into two branches, called the *common rosary*, and the *perpetual rosary*; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. 2. The fraternity of the scapulary, whom the blessed Virgin, according to the sabbatine bull of Pope John XXII. has promised to deliver out of hell the first Sunday after their death. 3. The fraternity of St Francis's girdle, are clothed with a sack of a gray colour, which they tie with a cord, and in processions walk barefooted, carrying in their hands a wooden cross.—4. That of St Austin's leathern girdle comprehends a great many devotees. Italy, Spain, and Portugal, are the countries where one sees the greatest number of these fraternities, some of which assume the name of *arch-fraternities*. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to 40 poor girls on the feast of St Jerome their patron. The fraternity of death buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

FRATRES ARVALES. See ARVALES.

FRATRIAGE, the partition among brothers, or coheirs, coming to the same inheritance or succession.

FRATRICELLI, in ecclesiastical history, an enthusiastic sect of Franciscans, which rose in Italy, and particularly in the marquisate of Ancona, about the year 1294. The word is an Italian diminutive, signifying *fraterculi*, or "little brothers;" and was here used as a term of derision, as they were most of them apostate monks, whom the Italians call *fratelli*, or *fratricelli*. For this reason the term *fratricelli*, as a nickname, was given to many other sects, as the Catharists, the Waldenses, &c. however different in their opinions and in their conduct. But this denomination applied to

Fratricelli, Fratricide. the austere part of the Franciscans was considered as honourable. See FRANCISCANS.

The founders were P. Maurato, and P. de Fossombroni, who having obtained of Pope Celestin V. a permission to live in solitude, after the manner of hermits, and to observe the rule of St Francis in all its rigour, several idle vagabond monks joined them, who, living after their own fancies, and making all perfection to consist in poverty, were soon condemned by Pope Boniface VIII. and his successor, and the inquisitors ordered to proceed against them as heretics: which commission they executed with their usual barbarity. Upon this, retiring into Sicily, Peter John Oliva de Serignan had no sooner published his Comment on the Apocalypse, than they adopted his errors. They foretold the reformation of the church, and the restoration of the true gospel of Christ, by the genuine followers of St Francis, and declared their assent to almost all the doctrines which were published under the name of the abbot Joachim, in the "Introduction to the everlasting Gospel," a book published in 1520, and explained by one of the spiritual friars whose name was Gerhard. Among other enormities inculcated in this book, it is pretended that St Francis was the angel mentioned in Rev. xiv. 6. and had promulgated to the world the true and everlasting Gospel of God; that the Gospel of Christ was to be abrogated in 1620, and to give place to this new and everlasting Gospel, which was to be substituted in its room; and that the ministers of this great reformation were to be humble and bare-footed friars, destitute of all worldly employments. Some say they even elected a pope of their church; at least they appointed a general, with superiors, and built monasteries, &c. Besides the opinions of Oliva, they held, that the sacraments of the church were invalid; because those who administered them had no longer any power or jurisdiction. They were condemned afresh by Pope John XXII. in consequence of whose cruelty they regarded him as the true antichrist; but several of them returning into Germany, were sheltered by Lewis, duke of Bavaria, the emperor.

There are authentic records, from which it appears that no less than 2000 persons were burnt by the inquisition, from the year 1318 to the time of Innocent VI. for their inflexible attachment to the poverty of St Francis. The severities against them were again revived towards the close of the 15th century by Pope Nicolas V. and his successors. However, all the persecutions which this sect endured were not sufficient to extinguish it; for it subsisted until the times of the reformation in Germany, when its remaining votaries adopted the cause and embraced the doctrine and discipline of Luther. And this has led popish writers to charge the Fratricelli with many enormities, some of which are accounted by M. Bayle, art. *Fratricelli.*

The Fratricelli had divers other denominations: they were called *fratricelli*, according to some, because they lived in community, in imitation of the primitive Christians, or rather through the humility of the founder of the Franciscan order, to which the Fratricelli originally belonged; *Dulcini*, from one of their doctors; *Bizochi*, *Beguins*, and *Beghardi.*

FRATRICIDE, the crime of murdering one's brother. See PARRICIDE.

FRAUD, in *Law*, signifies deceit in grants or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

A fraudulent conveyance of lands or goods to deceive creditors, as to creditors is void in law. And a fraudulent conveyance in order to defraud purchasers, is also to such purchasers void; and the persons justifying or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewise shall be imprisoned. See CHEATING.

FRAUSTADT, a town of Silesia, on the frontiers of Poland, remarkable for a battle gained by the Swedes over the Saxons in 1706. It is 70 miles N. N. W. of Breslau. E. Long. 15. 50. N. Lat. 51. 45.

FRAXINELLA. See DICTAMNUS, BOTANY *Index.* —It is remarkable of this odorous plant, that, when in full blossom, the air which surrounds it in a still night may be inflamed by the approach of a lighted candle. Dr Watson doubts whether this inflammability proceeds from an inflammable air which is exhaled by the plant, or from some of the finer parts of the essential oil of the plant being dissolved in the common atmospherical air. The latter is the most probable supposition; for were it the pure inflammable air, as Mr Cavallo observes, it would, on account of its small specific gravity, leave the plant as soon as it was produced. Common air acquires the property of becoming inflammable, by being transmitted through several essential oils.

FRAXINUS, the ASH; a genus of plants belonging to the polygamia class; and in the natural method ranking under the 44th order, *Sepiariæ.* See BOTANY *Index.*

FRAY literally signifies to fret; as cloth or stuff does by rubbing, or over much wearing.

Among hunters a deer is said to fray his head, when he rubs it against a tree, to cause the skins of his new horns to come off.

FREA, or FRIGGA, the wife of Odin, was, next to him, the most revered divinity among the Heathen Saxons, Danes, and other northern nations. As Odin was believed to be the father, Frea was esteemed the mother of all the other gods. In the most ancient times, Frea was the same with the goddess Herthus, or Earth, who was so devoutly worshipped by the Angli and other German nations. But when Odin, the conqueror of the north, usurped the honours due only to the true Odin, his wife Frea usurped those which had been formerly paid to mother Earth. She was worshipped as the goddess of love and pleasure, who bestowed on her votaries a variety of delights, particularly happy marriages and easy childbirths. To Frea the sixth day of the week was consecrated, which still bears her name.

FREAM, a name given by farmers to ploughed land worn out of heart, and laid fallow till it recover.

FREATS, or FREITS, a term used in Scotland for *ill omens*, and sometimes denoting accidents supernaturally unlucky. King James VI. in his *Dæmonologie, MS. pen. Edit.* B. I. ch. iv. p. 13. "But I pray you forget not likewise to tell what are the Devill's rudiments? E. His rudiments I call first in general all that quhilk is called vulgairelie the virtu of woode, herbe, Freits. Frederick.

herbe, and staine; quhilk is used by unlawful charmis without natural causis. As lykeways all kynd of prattiques, *freitis, or other lyk extraordinair actions, quilk cannot abyde the trew twiche of naturall raison.*" It occurs again in the same sense in p. 14. *marg. note;* and in p. 51. speaking of *Sorcerers*, "And in generall that naime was gevin thaime for using of sic chairmis and *freitis*, as that craft teachis thaime."

FRECKLES, Lentigines, spots of a yellowish colour, of the bigness of a lentile seed, scattered over the face, neck, and hands. Freckles are either natural, or proceeding accidentally from the jaundice or the action of the sun upon the part. Heat or a sudden change of the weather, will often cause the skin to appear of a darker colour than natural; and thereby produce what is called *tan, sunburn*, and *morphew*, which seem to differ only in degree; and usually disappear in winter.

Persons of a fine complexion, and whose hair is red, are the most subject to freckles, especially in those parts which they expose to the air.

To remove freckles, put juice of lemons in a glass phial, and mixing it with sugar and borax finely powdered, let it digest eight days, and then use it. Homberg proposes bullocks gall mixed with alum, and, after the alum has precipitated, exposed three or four months to the sun in a close phial, as one of the best remedies known for the removing of freckles.

FREDBERG. See Freyberg.

FREDERICA, a town of North America, in Georgia, seated at the mouth of the river Alatamaha. It was founded by General Oglethorpe. The island it stands upon is called *St Simons's;* and is about 13 miles in length, and 4 in breadth. W. Long. 81. 25. N. Lat. 31. 13.

FREDERICK II. the Great, of Prussia, one of the greatest warriors of the age in which he lived, was the son of Frederick-William then hereditary prince of Brandenburg, and Maria Dorothea a princess of the house of Brunswick. He was born in 1712, the year before his father Frederick I. mounted the throne of Prussia. The latter was so far from being a patron of literature, that he regarded nothing but what related to the military art; and most of his generals, whatever their merits in their own line might be, scarce knew how to sign their names. So great indeed was the ignorance of the monarch himself, that he banished from his dominions a philosopher of the name of *Wolf*, merely because he maintained the doctrine of pre-established harmony; upon which a theologian named *Lange* asserted, that on such principles his majesty's grenadiers were not culpable when they deserted, it being only the necessary consequence of the impulse their machine had received from their Creator. His son was of a disposition the very reverse of his father. Being put from his birth under the care of Val de Recoule a French lady of great merit and understanding, he acquired, in his early years, not only a taste for literature in general, but a predilection for the French language, which was not obliterated throughout his whole life.

It is not to be supposed that a prince of the disposition above mentioned, would suffer his son to be long engaged in literary pursuits. At seven years of age, young Frederick was taken out of the hands of Madame de Recoule, and put under the care of military tutors. General count de Finkestein, an old warrior, was appointed his governor; his sub-governor was Colonel de Kalkstein, an officer renowned for his courage and experience; he was taught mathematics and fortification by Major Senning; Han de Jendun, a Frenchman, instructed him in other branches of knowledge; and a cadet of the name of *Kenzel*, taught him his exercise. At eight years of age he was furnished with a small arsenal stored with all sorts of arms proportioned to his age and strength, of which his father left him absolute master. In a short time he was named captain and chief of the corps of cadets; and the young prince performed every day, in miniature, with his little soldiers, all the evolutions with which his father exercised his giants. At last he received the command of a company in his father's regiment, famous throughout all Europe, and which was composed of men of whom scarce one was short of seven French feet.

Born, however, with a taste for the arts, he devoted to their cultivation every moment he could escape from the vigilance of his guardians. He was more particularly fond of poetry and music, and when he could find a moment's leisure, he read French authors, or played on the flute; but his father as often as he surprised him playing or reading, broke his flute and threw his books into the fire. The prince, chagrined at such injurious treatment, and having a great desire to visit Germany, England, France, and Italy, desired permission to travel. This, however, his father would not allow, but permitted him to accompany himself in the little journeys he made from time to time into Germany; and, in 1728, took him to Dresden to see the king of Poland. By these little expeditions the desire of the prince to visit other countries was only the more inflamed, so that at last he formed a design of setting out without his father's knowledge. The design was intrusted to two of the prince's young friends, named *Kat* and *Keit;* money was borrowed for the occasion, and the day of their departure fixed, when unluckily the whole project was discovered. The old king, implacable in his resentment, and considering his son as a deserter, determined to put him to death. He was shut up in the fortress of Custrin; and it was with the utmost difficulty that the count de Seckendorf, sent for the purpose by the emperor Charles VI. was able to alter the king's resolution. Certain vengeance, however, was determined on both the intended associates in Frederick's journey. Keit escaped the danger by flying into Holland; but Kat had not that good fortune. The king first directed that he should be tried by a court martial; but as they, contrary to his expectation, only sentenced the criminal to perpetual imprisonment, the revengeful monarch by an unheard-of exercise of the royal prerogative, caused him to be beheaded. The execution was performed under the windows of the prince royal, whose head was held towards the scaffold by four grenadiers: but no sooner did he approach the window, and see his friend in the hands of the executioner, than he stretched out his arms towards him, crying out, "Kat! Kat!" and instantly fainted away. During the remainder of his life he considered capital punishments with a great degree of horror, and they were rare throughout the Prussian dominions while he continued to reign. When the emperor had succeeded in preventing the execution of Frederick, the king remarked, that

Frederick. "Austria would one day see what a serpent she had nourished in her bosom." The royal prisoner remained a year at Custrin; during which time his father wished that he should learn the maxims of government and finance. For this purpose, M. de Munchow, president of the chamber of domains and finances, was ordered to make him assist at all their assemblies, to consider him as a simple counsellor, to treat him as such, and make him work like others. The young counsellor, however, though he assisted at their meetings, did not trouble himself with reading acts or copying decrees. Instead of this, he amused himself sometimes with reading French pamphlets, and at others with drawing caricatures of the president or members of the assembly. M. Munchow himself was likewise very favourable to the prince at this time, by furnishing him with books and other articles of amusement, notwithstanding the express prohibition of his father; though in this he certainly ran great risk; for the old king, who set but a very light value on human life, would undoubtedly have put him to death had he received intelligence of his complaisance.

Frederick, after passing the time above mentioned in confinement, was recalled to Berlin, on pretence of being present at the celebration of his eldest sister's marriage with the hereditary prince of Bareith; but the trne reason was, that the king had now prepared a match for the prince himself. This was the princess Elizabeth Christina of Brunswick, niece to the empress. Frederick, who was not only totally indifferent to the fair sex in general, but particularly prejudiced against this princess, made some objections; his father, however, overcame all obstacles with "his usual arguments (says the author of the life of Frederick), viz. his cane, and a few kicks."

The coldness which Frederick at this time showed for the fair sex appears not to have been natural; for as early as the year 1723, though then only in the 11th year of his age, he is said to have fallen in love with the princess Anne, daughter of George II. Even at this early period he entered into vows to refuse every other but her for his consort; nor were these ever broken, as far as depended on himself. The marriage perhaps would have taken place, had it not been for some differences which arose between the courts of Prussia and Hanover about a few acres of meadow land, and two or three Hanoverians inlisted by the Prussian recruiters. It is supposed also, that it was intended at one time to marry him to Maria Theresa of Austria; but, as in that case it would have been necessary to change his religion, Frederick derived from thence a plausible pretence for refusing the match. The princess whom he espoused had a large share of beauty; and, what was still better, an excellent heart: but Frederick is said to have suffered so much in his former amours, that certain natural and unsurmountable impediments remained to the completing of his marriage with any woman. Scarcely therefore was he in bed with his young spouse, when a cry of *Fire!* was raised by his friends. Frederick got up to see where the conflagration was: but finding it to be a false alarm, he sent messengers to compose the princess; but neither that night, nor any other, did he think proper to disturb her rest.

On occasion of this marriage, Frederick received from his father the county of Rupin. He resided in the capital of this county, named also *Rupin*, for some time; but afterwards chose Rheinsberg for his place of abode. This is a little town built in the sands, on the confines of Mecklenburg, and at that time containing only 1000 inhabitants; but it was soon greatly improved by Frederick. Having put over the great gate of the castle, however, the following inscription, FREDERICO TRANQUILLITATEM COLENTI, his father was displeased with it, and therefore hurried him from his peaceful retreat into the noise and tumult of war. At this time the succession to the crown of Poland had kindled a general war throughout Europe, and the king of Prussia was to send 10,000 auxiliaries to the Imperial army, then commanded by Prince Eugene. The king conducted his troops in person, and resolved to take this opportunity of giving his son an idea of war. At this time, however, he learnt but little; and only saw, as he himself expresses it, the shadow of the great Eugene. That consummate general, nevertheless, did not overlook his merit; but predicted that he would one day be a great captain. Frederick having gone to reconnoitre the lines at Philipsburg, in his return through a very open wood, was exposed to the cannon of the lines, which thundered incessantly. The balls broke a number of branches on every side of him: notwithstanding which, he never caused his horse to move quicker; nor did his hand which held the bridle ever alter its motion even for a moment. He continued to converse quietly with the generals who attended him, and never showed the smallest sign of apprehension. Being one night at supper with Field-Marshal Grumkow, the conversation turned on the young Prince Eugene who died on the Rhine; and he was asked whether that prince would ever have become a great man? Frederick decided in the negative, on account of young Eugene's not having known at any period of his life how to choose a friend who dared to tell him the truth.

During this campaign the health of the old king was so much impaired, that he was obliged to leave the army; and Frederick, on his return, was for some time intrusted with signing all the orders in his father's name. On the king's recovery the prince was sent to Stettin, under the care of the prince of Dessau, that he might see the fortifications of that town. He was afterwards permitted to go to Konigsberg to see the unfortunate Stanislaus, who had taken refuge in that place, and who was no less remarkable for his philosophy and constancy than for his misfortunes. With him Frederick remained for some weeks, and contracted a friendship which was not dissolved but by the death of Stanislaus. At last he was allowed to return to his peaceful mansion at Rheinsberg, where he remained till the death of his father. In this place his time was occupied alternately by the study of the sciences, the cultivation of the arts, and the pleasures of friendship. Philosophy, history, politics, the military art, poetry, and music, agreeably succeeded each other, and had each its stated period. The prince passed the greatest part of the day in his library; and the remainder in the society of a select company of agreeable and learned men. The principal of these were Chasot, a French officer; Kayserling, a gentleman of Courland, on whom the prince bestowed the name of *Cæsarion;* Jordan, a French refugee; and Knobelsdorf, director of the buildings and gardens; but who could converse on all the arts of designing with great taste and judgment.—In these meetings, gaiety generally presided; there were generals to speak of war, musicians to form concerts, and excellent painters to decorate the apartments. Whilst Knobelsdorf was executing landscapes and laying out the gardens, Pesne was immortalizing himself by his ceilings, and Du Buisson by his pictures of flowers. The two Grauns composed excellent music, or directed the orchestra; and Benda, one of the first violins of Europe, accompanied the prince, who played extremely well on the flute. The morning was usually dedicated to study; gaiety and agreeable conversation prevailed at every repast; and every evening there was a little concert.—In this retreat Frederick conceived that ardent passion for military glory, and the aggrandizement of his kingdom, for which he became at last so remarkable; and here he is supposed to have formed the most sublime and daring projects. He was fired with a desire of imitating the celebrated heroes of antiquity, of whom he read in the ancient authors, and for which he set apart some hours every day. Amongst the works which he read almost every year were Herodotus, Thucydides, Xenophon, Plutarch, Tacitus, Sallust, Livy, Quintus Curtius, Cornelius Nepos, Valerius Maximus, Polybius, Cæsar, Vegetius, &c. He never spoke but with enthusiasm of the great warriors of Greece and Rome; and when seated on the throne thought he could never distinguish an able soldier in a more honourable manner than by conferring on him a Roman sirname. Hence he distinguished by the name of *Quintus Icilius* M. Guichard, who had written some treatises on the military art of the ancients; giving him at the same time a free battalion. This name of *Quintus Icilius* was retained by M. Guichard as long as he lived.

In his pursuit of glory Frederick found that it was not improper to cultivate the friendship of celebrated poets, philosophers, and others of the literary class; for which purpose he flattered, commended, and complimented all the most celebrated literati of Europe at that time. "The philosophers (says the author of his life) answered him as a mad lover writes to his mistress. They wrote to him that he was a great poet, a great philosopher, the *Solomon* of the north. All these hyperboles were printed; and Solomon was not sorry for it, though he had too much understanding to believe in them. Wolf, Rollin, Gravesande, Maupertuis, Algarotti, Voltaire, were honoured with his correspondence. The last especially, accustomed to offer up incense to the idol of the day, were it transported from the dunghill to the altar, did not fail to exalt as the first man of the universe a prince who was in expectancy of the throne, and who assured him that he was the greatest philosopher of the age and the first poet in the world."

That Frederick might keep up his character with the literati, or perhaps from a real predilection for his principles, he patronized the Apology of Wolf, and had his principal treatises translated into French. He even prevailed upon his father to relax a little in favour of that philosopher. A commission of reformed and Lutheran theologians was appointed in 1736, to examine into the tenets of that unfortunate philosopher. Wolf was declared innocent, and a letter was sent to him at Marpourg containing an invitation to return; but the philosopher did not think proper to make his appearance till the year 1740, when his protector was seated on the throne.

During his residence at Rheinsberg, Frederick composed his refutation of the principles of Machiavel, under the title of *Anti-Machiavel:* of which he sent the manuscript to Voltaire to correct, and to get printed.

The old king, now almost worn out with infirmity, saw with regret the predilection his son entertained for men of letters; and, in his peevish fits, often threatened the whole society with confinement in the fortress of Spandau. These threats frequently occasioned a violent alarm among the joyous company at Rheinsberg, which it required all the eloquence of Frederick to quiet. Their apprehensions on this account, however, were soon removed. At the commencement of the year 1740, the king's disorder increased to a great degree, and in the month of May his case became desperate. He lived, however, till the 31st of that month, when he expired, and left the throne to his son Frederick II.

The acquisition of a kingdom did not abate Frederick's passion for literature, though to this he was now obliged to superadd the qualities and labours of a great king. A consideration of his transactions in this character falls under the article PRUSSIA, to which we refer: these, indeed, so totally engrossed the remaining part of his life, that little more remains to be said under this article, than to relate some anecdotes by which we may be in some measure able to trace the character of this great and singular personage.

It has already been mentioned, that in the early part of his life, Frederick had conceived a great inclination to travel. This passion seems not to have been extinguished by the splendour of his new situation; for having, soon after his accession, gone into Prussia and Westphalia to receive the homage of the inhabitants, he formed a resolution of proceeding *incognita* as far as Paris. Being discovered at Strasbourg, however, he laid aside the design of proceeding to Paris, and went to see his states in Lower Germany. Here he wrote the celebrated Voltaire, that he should come *incognito* to visit him at Brussels; but being seized with an indisposition in the little palace of Meuse, two leagues from Cleves, he wrote again to that philosopher, informing him that he expected he should make the first advances. The following curious account is given by him of his reception, &c. "The only guard I found at the gate was one soldier. The privy counsellor, Bambonet, was cooling his heels in the court: he had large ruffles of dirty linen; a hat full of holes; and an old magisterial peruke, one end of which descended as low as his pockets, and the other scarcely reached his shoulder. I was conducted into his majesty's apartment, where there was nothing but bare walls. I perceived in a cabinet, by the glimmering of a taper, a truckle bed, two feet and a half wide, on which lay a little man muffled up in a night gown of coarse blue cloth. This was the king, in a strong perspiration, and even trembling, under a wretched blanket, in a violent fit of the ague. I bowed to him; and began by feeling his pulse, as if I had been his first physician. The fit over, he dressed himself and sat down to table. Algarotti, Kayserling, Maupertuis, the king's minister to the States General, and myself, were of the party; where we

Frederick. we conversed profoundly on the immortality of the soul, on liberty, and the androgynes of Plato."

This rigid economy, and contempt of every luxury with regard to his own person, was maintained by Frederick as long as he lived. The following account, taken likewise from Voltaire, will give an idea of his manner of living. "He rose at five in the morning in summer, and six in winter. A lacquey came to light his fire, and dress and shave him; and indeed he almost wholly dressed himself. His room was not inelegant. A rich ballustrade of silver, ornamented with little cupids, seemed to enclose an alcove bed, the curtains of which were visible; but behind them, instead of a bed, there was a library: the king slept on a truckle bed with a slight mattress concealed behind a screen. Marcus Aurelius and Julian, those apostles of Stoicism, did not sleep in a more homely manner. At seven his prime minister arrived with a great bundle of papers under his arm. This prime minister was no other than a clerk who had formerly been a soldier and valet-de-chambre. To him the secretaries sent all their dispatches, and he brought extracts of them, to which the king wrote answers in two words on the margin: and thus the affairs of the whole kingdom were expedited in an honr. Towards eleven the king put on his boots, reviewed his regiment of guards in the garden, and at the same hour the colonels were following his example in their respective provinces. The princes his brothers, their general officers, and one or two chamberlains, dined at his table; which was as good as it could be in a country where there is neither game, tolerable butchers meat, nor a pullet, and where the very wheat is brought from Magdebourg. After the repast, he retired alone into his cabinet, where he made verses till five or six o'clock. Then came a young man named D'Arget, formerly secretary to Valory the French envoy, who read to him. A little concert began at seven, in which the king played on the flute with as much skill as the first performer; and pieces of his composition were frequently executed. Supper was served in a little hall, the singular and striking ornament of which was a picture, the design of which he had given to Pesne, one of our best colourists. It was a fine picture of Priapus. These repasts were not in general the less philosophic on that account. Never did men converse in any part of the world with so much liberty respecting all the superstitions of mankind, and never were they treated with more pleasantry and contempt. God was respected; but none of those who had deceived men in his name were spared. Neither women nor priests ever entered the palace. In a word, Frederick lived without a court, without counsel, and without religious worship."

As Frederick had espoused his princess entirely contrary to his inclination, it was imagined that on his accession to the throne he would embrace the opportunity of setting himself free from engagements so disagreeable to himself. The queen was not without suspicions of this kind, insomuch that she was on the point of fainting away when he made his first visit to her. To the surprise of all parties, however, he made her a very affectionate speech, apologizing for his indifference, and inviting her to participate with him the throne of which she was so worthy. In the first year of his reign he restored the academy of sciences at Berlin which had been founded in 1700; but he soon became disgusted with its members, whom he endeavoured at all times to ridicule rather than encourage. His war with the queen of Hungary, however, which took place almost immediately after his accession, for some time prevented him from taking such an active part in literary matters as he was naturally inclined to do. After the peace, being at liberty to follow his inclination, he gave full scope to his passion for literature; and in the interval betwixt the conclusion of the first war and beginning of that of 1756, he composed most of the works which are now ascribed to him. At this time he wrote his *History of my own Times*, afterwards announced among his posthumous works. In writing history he acquired a taste for historians; and justly gave the preference to the ancients, the most celebrated of whose works he perused every year. Voltaire was his principal literary correspondent, whom he invited to reside with him. Afraid of losing his liberty, however, that philosopher hesitated, excused himself, and entered into pecuniary treaties, first for himself, and afterwards for his niece Madame Dennis, whom he wished to accompany him. At last he was determined by seeing a poem from Frederick to M. d'Arnaud, in which the latter was compared to the rising, and Voltaire to the setting sun. By this Voltaire was so much piqued, that he set out for Berlin without delay, and arrived there in June 1750. He was received in the most magnificent and affectionate manner, and for some time his situation was very agreeable; but the disputes and rivalship which took place betwixt him and Maupertuis soon threw every thing into confusion. In these the king interfered in such a manner as was certainly below his dignity; and he often exercised himself in making a jest of the other men of letters in a way exceedingly disgusting, and which induced many of them to leave him. The squabbles with Voltaire were sometimes very diverting; an account of some of which is given under the article VOLTAIRE. They ended at last in a final quarrel with that wit, and his departure from the kingdom. The restless disposition of Frederick showed itself after his departure, by his attempts to provoke the literati who remained at his court to quarrel with him as Voltaire had been accustomed to do. But they were of too passive a disposition to gratify him in this respect, choosing rather to suffer the most mortifying strokes of raillery, or to leave the kingdom altogether, than to contend with him. This proved so uneasy to the king, that he one day exclaimed, "Shall we have no more quarrels then?" The breaking out of the war in 1756, however, put a stop to his diversion, and afforded him as many enemies as he could wish. The exploits he performed during the seven years which this unequal contest lasted, are almost incredible *; and it is amazing how the fortitude and resolution of any person could enable him to sustain the difficulties which during this period he had to encounter. In one fatal moment, indeed, even the resolution of Frederick was on the point of giving way. This happened after the battle of Colin, when his affairs seemed altogether desperate, before they were retrieved by the victory at Rosbach. At this time he wrote to his sister at Bareith, that he was on the point of putting an end to his own life; but as this resolution did not extinguish in him the love of glory, he wished

* See Prussia.

Frederick. wished to have it said that he made verses on the brink of the grave. With this view he wrote a long poetical epistle to the marquis d'Argens, in which he communicated to him his design, and bade him farewell.

Happily, at last, the king's affairs took a better turn, and such desperate thoughts were laid aside. His constitution, however, was irreparably injured by the excessive fatigues he had sustained. Soon after the conclusion of the peace, his body began to bend, and his head to incline to the right side: by degrees he became very infirm; he was tormented with the gout, and subject to frequent indigestions. All his distempers, however, were born with invincible patience; and, till a very short time before his death, he never ceased to attend his reviews, or visit the different provinces of his dominions. He has been known to review his troops, and gallop through all the ranks as if he felt no pain, notwithstanding that an abscess which had broken out upon him, and approached to a suppuration, frequently, upon such occasions, touched the saddle. In August 1785 he impaired his health still farther by assisting at a review, where he was exposed without even a cloak to a heavy rain for four or five hours. On his return to Potzdam he was seized with a fever; and, for the first time, became unable to assist at the military exercises of Potzdam, which take place in September. His malady, however, did not prevent him from dictating the disposition of these exercises during the three days they lasted, and he always gave the word in presence of his generals and the foreigners of distinction then at Potzdam. About the end of autumn the fever left him, but was succeeded by a violent cough; and he continued free from the gout which had usually attacked him at this season. He was greatly weakened by the cough, which prevented him from sleeping; but this did not in the least interrupt him in the execution of business. Every morning at four or five o'clock, he ordered the three cabinet secretaries to enter his apartment, where he dictated answers to their papers. It was not till after the dispatch of all his affairs that he saw a surgeon or sometimes a physician, though he had a bad opinion of the physicians in general, whom he consulted on his distemper. In the evening he amused himself from five to eight with some of his society; and after that hour he passed the remainder of the time before he went to rest, in hearing some ancient authors read to him; and thus he continued to employ himself till the very day before he died. On the 17th and 18th of May 1786, he was unable to assist at the ordinary reviews, but still he hoped to be present at those of Silesia. He several times attempted to mount his horse to go to the parade at Potzdam; but finding his powers insufficient, he was obliged to return, after having proceeded a few paces. He made other attempts, but with as little success; and at last his disorder terminated in a dropsy. Being now no longer able to remain in bed, he sat day and night in an arm chair with springs which could be moved at pleasure. For near a month before his death the swelling of his feet gave him violent pain, so that he wished an incision to be made; but the surgeon refused to perform the operation, suspecting that it might hasten his death. Nature, however, accomplished his desires; his right leg opened, and discharged such a quantity of matter, that he was greatly relieved: and those unacquainted with the medical art began to entertain hopes of his recovery. The physicians, however, were of a very different opinion; and the event justified their apprehensions. On the 16th of August 1786 his throat began to rattle violently, and his attendants expected every moment that he would breathe his last. In this situation his three secretaries entered the room for the despatch of business as usual. Even then Frederick made an effort to collect his force, giving them a sign to wait, as if he would speak with them in a short time. This, however, was the last he could make: for he soon after fell into a stupor; though from this he recovered so far as to be able to speak. In the evening he asked what o'clock it was? and on being answered that it was nine, he said, "Well then I am going to rest." His respiration and voice became gradually more feeble; and he expired on Thursday at 19 minutes after two in the morning, without any convulsion or symptom of pain.

This great monarch was of the middle size, had large blue eyes and a piercing look. He spoke German incorrectly, and in a very rough manner; but talked French very fluently, and his voice was then mild and agreeable. His constitution was naturally feeble, but he had greatly improved it by his activity and laborious life. He had the art of relieving every one from that embarrassment which frequently occurred in accosting such a celebrated monarch; and it seems probable that he himself considered on what he should say to any illustrious person who happened to come to his court. His universal knowledge enabled him to converse on all subjects; and thus he talked of war with military men, of verses with the poet, of agriculture with the farmer, jurisprudence with the lawyer, commerce with the merchants, and politics with the Englishman. He had a very retentive memory; was fond of solitude and gardening; and likewise took great pleasure in dogs, of which animals he constantly kept a number about him, giving them little balls covered with leather to play with. In company, he was fond of asking questions and jesting; in which last he proceeded such lengths as undoubtedly was unbecoming in a superior towards his inferiors, who would not have failed to resent such jokes from persons more on an equality with them. In military affairs he was excessively severe, not to say cruel; of which the following anecdote may serve as an instance. In the first war of Silesia, wishing to make some alterations in his camp during the night, he forbade every person, under pain of death, to keep, after a certain hour, a fire or other light in his tent. He himself went the rounds; and in passing the tent of a Captain Zietern he perceived a light. Entering the tent, he found the captain sealing a letter to his wife, for whom he had a great affection. "What are you doing there? (says the king): Do you not know the order?" The captain fell on his knees and asked pardon, but did not attempt to make any excuse. "Sit down (says Frederick), and add a few words I am going to dictate to you." Zietern obeyed; and the king dictated, "To morrow I shall perish on a scaffold." The unfortunate man wrote them, and next day was executed. In matters of domestic legislation, he was more arbitrary than just; of which we have a notable example in the

famous

Frederick, Fredericksburg.

famous case of Arnold the miller. The man had refused to pay the rent of the mill he possessed, on pretence that the stream which turned it had been diverted into a fish pond. This was evidently a frivolous excuse; because the water which ran into the pond also ran out of it into the same channel as before, so that nothing could be lost, except what evaporated from the surface of the fish-pond. The judges therefore gave sentence against the miller; but the king not only reversed their sentence, but disgraced them. For this he was celebrated through all the newspapers in Europe; and yet he was in the wrong, and afterwards even acknowledged himself to have been so: but, notwithstanding he knew his error, he not only made no reparation to the parties he had injured, but allowed them to lie in prison at Spandau all his lifetime, so that they were not released till the commencement of the succeeding reign. He entertained certain and almost unaccountable prejudices against certain places and persons, which neither conduct nor merit could eradicate. One of these unfortunate places was Westphalia, on which he never conferred any bounty: and one day a native of that country, a man of great merit, being proposed to him for a place, he refused, saying, "He is a Westphalian; he is good for nothing." Voltaire accuses him of ingratitude to the count de Seckendorf; who, as we have already seen, saved his life, and against whom he afterwards conceived most implacable hatred. His indifference towards those who afforded him the most essential service, was evident: when a robust butcher prevented him from falling, horse and all, over a precipice, where both would have undoubtedly been killed, the king, sensible of the assistance that had been afforded him, turned about, and saying, "Thank you, friend," rode off without ever enquiring farther about the person who had just preserved him from destruction.

With regard to the literary merits of this monarch, we certainly cannot pronounce them extraordinary. Voltaire boasts of having corrected his works, and others of having furnished him with materials for his history. He has been accused of borrowing whole hemistichs of poetry from Voltaire, Boileau, Rousseau, and others; nor does the charge appear to be at all void of foundation. Such of his verses as appear to have undergone no correction, are very indifferent, nor indeed can we pronounce any of his poetic works to be of the first rate. In the former part of his life he entertained a great partiality for the French learning and language; but as he advanced in years, he entirely lost this predilection, and inclined much more to favour the English and Germans. Towards the end of his life, indeed, he affected a contempt for the French, without whom it is said he would scarcely ever have made any figure except in military affairs.

Frederick, is the name of two counties, and of several townships in America, such as the county of Frederick in Maryland, which contains 30,791 inhabitants, in which are included 3641 slaves. It is also the name of a county in Virginia, 30 miles long and 20 broad, with a population of 19,681 souls, including 4250 slaves.

FREDERICKSBURG, a fort and colony of Brandenburg, on the Gold coast of Guinea, in Africa, near Cape Threepoints, and about 75 miles from Cape Coast. It mounts 46 pieces of cannon on four batteries; and formerly belonged to the Prussians, but is now subject to Denmark. W. Long. 1. 15. N. Lat. 6. 40.

Fredericksburg, Free stone.

FREDERICKSHALL, or Frederickstadt, a strong town of Norway, in the prefecture of Agerhuys, where Charles XII. king of Sweden was killed by a musket ball in 1718, when he was besieging this town. It is seated on the coast of the Categate, in E. Long. 10. 45. N. Lat. 59. 2.

FREDERICKSODE, a town of Denmark, in Jutland, taken by the Swedes in 1657, but now subject to Denmark. It is seated near the sea, in E. Long. 99. 44. N. Lat. 55. 35.

FREDERICKSTADT, a town of Denmark, in South Jutland, built in 1621. It is seated on the river Eyder, in E. Long. 9. N. Lat. 54. 28.

Frederickstadt, a town of Norway, in the province of Agerhuys, seated on a bay of the sea, near the frontiers of Sweden, in E. Long. 11. 6. N. Lat. 59. 12.

FREE, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

Free Bench, signifies that estate in copyhold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor.

In regard to this free bench, different manors have different customs: and in the manor of East and West Enbourne in the county of Berks, and in other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free bench in all the deceased husband's lands, *dum sola et casta fuerit*, "while she lives single and chaste;" but if she is found to be guilty of incontinency, she shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, the steward is bound by custom to restore her to her free bench. The words are,

Here I am,
Riding on a black Ram,
Like a whore as I am;
And for my crincum crancum
Have lost my bincum bancum,
And for my tail's game
Have done this wordly shame:
Therefore, pray Mr Steward, let me have my land again.

Free or *Imperial Cities*, in Germany, are those not subject to any particular prince; but governed, like republics, by their own magistrates.

There were free cities (*liberæ civitates*) even under the ancient Roman empire: such were those to whom the emperor, by the advice or consent of the senate, gave the privilege of appointing their own magistrates, and governing themselves by their own laws. See City.

Free Fishery. See *Free Fishery*.

Free Warren. See Warren.

Free Mason. See Mason.

Free Stone, a whitish stone, dug up in many parts of of Britain, which is hard and durable, and of excellent use in building, &c. It is a kind of the grit stone, but finer sanded and smoother; and is called *free*, from its being of such a construction as to cut freely in any direction.

The qualities of the several kinds of free stones used in the different parts of Europe are very different. They all agree in this general property, indeed, that they are softer while in the quarry than when they have been some time exposed to the air: but even this general property differs greatly in degree. There is a sort of gray free stone in use at Paris (of which we do not yet seem to have met with any in this country), which has the above-mentioned quality in so great a degree, that the expence of working it is in a great measure saved.

This stone lies everywhere on the south side of the river Seine, and is of a coarse and large grit. It is so soft when newly taken out of the strata, that they fashion it very conveniently with a sort of broad axe, and form as many stones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this stone is as soft as dry clay when first taken up, it is found to harden so considerably in the air, that it becomes more than equal to our ordinary free stone.

The Portland free stone of Britain of the finest kind, which is white and of a close grit, is very fit for hewing and carving; but it will neither resist water nor fire, which is a very singular instance in so dense a stone; while the free stone of Kent, which is less beautiful to the eye, and is of a grayish colour, and considerably close, though of a larger grain, resists the air and water very well. The freestone of Derbyshire, on the other hand, is so brittle as to be unfit for any fine working; and so coarse and open in its texture, that it lets water through: yet it bears the fire extremely well, and is fit for ovens, hearths, &c.

FREEBOOTER, or Flibuster, a name given to the pirates who scour the American seas, particularly such as make war against the Spaniards. See Bucanier.

FREEDOM, in general, the state or quality of being free. See Liberty.

Freedom of a Corporation, the right of enjoying all the privileges and immunities belonging to it. See Corporation.

The freedom of cities, and other corporations, is regularly obtained by serving an apprenticeship; but it is also purchased with money, and sometimes conferred by way of compliment.

Freedom of Conscience. See Toleration.

Freedom of the Will, that power or faculty of the mind, whereby it is capable of acting or not acting, choosing or rejecting whatever it judges proper †. Of this every man must be sensible, who finds in himself a power to begin or forbear, continue or end several actions, barely by a thought or preference of the mind.

† See Metaphysics.

FREEHOLD, Frank Tenement, (*liberum tenementum*), is land, or tenement, which a man holds in *fee-simple*, *fee-tail*, or for term of life. See Fee and Tail.

Freehold is of two kinds, in *deed* and in *law*.

The first is the real possession of land or tenement in fee, fee-tail, or for life: the other is the right a man has to such land or tenement before his entry or seizure.

A freehold, by the common law, cannot commence *in futuro*; but it must take effect presently, either in possession, reversion, or remainder. Whatever is part of the freehold goes to the heir; and things fixed thereto may not be taken in distress for rent, or in execution, &c. No man shall be disseised of his freehold by stat. Magna Charta, cap. 29. but by judgment of his peers, or according to the laws of the land; nor shall any distrain freeholders to answer for their freehold in any thing concerning the same, without the king's writ. Freehold estates, of certain value, are required by statutes to qualify jurors, electors of the knights of the shire in parliament, &c.

Freehold is likewise extended to such offices as a man holds in fee, or for life.

Freehold is also sometimes taken in opposition to villenage.

Lambard observes, that land, in the Saxons time, was distinguished into *bockland*, i. e. holden by book or writing; and *folkland*, held without writing. The former, he says, was held on far better condition, and by the better sort of tenants, as noblemen and gentlemen; being such as we now call *freehold*: the latter was mostly in possession of peasants; being the same with what we now call *at the will of the lord*.

In the ancient laws of Scotland, freeholders are called *milites*, "knights." In Reg. Judicial. it is expressed, that he who holds land upon an execution of a statute merchant, until he hath satisfied the debt, *tenet ut liberum tenementum sibi et assignatis suis*; and the same of a tenant *per elegit*: the meaning of which seems to be, not that such tenants are freeholders, but as freeholders for the time, till they have received profits to the value of their debt.

FREETHINKER. See Deist.

FREEZE, Frieza, or *Frize*, in *Commerce*. See Frize.

Freeze, in *Architecture*, that part of the entablature of columns, between the architrave and corniche.

The freeze is properly a large flat face, or member, separating the architrave from the corniche.

The ancients called it *zoophorus* (ζωφορος) because it was usually enriched with figures of animals; and our denomination *freeze* has a like origin, being formed of the Latin *phrygio*, "an embroiderer," because it is commonly adorned with sculptures in basso relievo, imitating embroidery.

FREEZING, in *Philosophy*, the same with congelation. See Freezing, Chemistry *Index*; and Salts.

Freezing Rain, or *Raining Ice*, a very uncommon kind of shower, which fell in the west of England, in December 1672; whereof we have divers accounts in the Philosophical Transactions.

The rain, as soon as it touched any thing above ground, as a bough or the like, immediately settled into ice, and by multiplying and enlarging the icicles, broke all down with its weight. The rain that fell on the snow immediately froze into ice, without sinking in the snow at all.

It made an incredible destruction of trees, beyond any thing in all history. "Had it concluded with some gust of wind (says a gentleman on the spot), it might

might have been of terrible consequence. I weighed the sprig of an ash tree, of just three quarters of a pound; the ice on which weighed 16 pounds. Some were frighted with the noise in the air; till they discerned it was the clatter of icy boughs, dashed against each other." Dr Beale observes, that there was no considerable frost observed on the ground during the whole; whence he concludes, that a frost may be very intense and dangerous on the tops of some hills and plains, while in other places it keeps at two, three, or four feet distance above the ground, rivers, lakes, &c. and may wander about furious in some places and remiss in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits.

FREIGHT, in *Navigation* and *Commerce*, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel. See *Maritime Laws*.

FREIND, John, a most learned English physician and writer of the 18th century, was born at Croton, Northamptonshire, in 1675. In 1696, he published, in conjunction with Mr P. Foulkes, an edition of two Greek orations, one of Æschines against Ctesiphon, and the other of Demosthenes *de Corona*, with a new Latin version. In 1699, he wrote a letter to Dr Solane concerning an *Hydrocephalus*, published in the Philosophical Transactions; and another letter in Latin to the same gentleman, *De spasmis rarior. historia*, printed in the same Transactions. In 1703, his *Emmenalogia* appeared, which gained him great reputation. In 1704, he was chosen professor of chemistry in the university of Oxford. In 1705 he attended the earl of Peterborough to Spain, as physician to the army there; and, upon his return in 1707, published an account of the earl's expedition and conduct. In 1709 he published his Chemical Leetures. In 1712 he attended the duke of Ormond in Flanders, as his physician. In 1716 he was admitted a fellow of the College of Physicians in London. This year he published the first and third books of Hippocrates *De morbis popularibus*, with a Commentary on Fevers, written by himself. He sat member for the borough of Launceston in Cornwall in 1722, where he distinguished himself by his opposition to the administration. March 1722, he was committed to the Tower on a charge of high treason; and while he was under confinement, he wrote a Latin epistle to Dr Mead, *de quibusdam variolarum generibus;* and began his History of Physic, the first part of which was published in 1725, and the second in 1726. Upon the accession of George II. to the throne, he was appointed physician in ordinary to the queen, who showed the utmost regard and esteem for him. He died at London in 1728. His works were published together in Latin at London, 1733, in folio, and dedicated to the queen.

FREITS. See Freats.

FRENCH, in general, something belonging to France: thus we say, the French language, French custom, polity, &c.

The French language, as it now stands, is no original or mother language, but a medley of several. Those that prevail most, and which are, as it were, the basis thereof are, 1. The Celtic; whether that were a particular language itself, or whether it were only a dialect of the Gothic, as spoke in the west and north. 2. The Latin, which the Romans carried with them into Gaul, when they made the conquest thereof. And, 3. The Teutonic, or that dialect of the Teutonic spoke by the Franks, when they passed the Rhine, and established themselves in Gaul. Of these three languages, in the space of about thirteen hundred years, was the present French formed, such as it is now found. Its progress was very slow; and both the Italian and Spanish were regular languages long before the French.

Pasquier observes, it was under Philip de Valois that the French tongue first began to be polished; and that, in the register of the chamber of accounts of that time, there is a purity seen almost equal to that of the present age. However, the French was still a very imperfect language till the reign of Francis I.; the custom of speaking Latin at the bar, and of writing the public acts and instruments of the courts of justice in that language, had made them overlook the French, their own language. Add that the preceding ages had been remarkable for their ignorance, which was owing, in a good measure, to the long and calamitous wars which France had been engaged in; whence the French noblesse deemed it a kind of merit not to know any thing; and the generals regarded little whether or not they wrote and talked politely, provided they could but fight well.

But Francis I. who was the restorer of learning, and the father of the learned, changed the face of things; and after his time, Henry Stevens printed his book, *De la Precellence du Langage François*. The change had become very conspicuous at the end of the 16th century; and under Henry IV. Amyot, Coeffeteau, and Malherbe, contributed towards bringing it to its perfection; which the Cardinal de Richelieu completed, by the establishment of the French academy; an assembly, wherein the most distinguished persons of the church, the sword, and the gown, have been members. Nor did the long reign of Louis XIV. contribute a little to the improvement of the language; the personal qualities of that prince, and his taste for the fine arts, and that of the princes of the blood, rendered his court the politest in Europe. Wit and magnificence seemed to vie; and his generals might have disputed with the Greeks, Romans, &c. the glory of writing well, if they could not that of fighting. From court, the elegance and purity of the language soon spread itself into the provinces; and now there is scarce anybody there who does not write and speak good French.

One of the characters of the French language is, to be natural and easy. The words are ranged in it much in the same order as the ideas in our minds; in which it differs exceedingly from the Greek and Latin, where the inversion of the natural order of words is reputed a beauty. Indeed the Hebrew surpasses even the French in this point; but then it comes short of it in copiousness and variety.

It must be added, however, that as to the analogy of grammar, and the simplicity wherewith the moods of verbs are formed, the English has the advantage not only over the French, but over all the known languages in in the world; but then the turns, the expressions, and the idioms of the English, are sometimes so quaint and extraordinary, that it loses a good deal of the advantage which its grammatical simplicity gives it over the rest.

The French has but few compound words; wherein it differs widely from the Greek, High Dutch, and English. This the French authors own a great disadvantage in their language; the Greek and Dutch deriving a great part of their force and energy from the composition of words, and frequently expressing that in one sounding word, which the French cannot express but by a periphrasis. The diminutives in the French are as few as the compounds; the greatest part of those remaining in use having lost their diminutive signification; but what distinguish the French most, are its justness, purity, accuracy, and flexibility.

French is the most universal and extensive language in Europe. The policy of states and courts has rendered it necessary for the ministers of princes, and their officers, &c. and the taste of arts and sciences has had the same effect with regard to the learned. In Germany, and elsewhere, the princesses and persons of distinction value themselves on understanding French; and in several courts of Europe, French is almost as much known as the language of the country.

FRESCATI, or FRASCATI, a small town, situated on the brow of a hill, about twelve miles to the eastward of Rome. It derives its name from the coolness of the air, and *fresh* verdure of the fields around. It is built of the ruins of the ancient Tusculum; and the Tusculan villa where Cicero wrote his famous questions is at a place now called *Grotta Ferrata*, about two miles distant. E. Long. 11. 43. N. Lat. 41. 48. There is a very fine prospect from this town into the neighbouring country, which abounds with the seats of cardinals and other nobility. It is the see of a bishop, who is one of the six senior cardinals, and is surrounded by some of the most beautiful villas in Italy; the principal of which are the villa Aldobrandini, belonging to Prince Pamfili; the villa Taberna, belonging to Prince Borghese; and villa Ludovisi, to the family of Colonna. The villa Aldobrandini, called also *Belvedere* from its beautiful prospect, is the most remarkable, on account of its fine situation, extensive gardens, airy terraces, its grottoes, cascades, and water-works. Over a saloon, near the grand cascade, is the following inscription:

Huc ego migravi musis comitatus Apollo;
Hìc Delphi, hìc Helicon, hìc mihi Delos erit.

The walls are adorned with a representation of Apollo and the Muses; and some of that god's adventures are painted in fresco by Domenichino. The villa Taberna is one of the finest and best furnished of any in the neighbourhood of Rome. From this you ascend through gardens to Monte Dracone, another palace on a more lofty situation, belonging also to that prince, and deriving its name from the arms of his family. From hence you may see Rome, and the whole extent of the plain; it has a noble ascent, with a broad paved walk; and among other curiosities there is a hall adorned with the pictures of a vast number of men eminent for learning and arms. The gardens, laid out by Vignola, contain three miles in compass; and have many delightful walks and curious water-works. Near this place are the monks of Camaldoli and the capuchins; and higher up are ruins of the ancient Tusculum. Ascending towards the plain, two miles on the right hand, you find the famous abbey of Grotta Ferrata, belonging to the monks of St Basil, and situated on the ruins of Cicero's house. The Virgin Mary of the great altar is an ancient Greek picture; in the chapel the pictures of St Nilus and St Bartholomew the abbot, are by Annibal Caracci; and all the paintings in fresco of this chapel are by Domenichino. Villa Ludovisi has a charming walk going up to it, where you see the ruins of Lucullus's palace. The house is small; but the gardens are large, embellished with a great variety of walks and fountains, and a beautiful cascade.

FRESCO, a method of painting in relievo on walls, so as to endure the weather. It is performed with water-colours on fresh plaster, or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar; and drying along with it, becomes very durable. The Italians, from whom we borrow the term, call it *fresco;* because it is frequently used for walls, alcoves, and other buildings in the *open air.* Vitruvius, lib. vii. cap. 4. calls it *udo tectorio.*

Painting in fresco is very ancient, having been practised in the earliest ages of Greece and Rome. It is chiefly performed on walls and vaults, newly plastered with lime and sand; but the plaster is only to be laid, in proportion as the painting goes on; no more being to be done at once than the painter can despatch in a day, while it dries. Before he begins to paint, a cartoon or design is usually made on paper, to be chalked, and transferred to the wall, about half an hour after the plaster is applied.

The ancients painted on stucco; and we may remark in Vitruvius what infinite care they took in making the incrustation or plastering of their buildings to render them beautiful and lasting; though the modern painters find a plaster of lime and sand preferable to it; both as it does not dry so hastily, and as being a little brownish, it is fitter to lay colours on, than a ground so white as stucco.

In this kind of painting all the compound and artificial colours, and almost all the minerals, are set aside, and scarce any thing is used but earths; which are capable of preserving their colour, defending it from the burning of the lime, and resisting its salt, which Vitruvius calls its bitterness.

For the work to come out in all its beauty, the colours must be laid on quick, while the plaster is yet moist; nor should they ever be retouched dry, with colours mixed up with the white of an egg, or size, or gum, as some workmen do; because such colours grow blackish; nor do any preserve themselves, but only such as were laid on hastily at first.

The colours used are white made of lime slaked long before, and white marble dust; ochre, both red and yellow; verditer; lapis lazuli; smalt; black chalk, &c. All which are only ground, and worked up with water; and most of them grow brighter and brighter as the fresco dries.

The brushes and pencils for this work ought to be

 long

long and soft, otherwise they will rake and raise the painting. The colours should be full, and flowing from the brush; and the design perfect; for in this work you cannot alter or add upon any colour.

FRESH WATER, is that not tinctured or impregnated with salt or saline particles enough to be discovered by the sense. Such generally is that of springs, rains, wells, lakes, &c.

The dulcifying or making of salt water fresh is a secret that has been long sought with great attention. For an account of the principal attempts that have been made with this view, see *Sea Water*.

Fresh Wind signifies strong, but not violent; hence when the gale increases, it is said to freshen.

FRESHES, in sea language, denotes the impetuosity of an ebb tide, increased by heavy rains, and flowing out into the sea, often discolouring it to a considerable distance, and forming a line that separates the two colours, and which may be distinctly perceived for a great length along the coast.

FRESHES, a local term signifying annual inundations, from the river being swollen by the melted snows and other fresh waters from the uplands, as is the Nile, &c. from periodical or tropical rains. As a sailor's term, it is opposed to marine or salt water floodings, tides, &c. The word is of common use in America, where the inundations so called are of great service. They bring down the soil to the intervals below, and form a fine mould, producing corn, grain, and herbage, in the most luxuriant plenty. They also afford another benefit, in regard to many rivers in America, viz. in equalizing the surface of the stream (where rapid falls, or cascades, obstruct the navigation), so that rafts of timber and other gross produce are then floated down to the sea ports in great quantities.

FRESNOY, CHARLES ALPHONSE DU, an excellent poet and painter, was born at Paris in 1611. He was instructed there by Perrier and Simon Vouet in painting; but he did not long adhere to Vouet's manner of colouring; for as soon as he fixed himself at Rome, he made the works of Titian the models for his imitation. He was, however, more celebrated as a poet than as a painter; and gave more attention to the theory than to the practice of the pencil. Accordingly he is better known by his incomparable poem *De arte graphica*, than by his performances on the canvas: and on this poem he bestowed so much pains, that he died in 1665, before it was published. It was printed afterwards with a French prose translation and notes by M. de Piles; and was translated into English by Mr Dryden, who prefixed to it an original preface containing a parallel between painting and poetry.

FRET, or FRETTE, in *Architecture*, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

FRET, in *Heraldry*, a bearing composed of six bars, crossed and variously interlaced. Some call it the *true-lover's knot*. See HERALDRY.

FRET, in *Music*, signifies a kind of stop on some instruments, particularly bass viols and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

FRET-*Work*, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but it is mostly practised in roofs, which are fretted over with plaster work.

FRETTS, in *Mineralogy*, a term used by our miners to express the worn side of the banks of the rivers in mine countries, where they search for the shoad stones or grewts washed down from the hills, in order from thence to trace out the running of the shoad up to the mine.

FRETTS, *Freats* or *Freits*. See FREATS.

FREYBERG, or FRIEDBERG, a town in the circle of Upper Saxony, containing upwards of 9000 people. There are mines of copper, tin, lead, and silver, in its vicinity, which afford employment to a considerable number of workmen, and produce an annual revenue of more than 10,000 rix-dollars. The princes of the house of Saxony are usually buried here, where there is also an academy for the study of mineralogy, instituted in the year 1765, and reckoned the most famous for that science of any in Germany. It is situated on a branch of the Muldau, 19 miles south-west of Dresden, in N. Lat. 51. and E. Long. 13. 18.

FRIABLE, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are pumice and all calcined stones.

FRIAR, or FRIER, by the Latins called *frater*, the Italians *fra*, and the French *frere*, that is, *brother*: a term common to the monks of all orders; founded on this, that there is a kind of fraternity or brotherhood presumed between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, viz. 1. Minors, Gray friars, or Franciscans. 2. Augustines. 3. Dominicans, or Black friars. 4. White friars or Carmelites. From these four the rest of the orders descend. See FRANCISCANS, AUGUSTINES, &c.

FRIAR, in a more peculiar sense, is restrained to such monks as are not priests; for those in orders are usually dignified with the appellation of *father*.

FRIARS *Observant* (*fratres observantes*) were a branch of the Franciscans; thus called, because not combined together in any cloister, convent, or corporation, as the conventuals are; but only agreed among themselves to observe the rules of their order, and that more strictly than the conventuals did, from whom they separated themselves out of a singularity of zeal, living in certain places of their own choosing.

FRIBURG, a large town of Germany, and capital of Brisgaw; remarkable for the steeple of the great church, which, next to that of Strasburg, is the finest in Germany; and for its university. The inhabitants are famous for polishing crystal and precious stones. It has been several times taken and retaken; particularly by the French in 1744, who demolished the fortifications. It was also taken by them in June 1796. It is seated on the river Triset, ten miles east of Brisach, and 26 south of Strasburg. E. Long. 7. 57. N. Lat. 48. 4.

FRIBURG, a town of Swisserland, and capital of the canton of the same name, seated on the river Sane, in E. Long. 6. 48. N. Lat. 46. 50. Its situation is most singular and picturesque: "It stands partly in a small plain, partly on bold acclivities on a ridge

Cox's Trav. Swisserland

ridge of rugged rocks, half encircled by the river Sane; and is so entirely concealed by the circumjacent hills, that the traveller scarcely catches the smallest glimpse, until he bursts upon a view of the whole town from the overhanging eminence. The fortifications, which consist of high stone walls and towers, enclose a circumference of about four miles, within which space the eye comprehends a singular mixture of houses, rocks, thickets, and meadows, varying instantly from wild to agreeable, from the bustle of a town to the solitude of the deepest retirement. The Sane winds in such a serpentine manner as to form in its course, within the space of two miles, five obtuse angles, between which the intervening parts of the current are parallel to each other. On all sides the descent to the town is extremely steep: in one place the streets even pass over the roofs of the houses. Many of the edifices are raised in regular gradation like the seats of an amphitheatre; and many overhang the edge of a precipice in such a manner, that on looking down, a weak head would be apt to turn giddy. But the most extraordinary point of view is from the Pont-neuf. To the north-west, part of the town stands boldly on the sides and the piked back of an abrupt ridge; and from east to west a semicircle of high perpendicular rocks is seen, whose base is washed and undermined by the winding Sane, and whose tops and sides are thinly scattered with shrubs and underwood. On the highest point of the rocks, and on the very edge of the precipice, appears, half hanging in the air, the gate of the town called *Bourguillon*: a stranger standing on the bridge would compare it to Laputa, or the Flying island in Gulliver's Travels; and would not conceive it to be accessible but by means of a cord and pulleys. The houses, constructed with a gray sand stone, are neat and well built; and the public edifices, particularly the cathedral, are extremely elegant. The inhabitants are Roman Catholics, as are those of the whole canton. The bishop of Lausanne, called here the bishop of Friburg, resides in this city. He is appointed by the pope, usually at the recommendation of the French court: and his revenues, including a small pension from France, and from the abbey of Hauterive, of which he was abbot, amount to about 400l. per annum. His diocese extends over the whole canton, and part of that of Soleure. In all his acts and deeds he signs himself bishop and count of Lausanne, and prince of the German empire. The sovereign power resides in the great council of two hundred; comprising the two advoyers, the chancellor, the grand sautier, the senate or little council of twenty-four, the sixty, from which body are chosen the bannerets and principal magistrates, and the remaining hundred and twelve members, who are simply denominated burghers."

FRIBURG, *the Canton of*, one of the 13 republics of Switzerland. It is surrounded on all sides by the canton of Bern. The land is fertile in corn, fruits, and pastures; and it is said the canton can send 18,000 men into the field. This canton is entirely Catholic.

FRICASSEE, a dish or mess hastily dressed in a frying pan, and seasoned with butter, oil, or the like. The word is French, formed of the Latin *frixatura*, "frying." Others will have fricassee formed in imitation of the noise made by butter, or other fat, when melted in the pan. We say a fricassee of pullets, of rabbits, of tench, of tripe, of frogs, of eggs, of peas, &c.

FRICENTI, an episcopal town of Italy, in the kingdom of Naples, and in the farther principato, near the river Tripalto, in E. Long. 15. 2. N. Lat. 40. 59.

FRICTION, the act of rubbing or grating the surface of one body against that of another, called also *attrition*. The phenomena arising upon the friction of divers bodies, under different circumstances, are very numerous and considerable. Mr Hawksbee gives us a number of experiments of this kind; particularly of the attrition or friction of glass, under various circumstances, the result of which was, that it yielded light and became electrical. All bodies by friction produce heat; many of them emit light; particularly a cat's back, sugar, beaten sulphur, mercury, sea water, gold, copper, &c. but, above all, diamonds, which, when briskly rubbed against glass, gold, or the like, yield a light equal to that of a live coal when blowed by the bellows. See ELECTRICS and ELECTRICITY.

FRICTION, in *Mechanics*, denotes the resistance a moving body meets with from the surface on which it moves. Friction arises from the roughness or asperity of the surface of the body moved on, and that of the body moving: for such surfaces consisting alternately of eminences and cavities, either the eminences of the one must be raised over those of the other, or they must be both broke and worn off: but neither can happen without motion, nor can motion be produced without a force impressed. Hence, the force applied to move the body is either wholly or partly spent on this effect: and consequently there arises a resistance or friction, which will be greater, *cæteris paribus*, as the eminences are the greater and the substance the harder: and as the body, by continual friction, becomes more and more polished, the friction diminishes. See MECHANICS.

FRICTION, in *Medicine* and *Surgery*, denotes the act of rubbing a diseased part with oils, unguents, or other matters, in order to ease, relieve, and cure it. Frictions are much used of late in venereal cases. They prefer the applying of mercury externally by way of friction, to that of giving it internally, to raise a salivation.

There are also frictions with the flesh brush, a linen cloth, or the hand only. These frictions are a sort of exercise which contributes greatly to health; as they excite and stir up the natural warmth, divert defluxions, promote perspiration, open the pores of the skin, and carry off stagnant humours.

The flesh brush (Dr Cheyne observes) is an exercise extremely useful for promoting a full and free perspiration and circulation. Every body knows the effect of currying horses; that it makes them sleek, gay, lively, and active; so as even to be judged equivalent to half the feeding. This it can no otherwise effect, but by assisting nature to throw off the recrements of the juices, which stop the free circulation, and, by constant friction, irritation, and stimulation, to bring the blood and spirits to the parts most distant from the seat of heat and motion; and so plump up the superficial muscles. And the same effect it would have in other creatures, and man himself, if managed in the same manner, and with the same care and regularity.

Persons

Persons, therefore, of weak nerves and sedentary lives, would do well to supply the want of other exercise with spending half an hour, morning and night, in currying and rubbing their whole body, especially their limbs, with a flesh brush. But this means of health is most advantageously used when the *primæ viæ* are most empty.

FRIDAY, the sixth day of the week; so named of *Freya*, a Saxon deity. By the Romans it was called *dies Veneris*. See FREA.

*Good-*FRIDAY. See *Good-Friday*.

FRIDSTOL, mentioned, in our ancient writers, among the immunities granted to churches, signifies a seat, chair, or place of peace and security, where criminals might find safety and protection: of these there were many in England: but the most famous were that at Beverly, and that in St Peter's church at York, granted by charter of King Henry I.

FRIEDENSHUETTEN, a Moravian settlement, whose name signifies *tents of peace*, situated on the Susquehannah river in Pennsylvania, about 24 miles below Tioga point, which owed its origin to the united brethren, in the year 1765. At that period it contained 13 huts belonging to the Indians, besides 40 houses constructed after the European manner, and a very neat chapel.

FRIENDLY ISLANDS, a cluster of islands in the Pacific ocean, so named by Captain Cook in the year 1773, on account of the friendship which appeared to subsist among the inhabitants, and from their courteous behaviour to strangers. Abel Jansen Tasman, an eminent Dutch navigator, first touched here in 1643, and gave names to the principal islands. Captain Cook laboriously explored the whole cluster, which he found to consist of more than 60. The three islands which Tasman saw he named *New Amsterdam*, *Rotterdam*, and *Middleburgh*. The first is the largest, and extends about 21 miles from east to west, and about 13 from north to south. These islands are inhabited by a race of Indians, who cultivate the earth with great industry. The island of Amsterdam is intersected by a straight and pleasant road with fruit trees on each side, which provide shade from the scorching heat of the sun. The chief islands are Annamooka, Tongataboo (the residence of the sovereign and the chiefs), Lefooga, and Eooa. Lefooga is about seven miles long, and in some places not above two or three broad. It is in many respects superior to Annamooka. The plantations are both more numerous and more extensive; and enclosed by fences which, running parallel to each other, form fine spacious public roads, which would appear beautiful in countries where rural conveniences have been carried to the highest perfection. They are, in general, highly cultivated, and well stocked with the several roots and fruits which these islands produce; and Captain Cook endeavoured to add to their number, by planting Indian corn, and the seeds of melons, pumpkins, and the like. Eooa, when viewed from the ship at anchor, formed one of the most beautiful prospects in nature, and very different from the others of the Friendly Isles; which being low, and perfectly level, exhibit nothing to the eye but the trees which cover them: whereas here, the land rising gently to a considerable height, presents us with an extensive prospect, where groves of trees are only interspered at irregular distances, in beautiful disorder, and all the rest is covered with grass, except near the shores, where it is entirely covered with fruit and other trees; amongst which are the habitations of the natives. In order to have a view of as great a part of the island as possible, Captain Cook and some of his officers walked up to the highest point of the island. From this place they had a view of almost the whole island, which consisted of beautiful meadows of prodigious extent, adorned with tufts of trees, and intermixed with plantations. 'While I was surveying this delightful prospect (says Captain Cook), I could not help flattering myself with the pleasing idea that some future navigator may, from the same station, behold these meadows stocked with cattle, brought to these islands by the ships of England; and that the completion of this single benevolent purpose, independent of all other considerations, would sufficiently mark to posterity, that our voyages had not been useless to the general interests of humanity. 'The next morning,' says our benevolent commander, 'I planted a pine apple, and sowed the seeds of melons and other vegetables in Taoofa's plantation. I had indeed some encouragement to flatter myself that my endeavours of this kind also would not be fruitless: as I had this day a dish of turnips served up at my dinner, which was the produce of seeds I left here in my former voyage.'

The natives of these islands seldom exceed the common stature; but are very strong and well made, especially as to their limbs. They are generally broad about the shoulders; and though the muscular disposition of the men, which seems a consequence of much action, rather conveys the appearance of strength than of beauty, there are several to be seen who are really handsome. The women are not so much distinguished from the men by their features as by their general form, which is for the most part destitute of that strong fleshy firmness that appears in the latter. The features of some are so delicate, as not only to be a true index of their sex, but to lay claim to a considerable share of beauty and expression: for the bodies and limbs of most of the females are well proportioned; and some absolutely perfect models of a beautiful figure. But the most remarkable distinction in the women is the uncommon smallness and delicacy of their fingers, which may be put in competition with the finest in Europe. The general colour is a cast deeper than the copper brown; but several of the men and women have a true olive complexion: and some of the last are even a great deal fairer. Their countenances very remarkably express the abundant mildness or good nature which they possess; and are entirely free from that savage keenness which marks nations in a barbarous state. They are frank, cheerful, and good-natured.

There are, upon the whole, few natural defects or deformities to be found among these people. The most common is the tetter or ring worm, that seems to affect almost one half of them, and leaves whitish serpentine marks everywhere behind it; but this is of less consequence than another which is very frequent, and appears on every part of the body. Captain Cook had the mortification to learn that all the care he took when he first visited these islands, to prevent the venereal disease from being communicated to the inhabitants, tenants, had proved ineffectual. What is extraordinary, they do not seem to regard it much; and as there appeared few signs of its destroying effects, probably the climate, and the way of living of these people, greatly abated its virulence. There are two other complaints frequent amongst them; one of which is an indolent firm swelling, that affects the legs and arms, and increases them to an extraordinary size in their whole length. The other is a tumor of the same sort in the testicles, which sometimes exceeds the size of the two fists. But in other respects they may be considered as uncommonly healthy.

Their hair is in general straight, thick, and strong, though a few have it bushy or frizzled. The natural colour is black; but the greatest part of the men, and some of the women, have it stained of a brown or purple colour, and a few of an orange cast. They wear it variously cut. Some have it cut off on one side of the head only; others have it entirely cut off except a single lock; the women in general wear it short. The men have their beards cut short; and both men and women strip the hair from the armpits. The men are stained from about the middle of the belly to about half way down the thighs with a deep blue colour. The women have only a few small lines or spots thus imprinted on the inside of their hands. Their kings, as a mark of distinction, are exempted from this custom.

The men are all circumcised, or rather supercised, as the operation consists in cutting off only a small piece of the foreskin at the upper part: which by that means is rendered incapable ever after of covering the glans. This is all they aim at, as they say the operation is practised from a notion of cleanliness.

The dress of both men and women is the same: and consists of a piece of cloth or matting (but mostly the former) about two yards wide and two and a half long: at least so long as to go once and a half round the waist, to which it is confined by a girdle or cord. It is double before, and hangs down like a petticoat, as low as the middle of the leg. The upper part of the garment above the girdle is plaited into several folds; so that, when unfolded, there is cloth sufficient to draw up and wrap round the shoulders; which is very seldom done. The inferior sort are satisfied with small pieces; and very often wear nothing but a covering made of leaves of plants, or the maro, which is a narrow piece of cloth or matting like a sash. This they pass between the thighs and wrap round the waist; but the use of it is chiefly confined to the men. The ornaments worn by both sexes are necklaces made of the fruit of the pandanus, and various sweet smelling flowers, which go under the general name of *kahulla.* Others are composed of small shells, the wing and leg-bones of birds, sharks teeth and other things; all which hang loose upon the breast; rings of tortoise shell on the fingers; and a number of these joined together as bracelets on the wrists. The lobes of the ears (though most frequently only one), are sometimes perforated with two holes, in which they wear cylindrical bits of ivory about three inches long.

Cleanliness induces them to bathe in the ponds, which seem to serve for no other purpose. They are sensible that salt water hurts their skin; and when necessity obliges them to bathe in the sea, they commonly have some cocoa nut shells filled with fresh water poured over them to wash it off. People of superior rank use cocoa nut oil, which improves the appearance of the skin very much.

The employment of the women is of the easy kind, and, for the most part, such as may be executed in the house. The manufacturing their cloth is wholly consigned to their care; as is also that of their mats, which are esteemed both for their texture and their beauty. There are many other articles of less note that employ the spare time of their females; as combs, of which they make vast numbers, and little baskets with small beads; but all finished with such neatness and taste in the disposition of the various parts, that a stranger cannot help admiring their assiduity and dexterity.

The province allotted to the men, as might be expected, is far more laborious and extensive than that of the women. Agriculture, architecture, boat building, fishing, and other things that relate to navigation, are the objects of their care. Cultivated roots and fruits being their principal support, this requires their constant attention to agriculture, which they pursue very diligently, and seem to have brought almost to as great perfection as circumstances will permit. In planting the plantains and yams, they observe so much exactness, that, which ever way you look, the rows present themselves regular and complete. The cocoa nut and bread fruit trees are scattered about without any order, and seem to give them no trouble after they have attained a certain height.

The houses of the lower people are poor huts, and very small; those of the better sort are larger and more moderate. The dimensions of one of a middling size are about 30 feet long, 20 broad, and 12 high. Their house is, properly speaking, a thatched roof or shed, supported by posts and rafters, disposed in a very judicious manner. The floor is raised with earth smoothed, and covered with thick strong matting, and kept very clean. A thick strong mat, about two and a half or three feet broad, bent into the form of a semicircle, and set upon its edge, with the ends touching the side of the house, in shape resembling the fender of a fire heath, encloses a space for the master and mistress of the family to sleep in. The rest of the family sleep upon the floor, wherever they please to lie down; the unmarried men and women apart from each other: Or if the family be large, there are small huts adjoining, to which the servants retire in the night; so that privacy is as much observed here as one could expect. The clothes that they wear in the day serve for their covering in the night. Their whole furniture consists of a bowl or two, in which they make kava; a few gourds; cocoa nut shells; and some small wooden stools, which serve them for pillows.

They display much ingenuity in the building of their canoes, as well as in the navigating them.

The only tools which they use to construct them, which are very dexterously made, are hatchets, or rather thick adzes, of a smooth black stone that abounds at Toofoa; augres, made of sharks teeth, fixed on small handles, and rasps of a rough skin of a fish, fastened on flat pieces of wood, thinner on one side, which also have handles. The cordage is made from the fibres of the cocoa nut husk, which, though not more than nine or ten inches long, they plait, about the size of a

Friendly Islands.

a quill, or less, to any length that they please, and roll it up in balls, from which the larger ropes are made by twisting several of these together. The lines that they fish with are as strong and even as the best cord we make, resembling it almost in every respect. Their other fishing implements are large and small hooks made of pearl shell. Their weapons are clubs of different sorts, (in the ornamenting of which they spend much time), spears and darts. They have also bows and arrows; but these seemed to be designed only for amusement, such as shooting at birds, and not for military purposes. The stools are about two feet long, but only four or five inches high, and near four broad, bending downward in the middle, with four strong legs, and circular feet; the whole made of one piece of black or brown wood, neatly polished, and sometimes inlaid with bits of ivory.

Yams, plantains, and cocoa nuts, composed the greatest part of their vegetable diet. Of their animal food, the chief articles are, hogs, fowls, fish, and all sorts of shell fish; but the lower people eat rats. The two first vegetable articles, with bread fruit, are what may be called the basis of their food, at different times of the year, with fish and shell fish; for hogs, fowls, and turtle, seem only to be occasional dainties, reserved for their chiefs. Their food is generally dressed by baking, and they have the art of making, from different kinds of fruit, several dishes which most of us esteemed very good. The generality of them lay their victuals upon the first leaf they meet with, however dirty it may be; but when food is served up to the chiefs, it is commonly laid upon green plantain leaves. The women are not excluded from eating with the men; but there are certain ranks or orders amongst them that can neither eat nor drink together. This distinction begins with the king; but where it ends could not be learnt. They seem to have no set time for meals. They go to bed as soon as it is dark, and rise with the dawn in the morning.

Their private diversions are chiefly singing, dancing, and music performed by the women. The dancing of the men has a thousand different motions with the hands, to which we are entire strangers; and they are performed with an ease and grace which are not to be described but by those who have seen them.

Whether their marriages be made lasting by any kind of solemn contract, our voyagers could not determine with precision; but it appeared that the bulk of the people satisfied themselves with one wife. The chiefs, however, have commonly several women, though it appeared as if one only was looked upon as the mistress of the family.

When any person of consequence dies, his body is washed and decorated by some woman or women, who are appointed on the occasion; and these women are not, by their customs, to touch any food with their hands for many months afterwards; and it is remarkable, that the length of the time they are thus proscribed, is the greater in proportion to the rank of the chief whom they had washed.

The concern of these people for the dead is most extraordinary. They beat their teeth with stones, strike a shark's tooth into the head until the blood flows in streams, and thrust spears into the inner part of the thigh, into their sides below the armpits, and through the cheeks into the mouth. All these operations convey an idea of such rigorous discipline, as must require either an uncommon degree of affection, or the grossest superstition, to exact. It should be observed, however, that the more painful operations are only practised on account of the death of those most nearly connected.

Friendly Islands.

Their long and general mourning proves, that they consider death as a very great evil. And this is confirmed by a very odd custom which they practise to avert it. They suppose that the Deity will accept of the little finger, as a sort of sacrifice efficacious enough to procure the recovery of their health. They cut it off with one of their stone hatchets. There appeared scarcely one in ten of them who was not thus mutilated in one or both hands. According to Captain King, it is common also for the inferior people to cut off a joint of their little finger on account of the sickness of the chiefs to whom they belong.

They seem to have little conception of future punishment. They believe, however, that they are justly punished upon earth; and consequently use every method to render their divinities propitious. The Supreme Author of all things they call *Kallafootonga*; who, they say, is a female residing in the sky, and directing the thunder, wind, rain, and in general all the changes of weather. They believe that when she is angry with them, the productions of the earth are blasted; that many things are destroyed by lightning; and that they themselves are afflicted with sickness and death as well as their hogs and other animals. When this anger abates, they suppose that every thing is restored to its natural order. They also admit a plurality of deities, though all inferior to *Kallafootonga*. They have less absurd sentiments about the immateriality and the immortality of the soul. They call it *life*, the living principle; or, what is more agreeable to their notions of it, *Otooa*; that is, a divinity or invisible being.

Of the nature of their government no more is known than the general outline. According to the information received, the power of the king is unlimited, and the life and property of the subject are at his disposal; and instances enough were seen to prove that the lower order of people have no property, nor safety for their persons, but at the will of the chiefs to whom they respectively belong. When any one wants to speak with the king or chief, he advances and sits down before him with his legs across; which is a posture to which they are so much accustomed, that any other mode of sitting is disagreeable to them. To speak to the king standing would be accounted here a striking mark of rudeness.

Though some of the more potent chiefs may vie with the king in point of actual possessions, they fall very short in rank and in certain marks of respect, which the collective body have agreed to pay the monarch. It is a particular privilege annexed to his sovereignty, not to be punctured nor circumcised, as all his subjects are. Whenever he walks out, every one whom he meets must sit down till he has passed. No one is allowed to be over his head; on the contrary all must come under his feet; for there cannot be a greater outward mark of submission than that which is paid to the sovereign and other great people of these islands by by their inferiors. The method is this: the person who is to pay obeisance squats down before the chief, and bows the head to the sole of his foot; which, when he sits, is so placed that it cannot easily be come at; and having tapped or touched it with the under and upper side of the fingers of both hands, he rises up and retires. The hands, after this application of them to the chief's feet, are in some cases rendered useless for a time; for, until they be washed, they must not touch any kind of food. When the hands are in this state, they call it *taboo rema*. *Taboo*, in general, signifies "forbidden," and *rema* is their word for "hand." Their great men are fond of a singular piece of luxury; which is, to have women sit beside them all night, and beat on different parts of their body until they go to sleep; after which they relax a little of their labour, unless they appear likely to awake; in which case they redouble their drumming until they are again fast asleep.

Definition of friendship.

FRIENDSHIP may be defined, a mutual attachment subsisting between two persons: and arising, not merely from the general principle of benevolence, from emotions of gratitude for favours received, from views of interest, or from instinctive affection or animal passion; but from an opinion entertained by each of them, that the other is adorned with some amiable or respectable qualities.

Illustration of the above definition.

The object of the general principle of benevolence is *mankind*, not any particular individual. Gratitude regards the person from whom he who feels its emotions has received a favour, whether that person be a virtuous or vicious, a respectable or a contemptible, character: it prompts the person obliged to make a suitable return to his benefactor, but not to enter into any particular intimacy with him, merely on account of the favours which he has received. Many connections are formed, and dignified with the name of *friendship*, upon no other principle but the sordid hope which one or perhaps each of the parties entertains of accomplishing some selfish purpose through the assistance of the other: but such a connexion is so base in its nature, and so transitory in its duration, as to render it unnecessary for us to spend time in demonstrating it to be unworthy of the name of friendship. The instinctive affection which a parent entertains for his child, as well as that which the child feels for his parent, seems intended by nature to form an union between the persons thus related to each other: but the union between parents and children, when supported by no other principle but instinct, is different from friendship: it extends no farther than to cause the parent to provide for his child during his helpless years, and the child to look up to his parent for protection and support. We need not mention that appetite which is the foundation of love, and is the provision which nature has made for the continuation of our species. This appetite alone, and unassisted by some nobler principle, cannot give rise to any connexion worthy of an honourable name.

After excluding these principles, we can refer the origin of friendship only to "an opinion entertained by each of the parties between whom it subsists, that the other is adorned with some amiable or respectable qualities." A connexion founded on different principles we cannot honour with the name of friendship; but that which flows from this pure source must be noble and virtuous. When two persons of virtue and abilities contemplate each the other's character and conduct, they cannot but view them with complacency and esteem. Habits and actions displaying prudence, fortitude, moderation, integrity, benevolence, and piety, naturally command the approbation of the impartial spectator, and even affect him with delight. But as we are disposed to revisit a landscape the beauties of which we have contemplated with rapture, and read with frequent delight a poem in which genius has faithfully delineated some of the most enchanting scenes or the most interesting events in nature; so we also become desirous to enjoy frequent opportunities of contemplating a character distinguished for eminent abilities and illustrious virtues. The society of such a person is preferred to his who is disgraced by the opposite qualities. Hence, whenever men of truly respectable characters enjoy opportunities of mutual intercourse, an attachment naturally takes place between them; entirely disinterested, and founded solely on the approbation with which the one cannot avoid regarding the conduct of the other. The esteem which the one is thus induced to entertain for the other will lead them to seek frequent opportunities of enjoying each other's society, mutually to ask and listen to advice, to trust their most secret and important purposes to each other's confidence, and to be no less concerned each of them for the other's interest and honour than for his own. This, and this alone, is genuine friendship; founded on virtue, and on that approbation which virtue never fails to command: it is a natural consequence of intercourse between virtuous men.—Where it is once established, it cannot die, while those virtues to which it owes its origin continue to adorn the persons between whom it subsists.

3
Circumstances favourable to the rise and continuance of friendship.

But, perhaps, such a pure and sublime attachment can scarce be expected to exist among beings of so mixed and imperfect a character as mankind. The wise man of the ancient Stoics, or the Christian who fully obeys the precepts, and follows the steps of his Saviour, might be capable of it; but, unfortunately, humanity never reaches such perfection. Virtue and vice are so blended together in every human character, that while none is so worthless as to excite no other sentiment but abhorrence, there is scarcely any so uniformly virtuous as to command unvaried esteem or admiration. Even the purest and most disinterested of those friendships which prevail among men, owe their origin to other meaner principles, as well as to that which has been mentioned as the principle of genuine friendship. There are certain circumstances favourable, and others adverse, to the formation and continuance of friendship. These, making amends, as it were, for the imperfection of human virtue and human knowledge, lead men to overlook each other's faults and follies, and to unite in the bonds of friendship; a friendship which, though less solid, less generous, and less lasting, than that which we have above described, is yet attended with effects favourable to the happiness of individuals, and to the interests of society in general.

Equality of age is favourable to friendship. Infancy, manhood, and old age, differ so considerably from each other in their views, passions, and pursuits, that the *man* will seldom be disposed to associate with the *boy* or

Friendship.

or the *youth*, in preference to one who has had equal experience in the world with himself; and the *old man* will generally wish for the company of some ancient friend, with whom he may speak of "the days of former years."

They who cultivate the *same trade or profession*, enjoy opportunities favourable to the formation of friendship. Being engaged among the same objects, and acquiring skill in the same arts, their knowledge, their sentiments, and habits, are nearly the same; they cannot avoid frequent intercourse with each other; they naturally enter into each other's prejudices and views, and therefore cannot but take pleasure in each other's conversation and society. Physicians, lawyers, and divines, form each of them a distinct body; and the members of each of those bodies associate with one another more readily than with men of a different profession. It is related by Swift or Addison, that, in the beginning of the last century, there was a particular coffeehouse in London which clergymen used to frequent, and that a son of the church scarcely ever ventured to show his head in any other. In the days of Dryden, poets, and all who pretended to poetical genius or taste, resorted to *Will's*, as to another Parnassus, to sip cups of coffee, and now and then perhaps to drink of some more inspiring liquor, instead of the waters of the fountain Hippocrene.

Equality of rank and fortune is also favourable to friendship. Seldom will a man of fortune be able to gain the sincere friendship of any of his dependents. Though he treat them with the most obliging condescension, and load them with favours; yet still, either the sense of dependence, or resentment for imaginary injuries, or impatience of the debt of gratitude, or some other similar reason, will be likely to prevent them from regarding him with cordial affection. Servants are but rarely faithful even to the most indulgent master: Shakespeare's old Adam is a very amiable but a very uncommon character. Indeed you may as soon expect to find the virtues and the generous courage of the chevalier Bayard among our military men of the present age, as to find an old Adam among the present race of servants. It is no less vain for the poor man to hope to acquire a sincere friend among his superiors in rank and fortune. The superior is generally disposed to exact such profound deference, such gratitude, such respect, even from the inferior whom he admits into his intimacy, that the equal amicable intercourse of friendship can scarce ever take place between them. Among the letters of the younger Pliny, we are pleased to find many monuments of the goodness of his heart. A number of his epistles addressed to friends in meaner circumstances appear to have been accompanied with very considerable presents, which by his opulence he was well enabled to bestow. But he takes care to let those humble friends know the weight of the obligations which he conferred, and the vastness of the debt of gratitude which they owed to him, in such plain, nay even indelicate terms, that though they might receive his favours with gratitude, and regard him as their benefactor, yet they could never regard him as a man with whom they might cultivate the free easy intercourse of friendship. Some one or other of the Greek writers mentions a singular instance of cordial friendship subsisting between two persons in unequal circumstances. One of them dying before the other, and leaving a wife and daughter to whom he had no fortune nor even means of subsistence to bequeath, enjoined his rich friend, in his will, to take the charge of them on himself, and to support them in a liberal manner: nor did he entreat this from his humanity, but demanded it from his friendship. He had made a sure provision for his family. His rich friend delayed not to comply with his dying injunction. He readily took upon himself the charge of the wife and daughter of his deceased friend, treated them with kindness, and at last divided his whole fortune equally between his own only daughter and the child of his friend. This is an agreeable instance of the power of friendship: but such instances are not to be expected to occur frequently in ordinary life, any more than the Stoic virtue of Cato, or the modest piety of a Nelson.

Similarity of taste and temper will generally be found favourable to friendship. Two peevish men, indeed, will not long endure each other's company with much satisfaction; but two persons of mild, humane dispositions will naturally take delight in each other's society and conversation. They who are charmed with the bustle of a gay and active life, avoid the haunts of the indolent and contemplative, and join hand in hand to climbs the heights of ambition, or tread the round of amusement and dissipation. Those whom taste leads to cultivate the elegant objects of literature amid the sweets of a rural retirement, to wander through the grove, or recline on the brink of some romantic rill, and peruse the pages of one of those geniuses who have shown themselves able to enlighten the understanding, and to kindle the glow of generous sentiment in the breast;—those children of taste frequently associate in their elegant pursuits. We are pleased to read the correspondence of Pliny and Tacitus, of Loeke and Molineaux, of Swift and Pope. We rejoice to find, that nothwithstanding the rivalry of learning and genius, taste and philosophy have a natural tendency to promote benevolence and friendship among their votaries. The bustle of the world must be acknowledged to be generally unfavourable to friendship. When the heart is occupied with the sordid objects of ambition, or avarice, or gay dissipation, there is no room left for the pure and generous sentiments of friendship. Interests often interfere, competitions and jealousies arise, fatal to all the sweets of social intercourse. It is in active life that virtue shines with the most brilliant lustre; but seldom, alas! does pure virtue appear in the scenes of active life. How beautifully does the character of Atticus shine amid the characters of his illustrious cotemporaries! *ut Luna inter minores ignes!* Sylla, Cæsar, Cicero, Brutus, Antony, and Augustus, were eminent for their abilities and virtues; but being engaged in the bustling pursuits of ambition, they seem to have been strangers to the calm and elegant happiness which Atticus enjoyed. Though those of them who were cotemporaries could not avoid perceiving and admiring each other's merits, yet never did cordial friendship subsist between them. Even Cicero, who could so well define the duties and describe the happiness of friendship, yet appears to have but seldom enjoyed its delights. But Atticus, who constantly declined entering the scenes of public life, Friendship. life, experienced such happiness in a private condition, as must have been more than an ample reward to him for shunning all the splendid pursuits of ambition. He was the disinterested friend of all those eminent men, and enjoyed their esteem and friendship. So upright was his character, so amiable his manners, that they who were mortal enemies to each other, yet agreed in cultivating at the same time the friendship of Atticus. None of them appear to have hated him on account of his attachment to their enemies; and while he was the friend of Cicero and Octavius, he was at the same time the protector of the wife of Antony. Perhaps the virtue of such a character may be regarded as problematical. It may be alleged, that while such inveterate dissensions arose among his friends, the neutrality which he preserved was inconsistent with integrity. He has indeed been rashly branded by some writers as an avaricious time-serving man. But no evidence appears to justify their assertions; on the contrary, the most respectable testimony, the nicest scrutiny, exhibit his character in those amiable colours in which we have chosen to view it. Atticus is indeed no ordinary character. The general principles of human nature, and the examples which most frequently occur in the world, naturally suggest a suspicion, that had he been a man of genuine integrity, he must have observed a different tenor of conduct. But there is one circumstance which tends to strengthen considerably the respectable testimony of his cotemporaries in his behalf. In Cato, in Epictetus, in the philosopher, who, while suffering under all the violence of an acute distemper, maintained to Pompey that pain was no evil, we have instances of the tenets of philosophy opposing and repressing the principles of nature. We know how often religious enthusiasm has produced the same effects. But Atticus was the votary of the mild and elegant philosophy of Epicurus; which, though there appears to have been a palpable inconsistency between its principles and the superstructure raised upon them, was yet in its general tendency not unfriendly to virtue, and recommended to its votaries that calm and innocent mode of life which Atticus cultivated. There is no small resemblance between the character of Atticus and that of Epicurus, the founder of this philosophy. The same tenets seem to have produced the same effects on both; and we will venture to pronounce so high an encomium on the Epicurean philosophy, as to assert, that it chiefly contributed to form the character of this amiable Roman.

We know not if we may venture to affirm, that friendships are most naturally contracted among persons of the same sex. We believe they often are. If similarity of taste, of sentiments, of manners, be favourable to friendship, this cannot but happen. The distinction which nature has established between the two sexes, the new distinctions which are introduced by the different views with which their education is conducted, and the different duties which they are called to perform in life, have all a tendency to dispose men and women to enter into habits of intimacy with persons of their own sex rather than with the other. Young girls have their peculiar amusements, as boys have theirs: they knit and sew together, consult each other concerning their dress, and associate at their idle hours. Young men, in the same manner, prefer the society of their equals of the same sex till such time as their hearts begin to feel the impulse of a new passion. This soft passion, indeed, causes the youth to prefer the company of his favourite maid to that of his dearest companion; and it perhaps causes the virgin to view her female companions with a jealous eye, while she fears that their charms may win the heart of the youth, whose fond regard she herself wishes to engage. But the fears, the jealousies, the timidity, nay even the fondness of love, are incompatible with friendship. Though the lover and his mistress be dear to each other, yet the free confidence of friendship cannot take place between them. They dare not yet venture to trust to each other all the secrets of their hearts. But if their mutual wishes be crowned by marriage; then, indeed, as their interests become the same, if the transports of love are not succeeded by the calm delights and the free confidence of friendship, they must be unhappy. The marriage state is peculiarly favourable to friendship. Persons whose relations to each other are the more remote, will often find circumstances concurring to induce them to cultivate a friendly intercourse with each other. But here indifference is almost impossible. It is absolutely requisite, in order that they may not render each other miserable, that the husband and the wife be united in the bonds of friendship. This seems even to be one of the great laws of nature, by means of which provision is made for the happiness and the preservation of society. But though the wife and the husband be particularly attached to each other by the ties of friendship no less than by those of love, yet their mutual affection will not detach them from the rest of the world: their relations to the society around them will still remain; the husband will still cultivate the intimacy of those of his own sex, and the wife will still choose female in preference to male friends. Upon even a superficial view of life, we find reason to declare without hesitation, that acquaintance and intimacy most naturally take place among persons of the same sex. The husband and the wife are more than friends; they are *one bone and one flesh*. It has been sometimes slightly insinuated, and sometimes more openly asserted, by people who have but carelessly viewed the phenomena of social life, or have been disposed to cavil against the fair sex, that women are incapable of sincerity or constancy in friendship with each other. But it seems unnecessary to offer a serious refutation of this cavil. Neither is the general character of the female sex so inferior to that of the male, nor are their circumstances so very different from ours, as to render them totally incapable of those virtues which are necessary to establish and support mutual friendship. They are in general possessed of more exquisite sensibility, nicer delicacy of taste, and a juster sense of propriety, than we: nor are they destitute of generosity, fidelity, and firmness. But such qualities are peculiarly favourable to friendship; they communicate a certain charm to the manners of the person who is adorned with them; they render the heart susceptible of generous disinterested attachment; and they elevate the soul above levity, insincerity, and meanness. Competitions and jealousies must no doubt arise now and then even among the most amiable of the female sex, as well as among us. These will preclude or destroy

 friendship.

Friendship. friendship. But the rivalry of beauty, of dress, of fashion, is not oftener fatal to friendship among the fair sex, than the contests of pride, avarice, vanity, and ambition, among their haughty lords. If friendship be ranked among the virtues, it is not less a female than a male virtue.

5
Relations of consanguinity.

The delightful intercourse and intimacy of friendship may be naturally expected to subsist not only between the husband and the wife, but among all who are connected by any of the relations of consanguinity. The power of instinct does not always continue to unite the parent and the child. Its offices are of a temporary nature; but when these are performed, it ceases to operate. During the infancy, the childhood, and even the youth of his son or daughter, the parent watches over them with fond affection, and labours with anxious assiduity to promote their welfare, for no other reason but because the yearnings of paternal affection draw him towards them. But as they advance farther in life, and become able to care for themselves, it has been so ordered by the wisdom of nature, that the attachment of the parent almost dies away, unless the grateful affection and the merit of his children afford him reason to rejoice over them and bless them. How shocking, how miserable, the condition of that family, whose members are not united by the mutual esteem and confidence of friendship! where the parent views his children with jealousy, shame, indignation, or sorrow: and the children anxiously avoid the society of their parents! Their interests are so nearly connected; they have so many occasions for acting in concert, and must live so long together; that we may almost venture to affirm, that the parent and the child, like the husband and the wife, must be either friends or enemies. But the ties of nature, the influence of habit, sentiments, and circumstances, all concur to form between them the sacred connexion of friendship. Brothers and sisters, the children of the same parents, and for a while members of the same family, may be expected to regard each other through life with kindness and esteem; and these we would rather choose to attribute to a rational attachment, founded on certain principles, than to a blind instinctive affection.

These are a few of the distinctions and relations in society which appear most favourable to friendship.—Were we to descend to minuter particulars, we might enumerate all the varieties of taste, of temper, and of circumstances, by which mankind are distinguished from one another, and distributed into particular classes. But this would be too tedious, and does not appear necessary.

6
Laws of friendship.

As friendship is an attachment which takes place between certain human characters when placed in certain circumstances, there must therefore be laws for supporting the attachment and regulating the intercourse of friendship. Mutual esteem is the basis on which true friendship is established; and the intercourse of friendship ought surely to be conducted in such a manner that this foundation be not injured. Friendship must diminish neither our benevolence nor prudence: it must not seduce us from an honest attention to our private interest, nor contract our social affections.

Sincerity may be considered as the first law of friendship. Artifice and hypocrisy are inimical to all social intercourse. Between the deceitful and the honest, friendship can never subsist. For a while, the one may impose on the other; unsuspicious integrity may not be able to see through the mask under which the hideous features of selfish cunning are veiled; but the deceitful friend must ever be a stranger to the delightful sentiments of genuine friendship. To enjoy these, your virtues must be sincere, your affection for the person whom you call your friend unfeigned; in communicating to each other your sentiments, in offering and listening to mutual advice, in joining to prosecute the same designs, or share in the same amusements, candid sincerity must still be observed between you. Attempt not to persuade each other, that your mutual affection is more ardent, or your mutual esteem more profound, than it really is. If the sentiments or opinions which the one expresses appear to the other improper or ill-founded, let not a false delicacy prevent him from declaring his reasons against them; let him not applaud where, if he were sincere, he must blame. Join not even your friend in an undertaking which you secretly dislike, or an amusement insufferably disagreeable to you. You cannot, consistently with sincerity and candour: and you will soon begin to think the blessings of friendship too dear, when bought at the price of such sacrifices.

But though sincerity is to be faithfully observed in the intercourse of friendship; yet the harshness of contradiction must be carefully avoided. Those obliging manners which are so agreeable in an acquaintance or casual companion, are still more so in a friend. If they are necessary to recommend the advantages of social intercourse in general to the members of society, they are no less necessary to communicate a charm to the intercourse of friendship. People often think themselves entitled to behave to those whom they call their friends, and whose interests they profess to regard as their own, with harshness, negligence, and indiscreet familiarity; but nothing can be more fatal to friendship. It is a well known maxim, established by general and uniform experience, that *too much familiarity occasions mutual contempt*. And indeed how can it be otherwiss? Mild obliging manners are understood as the natural and genuine expression of kindness and affection: boisterous rudeness, petulance, and neglect, are naturally considered as expressive of opposite sentiments. But if friendship assume the tone, the carriage, and the language of enmity or indifference, it must soon lose all its native charms and advantages. Let the friend, as well as the casual companion, when he finds reason to disapprove of the sentiments and conduct, or to dissent from the opinions of his friend, express himself in the gentlest terms, with honesty and sincerity, but without carelessness or harshness. Let no frequency of intercourse nor union of interests ever tempt to careless or contemptuous familiarity. Stiff and unmeaning ceremony may be banished; but ease, and delicacy, and respectful deference, and obliging attention, must supply its room. Much of the unhappiness of the marriage state, and much of the mutual uneasiness which arises among those who are related by the endearing ties of consanguinity, is occasioned by the parties who are thus closely connected, thinking it unnecessary to observe the ordinary rules of good breeding in their mutual intercourse. Even kindness puts

Friendship.

puts on a disgusting garb, and assumes a harsh aspect. But mutual kindness cannot there long subsist. Home, which ought to be a sanctuary to shelter from the anxieties and ills of life, a little paradise where those pure and innocent pleasures might be enjoyed which afford the most genuine happiness, and which are not to be tasted in the bustle of the busy and the dissipation of the gay world; home thus becomes a place of torment, which is never entered but with pain and unwillingness; and from which the son, the daughter, the husband, and the wife, eagerly seize every opportunity to escape.

Mutual confidence is the very soul of friendship. If friendship be rightly defined to be a mutual affection founded on mutual esteem, those who are united in the bonds of friendship cannot but repose mutual confidence in each other. Am I conscious of none hut generous worthy sentiments, and none but upright honest intentions? I readily disclose all the secrets of my soul to him whom I regard as capable only of similar designs and similar sentiments. But it may be asked, how far the confidence of friendship ought to be carried? Must I reveal to my friend all my sentiments, opinions, and designs? Must I communicate to one friend the secrets which have been intrusted to me by another? Or must I rather observe the most suspicious caution in my intercourse with my friends, remembering that he who is now my friend may one day become my enemy? It seems most prudent to observe a medium between suspicious caution and unlimited confidence. Were human virtue perfect, and were there no instances of friends ever becoming enemies, those who regard each other with friendly affection might very reasonably be required to set no bounds to their mutual confidence. But as this is far from being the case, different measnres are to be observed. Contract no friendships, if you think it necessary to treat a friend with the same reserve as an enemy. Yet venture not to disclose to your friend all the foolish or evil designs which the wantonness of imagination máy seduce you to form. When you feel the emotions of pride, of vanity, or of any evil passion, if you are able to repress them by the strength of reason and conscience, it seems unnecessary for you to tell the struggle, or to boast of the victory. If, at any former period of life, you have been so unfortunate as to commit actions which you cannot now recollect without shame and contrition, there can be no reason why you may not, as far as possible, bury the remembrance of them in your own breast. In short, not to become tedious by descending to minute particulars, the laws of friendship do not require friends to unbosom themselves to each other any farther than is necessary—to give them just ideas of each other's character and temper,—to enable them to be serviceable to each other in the prosecution of honest designs,—and to afford each of them proper opportunities of exciting the other to virtue and wisdom, and of interposing his influence to preserve him from vice and folly. Whatever is necessary for any of these purposes ought to be mutually communicated; whatever is not, may be concealed without violating the laws of friendship. As mutual esteem is the foundation of friendship, and as human friendships are not always lasting, you ought not to pour into the ear of your friend all the impertinences which you may happen to conceive, nor even all the projects which may float in your imagination: but as much of the felicity of friendship arises from the mutual confidence to which it affords room, call not any man your friend in whose presence you find it proper to observe the same suspicious caution as if he were your enemy. The ancients, who talked of friendship with enthusiasm as one of the most elevated among the virtues, required a still closer union and a more disinterested attachment among friends than we dare venture to insist upon. The mutual duties which they have described as incumbent on friends, appear somewhat extravagant. Among other things, some of them have gone so far as to require a degree of mutual confidence which would soon destroy all confidence, and could not fail to counteract all the purposes of friendship: they have required one friend to communicate to another, not only all his own thoughts and purposes, but even those secrets which have been confided to his honour by any other friend. But the evil consequences which would result are easily to be foreseen. Perhaps, like Atticus, you enjoy the friendship of men who are mutual enemies; and by communicating the secrets of the one to the other, you will then become the betrayer of both. Or, though not absolutely enemies, yet those who are *your* friends may happen not to be in habits of friendship with each other; and they may then perhaps not scruple to divulge those secrets of one another which you have imprudently blabbed to them. Indeed, might we suppose all mankind absolutely faultless, and not liable to moral imperfection, we need not fear these bad consequences from unbounded confidence in our friends. But friendship would in such a state of society be unknown: just as in the golden age of the poets there are supposed to have been no distinctions of property. We cannot here forbear dropping an observation, which will readily be acknowledged as just by all who have any tolerable knowledge of the morality of the philosophers of ancient Greece. All their doctrines and precepts appear calculated for a different order of beings than mankind. They glanced carelessly at the phenomena of the moral world; and gleaning a few facts, immediately set themselves to erect systems: From these, however wild and theoretical, they then pretended to deduce laws for the regulation of human conduct; and their rules are generally such as might be expected from the means which they appear to have employed in order to arrive at them. An apology has, however, been offered for some of them, which, in our opinion, could occur only to superficial observers of human life. It has been alleged in behalf of the Stoics, that their system indeed required more exalted virtue than human nature is capable of attaining; but that, notwithstanding this, it could not fail to produce the happiest effects on the manners and sentiments of its votaries. Instances, too, have been produced in support of this assertion; a Cato, an Epictetus, an Antoninus. When we contemplate a model of perfection beyond what we can hope to reach, say the advocates of the Stoic philosophy, though we despair of attaining, yet we are prompted to aspire after it. Now, the most natural way of reasoning here seems to lead to a very different conclusion. If an object is set before me which I must not hope to obtain, I am unwilling to waste my time and exhaust

Friendship. exhaust my vigour in the pursuit of it: bid me ascend an inaccessible height, I view the vale below with new fondness. Philosophy, as well as superstition and enthusiasm, might in a few instances triumph over the principles of nature; but was it always equally powerful? Were all the disciples of Zeno Catos or Epictetuses? Have all the monks and anchorites of the Romish church been holy as the founders of their orders? No: The Greek philosophers who infested Rome, and taught those *whimsical* doctrines which we hear frequently dignified with the name *sublime*, were singularly corrupted and licentious in all their manners. If those of the *regular* clergy of the church of Rome have been always more pure, they have been cruelly calumniated. Ask, then, only what I am capable of performing: If you demand what is above my strength, I sit still in indolence. In its general tendency, the Stoic philosophy was favourable rather to vice than to virtue.

But we have not yet exhausted all the duties of friendship. We have inculcated sincerity, and mutual respect and obligingness of manners; we have also endeavoured to ascertain what degree of mutual confidence ought to take place between friends. But an important question still remains to be considered: how far is an *union of interests* to take place between friends? Am I to study the interest of my friend in preference to my own? May I lawfully injure others, in order to serve him? Here, too, we must consider the circumstances and the strength of human nature; and let us beware of imposing burdens too heavy to be borne. The greater and more perfect the union which reigns in society, the greater will be its strength and happiness; the closer the union of friends, the more advantages will each of them derive from their union. Where other ties besides those of friendship concur to unite two individuals, their interests will be more closely conjoined than if they were connected by the ties of friendship alone. The order of nature seems here to be,—the husband and wife—the parent and child—brothers and sisters, the offspring of the same parents—friends, connected by the ties of friendship alone. And, if we may presume to guess at the intentions of the Author of nature from what we behold in his works and read in his word, the closest union in society ought to be that between the husband and the wife; their interests are altogether the same; they ought mutually to forego convenience and gratification for each other's sake. The interests of parents and children are somewhat less closely connected; much is due from the one to the other, but somewhat less than in the former relation; their interests may sometimes be separate, but never ought to be opposite. Next come brethren, and other more distant relations; and next, the friend. In these cases, where we suppose the attachment of friendship to operate together with the ties of nature, we perceive that interests are variously united, and various duties are due; scarcely in any of them does it appear that the interests of two can become entirely one. Still less can that be expected to happen, where the ties of friendship act not in concert with those of nature. We give up, therefore, all those romantic notions, which some have so earnestly insisted on, of requiring the friend to consider his friend as himself. We cannot expect any two individuals to possess precisely the same degree of knowledge, to entertain exactly the same sentiments, or to stand in circumstances precisely similar. But till this happen, the interests of two can never be precisely the same. And we will not, therefore, require the friend actually to prefer his friend to himself; nay, we will even allow him to prefer himself to his friend; convinced that such is the design of nature, and that by presuming to counteract the principles of nature we shall be able to serve no useful purpose. But as far as the first principles of human action and the institutions of society permit, we may reasonably require of friends, that they mutually endeavour to contribute each to the other's interest. You will not desert your own family, nor neglect what is absolutely necessary for your own preservation, in order that you may serve a friend. It is not requisite that you be either a Damon or a Pythias. Away with what is romantic; but scruple not to submit to what is natural and reasonable. When your friend needs your direction and advice, freely and honestly give it: does he need more than advice; your active exertions in his behalf? the laws of friendship require you not to refuse them. Is it necessary for him to receive still more substantial assistance? You may even be expected to aid him with your fortune. But remember, that even the amiable principle of benevolence must be subject to the directions of prudence; if incapable of taking care of ourselves, we cannot be expected to contribute to the good of others; society would not be favourable to the happiness of the human race, if every individual studied the general interest so far as to neglect his own. We are not born to be citizens of the world; but Europeans, Britons, Englishmen or Scotchmen. Let every one, then, seek the interest and happiness of his friends with whom he is connected by the laws of friendship alone, in subordination to his own particular interest and happiness, and to the interest and happiness of those with whom he is connected by the ties of nature and the general institutions of society. Engage not in the service of your friend, nor lavish your fortune in his behalf, if by that means you are likely to injure either yourself or your family. Still less will you think it requisite to carry your friendship to such romantic excess as to commit crimes in the service of your friend. The ancients, whose ideas of the nature and duties of friendship were romantic and extravagant, have, some of them, required that a friend should hesitate at no action, however atrociously wicked, by which he can be useful to his friend. Have I been guilty of theft or murder, or any other heinous violation of the laws of morality or the institutions of society: when I am brought to justice for my crime, if you, being my friend, are appointed to sit as my judge, the laws of friendship, say those admirable masters of morality, require that you pronounce me innocent, though convinced of my guilt. But we need not declaim against the absurdity of enjoining such base deeds as duties of friendship. The idea of a connection, the laws of which are inimical to the order of society, must strike with horror every person who thinks of it. Such a connection is the union of a knot of villains, conspiring against the peace, nay even the existence of society.

7 General view of advantages of friendship.

Such we apprehend to be the nature of rational friendship; such the circumstances in the order of nature

Friendship.

ture and of society which are most favourable to this union; and such the duties, by the performance of which it may be maintained. When founded on these principles, and regulated by these laws, friendship is truly virtuous, and cannot but be highly beneficial to the individuals between whom it subsists, and to the interest of society in general. How delightful to have some person of an amiable and virtuous character in whom you can confide; who will join with you in the prosecution of virtuous designs, or will be ready to call you back when you heedlessly stray into the paths of vice and folly! who will administer to you honest, upright advice; will rejoice in your prosperity, will glory over your virtues, and will be ready to console and relieve you when sinking under the pressure of distress! Must not your connexion with such a person be favourable to your virtue, your interest, and your happiness? When we survey any sublime or beauteous scene in nature, we wish for some person of congenial taste and feelings to participate with us in the noble enjoyments which the prospect affords; when we read any fine piece of composition, the pleasure which we receive from it is more exquisite if others join with us in applauding it. The landscape which we have often surveyed, the poem which we have often read, please us anew, with all the charms of novelty, when we have an opportunity of pointing out their beauties to some person to whom they have been hitherto unknown. Friendship communicates new charms and a more delicate relish to all our most refined and elegant pleasures. It enlivens our joys, it soothes and alleviates our sorrows. What Cicero has said of polite letters and philosophy, may be with still stronger propriety said of friendship. In every condition of life the influence of virtuous friendship is favourable to our welfare and our happiness: in prosperity; in adversity; in the silence and tranquillity of retirement, as well as amid the hurry of business; in the bosom of your family, and when surrounded by your nearest connections, no less than when removed to a strange country. Indeed, whatever advantages society bestows above what are to be enjoyed in a savage state, not less numerous nor less important are those which we may derive from uniting in the bonds of friendship, rather than living in a state of enmity or indifference.

nstancy.

But though friendship, when founded on mutual esteem, and regulated by the laws of prudence, benevolence, and honesty, be productive of so many happy effects; yet many instances occur in the world, in which connexions dignified with the name of friendship are unfavourable both to the virtue and the happiness of those between whom they subsist. When men associate from views of convenience; when their union is hastily formed without a knowledge of each other's temper and character; when they are drawn together by accident, as when they happen to agree in the pursuits of the same interests or pleasures; when the young and the gay resort together to the haunts of dissipation, and the covetous and ambitious find it convenient to toil in concert for riches and power: on all such occasions, the connexion which is formed and dignified with the name of friendship is unworthy of that honourable appellation. It is not virtuous; it is productive of no happy effects, and is quickly dissolved. He, therefore, who is not incapable of virtuous friendship, and is desirous of enjoying its advantages, must carefully consider the nature of the connexion which he wishes to form, gain a thorough acquaintance with the character of the person whose esteem and affection he wishes to acquire, and attend to those rules by the observance of which true friendship may be maintained.

9
Relation illustrating the power of friendship over the human heart.

Many instances are related, which show what power it is possible for friendship to acquire over the human heart. We need not here repeat the well known story of Damon and Pythias, whose generous friendship afforded a spectacle which softened even the savage heart of Dionysius. It is known to every school-boy; and, after the affecting narrative of Valerius Maximus, has been studiously detailed and commented on by almost every succeeding story-teller or moralist. Addison, in one of his Spectators, gives a beautiful little relation, we know not upon what authority, which finely illustrates the power of both friendship and love. Two male negroes, in one of our West Indian islands, nearly of the same age, and eminent among their fellows in slavery for gracefulness of figure, strength, agility, and dexterity, were also distinguished for their mutual friendship and for their common attachment to a young female negro, who was generally esteemed the most beautiful of her complexion in the whole island. The young female appeared to be equally pleased with both her lovers; and was willing to accept either of them for a husband, provided they could agree between themselves which of them should yield to the pretensions of the other. But here lay the difficulty; for while neither would treacherously supplant, neither of them was willing to yield to his friend. The two youths, therefore, long suffered the severest affliction, while their hearts were torn between love and friendship. At length when they were no longer able to endure the agony of such a contest, being still unable to repress their passion for their lovely countrywoman, and incapable of violating the laws of friendship,—on a certain day, they both, in company with the object of their ill-fated love, retired into a wood adjoining to the scene of their labours. There, after fondly embracing the maid, calling her by a thousand endearing names, and lamenting their own unhappy fate, they stabbed a knife into her breast; which, while still reeking with her blood, was by each of them in his turn plunged into his own. Her cries reached the people who were at work in the next field: some of them hastening to the spot, found her expiring, and the two youths already dead beside her.

We have introduced this little narrative as a striking instance of the noble effects which naturally result from genuine friendship. Here we see it superior to the force of the most violent of passions. Had the elevated souls of those negro youths been refined and enlightened by culture and education in the principles of morality and true religion, we may reasonably suppose that their friendship would have triumphed over their love, without prompting them to the rash and desperate deed which they committed.

10
Not inconsistent with the spirit of Christianity.

Friendship, thus amiable in its character, thus beneficial in its influence and effects, the theme of unbounded panegyric to the philosophers and moralists of every age, has been said by some respectable modern writers to be inconsistent with the spirit of that holy

religion

Friendship.

religion which we profess, and which we regard as the revelation of heaven. General benevolence is frequently inculcated through the gospel: Jesus often earnestly entreated his disciples, "to love one another;" and directed them in what manner to display their mutual love, by telling them that "whatsoever things they could reasonably wish to receive from others, the same ought they to do to them." The writers of the epistles often enlarge on the topics of charity and brotherly love. But private friendship is nowhere recommended in the code of Christianity. Nay, it is so inconsistent with that universal benevolence which the gospel enjoins, that where the one is recommended and enforced, the other may be understood to be tacitly forbidden. But can that religion be true, or can it be favourable to the happiness of its votaries, which is inimical, nay, which is even not friendly to virtuous friendship? Such are the suggestions of Lord Shaftesbury and Soame Jenyns on this head.

We must grant them, that the system of morals or religion which discourages a connection so noble in its origin, so amiable in its character, and so beneficial in its influence, as virtuous friendship, is rather unfavourable to the happiness and virtue of its votaries. But we must consider the genius of Christianity with more careful attention, before we suffer ourselves to be persuaded that friendship is inconsistent with it. Universal benevolence is, indeed, inculcated in the gospel: we are required to love our neighbour as ourselves: and our Saviour seems to insinuate, in the story of the humane Samaritan, that we ought to regard as neighbours all our brethren of the human race, however separated from us by any of the distinctions of society. But it would be unfair to conclude from this, that the great Author of the gospel meant to abolish the order of social life, or to oppose the ties of nature. These may still be respected, though the laws of this benevolence be obeyed. The parent is not required to desert his child, in order that he may assist or relieve his neighbour; nor the child to leave his parent to perish under the infirmities of old age, while he hastens to lend assistance to a stranger. The gospel was not intended to dissolve communities, or to abrogate the distinctions of rank. In Jesus, the end of the ceremonial law was accomplished: by him, therefore, that burden of types and ceremonies with which the Jews had been loaded was taken away. But he who abolished the ceremonial law declared, that the obligations of the moral law should be more permanent than heaven or earth: The duties which it enjoined were still to be religiously discharged: The precepts of the gospel were to illustrate and enforce, not to contradict, the institutions of the moral law. The relative duties of parents and children were still to be performed; though men were directed not to confine all their sentiments of benevolence to domestic relations. Jesus, in his conduct, did not set himself to oppose the order of society. In various parts of the New Testament all the social duties are defined and enforced; the mutual duties of parents and children, of husbands and wives, and of masters and servants. The submission of all the members of a community to that power which is vested with the authority of the whole, is also strictly enjoined in the gospel. Jesus, when in his last moments he recommended his mother to the protection of his beloved disciple, chose to ask *him* to consider *her* as a parent; and directed *her* to expect from *him* the respect and kindness of a son. These facts and observations teach us in what sense to understand that universal benevolence which is inculcated in the gospel. Though we are to love all mankind, yet it is not necessary that all the individuals of the human race share our affection alike. Were we powerful, and wise, and benevolent, as the Deity, such extensive benevolence might be required of us: But our sphere of action and observation is narrow; we cannot extend our acquaintance or influence beyond a very limited circle. Were we to endeavour to be equally useful to all mankind, we should become incapable of being useful to any individual. We cannot become citizens of the world in the sense in which some philosophers have affected to call themselves such, without becoming outcasts from every particular society. A son, a brother, a countryman, a stranger, lie around you, each in circumstances of extreme distress; you pity their misfortunes, and would gladly administer relief; but such is your benevolence, that you feel precisely the same degree of compassion for each of them; you cannot determine to whom you should first stretch out an helping hand; and you therefore stand like that venerable ass of the schoolmen, whose tantalizing situation between two bundles of hay has been so long celebrated and lamented by metaphysicians; and suffer son, and brother, and countryman, and stranger, to perish, without relieving any of them by your kind offices. It is therefore the design of the gospel, that we should submit to the laws of nature, and comply with the institutions of society. First, attend to self-preservation; next, perform the duties of a wife or husband,—a parent,—a child,—a brother,—a citizen,—an individual of the human race. You will do well, indeed, to regard all mankind with benevolence; but your benevolence will be unavailing to the objects of it, if you overlook the distinctions of nature and those institutions which support the union of social life.

But if the spirit of Christianity be not inimical to the institutions and relations of society, neither can it be unfavourable to friendship. If that benevolence which the gospel enjoins admit of any modifications, why not of that particular modification which constitutes private friendship? It is not, indeed, directly enjoined; but neither is it forbidden. It is perfectly consistent with the general tendency and spirit of the gospel system; being favourable to the interests of society, it cannot but be agreeable to our holy religion.

But it is recommended by no direct precept, say those who would represent Christianity as inimical to it; while it has been the favourite theme of the philosophers and moralists of the heathen world.

But why should friendship be recommended by means different from those which the gospel employs for the purpose? Make yourself well acquainted with that admirable system which you so earnestly oppose; you will find that even the duties of private friendship are better explained and more powerfully enforced in the gospel, than by all the heathen philosophers and poets from Hesiod to Plutarch. The gospel makes a distinction between the virtuous and the vicious; it represents one character as more amiable and respectable than another. As it distinguishes between virtue and vice, Friendship. vice, between piety and impiety; so its great object is to deter us from vice, and to encourage us to the practice of virtue. It cannot be supposed, then, that the gospel will direct us to associate indifferently with virtuous and profligate characters. It does not. It directs us to seek improvement, by associating with those whom we have reason to esteem. It directs those who are incorrigibly wicked to be expelled from society. What is this but to command us to enter into habits of intimacy wherever there is ground for mutual esteem? But this is the only basis of genuine friendship. When all the means which lead to a certain end are laid before you, and when you are particularly directed by some high authority to employ those means; though the end which you thus attain be not pointed out, yet the commanding you to employ such a series of means, is evidently the same as if you were directed to accomplish the purpose to which they tend. Thus, though the precepts of Christianity do not directly enjoin private friendship; yet they have a direct tendency to form those exalted characters who alone are capable of true friendship; they inculcate those virtues which naturally give rise to this generous attachment, and are absolutely necessary to support it where it is formed; they inculcate benevolence by the most effectual motives, and admit of modifications of that benevolence, correspondent to the relations and institutions of society: And therefore they may be considered in as strong and direct terms as if it had been expressly said, "Cultivate private friendship." Besides, friendship is rather an *accident* of society, a natural consequence of our character as moral and social beings, than a relation to be regulated and defined by institutions.

Friendship countenanced by our Saviour's example. This union, so natural between virtuous persons, has been countenanced by the example of the Author of our religion; to whose life, no less than to his doctrines and precepts, we will do well to look for a standard by which we may regulate our conduct. We allude to two remarkable instances which occur in the evangelical history; and with the recital of which, as stated in all their striking circumstances by a very elegant writer *, we shall conclude the present article.

"The evangelist, in relating the miracle which Christ performed at Bethany by restoring a person to life who had lain some days in the grave, introduces his narrative by emphatically observing, that 'Jesus loved Lazarus;' intimating, it should seem, that the sentiments which Christ entertained of Lazarus were a distinct and peculiar species of that general benevolence with which he was actuated towards all mankind. Agreeably to this explication of the sacred historian's meaning, when the sisters of Lazarus sent to acquaint Jesus with the state in which their brother lay, they did not even mention his name; but, pointing him out by a more honourable and equally notorious designation, the terms of their message were 'Behold! he whom thou lovest is sick!' Accordingly, when he informs his disciples of the notice he had thus received, his expression is, 'Our friend Lazarus sleepeth.' Now that Christ did not upon this occasion use the word *friend* in its loose undistinguished acceptation, but in a restrained and strictly appropriated sense, is not only manifest from this plain account of the fact itself, but appears farther evident from the sequel. For as he was advancing to the grave, accompanied with the relations of the deceased, he discovered the same emotions of grief as swelled the bosoms of those with whom Lazarus had been most intimately connected; and sympathizing with their common sorrow, he melted into tears. This circumstance was too remarkable to escape particular observation: and it drew from the spectators, what one should think it must necessarily draw from every reader, this natural and obvious reflection, 'Behold! how he loved him!'

"But in the concluding catastrophe of our Saviour's life, he gave a still more decisive proof that sentiments of the strongest personal attachment and friendship were not unworthy of being admitted into his sacred bosom: they were too deeply, indeed, impressed, to be extinguished even by the most excruciating torments. In those dreadful moments, observing among the afflicted witnesses of his painful and ignominious sufferings, that faithful follower who is described by the historian as 'the disciple whom he loved;' he distinguished him by the most convincing instance of superior confidence, esteem, and affection, that ever was exhibited to the admiration of mankind. For, under circumstances of the most agonizing torments, when it might be thought impossible for human nature to retain any other sensibility but that of its own inexpressible sufferings, he recommended to the care and protection of this his tried and approved friend, in terms of peculiar regard and endearment, the most tender and sacred object of his private affections. But no language can represent this pathetic and affecting scene with a force and energy equal to the sublime simplicity of the Evangelist's own narrative: 'Now there stood by the cross of Jesus, his mother and his mother's sister, and Mary Magdalene. When Jesus saw his mother and the disciple (standing) by, whom he loved; he saith to his mother, Behold thy son! then he saith to the disciple, Behold thy mother! And from that hour that disciple took her to his own home.'

"It may safely be asserted, that among all those memorable examples of friendship, which have been celebrated with the highest encomiums by the ancients, there cannot be produced a single instance in which the most distinguished features of exalted amity were so strongly displayed as in the foregoing relation. The only one, perhaps, that bears even a faint similitude to it, is that famous transaction recorded by a Greek author, which passed between Eudamidas and Aretheus. But when the very different circumstances attending the respective examples are duly considered, it must be acknowledged, that the former rises as much above the latter in the proof it exhibits of sublime friendship, as it does in the dignity of the characters concerned.

"Upon the whole, then, it appears, that the divine Founder of the Christian religion, as well by his own example as by the spirit of his moral doctrine, has not only encouraged but consecrated friendship."

Friendship, Friesland. **FRIESLAND**, one of the united provinces of the Low Countries. It is bounded on the east by the river Lauvers, which parts it from the lordship of Groningen, on the south by Overyssel, on the west by the Zuider-Zee, and on the north by the German ocean. It is 30 miles from north to south, and 28 from east to west. The land is very fertile in corn and pasture;

Friesland || Fright.

sture; the horses are large, and the cows and sheep prolific. It is divided into three parts; Westergo to the west, Ostergo to the east, and Sevenwalden to the south. The islands of Sheling, Ameland, and other small ones, are dependent on this province. The principal towns are Leuwarden the capital, Franeker, Dockum, Harlingen, and Staveren.

FRIESLAND, East, a province of Germany, in the circle of Westphalia, lying near the German ocean. It is bounded on the south by the bishopric of Munster, on the east by the country of Oldenburgh, on the west by the province of Groningen, and on the north by the sea, being about 50 miles in length, and 30 in breadth, It belonged to Prussia, but was ceded to Hanover in 1814. It is a very fertile country, and feeds a great number of cattle; but it was greatly damaged by an inundation in 1717, and the repair of the dykes cost an immense sum. The principal towns are Norden, Leer, Essens, Whitmunde, and Aurick. Embden was an imperial city, and the principal place in the country. The inhabitants are Calvinists, with a few Catholics and Baptists.

FRIGATE, in naval affairs, a ship of war usually of two decks, light built, designed for swift sailing. When it hath but one deck, and consequently is of a smaller size, they call her a light frigate.

Frigates mount from 20 to 44 guns, and are esteemed excellent cruisers. The name was formerly known only in the Mediterranean, and applied to a long kind of vessel navigated in that sea with sails and oars. The English were the first who appeared on the ocean with these ships, and equipped them for war as well as for commerce.

FRIGATE-Built, denotes the disposition of the decks of such merchant ships as have a descent of four or five steps from the quarter-deck and forecastle into the waist, in contradistinction to those whose decks are on a continued line for the whole length of the ship, which are called *galley-built*.

FRIGATOON, a Venetian vessel, commonly used in the Adriatic, built with a square stern, and without any foremast, having only a mainmast, mizenmast, and bowsprit.

FRIGHT, or TERROR, a sudden and violent degree of fear. See FEAR.

Sudden fear is frequently productive of very remarkable effects upon the human system. Of this many instances occur in medical writings.—In general, the effects of terror are a contraction of the small vessels and a repulsion of the blood in the large and internal ones; hence proceed a suppression of perspiration, a general oppression, trembling, and anguish of the heart, and lungs overcharged with blood.

Frights often occasion incurable diseases, as epilepsy, stupor, madness, &c. In acute diseases, they have evidently killed many, by the agitation into which they have thrown the spirits, already too much disordered. We have also accounts of persons absolutely killed by terrors when in perfect health at the time of receiving the shock from them: people ordered to be executed, but with private orders for a reprieve, have expired at the block without a wound.—Out of many instances of the fatal effects of fear recorded in writers, the following is selected as one of the most singular. "George Grochantzy, a Polander, who had enlisted as a soldier in the service of the king of Prussia, deserted during the war. A small party was sent in pursuit of him; and when he least expected it, they surprised him singing and dancing among a company of peasants, who were got together in an inn and were making merry. This event, so sudden and unforeseen, and at the same time so dreadful in its consequences, struck him in such a manner, that, giving a great cry, he became at once altogether stupid and insensible, and was seized without the least resistance. They carried him away to Glocau, where he was brought before the council of war, and received sentence as a deserter. He suffered himself to be led and disposed of at the will of those about him, without uttering a word, or giving the least sign that he knew what had happened or would happen to him. He remained immoveable as a statue wherever he was placed, and was wholly passive with respect to all that was done to him or about him. During all the time that he was in custody, he neither ate, nor drank, nor slept, nor had any evacuation. Some of his comrades were sent to see him; after that he was visited by some officers of his corps, and by some priests; but he still continued in the same state, without discovering the least signs of sensibility. Promises, intreaties, and threatenings were equally ineffectual. The physicians who were consulted upon his case, were of opinion, that he was in a state of hopeless idiocy. It was at first suspected that those appearances were feigned; but these suspicions necessarily gave way, when it was known that he took no sustenance, and that the involuntary functions of nature were in great measure suspended. After some time they knocked off his fetters, and left him at liberty to go whither he would. He received his liberty with the same insensibility that he had showed upon other occasions: he remained fixed and immoveable; his eyes turned wildly here and there without taking cognizance of any object, and the muscles of his face were fallen and fixed like those of a dead body. Being left to himself, he passed 20 days in this condition, without eating, drinking, or any evacuation, and died on the 20th day. He had been sometimes heard to fetch deep sighs; and once he rushed with great violence on a soldier, who had a mug of liquor in his hand, forced the mug from him, and having drank the liquor with great eagerness, let the mug drop to the ground."

When a person is affected with terror, the principal endeavour should be to restore the circulation to its due order, to promote perspiration, and to allay the agitation of the patient. For these purposes he may drink a little warm liquor, as camomile tea, &c. the feet and legs may be put into warm water, the legs rubbed, and the camomile tea repeated every six or eight minutes; and when the skin is warm, and there is a tendency to perspiration, sleep may be promoted by a gentle opiate.

But frights have been known not only to cause, but also to cure diseases. Mr Boyle* mentions agues, gout, and sciatica, cured by this means.

* Works Abr. p. &c.

To turn from the serious to the ludicrous effects of fear, the following instance of the latter sort, quoted from a French author by Mr Andrews in his volume of Anecdotes, shows upon what slight occasions this passion may be sometimes excited in a very high degree, even in persons the most unlikely to entertain

Fright ‖ Frilazin.

tain such a guest. "Charles Gustavus (the successor of Christina of Sweden) was besieging Prague, when a boor of most extraordinary visage desired admittance to his tent; and being allowed entrance, offered, by way of amusing the king, to devour a whole hog of one hundred weight in his presence. The old general Konigsmarc, who stood by the king's side, and who, soldier as he was, had not got rid of the prejudices of his childhood, hinted to his royal master that the peasant ought to be burnt as a sorcerer. 'Sir,' said the fellow, irritated at the remark, 'if your majesty will make but that old gentleman take off his sword and his spurs, I will eat him immediately before I begin the hog.' General Konigsmarc (who had, at the head of a body of Swedes, performed wonders against the Austrians, and who was looked upon as one of the bravest men of the age) could not stand this proposal, especially as it was accompanied by a most hideous and preternatural expansion of the frightful peasant's jaws. Without uttering a word, the veteran suddenly turned round, ran out of the court, and thought not himself safe until he had arrived at his quarters; where he remained above twenty-four hours locked up securely, before he had got rid of the panic which had severely affected him."

Fear (Dr Beattie † observes) should not rise higher than to make us attentive and cautious; when it gains an ascendancy in the mind, it becomes an insupportable tyranny, and renders life a burden. The object of fear is evil; and to be exempt from fear, or at least not enslaved to it, gives dignity to our nature, and invigorates all our faculties. Yet there are evils which we ought to fear. Those that arise from ourselves, or which it is in our power to prevent, it would be madness to despise, and audacity not to guard against. External evils, which we cannot prevent, or could not avoid without a breach of duty, it is manly and honourable to bear with fortitude. Insensibility to danger is not fortitude, no more than the incapacity of feeling pain can be called patience; and to expose ourselves unnecessarily to evil is worse than folly, and very blameable presumption. It is commonly called *fool-hardiness;* that is, such a degree of hardiness or boldness as none but fools are capable of. See the article FORTITUDE.

† Elements of Moral Science.

FRIGID (*frigidus*), in a general sense, denotes the quality of being cold. It is frequently applied to a jejune style, that is unanimated by any ornaments, and consequently without any force or vigour.

FRIGID-zone. See ZONE, GEOGRAPHY *Index*.

FRIGIDITY, in *Medicine*, the same with IMPOTENCE.

FRIGORIFIC, in *Physiology*, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which is called *cold*, or, according to others, merely the absence or diminution of the particles of heat. See COLD, CHEMISTRY *Index;* and SALTS.

FRILAZIN, the name of a class or rank of people among the Anglo-Saxons, consisting of those who had been slaves, but had either purchased, or by some other means obtained, their liberty. Though these were in reality free men, they were not considered as of the same rank and dignity with those who had been born free, but were still in a more ignoble and dependent condition, either on their former masters or on some new patrons. This custom the Anglo-Saxons seem to have derived from their ancestors in Germany, among whom those who had been made free did not differ much in point of dignity or importance in the state from those who continued in servitude. This distinction between those who had been made free and those who enjoy freedom by descent from a long race of free men, still prevails in many parts of Germany; and particularly in the original seats of the Anglo-Saxons. Many of the inhabitants of towns and cities in England, in this period, seem to have been of this class of men, who were in a kind of middle state between slaves and freemen.

Frilazin ‖ Frit.

FRILL, in *Falconry*. When a hawk trembles or shivers, they say she frills.

FRINGILLA, a genus of birds belonging to the order of passeres. See ORNITHOLOGY *Index*.

FRIO, a small island on the coast of the Brasils, situated in 32° 2′ S. Lat. and 41° 31′ 45″ W. Long. The land of Frio is high, with a hollow in the middle, which gives it, at a distance, the appearance of two separate islands.

FRIPPERY, a French term sometimes used in our language to signify the trade or traffic of old second-hand clothes and goods. The word is also used for the place where such sort of commerce is carried on, and even for the commodities themselves. The company of frippiers, or fripperers, at Paris, are a regular corporation, of an ancient standing, and make a considerable figure in that city.

FRISI, PAUL, an eminent Italian mathematician. See SUPPLEMENT.

FRISII, FRISEI, FRISIONES, and FRISONES, in *Ancient Geography*, a people of Germany, so called either from their ardent love of freedom, or from the fresh and unbroken lands they occupied, contradistinguished from the old lands. Tacitus divides them, from their extent of power and territory, into the Majores, situated on the coasts between the Rhine and the Ems; and into the Minores, occupying the parts about the lakes lying between the channels of the Rhine.

FRIT, or FRITT, in the glass manufacture, is the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace.

A salt drawn from the ashes of the plant kali, or from fern or other plants, mixed with sand or flint, and baked together, makes an opaque mass called by glassmen *frit;* probably from the Italian *frittare*, to fry; or because the frit, when melted, runs into lumps, like fritters, called by the Italians *fritelli*.

Frit, by the ancients, was called *ammonitrum*, of *αμμος, sand*, and *νιτρον, nitre;* under which name it is described by Pliny thus: Fine sand from the Volturnian sea, mixed with three times the quantity of nitre, and melted, makes a mass called *ammonitrum;* which being rebaked makes pure glass.

Frit, Neri observes, is only the calx of the materials which make glass; which, though they might be melted, and glass be made, without thus calcining them, yet it would take up much more time. Thus calcining, or making of frit, serves to mix and incorporate the materials

terials together, and to evaporate all the superfluous humidity. The frit, once made, is readily fused, and turned into glass.

There are three kinds of frits. The first, crystal frit, or that for crystal metal, is made with salt of pulverine and sand. The second and ordinary frit, is made of the bare ashes of pulverine or barilla, without extracting the salt from them. This makes the ordinary white or crystal metal. The third is frit for green glasses, made of common ashes, without any preparation. This last frit will require ten or twelve hours baking.

The materials in each are to be finely powdered, washed, and searced; then equally mixed, and frequently stirred together in the melting pot. See Glass.

FRITILLARIA, Fritillary; a genus of plants belonging to the hexandria class; and in the natural method ranking under the 10th order, *Coronariæ*. See Botany *Index*.

The different species of fritillary were, according to Beckman, introduced into gardens about the middle of the 16th century. The crown imperial (*fritillaria imperialis*) is supposed by some to be the lily which is much celebrated in sacred scripture; because a figure resembling this splendid plant, they imagine, is found represented on the coins of Herod. Invent. vol. iii.

FRIULI, a province of Italy, subject to Austria, and bounded by Carinthia in Germany on the north, by Carniola on the east, by the gulf of Venice on the south, and by the Bellunese and Feltrin on the west.

FRIZE, or Frieze, in *Architecture*, a part of the entablature of columns, more usually written and pronounced *freeze*. See Freeze.

Frize, or Freeze, in *Commerce*, a kind of woollen cloth or stuff for winter wear, being frized or knapt on one side; whence, in all probability, it derives its name.

Of frizes, some are crossed, others not crossed; the former are chiefly of English manufacture, the latter of Irish.

FRIZING of Cloth, a term in the woollen manufactory, applied to the forming of the nap of cloth or stuff into a number of little hard burrs or prominences, covering almost the whole ground thereof.

Some cloths are only frized on the back side, as black cloths; others on the right side, as coloured and mixed cloths, rateens, bays, freezes, &c.

Frizing may be performed two ways. One with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument. The other is by a mill, worked either by water, or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The structure of this useful machine is as follows:

The three principal parts are the frizer or crisper, the frizing table, and the drawer or beam. The two first are two equal planks or boards, each about 10 feet long and 15 inches broad; differing only in this, that the frizing table is lined or covered with a kind of coarse woollen stuff, of a rough sturdy nap; and the frizer is incrusted with a kind of cement composed of glue, gum arabic, and a yellow sand, with a little aqua-vitæ, or urine. The beam or drawer, thus called, because it draws the stuff from between the frizer and the frizing table, is a wooden roller, beset all over with little, fine, short points or ends of wire, like those of cards used in carding wool.

The disposition and use of the machine is thus: The table stands immoveable, and bears or sustains the cloth to be frized, which is laid with that side uppermost on which the nap is to be raised; over the table is placed the frizer, at such a distance from it as to give room for the stuff to be passed between them; so that the frizer, having a very slow perpendicular motion, meeting the long hairs or naps of the cloth, twists and rolls them into little knobs or burrs; while at the same time, the drawer, which is continually turning, draws away the stuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is a-going, is to stretch the stuff on the table as fast as the drawer takes it off, and from time to time to take off the stuff from the points of the drawer.

The design of having the frizing table lined with stuff of a short, stiff, stubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which must otherwise be the case, as it is not held by any thing at the other end. It were unnecessary to say any thing particular of the manner of frizing stuffs with the hand, it being the aim of the workmen to imitate, as near as they can with their wooden instrument, the slow, equable, and circular motion of the machine: it needs only be added, that their frizer is but about two feet long and one broad; and that to form the nap more easily, they moisten the surface of the stuff lightly, with water mingled with whites of eggs or honey.

FROBENIUS, John, a famous and learned printer in the 16th century, was born at Hamelburgh in Franconia, and settled at Basil. He had before studied in that university, where he acquired the reputation of being uncommonly learned; and now setting up a printing house in that city, was the first of the German printers who brought that admirable art to any degree of perfection. Being a man of great probity and piety, as well as skill, he was particularly choice in the authors he printed; and would never, for the sake of profit, suffer libels, or any thing that might hurt the reputation of another, to go through his press. The great character of this printer was the principal motive which induced Erasmus to reside at Basil, in order to have his own works printed by him. A great number of valuable authors were printed by Frobenius, with great care and accuracy; among which were the works of St Jerome, Augustine, and Erasmus. He designed to have printed the Greek Fathers; but died in 1527, before he could execute his design. Erasmus wrote his epitaph in Greek and Latin.

John Frobenius left a son named *Jerome Frobenius*, and a daughter married to Nicholas Episcopius; who, joining in partnership, continued Frobenius's printing house with reputation, and printed correct editions of the Greek Fathers.

FROBISHER, or Forbisher, Sir Martin, an excellent navigator and sea officer in the 16th century, was born near Doncaster in Yorkshire, and was from his

his youth brought up to navigation. He was the first Englishman who attempted to find a north-west passage to China, and in 1576 he sailed with two barks and a pinnace in order to attempt that passage. In this voyage he discovered a cape, to which he gave the name of *Queen Elizabeth's Foreland*, and the next day discovered a strait to which he gave his own name. This voyage proving unsuccessful, he attempted the same passage in 1577; but discovering some ore in an island, and his commission directing him in this voyage only to search for ore, and to leave the farther discovery of the north-west to another time, he returned to England. He sailed again, with 15 ships and a great number of adventurers, to form a settlement: but being obstructed by the ice, and driven out to sea by a violent storm, they, after encountering many difficulties, returned home, without making any settlement, but brought a large quantity of ore.—He afterwards commanded the Aid in Sir Francis Drake's expedition to the West Indies, in which St Domingo in Hispaniola, Carthagena, and Santa Justina, in Florida, were taken and sacked. In 1588, he bravely exerted himself in defence of his country against the Spanish armada, when he commanded the Triumph, one of the largest ships in that service; and, as a reward for his distinguished bravery, received the honour of knighthood from the lord high admiral at sea. He afterwards commanded a squadron which was ordered to cruise on the Spanish coast; and, in 1592, took two valuable ships and a rich carrack. In 1594 he was sent to the assistance of Henry IV. king of France against a body of the Leaguers and Spaniards, who had strongly entrenched themselves at Croyzon near Brest; but in an assault upon that fort, on the 7th of November, Sir Martin was unfortunately wounded with a ball, of which he died soon after he had brought back the fleet to Plymouth, and was buried in that town.

Frobisher's Straits, lie a little to the northward of Cape Farewell in West Greenland, and were discovered by Sir Martin Frobisher. W. Long. 48. 16. N. Lat. 63. 12.

FRODSHAM, a town of Cheshire in England, 162 miles from London, is noted for its ancient castle. It has a stone bridge over the river Weaver near its conflux with the Mersey, and a harbour for ships of good burden. By means of inland navigation, it has communication with the rivers Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c.

FROG. See Rana. } Erpetology *Index*.
Bull Frog. See Rana. }

Frog Fish of Surinam, a very singular animal, of which a figure is given by Mr Edwards, *Hist. of Birds*, vol. i. There is no specimen in the British museum, nor in any private collection, except that of Dr Fothergill. It was brought from Surinam in South America. Frogs, both in Asia and Africa, according to Merian, change gradually from fishes to frogs, as those in Europe; but after many years revert again into fishes, though the manner of their change has never been investigated. In Surinam these fishes are called *jakjés*. They are cartilaginous, of a substance like our mustela, and exquisite food: they are formed with regular vertebræ, and small bones all over the body divided into equal parts; are first darkish, and then gray: their scales make a beautiful appearance. Whether this animal is, in its perfect state, a species of frog with a tail, or a kind of water lizard, Mr Edwards does not pretend to determine; but observes, that when its size is considered, it should be deemed a tadpole at first produced from spawn, and in its progress towards a frog, such an animal, when full grown, if it bears the same proportion to its tadpole as those in Europe do, must be of enormous size; for our full grown frogs exceed the tadpoles at least 50 times. See Erpetology *Index*.

FROME, a river that rises from several springs in the western parts of Dorsetshire in England, the principal of which is near Evershot; and directing its course almost due west, passes under Frampton bridge, washes the town of Dorchester, and falls into a bay of the English channel called *Poolhaven*, near Wareham.

Frome-Selwood, a town of Somersetshire in England, 150 miles from London. It is the chief town of this part of the country, which was anciently one great forest called *Selwoodshire*; and in the latter end of the last century, in those called *Frome Woodlands*, there was a considerable gang of money coiners or clippers, of whom many were taken and executed, and their covert laid open. Though the town is bigger than some cities, yet it has only one church; but it has six or seven meeting houses of Protestant dissenters. The inhabitants amounted to 9493 in 1811, and their chief manufactory is broad cloth. About 50 years ago, more wire cards for carding the wool for the spinners were made at this place than in all England besides, which was for the most part supplied with them from hence; for here were no less than 20 master cardmakers, one of whom employed 400 men, women, and children, in that manufactory, at one time; so that even children of 7 or 8 years of age could earn half-a-crown a-week. The river here, which abounds with trout, eels, &c. rises in the woodlands; and runs under its stone bridge towards Bath, on the east side of which it falls into the Avon. This town has been a long time noted for its fine beer, which they keep to a great age, and is generally preferred by the gentry to the wines of France and Portugal. It was governed formerly by a bailiff, and now by two constables of the hundreds of Frome, chosen at the court leet of the lord of the manor.

FRONDESCENTIA, from *frons*, "a leaf;" the precise time of the year and month in which each species of plants unfolds its first leaves.

All plants produce new leaves every year; but all do not renew them at the same time. Among woody plants, the elder, and most of the honeysuckles; among perennial herbs, the crocus or tulip, are the first that push or expand their leaves. The time of sowing the seeds decides with respect to annuals. The oak and ash are constantly the latest in pushing their leaves: the greatest number unfold them in spring; the mosses and firs in winter. These striking differences with respect to so capital a circumstance in plants as that of unfolding their leaves, seem to indicate that each species of plants has a temperature proper or peculiar to itself, and requires a certain degree of heat to extricate the leaves from their buds, and produce the appearance in question.

This temperature, however, is not so fixed or constant as it may appear to a superficial observer. Among plants of the same species, there are some more early than others; whether that circumstance depends, as it most commonly does, on the nature of the plants, or is owing to differences in heat, exposure, and soil. In general, it may be affirmed, that small and young trees are always earlier than larger or old ones.

The pushing of the leaves is likewise accelerated or retarded according to the temperature of the season; that is, according as the sun is sooner or later in dispensing that certain degree of heat which is suitable to each species.

FRONT, the forehead, or that part of the face above the eyebrows. The word is formed of the Latin *frons;* and that from the Greek φρονειν, "to think, perceive;" of φρην, *mens*, "the mind, thought." Martinius, to make out this etymology, observes, that from the forehead of a person we perceive what he is, what he is capable of, and what he thinks of.

FRONT is also used where several persons or things are ranged side by side, and show their front or fore parts.

FRONT, in *Architecture*, denotes the principal face or side of a building, or that presented to their chief aspect or view.

FRONTAL, in *Architecture*, a little fronton or pediment, sometimes placed over a small door or window.

FRONTAL, *Frontlet*, or *Brow-band*, is also used in speaking of the Jewish ceremonies. This frontal consists of four several pieces of vellum, on each whereof is written some text of scripture. They are all laid on a piece of a black calf's leather with thongs to tie it by. The Jews apply the leather with the vellum on their foreheads in the synagogue, and tie it round the head with the thongs.

FRONTIER, the border, confine, or extreme, of a kingdom or province, which the enemies find in front when they would enter the same. Thus we say, a frontier town, frontier province, &c. Frontiers were anciently called *marches*.

The word is derived from the French *frontiere*, and that from the Latin *frontaria;* as being a kind of front opposed to the enemy. Skinner derives *frontier* from *front;* inasmuch as the frontier is the exterior and most advanced part of a state, as the front is that of the face of a man.

FRONTIGNIAC WINE, is so called from a town of Languedoc in France, situated 16 miles south-west of Montpelier, remarkable for producing it.

FRONTINAC, a fortress in Canada, situated at the head of a fine harbour, on the north-west side of the outlet of Lake Ontario, where vessels of every description may ride in perfect safety. It is 300 miles from Quebec, and in comparison of that place has a very short winter.

FRONTINUS, SEXTUS JULIUS, an ancient Roman writer, was of consular dignity, and flourished under the emperors Vespasian, Titus, Domitian, Nerva, and Trajan. He commanded the Roman armies in Britain; was made city prætor when Vespasian and Titus were consuls; and Nerva made him curator of the aqueducts, which occasioned his writing *De Aquæductibus urbis Romæ*. He wrote four books upon the Greek and Roman art of war; a piece *De Re Agraria*, and another *De Limitibus*. These have been often separately reprinted; but were all collected together in a neat edition at Amsterdam in 1661, with notes by Robertus Keuchenius. He died under Trajan.

FRONTISPIECE, in *Architecture*, the principal face of a fine building. The word is formed of the Latin *frontispicium*, q. d. *frontis hominis inspectio*. Hence also, by a figure, we say, the frontispiece of a book; meaning an ornament with an engraven title on the first page.

FRONTLET. See FRONTAL.

FRONTO, MARCUS CORNELIUS, was chosen for his eloquence to instruct the emperors Marcus Aurelius and Lucius Verus in rhetoric; in recompense of which he was promoted to the consulate, and a statue was erected to his honour. He taught Marcus Aurelius not only eloquence, but the duty of kings, and excellent morals. Some say he wrote against the Christians. A sect was formed of those who looked upon him as a model of perfect eloquence, and those were called *Frontoniani*. The Civilians, whose names were *Fronto*, mentioned in the Pandects, were probably descended from him.

FROST, in *Physiology*, such a state of the atmosphere as occasions the congelation or freezing of water and other fluids. See COLD, CHEMISTRY *Index*, and METEOROLOGY *Index*.

Water and other fluids are capable of containing the element of fire or heat in two very different states. In the one, they seem to imbibe the fire in such a manner, that it eludes all the methods by which we are accustomed to observe it, either by our sensation of feeling, or the thermometer; in the other, it manifests itself obviously to our senses, either by the touch, the thermometer, or the emission of light.

In the first of these states, we call the body *cold;* and are apt to say that this coldness is occasioned by the *absence* of heat. But this manner of expressing ourselves, excepting in a relative degree, is certainly improper; for even those fluids which are coldest to the touch contain a vast deal of heat. Thus vapour, which is colder to the touch than the water from which it was raised, contains an immense quantity of fire, even more than sufficient to heat it red hot. The like may be said of common salt and snow, or ice. If a quantity of each of these substances is separately reduced to the degree of 28 or 30 of Fahrenheit's thermometer, upon mixing them together, the heat which would have raised the thermometer to the degree above mentioned, now enters into the substance of them in such a manner that the mercury falls down to 0.—Here an excessive degree of cold is produced, and yet we are sure that the substances contain the very same quantity of heat that they formerly did: nay, they will even seem exceedingly cold, when they must certainly contain a great deal more heat than they originally did; for they absorb it from all bodies around them; and if a small vessel full of water is put into the middle of such a mixture, it will in a short time be full of ice.

It appears, therefore, that our senses, even when assisted by thermometers, can only judge of the state in which the element of fire is with relation to the bodies

dies around us, without regard to the quantity contained in them. Thus, if heat flows from any part of our body into any substance actually in contact with it, the sensation of cold is excited, and we call that substance *cold;* but if it flows from any substance into our body, the sensation of heat is excited, and we call that substance *hot*, without regard to the absolute quantity contained in either case.

Of all known substances, the atmosphere either absorbs or throws out heat with the most remarkable facility: and in one or other of these states it always is with respect to the surface of the earth, and such bodies as are placed on or near it; for these, properly speaking, have no temperature of their own, but are entirely regulated by that of the atmosphere.—When the air has been for some time absorbing the heat from terrestrial bodies, a frost must be the undoubted consequence, for the same reason that water freezes in a vessel put into a freezing mixture; and were this absorption to continue for a length of time, the whole earth would be converted into a frozen mass. There are, however, certain powers in nature, by which this effect is always prevented; and the most violent frost we can imagine, must always as it were defeat its own purposes, and end in a thaw. To understand this subject, we must observe,

1. In that state of the atmosphere which we denominate frost, there is a most intimate union between the air and the water it contains; and therefore frosty weather, except in very high latitudes, is generally clear.

2. When such a union takes place, either in winter or summer, we observe the atmosphere also inclined to absorb heat, and consequently to frost. Thus in clear settled weather, even in summer, though the day may be excessively hot by reason of the continued sunshine, yet the mornings and evenings are remarkably cold, and sometimes even disagreeably so.

3. The air being therefore always ready in the time of frost or in clear weather, to absorb heat from every substance which comes into contact with it, it follows that it must also absorb part of that which belongs to the vapours contained in it.

4. Though vapour is capable of becoming much colder than water without being frozen, yet by a continued absorption it must at last part with its latent heat, i. e. that which essentially constitutes its vapour, and without which it is no longer vapour, but water or ice. No sooner, therefore, does the frost arrive at a certain pitch, than the vapours, everywhere dispersed through the air, give out their latent heat: the atmosphere then becomes clouded: the frost either totally goes off, or becomes milder by reason of the great quantity of heat discharged into the air; and the vapours descend in rain, hail, or snow, according to the particular disposition of the atmosphere at the time.

5. Even in the polar regions, where it may be thought that the frost must increase beyond measure, there are also natural means for preventing its running to extremes. The principal cause here is, the mixture of a great quantity of vapours from the more temperate regions of the globe with the air in those dreary climates. It is well known, that aqueous vapour always flies from a warm to a colder place. For this reason, the vapours raised by the sun in the more temperate regions of the earth, must continually travel northward and southward in great quantities. Thus they furnish materials for those immense quantities of snow and ice which are to be found in the neighbourhood of the poles, and which we cannot imagine the weak influence of the sun in these parts capable of raising. It is impossible that a quantity of vapour can be mixed with frosty air, without communicating a great deal of heat to it; and thus there are often thaws of considerable duration even in those climates where, from the little influence of the sun, we should suppose the frost would be perpetual.

Frost.

6. We may now account with some probability for the uncertain duration of frosts. In this country they are seldom of a long continuance; because the vapours raised from the sea with which our island is surrounded, perpetually mix with the air over the island, and prevent a long duration of the frost. For the same reason, frosts are never of such long duration in maritime places on the continent, as in the inland ones. There is nothing, however, more uncertain than the motion of the vapours with which the air is constantly filled; and therefore it is impossible to prognosticate the duration of a frost with any degree of certainty. In general, we may always be certain, that if a quantity of vapour is accumulated in any place, no intense frost can subsist in that place for any length of time; and by whatever causes the vapours are driven from place to place, by the same causes the frosts are regulated throughout the the whole world.

The effects of frost in different countries are enumerated under the article CONGELATION. In the northern parts of the world even solid bodies are liable to be affected by frost. Timber is often apparently frozen, and rendered exceedingly difficult to saw. Marl, chalk, and other less solid terrestrial concretions will be shattered by strong and durable frosts. Metals are contracted by frost: thus, an iron tube, 12 feet long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, frost swells or dilates water near one-tenth of its bulk. Mr Boyle made several experiments with metalline vessels, exceedingly thick and strong; which being filled with water, close stopped, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently destroyed by frost, as if burnt up by the most excessive heat; and in very strong frosts, walnut trees, ashes, and even oaks, are sometimes split and cleft, so as to be seen through, and this with a terrible noise, like the explosion of firearms.

Frost naturally proceeds from the upper parts of bodies downwards: but how deep it will reach in earth or water, is not easily known; because this depth may vary with the degree of coldness in the air, by a longer or shorter duration of the frost, the texture of the earth, the nature of the juices wherewith it is impregnated, the constitution of its more internal parts as to heat and cold, the nature of its effluvia, &c. Mr Boyle, in order to ascertain this depth, after four nights of hard frost, dug in an orchard, where the ground was level and bare, and found the frost had scarce reached three inches and a half, and in a garden nearer the house only two inches below the surface.

Nine

Frost. Nine or ten successive frosty nights froze the bare ground in the garden six inches and a half deep; and in the orchard, where a wall sheltered it from the south sun, to the depth of eight inches and a half. He also dug in an orchard, near a wall, about a week afterwards, and found the frost to have penetrated to the depth of 14 inches. In a garden at Moscow, the frost in a hard season only penetrates to two feet: and the utmost effect that Captain James mentions the cold to have had upon the ground of Charlton island, was to freeze it to 10 feet deep: whence may appear the different degrees of cold of that island and Russia. And as to the freezing of water at the above-mentioned island, the Captain tells us it does not naturally congeal above the depth of six feet, the rest being by accident. Water also, exposed to the cold air in large vessels, always freezes first at the upper surface, the ice gradually increasing and thickening downwards; for which reason, frogs retire in frosty weather to the bottom of ditches; and it is said, that shoals of fish retire in winter to those depths of the sea and rivers where they are not to be found in summer. Water, like the earth, seems not disposed to receive any very intense degree of cold at a considerable depth or distance from the air. The vast masses of ice found in the northern seas being only many flakes and fragments, which, sliding under each other, are, by the congelation of the intercepted water, cemented together.

In cold countries, the frost often proves fatal to mankind; not only producing gangrenes, but even death itself. Those who die of it have their hands and feet first seized, till they grow past feeling it; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which, if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, viz. by freezing the abdomen and viscera, which on dissection are found to be mortified and black.

The great power of frost on vegetables is a thing sufficiently known; but the differences between the frosts of a severe winter, and those which happen in the spring mornings, in their effects on plants and trees, were never perfectly explained, till by Mess. Du Hamel and Buffon in the Memoirs of the Paris Academy.

The frosts of severe winters are much more terrible than those of the spring, as they bring on a privation of all the products of the tenderer part of the vegetable world; but then they are not frequent, such winters happening perhaps but once in an age; and the frosts of the spring are in reality greater injuries to us than these, as they are every year repeated.

In regard to trees, the great difference is this, that the frosts of severe winters affect even their wood, their trunks and large branches; whereas those of the spring have only power to hurt the buds.

The winter frosts happening at a time when most of the trees in our woods and gardens have neither leaves, flowers, nor fruits upon them, and have their buds so hard as to be proof against slight injuries of weather, especially if the preceding summer has not been too wet; in this state, if there are no unlucky circumstances attending, the generality of trees bear moderate winters very well; but hard frosts, which happen late in the winter, cause very great injuries even to those trees which they do not utterly destroy. These are, 1. Long cracks following the direction of the fibres. 2. Parcels of dead wood enclosed round with wood yet in a living state. And, 3, That distemperature which the foresters call the *double blea*, which is a perfect circle of blea, or soft white wood, which when the tree is afterwards felled, is found covered by a circle of hard and solid wood.

The opinions of authors about the exposition of trees to the different quarters, have been very different, and most of them grounded on no rational foundation. Many are of opinion that the effects of frost are most violently felt on those trees which are exposed to the north; and others think the south or the west the most strongly affected by them. There is no doubt but the north exposure is subject to the greatest cold. It does not, however, follow from this, that the injury must be always greatest on the trees exposed to the north in frosts: on the contrary, there are abundant proofs that it is on the south side that trees are generally more injured by frost: and it is plain from repeated experiments, that there are particular accidents, under which a more moderate frost may do more injury to vegetables, than the most severe one which happens to them under more favourable circumstances.

It is plain from the accounts of the injuries trees received by the frosts in 1709, that the greatest of all were owing to repeated false thaws, succeeded by repeated new frosts. But the frosts of the spring season furnish abundantly more numerous examples of this truth; and some experiments made by the Count de Buffon at large in his own woods, prove incontestably, that it is not the severest cold or most fixed frost that does the greatest injury to vegetables.

This is an observation directly opposite to the common opinion; yet is not the less true, nor is it in any way discordant to reason. We find by a number of experiments, that humidity is the thing that makes frost fatal to vegetables; and therefore every thing that can occasion humidity in them, exposes them to these injuries, and every thing that can prevent or take off an over proportion of humidity in them, every thing that can dry them though with ever so increased a cold, must prevent or preserve them from those injuries. Numerous experiments and observations tend to prove this. It is well known that vegetables always feel the frost very severely in low places where there are fogs. The plants which stand by a river side are frequently found destroyed by the spring and autumnal frosts, while those of the same species which stand in a drier place, suffer little or perhaps none at all by them; and the low and wet parts of forests are well known to produce worse wood than the high and drier. The coppice wood in wet and low parts of common woods, though it push out more vigorously at first than that of other places, yet never comes to so good a growth; for the frost of the spring killing these early top shoots, obliges the lower part of the trees to throw out lateral branches: and the same thing happens in a greater or lesser degree to the coppice wood that grows under cover of larger trees in great forests; for here the vapours not being carried off either by the sun or wind, stagnate and freeze, and in the same manner destroy the young shoots, as the fogs of marshy places. It

It is a general observation also, that the frost is never hurtful to the late shoots of the vine, or to the flower-buds of trees, except when it follows heavy dews, or a long rainy season, and then it never fails to do great mischief, though it be ever so slight.

The frost is always observed to be more mischievous in its consequences on newly cultivated ground than in other places; and this is because the vapours which continually arise from the earth, find an easier passage from those places than from others. Trees also which have been newly cut, suffer more than others by the spring frosts, which is owing to their shooting out more vigorously.

Frosts also do more damage on light and sandy grounds, than on the tougher and firmer soils, supposing both equally dry; and this seems partly owing to their being more early in their productions, and partly to their lax texture suffering a greater quantity of vapours to transpire.

It also has been frequently observed, that the side-shoots of trees are more subject to perish by the spring frosts than those from the top; and M. Buffon, who examined into this with great accuracy, always found the effects of the spring frosts much greater near the ground than elsewhere. The shoots within a foot of the ground quickly perished by them; those which stood at two or three feet high, bore them much better; and those at four feet and upwards frequently remained wholly unhurt; while the lower ones were entirely destroyed.

There is a series of observations, which have proved beyond all doubt, that it is not the hard frosts which so much hurt plants, as those frosts, though less severe, which happen when they are full of moisture; and this clearly explains the account of all the great damages done by the severe frosts being on the south side of the trees which are affected by them, though that side has been plainly all the while less cold than the north. Great damage is also done to the western sides of trees and plantations, when after a rain with a west wind the wind shifts to the north at sunset, as is frequently the case in spring, or when an east wind blows upon a thick fog before sunrising.

Frost, it is well known, is particularly destructive to the blossom of fruit trees. The following method of securing such trees from being damaged by early frosts may be acceptable to many of our readers. A rope is to be interwoven among the branches of the tree, and one end of it brought down so as to be immersed in a bucket of water. The rope, it is said, will act as a conductor, and convey the effects of the frost from the tree to the water. This idea is not new, for the following passage may be found in Colerus. "If you dig a trench around the root of a tree, and fill it with water, or keep the roots moist till it has bloomed, it will not be injured by the frost. Or, in spring, suspend a vessel filled with water from the tree. If you wish to preserve the blossom from being hurt by the frost, place a vessel of water below it, and the frost will fall into it."

Hoar FROST, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, when it is congealed into icy crystals of various figures. Hoar frost, therefore, is nothing but dew turned into ice by the coldness of the air.

Melioration of Aromatic Spirits by FROST. Mr Beaume observes, that aromatic spirituous waters have less scent when newly distilled than after they have been kept about six months: and he found that the good effect of age was produced in a short time by means of cold; and that, by plunging quart bottles of the liquor into a mixture of pounded ice and sea salt, the spirit, after having suffered for six or eight hours the cold hence resulting, proves as grateful as that which hath been kept many years. Simple waters also, after having been frozen, prove far more agreeable than they were before. Geoffroy takes notice of this melioration by frost. *Hist. Acad.* 1713.

Melioration of Land by FROST. See AGRICULTURE *Index*.

FROTH, a white light substance, formed on the surface of fluids by vehement agitation, consisting of air included in the films of water.

FROTH *Spit*, or *Cuckoo Spit*, a name given to a white froth, or spume, very common in the spring and first months of summer, on the leaves of certain plants, particularly on those of the common white field lychnis, or catchfly, thence called by some *spatling poppy*.

All writers on vegetables have taken notice of this froth, though few have understood the cause or origin of it till of late. It is formed by a little leaping animal, called by some the *flea grashopper*, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which, containing some air in it, is soon elevated into a small bubble: before this is well formed, it deposits such another drop; and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see. Within this spume it is seen to acquire four tubercles on its back, wherein the wings are enclosed: these bursting, from a reptile it becomes a winged animal: and thus, rendered perfect, it flies to meet its mate, and propagate its kind. It has an oblong, obtuse body, and a large head with small eyes. The external wings (for it has four) are of a dusky brown colour, marked with two white spots: the head is black. It is a species of CICADA.

FROWDE, PHILIP, an English poet, was the son of a gentleman who had been postmaster in the reign of Queen Anne. He was sent to the university of Oxford, where he had the honour of being distinguished by Addison, who took him under his protection. While he remained there, he became the author of several pieces of poetry, some of which in Latin were pure and elegant enough to entitle them to a place in the *Musæ Anglicanæ*. He likewise wrote two tragedies: The Fall of Saguntum, dedicated to Sir Robert Walpole; and Philotas, addressed to the earl of Chesterfield. He died at his lodgings at Cecil Street in the Strand, in 1738; and in the London Daily Post had the following character given him: "Though the elegance of Mr Frowde's writings has recommended him to the general public esteem, the politeness of his genius is the least amiable part of his character; for he esteemed the talents of wit and learning only as they were conducive to the excitement and practice of honour and humanity. Therefore, with a soul cheerful, benevolent, and virtuous, he was in conversation genteelly delightful, in friendship punctually sincere, in death Christianly resigned. No man could live more beloved, no private man could die more lamented." A fine eloge! and we have no reason to doubt the truth of it.

FRUCTESCENTIA, (from *fructus*, "fruit,") comprehends the precise time in which, after the fall of the flowers, the fruits arrive at maturity, and disperse their seeds.

In general, plants which flower in spring, ripen their fruits in summer, as rye; those which flower in summer have their fruits ripe in autumn, as the vine; the fruit of autumnal flowers ripens in winter, or the following spring, if kept in a stove or otherwise defended from excessive frosts. These frosts, says M. Adanson, are frequently so pernicious and violent as to destroy the greatest part of the perennial plants of Virginia and Mississippi, that are cultivated in France, even before they have exhibited their fruit. The plants which flower during our winter, such as those of the Cape of Good Hope, ripen their fruit in spring in our stoves.

FRUCTIFEROUS, signifies properly any thing that produces fruit.

FRUCTIFICATION of Plants, is defined by Linnæus to be the temporary part of a vegetable appropriated to generation, terminating the old vegetable and beginning the new. It consists of the following seven parts; viz. the calyx, corolla, stamen, pistillum, pericarpium, semen or seed, and receptaculum. See Botany.

FRUIT, in its general sense, includes whatever the earth produces for the nourishment and support of animals; as herbs, grain, pulse, hay, corn, and flax, every thing expressed by the Latins under the name *fruges*.

Fruit, in *Natural History*, denotes the last production of a tree or plant, for the propagation or multiplication of its kind; in which sense fruit includes all kinds of seeds, with their furniture, &c.

Fruit, in *Botany*, is properly that part of a plant wherein the seed is contained; called by the Latins *fructus*; and by the Greeks καρπος. The fruit in the Linnæan system is one of the parts of fructification, and is distinguished into three parts, viz. the pericarpium, seed, and receptacle, or *receptaculum seminum*. See Botany.

Colours extracted from Fruits. See the article *Colour-Making*.

Bread-Fruit. See Artocarpus, Botany *Index*.

Fruits, with regard to commerce, are distinguished into *recent*, *fresh*, and *dry*.

Recent Fruits are those sold just as they are gathered from the tree, without any farther preparation; as are most of the productions of our gardens and orchards, sold by the fruiterers.

Dry Fruits are those dried in the sun, or by the fire, with other ingredients sometimes added to them to make them keep; imported chiefly from beyond sea, and sold by the grocers. Such are raisins, currants, figs, capers, olives, cloves, nutmegs, pepper, and other spices; which see under their respective articles.

Under the denomination of *dry fruits* are also frequently included apples, pears, almonds, filberds, &c.

Fruit-Flies, a name given by gardeners and others to a sort of small black flies found in vast numbers among fruit trees, in the spring season, and supposed to do great injury to them. Mr Leeuwenhoeck preserved some of these flies for his microscosical observations. He found that they did not live longer than a day or two, but that the females during this time laid a great number of longish eggs. The gardeners, who suppose that these flies wound the leaves of the trees, are mistaken: it is true that they feed on their juices; but they have no instruments wherewith they can extract these for themselves: they feed on such as are naturally extravasated; and when there is not a sufficient quantity of these for their purpose, they haunt the places to which the pucerons resort, and feed on the juices which these little creatures extravasate by means of the holes they bore in the leaves with their trunks.

Fruit-Stones. The mischiefs arising from the custom which many people have of swallowing the stones of plums and other fruit are very great. The Philosophical Transactions give an account of a woman who suffered violent pains in her bowels for 30 years, returning once in a month or less. At length a strong purge being given her, the occasion of all these complaints was driven down from the bowels to the anus; where it gave a sensation of distension and stoppage, producing a continual desire of going to stool, but without voiding any thing. On the assistance of a careful hand in this case, there was taken out with a forceps a ball of an oval figure, of about ten drachms in weight, and measuring five inches in circumference. This had caused all the violent fits of pain which she had suffered for so many years; and, after voiding it, she became perfectly well The ball extracted looked like a stone, and felt very hard, but it swam in water. On cutting it through with a knife, there was found in the centre of it a plum stone; round which several coats of this hard and tough matter had gathered. Another instance given in the same papers is of a man, who, dying of an incurable colic, which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found a ball similar to that above mentioned; but somewhat larger, being six inches in circumferance, and weighing an ounce and a half. In the centre of this, as of the other, there was found the stone of a common plum, and the coats were of the same nature with those of the former.

These and several other instances mentioned in the same place, sufficiently show the folly of that common opinion that the stones of fruits are wholesome. For though by nature the guts are so defended by their proper mucus, that people very seldom suffer by things of this kind; yet if we consider the various circumvolutions of the guts, their valves and cells, and at the same time consider the hair of the skins of animals we feed on, the wool or down on herbs and fruit, and the fibres, vessels, and nerves of plants, which are not altered by the stomach; it will appear a wonder that instances of this sort of mischief are not much more common. Cherry stones, swallowed in great quantities, have occasioned the death of many people; and there have been instances even of the seeds of strawberries collecting into a lump in the guts, and causing violent disorders, which could not be cured without great difficulty.

Fruit Trees. With regard to these it may be observed, 1. That the cutting and pruning them when young hurt their bearing, though it contributes to the

the richness and flavour of the fruit, as well as to the beauty of the tree. 2. That kernel fruit trees come later to bear than stone fruit tress: the time required by the first, before they come to any fit age for bearing, being one with another five years; but when they do begin, they bear in greater plenty than stone fruit. 3. That stone fruit, figs, and grapes, commonly bear considerably in three or four years, and bear full crops the fifth and sixth year; and hold it for many years, if well ordered. 4. That fruit trees in the same neighbourhood will ripen a fortnight sooner in some grounds than in others of a different temperature. 5. That in the same country, hot or cold summers set considerably forwards, or put backwards, the same fruit. 6. That the fruit on wall trees generally ripen before those on standards, and those on standards before those on dwarfs. 7. That the fruit of all wall trees planted in the south and east quarters commonly ripen about the same time, only those in the south rather earlier than those in the east; those in the west are later by eight or ten days; and those in the north by 15 or 20. For the planting, pruning, grafting, &c. of fruit trees, see GARDENING.

FRUITERY, a place for the keeping of fruit, a fruit house, or fruit loft.

A fruitery should be inacessible to any thing of moisture; and should be as much as possible so, even to frost.

FRUMENTACEOUS, a term applied by botanists to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

FRUMENTARII, a kind of soldiers or archers under the western empire.

The first time we read of these officers is in the reign of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed, that they were at first a number of young persons, disposed by Augustus throughout the provinces, particularly on all the great roads, to acquaint the emperor, with all expedition, of every thing that happened.

Afterwards they were incorporated into the troops themselves, where they still retained their ancient name. As their principal office was the giving intelligence, they were often joined with the curiosi, with whom they agreed in that part of their office.

Their name of *frumentarii* is derived from their being also a sort of purveyors to the armies, cities, &c. collecting all the corn from the several provinces to furnish the commonwealth.

FRUMENTATION, in Roman antiquity, a largess of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans, and frequently used to soothe the turbulent humour of the populace. At first the number of those to whom this largess was given was indeterminate, till Augustus fixed it at 200,000.

FRUSH, or RUNNING THRUSH. See FARRIERY *Index*.

FRUSTUM, in *Mathematics*, a part of some solid body separated from the rest.

The frustum of a cone is the part that remains, when the top is cut off by a plane paralled to the base; and is otherwise called a *truncated cone*. See CONIC *Sections*.

The frustum of a pyramid is also what remains after the top is cut off by a plane parallel to its base.

The frustum of a globe or sphere is any part thereof cut off by a plane, the solid contents of which may be found by this rule: To three times the square of the semidiameter of the base add the square of its height; then multiply that sum by the height, and this product multiplied by .5236 gives the solidity of the frustum.

FRUTEX, a SHRUB. Shrubs, according to Linnæus, make a branch of the seventh family in the vegetable kingdom; and are distinguished from trees, in that they come up without buds. But this distinction is not universal, though it be generally just with regard to those of Europe. Nature hath made no absolute distinction between trees and shrubs. *Frutex*, in its general acceptation, is a plant whose trunk is pereninal, gemmiparous, woody, dividing and subdividing into a great number of branches. In short, it is the epitome of a tree, exemplified in the rose bush.

FRY, in *Zoology*, signifies the spawn, or rather young, of fish.

FRYING-PAN, a dangerous shoal, which has received this appellation from its figure. It is situated at the entrance of Cape Fear river, in North Carolina, the southern part of which is in long. 75° W. and 33° 22′ N. Lat. 24 miles south-east by south of the light house on Bald Head.

FRYTH, JOHN, a martyr to the Protestant religion in the reign of Henry VIII. He was the son of an innkeeper at Seven Oaks in Kent; and educated in King's College, Cambridge, where he took the degree of bachelor of arts. Thence he removed to Oxford, and was made a junior canon of Wolsey's college. He had not been long in that university before he became acquainted with William Tyndale, a zealous Lutheran, with whom he conversed frequently on the abuses in religion. Fryth became a convert to Lutheranism, and publicly avowed his opinions. He was apprehended, examined by the commissary, and confined to his college. At length having obtained his liberty, in 1528 he went over to Germany, where he continued about two years; and then returned to England, more than ever determined in his religious sentiments. Finding at that time but few associates, he wandered about from place to place, till at last he was taken up at Reading as a vagrant, and set in the stocks, where he remained till he was near expiring for want of sustenance. He was at length relieved by the humanity of Leonard Cox, a schoolmaster; who finding him a man of letters, procured his enlargement, and administered to his necessities. Fryth now set out for London, where with more zeal than prudence, he began to make proselytes; but was soon apprehended by order of the chancellor Sir Thomas More, and sent prisoner to the Tower. Refusing to recant his opinions, he was condemned to the flames, and accordingly burnt in Smithfield, on the 4th of July 1533. He left several works behind him, which were printed in folio in 1573.

FUAGE, in old English writers, a tax of 12d. for every fire, levied in the time of Edward III

FUCINUS LACUS, in *Ancient Geography*, a lake of Italy

Fucinus. Italy in the country of the Marsi. Now *Lago di Celano*, from a cognominal citadel, lying on the south of the Abruzzo Ultra, in the kingdom of Naples, near the Apennines. This lake was under the protection of a god of the same denomination, whose temple stood on its banks. According to the testimony of ancient authors, it was subject to extraordinary risings and decreasings. The actual circumference is 47 miles: the breadth in the widest part is 10, in the narrowest 4; its depth 12 feet upon an average. But all these have varied prodigiously. Two miles up the plain, behind Avezzano, the fragments of boats, shells, and other marks of its ancient extent, have been casually discovered: and, on the contrary, there are people who remember when it did not flow nearer than within two miles of Avezzano. An immense tract of excellent lands is lost at every increase of its level. All round this noble piece of water rises a circle of grand mountains, some of them the highest in Italy, if we except the Alps, and many of them covered with snow; and at the foot of them are numerous villages, with rich and well cultivated farms. The environs of the lake, Mr Swinburne describes as all well enclosed, and the sides of the hills as covered with fine woods; its waters abound with fish of various kinds, and thither repair at stated seasons innumerable flights of wild fowl. As the swelling of the lake was attended with incredible damage, the Marsi had often petitioned the senate to drain it: Julius Cæsar would have attempted it, had he lived longer. His successors were averse to the project; till Claudius, who delighted in expensive difficult enterprises, undertook it. During the space of 11 years he employed 30,000 men in digging a passage through the mountain; and when every thing was ready for letting off the water, exhibited a superb naval spectacle on the lake. A great number of condemned criminals were obliged to act the parts of Rhodians and Sicilians in separate fleets, to engage in earnest, and to destroy one another for the entertainment of the court and the multitude of spectators that covered the hills: A line of well armed vessels and rafts loaded with soldiers surrounded the scene of action, in order to prevent any of the wretches from escaping; but it was with great difficulty and many threats that they could be brought to an engagement. When this savage diversion was ended, the operations for opening the passage commenced, and the emperor was very near being swept away and drowned by the sudden rushing of the waters towards it. However, either through the ignorance or negligence of the engineers, the work did not answer as was expected, and Claudius did not live long enough to have the faults amended: Nero abandoned the scheme through envy. Hadrian is said to have let off the water of the Fucinus; but none now escapes except through hidden channels formed by nature, which are probably subject to be obstructed, and thus occasion a superabundance of water in the lake, till some unknown cause removes the obstructions and again gives free passage.

Sir William Hamilton, who visited the Fucinus in 1785, says, "it is the most beautiful lake he ever saw, and would be complete if the neighbouring mountains were better wooded." It furnishes abundance of fish, though not of the best quality. There are a few large trout, but mostly tench, barbel, and dace. In the shallow water on the borders of the lake, he saw thousands of water snakes pursuing and preying upon a little kind of fish like our thornbacks, but much better armed; though their defensive weapons seemed to avail them but little against such ravenous foes. The opening made by Claudius he describes as still entire, though in many parts filled with earth and rubbish. He went into it with torches as far as he could. It is a covered underground canal three miles long, and part of it cut through a hard rock, and other parts supported by mason work, with wells to give light. Hadrian is said to have let off the waters of the lake: and our author is of opinion, that if the canal were cleared and repaired it would still answer that purpose, and thereby restore a great deal of rich land fit for cultivation.

Fucus. FUCUS, a name given by the ancients to certain dyes and paints. By this name they called a purple sea plant used by them to dye woollen and linen things of that colour. The dye was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. This is the account Theophrastus gives of it.

The women of those times also used something called *fucus*, to stain their cheeks red; and many have supposed, from the same word expressing both, that the same substance was used on both occasions. But this, on a strict inquiry, proves not to be the case. The Greeks called every thing *fucus* that would stain or paint the flesh. But this peculiar substance used by the women to paint their cheeks was distinguished from the others by the name of *rizion* among the more correct writers, and was indeed a root brought from Syria into Greece. The Latins, in imitation of the Greek name, called this root *radicula;* and Pliny very erroneously confounds the plant with the *radix lunaria*, or *struthion* of the Greeks.

The word *fucus* was in those times become such an universal name for paint, that the Greeks and Romans had a *fucus metallicus*, which was the ceruse used for painting the neck and arms white: after which they used the *purpurissum*, or red fucus of the *rizium*, to give the colour to the cheeks. In after-times they also used a peculiar *fucus* or paint for the purpose, prepared of the *creta argentaria*, or silver-chalk, and some of the rich purple dyes that were in use at that time: and this seems to have been very little different from our rose-pink; a colour commonly sold at the colour shops, and used on like occasions.

Fucus, in the Linnæan system of botany, is a genus of the order of algæ, belonging to the cryptogamia class of plants.

Fuego. FUEGO, or Fogo, one of the Cape de Verd islands, in the Atlantic ocean. It is much higher than any of the rest; and seems at sea to be one single mountain, though on the sides there are deep valleys. There is a volcano at the top which burns continually, and may be seen a great way off at sea. It vomits a great deal of fire and smoke, and throws out huge pieces of rock to a vast height; and sometimes torrents of melted matter run down the sides. The Portuguese, who first inhabited it, brought negro slaves with them, and a stock of cows, horses, and hogs; but the chief inhabitants now are blacks of the Romish religion. W. Long. 24. 20. Lat. 15. 0.

FUEL,

FUEL, whatever is proper to burn or make a fire; as wood, turf, peat, bituminous earths, coal, &c.

FUEN-HOA, a city of China, in the province of Petcheli, celebrated for its extent and the number of its inhabitants, as well as for the beauty of its streets and triumphal arches. It is situated near the great wall, amidst mountains; and has under its jurisdiction, besides two cities of the second, and eight of the third class, a great number of fortresses, which bar the entrance of China against the Tartars.

FUGALIA, in Roman antiquity, a feast supposed by some to be the same with the *refugium*, held on the 24th of February, in memory of the expulsion of the kings and the abolishing of monarchical government. Others again distinguish the fugalia from the regifuge. And others think that the fugalia was the same with the *poplifugia*, or the feast of Fugia, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery.

FUGITIVE, a person obliged to fly his country, or remove from a place where he had some abode or establishment, on account of his crimes, debts, or other occasions.

Fugitive Pieces, among the learned, denote those little compositions which are printed on loose sheets or half sheets; thus called, because easily lost and soon forgotten.

FUGUE, in *Music*, (from the Latin *fuga*, "a chase"), a piece of music sometimes longer and sometimes shorter, in which, agreeable to the rules of harmony and modulation, the composer treats a subject; or, in other words, what expresses the capital thought or sentiment of the piece, in causing it to pass successively and alternately from one part to another.

These are the principal rules of the fugue; of which some are peculiar to itself, and others common to it with what the French call *imitation*.

1. The subject proceeds from the tonic to the dominant, or from the dominant to the tonic, in rising or descending.

2. Every fugue finds its response in the part immediately following that which commenced.

3. That response ought to resume the subject in the interval of a fourth or fifth above or below the key, and to pursue it as exactly as the laws of harmony will admit; proceeding from the dominant to the tonic when the subject is introduced from the tonic to the dominant, and moving in a contrary direction when the subject is introduced from the dominant to the tonic. One part may likewise resume the same subject in the octave or unison of the preceding; but in that case, it is a repetition rather than a real response.

4. As the octave is divided into two unequal parts, of which the one contains four gradations descending from the tonic to the dominant, and the other only three in continuing the ascent from the dominant to the tonic; this renders it necessary to have some regard to this change in the expression of the subject, and to make some alterations in the response, that we may not quit the cords that are essential to the mode. It is a different case when the composer intends to alter the modulation; for there the exactness of the response itself, when taken in a different tone, produces the alteration proper for this change.

5. It is necessary that the fugue should be planned in such a manner, that the response may commence before the close of the first air, so that both the one and the other may be in part heard at the same time: that, by this anticipation, the subject may be as it were connected with itself, and that the art of the composer may discover itself in this concourse. It is absolute mockery, instead of a fugue, to impose upon the hearers the same air, merely transposed from one key to another, without any other restraint than an accompaniment afterwards formed at pleasure. This deserves at best no better name than what the French call *imitation*. See Imitation.

Besides these rules, which are fundamental, there are others which, though prescribed by taste alone, are not less essential. Fugues, in general, render music more noisy than agreeable; it is for this reason that they are more agreeable in the chorus than anywhere else. Now, as their chief merit consists in fixing the ear on the principal air or subject, which for this reason is made to pass incessantly from part to part, and from mode to mode, the composer ought to exert his care in preserving that air always distinct; or to prevent it from being absorbed in, or confounded with, the other parts. To produce this effect, there are two different ways; one in the movement, which must be incessantly contrasted with itself; so that, if the procedure of the fugue be accelerated, the other parts move gravely and with protracted notes; or, on the contrary, if the motion of the fugue be slow and solemn, the accompaniments must have more and quicker business. The other method is to extend the harmony, by removing the parts at a greater distance one from the other; lest the others, too nearly approximated to that which contains the subject, should be confounded with it, and prevent it from being distinguished with sufficient clearness; so that what would be an imperfection anywhere else, becomes here a beauty.

The unity of melody should be preserved: this is the great and general rule, which must frequently be practised by different means. The cords must be chosen, and the intervals, so that one particular sound may produce the same effect; this can only result from the unity of the melody. It will sometimes be necessary to employ voices and instruments of different kinds, that the parts which ought to prevail may be most easily distinguished; this again shows the necessity of preserving the unity of the melody. Another object of attention, no less necessary, is, in the different connections of modulation which are introduced by the procedure and progress of the fugues, to cause all these modulations to correspond at the same time in all the parts, to connect the whole in its progress by an exact conformity of modes: lest, if one part be in one mode, and another in another, the general harmony should be in none at all, and for that reason should no longer be able to produce simple effects upon the ear, nor simple ideas in the mind; which is another reason for preserving unity of melody. In a word, in every fugue the confusion of melodies and modulations is at once what a composer has most to fear, and will find the greatest difficulty in avoiding; and as this kind of music never produces a pleasure above mediocrity, one may say that a fine fugue is, though the masterpiece of an excellent harmonist, ungrateful to his toil.

There

There are still several other kinds of fugues; such as the perpetual fugue*, the double fugue, the inverted fugue.

The inverted fugue is a manner of composition, in which the flying part proceeds in a contrary direction to the other fugue, which had been formerly fixed in the same piece of music. Thus, when the first fugitive part is heard in ascending from the tonic to the dominant, or from the dominant to the tonic, the counter fugue ought to be heard in descending from the dominant to the tonic, or from the tonic to the dominant, and *vice versa*. Its other rules are exactly like those of the common fugue.

* See *Canon*.

FULCRUM, in *Mechanics*, the prop or support by which a lever is sustained.

FULDA, a considerable town of Germany, in the circle of the Upper Rhine, and in the Buchow, with a celebrated abbey; whose abbot was primate of the abbeys of the empire, perpetual chancellor of the emperor, and sovereign of this small territory, which is now chiefly included in the dominions of Hesse Cassel. It is seated on the river Fulda, 55 miles south of Cassel. E. Long. 9. 33. N. Lat. 50. 32.

FULGORA, a genus of insects belonging to the order of hemiptera. See ENTOMOLOGY *Index*.

FULHAM, a village of Middlesex, four miles from London, with 5903 inhabitants in 1811. The Danes in 869 wintered at this place till they retired to the continent. It was in the Conqueror's time held of the king by the canons of St Paul's; and there is an ancient house here, which is moated about, and belongs to the see of London, whose bishop has a palace here, and the demesne has belonged to that diocese from 1067. From this place to Putney there is a wooden bridge over the Thames, where not only horses, coaches, and all carriages, but even foot passengers, pay toll. The church here is both a rectory and a vicarage.

FULICA, the GALLINULE and COOT, a genus of birds belonging to the order of grallæ. See ORNITHOLOGY *Index*.

FULIGINOUS, whatever proceeds from a thick sooty smoke, such as lamp black.

FULIGNO, a city of Italy, in the pope's territories, 10 miles north of Spoletto.

FULIGO, in *Natural History*, a species of pumice-stone. See PUMICE.

FULLER, DR THOMAS, a learned English divine, was born at Alvinckle, near Oundle, in Northamptonshire, about the year 1608, and studied at Cambridge. He was chosen minister of St Bennet's there; and at about 23 years of age, his merit procured him a fellowship in Sidney-college, and a prebend in Salisbury cathedral. He was soon after presented to the rectory of Broad Windsor in Dorsetshire; and afterwards was made lecturer of the Savoy in London: but upon the pressing of the covenant, he retired to Oxford; and soon after accompanied Sir Ralph Hopton as his chaplain in the army, which he attended in their marches from place to place. After the death of King Charles I. he obtained the living of Waltham-abbey, and was appointed lecturer of St Clement's; and shortly after removed to the lecture of St Bridge's, Fleet-street. Upon the restoration, he recovered his prebend in the cathedral of Salisbury, was appointed chaplain extraordinary to his majesty, and created doctor of divinity. It is said, his memory was so tenacious and comprehensive, that he could make use of a sermon *verbatim* if he once heard it. He once undertook, in passing to and from Temple-bar to the Poultry, to tell at his return every sign as it stood in order on both sides of the way, repeating them either backwards or forwards; and this task he actually performed. He wrote, 1. A History of the Holy War. 2. The Church-History of Britain, in folio. 3. Andronicus, or the Unfortunate Politician, in 8vo. 4. A Pisga-sight of Palestine. 5. A History of English Worthies; and other works. He died in August 1661; and was interred in the chancel of Cranford church, in Middlesex, whither his body was attended by at least 200 of his brethren of the ministry.

FULLER, a workman employed in the woollen manufactories to mill or scour cloths, serges, and other stuffs, in order to render them more thick, compact, and durable. See FULLING.

FULLER's Earth, in *Natural History*, a species of clay, of a grayish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast. It is very hard and firm, of a compact texture, of a tough and somewhat dusty surface that adheres slightly to the tongue. It is very soft to the touch, not staining the hands, nor breaking easily between the fingers. It has a little harshness between the teeth, and melts freely in the mouth. Thrown into water, it makes no ebullition or hissing; but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with aquafortis.

The greatest quantity and the finest earth of this kind in the world, is dug in the pits at Wavedon, near Woburn in Bedfordshire. The strata in these pits lie thus: From the surface to the depth of six feet, there are several layers or beds of sand, all reddish, but some lighter coloured than others. Under these there is a thin stratum of a sand-stone, which they break through, and then there is the fuller's earth. The upper stratum of this is about a foot thick: the workmen call it *cledge*, and throw it aside as useless; being commonly fouled with the sand which originally covered it, and which insinuates itself a good way into it. After this, they come to the fine fuller's earth for sale, which lies to the depth of eight feet more. The matter of this is divided into several layers, there being commonly about a foot and a half between one horizontal fissure and another. Of these several layers, the upper half, where the earth breaks itself, is tinged red; which seems to be owing to the running of the water upon it from among the sands above; some of which are probably of a ferruginous nature, or have ferruginous matter among them. This reddish fuller's earth the workmen call *crop;* and between the cledge and this there is a thin stratum of matter, of less than an inch, which in taste, colour, and external appearance, resembles the terra Japonica of the shops. The lower half of the strata of fuller's earth they call *wall-earth*. This is untinged with the red colour of the other, and seems the most proper for fulling. Under the fuller's earth there is a stratum of white and coarse stone about two feet thick. They seldom dig through this; but if they do, they find more strata of sand.

This earth is of great use in scouring cloths, stuffs, &c. imbibing all the grease and oil used in preparing, dressing,

dressing, &c. of the wool; for which reason it is made a contraband commodity, and is not to be exported under the penalty of 1s. for every pound weight. See FULLING.

FULLER's Weed, or *Teazle.* See DIPSACUS, BOTANY *Index.*

FULLERY, a place where cloths, &c. are fulled. See the next article.

FULLING, the art or act of cleansing, scouring, and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer: called also *milling.* Pliny (lib. vii. cap. 56.) assures, that one Nicias, the son of Hermias, was the first inventor of the art of fulling: and it appears by an inscription, quoted by Sir G. Wheeler, in his Travels through Greece, that this same Nicias was a governor in Greece in the time of the Romans.

Fulling of woollen cloths, depends, like felting, so entirely upon the structure of wool and hair, that those who have read our account of that process, will not find it difficult to comprehend the following observations.

The asperities with which the surface of wool is everywhere surrounded, and the disposition which it has to assume a progressive motion towards the root, render the spinning of wool, and making it into cloth, difficult operations. In order to spin wool, and afterwards convert it into cloth, its fibres must be covered with a coating of oil, which, filling the cavities, renders the asperities less sensible; in the same way as oil renders the surface of a very fine file less rough, when rubbed over it. When the piece of cloth is finished, it must be cleansed from this oil; which would cause it to soil whatever it came in contact with, besides giving it a disagreeable smell, and prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil, it is carried to the fulling-mill, where it is beat with hammers in a trough full of water, in which some clay has been mixed; the clay combines with the oil, which it separates from the cloth, and both together are washed away by the fresh water which is brought to it by the machine; thus, after a certain time, the oil is entirely washed out of the cloth.

But the scouring of the cloth is not the only object in fulling it; the alternate pressure given by the mallets to the piece of cloth, occasions, especially when the scouring is pretty far advanced, an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progressive movement, introduce themselves among those of the threads nearest to them, then into those which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together. The cloth, after having, by the above means, become shortened in all its dimensions, partakes both of the nature of cloth and of that of felt; it may be cut without being subject to ravel, and, on that account, we are not obliged to hem the edges of the pieces of which cloths are made. Lastly, as the threads of the warp and those of the woof are no longer so distinct and separated from each other, the cloth, which has acquired a greater degree of thickness, forms a warmer clothing. Knit worsted also is, by fulling, rendered less apt to run, in case a stitch should happen to drop in it.

The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called a *fulling* or *scouring mill.* Fulling.

These mills, excepting in what relates to the millstones and hopper, are much the same with corn-mills: and there are even some which serve indifferently for either use: corn being ground, and cloths fulled, by the motion of the same wheel. Whence, in some places, particularly in France, the fullers are called *millers;* as grinding corn and milling stuffs at the same time.

The principal parts of the fulling-mill are, The wheel, with its trundle; which gives motion to the tree or spindle, whose teeth communicate it to the pestles or stampers, which are hereby raised and made to fall alternately, according as its teeth catch on or quit a kind of latch in the middle of each pestle. The pestles and troughs are of wood; each trough having at least two, sometimes three pestles, at the discretion of the master, or according to the force of the stream of water. In those troughs are laid the cloths, stuffs, &c. intended to be fulled: then, letting the current of water fall on the wheel, the pestles are successively let fall thereon, and by their weight and velocity stamp and press the stuffs very strongly, which by this means become thickened and condensed. In the course of the operation, they sometimes make use of urine, sometimes of fuller's earth, and sometimes of soap. To prepare the stuffs to receive the first impressions of the pestle, they are usually laid in urine; then in fuller's earth and water; and, lastly, in soap dissolved in hot water. Soap alone would do very well; but this is expensive: though fuller's earth, in the way of our dressing, is scarce inferior thereto; but then it must be well cleared of all stones and grittinesses, which are apt to make holes in the stuff. As to urine, it is certainly prejudicial, and ought to be entirely discarded; not so much on account of its ill smell, as of its sharpness and saltness, which qualities are apt to render the stuffs dry and harsh.

The true method of fulling with soap is delivered by Mons. Colinet, in an authentic memoir on that subject, supported by experiments made by order of the marquis de Louvois, then superintendant of the arts and manufactories of France; the substance of which we shall here subjoin.

Method of FULLING *Cloths and Woollen Stuffs with Soap.*—A coloured cloth, of about 45 ells, is to be laid in the usual manner in the trough of a fulling-mill; without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required; one-half of which is to be melted in two pails of river or spring water, made as hot as the hand can well bear it. This solution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough: and thus it is to be fulled for at least two hours; after which it is to be taken out and stretched. This done, the cloth is immediately returned into the same trough, without any new soap, and there fulled two hours more. Then taking it out, they wring it well, to express all the grease and filth. After the second fulling, the remainder of the soap is dissolved as in the former, and cast four different times on the cloth; remembering to take out the cloth every two hours, to stretch it, and undo the plaits and wrinkles it has acquired in the trough.

When

When they perceive it sufficiently fulled, and brought to the quality and thickness required, they scour it for good in hot water, keeping it in the trough till it be quite clean. As to white cloths; in regard these full more easy and in less time than coloured ones, a third part of the soap may be spared.

Fulling of Stockings, Caps, &c. should be performed somewhat differently; viz. either with the feet or the hands; or a kind of rack, or wooden machine, either armed with teeth of the same matter, or else horses or bullocks teeth. The ingredients made use of herein are, urine, green soap, white soap, and fuller's earth. But the urine also is reckoned prejudicial here. Woven stockings, &c. should be fulled with soap alone: for those that are knit, earth may be used with the soap. Indeed it is frequent to full these kinds of works with the mill, after the usual manner of cloth, &c. But that is too coarse and violent a manner, and apt to damage the work unless it be very strong.

FULMAR, in *Ornithology*. See PROCELLARIA, ORNITHOLOGY *Index*.

FULMAR, or *Foumart*. See MUSTELA, MAMMALIA *Index*.

FULMINATING, something that thunders or resembles thunder.

Fulminating Gold, Silver, Copper, Quicksilver, &c. See CHEMISTRY *Index*.

FULMINATION, in *Chemistry*, the same with detonation.

FULMINATION, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed that some bull sent from the pope shall be executed.

FUMARIA, FUMITORY, a genus of plants belonging to the diadelphia class, and in the natural method ranking under the 24th order, *Corydales*. See BOTANY *Index*.

FUMIGATION, in *Chemistry*, a kind of calcination, when metals or other hard bodies are corroded or softened by receiving certain fumes for that purpose.

FUMIGATION, in *Medicine*. By the subtile fumes that are inspired as well as inhaled into our bodies, much benefit or prejudice is produced, according to the nature of the matter, and the constitution into which it is received; as is evident from the palsies produced among workers in lead-mines, &c. and the benefits received in many cases when the air is impregnated with salutary materials. Catarrhs and catarrhous coughs are relieved by fumes received with the breath; and, by the same method, expectoration is assisted in humoural asthmas; and even ulcers in the lungs are said to have been healed by this method. The advantage of mercurial fumigations in the cure of venereal ulcers is known to every practitioner.

FUMITORY. See FUMARIA, BOTANY *Index*.

FUNAMBULUS, among the Romans, was what we call a *rope-dancer*, and the Greeks *schœnobates*. See *Rope-Dancer*.

There was a funambulus, it seems, who performed at the time when the Hecyra of Terence was acted; and the poet complains, that the spectacle prevented the people from attending to his comedy. *Ita populus studio stupidus in* funambulo, *animum occuparat*.

At Rome, the funambuli first appeared under the consulate of Sulpicius Pæticus and Licinius Stolo, who were the first introducers of the scenic representations. It is added, that they were first exhibited in the island of the Tyber, and that the censors Messala and Cassius afterwards promoted them to the theatre.

In the *Floralia*, or *ludi Florales*, held under Galba, there were funambulatory elephants, as we are informed by Suetonius. Nero also showed the like, in honour of his mother Agrippina. Vopiscus relates the same of the time of Carinus and Numerianus.

FUNCHAL, the capital of Madeira, situated round a bay, on a gentle ascent, and containing about 15,000 inhabitants. It is watered by several streams from the mountains; and is defended by a castle on a steep rock, which is surrounded by the sea at high water. The houses are built of brick or free-stone; but the streets are narrow, dark, and dirty. W. Long. 16. 49. N. Lat. 32. 38.

FUNCTION, the act of fulfilling the duties of any employment.

FUNCTION, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The *vital* functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The *natural* functions are such as it cannot subsist any considerable time without; as the digestion of the aliment, and its conversion into blood. Under *animal* functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion; without any or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles; and this action consists chiefly in the shortening the fleshy fibres, which is called *contraction*, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

All parts of the body have their own functions, or actions, peculiar to themselves. Life consists in the *exercise* of these functions, and health in the *free and ready* exercise of them.

FUNCTION, a term used in analytics for an algebraical expression any how compounded of a certain letter or quantity with other quantities or numbers; and the expression is said to be a function of that letter or quantity. Thus $a-4x$, or $ax+3x^2$, or $2x-a\sqrt{a^2-x^2}$, or x^c, or c^x, is each of them a function of the quantity x.

FUND, in general, signifies any sum of money appropriated for a particular purpose. Thus, that part of the national revenue which is set apart for the payment of the national debt, is called the *sinking fund*. But, when we speak of *the funds*, we generally mean the large sums which have been lent to government, and constitute the national debt; and for which the lenders, or their assignees, receive interest from revenues allotted for that purpose. The term *stock* is used in the same sense, and is also applied to the sums which form the capital of the bank of England, the East India and South Sea companies; the proprietors of which are entitled to a share of the profits of the respective companies.

The

Fund.

The practice of funding was introduced by the Venetians and Genoese in the 16th century, and has been adopted since by most of the nations in Europe. Princes had often borrowed money, in former times, to supply their exigencies, and sometimes mortgaged their territories in security: but these loans were generally extorted, and their payment was always precarious; for it depended on the good faith and success of the borrower, and never became a regular burden on posterity. The origin of funds is derived from the peculiar manners and circumstances of modern Europe. Since the invention of gunpowder, and the progress of commerce, the military occupation has become a distinct employment in the hands of mercenaries; the apparatus of war is attended with more expence; and the decision of national quarrels has often been determined by command of money rather than by national bravery. Ambitious princes have therefore borrowed money, in order to carry on their projects with more vigour. Weaker states have been compelled, in self-defence, to apply to the same resource; the wealth introduced by commerce has afforded the means; the regularity of administration, established in consequence of the progress of civility, has increased the confidence of individuals in the public security; the complicated system of modern policy has extended the scenes of war, and prolonged their duration; and the colonies established by mercantile nations have rendered them vulnerable in more points, and increased the expence of defending them.

When a greater sum has been required for the annual expence than could easily be supplied by annual taxes, the government have proposed terms to their own subjects, or foreigners, for obtaining an advance of money by mortgaging the revenue of future years for their indemnification. This mortgage may either be for a limited period, or perpetual. If the sum allotted annually for the benefit of those who advance the money, be considerably greater than the interests of the sums advanced, they may agree to accept of such allowance, for a limited time, as a full equivalent. Thus, they may either agree for the casual produce of the revenue assigned; or a fixed annuity for a greater or less number of years; or a life annuity to themselves or nominees; or an annuity for two or more lives; or an annuity, with the benefit of survivorship, called a *tontine*, in which scheme, the whole sum to which the original annuitants were entitled continues to be distributed among the survivors.

The establishment of the funds was introduced in Britain at the Revolution; and has since been gradually enlarged, and carried to an amazing extent. The various methods above mentioned have been used in their turns, but perpetual annuities have been granted for the greatest part; and, even when the money was originally advanced on other conditions, the lenders have been sometimes induced, by subsequent offers, to accept of perpetual annuities, instead of the former terms. The debt for which perpetual annuities are granted, is called the *redeemable debt*, and the other is called the *irredeemable debt*. Although the debts thus contracted by government are seldom paid for a long term of years; yet any creditor of the public may obtain money for what is due him when he pleases, by transferring his property in the funds to another; and regular methods are appointed for transacting these transfers in an easy manner. By means of this, the stocks become a kind of circulating capital; and have the same effect, in some respects, as the circulating money in the nation. When a stockholder transfers his share, he may sometimes be able to obtain a greater price than the original value, and at other times be obliged to accept of a less one. The value of the funds depends on the proportion between the interest they bear, and the benefit which may be obtained by applying the money to other purposes. It is influenced by the plenty or scarcity of money, and by the quantity of the public debt; and it is impaired by any event which threatens the safety, or weakens the credit, of the government.

The business of stock-jobbing is founded on the variation of the prices of stock. Persons possessed of real property may buy or sell stock, according to their notion that the value is likely to rise or fall, in expectation of making profit by the difference of price. And a practice has taken place among persons who often possess no property in the funds, to contract for the sale of stock, against a future day, at a price now agreed on. For instance: A agrees to sell B 1000l. of bank stock, to be transferred, in 20 days, for 1200l. A has, in fact, no such stock; but, if the price of bank stock, on the day appointed for the transfer, should be only 118 per cent. A may purchase as much as will enable him to fulfil his bargain for 1180l. and thus gains 20l. by the transaction; on the contrary, if the price of bank stock be 125 per cent. he will lose 50l. The business is generally settled without any actual purchase or transfer of stock, by A paying to B, or receiving from him, the difference between the current price of the stock on the day appointed and the price bargained for.

This practice, which is really nothing else than a wager concerning the price of stock, is contrary to law; yet it is carried on to a great extent. In the language of Exchange Alley, where matters of this kind are transacted, the buyer is called a *bull*, and the seller a *bear*. As neither party can be compelled by law to implement these bargains, their sense of honour, and the disgrace and loss of future credit, which attend a breach of contract, are the principles by which the business is supported. When a person declines to pay his loss, he is called a *lame duck*, and dare never afterwards appear in the Alley. This opprobrious appellation, however, is not bestowed on those whose failure is owing to want of ability, providing they make the same surrender of their property voluntarily, which the law would have exacted if the debt had been entitled to its sanction.

The interest or dividend on the stock is paid half-yearly; and the purchaser has the benefit of the interest due on the stock he buys, from the last term to the time of purchase. Therefore the prices of the stocks rise gradually, *cæteris paribus*, from term to term, and fall at the term when the interest is paid. In comparing the prices of the different stocks, it is necessary to advert to the term when the last interest was paid: and, allowance being made for this circumstance, the prices of all the government stocks, which bear interest at the same rate, must be nearly the same, as they all depend on the same security.

When a loan is proposed, such terms must be offered to the lenders, as may render the transaction beneficial: and this is now regulated by the prices of the old stocks. If the stocks, which bear interest at 4 per cent. sell at par, or rather above, the government may expect to borrow money at that rate; but, if these stocks are under par, the government must either grant a higher interest, or some other advantage to the lenders, in compensation for the difference. For this purpose, besides the perpetual annuity, another annuity has sometimes been granted for life, or for a term of years. Lotteries have frequently been employed to facilitate the loan, by entitling the subscribers to a certain number of tickets, for which no higher price is charged than the exact value distributed in prizes, though their market price is generally 2l. or 3l. higher. Sometimes an abatement of a certain proportion of the capital has been granted, and a lender entitled to hold 100l. stock, though in reality he advanced no more perhaps than 95l.

It belongs to the chancellor of the exchequer to propose the terms of the loan in parliament: and he generally makes a previous agreement with some wealthy merchants, who are willing to advance the money on the terms proposed. The subscribers to the loan deposit a certain part of the sum subscribed; and are bound to pay the rest by instalments, or stated proportions, on appointed days, under pain of forfeiting what they have deposited. For this they are entitled, perhaps, not only to hold their share in the capital, but to an annuity for 10 years, and to the right of receiving a certain number of lottery tickets on advantageous terms. They may sell their capital to one person, their annuity to a second, and their right to the tickets to a third. The value of all these interests together is called *omnium;* and, in order to obtain a ready subscription, it ought to amount to 102l. or upwards, on 100l. of capital. This difference is called the bonus to the subscribers.

The capital advanced to the public, in the form of transferable stocks, and bearing interest from taxes appropriated for that purpose, is called the *funded debt.* Besides, there is generally a considerable sum due by government, which is not disposed of in that manner, and therefore is distinguished by the appellation of the *unfunded debt.* This may rise from any sort of national expence, for which no provision has been made, or for which provision has proved insufficient. The chief branches are,

1st, *Exchequer Bills.* These are issued from the exchequer, generally by appointment of parliament, and sometimes without such appointment, when exigencies require. They bear interest from the time when issued, and are taken in by the Bank of England, which promotes their circulation.

2d, *Navy Bills.* The sums annually granted for the navy have always fallen short of what that service required. To supply that deficiency, the admiralty issues bills in payment of victuals, stores, and the like, which bear interest six months after the time issued. The debt of the navy thus contracted is discharged, from time to time by parliament.

In time of war, the public expences, since the Revolution, have always been much greater than the annual revenue; and large sums have consequently been borrowed. In time of peace, the revenue exceeds the expence, and part of the public debt has frequently been paid off. But, though there have been more years of peace than of war since the funds were established, the debts contracted during each war have much exceeded the payments during the subsequent peace. This will appear by the following abstract of the progress of the national debt.

Debt at peace of Ryswick, 1697	L. 21,515,472
Debt at the beginning of war 1701	16,394,701
Discharged during peace 1697 to 1701	5,121,071
Debt at peace of Utrecht 1714, including value of annuities afterwards subscribed to South Sea stock -	55,282,978
Contracted in war 1701 to 1714	38,888,277
Debt at beginning of war 1740, including 1,000,000l. charged on civil list	47,954,623
Discharged during peace 1714 to 1739	7,328,355
Debt at peace of Aix-la-Chapelle, 1748	79,193,313
Contracted during war 1740 to 1748	31,238,690
Debt at beginning of war 1756	73,289,673
Paid off during peace 1748 to 1756	5,903,640
Debt funded at the peace 1763, including 9,839,597l. then owing, which was funded in the subsequent years	133,957,270
Besides this, there was about 6,000,000l. of debt paid off, without ever being funded.	
Funded debt, 1775 - - -	125,000,000
Paid off during peace 1763 to 1775, besides unfunded debt above mentioned	8,959,270
Funded at the peace 1783 -	211,363,254

The following is a state of the national debt at a later period.

Amount of funded debt on 5th January 1805 - - -	L. 603,925,792
Stock created by loan of 1805 -	38,700,000
	L. 642,625,792
Transferred for the redemption of the land tax - - -	22,000,000
	L. 620,925,792
Redeemed by the commissioners for managing the sinking fund -	113,500,000
Leaving as the amount of the national debt on the 31st January 1806	L. 507,125,792

The total amount of the public funded debt of the united kingdom, on the 5th January 1819, according to the finance book, was 900,212,132l. and the annual interest at the same period was 30,947,150l. Of this debt 8,398,155l. consists of loans to Germany and Portugal. The above, however, is the *nominal* amount of the public debt; but its real amount, or the sum necessary to extinguish it, supposing the average interest received to be 5 per cent. would be about 619,000,000l.

The original provision of the sinking fund, of a million per annum, with the additions that have since been made to it; and the dividends on stock, bought up by the commissioners for managing that fund, amount at this time (1820) to fifteen millions per annum. It was calculated that the future rate of accumulation of the sinking fund, continuing the same as hitherto, namely,

namely, at 5 per cent. the whole amount of the national debt would be extinguished in 45 years. But the abolition of the income tax in 1816, and the great distress felt by the agricultural, commercial, and manufacturing classes, has put an end to these expectations. Since the close of the war, the real sinking fund, or the excess of the revenue over the expenditure, has not exceeded two millions per annum. The fruitless attempt to enlarge this fund, by imposing 3,000,000l. of new taxes in 1819, has only shewn, that taxation in the present state of the country has nearly reached its limit. See the nature and operation of the system fully explained in the article FUNDING SYSTEM, in the SUPPLEMENT.

FUNDAMENT, in *Anatomy*, the lowest part of the intestinum rectum, called by anatomists the *anus*. See ANATOMY.

FUNDAMENTAL, in general, something that serves as a base or foundation for another.

FUNDAMENTAL, in *Music*. A *fundamental sound* is that which forms the lowest note of the CHORD, and from whence are deduced the harmonical relations of the rest; or, which serves for a key to the tone †. The *fundamental bass* is that which serves for a foundation to the harmony. A *fundamental chord* is that whose base is fundamental, and in which the sounds are ranged in the same order as when they are generated, according to the experiment so often repeated by M. d'Alembert in his Preliminary Discourse and Elements of Music ‡. But as this order removes the parts to an extreme distance one from the other, they must be approximated by combinations or inversions; but if the bass remains the same, the chord does not for this reason cease to bear the name of *fundamental*. Such an example is this chord, *ut mi sol*, included in the interval of a fifth: whereas, in the order of its generation, *ut sol mi*, it includes a tenth, and even a seventeenth; since the fundamental *ut* is not the fifth of *sol*, but the octave of that fifth.

Fundamental Bass. This part in music is, according to Rousseau, and indeed according to all authors who have proceeded upon M. Rameau's experiment, in its primary idea, that bass which is formed by the fundamental notes of every perfect chord that constitutes the harmony of the piece; so that under each chord it causes to be heard, or understood, the fundamental sound of that particular chord; that is to say, the sound from whence it is derived by the rules of harmony. From whence we may see, that the fundamental bass can have no other contexture than that of a regular and fundamental succession, without which the procedure of the upper parts would be illegitimate.

To understand this well, it is necessary to be known, that, according to the system of Rameau, which Rousseau has followed in his Dictionary, every chord, though composed of several sounds, can only have one which is its fundamental, viz. that which produces this chord, and which is its bass according to the direct and natural order. Now, the bass which prevails under all the other parts, does not always express the fundamental sounds of the chords; for amongst all the sounds which form a chord, the composer is at liberty to transfer to the bass that which he thinks preferable; regard being had to the procedure of that bass, to the beauty of the melody, and above all to the expression, as may afterwards be explained. In this case the real fundamental sound, instead of retaining its natural station, which is in the bass, will either be transferred to some of the other parts, or perhaps even entirely suppressed, and such a chord is called an *inverted* chord. Fundamental

In reality, says Rameau, a chord inverted does not differ from the chord in its direct and natural order from which it was produced: but as these sounds form different combinations, these combinations have long been taken for fundamental chords; different names have been given them, (which may be seen at the word ACCORD, in Rousseau's Dictionary). These names, by the persons who bestowed them, were thought to create and sanctify their distinctions; as if a difference in names could really produce a difference in the species.

M. Rameau in his Treatise of Harmony has shown, and M. d'Alembert in his Elements of Music has still more clearly evinced, that many of these pretendedly different chords were no more than inversions of one single chord. Thus the chord of the sixth is no more than the perfect chord of the third transferred to the bass; by adding a fifth, we shall have the chord of the sixth and fourth. Here there are three combinations of a chord, which only consists of three sounds; those which contain four sounds are susceptible of four combinations, since each of these sounds may be transferred to the bass. But in adding beneath this another bass which, under all the combinations of one and the same chord, always presents the fundamental sound; it is evident, that consonant chords are reduced to the number three, and the number of dissonant chords to four. Add to this all the chords by supposition, which may likewise be reduced to the same fundamentals, and you will find harmony brought to a degree of simplicity in which no person could ever hope to see it whilst its rules remained in that state of confusion where M. Rameau found them. It is certainly, as that author observes, an astonishing occurrence, that the practice of this art could be carried so far as it really was, without knowing its foundation; and that all the rules were so exactly found, without having discovered the principle on which they depended.

After having shown what is the fundamental bass beneath the chords, let us now speak of its procedure, and of the manner in which it connects these chords among themselves. Upon this point the precept of the art may be reduced to the six following rules.

1. The fundamental bass ought never to sound any other notes than those of the series or tone in which the composer finds himself, or at least those of the series or tone to which he chooses to make a transition. This of all the rules for the fundamental bass is the first and most indispensable.

2. By the second, its procedure ought to be so implicitly subjected to the laws of modulation, as never to suffer the idea of a former mode to be lost till that of a subsequent one can be legitimately assumed; that is to say, that the fundamental bass ought never to be devious, or suffer us to be one moment at a loss in what mode we are.

3. By the third, it is subjected to the connexion of chords and the preparation of dissonances: a manœuvre, which, as we shall afterwards see, is nothing else but a method of producing this connexion, and which of consequence is only necessary when the connexion cannot subsist without it. See CONNEXION, PREPARATION.

4. By the fourth, it is necessitated, after every dissonance,

Fundamental. sonance, to pursue that career which the resolution of the dissonance indispensably prescribes. See RESOLUTION.

5. By the fifth, which is nothing else but a consequence of the former, the fundamental bass ought only to move by consonant intervals; except alone in the operation of a broken cadence, or after a chord of the seventh diminished, where it rises diatonically. Every other motion of the fundamental bass is illegitimate.

6. By the sixth, in short, the fundamental bass or harmony ought not to be syncopated; but to distinguish the bars and the times which they contain, by changes of chords properly marked with cadences; in such a manner, for instance, that the dissonances which ought to be prepared may find their preparation in the imperfect time, but chiefly that all the reposes may happen in the perfect time. This sixth rule admits of an infinite number of exceptions; but the composer ought however to be attentive to it, if he would form a music in which the movements are properly marked, and in which the bars may end gracefully.

Wherever these rules are observed, the harmony shall be regular and without fault: this, however, will not hinder the music from being detestable. See COMPOSITION.

A word of illustration on the fifth rule may not be useless. Whatever turn may be given to a fundamental bass, if it is properly formed, one of these alternatives must always be found; either perfect chords moving by consonant intervals, without which these chords would have no connexion; or dissonant chords in operations of cadence: in every other case, the dissonance can neither be properly placed nor properly resolved.

From thence it follows, that the fundamental bass cannot move regularly but in one of these three manners: 1st, To rise or descend by a third or by a sixth. 2dly, By a fourth or a fifth. 3dly, To rise diatonically by means of the dissonance which forms the connexion, or by a license upon a perfect chord. With respect to a diatonic descent, it is a motion absolutely prohibited to the fundamental bass; or, at most, merely tolerated in cases where two perfect chords are in succession, divided by a close expressed or understood. This rule has no other exception: and it is from not discerning the foundation of certain transitions, that M. Rameau has caused the fundamental bass to descend diatonically under chords of the seventh; an operation which is impracticable in legitimate harmony. See CADENCE, DISSONANCE.

The fundamental bass, which they add for no other reason than to serve as a proof of the harmony, must be retrenched in execution, and often in practice it would have a very bad effect; for it is, as M. Rameau very properly observes, intended for the judgment, and not for the ear. It would at least produce a monotony extremely nauseous by frequent returns of the same chord, which they disguise and vary more agreeably by combining it in different manners upon the continued bass, without reckoning upon the different inversions of harmony, which furnish a thousand means of adding new beauties to the music and new energy to the expression. See CHORD, INVERSION.

But it will be objected, If the fundamental bass is not useful in composing good music, if it must even be retrenched in practice, what good purpose, then, can it serve? We answer, that, in the first place, It serves for a rule to scholars, upon which they may learn to form a regular harmony, and to give to all the parts such a diatonic and elementary procedure as is prescribed them by that fundamental bass. It does more, as we have already said: it proves whether a harmony already formed be just and regular; for all harmony which cannot be subjected to the test of a fundamental bass, must according to all rules be bad. Finally, It serves for the investigation of a continued bass under a given air: though, in reality, he who cannot directly form a continued bass will scarcely be able to form a fundamental bass, which is better; and much less still will he be able to transform that fundamental bass into a legitimate continued bass. These which follow are, however, the principal rules which M. Rameau prescribes for finding the fundamental bass of a given air.

1. To ascertain with precision the mode in which the composer begins, and those through which he passes. There are also rules for investigating the modes; but so long, so vague, so incomplete, that with respect to this, the ear may be formed long before the rules are acquired; and the dunce who should try to use them would gain no improvement but the habit of proceeding always note by note, without even knowing where he is.

2. To try in succession under each note the principal chords of the mode, beginning by those which are most analogous, and passing even to the most remote, when the composer sees himself under a necessity of doing so.

3. To consider whether the chord chosen can suit the upper part in what precedes and in what follows, by a just fundamental succession; and when this is impracticable, to return the way he came.

4. Not to change the note of the fundamental bass till after having exhausted all the notes which are allowed in succession in the upper part, and which can enter into its chord; or till some syncopated note in the air may be susceptible of two or a greater number of notes in the bass, to prepare the dissonance which may be afterwards resolved according to rule.

5. To study the intertexture of the phrases; the possible succession of cadences, whether full or avoided; and above all, the pauses which for ordinary return at the end of every four, or of every two bars, so that they may always fall upon perfect and regular cadences.

6. In short, to observe all the rules formerly given for the composition of the fundamental bass.—These are the principal observations to be made for finding one under any given air; for there are sometimes several different ones which may be investigated. But, whatever may be said to the contrary, if the air has accent and character, there is only one just fundamental bass which can be adapted to it.

After having given a summary explication of the manner in which a fundamental bass should be composed, it should remain to suggest the means of transforming it into a continued bass; and this would be easy, if it were only necessary to regard the diatonic procedure and the agreeable air of this bass. But let us not imagine that the bass, which is the guide and support of the harmony, the soul, and as it were the interpreter of the air, should be limited to rules so simple: there are others which depend upon principles more certain and more radical; fruitful, but latent principles, which have been felt by every artist of genius, without having been detected by any one. Rousseau hopes, that in his letter upon French music he insinuated this principle. For those who understand him, he imagines he has said enough concerning it, and can never say enough of it for those who do not. See *Rousseau's Miscellanies*, vol. ii. p. 1.

He does not here mention the ingenious system by M. Serre of Geneva, nor his double fundamental bass; because the principles which, with a sagacity meritorious of praise, he had half detected, have afterwards been unfolded by M. Tartini, in a work of which Rousseau has given an account in his article SYSTEM.

FUNDI, in *Ancient Geography*, a town of Latium, on the Via Appia, near Cajeta; enjoying all the privileges of Roman citizens, except the right of suffrage and of magistracy. Now *Fondi;* a city of Naples, on the confines of the pope's dominions. E. Long. 14. 20. N. Lat. 41. 35.

FUNDY, a bay of considerable extent in North America, opening between the islands of Penobscot bay, in the county of Lincoln, and Cape Sable, the south-west point of Nova Scotia. It reaches about 200 miles in a north-east direction, and forms a very narrow isthmus with Verte bay, which reaches into the land in a south-west direction from the straits of Northumberland. It is 12 leagues from St John's in New Brunswick, to the Gut of Annapolis in Nova Scotia, where the tides are remarkably rapid, and rise to the height of 30 feet. The tides in this bay are so rapid, that it is said, they will overtake animals feeding on the shore.

FUNEN, or FIONIA, a considerable island in Denmark, seated in the Baltic sea, and separated from Jutland by a strait called the *Lesser Belt*, and from the island of Zealand by another called the *Great Belt*. It is fertile in wheat and barley; and abounds in cattle, horses, game of all sorts, and fish. Odensee is the capital town.

FUNERAL RITES, ceremonies accompanying the interment or burial of any person. The word is formed of the Latin *funus;* and that of *funalia*, on account of the torches (which were *funes cera circumdati*) used in the funerals of the Romans; though others derive *funus* from the Greek, φονος, *death* or *slaughter*.

These rites differed among the ancients according to the different genius and religion of each country.

The first people who seem to have paid any particular respect to their dead, were the Egyptians, the posterity of Ham, the first cultivators of idolatrous worship and superstition after the flood: they were also the first who asserted the immortality of the soul, its migration into all kinds of animals in earth, air, and sea, and its return to the human body; which they supposed to be within the term of 3000 years: Hence proceeded their very great care in embalming of their dead bodies, and their being at such vast expences, as they were, in building proper repositories for them; for they were more solicitous about their graves than their houses: This gave birth to those wonders of the world, the pyramids, which were built for the burial of their kings, with such vast charges, and almost incredible magnificence. See PYRAMID.

Whenever a person died among the *Egyptians*, his parents and friends put on mournful habits, and abstained from all banquets and entertainments. This mourning lasted from 40 to 70 days, during which time they embalmed the body. See EMBALMING.

When this ceremony was finished, the embalmed body was restored to the friends, who placed it in a kind of open chest, which was preserved either in their houses, or in the sepulchres of their ancestors. But before the dead were allowed to be deposited in the tomb, they underwent a solemn judgment, which extended even to their kings. Of this remarkable custom we have a particular account in the first book of Diodorus Siculus. "Those who prepare to bury a relation, give notice of the day intended for the ceremony to the judges, and to all the friends of the deceased; informing them, that the body will pass over the lake of that district to which the dead belonged: when, on the judges assembling, to the number of more than 40, and ranging themselves in a semicircle on the farther side of the lake, the vessel is set afloat, which those who superintend the funeral have prepared for this purpose. This vessel is managed by a pilot, called in the Egyptian language Charon; and hence they say, that Orpheus, travelling in old times into Egypt, and seeing this ceremony, formed his fable of the infernal regions, partly from what he saw, and partly from invention. The vessel being launched on the lake, before the coffin which contains the body is put on board, the law permits all, who are so inclined, to produce an accusation against it. If any one steps forth, and proves that the deceased has led an evil life, the judges pronounce sentence, and the body is precluded from burial; but if the accuser is convicted of injustice in his charge, he falls himself under a considerable penalty. When no accuser appears, or when the accusation is proved to be an unfair one, the relations, who are assembled, change their expressions of sorrow into encomiums on the dead, yet do not, like the Greeks, speak in honour of his family, because they consider all Egyptians as equally well born: but they set forth the education and manners of his youth, his piety and justice in maturer life, his moderation, and every virtue by which he was distinguished; and they supplicate the infernal deities to receive him as an associate among the blest. The multitude join their acclamations of applause in this celebration of the dead, whom they consider as going to pass an eternity among the just below." Such is the description which Diodorus gives of this funeral judicature, to which even the kings of Egypt were subject. The same author asserts, that many sovereigns had been thus judicially deprived of the honours of burial by the indignation of their people: and that the terrors of such a fate had the most salutary influence on the virtue of their kings.

The funeral rites among the *Hebrews* were solemn and magnificent. When any person was dead, his relations and friends rent their clothes; which custom is but faintly imitated by the modern Jews, who only cut off a bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string; be-

cause

Funeral. cause the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a speech to the dead in the following terms: "Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life," &c. Then they spoke the elogium, or funeral oration, of the deceased; after which they said a prayer, called the *righteousness of judgment;* then turning the face of the deceased towards heaven, they called out, "Go in peace."

Among the ancient *Greeks* it was usual sometimes before the interment, to put a piece of money into the mouth of the deceased, which was thought to be Charon's fare for wafting the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake, composed of flour, honey, &c. which was designed to appease the fury of Cerberus the door-keeper of hell, and to procure the ghost a safe and quiet entrance. During the time the corpse continued in the house, there stood before the door a vessel of water: the design of which was, that those concerned about the body might purify themselves by washing; it being the opinion of the Greeks, as well as of the Jews, that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground and rolled in the dust, or covered their heads with ashes; they beat their breasts, and even tore their flesh with their nails, upon the loss of a person they much lamented. When persons of rank, such as public magistrates or great generals, died, the whole city put on a face of mourning: all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse, were shut up.

After interment followed the *epulæ* or feasts, at which the company used to appear crowned; when they spoke in praise of the dead, so far as they could go with truth, it being esteemed a notorious wickedness to lie upon such an occasion. And not only at those feasts, but even before the company departed from the sepulchre, they were sometimes entertained with a panegyric upon the dead person.

The Grecian soldiers, who died in war, had not only their tombs adorned with inscriptions showing their names, parentage, and exploits, but were also honoured with an oration in their praise. Particularly the custom among the Athenians in the interment of their soldiers was as follows, namely, "They used to place the bodies of their dead in tents three days before the funeral, that all persons might have opportunity to find out their relations, and pay their last respects to them. Upon the fourth day, a coffin of cypress was sent from every tribe, to convey the bones of their own relations; after which went a covered herse, in memory of those whose bodies could not be found. All these, accompanied by the whole body of the people, were carried to the public burying place, called *Ceramicus*, and there interred. One oration was spoken in commendation of them all, and their monuments were adorned with pillars, inscriptions, and all other ornaments usual about the tombs of the most honourable persons. The oration was pronounced by the fathers of the deceased persons who had behaved themselves most valiantly. Thus after the famous battle at Marathon, the fathers of Callimachus and Cynægyrus were appointed to make the funeral oration. And upon the return of the day upon which the solemnity was first held, the same oration was constantly repeated every year."

Interring or laying the dead in the ground seems to have been the most ancient practice among the Greeks; though burning came afterwards to be generally used among them. It was customary to throw into the funeral pile those garments the deceased usually wore. The pile was lighted by one of the deceased's nearest relations or friends, who made prayers and vows to the wind to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead person's friends stood by it, pouring libations of wine, and calling upon the deceased.

The funeral rites among the *ancient Romans* were very numerous. The deceased was kept seven days; and every day washed with hot water, and sometimes with oil, that, in case he was only in a slumber, he might be thus waked; and every now and then his friends meeting, made a horrible outcry or shout, with the same view; which last action they called *conclamatio*. The third conclamation was on the seventh day; when, if no signs of life appeared, the defunct was dressed and embalmed by the pollinctores; placed in a bed near the door, with his face and heels towards the street; and the outside of the gate, if the deceased were of condition, was garnished with cypress boughs. In the course of these seven days, an altar was raised near his bed side, called *acerra;* on which his friends every day offered incense: and the libitinarii provided things for the funeral.

On the seventh day a crier was sent about the city, to invite the people to the solemnization of the funeral in these words: *Exequias L. Tit. filii, quibus est commodum ire, jam tempus est. Olus* (i. e. *ille*) *ex ædibus effertur*. The people being assembled, the last conclamation ended, and the bed was covered with purple: a trumpeter marched forth, followed by old women called *præficæ*, singing songs in praise of the deceased: lastly, the bed followed, borne by the next relations; and if the person were of quality and office, the waxen images of all his predecessors were carried before him on poles. The bed was followed by his children, kindred, &c. *atrati*, or in mourning: from which act of following the corpse, these funeral rites were called *exequiæ*. The body thus brought to the rostra, the next of kin *laudabat defunctum pro rostris*, made a funeral oration in his praise and that of his ancestors. This done, the body was carried to the *pyra*, or funeral pile, and there burnt: his friends first cutting off a finger, to be buried

Funeral. ried with a second solemnity. The body consumed, the ashes were gathered; and the priest sprinkling the company thrice with clean water, the eldest of the *præficæ* crying aloud, *Ilicet*, dismissed the people, who took their leave of the deceased in this form, *Vale, vale, vale: nos te ordine quo natura permiserit sequemur.*—The ashes, enclosed in an urn, were laid in the sepulchre or tomb.

The *ancient Christians* testified their abhorrence of the Pagan custom of burning their dead; and always deposited the body entire in the ground: and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial by washing it with water, and dressing it in a funeral attire. The exportation or carrying forth of the body was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of psalms, was the great ceremony used in all funeral processions among the ancient Christians.

In the *Romish church*, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the *miserere*, and some other psalms; and at the end of each psalm a *requiem*. We learn from Alet's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy towards the people. The corpse is placed in the church surrounded with lighted tapers; after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the *Greek church* are much the same with those of the Latin. It needs only be observed, that, after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased; after which each of the company eats a bit of bread and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

Funeral Games, a part of the ceremony of the ancient funerals.

It was customary for persons of quality among the ancient Greeks and Romans, to institute games with all sorts of exercises, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus's funeral games take up the greatest part of one of Homer's Iliads; and Agamemnon's ghost is introduced by the same poet, telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks mostly consisted of horse races; the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The garlands given to victors on this occasion were usually of parsley, which was thought to have some relation to the dead. Funeral.

Those games, among the Romans, consisted chiefly of processions; and sometimes of mortal combats of gladiators around the funeral pile. They, as well as the Greeks, had also a custom, though very ancient, of cutting the throats of a number of captives before the pile, as victims to appease the manes of the deceased. Cæsar relates, that the Gauls had this custom.

The funeral games were abolished by the emperor Claudius.

Funeral Oration, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

This custom is very ancient. In the latter part of the account above given of the Egyptian ceremonies of interment, may be perceived the first rudiments of funeral orations, and what was the subject of them, which were afterwards moulded into a more polite and regular form by other nations, who adopted this custom. Nor can we omit remarking, that those funeral solemnities were attended not only with orations in praise of the deceased, but with prayers for him: which prayers, it seems, were made by one who personated the deceased: an entire form of one of them is preserved by Porphyry, and perhaps it may in some measure gratify the reader's curiosity to recite it from him. "When (says he) they (the Egyptians) embalm their deceased nobles, they privately take out the entrails, and lay them up in an ark or chest: moreover, among other things which they do in favour of the deceased, lifting up the ark or chest to the sun, they invoke him; one of the *libitinarii* making a prayer for the deceased, which Euphantes has translated out of the Egyptian language, and is as follows:—O lord, the sun, and all the gods who give life to men, receive me and admit me into the society of the immortal ones; for, as long as I lived in this world, I religiously worshipped the gods whom my parents showed me, and have always honoured those who begat my body; nor have I killed any man, nor have I defrauded any of what has been committed to my trust, nor have I done any thing which is inexpiable. Indeed, whilst I was alive, if I have sinned either by eating or drinking any thing which was not lawful; not through myself have I sinned, but through these, showing the ark and chest where the entrails were. And having thus spoke, he casts it into the river, but the rest of the body he embalms as pure."

The Grecians received the seeds of superstition and idolatrous worship from the Egyptians, through the coming of Cecrops, Cadmus, Danaus, and Erechtheus, into Greece; and among other customs transplanted from Egypt, were the solemnities used at the burial of the dead. Of these, an encomium on the deceased always formed a part, as particularly noticed under the preceding article.

From the Egyptians and Grecians, especially from the latter, the Romans received many of their laws and customs, as well as much of their polytheism and idolatrous worship. It is well known, that the custom of making funeral orations in praise of the dead obtained among them; and the manner in which their funeral services were performed has been already described. The corpse being brought into their great oratory, Funeral. oratory, called the *rostra*, the next of the kin *laudabat defunctum pro rostris*, that is, made a funeral oration, in the commendation principally of the party deceased, but touching the worthy acts also of those his predecessors whose images were there present. The account given by Dr Kennet is in these words: "In all the funerals of note, especially in the public or indictive, the corpse was first brought with a vast train of followers into the forum; here one of the nearest relations ascended the rostra, and obliged the audience with an oration in praise of the deceased. If none of the kindred undertook the office, it was discharged by some of the most eminent persons in the city for learning and eloquence, as Appian reports of the funeral of Sylla. And Pliny the younger reckons it as the last addition to the happiness of a very great man, that he had the honour to be praised at his funeral by the most eloquent Tacitus, then consul; which is agreeable to Quintilian's account of this matter, *Nam et funebres*, &c. For the funeral orations (says he) depend very often on some public office, and by order of senate are many times given in charge to the magistrates to be performed by themselves in person. The invention of this custom is generally attributed to Valerius Poplicola, soon after the expulsion of the regal family. Plutarch tells us, that honouring his colleague's obsequies with a funeral oration, it so pleased the Romans, that it became customary for the best men to celebrate the funerals of great persons with speeches in their commendations." Thus Julius Cæsar, according to custom, made an oration in the rostra, in praise of his wife Cornelia, and his aunt Julia, when dead; wherein he showed, that his aunt's descent, by her mother's side, was from kings, and by her father's from the gods. Plutarch says, that "he approved of the law of the Romans, which ordered suitable praises to be given to women as well as to men after death."—Though by what he says in another place, it seems that the old Roman law was, that funeral orations should be made only for the elder women; and therefore he says, that Cæsar was the first that made one upon his own wife, it not being then usual to take notice of younger women in that way: but by that action he gained much favour from the populace, who afterwards looked upon him, and loved him, as a very mild and good man. The reason why such a law was made in favour of the women, Livy tells us was this, That when there was such a scarcity of money in the public treasury, that the sum agreed upon to give the Gauls to break up the siege of the city and capitol could not be raised, the women collected among themselves and made it up; who hereupon had not only thanks given them, but this additional honour, that after death, they should be solemnly praised as well as the men: which looks as if, before this time, only the men had those funeral orations made for them.

This custom of the Romans very early obtained among the Christians. Some of their funeral sermons or orations are now extant, as that of Eusebius on Constantine; and those of Nazianzen on Basil and Cæsarius; and of Ambrose on Valentinian, Theodosius, and others. Gregory, the brother of Basil, made επικηδειον λογον, a funeral oration, for Melitus bishop of Antioch: in which orations, they not only praised the dead, but addressed themselves to them, which seems Funeral Fungi. to have introduced the custom of praying to departed saints. Now these orations were usually made before the bodies of the deceased were committed to the ground; which custom has been more or less continued ever since, to this day.

Thus it appears, that those rites and ceremonies among the heathens, which have been delivered from one people to another, are what have given birth to

FUNERAL Sermons and Orations, among Christians. Though this practice is considerably improved, and cleared of many things which would smell too rank of paganism, and is thrown into a method which, perhaps, may be of some service to Christianity; yet, notwithstanding this new dress, its original may very easily be discerned. The method in which the characters of deceased persons are given in our funeral sermons, is very much the same with that observed in those pagan orations; where first an account is given of the parentage of the deceased, then of his education; after that, we hear of his conduct in riper years: then his many virtues are reckoned up, with his generous, noble, and excellent performances.—Nor let the practice be condemned because of its rise and original; for why may not the customs of heathens, if just and laudable in themselves, and nowise pernicious to Christianity in their consequences, be followed by Christians? Only, since we are come into this practice, there is one thing we should take care to follow them in; and that is, not to make those sermons or orations for every one; but for those only whose characters are distinguished, who have been eminently useful in the world, and in the church of Christ. The old heathens honoured those alone with this part of the funeral solemnity, who were men of probity and justice, renowned for their wisdom and knowledge, or famous for warlike exploits: This, as Cicero* informs us, being part of the law for burials, which directs, that the praises only of honourable persons shall be mentioned in the oration. It would be much more agreeable, therefore, if our funeral discourses were not so common, and if the characters given of the deceased were more just; devoid of that fulsome flattery with which they too often abound.

* De Leg. l. 2.

FUNGI (from σφογγος, *fungus*), the name of the 4th order of the 24th class of vegetables, in the Linnæan system; comprehending all those which are of the mushroom kind, and which in Tournefort constitute the 2d, 3d, 4th, 5th, 6th, 7th, and 8th genera of the first section in the class XVII. This order in the Linnæan arrangement, contains 10 genera; and it constitutes one of the natural order of plants in the *Fragmenta Methodi Naturalis* of Linnæus. See BOTANY *Index*.

But as the classification of this order only has been given under the article BOTANY, we shall here detail some of the speculations of naturalists concerning their nature and mode of production.

The ancients called fungi *children of the earth*, meaning, no doubt, to indicate the obscurity of their origin. The moderns have likewise been at a loss in what rank to place them; some referring them to the animal, some to the vegetable, and others to the mineral kingdom.

Messrs Wilck and Munchausen have not scrupled to rank these bodies in the number of animal productions; because,

because, when fragments of them or their seeds were macerated in water, these gentlemen perceived a quantity of animalcules discharged, which they supposed capable of being changed into the same substance. It was the ancient opinion, that beef could produce bees; but it was reserved for Messrs Wilck and Munchausen to suppose, that bees could produce beef. Wilck asserts, that fungi consist of innumerable cavities, each inhabited by a polype; and he does not hesitate to ascribe the formation of them to their inhabitants, in the same way as it has been said that the coral, the lichen, and the mucor, were formed. Hedwig has lately shown how ill founded this opinion is with respect to the lichen; and M. Durande has demonstrated its falsity with regard to the corallines. "Indeed (says M. Bonnet, talking of the animality of fungi) nothing but the rage for paradox could induce any one to publish such a fable; and I regret that posterity will be able to reproach our times with it. Observation and experiment should enable us to overcome the prejudices of modern philosophy; now, that those of the ancient have disappeared and are forgotten."

It cannot be denied that the mushroom is one of the most perishable of all plants, and it is therefore the most favourable for the generation of insects. Considering the quickness of its growth, it must be furnished with the power of copious absorption; the extremity of its vessels must be more dilated than in other plants. Its root seems, in many cases, to be merely intended for its support: for some species grow upon stones or moveable sand, from which it is impossible that they can draw much nourishment. We must therefore suppose, that it is chiefly by the stalk that they absorb. These stalks grow in a moist and tainted air, in which float multitudes of eggs, so small, that the very insects they produce are with difficulty seen by the microscope. These eggs may be compared to the particles of the byssus, 100,000 of which, as M. Gleditsch says, are not equal to the fourth of a grain. May we not snppose, that a quantity of such eggs are absorbed by the vessels of the fungus, that they remain there, without any change, till the plant begins to decay? Besides, the eggs may be only deposited on the surface of the plant, or they may exist in the water into which they are thrown for examination. Do not we see that such eggs, dispersed through the air, are hatched in vinegar, in paste, &c. and wherever they find a convenient nidus for their developement? Can it be surprising then, that the corruption of the mushroom should make the water capable of disclosing certain beings that are really foreign to both?

It is not more easy to acquiesce in the opinions of those naturalists who place the fungi in the mineral kingdom, because they are found growing on porous stones, thence called *lapides fungarii*; which, however, must be covered with a little earth, and be watered with tepid water, in order to favour the growth. Such mushrooms are no more the produce of the stone, than the lichen is of the rock to which it adheres, or the moss of the tree on which it is found. We have only to observe the growth of mushrooms, to be convinced, that this happens by developement, and not by addition or combination of parts as in minerals. The opinion of Boccone, who attributed them to an unctuous matter performing the function of seed, and acquiring extension by apposition of similar parts; and that of Morison, who conceived that they grew spontaneously out of the earth by a certain mixture of salt and sulphur, joined with oils from the dung of quadrupeds; have now no longer any adherents. Fungi are produced, they live, they grow, by developement; they are exposed to those vicissitudes natural to the different periods of life which characterize living substances; they perish and die. They extract, by the extremity of their vessels, the juices with which they are nourished: they elaborate and assimilate them to their own substance. They are, therefore, organized and living beings, and consequently belong to the vegetable kingdom. But whether they are real plants, or only the production of plants, is still a matter in dispute with the ablest naturalists.

Some ancient authors have pretended to discover the seed of mushrooms; but the opinion was never generally received. Petronius, when he is laughing at the ridiculous magnificence of his hero Trimalcio, relates, that he had written to the Indies for the seed of the morelle.

These productions were generally attributed to the superfluous humidity of rotten wood, or other putrid substances. The opinion took its rise from observing that they grew most copiously in rainy weather. Such was the opinion of Tragus, of Bauhin, and even of Columna, who, talking of the peziza, says, that its substance was more solid and harder, because it did not originate from rotten wood, but from the *pituita* of the earth. It is not surprising, that, in times when the want of experiment and observation made people believe that insects could be generated by putrefaction, we should find the opinion general, that fungi owed their origin to the putrescence of bodies, or to a viscous humour analogous to putridity.

Malpighi could not satisfy himself as to the existence of seeds which other botanists had pretended to discover. He only says, that these plants must have them, or that they perpetuate themselves and shoot by fragments. Micheli, among the moderns, appears to have employed himself most successfully on this subject. He imagined, that he not only saw the seeds, but even the stamina, as well as the little transparent bodies destined to favour the dissemination and the fecundation of these seeds. Before this author, Lister thought he perceived seeds in the *Fungus perosus crassus magnus* of John Bauhin: the little round bodies that are found in the pezizæ and hevellæ, at that time passed for seeds; which did not appear at all probable to Marsigli, considering that the eye, when assisted with the very best microscopes, could perceive nothing similar in much larger fungi. Indeed these bodies may be the capsules or covers of the seeds, if they are not the seeds themselves. However this may be, Marsigli, observing that fungi were often without roots or branches, and that they wanted flowers and seeds, the means which nature employs for the production of perfect plants, thought himself warranted in doubting whether these beings could be ranked in the number of vegetables.

The doubts of Marsigli prompted him to observe the formation of fungi. Their matrix he called *Situs:* he imagined they grew in places where they met with an unctuous matter, composed of an oil mixed with nitrous salt, which, by fermentation, produced heat and mois-

Fungi. ture, and insinuated itself between the fibres of wood; that is, he imagined them to be the production of a viscous and putrescent humour. Lancisi, in like manner, considered fungi as owing their existence to the putrefaction of vegetables, and supposed them a disease in the plant; but he imagined, "that the fibres of the tree were necessary to their production," as is the case in the formation of galls; he compared them to the warts and other excrescences of the human body. He added, that such fungous vegetable tumours must necessarily assume various forms and figures, from the fluids which distend the tubes and vessels relaxed by putrescence, from the ductility of the fibres and their direction, and from the action of the air.

This opinion has been refuted by the celebrated naturalist M. de Jussieu, in the Memoirs of the Academy of Sciences for the year 1728. He maintains, that the fungi have a great analogy with the lichen, which is allowed to be a vegetable; that, like the lichen, they are divested of stalk, branches, and leaves; that, like it, they grow and are nourished upon the trunks of trees, on pieces of rotten wood, and on all sorts of putrid vegetables; that they resemble the lichen too in the rapidity of their growth, and the facility with which many of them may be dried, and restored to their former figure upon being immersed in water; and, lastly, that there is a great similarity in the manner in which their seeds are produced. He affirms, that only the warts and excrescences which grow on animal bodies, and the knots and other tumours that are to be found on trees, can be compared with one another; for they are composed equally of the solid and liquid substance of the plant or animal on which they grow; whereas, the matter of the fungi is not only quite distinct from that of the plants on which they are found, but often entirely similar to the substance of those that spring immediately from the earth.

The organization, says M. de Jussieu, which distinguishes plants and other productions of nature, is visible in the fungi; and the particular organization of each species is constant at all times and in all places; a circumstance which could not happen if there were not an animal reproduction of species, and consequently a multiplication and propagation by seed. This is not, he says, an imaginary supposition; for the seeds may be felt like meal upon mushrooms with gills, especially when they begin to decay; they may be seen with a magnifying glass, in those that have gills with black margins; and lastly, says he, botanists can have no doubt that fungi are a distinct class of plants, because, by comparing the observations made in different countries with the figures and the descriptions of such as have been engraven, the same genera and the same species are everywhere found.

Notwithstanding this refutation by M. de Jussieu, another naturalist, M. de Necker, has lately maintained, in his work entitled *Mycitologia*, That the fungi ought to be excluded from the three kingdoms of nature, and be considered as intermediate beings. He has observed, like Marsigli, the matrix of the fungi: and has substituted the word *carchte* (initium faciens) instead of *situs*; imagining that the rudiment of the fungus cannot exist beyond that point in which the developement of the filaments or fibrous roots is perceived. He allows, that fungi are nourished and grow like vegetables; but he thinks that they differ very much from them in respect of their origin, structure, nutrition, and rapidity of growth. He says, that the various vessels which compose the organization of vegetables are not to be found in the fungi, and that they seem entirely composed of cellular substance and bark; so that this simple organization is nothing more than an aggregation of vessels endowed with a common nature, that suck up the moisture in the manner of a sponge; with this difference, that the moisture is assimilated into a part of the fungus. Lastly, That the fructification, the only essential part of a vegetable, and which distinguishes it from all other organized bodies, being wanting, fungi cannot be considered as plants. This he thinks confirmed by the constant observation of those people who gather the morelle and the mushroom, and who never find them in the same spots where they had formerly grown. As the generation of fungi (says M. Necker) is always performed when the parenchymatous or cellular substance has changed its nature, form, and function, we must conclude that it is the degeneration of that part which produces these bodies.

But if fungi were owing merely to the degeneration of plants, they would be still better entitled to constitute a new kingdom. They would then be a decomposition, not a new formation or new bodies. Besides, we cannot deny, that in those bodies which form the limit between the animal and vegetable kingdoms, the organization becomes simple, as the organs destined for nutrition are multiplied: but, as the last in the class of insects belongs to the animal kingdom, fungi ought, notwithstanding the simplicity of their organization, still to belong to the vegetable kingdom. The parenchymatous or cellular substance, which, as Mr Bonnet says, is universally extended, embraces the whole fibrous system, and becomes the principal instrument of growth, must naturally be more abundant in these productions; and this accounts for the rapidity of their enlargement. Besides, growth, whether slow or rapid, never was employed to determine the presence or absence of the vegetable or animal character. The *draba verna*, which in a few weeks shoots, puts forth its leaves, its flowers, and fruit, is not less a plant than the palm. The insect that exists but for a day, is as much an animal as the elephant that lives for centuries. As to the seeds of the fungi, it is probable that nature meant to withdraw from our eyes the dissemination of these plants, by making the seeds almost imperceptible; and it is likewise probable that naturalists have seen nothing but their capsules. Since, however, from the imperfection of our senses, we are unable to perceive these seeds, ought we to infer that they do not exist? Are we authorized to conclude this, because we do not find mushrooms where we have found them a year before? Undoubtedly not; for the greater part of plants require a particular soil, and the same mould that this year will foster a rare plant, will next year allow it to perish. Neither are we at liberty to deny the existence of these seeds, because those bodies which have been called their seeds, and the fragments or cuttings of the plants themselves, have not produced others of the same species. Nature seems to have reserved for herself the care of disseminating certain plants: It is in vain, for instance, that the botanist

nist sows the dust found in the capsules of the orchis, which every one allows to be the seed. But, after all, what are those parts in the fungi casually observed by naturalists, and which they have taken for the parts of fructification? These are quite distinct from the other parts; and whatever may be their use, they cannot have been formed by a prolongation of the cellular substance, or of the fibres of the tree on which the fungus grows: they are, therefore, owing, like flower and fruit, to the proper organization of the plant. These plants, therefore, have a particular existence, independent of their putrefying nidus. The gills of certain fungi, which differ essentially from the rest of the plant in their conformation, would be sufficient to authorize this latter opinion. But can putrefaction create an organic substance?

Nature undoubtedly disseminates through the air, and over the surface of the earth, innumerable seeds of fungi, as well as eggs of insects. The plant and the animal are excluded, when the nidus or the temperature is favourable for their developement. No fortuitous concourse, either of atoms or fluids, could produce bodies so exquisitely and so regularly organized. It is sufficient to throw one's eyes on the beautiful plates which Schæffer has published of them, and compare them, by the glass, with the warts and other excrescences of animals, to be convinced that they have not the same origin. The function of the cellular substance in vegetables must be greatly superior to that in animals, if it could produce any thing but deformities.

The greater part of fungi exhibit a configuration much too regular, constant, and uniform, to be the effect of chance or putrefaction. As this form is preserved the same in all places where fungi have been found, it follows, that they contain in themselves the principles of their reproduction. They resemble the misletoe, and other parasitic plants, which are perfectly distinct from the trees on which they grow. The fungi, therefore, are organized and living substances, or true plants. If the manner of their production is unknown, that of some insects is so too.

FUNGIBLES, in *Scots Law*, are such things as are estimated by number, weight, or measure; as coin, butter, ale, &c.

FUNGITÆ, in *Natural History*, a kind of fossil coral, of a conic figure, though sometimes flatted and striated longitudinally.

FUNGUS, in *Surgery*, denotes any spongy excrescence. See SURGERY *Index*.

FUNNEL *of a* CHIMNEY, the shaft or smallest part of the waste, where it is gathered into its least dimensions.

Palladio directs, that the funnels of chimneys be carried through the roof four or five feet at least, that they may carry the smoke clear from the house into the air. See CHIMNEY.

He also advises, that chamber chimneys be not made narrower than 10 or 11 inches, nor broader than 15; for if too narrow, the smoke will not be able to make its way; and, if too wide, the wind will drive it back into the room.

FUR, or FURR, in commerce. See FURR.

FURBISHER, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c. which is chiefly performed with emery. See the article EMERY.

FURCA, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced a servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca upon his neck, and whipped all the way. The third was capital, when the malefactor having his head fastened on the furca, was whipped to death.

FURCHE', in *Heraldry*, a cross forked at the ends.

FURETIERE, ANTONY, an ingenious and learned Frenchman, was born at Paris in 1620; and after a liberal education became eminent in the civil and canon law. He was first an advocate in the parliament; and afterwards taking orders, was presented with the abbey of Chalivoy, and the priory of Chuines. Many works of literature recommended him to the public; but what he is chiefly known by and valued for is, his Universal Dictionary of the French Tongue, in which he explains the terms of art in all sciences. He had not, however, the pleasure of seeing this useful work published before his death; which happened in 1688. He was a member of the French academy; and the disputes and quarrels which he had with certain members of it made a great noise in the world.

FURIA, in *Zoology*, a genus of insects belonging to the order of vermes zoophyta. There is but one species, viz. the infernalis, which has a linear smooth body ciliated on each side, with reflexed feelers pressed to its body. In Finland, Bothnia, and the northern provinces of Sweden, it was not unfrequently that people were seized with a pungent pain, confined to a point, in the hand or other exposed part of the body, which presently increased to a most excruciating degree, and hath sometimes been suddenly fatal. This disorder was more particularly observed in Finland, especially about boggy and marshy places, and always in autumn. At length it was discovered that this pain instantly succeeded somewhat that dropped out of the air, and in a moment penetrated and buried itself in the flesh. The Finlanders had tried variety of applications to no purpose, until at length a poultice of curds or cheese was found the most effectual in easing the pain: and the event confirmed that the insect was allured by this application to leave the flesh; as, on its removal, this worm, no longer than the sixth of an inch, was found in it, and thus the cause of this painful disease explained. But by what means this creature is raised into the air, is as yet unknown.

FURIES, in Pagan antiquity, certain goddesses whose office it was to punish the guilty after death. They were three in number: Alecto, Megæra, and Tisiphone; who were described with snakes instead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish, the guilty: and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tisiphone punished the crimes which sprang from hatred or anger; Megæra,

 those

those from envy; and Alecto, those from an insatiable pursuit after riches and pleasure.

FURLING, in naval affairs, signifies the operation of wrapping up and binding any sail close to the yard.

FURLONG, an English long measure containing the one-eighth of a mile, and therefore equal to 660 feet, or 220 yards.

FURLOUGH, in the military language, is a license granted by an officer to a soldier to be absent from his duty for a limited time.

FURNACE,

Furnace.

IS a vessel or building, for the purpose of containing combustible materials, whether of coal or wood, and so constructed that great heat may be produced and concentrated. There is a great variety of furnaces, and they are variously constructed, according to the views of the operator, and the purposes to which they are applied. But in all furnaces there are four things which require to be particularly attended to. 1. To be able to concentrate the heat, and direct it as much as possible to the substances which are to be acted upon. 2. To prevent the dissipation of the heat after it is produced. 3. To obtain the greatest quantity of heat from the smallest quantity of fuel; and, 4. To be able to regulate at pleasure the necessary degree of heat.

Requisites of a good furnace.

To concentrate the heat.

1. To accomplish the first object, namely to concentrate the heat, it is usual to confine the fire in a chamber or cavity properly constructed, furnished with a door or opening, by which the fuel is introduced; a grate for supporting it, and allowing a free passage to the air, as well as for the ashes to fall through into the cavity below, called the *ash-pit*. In this way the heat produced by the combustion of the fuel is confined by the sides of the furnace, and so concentrated that its force is chiefly spent on the substances inclosed.

To prevent its dissipation.

2. The dissipation of the heat is prevented by keeping the door of the furnace shut, by constructing the chimney no wider than to allow a passage for the smoke, and placing the substance to be acted upon in such a manner that the fire may have its full effect as it goes up the chimney.

To produce the greatest proportion of heat.

3. The third object, which is not the least important, is to produce the greatest quantity of heat from the smallest quantity of fuel. In an economical point of view, this object is worthy of the greatest attention, though it is often difficult to attain it. In this view much depends upon the proportion between the spaces between the bars of the furnace, and the wideness and height of the chimney. This is obvious from considering the circumstances which regulate the process of combustion; for this depends on the current of air passing through the combustible matter. When the fuel in the furnace is kindled, a certain degree of heat is produced; but without a current of fresh air passing through the burning matter, the fire is instantly extinguished; and without this stream of fresh air the inflammation cannot go on. But when this takes place, the air within the furnace is rarefied, and being no longer a balance for the external air, it is driven up the chimney by a current of denser air, rushing in at the openings. This having passed through the fuel, is also rarefied, and passes off, giving place in its turn to a new current, so that in this way there is a constant flux of air up the chimney. From this it must appear, that the greater the rarefaction of the air in the fire-place is, the greater will be the intensity of the heat produced. By constructing a furnace in a particular way, the heat may be so managed that the under part of the chimney may be nearly as strongly heated as the fire-place itself; so that, although a strong current of air passes through the fuel, yet as the heat is uselessly spent on the chimney, there is a great and unnecessary waste of fuel. To prevent this, there is a contrivance by which the throat of the chimney is occasionally contracted, by means of a sliding plate, which, when it is pushed in, closes up the whole vent; but may be drawn out in such a way as to form a larger or smaller opening as may be thought necessary. Till the fuel is thoroughly kindled, and the furnace fully heated, the plate should be quite drawn out, so that the largest column of air which the furnace will admit, may pass through the fuel. The plate is then put in to a certain length, and so regulated that the smoke may be prevented from issuing at the door of the furnace. The current of air increases in proportion to the rarefaction of the air in the fire-place, and this increases the inflammation of the fuel; and the heat now being reflected from every point of the furnace, excepting the narrow passage by which the smoke passes off, becomes extremely intense. If a large quantity of fuel be introduced at once, it will consume slowly, and require little attention, in comparison with those furnaces where this precaution is not observed. When the intensity of the heat is not very great, the sliding-plate may be of cast-iron; but to resist great degrees of heat, it will be found more convenient to have it made of fire-clay. But it must be observed, that the advantage derived from the sliding-plate is lost to those furnaces which are of a large construction, and where great quantities of metal are to be melted; and there it is commonly found, that the waste of fuel is very great.

Method of regulating the heat.

4. To attain the fourth object, namely, to be able to regulate conveniently the degree of heat, a certain proportion of air only is to be allowed to pass through the fuel. With this view it is necessary to have the command of the furnace below, because the parts above are often filled with small quantities of soot. To manage this in the most effectual manner, the door of the ash-pit is to be perfectly closed, and furnished with a series of round holes which have a certain proportion to each other. In the furnaces constructed according to Dr Black's direction, the areas of these holes are as 1, 2, 4, 8, 16, &c. in geometrical progression. Seven or eight of these in the door of the ash-pit give a sufficient command over the fire. When the utmost intensity of heat is required, all the passages are thrown open, and the height of the chimney is increased, so that the height of the column of rarefied air being augmented, the motion of the current of air through the fuel is proportionably more rapid, and consequently the heat of the furnace becomes more intense. In the construction of a furnace recommended by Macquer, another tube is applied to the ash-pit, having the extremity most

Furnace.

most distant from the furnace widest, and gradually tapering as it approaches it. By this contrivance, it was proposed to increase the velocity of the current of air as it passes from a wider into a narrower tube. But it is found that the air will not ultimately move with greater velocity than if the tube were not applied. It may indeed be useful where the furnace is placed in a small apartment, and the tube itself forms a communication with the external air.

After these preliminary observations on the general principles of furnaces, we propose in the following treatise to give a short account of the construction and application of some of the more important furnaces which are employed in the arts and manufactures.

But before we enter into the detail and description of particular furnaces, we shall lay before our readers the description of one which was invented by Messrs Robertons of Glasgow, for the purpose of consuming its own smoke, and saving fuel.

Furnace for consuming its own smoke.

"To construct furnaces (says the editor of the Philosophical Magazine, from which this account is taken), on such a principle as should enable them to consume their own smoke, has long been a desideratum; and we believe the public in general, but especially those who have been annoyed by the smoke of steam engines, founderies, and similar erections in their neighbourhood, will be glad to learn that a furnace has been contrived which effectually gains this end.

"The construction is extremely simple, and will be easily understood by the following description, and the plate to which it refers.

Plate CCXM. fig. 1. &c.

Fig. 1. represents a vertical section, and fig. 2. a front view of a steam-engine boiler, furnished with one of Messrs Robertons furnaces; and the same letters refer in both to the same parts of the construction.

"The opening A, through which the fuel is introduced into the furnace, is shaped somewhat like a hopper, and is made of cast iron built into the brick-work H, H. From the mouth it inclines downward to the place where the fire rests on the bottom grate B. The coals in this mouth piece or hopper answer the purpose of a door (A), and those that are lowest are by this means brought into a state of ignition before they are forced into the furnace. Below the lower plate of the hopper K, *e* the furnace is provided with front bars G (B), which not only serve to admit air among the fuel, but offer a ready way to force the fuel back, from time to time, from *c* to *d* (C), to make room for fresh quantities to fall into the furnace from the hopper or mouth-piece. By this arrangement the fuel is brought into a state of ignition before it reaches the farther side of the bottom grate, where it is stopped by the rising breast, *b*, of the brick-work, so that any smoke liberated from the raw coals in the mouth-piece, must pass over these burning coals before it can reach the flue FFF. But this, though it would cause a large quantity of the smoke to be burnt, would not completely prevent the escape and ascent of smoke up the chimney; for it is not merely necessary that the smoke should be exposed to a heat sufficient to ignite it before it escapes: unless, at the same time, a quantity of fresh air, able to furnish a sufficiency of oxygen for the combustion of the smoke, can be brought into contact with it, it will still escape in an undecomposed state. The judicious admission of fresh air, in such a manner that it can reach the smoke, without previously passing through the fire, and parting with its oxygen in its passage, and in such quantity as not to cool the bottom of the boiler, but merely to cause the smoke to burn, constitutes the chief merit of this invention; and to us it appears that it will fully answer the proposed end. Below the upper side of the mouth-piece or hopper, and at about the distance of three-fourths of an inch from it, (this space being a little more or less, according to the size of the furnace), is introduced a cast iron plate *a n*. This plate is above the fuel, and the space between it and the top of the hopper is open for the admission of a thin stream of air, which, rushing down the opening, comes first in contact with that part of the fire which is giving off the greatest part of the smoke, viz. the fuel that has been last introduced, mixes with it before it passes over the fuel in the interior, which is in a high state of combustion, and enables it to inflame so completely, that not a particle of smoke ever escapes undecomposed.

"The quantity of air thus admitted to pass over the upper surface of the fire, is regulated by a very simple contrivance. The plate *a n* rests at each end on a stud, or pin, projecting from the cheeks of the mouth-piece A, or is furnished at each end with a pivot which works in the cheeks; the said pins or pivots being placed about midway between the outside and inside of the mouth-piece or hopper, so that, by elevating or depressing the edge *a* of the plate, the opening at *n* is enlarged or diminished. When that degree of opening which produces the best effects are obtained, which is easily known, the plate *a n* is kept in its place by means of a piece of iron introduced above it, and answering the purpose of a wedge.

"Under the grates is the ash-hole I, the upper part of which is furnished with doors SS, which, when shut, prevent the heat from the front bars G from coming out into the apartment, and incommoding the workmen.

"Invited by an advertisement, we went to Messrs Bunnell

(A) "In the management of this furnace, what is chiefly to be attended to is, that the hopper be kept full of coal, and either wholly or in part small coal, to prevent, as much as possible, air getting in by that passage; it is also necessary at some times to use a shutter of thin plate-iron, to be applied to the mouth of the hopper to exclude the entrance of air by that passage.

(B) "These bars are, in fact, a grated door, kept in their position by a catch L, and which may be opened at pleasure for cleaning the fire out. In small furnaces an opening here is all that is necessary; the bars may be dispensed with.

(C) "Between the back end, *d*, of the bottom bars, and the breast brickwork *b*, is represented in the plate a section of a shutter, which is sometimes opened for the purpose of getting out the refuse of the fuel.

Furnace. Bunnell and Silver, Bedford-street, Covent-Garden, to see one of these furnaces at work, and we were not a little gratified in observing that the smallest appearance of smoke could not be perceived issuing from the top of the chimney. The advantages of such an improvement can hardly be better illustrated than by mentioning what had actually happened with this steam engine. The smoke, before the improved furnace was employed, incommoded the neighbourhood so much, that it was stopped as an intolerable nuisance. Now it is so far from disturbing any one, that, without being admitted to see the engine, it would be actually impossible to know when it is at work.

"These furnaces, we understand, have also been adopted by many intelligent manufacturers at Leeds and at Manchester. At the latter place, if we may credit newspaper reports, several manufacturers have had their works indicted as nuisances for not having adopted the improvement; the magistrates arguing, that, though the welfare of the place required that such inconveniences should be submitted to while no possible cure for them was known, the health and comfort of the inhabitants equally demand, now that the evil can be done away, that smoking furnaces should not be permitted in the place.

"We earnestly recommend to owners of steam engines, and also to those who are annoyed by them, to endeavour to bring this improvement into general use. Indeed, we entertain no doubt of its being universally adopted sooner or later; for it yields advantages not only in point of cleanliness, comfort, and health, but also in point of interest; all the smoke usually discharged at the top of the chimney, being in fact, so much good fuel, that only wanted the contact of fresh air to inflame it under the boiler. It is a fact well known, that the flame which is often seen issuing from the chimneys of founders, &c. has no existence except at the top of the chimney: while ascending the flue it is only dense smoke, consisting of the azote of the atmospheric air decomposed in passing through the fire, of hydrogen, coal tar, and carbonaceous matter, of such a high temperature, that it only wants oxygen to make it inflame spontaneously: this it obtains from the atmospheric air into which it ascends, and then presents such appearances as would make a hasty observer adopt the opinion that the flame had ascended, as flame, from the fuel in the furnace; which is by no means the case. A consideration of this simple fact will convince any person that it is not an inconsiderable proportion of the fuel that is thus wasted. Nor is this the only loss sustained; the quantity of heat required not merely to render such a portion of the fuel volatile, but to give to it a temperature able to produce the effect of which we have taken notice, is itself furnished at the expence of an extra and unnecessary quantity of fuel. The whole waste in many cases is, we are persuaded, not less than an eighth of the whole fuel employed."

Furnace for smelting iron.

One of the most important furnaces, particularly for this country, where, although great and essential improvements have been made by industry and ingenuity, the manufacture is yet in its infancy, is that for the smelting of iron.

We shall therefore enter more fully into the detail of the history, construction, and general principles of the operation of blast furnaces; and in tracing their progressive history, it may be observed, that in this country it has experienced a revolution, of which no analogous instance has occurred in other countries.

History.

In the early and barbarous periods of society, before the introduction of agriculture, the surface of a country is usually covered with extensive forests. From this circumstance wood, as being most accessible, abundant, and of easiest application, is usually employed by mankind for the purposes of fuel. In the progress of population and improvement, other advantages were derived from the general use of wood as fuel; and among these the improvement of the climate, and clearing land for the purposes of agriculture, were none of the least. The application of wood as fuel to different manufactories, had no doubt also an early origin; and in the manufacture of iron, if conducted on a scale of any extent, the demand for fuel of this kind must have been very great. If, then, during the gradual improvement and prosperity of this country, this manufacture, in place of remaining stationary, or declining, from diminished consumption, has increased in capital and extent, without some substitute for wood, the art would have been long before this time entirely lost, because it depended on a stock which must have rapidly declined, and even its very existence was often far from being compatible with the views and interest of landholders. Such were the circumstances in which Great Britain was placed, from the reign of Charles II. to the middle of the 18th century. During this period, being in a prosperous state, the manufactures and commerce of the country increased the demand for iron, while the supply of wood, one of the most necessary materials in its manufacture, was greatly diminished. It is true, indeed, that, previous to this period, pit-coal had been employed as a substitute; but the prejudice of some, and the selfish views of others, and especially the want of sufficient meehanical powers, obstructed the progress of this mode of manufacture. When, however, these difficulties were surmounted, and it was found that the change of fuel in the blast furnace was likely to prove beneficial, this manufacture acquired new vigour, and improvements succeeded each other in rapid succession. In a period of about 50 years, a complete revolution was effected, not only in relinquishing the mode of making iron with charcoal and in employing pit-coal in the blast furnace, but also in the immense increase of the manufacture.

and progress of in Britain.

At what period the manufacture of iron commenced in Britain, cannot be precisely ascertained. It has, however, been supposed, that the Phœnicians, who wrought the tin mines of Cornwall, may have introduced into the country men who were skilled in metallic ores, and were capable of estimating their value, by converting these mineral riches to such purposes as their own necessities, or the wants of the inhabitants, might require. It is probable also, that the invasion of England by the Danes, and their establishment in this country, added something to their former knowledge in the art of mining and manufacturing the ores of iron. In support of this conjecture, the large heaps of scoria found in many parts of England, and having a considerable thicknes of soil upon them, have been denominated from time immemorial, "Danes cinders;" and indeed so early as the year 1620, large oaks were found in a state of decay, upon the tops of some of those hills of of scoria. But although these may have been very ancient manufactures, it is the less probable that the production of these cinders is to be ascribed to the blast furnace; for at that remote period the manufacture was chiefly directed to the fabrication of small portions of malleable iron, in what were called foot-blasts and bloomeries. The art of casting or moulding in iron was either altogether unknown, or in so rude a state, that it could not be prosecuted with much prospect of advantage. Pig or cast iron, if it was at all produced, was then of the most refractory nature for being converted into malleable iron. It was not till a future period, when improvements had been made in machinery, and the advantages of a division of labour were known, that different furnaces were constructed; one for manufacturing pig iron, and another for converting it into malleable iron. To this the blast furnace seems to have owed its existence, and it is to be considered as an improvement of the advantages which are derived from a division of labour. The blast furnaces being exclusively appropriated to the making of pig iron, the attentive manufacturer would soon perceive that the products of the furnace were often different from each other. Repeated observation and experience would enable him to ascertain what was the cause of this difference. Observing that an additional quantity of fuel rendered the forged pig iron more fusible, this circumstance would suggest the practicability of casting it into shape. Hence probably arose the art of moulding, which afterwards, as well as the bar-iron forge, became an appendage to the blast furnace. After this new manufacture became familiar, the advantage of dividing the product of the blast furnace into gray melting iron, or into forged pigs, according to the demand, would be obvious.

[Nu]mber [of fur]naces [in E]ngland

In the year 1615, according to Dudley, who has stated the fact in his *Metallum Martis*, there were no less than 300 blast furnaces in England for smelting iron ore with charcoal, and each furnace was supplied with fuel upon an average of 40 weeks in the year. Taking the average produce of pig iron at each furnace of 15 tons per week, or 600 tons per annum, the total annual quantity will amount to 180,000 tons, which is a greater quantity than has ever been produced in Britain since that period. It is supposed that this quantity may be greatly exaggerated, but at the same time it is allowed that the iron manufactory was, at this early period, highly prosperous and productive. But in the progress of agriculture and the increase of population, it was necessary to clear the land for the purpose of cultivation. From this circumstance, as well as from the great consumption of wood for the navy, the supply of fuel was greatly diminished; so that the iron manufacture became consequently less productive.

[Pit-]coal used.

It is curious to remark that, although pit-coal was known long before this period, and was wrought at Newcastle previous to the year 1272, and great quantities of it were annually exported to Holland and the Low Countries, and was used in the smith's forge, and other manufactures which require a strong continued heat, yet in England the prejudice against its use in the manufacture of cast iron was so inveterate, that when it was first proposed and attempted, every obstacle which could be devised was thrown in its way. During the reign of James I. several patents were granted for the exclusive privilege of manufacturing iron with pit-coal. None of the adventurers, however, succeeded in their attempts till the year 1619, when Dudley made pig-iron in a blast furnace, but produced only three tons in the week. At this time the price of iron had risen, in consequence of many of the iron-works having stopped for want of wood as fuel. To those manufacturers, therefore, who could still be furnished with a supply of wood, the manufacture was highly profitable, so that they opposed any new attempt by which the price of iron was likely to be diminished.

After this period, the progress of the iron manufacture was greatly interrupted from other causes. Amidst the distraction occasioned by the civil wars which raged in England, little improvement was to be expected. It appears, however, that patents were granted during the Commonwealth, for the exclusive privilege of manufacturing iron in the new way; and in one of these, it was believed at the time, that the Protector himself had a share. All these experienced the fate of the former, and no manufacture of any extent was successfully established. In the year 1663, Dudley in his application for his last patent, stated that he could produce at one time seven tons of pig iron in the week with a furnace of an improved construction, 27 feet square, and with bellows which one man, without much fatigue, could work for an hour.

Thus, as the demand for wood for the purposes of fuel in this manufacture increased, and the growth of timber was greatly diminished, the manufacturer was forced by necessity to have recourse to the use of pit-coal; and when various valuable improvements had been made on machinery, and particularly when the beneficial effects of the steam engine had been ascertained, the iron manufacturer saw himself in possession of a command of power in the management of his materials, of which he had formerly no conception. The small furnace supplied with air from bellows constructed of leather, which was moved by means of oxen, horses, or men, went into disuse, when larger furnaces were introduced, with an increase of the column of air, for the purpose of exciting combustion. But at this period, when the manufacture derived new vigour from the introduction of the steam engine, and the general improvement in machinery, it seemed, from the operation of other causes, and particularly from the deficiency of fuel, to decline rapidly. The demand for iron in the manufactured state, and particularly for bar iron, had increased, while the quantity produced gradually diminished. Recourse was now had to foreign markets for a supply, and the importation of Russian and Swedish iron then commenced. Of the 300 blast furnaces spoken of by Dudley, 59 only existed; and estimating their annual produce at about 295 tons to each furnace, the total amount did not much exceed 17,000 tons.

Such was the state of the manufacture of iron in England and Wales, before the introduction of pit-coal; and thus it appears, that in a period of from 100 to 130 years, it had suffered a diminution of more than 50,000 tons annually. It proved of singular benefit to this manufacture, that the steam engine, which had then become a powerful machine, was introduced, for the purpose of raising and compressing the air, and could be employed in those places where materials were abundant, but where there was a deficiency of water for moving the machinery. Besides, experience now taught the

the manufacture, that the produce of his furnace could be increased by enlarging the diameter of the steam cylinder, for rendering the vacuum under the piston more perfect; and it was soon found that, by increasing these effects, such a quantity of pig iron could be produced from the coak of pit-coal, as would be attended with a suitable profit. It is scarcely to be wondered at, that this circumstance should have long remained a secret; for a small quantity of air only being necessary to ignite the charcoal furnace, whether it arose from the peculiar inflammability of the fuel, or the small capacity of the furnace, it was always under the eye of the manufacturer, and he would more frequently experience the inconveniences of overblowing than underblowing the furnace. It seems too extremely probable, that pit-coal, being considered in every respeet inferior to charcoal, the manufacturer would proceed with great caution in enlarging the column of air, or increasing its density; and thus the advantages to be derived from its use would be in a great measure lost. When, however, experience had taught them a different lesson, the limits to the quantity of air that might be directed to a coak blast furnace, before any injurious effects arose, were not very observable. It was found, indeed, that the density of air diminished the quantity of the produce, and the same law seemed to hold with regard to pit-coal as well as to wood,—that the softer qualities might be overblown, while the strata of a denser and more compact consistence remained undiminished before a heavier blast.

Comes into general use.

Between the years 1750 and 1760 the coak of pit-coal was pretty generally substituted for charcoal, in the blast furnace. The iron manufacture assumed new vigour, and in a period of 30 years it experienced in England and Wales a very remarkable progress. From the general and increasing use of pit-coal, it is probable that many of the charcoal works were sooner relinquished than they would otherwise have been. The history of the celebrated foundery of Carron in Scotland, affords us a curious instance of the progress of the use of pit-coal in this mannfacture. These extensive operations commenced about the year 1760. The blowing, as was the practice at the time, was performed by means of large bellows, moved by a water wheel. But as there was a scanty supply of air, and as this was deficient in density, the weekly produce of the furnace rarely exceeded 10 or 12 tons, and often in summer this quantity was considerably diminished. With a view to improve the operation, immense quantities of wood charcoal were prepared, and it was found that the process of smelting succeeded much better with this kind of fuel than with the mineral coal which was dug out in the neighbourhood. But in the improvement of machinery, more effectual means were discovered to procure a blast of sufficient force and density for the ignition of pit-coal, wheels of greater force were constructed; the use of the bellows was relinquished, and in their place large iron cylinders, so contrived as to blow both up and down, were introduced. Thus, a larger column of air, of three or four times the former density, was obtained, and the beneficial effects arising from the improvements were soon perceived; for the same furnace which formerly produced 10 or 12 tons in the week, sometimes yielded 40 tons in the same time; and on an annual average, not less than 15,000 tons of metal.

About the end of the reign of Queen Elizabeth, we are informed by Dudley, that blast furnaces had been constructed on so large a scale, and with such a power of machinery, as to yield a daily produce of more than two tons of charcoal iron; but it is probable that so large a produce could only be obtained in situations where there was a copions supply of water, and where the water wheels and bellows employed were of large size. In the more ordinary modes of conducting this process, furnaces of a much smaller size were employed, and these received the supply of air from hand bellows which were moved by men, and sometimes by cattle. From the superiority of the manufacture of iron guns, mortars, &c. England possessed at this time a considerable export trade; but as pit-coal had not yet been applied to any departments in the manufacture of iron, it seems probable that these articles were cast from the large blast furnaces, because the flame of wood, comparing it with that of pit-coal, possessing but feeble effects, would render the application of the reverberating furnace (if it was then known), of no use in the casting of guns and mortars. The want of pit-coal in every department of the foundery, greatly retarded the perfection to which the art of moulding might have arrived, and even obstructed its improvement. The backward state in which the art of casting and moulding long remained in this country, shewed that the want of this material of the smelting fuel in the blast furnace was long severely felt; and owing to this, other nations, who in many other respects enjoyed fewer advantages, made more rapid progress in the improvement of this manufacture. Before this period, it is not improbable that the use of pit-coal might have been suggested to the manufacturer, and that this material, employed as a fuel, might have been considered as an auxiliary, or as a substitute in various departments of the process. The inflammability of this substance, and its tendency to be converted into a cinder, as well as the general decay of wood, would afford sufficient ground for what might be considered by many as a useful speculation. The benefits of this manufacture as it then stood, had been carefully investigated, and fully appreciated by those who were interested in it. The supply of wood only seemed to limit its extent, but for want of a sufficient supply of materials, the establishment of new works became impracticable, those already engaged in the business were anxious to preserve the supply they enjoyed, however limited, rather than encourage any innovation or change in the process, which, by the substitution of pit-coal for charcoal from wood, would probably give to new adventurers and speculators a superiority of the market. Besides, many of the furnaces which were then going, were at a great distance from pit-coal, so that the general use of this substance, and the advantages to be derived from it, would be highly injurious to their interests.

Such was the state of this manufacture when the use of pit-coal in this process was discovered, or when it was proposed to employ it for this purpose. With this view, James I. in the year 1612, granted a patent to Simon Sturtevant, for the exclusive manufacture of iron with pit-coal, for the period of 31 years. In obtaining this privilege,

privilege, the patentee obliged himself to publish a full account of his discoveries, and this appeared in a work in quarto, under the title of "Metallica." It appears, however, that Sturtevant had not succeeded in his schemes; for in the following year he gave up his privilege, but it is not known to what causes the failure is to be ascribed.

Another adventurer.

After Sturtevant, a John Ravenson, embarked in the same hazardous undertaking; and although he procured a patent without much trouble, he had soon to encounter difficulties in the way of ultimate success, analogous to those which had prevailed over the perseverance of Sturtevant, and induced him to relinquish the farther prosecution of his schemes. He obtained his patent on conditions similar to those on which his predecessor procured it, in consequence of which he published his "Metallica" in 1613. All his successors were, like him, obliged to resign their patents from the want of adequate success.

Dudley obtains patent.

Dudley procured his patent in the year 1619, and notwithstanding he affirmed that he manufactured not more than three tons per week, he found it a lucrative undertaking. This discovery he brought to perfection at the works of his father in Worcestershire; but by the influence of those who wished to share in the emoluments arising from the manufacture of iron with pit-coal, his patent was limited to 14 instead of 31 years. He informs us himself, that, during the greater part of this period, he was enabled to sell pig and bar iron much cheaper than any of his competitors; but as his remarkable success drew their envy upon him, his devoted works were at length destroyed by a lawless mob, urged on, it is supposed, to perpetrate so atrocious a deed by his rivals in business. In this unmerited treatment of the sanguine but unfortunate Dudley, the coke pig process unquestionably experienced an irreparable loss. He had so many rivals to contend with, by virtue of the original ground he occupied as a manufacturer, and his attachment to the cause of royalty was so sincere, that his improvements were effectually prevented from arriving at lasting or general utility. Could he have procured a new patent after the restoration, there is little doubt but he would have again entered with avidity on the laborious paths of discovery. In petitioning for the recovery of his ancient privileges, we find him declaring that instead of three, he was enabled to manufacture seven tons per week of coke pig iron, in consequence of a large furnace, and an improved bellows.

Attempts to evade it.

To stand clear as much as possible of the method of operation which Dudley had discovered, one Captain Buck, Major Wildman, and some others, constructed large air-furnaces in the forest of Dean, into which they put clay pots, for containing the requisite preparations of ore and charcoal. Pit-coal was employed for the purpose of heating the furnaces; and it is highly probable that these new adventurers were sanguine enough to believe that, by tapping the pots below, the separated metal would flow out. This strange method of assaying was soon found impracticable; for the heat was not of sufficient intensity to produce an entire separation; the pots gave way, and the prosecution of this ridiculous scheme was speedily relinquished.

The manufacture of iron received no farther improvements for about a century after this period. It was found to be practicable; but how to procure such a quantity as to produce a lucrative return, was not to be derived from the mere knowledge of the particular proportions of the raw materials. Had machinery reached that degree of perfection in the time of the ill-fated Dudley which it has since done, we have good reason to believe that the rapid progress of the pig iron manufacture would have dated its origin from the æra of that enterprising genius.

Produce of furnaces in Britain.

We shall conclude this historical account of the iron manufacture, with a view of the progressive quantity produced at the different furnaces in Great Britain at different periods.

	Tons.
In 1620, the 300 blast furnaces mentioned by Dudley, which existed in England and Wales, produced each at an average -	250
At a later period, but previous to the use of pit-coal, 59 furnaces produced each on an average	294
In 1788, 24 charcoal furnaces, which were then going in England, produced each on an average - - - -	545
In 1788, 53 blast furnaces, in which coak from pit-coal was used, yielded each on an average, nearly - - - -	907
In 1788, eight furnaces in Scotland produced on an average, each - -	875
In 1796, there were in England and Wales, 104 furnaces, from each of which was obtained on an average - - -	1048
In 1796, 17 furnaces in Scotland produced each on an average - - -	946

But from the above statement we are not enabled to draw an accurate conclusion of the degree of improvement which has been introduced in blowing machinery; for among the furnaces mentioned in 1796, were included a number of charcoal blasts, which yielded only a small produce. But the average produce of iron manufactured at pit-coal blast furnaces, at no less an amount than

	Tons.
At melting furnaces - - - -	1200
At forge pig works - - - -	2000

Prices at different periods.

To what we have now said, we shall only give a view of the prices of the produce of this manufacture, and the channels of consumption for this immense quantity of materials.

	Per Ton.		
Charcoal pig iron sold in 1620 for - -	L.6	0	0
Ditto for melting in 1788 - -	8	0	0
Ditto in 1798 - - - -	9	10	0
Coak pig iron in the time of Dudley -	4	0	0

Melting iron in 1802 - - - -	8	10	0

The produce of pig iron in England and Wales, and in Scotland, from 168 furnaces, has been calculated at the immense quantity of 172,000 tons. It will be impossible to say with absolute precision what are the channels into which this immense quantity of raw materials passes for consumption; but the following views will enable the reader to account for part of it.

Consumption of pig iron.

	Tons.
Annual consumption in the erection of new furnaces, forges, &c. - - - -	5000

Furnace.

	Tons.
Annual consumption at forges in Britain, for the manufacture of bar iron	70,000
Purchased by government in the state of cannons, mortars, &c. on an average of three years, including the waste in melting, &c. with what is employed in the navy as ballast	14,899
Ditto by the India Company	5,700
Ditto for merchantmen	11,000
Ballast for India and merchantmen	5,000

Principles of the blast furnace.

Let us now consider the construction and general principles of the blast furnace. The term *blast* is employed at iron founderies, to signify the column of air which is forced into the furnace for the purpose of promoting combustion. The velocity of this blast is produced by the blowing machine impelling the contents of the air-pump through one or two small apertures, and in this way a column of air of various density is produced.

Here we propose to avail ourselves of what has been done by Mr Mushet, formerly of the Calder iron works near Glasgow, a manufacturer himself, who with much philosophical discrimination joins a great deal of excellent practical observation. The many valuable hints which he has suggested, will, we trust, not only be acceptable, but prove highly beneficial in directing and assisting the views and operations of those concerned in this important manufacture.

To have a clear view of his reasonings and observations on the nature and principles of the blast furnace, we shall first give his description of the building and apparatus, and then detail what he has said concerning its management and mode of operation.

Plate CCXXV. fig. 3. Description of a furnace.

Fig. 3. represents a blast furnace with part of the blowing machine. A, the regulating cylinder, eight feet diameter and eight feet high. B, the floating piston, loaded with weights proportionate to the power of the machine. C, the valve, by which the air is passed from the pumping cylinder into the regulator: its length 26 inches, and breadth 11 inches. D, the aperture by which the blast is forced into the furnace. Diameter of this range of pipes 18 inches. The wider these pipes can with conveniency be used, the less is the friction, and the more powerful are the effects of the blast. E, the blowing or pumping cylinder, six feet diameter, nine feet high: travel of the piston in this cylinder from five to seven feet per stroke. F, the blowing piston, and a view of one of the valves, of which there are sometimes two, and sometimes four, distributed over the surface of the piston. The area of each is proportioned to the number of valves: commonly they are 12+46 inches. G, a pile of solid stone building, on which the regulating cylinder rests, and to which the flanch and tilts of the blowing cylinder are attached. H, the safety-valve, or cock; by the simple turning of which the blast may be admitted to, or shut off from the furnace, and passed off to a collateral tube on the opposite side. I, the tuyere, by which the blast enters the furnace. The end of the tapered pipe, which approaches the tuyere, receives small pipes of various diameters, from two to three inches, called *nose pipes*. These are applied at pleasure, and as the strength and velocity of the blast may require. K, the bottom of the hearth, two feet square. L, the top of the hearth two feet six inches square. KL, the height of the hearth six feet six inches. L is also the bottom of the boshes, which here terminate of the same size as the top of the hearth; only the former are round, and the latter square. M, the top of the boshes, 12 feet diameter and eight feet of perpendicular height. N, the top of the furnace, at which the materials are charged; commonly three feet diameter. MN, the internal cavity of the furnace from the top of the boshes upwards, 30 feet high. NK, total height of the internal parts of the furnace, $44\frac{1}{2}$ feet. OO, the lining. This is done in the nicest manner with fire bricks made on purpose, 13 inches long and three inches thick. PP, a vacancy which is left all around the outside of the first lining, three inches broad, and which is beat full of coke-dust. This space is allowed for any expansion which might take place in consequence of the swelling of the materials by heat when descending to the bottom of the furnace. QQ, the second lining, similar to the first. R, a cast-iron lintel, on which the bottom of the arch is supported. RS, the rise of the arch. ST, height of the arch; on the outside 14 feet, and 18 feet wide. VV, the extremes of the hearth, ten feet square. This and the bosh-stones are always made from a coarse gritted freestone, whose fracture presents large rounded grains of quartz, connected by means of a cement less pure.

Fig. 4.

Fig. 4. represents the foundation of the furnace, and a full view of the manner in which the false bottom is constructed.

AA, the bottom stones of the hearth. B, stratum of bedding sand. CC, passages by which the vapours, which may be generated from the damps, are passed off. DD, pillars of brick. The letters in the horizontal view, of the same figure, correspond to similar letters in the dotted elevation.

Fig. 5.

Fig. 5. AA, horizontal section of the diameter of the boshes, the lining and vacancy for stuffing at M. C, view of the top of the hearth at L.

Fig. 6.

Fig. 6. vertical side-section of the hearth and boshes; shewing the tymp and dam-stones, and the tymp and dam-plates. *a*, the tymp-stone. *b*, the tymp-plate, which is wedged firmly to the stone, to keep it firm in case of splitting by the great heat. *c*, dam-stone, which occupies the whole breadth of the bottom of the hearth, excepting about six inches, which, when the furnace is at work, is filled every cast with strong sand. This stone is surmounted by an iron plate of considerable thickness, and of a peculiar shape *d*, and from this called the dam-plate. The top of the dam-stone and plate is two, three, or four inches under the level of the tuyere hole. The space betwixt the bottom of the tymp and the dotted line is also rammed full of strong sand, and sometimes fire-clay. This is called the tymp-stopping, and prevents any part of the blast from being unnecessarily expended.

The square of the base of this blast-furnace is 38 feet; the extreme height from the false bottom to the top of the crater is 55 feet.

Mode of operation.

Having given the above description of the construction of the furnace, Mr Mushet next proceeds to take a view of its mode of operation and management. "The operations (he observes) I am about to describe have never as yet received any explanation consonant to true philosophy or chemical facts; yet there are few which present

Furnace. present a more beautiful chain of affinities, decomposition, and recombination, than the manufacture of iron in all its various stages. An extensive foundery is a laboratory fraught with phenomena of the most interesting nature in chemistry and natural philosophy: are we not then justly surprised to find that prejudice still reigns there; and that the curious manipulations of these regions are still shrouded with error and misconception; as if their dingy structure forbade the entrance of genius, or consigned her laborious unlettered sons to an endless stretch of mental obscurity?"

Having described the furnace, he continues, "I shall proceed to detail the train of preparation necessary before the furnace is brought to produce good melting iron.

Putting in preparation.

"The furnace being finished, the bottom and sides of it, for two feet up the square funnel, receive a lining of common bricks upon edge, to prevent the stones from shivering or mouldering when the fire comes in contact with it. On the front of the furnace is erected a temporary fire-place, about four feet long, into the bottom of which are laid corresponding bars. The side-walls are made so high as to reach the under surface of the tymp-stone; excepting a small space, which afterwards receives an iron plate of an inch and a half thick, by way of a cover: This also preserves the tymp-stone from any injury it might sustain by being in contact with the flame. A fire is now kindled upon the bars, and is fed occasionally with small coals. As the whole cavity of the furnace serves as a chimney for this fire, the draught in consequence is violent, and the body of heat carried up is very considerable. In the course of three weeks the furnace will thus become entirely free from damp, and fit for the reception of the materials: when this is judged proper the fire-place is removed, but the interior bricks are allowed to remain till the operation of blowing commences. Some loose fuel is then thrown upon the bottom of the furnace, and a few baskets of cokes are introduced; these are allowed to become thoroughly ignited before more are added. In this manner the furnace is gradually filled; sometimes entirely full, and at other times 5-8ths or 3-4ths full. The number of baskets full depend entirely upon the size of the furnace: that in the plate will contain 900 baskets. If the coal is splint, the weight of each basket-full will be nearly 110lb. $\times$ 900=99,000lb. cokes. As this quality of cokes is made with a loss of nearly 50 per cent. the original weight in raw coals will be equal to 198,000lb. When we reflect that this vast body of ignited matter is replaced every third day, when the furnace is properly at work, a notion may be formed of the immense quantity of materials requisite, as also the consequent industry exerted to supply one or more furnaces for the space of one year.

"When the furnace is sufficiently heated throughout, specific quantities of cokes, iron-stone, and blast-furnace cinders are added: these are called charges. The cokes are commonly filled in baskets, which, at all the various iron-works, are nearly of a size. The weight of a basket, however, depends entirely upon the nature and quality of the coal, being from 70 to 112lb. each (D). The iron-stone is filled into boxes, which, when moderately heaped, contain 56lb. of torrefied iron-stone; they often exceed this when the stone has been severely roasted. The first charges which a furnace receives, contain but a small proportion of iron-stone to the weight of cokes: this is afterwards increased to a full burden, which is commonly four baskets cokes, 320lb.; two boxes iron-stone, 112lb.; one box of blast-furnace cinders, 60 or 70lb. (E). At new works, where these cinders cannot be obtained, a similar quantity of limestone is used.

Furnace. Charging it.

"The descent of the charge, or burden, is facilitated by opening the furnace below two or three times a-day, throwing out the cold cinders, and admitting, for an hour at a time, a body of fresh air. This operation is repeated till the approach of the iron-stone and cinder, which is always announced by a partial union, and the dropping of lava through the iron bars, introduced to support the incumbent materials while those on the bottom are carried away. The filling above is regularly continued, and when the furnace at the top has acquired a considerable degree of heat, it is then judged time to introduce the blast; the preparations necessary for which are the following:—

Time to apply the blast.

"The dam-stone is laid in its place firmly imbedded in fire-clay; the dam-plate is again imbedded on this with the same cement, and is subject to the same inclination. On the top of this plate is a slight depression, of a curved form, towards that side farthest distant from the blast, for the purpose of concentrating the scoria, and allowing it to flow off in a connected stream, as it tends to surmount the level of the dam. From this notch to the level of the floor a declivity of brick-work is erected, down which the scoria of the furnace flows in large quantities. The opening betwixt the dam and side-walls of the furnace, called the *fauld*, is then built up with sand, the loose bricks are removed, and the furnace bottom is covered with powdered-lime or charcoal-dust. The ignited cokes are now allowed to fall down, and are brought forward with iron bars nearly to a level with the dam. The space between the surface of the cokes and the bottom of the tymp-plate is next rammed hard with strong binding sand; and these cokes, which are exposed on the outside, are covered with coke-dust. These precautions being taken, the tuyere-hole is then opened and lined with a soft mixture of fire clay and loam: the blast is commonly introduced into the furnace at first with a small discharging-pipe, which is afterwards increased as occasion may require. In two hours

(D) "This same variety in the coal renders it almost impossible, under one description, to give a just idea of the proportions used at various blast furnaces: to avoid being too diffuse, I shall confine my description connected with a coal of a medium quality, or a mixture of splint and free-coal, a basket of which will weigh from 78lb. to 84lb.

(E) "A preference at first is always given to blast-furnace cinders in place of lime; being already vitrified, they are of much easier fusion, and tend to preserve the surface of the hearth by glazing it over with a black vitrid crust.

Furnace. hours after blowing, a considerable quantity of lava will be accumulated; iron bars are then introduced, and perforations made in the compressed matter at the bottom of the furnace; the lava is admitted to all parts of the hearth, and soon thoroughly heats and glazes the surfaces of the fire-stone. Shortly after this it rises to a level with the notch in the dam-plate, and by its own accumulation, together with the forcible action of the blast, it flows over. Its colour is at first black; its fracture dense and very ponderous; the form it assumes in running off is flat and branched, sometimes in long streams, and at other times less extensive. If the preparation has been well conducted, the colour of the cinder will soon change to white; and the metal, which in the state of an oxyde formerly coloured it, will be left in a disengaged state in the furnace. When the metal has risen nearly to a level with the dam, it is then let out by cutting away the hardened loam of the fauld, and conveyed by a channel, made in sand, to its proper destination; the principal channel, or runner, is called the *sow*, the lateral moulds are called the *pigs*.

Fused metal let out.

"In six days after the commencement of blowing, the furnace ought to have *wrought herself clear*, and have acquired capacity sufficient to contain from 5000 to 7000 weight of iron. The quality ought also to be richly carbonated, so as to be of value and estimation in the pig-market. At this period, with a quality of coal as formerly mentioned, the charge will have increased to the following proportions:—Five baskets cokes, 400lb.; six boxes iron-stone, 336lb.; one box limestone, 100lb.

"An analysis of the smelting operation, and the tendency which the individual agents have to produce change in the quality and quantity of the iron, come next under consideration. Let us, however, first notice the characteristic features exhibited by the different kinds of iron while in fusion, whereby the quality of the metal may be justly defined.

Characters of the produce.

"When fine (N° 1.) or super-carbonated crude iron is run from the furnace, the stream of metal, as it issues from the fauld, throws off an infinite number of brilliant sparkles of carbone. The surface is covered with a fluid pellicle of carburet of iron, which, as it flows, rears itself up in the most delicate folds: at first the fluid metal appears like a dense, ponderous stream, but, as the collateral moulds become filled, it exhibits a general rapid motion from the surface of the pigs to the centre of many points; millions of the finest undulations move upon each mould, displaying the greatest nicety and rapidity of movement, conjoined with an uncommonly beautiful variegation of colour, which language is inadequate justly to describe. Such metal, in quantity, will remain fluid for 20 minutes after it is run from the furnace, and when cold will have its surface covered with the beautiful carburet of iron, already mentioned, of an uncommonly rich and brilliant appearance. When the surface of the vessel is not carbureted, it is smooth like forged iron, and always convex. In this state iron is too rich for melting without the addition of coarse metal, and is unfit to be used in a cupola furnace for making fine castings, where thinness and a good skin are requisite.

"N° 4. or oxygenated crude iron, when issuing from the blast furnace, throws off from all parts of the fluid surface a vast number of metallic spars: they arise from a different cause than that exerted in the former instance. The extreme privation of carbone renders the metal subject to the combination of oxygen so soon as it comes into contact with atmospheric air. This truth is evidently manifested by the ejection of small spherules of iron from all parts of the surface; the deflagration does not, however, take place till the globule has been thrown two or three feet up in the air; it then inflames and separates with a slight hissing explosion, into a great many minute particles of a brilliant fire. When these are collected they prove to be a true oxyde of iron, but so much saturated with oxygen, as to possess no magnetic obedience. The surface of oxygenated iron, when running, is covered with waving flakes of an obscure smoky flame, accompanied with a hissing noise; forming a wonderful contrast with the fine rich covering of plumbago in the other state of the metal, occasionally parting and exhibiting the iron in a state of the greatest apparent purity, agitated in numberless minute fibres, from the abundance of the carbone united with the metal.

"When iron thus highly oxygenated comes to rest, small specks of oxyde begin to appear floating upon the surface: these increase in size; and when the metal has become solid, the upper surface is found entirely covered with a scale of blue oxyde of various thicknesses, dependent upon the stage of oxygenation or extreme privation of carbone. This oxide, in common, contains about 15 per cent. of oxygen, and is very obedient to the magnet. In place of a dark blue smooth surface, convex and richly carbonated, the metal will exhibit a deep, rough, concave face, which, when the oxyde is removed, presents a great number of deep pits. This iron in fusion stands less convex than carbonated iron, merely because it is less susceptible of a state of extreme division; and indeed it seems a principle in all metallic fluids, that they are convex in proportion to the quantity of carbone with which they are saturated. This iron flows dead and ponderous, and rarely parts in shades but at the distance of some inches from each other.

"This is a slight sketch of the appearance of the two extreme qualities of crude or pig iron, when in a state of fusion. According to the division formerly made, there still remain two intermediate stages of quality to be described: these are, carbonated and carbo-oxygenated iron; that is N° 2. and 3. of the manufacturers. Carbonated iron exhibits, like N° 1. a beautiful appearance in the runner and pig. The breakings of the fluid, in general, are less fine; the agitation less delicate; though the division of the fluid is equal, if not beyond that of the other. When the internal ebullition of the metal is greatest, the undulating shades are smallest and most numerous: sometimes they assume the shape of small segments; sometimes fibrated groups; and at other times minute circles, of a mellower colour than the ground of the fluid. The surface of the metal, exposed to the external air, when cooling, is generally slightly convex, and full of punctures: these, in iron of a weaker and fusible nature, are commonly small in the diameter, and of no great depth. In strong metal the punctures are much wider and deeper. This criterion, however, is not infallible, when pig-iron of different works, is taken collectively. At each individual work, however, that iron will be strongest whose honeycombs are largest and deepest.

"Carbo-

"Carbo-oxygenated, or N° 3. pig-iron, runs smoothly, without any great degree of ebullition or disengagement of metallic sparks. The partings upon its surface are longer, and at greater distances from each other than in the former varieties: the shape they assume is either elliptical, circular, or curved. In cooling, this metal acquires a considerable portion of oxyde; the surface is neither markedly convex nor concave; the punctures are less, and frequently vanish altogether. Their absence, however, is no token of a smooth face succeeding: in qualities of crude iron oxygenated beyond this, I have already mentioned that a concave surface is the consequence of the extreme absence of carbone; and that, in proportion as this principle is absent, the surface of the iron acquires roughness and asperity.

"It may perhaps be proper here to mention, once for all, that although, for convenience, the manufacturer has, from a just estimation of the value of the metal in a subsequent manufacture, affixed certain numbers for determinate qualities of iron, yet it is difficult to say at what degree of saturation of carbone each respective term commences: suffice it then to say, that the two alternative principles, oxygen and carbone, form two distinct classes, that in which oxygen predominates, and that in which carbone predominates; the latter comprehends N° 1. and 2. of the manufacturers, the former includes oxygenated, white and mottled; and the equalization of these mixtures form, as has already been noticed, the variety of carbo-oxygenated crude iron.

"I shall now observe some things relative to the various faces which crude iron assumes. N° 1. and 2. with their intermediate qualities, possess surfaces more or less convex, and frequently with thin blisters: this we attribute to the presence of carbone, which being plentifully interspersed betwixt and throughout the particles of the metal, the tendency which the iron has to shrink in cooling is entirely done away; it tends to distend the aggregate of the mass, and to give a round face, by gradually elevating the central parts of the surface, which are always last to lose their fluidity.

"Again, that quality of iron known by the name of N° 3. or carbo-oxygenated, is most commonly found with a flat surface. If we still farther trace the appearance of the surface of pig-iron, when run from the furnace, we shall find N° 4. either with a white or mottled fracture, possessed of concave faces rough and deeply pitted. Beyond this it may be imagined that every degree of further oxygenation would be productive of a surface deeper in the curve, and rougher, with additional asperities. The contrary is the case: when crude iron is so far debased as to be run from the furnace in clotted lumps highly oxygenated, the surface of the pigs is found to be more convex than that of N° 1. iron; but then the fracture of such metal presents an impure mass covered on both faces with a mixture of oxydated iron, of a blueish colour, nearly metallic. In short, this quality of iron is incapable of receiving such a degree of fluidity as to enable us to judge whether the convexity of its surface is peculiar to its state, or is owing to its want of division as a fluid, whereby the gradual consolidation of the metal is prevented.

"These features sufficiently distinguish betwixt the various qualities of crude iron after they are obtained from the blast furnace: there are, however, criterions not less infallible, whereby we can prejudge the quality of the metal many hours before it is run from the furnace. These are the colour and form of the scoria, the colour of the vitrid crust upon the working bars, and the quantity of carburet which is attached to it. The variety of colour and form in the cinder almost universally indicate the quality of the metal on the hearth. Hence, from a long course of experience, have arisen the following denominations: "Cinder of sulphury iron;" "Cinder of N° 1. N° 2. and N° 3.;" and "Cinder of ballast iron." Although at different works, from local circumstances, the same kind of scoria may not indicate precisely the same quality of iron, yet the difference is so small that the following description of the various cinders may convey a very just idea of their general appearance.

Determined from the colour and form of the scoria.

"When the scoria is of a whitish colour and short form, branching from the notch of the dam, and emitting from its stream beautiful sparks of ignited carbone, resembling those ejected from a crucible of cast steel in fusion, exposed to external air, or to the combustion of fine steel filings in a white flame; if, when issuing from the orifice of the furnace, it is of the purest white colour, possessing no tenacity, but in a state of the greatest fluid division, and, when cold, resembles a mass of heavy torrefied spar, void of the smallest vitrid appearance, hard and durable, it is then certain that the furnace contains *sulphury iron*, i. e. super-carbonated iron. At blast furnaces, where a great quantity of air is thrown in per minute, super-carbonated crude iron will be obtained with a cinder of a longer form, with a rough flint fracture towards the outside of the column.

"That cinder which indicates the presence of carbonated iron in the hearth of the furnace, forms itself into circular compact streams, which become consolidated and inserted into each other; these are in length from three to nine feet. Their colour when the iron approaches the first quality, is a beautiful variegation of white and blue enamel, forming a wild profusion of the elements of every known figure; the blues are lighter or darker according to the quantity of the metal and the action of the external air while cooling. When the quality of the pig-iron is sparingly carbonated, the blue colour is less vivid, less delicate; and the external surface rougher, and more sullied with a mixture of colour. The same scoria, when fused in vessels which are allowed to cool gradually, parts with all its variety and shade, and becomes of a yellowish colour, sometimes nearly white when the quantity of incorporated metals has been small.

"The cinder which is emitted from the blast furnace when carbo-oxygenated (or N° 3.) iron is produced, assumes a long zig zag form. The stream is slightly convex in the middle; broad, flat, and obliquely furrowed towards the edges. The end of the stream frequently rears itself into narrow tapered cones, to the height of six or eight inches: these are generally hollow in the centre, and are easily demolished, owing to their excessive brittleness. The colour of this lava is very various; for the most it is pale yellow, mixed with green. Its tenacity is so great, that if, while fluid, a small iron hook is inserted into it at a certain degree of heat, and then drawn from it with a quick but steady motion, 20 to 30 yards of fine glass thread may be formed with ease. If the colours are vivid and variegated, the thread will possess, upon a minute scale, all the

Furnace. the various tints of colouring which is found in the columnar mass. When by accident a quantity of this lava runs back upon the discharging-pipe, it is upon the return of the blast impelled with such velocity as to be blown into minute delicate fibres, smaller than the most ductile wire; at first they float upon the air like wool, and when at rest very much resemble that substance.

"The presence of oxygenated crude iron (N° 4.) on the furnace hearth, is indicated by the lava resolving itself into long streams, sometimes branched, sometimes columnar, extending from the notch to the lowest part of the declivity; here it commonly forms large, flat, hollow cakes, or inclines to form conical figures: these are, however, seldom perfect; for the quantity of fluid lava, conveyed through the centre of the column, accumulates faster than the internal sides of the cone are consolidated; and thus, when the structure is only half finished, the small crater vomits forth its superabundant lava, and is demolished. The current of such lava falls heavily from the dam as if surcharged with metal, and emits dark red sparks resembling the agitation of straw embers. Its colour is still more varied than the former descriptions of scoriæ, and is found changing its hues through a great variety of greens shaded with browns. Another variety of scoria, which indicates the same quality of iron, assumes a similar form; but has a black ground colour mixed with browns, or is entirely black. When the latter colour prevails, the texture of the cinder becomes porous; the quantity of iron left is now very considerable, and such as will be easily extracted in the assay-furnace with proper fluxes. In cases of total derangement in the furnace, the scoria will still retain this black colour, although the quantity of metal may amount to 25 per cent.; the fracture, however, becomes dense, and its specific gravity increases in proportion to the quantity of metal it holds incorporated.

"The next source of information, as to the quality of the iron in the furnace, is to be got from the colour of the scoria upon the working bars, which are from time to time inserted to keep the furnace free from lumps, and to bring forward the scoria. When supercarbonated crude iron is in the hearth, the vitrid crust upon the bars will be of a black colour and smooth surface, fully covered with large and brilliant plates of plumbago.

"As the quality of the metal approaches to N° 2. (carbonated), the carburet upon the scoria decreases both in point of quantity and size.

"When carbo-oxygenated iron (N° 3.) is in the furnace, the working bars are always coated with a lighter coloured scoria than when the former varieties exist; a speck of plumbago is now only found here and there, and that of the smallest size. When the quality of the metal is oxygenated (N° 4.), not only have the plates of carburet disappeared, but also the coally colour on the external surface of the scoria; what now attaches to the bars, is nearly of the same nature and colour as the lava emitted at the notch of the dam.

"These criterions are infallible; for, as the fusibility or carbonation of the metal is promoted in a direct ratio to the comparative quantity of the coally principle in the furnace, so in the same proportion will the vitrid crust encircling the working bars exhibit the presence of that principle in the furnace.

"In the smelting operation a just proportion and association of materials and mechanical construction ought to be blended in order to produce the best possible effects. Under the former are comprehended the cokes, iron-stone, limestone, and blast; by the latter is understood the furnace, the power of the blowing-machine, or the compression and velocity under which the air is discharged into the furnace, and the genius or mechanical skill of the workmen. According to this division I shall endeavour to point out the very various effects which disproportion in any case produces, and *vice versa*.

"In the preceding observations the coal and iron stone have been traced through their various stages of preparation, and that stage pointed out in which they were most suitable for the profitable manufacture of the metal. It will be necessary to carry along with us this fact, that in the exact proportion which the quantity of carbone bears to the quantity of metal in the ore, and its mixtures, so will be the fusibility, and of course the value of the pig-iron obtained. The importance of this truth will still farther appear when we consider the very various qualities of pit-coal, the different proportions of carbone which they contain, and the various properties attached to every species of this useful combustible.

"Among the many strata of coal which I have distilled, some I have found to contain 70 parts in the 100. This large proportion is peculiar to the clod-coal, used at some of the iron works in England, and justly preferred for the purpose of manufacture, to the purest and hardest variety of splint-coal. The latter I have found to average from 50 to 59 parts of carbone in the 100; and the soft, or mixed qualities of coal, from 45 to 53 parts. Such various proportions of carbone plainly point out that the operations to be followed at each individual iron-work ought not to rest upon precedent, unless borrowed from those works where exactly the same quality of coal is used. This analysis also lays open part of the source from whence originates the widely different quantities of metal produced per week at various blast-furnaces, and the great disproportions of ore used to different coals.

"Experience has shewn that the three qualities of coal just mentioned, will smelt and give carbonation to the following proportions of the same species of torrefied iron-stone:

112 lb. of clud-coal cokes will smelt	-	130 lb.
112 lb. of splint-coal cokes will smelt	-	105 lb.
112 lb. mixed soft and hard coal cokes will smelt		84 lb.

"Let the iron-stone be supposed in the blast-furnace to yield 40 per cent. then we find that the one-twentieth of a ton of the respective qualities of cokes will smelt and carbonate the following proportions of iron, viz. 112 lb. clod-coal cokes, 130 lb. iron-stone, at 40 per cent. = 52 lb. iron; 112 lb. of splint-coal cokes, 105 lb. of the stone = 42 lb. of iron; and 112 lb. soft and hard coal cokes, 84 lb. of the iron stone = $33\frac{6}{10}$ lb. of iron. We then have for the quantity of metal produced by one ton of each quality of cokes:

Clod-coal	52	× 20 =	1040 lb.
Splint ditto	42	× 20 =	840 lb.
Mixed ditto	$33\frac{6}{10}$	× 20 =	702 lb.

"This furnishes a datum whereby we easily obtain the

the quantity of the various cokes necessary to produce one ton of carbonated crude iron by common proportion: for if 1040lb. of metal are produced by one ton, or 2240lb. of clod-coal cokes, the quantity of the same cokes requisite for the production of one ton, or 2240lb. of metal will be—

		T.	C.	Q.	lb.
	4824.6lb.=	2	3	0	8
Splint-coal cokes	840:2240::2240:5973.3lb.=	2	13	1	9
Mixed ditto	702:2240::2240:7147.5lb.=	3	3	3	7

"If to the quantity of cokes necessary to manufacture one ton of crude iron, we add the quantity of volatile matter driven off in the process of charring, which may be thus estimated upon the average of each quality:

Clod-coal	$\frac{3}{8}$ or $37\frac{1}{2}$ per c. produce in cokes	$\frac{5}{8}$ *a* $62\frac{1}{2}$ per c.
Splint coal	$\frac{4}{8}$—50	$\frac{4}{8}$ or 50
Mixed coal	$\frac{5}{8}$—62,5	$\frac{3}{8}$—$37\frac{1}{2}$

"Then, for the quantity of the respective coals used in the raw state, we have the following results in proportion.

		T.	C.	Q.	lb.
Clod-coal	5 : 4824.6 :: 8 : $7719\frac{1}{4}$ =	3	8	2	19
Splint coal	3 : 5973.3 :: 8 : 11946 =	5	6	2	18
Mixed coal	3 : 7147.1 :: 8 : $16158\frac{2}{3}$ =	8	11	0	16

Difference of produce from different kinds of coal.

"These great disproportions of quantity, used to fabricate one ton, or 2240 averdupoise pounds of the same quality of crude iron, will convey a striking and impressive idea of the multifarious qualities of coal which may be applied and made to produce the same effects. It should also convince the manufacturer that the study and analysis of his own materials is the first and radical approach to true knowledge, and certainty of operation. Divest him of this knowledge, and view him guided by the customs and rules prevalent at another manufactory, where the coals and ores may be as different as has been already mentioned, and we will no longer wonder at the uncertainty of his results, and the numberless errors of his direction.

"Before I enter into the practical discussion of the application of coal, I beg leave to indulge myself in the following calculations:—We have already seen that the production of 2240lb. of carbonated crude iron requires 4824lb. of clod-coal cokes; these may be averaged to contain 4.5 per cent. of ashes, which, deducted from 4824, gives 4607lb. of carbone used for one ton of metal: this sum, divided by 2240, farther gives, for one lb. of cast iron thus manufactured, 2.056lb. of carbone.

"We next find that 2240lb. of the same metal requires of splint coal cokes 5973.3lb.; we farther find, from a table of the analysis of coal, furnished in a former paper, that 100 parts of the raw coal contained 4.2 parts of ashes. As it is there stated to lose 50 per cent. in charring, 100 parts of cokes will contain 8.4 of ashes; and 8.4 per cent. deducted from 5973.3, gives 5472 lb. of carbone. This again, reduced by 2240lb. gives for each pound of metal manufactured, 2.442lb.

"Again, 7147.1lb. of cokes obtained from soft mixed coals are consumed for every ton of 2240 averdupoise pounds of crude iron produced; every 100 parts of the same coals contain 3.3 parts of ashes; and 100 parts of cokes contain nearly 6.5 per cent. of ashes, which, deducted from 7147.3, gives 6672.6 of carbone, which divided by 2240, gives, for the quantity used for one pound of cast iron, 2.978lb.

"From these calculations it appears, that 2240lb. of carbonated iron, requires of carbone from clod-coal 4607lb.; of carbone from splint-coal, 5472lb.; and of carbone from mixed coal, 6672lb.: that one pound of carbonated iron requires of carbone from clod-coal cokes 2.056lb.; from splint, 2.442lb.; from mixed, 2.983lb.; and that carbonated crude iron may be obtained when widely different quantities of carbone have been consumed.

"In seeking for a solution of the latter fact, we must have recourse to the different degrees of inflammability of the carbone, according to the various laws of continuity imposed upon it in its fossil construction. It can easily be conceived, that owing to this structure, and the nature of the interposed ashes, the particles of carbone of some cokes will be more easily oxygenated than those of others; in the same way that we find splint-coal, when exposed to ignition in contact with open air, affords one-third of more cokes than are obtained from soft mixed coals, though the latter, when distilled, yield more pure carbone than the former.

By experiment it is proven that 100 grains of carbonic acid gas is composed of 72 parts of oxygen, united with 28 parts of carbone: if the quantity of the carbone of clod-coal, viz. 2.056lb. used for the manufacturing of every pound of cast iron, is reduced to grains, we will find it to consist of 14392 grains; this, divided by 28, gives the acidifiable principle of 514 $\times 100 = 51400$ grains of carbonic acid gas (F): hence as one cubic foot of this gas, at 29.84 of barometrical pressure, and 54.5 of temperature, weighs near 761 grains, we find that in the formation of every pound of cast iron $\frac{51400}{761} = 67.54$ cubical feet of carbonic acid gas will be formed; and in the production of one ton of metal, the astonishing quantity of 151289.60 cubic feet. This quantity, however incredible it may seem, is only what would be formed under the above pressure, and at the above temperature: when we take into the account the high temperature at which the decomposition and recombination are effected, with the consequent

(F) "This is supposing, for the moment, that the whole of the carbone is oxygenated, either by the oxygen contained in the ore, or obtained from the discharging-pipe by the decomposition of the atmospheric air: this, however, is not strictly true, as the metal takes up a small portion, by weight, of the carbone; and when, by accident, moisture has been introduced into the furnace, either through the medium of the blast, or of the materials, its decomposition furnishes a portion of both oxygen and hydrogen, which may dissolve, and also carry off, a part of the carbone. Atmospheric air being found to hold water in solution, a small quantity of hydrogen will, even in the driest weather, be present in the blast furnace.

Furnace.

quent increase of elastic force and of volume, our ideas are almost unable to commensurate the sum of the gas hourly formed, and thrown off, ignited to the highest degree of heat.

" If the same mode of calculation is adopted with the other qualities of coal, we will have the following results:

" For the splint-coal 2,442 lb. or $\frac{17094}{28} = 610{,}5 \times 100 = 61050$ grains of carbonic acid, which gives $\frac{61050}{761} = 82.85$ cubic feet for 1 lb. and $82{,}85 \times 2240 = 185.584$ cubic feet for one ton. For the mixed coal 2.983 or $\frac{20881}{28} = 710 \times 100 = 71000$ grains carbonic acid; that is, $\frac{71000}{761} = 93.3$ cubical feet for 1 lb.; and $93.3 \times 2240 = 208{,}992$ cubical feet for one ton. By the same calculation we may attain a pretty accurate notion of the quantity of atmospheric air necessary to produce 1 lb. or one ton of cast iron; an average of the three varieties of coal will be sufficiently accurate for this purpose; thus $\frac{14392 \times 17094 \times 20881}{3} = 17455\frac{2}{3}$ or 2.4935 lb. of carbone are consumed upon the average of each pound of pig-iron: this is found to produce of carbonic acid gas $\frac{17455\frac{2}{3}}{28} = 62.341 \times 100 = 62.30041$ grains; which again divided by 761, the grains in one cubic foot, gives 81.86 cubic feet for the gas discharged in manufacturing one pound of cast iron. As carbonic acid contains, as has already been noticed, 72 parts of oxygen in 100, then we have for the quantity of oxygen gas 100 : 72 :: 62400.41 : 44856.29 grains oxygen gas; and as, at the ordinary temperature and pressure of the atmosphere, a cubic foot of oxygen gas weighs 591 grains, we find 44856.29 divided by 591 = 75.89 cubic feet of oxygen gas necessary to form the acidifying principle of 81.86 cubic feet of carbonic acid gas; and that the same quantity of oxygen gas is necessary to the production of one pound of carbonated crude iron. This leads us to the following statement for the quantity of atmospheric air used during the same operation; first premising that the constituent parts of atmospheric air are nearly 73 of azote and 27 of oxygen gas; of atmospheric air then necessary, we have 27 : 100 :: 75.89 : 281 cubic feet.

" I shall now proceed from mere calculation to matter of fact, and attempt to prove the correctness of the former by the approximation of the latter to its results. Let a blast furnace be supposed to produce $20\frac{1}{2}$ tons of pig-iron per week, = 45360 avoirdupoise pounds; this divided by days, hours, minutes, and seconds, gives per day 6480 pounds, per hour 270, per minute $3\frac{1}{4}$ lb. and per second 525 grains.

" From this it is evident that one pound of cast iron is produced in $13\frac{33}{100}$ seconds; experience has shewn that a blast-furnace, producing, in any of the above periods, the respective quantity of metal, requires a discharge of air per minute nearly cqual to 1350 cubic feet; this, divided by 4,5 lb. the quantity produced per minute gives, for one pound of iron, 300 cubic feet. The quantity, by calculation, we have seen to be 281 cubic feet, difference 10; a sum no way considerable when we reflect upon the inequality of the movements of a blowing machine, and when it is recollected that some allowance ought also to be made for what air may pass through the furnace undecomposed, or may be lost at the place of entrance.

" From this coincidence of theory with practice, we cannot help admiring the rigorous principles on which the Lavoisierian system is founded; nor are we less pleased to find, that, small as the operations of the chemist may be, yet they are a just epitome of what takes place in the philosophy of extensive manufactories. The following table exhibits the quantity of carbone which may be used upon an average, with the relative quantity of carbonic acid formed, and air used:

" In the manufacture of	1 lb.—	1 ton of iron,
The pure carbone requisite is	2.49—	5585.44 lb.
Carbonic acid formed	81.86—	183366.40 cub. ft.
Oxygen gas used	75.89—	169993.60 cub. ft.
Atmospheric air employed	281.00—	629440.00 cub. ft.

" From the foregoing particulars upon coal may be learned how much is dependent upon the native construction of coal and its constituent parts; I shall next advert to the effects produced by its improper preparation.

Quality of well-charred c[...]

" When coals intended for the blast furnace are sufficiently charred, they ought, in point of colour, to be of a silver-gray: their fracture will appear lamellated and porous if splint-coals have been used; softer coals form themselves into branches slightly curved, and, when properly prepared, are always very porous. I have frequently found that the better the cokes were charred, the more water they will absorb. Coals half burnt do not take up half so much water, because their fracture continues in part to be smooth and less porous than when thoroughly burnt.

" When half-prepared cokes are introduced into the furnace, the metal formerly carbonated will lose its gray fracture, and approach to the quality of oxygenated iron. Their presence is easily detected by the unusual quantity of thick vapour arising along with the flame. Besides, the water and sulphur, which raw coals introduce into the furnace, and which always impair the quantity of carbone by the various solutions effected by the presence of oxygen, hydrogen, &c. the fitness of the coal for combustion, and the support of the ore, is much diminished by this second course of ignition and disengagement of bitumen. The pressure of the incumbent ores also fracture and reduce the cokes into small pieces, which produce a considerable portion of coke-dust; this is partly carried to the top of the furnace before the blast; sometimes below it appears in immense quantities, ignited to whiteness, and liquid as sand. Coal thus detached from the mass, exposed to the action of a compressed current of air, is unfit for conveying the carbonic principle to the metal; and as it frequently belongs to the just proportion of charcoal necessary to smelt the ores, and to carbonate their iron, its loss must be felt, and the quality of iron impaired.

Eff[...] cok[...] ly [...] ed [...] sor[...] wa[...]

" When cokes of any quality are exposed to a moist atmosphere, so as to absorb water, their effects in the blast furnace become much reduced, and the presence of the water is productive of the most hurtful consequences in the production of carbonated crude iron. I have found, by repeated experiment, that one pound of well-

well prepared cokes will, when laid in water, take up $1\frac{3}{4}$ ounce in the space of half an hour; at this rate, a basket of cokes weighing 80 lb. saturated with water, will contain 140 ounces of water, or $8\frac{3}{4}$ lb. If the charge contains six baskets, then we see that upwards of 50 lb. of water is introduced regularly along with the charge, furnishing an additional quantity of oxygen equal to $42\frac{1}{2}$ lb. and of hydrogen equal to $7\frac{1}{2}$ lb.; but it frequently happens that the cokes contain a larger portion of water than is here stated. When cokes thus surcharged are introduced in quantity into the blast furnace, the quality of the metal is not always instantaneously changed, and frequently the colour and form of the cinder remain long without any great alteration. The contact of wetted cokes with the ore is first seen by the great discharge of pale blue gas, with the whiter flame at the top of the furnace; next, the accumulating oxyde upon the surface of the pig when consolidating indicates their presence. Iron thus oxygenated frequently exhibits, while fluid, that agitation and delicate partings peculiar to carbonated metal: the remelting of this iron is never attended with advantage, and is always unprofitable to the founder.

"From the properties which have been assigned to pit-coal, the following facts may be deduced:—That charcoal is the basis of the manufacture of crude iron; that its proper application produces the most valuable quantities of pig-iron; that, by diminishing its relative proportion, or contaminating its quality by heterogeneous mixtures, the value and fusibility of the metal is lost; but, that, by a proper increase, and always in proportion to this increase, will the fusibility and value of the iron be mended. From the whole, an important lesson may be learned of the pernicious effects of water in the furnace, and how absolutely necessary it is to prepare the cokes without using water, either to damp the fires, as in the usual mode, or to cool the cinders obtained from the tar kilns, to prevent their consuming in the open air: in all this hurtful operation considerable quantities of water become fixed in the cokes, which require a very great degree of heat to expel.

"The preparation of iron stone has already been fully attended to, and the phenomena which it exhibits under every stage minutely described. In consequence of various experiments we are authorised to draw the following conclusions: That when pure calcareous iron-stone is used, it admits of having the local quantities of cokes diminished; that argillaceous requires a larger portion than the calcareous genus; and that siliceous iron-stone requires a greater proportion of fuel than any variety of the former genera. We have also seen that fusibility, either connected with strength or otherwise, is derived from the mixture of the ores; and that excessive brittleness, intimately connected with infusibility, is also derived from the same source. From a review of these facts, we are forcibly impressed with the importance of combining the prepared iron-stones with proportions of fuel suited to their various natures, in order to produce all the varieties of iron with the greatest possible economy. Contemplating farther the same subject, it is easy to be conceived that a want of knowledge of the component parts of iron-stones, and the effects which individually they produce, must lead to great uncertainty of operation in the smelting process, wherein the beautiful economy of nature, and even real property, will be often unprofitably sacrificed to precedent.

The oxygen of the iron-stone

"Besides the above causes of alteration, dependent upon mixtures of the earths, the existence of oxygen in various quantities in the ores ought never to be overlooked in proportioning the cokes to the iron-stone. This powerful agent, whose form and substance constantly eludes our vision; whose existence is only ascertained by the wonderful changes produced by its various combinations with the iron; and whose presence in the same iron-stone, in various quantities, may produce such variety of result as to characterise the ores, as containing *good* or *bad* iron, surely forms the most interesting mixture which ores or iron-stones possess. It will be a momentous epoch in the manufacture of iron when the existence of such a principle shall be fully admitted by the manufacturer, and its agency, from certain visible effects produced, adopted to explain its accompanying phenomena. Till that period he will not perceive the utility of ascertaining the quantity of oxygen, and devising economical methods of taking it from the ore. An attention to this powerful principle can alone root out those prejudices so inimical to the real interests of the manufacturer, and which seem to glance at nature, as having improvidently combined her most useful metal with mixtures which could resist the ingenuity of man, or set his comprehensive intellect at defiance. In the progress of this great inquiry, is it not possible that the present expensive exertions may in part be superseded? Is it not possible, that, by laying open the sources of information to individuals at large, a greater mass of intellect may engage in the practice of this art? While the present extensive and lofty buildings are necessary, the business is entirely confined in the hands of men of great capital: the extent of their manufactures require that a large tract of country be devoted to their supply; a natural consequence is, that innumerable tracts of land are overlooked, or held unworthy of notice, merely because they cannot, in a period necessary to clear a great capital and insure a fortune, afford the necessary supply of materials. Such situations, according to the present state of the iron business, must remain unexplored. Should, however, a desire for truth once gain footing in the manufactories of iron, and should this natural impulse of the unprejudiced mind keep pace with other branches of intellectual information, we may not despair of seeing many imperfections removed, which were the unavoidable consequence of the period of their creation.

"In the application of iron-stone in the blast furnace, the following particulars ought rigorously to be attended to:—

and its other qualities to be considered.

"1. Their mixture, whether clay, lime, or silex; their relative proportions to each other, judging according to the rules formerly laid down; which of them may admit of a diminution of fuel; which of them will afford the quality of iron at the time requisite; and which of them will be most likely, by a judicious arrangement, to give the greatest produce of metal, united with value and economy. Iron stones, united with large portions of silex, have already been stated to require a greater proportion of fuel to carbonate their metal than the other genera. When ballast or forge-pigs are wanted, it

Furnace. is obvious that siliceous iron-stones ought to be used; not that they contain a greater quantity of iron, but because they form a substitute for the other kinds, which may be more advantageously smelted for the production of more valuable qualities.

"2. The quantity of metal which each individual iron-stone may contain, is another object of consideration. Besides the proportion of mixtures, which chiefly contribute to the fusibility of iron-stones, a second degree of fusibility is dependent upon the richness of the ore in iron; this is so obvious in the use of the Cumberland and Lancashire ores, that the consequences of their introduction will be perceived, by the change of the scoria and metal, in half the time that change would be effected by ordinary iron-stones. It has been frequently noticed, that crude iron contained pure carbonic in proportion to its fusibility; then the more fusible or supercarbonated qualities must take up, comparatively, a considerable portion of the carbonaceous principle from the fuel. From this results a striking consequence, that the quantity of fuel should, over and above its relation to the mixtures, bear a just proportion to the quantity of iron in the stone: for example, let the weight per charge of fuel at a blast furnace be 400lb. and let this be supposed sufficiently to fuse and carbonate the iron contained in 360lb. of iron-stone; let the quantity of metal be supposed 35 per cent. then the produce will be 126lb. Should a change take place, and iron stone richer in iron be applied, though the same by weight, and should this iron stone yield of torrefied stone 45 per cent. its produce will be 162lb. or 40lb. more than the former. As there exists no greater proportion of carbone in the furnace, it is evident that the existing quantity, being distributed over nearly one-third of more metal, must therefore be in more sparing quantity in the whole, and the value of the metal consequently reduced.

Quantity of fuel to be proportionate to the richness of the ore.

"3. The weight of oxygen contained in iron stones is the next object of serious consideration. I have already shewn, from experiment, that our iron stones naturally contain from 9 to 14 per cent. of oxygen, which remains after torrefaction; it has also been shewn, that this quantity of hurtful mixture may be easily doubled by over-roasting or under-roasting the stone; and that the bad effects entailed are in the ratio of its combination with the iron. From a review of the facts which have been adduced on this subject, its agency and effects will easily be credited by men of science; its property of constituting the acidifying base of all the acids readily explains the unalienable consequence of its presence with acidifiable bases. The effects are still more pernicious when the oxygen is furnished by the decomposition of water in raw iron stone; the hydrogen in this case, set free, also seizes a portion of the carbone; and these abstractions, united to that produced by the native portion of oxygen in the stone, form an aggregate which frequently reduces the value of iron 40 per cent. So long as the principles of science are overlooked in the manipulations of the foundery and forge, the existence of such agents will be treated as chimeras of the philosopher and the chemist, and the effects hourly produced by them industriously attributed to causes which, in point of unity or consistency, will not bear the slightest touch of investigation*."

* Phil. Mag. vol. v.

The compression, velocity, and effects of the air are of the utmost importance in blast furnaces. The productions, management, and direction of these effects are therefore serious objects of consideration to the manufacturer of iron, since on their proper application the success of his operation chiefly depends. And here we shall renew our obligations to Mr Mushet for his interesting observations on this subject. "When it is considered," he says, "that in the smelting operation the reduction of immense quantities of materials is effected by a compressed current of air impelled by the whole power of a blowing machine, the consequences of the change of air, either in quantity or quality, must be very obvious: when, farther, we contemplate the metal called into existence by means of combustion thus excited; when we consider iron as having the most powerful affinity for the base of that part of the air which maintains combustion; and when we view the debased state to which the metal is reduced by coming into improper contact with it, we must conclude, that the application of blast in the manufacturing of iron calls for the most minute and thorough investigation. In order to take a comprehensive view of this subject, the following division will be requisite:—

"1st, The intimate connection which the quantity of blast bears to the area of the internal cavity of the furnace, and to the nature of the pit-coal.

"2d, The various modes by which air is procured, and how these respectively affect the quality of the air.

"3d, The various changes to which air is subjected by a change of temperature in the atmosphere, with the consequent effects.

"4th, How far increased or diminished velocity and compression alter the results of the furnace.

"5th, The form and diameter of the discharging-pipe.

"1st, Then, in the construction of a blast-furnace and blowing-machine, the quantity of air to be used ought to depend upon the internal dimensions of the former; which, again, ought to be formed according to the quality of the pit-coal. Upon the softness or hardness of the coal, ought more immediately to depend the height of the blast-furnace. This necessary precaution has given rise to a vast variety of furnaces, of different capacities, from 30 to 50 feet in height, and from nine to 16 feet diameter at the boshes. Furnaces from 30 to 36 feet are used for the softer qualities of coal, such as a mixture of free-coal and splint. Furnaces from 36 to 45 are appropriated to the burning of splint-coal cokes; and in Wales, such is the superior strength and quality of the pit-coal, that the furnaces admit of being reared to the height of 50 feet.

"These various qualities of coal, it has been formerly shewn, have appropriate weights of iron-stone, and, to use the language of the manufactory, are capable "of supporting a greater or less burden of mine." The former qualities admit not of having the air discharged in great quantity, unless it is impelled under an uncommon degree of compression and consequent velocity, incompatible with the operations of a steam-engine. The reason is obvious: when air, loosely compressed, or comparatively so, is thrown into a body of ignited fuel, the mechanical structure and continuity of whose particles are soft, the air is much more easily decomposed; the ignition, of course, is more rapid: the descent of the materials is promoted beyond their proper ratio, and long

Furnace.

long before the carbonaceous matter has penetrated the ore, or united to the metal, to constitute fusibility. I shall adduce an example, as being the most illustrative of this doctrine.

Illustrated by example.

"Suppose a blast furnace, 35 feet high, 11 wide at the boshes, properly burdened, and producing No 1. pig-iron. Let the discharge of the air be supposed equal to a pressure of two pounds and a half upon the square inch, or equivalent to one-sixth of the atmosphere, or five inches of mercury: under these circumstances let it farther be supposed, that 1500 cubical feet of air are discharged in one minute; and that the diameter of the discharging pipe is 2.625, the area of which is equal to 6.890625 circular inches. Let the discharging pipe be increased to three inches diameter, and let the same quantity of air be passed into the furnace; it is evident that as the area of the discharging pipe is increased to nine circular inches, or nearly one-third more than formerly, the compression of air must be proportionally diminished. The alteration is soon perceived by its effects; the quantity of scoria increases from the furnace, whilst the consumption of the materials above is also considerably augmented. In a few hours the scoria will have undergone a complete change, from pure white, enamelled with various blue shades, to a green, brown, or black colour, considerably charged with the oxide of iron (G). The same effects will continue, in greater or lesser degree, till all the materials are reduced which were existing in the furnace at the period of diminished compression. The philosophy of this fact may be investigated in the following manner:—

"While the just association of proportions remained, the air was discharged under such a degree of compression as to excite proper combustion: the decomposition of the air by means of the ignited fuel, was not effected in immediate contact with the separating metal, but had, by its uncommon degree of density, resisted decomposition in the ignited passage, and had been decomposed upon the cokes at a greater elevation in the furnace. As a proof of this, we frequently see a tube formed throughout the whole breadth of the furnace, quite black and apparently cold, formed of the fused materials: when this is removed, a considerable descent momently takes place of cokes heated visibly beyond the common pitch: these inflame rapidly, but are soon again cooled to blackness by the incessant discharge of air upon them. The descending mixture of iron and lava is in like manner cooled along the line of blast; the tube is again formed, and, if not removed, will remain for days together, while the furnace will be otherways working in the best manner.

"When by accident or design the compression and velocity of blast are diminished, the tube begins to burn, and throws off a great many fiery-coloured sparks, the sides and roof fail, and are carried before the blast in all directions. Sometimes considerable clots of imperfect iron are recoiled with such violence as to escape the vortex of blast, and issue from the tuyere-hole with such velocity as to inflame the air, and fall down in the state of oxide. In the end the tuyere will appear to flame, and all the passage inwards shews an astonishing degree of whiteness. The decomposition of the air is instantaneously effected upon its entering the ignited passage; the iron by this means is exposed to the oxygen that is disengaged; and the vast quantity of caloric set free, in consequence of its union with the iron and carbone, produces the astonishing heat now visible, but which formerly took place at a more proper height in the furnace.

"From this it will appear, that although a greater apparent degree of heat is visibly produced by the sudden decomposition of the air, and a more rapid descent of materials for some time is the consequence, yet, as the quality of the iron is impaired, and as in the end the furnace will return to its old consumption of materials as to quantity, the effects of a loose soft blast are obviously pernicious.

Pernicious effects of moisture in the air or in the fuel.

"It sometimes happens, that when a loose blast is surcharged with a considerable portion of moisture, or comes in contact with cokes which had been wet when introduced into the furnace, the inflammation which takes place at the tuyere is prodigious: fine fire clay will be melted down and blown to slag in a few minutes; the sides of the furnace, composed of very infusible fire stone, are next attacked, and in a few hours will be so completely destroyed as to stop the working, and require immediate repair. Effects similar to those now described will be felt when the blast is improperly proportioned to coal of a stronger continuity of fracture and superior quality. Besides the effects produced by the sudden decomposition of iron, others of like nature are produced where a soft coal is used, a small furnace, and a great discharge of blast.

"It has been found that crude iron, to be properly matured, ought to remain in the blast furnace, according to circumstances, 48 to 60 hours; that is, from the period that the iron stone is introduced till such time as the metal begins to occupy its place in the hearth in a state of perfect separation. When the contrary is the case, the mixture arrives at the hottest part of the furnace before the metal has taken up a sufficient quantity of carbone from the fuel; the action of the blast, and the immediate heat by which the ore is surrounded, forces the iron from its connections to the bottom of the furnace. The quality is de-carbonated, and reduced in its value: to restore this again, the local portion of fuel is increased; this adds to the expence of manufacturing, and diminishes, in some measure, the smelting of the furnace.

"When splint-coal cokes are used in the blast-furnace, the blast admits of being thrown in under the highest possible pitch of compression; the uncommon density of the charcoal sustains a very powerful discharge of blast before it is dissipated to facilitate the general descent. Most frequently, large masses of these cinders pass through the whole ignited cavity, and are thrown out below, possessing all the acuteness of their original form and fracture.

"This quality of coal is used in all the Curson blast furnaces, where, to ensure a respectable produce, the air is discharged under a pressure equal to $3\frac{1}{4}$ pounds upon the square inch, or $6\frac{1}{2}$ inches of mercury.

Nn 2 "The

(G) "The metal will have lost nearly all its carbone, and have become inferior in value 25 to 30 per cent.

Furnace.

"The same quality of coal was used at the Devon iron works, where at one time, having all the blast of a 48 inch cylider engine thrown into one furnace, the column of mercury supported was upwards of seven inches; the quantity of air discharged under such an impelling power, I found to exceed 2600 cubical feet per minute.

"The coals used at the Cleugh, Cleland, and Clyde iron works, are nearly of the same quality at each—a mixture of splint and soft coal. The Muirkirk and Glenbuck iron works have a coal different from any of the former, and in some particular spots it considerably resembles the English clod coal.

Methods of directing air into the furnace,

"2d, The various methods of procuring air for the blast furnace may be reduced to the following:—1st, That procured by cylinders, and discharged into the furnace by means of a floating piston heavily loaded, and working in a large receiver or regulating cylinder:—2d, That wherein pumping cylinders only are used, and the air thrown into chests inverted in water, called the *water vault*: 3d, That mode wherein the air is discharged from the pumping or forcing cylinder into an air-tight house, called the *air vault*.

by cylinders and water blowing machines;

"The first method is the original mode of blowing, and is still much used at those iron works whose erection has been prior to the last fifteen years. By this mode the quality of the air is less subject to alteration by a change of atmosphere. The principal objection to this manner of blowing, is the want of capacity in the receiving cylinder; which cannot be increased so much as to take away the considerable intervals which occur at different parts of the engine stroke. This effect is sensibly seen by the speedy and irregular ascent and descent of the column of mercury. In water blowing machines, where the air is raised by three or four cylinders worked by means of a crank, and where the air is received into an air chest, and forced into the furnace by the continual action of the blast of each successive cylinder, the current of the air is steady, and supports the column of mercury with great uniformity.

by means of the water vault.

"The use of the water vault has of late years become very general among new erected works. Its properties are, a steady and very cold blast: the largeness of the receiving cisterns gives them a sufficient capacity to retain every pound of air raised by the furnace, and distribute it to the greatest advantage. This is not the case with the floating pistons, where a certain quantity of spare wind is thrown out at every return of the engine, lest the great piston and weight should be blown out of the cylinder altogether; which, indeed, sometimes happens. The only objection which remains in force against the use of the water-vault, is the tendency which the air has to take up a considerable portion of water in solution, and introduce it into the furnace. A judicious arrangement of the conducting pipes would in some measure obviate this, as well as the more dangerous tendency which water has to rise in a pipe speedily emptied of its air by the stopping of the engine: a stream of water thus conveyed to the furnace would be productive of the most awful consequences.

The air vault.

"The air afforded by the air vault is much inferior to that obtained in the former methods. This immense magazine of compressed air generates a considerable portion of heat, which greedily seizes the damps, which are unavoidable in underground excavations, and conveys them to the furnace. The blast is, however, steady and uniform; and when the inside of the building is completely secured against the passage of air, it is productive of considerable effects in the furnace. In the summer months, however, the air becomes so far debased as to affect the quality of the iron, and change it from gray to white. Every change in the temperature of the atmosphere during this period, is indicated by various changes in the furnace.

"The largest air-vault hitherto in use was excavated out of solid rock at the Devon iron works; the fissures of the rock admitted considerable quantities of water; and the same degree of damp would always prevent the possibility of making the side walls and roof air-tight by means of pitch and paper, &c.

Quality and equality of the current.

"Besides the various natures of blast, as to the strength and equality of the current afforded by different modes of constructing the blowing machines, a variety in the quality of the air obtained is also an invariable consequence: this is sufficiently known by the effects which it produces in the blast furnace, and ought to be subject to scrupulous examination.

"In this, as in other countries, larger produces of cast iron are obtained in the winter months than during the summer and autumn seasons: the quality of the metal is also much more carbonated, and with a less proportion of fuel. In many parts of Sweden, where the summer heats are intense, the manufacturer is obliged to blow out or stop his furnace for two or three months: not only is he unable to make carbonated metal, but is frequently incapable of keeping the furnace in such trim as to make a produce of any quality whatever. In Britain, during the months of June, July, and August, more especially in dry seasons, the quality of the iron, with the local proportion of fuel, will be depreciated 30 per cent. and the quantity reduced to two-thirds or three-fourths.

"In seeking for a solution of this universally acknowledged fact, our attention is naturally directed to an examination of the various states of air. That the quality of the air in winter is more fit for combustion than in summer, is a truth which requires no farther demonstration. Greater coolness, whereby an almost complete refrigeration of moisture takes place, and the presence of perhaps a greater relative proportion of oxygen, may account for this phenomenon. On the contrary, the quality of air during the summer months becomes much contaminated for combustion, by holding in solution a much greater quantity of moisture: the abundance of nitrous particles may also diminish the usual proportion of oxygen.

"This will account for the inferior effects of combustion both in common fires and in the blast furnace; it will also in a great measure tend to solve the curious phenomenon of the pig-iron taking up less carbone in summer, although reduced with a superior quantity of fuel. The air discharged most probably contains less oxygen; yet the metal is much less carbonated than at other times, when contrary proportions of these exist. Most probably the deficient carbone is carried off by dissolving in hydrogen, forming a constant stream of hydro-carbonic gas, while the oxygen that is set free unites to the iron; and while it reduces its quality, at the

the same time the quantity is reduced by a portion of the metal being lost in the scoria (H).

"To correct these occasional imperfections in the quality of the air, and to devise methods to procure air always fit for proper combustion, ought to be an object of much consideration to the manufacturer of cast iron. Whether such a consideration has given rise to the different modes of receiving and discharging the air now in use, I cannot say; I rather think not: a great quantity of air has hitherto been a greater object than a certain and uniform quality; and in a country where there is more temperate and cold weather than hot, it is by far the most important object: to unite both, however, would be an attainment of the greatest utility, and would rank the discoverer amongst the well-deserving of his country. How far the mechanism of our present machinery has been adapted to the exigencies of our atmosphere, will appear upon examining the nature and properties of the air, judged by its effects upon the blast furnace.

"The air produced by the blowing and receiving cylinder is less changed, and less subject to change, than that produced and lodged in contact with a vast body of air or water. If the blowing cylinder is fixed in a dry cool spot, the only difference which the air undergoes is an increase of temperature; this is so very considerable, that upon entering the blowing cylinder immediately after stopping the engine, I have found the thermometer rise 15 to $17\frac{1}{2}$ degrees higher than the surrounding air. That this heat is generated in the cylinder is unquestionable; but whether it is occasioned by the friction of the piston leather upon the sides of the cylinder, or expressed from the air by its severe compression, I have not yet been able to decide. It very probably arises from both causes, although the latter is sufficient to produce a much greater degree of heat. What effect this increase of temperature has upon combustion we are unable to say, as the degree of heat accumulated will at all times bear a reference to the temperature of the surrounding air, and as there is no method likely to be devised where heat would not be generated by the action of the particles of air upon each other. When the bulb of a thermometer is held in the middle of the current of blast, as it issues from the discharging pipe, a temperature is indicated as much lower than the temperature of the surrounding air, as the temperature of the cylinder was higher; and it is most probable that a much higher degree would be obtained, were it not for the previous expression of some heat in the blowing cylinder. Upon the whole, I think, the quality of the air obtained in this way of blowing uniformly most fit for combustion, provided the numerous pauses and irregularities of the current of air were done away.

"Air forced into the furnace under water pressure always contains a considerable portion of moisture; the blast of course is colder, as it issues from the discharging pipe. The temperature differs so much from that of the external air as to sink the thermometer from 45° down to 28° and 30°. Such effects are produced by air coming into contact with water, that, although the temperature of the atmosphere is 60, 65, to 70, yet the blast at the orifice seldom rises above 38: the cold produced in this manner is much increased if the air is surcharged with so much water as to be visible in the state of a fine spray. The leading feature, therefore, of the water vault, as to its effects upon the quality of the air, seems to indicate an almost uniform degree of temperature in the blast: this can only be occasioned by the warm air in summer taking up a greater portion of the water in solution, the escape of which at a small orifice, and under a great degree of compression, produces the very great depression of the thermometer. I have already hinted at the bad effects produced by moist blasts, and shall, in a proper place, more minutely attend to them.

"The most inferior quality of air used in the blast furnace is that thrown into the air vault, and afterwards expressed from thence by its own elasticity and the successive strokes of the engine. The capacity of such a building is from 60 to 70,000 cubical feet; this, when filled, generates a much superior degree of heat to that sensible in the blowing cylinder. As this heat is produced many feet distant from any mechanical motion, it is most evident that it is extricated from the air, and will readily unite with the moisture which penetrates the building: the quality of the air introduced into the furnace will therefore be in proportion to the quantity of moisture taken up; this will be much more in summer than in winter, as the temperature of the former exceeds that of the latter. The sensation, on entering the air vault in the coldest months, immediately after stopping the engine, is exactly similar to that experienced upon entering a crowded room in the hottest summer day; the walls are covered with damp, and the superior regions of the vaults readily obscure the flame of a candle. The feeling, upon remaining in the air vault when the engine is at work, is less marked than would be expected where so great a compression of air existed; the sense of hearing, owing to the moisture in the conducting medium, is considerably impaired, and respiration is performed with some difficulty; the light of a candle is faint, and not visible at the distance of a few feet.

"I have explained the necessity of just proportions existing betwixt the area of the interior of the blast furnace, the quantity of air thrown per minute, and the quality of coal. The various modes of blowing, and their respective effects, deduced from strict observation, were also attended to. We have now, thirdly, to adduce examples where the various changes of the atmosphere, as to heat and pressure, occasion the most sensible difference in the quantity of materials consumed, and in the quality and quantity of metal produced.

"It has been already demonstrated, that the air in winter, by containing less moisture, is more proper for combustion, and more calculated to produce carbonated crude iron, than the air existing at any other season. From this superior quality the manufacturer obtains advantages, which induce him to wish for a continuance of

(H) "May not the superabundant azote of the summer atmosphere produce part of these effects, by dissolving a portion of the carbone, and forming carbonated azotic gas, as has been proved by M. Lavoisier."

Furnace.

of cool air throughout the whole year. These effects are not, however, uniform; they depend greatly upon a light or heavy atmosphere. The keener and more still the air, the more rapid the combustion. During a severe frost, the descent of the materials is facilitated from one-tenth to one-fifteenth more than in rainy or hazy weather, and at the same time the quality of the iron is rather improved than impaired. When a change from frost to snow or rain takes place, the effects frequently become almost immediately obvious; the colour of the flame at the furnace head is changed; the tuyere of the furnace inflames, and burns with great violence; the lava, as it flows from the notch of the dam stone, becomes lengthened and tenacious; the form of it is changed, and the colour undergoes the most visible alterations; the iron no longer retains its complete saturation of carbone, but flows out sensibly impaired of its fluidity; and when cold, the privation of carbone is most evident by the examination of its fracture.

Effects of a change of weather.

"When such consequences arise from the transition so frequent in winter from frost to thaw, it will be easily conceived that the change effected during the milder and warmer months must produce proportionally additional effects. The increase of temperature by taking up, and holding in solution, a much greater portion of aqueous vapour, will account for the ordinary effects which are annually observable in every work. Where these pernicious consequences approach to extremity, a solution of the phenomenon will likely be obtained by the examination of the blowing apparatus. If air is fitted for combustion in proportion as it is free from watery solutions, we are not to expect similar results from these blast furnaces in summer, which are blown by air from the regulating cylinder, and those blown by air from a water or air vault. I have for years seen this fact verified, and superior quantity and quality of iron during the hot weather, obtained from a furnace excited by means of blast, from the simple regulating cylinder, with a less proportion of fuel, than from furnaces whose air was expressed by means of the water or air vault. Observations thus made, where every day the effects of the different means could be justly estimated and compared, have led me to the following conclusion: That the quality of the air, as furnished by nature in our atmosphere, is uniformly more fit for the manufacture of crude iron to profitable account, when discharged simply by means of cylinders and pistons, than when brought into contact with moisture either in the water vault or air vault.

Air from cylinders preferred.

"So imperfect has the quality of the summer air been found in this country for combustion, where the water vault was used, that experiments have been made to repair the deficiency of effect by introducing steam into the furnace by means of an aperture above the tuyere. The inducing motive to this act, was a belief, that combustion was diminished in consequence of a diminution of oxygen gas during the summer; that, by introducing water upon a surface of materials ignited to whiteness, decomposition would ensue, a larger quantity of oxygen would then be presented to the fuel, and superior effects, as to combustion, obtained in this manner than hitherto witnessed. The idea was ingenious, and, in its application to the manufacture of cast iron, original; but the whole train of facts, which have been detailed, as to the effects of a superabundant quantity of oxygen, was overlooked. The event proved in the most complete manner, and on a great scale, the pernicious effects of moisture. The furnace gradually became cooled where the steam entered; the heat, set free by the decomposition of the water and the disengagement of the oxygen, increased to an alarming pitch a considerable way up the furnace; the quality of the iron became brittle, and as white in the fracture as silver; the introduction of the steam was still continued, the descending materials were instantly robbed of their heat to facilitate the decomposition of the water, and by and by the furnace closed entirely over, and the experiment ceased.

"This experiment, performed in a furnace 18 feet high, is a complete proof that heat is disengaged from bodies while they pass from the fluid to the aëriform state. The first instant of the discharge of steam, a very considerable portion of heat would be withdrawn from the fusing materials and united to the water. This, in its turn, would be ignited to whiteness, and decomposed upon the metals and cokes, in a superior region of the furnace. The process continuing for several hours, the materials at the tuyere were at last so completely deprived of the caloric by the continual torrent of steam, that they lost fluidity, cooled rapidly, and at last became black. Had another aperture for steam and for air been opened above these, now entirely shut up by the consolidated materials, the same effects would have been produced; the immense quantity of caloric, disengaged by the decomposition of the ignited water, would now approach nearer to the top of the furnace, another stratum of fusing materials would again become consolidated, till in the end the whole furnace would be set fast from top to bottom. From the introduction of steam into the blast furnace, either as such, or under a superior degree of expansive force, the following important truths may be learned: That the quantity of oxygen which enters into our atmospheric compound is generally more fit for the manufacture of the superior qualities of crude iron than any mixture which may be furnished by the addition of water: that, although the decomposition of water, by furnishing a superior quantity of oxygen, and by throwing off a regular proportion of caloric, increases the effects of combustion immediately in the vicinity of this chemical analysis; yet, as the water had previously abstracted the heat necessary to its decomposition from the inferior strata, a greater quantity by no means exists in the furnace. The water, in fact, only serves as a medium to convey the heat from one particular spot; but, by attempting to fly off with it, meets decomposition, and renders up not only the abstracted heat, but that which was contained in the oxygen of its decomposition.

"4th, The compression and velocity of the air discharged into the furnace, considerably affect the results of the smelting operations. In the consideration of this subject, the various qualities of coals will be found to have an intimate connexion with the area of the discharging pipe and the compression of the blast. It has already been more than once observed, that a soft or mixed quality of coal is more susceptible of combustion than either the splint or clod coal: the consequence of this is, that, unless the necessary compression of air is used, decomposition is too early accomplished, and the cokes become oxygenated by combustion in a greater ratio

Com[pres]sion velo[city] the side

ratio than is proper for the carbonation of the metal. To avoid this, the column of air ought to be discharged, in the case of soft coals being unavoidably used, under such a degree of compression, as to resist entire decomposition in the ignited passage. In that case, the iron does not so immediately come into contact with oxygen, as the decomposition is chiefly affected in the superior strata of the separating materials. Under the former circumstance, of a loose unconnected stream of air being thrown upon cokes easily combustible, the quality of the metal, with the same quantity of fuel, becomes oxygenated, the tuyere becomes fiery, and frequently emits sparks of metallic oxyde. The separating iron may be viewed as it oozes from the ore in small globular masses, frequently on fire, changing its state to that of an oxyde. The combination of oxygen, by altering its density, makes it subject to the re-action of the blast, which at times gives it a direction from the tuyere with considerable violence. Those parts of the iron (by far the greatest) thus oxydated, which escape not at the tuyere, mix along with the fused earths of the ores and limestone, alter their colour, and flow from the furnace more unrevived than at their first introduction. It is, however, very different, even with this inferior quality of coal, where the density of the blast is proportioned to the inflammability of the fuel. Qualities and quantities of crude iron may be produced from this, equal to those from coals reckoned of a superior nature. The metal becomes as highly saturated with carbonic principle as that made from clod or splint coal. The tuyere evinces that decomposition is effected in its proper place. The fluid masses of iron, as they become expressed from the ore, are shivered into spray, before the dense column of air, without exhibiting the least symptom of decomposition. They again unite under the level of the blast, increase in size, and sink through the fluid stratum of earths to the bottom of the furnace. This fact holds out one of the strongest proofs of the great affinity which carbone and iron mutually possess towards each other. In the case of the iron separating in an oxygenated state destitute of carbone, it immediately falls a prey to its affinity for oxygen. In the latter case, the iron, being completely carbonated, resists decomposition by the sacrifice of a very small portion of its carbone. It further proves, that the affinity of oxygen is greater to carbone than to iron; and that, before iron becomes oxydated, all the carbone is taken up.

"The continuity of the particles of splint coals renders the cokes of difficult combustion, capable of withstanding a most powerful discharge of air, in quantity and in the degree of compression, without entailing effects similar to those produced with the use of softer coals: this renders the operations with splint coal less subject to casuality and to change. Carbonated iron with a proper blast is more uniformly obtained, and frequently a very superior quantity. Similar effects are produced with the clod coal, but in a more eminent degree. Discharging pipes are used four inches in the diameter, and the compression only equal to two pounds on the square inch; yet the same fatal effects are not known as in the use of soft coal, which, with such a column of air, would require the pressure to be equal to three pounds and a half upon the square inch at least.

"5th, Upon the form and construction of the discharging pipe effects of more considerable importance depend than is either generally allowed or even conceived. At some iron works, no peculiar shape is adopted: if the tube is sufficient to convey the air, and the mouth of it nearly of the size wanted, the interior construction is entirely overlooked. This indifference, however, is by no means general: variously constructed pipes are used at different works, and at some places it is preferred to throw in the air from two pipes whose areas are only equal to one of the usual size.

Form of the discharging pipe important.

"To understand properly the objectionable parts of the construction of nose pipes, it must be recollected, that much has been said to depend upon the blast reaching the opposite extremity of the furnace, as little impaired of the compactness and velocity of its original discharge as possible. When it is otherwise, the results in the internal operations of the furnace must be consequently altered. If the compression is diminished one-half or two-thirds when it reaches the opposite wall, decomposition in that portion must be effected before the air has attained its elevated situation in the furnace. It is even possible to disperse the whole column of air in such a manner that the ignited materials of the opposite side may receive little of its effects to promote combustion.

"A discharging pipe is frequently used, in length 12 inches or more, the discharging aperture 3 inches, the other end 5 inches; but this is arbitrary, depending upon the size of the adjoining pipe. From a pipe thus constructed, the air disperses or diverges too suddenly; and at a small distance from the orifice, a considerable portion of it answers but imperfectly the purposes of combustion. Part of it is speedily decomposed, and the oxygen brought into immediate contact with the iron. The quantity of metal is reduced by the former, and the quality injured by the latter. Though long custom, by a continued use of such shaped pipes, has prevented their pernicious effects from being observed, yet they must prove in many cases detrimental to the economical distribution of air, and the manufacture of iron.

"A nose pipe, of another construction, even more exceptionable, is also used; and the air disperses still more suddenly, in a degree somewhat proportionate to the more sudden contracting of the pipe, a considerable quantity never enters the furnace, but, striking on the exterior wall, is thence repelled.

Best form of construction.

"A discharging pipe, of the following construction, would obviate, in a great measure, the imperfections of the two former: the length of the tapered piece is 12 inches, of the straight pipe, six inches; extreme diameter, as in the others, five inches; diameter of straight pipe, three inches. From such a pipe it is conceived that the blast will proceed to the greatest possible distance unimpaired in compression and velocity. So far, therefore, as the absolute force of the blast and breadth of the furnace will permit, decomposition will be prevented on the level of the pipe, and the manufacturer freed from the evils which I have above detailed, as attendant upon decomposition in that quarter."

Description of an air and water vault.

The following is a description, also taken from Mr Mushet, of an air and a water vault which is employed to equalize the discharge of air into a blast furnace.

Fig. 7.

"Fig. 7. represents a vertical section of the elevation of an air vault 60 feet long and 30 feet wide, consisting of

Furnace.

of four arches of regularly progressive sizes. This building is generally constructed under the bridgehouse, where the materials are daily collected for filling the furnace. AB, represents the acclivity to the furnace top. The space betwixt the arch tops and the level of the floor is filled with materials as dense as can be procured. The walls of the under part are three feet thick, besides a lining of brick and plaster from 18 inches to two feet. Still further precautions are necessary, and alternate layers of pitch and stout paper are requisite to prevent the escape of the compressed air. C, a view of the arched funnel which conveys the air from the cylinder to the vault. Large iron pipes with a well fitted door are preferable, and less apt to emit air. D, an end view of the pipe by which the blast is carried to the furnace.

Fig. 8. "Fig. 8. is a horizontal section of fig. 7. at the dotted line *ab*, representing the width of the cross arches, which are thrown in each partition to preserve an easy communication betwixt the vaults. D, is a section of the first range of pipes, meant to conduct the air to the furnace. In like manner pipes may be taken off from any part of the vault for the different purposes of blowing furnaces, fineries, hollow fires, &c.

Fig. 9. "Fig. 9. represents a vertical longitudinal section of what is generally called the water-vault. The walls of this building may be erected to the height of eight or nine feet, their thickness similar to those of the air vault. A brick lining, and even puddling with clay betwixt it and the stone building, is necessary to prevent the water from oozing by the accumulated pressure. A, is an end view of the horizontal range of pipes which conveys the blast from the blowing cylinder to the inverted chest. BBB, the range which conducts the air to the interior of the inverted chest, and conveys it to the furnaces, proceeding along the extremities of the columns broken off at BB. C, an inverted chest made of wood, iron, or even of well-hewn flags set on end and tightly cemented, is 54 feet within in length, 18 feet wide, and 12 feet high. The dimensions, however, vary at different works. When the chest is made of wood or iron, it is generally bolted by means of a flange to the logs on which it is supported, lest the great pressure of the air should overcome the gravitation of the chest, and displace it. DD, view of the centre log, and ends of the cross logs, on which the chest is laid. These should measure 18 inches in height, so as that the mouth of the chest may be that distance from the surface of the floor, and the water allowed to retreat from the interior of the chest with the least possible obstruction. EE, the outside walls of the building. FF, the brick-works, made perfectly water-tight. The dotted line G, represents the surface of the water when at rest. Let the depth of the water, outside and inside of the chest, be estimated at four feet. When the engine is at work, should the pressure of the air have forced the water down to the dotted line H, three feet and a half distant from the line G, and only six inches from the mouth of the chest, it follows, that the water must have risen in the outer building, or chest, three feet and a half above G, and have its highest surface nearly at rest at I. In this case the strength of the blast is reckoned equal to seven feet of water, or nearly six inches of mercury. The space betwixt the chest and outside building is three feet. When the engine is at rest, and the water has assumed its level, the quantity of water within the chest should be equal to that without.

Fig. 10. "Fig. 10. is a ground plan of fig. 9. The cross logs on which the cistern is supported are dotted within, but drawn full in the space betwixt the flange of the chest and outer building. The breadth of the flange-tops of the binding bolts, and thickness of the metal of the chest, are also drawn. The letters bear a reference to those in fig. 9."

Singular phenomena observed in an air vault.

An account of some curious phenomena observed by Mr Roebuck in the air vault of a blast furnace has been published in the 5th volume of the Transactions of the Royal Society of Edinburgh. This, as well as some remarks of practical utility on the management of blast furnaces, we doubt not, will be interesting to our readers. We shall therefore give it in his own words. It is addressed in the form of a letter to Sir James Hall.

"I have (says he) examined my memorandums, concerning the observations I made on the condensed air in the air vault of the Devon iron works, near Alloa, on the north side of the frith of Forth; and, according to your request, I now transmit you an account of them; and also of an experiment I made, when a partner and manager of these works, in order to increase the produce of blast furnaces."

The two blast furnaces at Devon are of large dimensions, each being 44 feet high, and about 13 feet wide in the boshes, or widest part, and are formed on a steep bank, by two pits sunk in a very solid stratum of coarse-grained freestone.

These pits were afterwards shaped and lined in the usual manner of blast furnaces, with common bricks and fire bricks, and the hearth was laid with large blocks of the stone that had been dug out, and which serve the purpose of fire stones. At the back of the two furnaces, next the bank, the air vault is excavated, and formed by a mine driven in the solid rock, distant from the furnaces about 16 feet. The bottom of the air vault is only about four feet higher than the level of the bottom of the furnaces. This vault has an aperture at one end to receive the air from the blowing machine, and has two at the opposite end, one of which receives the eduction pipe, and the other is a door to give admittance occasionally into the vault. As the rock is extremely close and solid, the vault is dry, except that a little water oozes very gently from the side next the bank in small drops, and does not appear to exceed an English pint in 24 hours.

These furnaces are provided with air, or blast, as it is termed, by the means of a fire-engine of the old, or Newcomen's, construction. The diameter of the steam cylinder is $48\frac{3}{4}$ inches; and the square area of its piston being about $1866\frac{1}{2}$ square inches, the power of this sort of engine cannot be rated at more than 7lb. to the square inch, amounting in all to about 13062lb. This power was employed to work an air pump, or blowing cylinder, of 78 inches diameter, and about seven feet long. The number of square inches on the piston of the air pump is 4778, and therefore this area, being multiplied by $2\frac{3}{4}$, will produce 13139, being a resistance that nearly balances the above-rated power, and shews that the air, which was expelled from the air pump, could not be condensed more in the ordinary way

way of working, than with a compressing power of about $2\frac{3}{4}$lb. on each square inch. As the engine was not regulated, at first, to make a longer stroke than about four feet eight inches, only one furnace being used, the quantity of air expelled at each stroke of the machine was about 155 cubic feet, which it discharged through a valve into the air vault, about 16 times in a minute. When two furnaces afterwards were blown, the engine was regulated to work much quicker, and with a longer stroke. The air vault is 72 feet long, 14 feet wide, and 13 feet high; and contains upwards of 13,000 cubic feet, or above 80 times the contents of the air pump. The top, sides, and bottom of this vault, where the least fissure could be discovered in the beds of the rock, were carefully caulked with oakum, and afterwards plastered, and then covered with pitch and paper. The intention of blowing into the vault is to equalize the blast, or render it uniform, which it effects more completely than any machinery ever yet contrived for the same purpose. The air is conducted from the vault by the eduction pipe, of 16 inches diameter, into an iron box or wind chest, and from this it goes off to each furnace, into smaller pipes that terminate in nozles, or blow-pipes, of only $2\frac{1}{2}$ to $3\frac{3}{4}$ inches diameter, at the tuyere of the furnace.

Di[...]sions of [...] air va[...]

"When the furnace was put in blast, after having been filled with cokes, and gently heated for more than six weeks, the keepers allowed it to have but little blast at first, giving it a small blow-pipe of about $2\frac{1}{4}$ inches diameter, and likewise letting off a very considerable quantity of air, at the escape or safety valve on the top of the iron wind chest, as it is a received though erroneous opinion among them, that the blast must be let on very gradually for several months. From the construction of this valve, it was impossible to ascertain the exact proportion of the blast which was thus lost, but I believe it was very considerable. The consequence was, that the furnace, after it had been in blast for several days, never seemed to arrive at its proper degree of heat, but was always black and cold about the tuyere in the hearth, and appeared in danger of choking, or gobbing as it is termed.

Tri[...] of the furn[...] fail[...]

"After various experiments tried in vain, by the keepers and the company's engineer, and others, (indeed they tried every thing, except giving the furnace a greater quantity of air, which, as I afterwards ascertained, was all that it wanted), they concluded, that the air vault was the cause of the whole mischief; and to confirm their opinion, they said they had now discovered that water was, in considerable quantities, driven out of the air vault through the blow-pipe, which cooled the furnace; and they insisted, that the power of the engine was such as to force water out of the solid rock; so that this method of equalizing the blast never would succeed. The other managing partner was so much alarmed by these representations, that he began to consult with the engineer, and others, about finding a substitute for the air vault at any expence.

"As the plan of the blowing apparatus had been adopted at my recommendation, and was now so loudly condemned on account of the water, I had other motives, than mere interest, for trying to become better acquainted with the phenomena attending it. I accordingly determined to go into the air vault, and to remain inclosed in the condensed air while the engine was blowing the furnace. It is an experiment that perhaps never was made before, as there never existed such an opportunity. I could not persuade the engineer, or any other of the operative people about the work, to be my companions, as they imagined that there was much danger in the experiment. Mr Neil Ryrie, however, one of the clerks of the Devon company, had sufficient confidence in my representations to venture himself along with me.

[...]e causes [...]esti[...]ted.

"The machine had been stopped about two hours previous to our entering the vault, and we found a dampness and mistiness in it, which disappeared soon after the door was shut fast upon us, and the engine began to work in its usual manner. After four or five strokes of the engine, we both experienced a singular sensation in our ears, as if they were stopped by the fingers, which continued as long as we remained in the condensed air. Our breathing was not in the least affected. I had no thermometer with me, but the temperature of the air felt to us the same as that without the vault. Sound was much magnified, as we perceived, when we talked to each other, or struck any thing; particularly, the noise of the air escaping at the blow-pipe, or waste-valve, was very loud, and seemed to return back to us. There was no appearance of wind to disturb the flame of our candles; on the contrary, I was surprised to find, that when we put one of them into the eduction pipe, which conveys the wind from the vault to the furnaces, it was not blown out. There was not the smallest appearance of any drops of water issuing out of this pipe. The oozing and dropping of water from the side of the rock, next the bank, seemed the same as before the condensation was made in the vault. In short, every thing appeared, in other respects, the same as when we were in the common atmosphere. Having remained about an hour in the condensed air, and satisfied ourselves that no water, during that time, that we could in the least discover, was agitated and forced out of the rock and vault by the power of the blast, as was imagined and insisted on, we gave the signal to stop the engine. As soon as it ceased to work, and the condensation abated, and before the door of the vault was unscrewed, the whole vault in a few seconds, became filled with a thick vapour, so that we could hardly see the candles at four or five yards distance. The door being now opened, the work people, anxious to know our situation, and what had occurred, came into the vault, and prevented any further observations.

Phenomena in the air vault, and peculiar sensations of persons within it.

"I now endeavoured to account for this curious appearance of the water, which only showed itself occasionally, in very small quantities, at the tuyere, at a hole I ordered to be made at the bottom of the wind chest to collect it more accurately, for it never was observed, but either when the engine, after working slowly, was made to work quicker, or, after having been stopped for a few minutes, was set to work again.

"I considered the vapour which we had discovered in the vault to arise from the moisture of the side of the rock next the furnace, which being expelled by the great heat of the furnace, and converted into vapour, was able to force its way through the pores of the rock into the vault, but that being in a manner confined within the rock, by the pressure of the condensed air, it found itself at liberty to come into the vault,

The vapour observed in the vault accounted for.

Furnace.

vault, only when the condensation abated considerably, or was totally removed by the going slow, or stopping of the engine. It also occurred to me, that the air, in a state of condensation, might possibly be capable of holding a greater quantity of water in solution, which might precipitate suddenly into vapour or mist when the condensation abated. I imagined, therefore, that the very small quantities of water we at times discovered, proceeded from nothing else but this vapour, in its passage to the furnace along with the blast, being condensed into water, by the coolness of the eduction pipe and iron wind chest. The quantity of water did not appear to amount to a gallon in twenty-four hours.

"A few days after I had made this experiment, the water ceased entirely to make its appearance, either at the tuyere, or at the hole in the wind chest, but the furnace did not come into heat for a long while after, and indeed not till the keepers let much more air into it by a larger blow-pipe, and allowed less air to escape at the safety valve. It is probable that the rock was now become perfectly dry by the continued heat of the furnace.

"My experiment had the good effect to remove all the prejudices against the plan I had adopted of blowing the furnaces, and likewise prevented the other partner from laying out a large sum of money, by stopping the works, and altering the blowing machinery. Indeed, it has since been admitted, by all who have seen it at work, to be the most simple and effective method of equalizing the blast which has yet been put in practice.

Wind gage applied and its effects.

"This experiment led me, some time afterwards, to apply a wind gage that I contrived, to ascertain precisely the state of the condensation of the air thrown into the furnaces. I found that a column of quicksilver was raised five inches, and sometimes, though seldom, six inches, and, in the interval of the engine to receive air into the air pump, it fell only half an inch. At this time only one furnace was worked. But when two furnaces were in blast, the engine only raised the mercurial gage about four inches, because the Devon company, for several reasons, did not, while I continued a partner, think proper to allow the blowing machinery to be completed, by putting to work their second boiler of 20 feet diameter for the fire engine, according to my original design, which, by adjusting the machinery, would have enabled us to blow two furnaces with two boilers, with as much effect, in proportion, as one furnace with one boiler. This instrument had the advantage of enabling the work people to discover the real power of their blast, and know the exact condition of the air valves, and the gearing of the blowing piston; for if these were not tight, and in order, (although the engine might, to appearance, be doing well, by making the same number of discharges of the air pump as usual per minute), yet the wind gage would not rise so high, and would shew that there was an imperfection somewhere, by reason of a quantity of air escaping at the valves, or piston, that could not so easily otherwise be known. This contrivance was considered as of much use, and was afterwards always quoted in the company's journal books, to show the actual state of the blowing machine, in comparing the daily produce of the furnaces.

"I hope you will not think me tedious, when I explain to you another experiment, which appears to me to be of considerable importance to all manufacturers of cast iron.

"I had reason to conjecture, from my own observations on the effects of blowing machinery on blast furnaces, as well as from the knowledge I had acquired from my father Dr Roebuck, and from my communications with other experienced iron masters, that a great part of the power of such machinery was misapplied in general practice, by throwing air into furnaces with much greater velocity than necessary, and that, if this velocity was, to a certain degree, diminished, the same power, by properly adjusting the blowing machinery, of whatever nature, would be capable of throwing into the furnace a proportionally greater quantity of air. For, *Since the quantities of any fluid, issuing through the same aperture, are as the square roots of the pressure;* it follows, that it would require *four* times the pressure, or power, to expel *double* the quantity of air, through the same aperture, in the same time; but if the area of the aperture was doubled, then the quantity of air expelled by the same power, and in the same time, would be increased in the ratio of the square root of 2 to 1, though its velocity would be diminished exactly in the same proportion. Again: I considered that the quantity and intensity of heat, produced in blast furnaces, and consequently its effects in increasing the produce, might be only in proportion to the quantity of air decomposed in the process of combustion, without regard to its greater velocity; that is to say, whether or not the same quantity of air was forced, in the same time, into the furnace through a small pipe, or through one of larger dimensions; for, in attending to the process of a common air furnace for remelting of iron, where there is a very large quantity of air admitted through the large areas between the bars, it is well known, that a much greater intensity of heat is produced than takes place in a blast furnace; and yet the air does not enter into the fire through the bars with increased density or great velocity. I therefore thought it probable, that increasing the *quantity* of air thrown into the blast furnace in a considerable degree, although the *velocity* or *density* might be much less, would have the effect of increasing its heat, and operations, and produce. And as, from the principles above stated, with regard to the machinery, I saw I could greatly increase the quantity of air thrown into the furnace, by enlarging the diameter of the blow pipe, and regulating the engine accordingly, without being obliged to employ more power, I was anxious to make this experiment.

The velocity of blast, and its quantity considered.

"A system of management, of which I did by no means approve, was adopted by the other partners of the Devon company, soon after the works were begun to be erected; and, in the prosecution of it, they ordered their second furnace to be put in blast, without permitting those measures to be taken that were necessary to provide and maintain a sufficient stock of materials; and also without allowing their blowing machine to be completed, according to the original design, by the addition of its second boiler. As might have been expected, a trial of several months to carry on two furnaces, with only half the power of steam that was necessary, and an inadequate stock of materials, proving unsuccessful,

unsuccessful, the company, as a remedy, instead of making up the above deficiencies, ordered one of the furnaces to be blown out, and stopped altogether. This improper measure, however, afforded me the opportunity of immediately putting in practice the plan I have mentioned.

"When one of the furnaces was stopped, the other continued to be blown by a blow-pipe of $2\frac{1}{4}$ inches diameter, and the produce of the furnace, for several weeks thereafter, was not 20 tons of iron per week at an average. The engine at this time was making about 16 strokes a minute, with a stroke of the air pump, about 4 feet 8 inches long; but when I altered the diameter of the blow-pipe, first to 3, and immediately after to $3\frac{1}{4}$ inches diameter, and regulated the working gears of the engine, so as to make a stroke of 5 feet 2 inches long, and about 19 strokes in a minute, on an average, the produce was immediately increased. It continued to be, on an average of nine months immediately after this improvement, at the rate of 33 tons of iron per week, of as good quality as formerly: for, during this period, from the 21st November 1795 to July 30, 1796, this one furnace yielded 1188 tons of iron. No more coals were consumed in working the blast engine, or other expences about the blowing machine incurred, and therefore no more power was employed to produce this great effect. It is also of much importance to remark, that the consumption of materials, from which this large produce was obtained, was by no means so great as formerly. The furnace required very considerably *less fuel, less iron stone, and less limestone*, than were employed to produce the same quantity of iron by the former method of blowing; and according to the statements made out by the company's orders, as great a change was effected in the economical part of the business.

and established by experiment.

"From the success of this experiment, so well authenticated, and continued for several months, I am led to be of opinion, that all blast furnaces, by a proper adjustment of such machinery as they are provided with, might greatly and advantageously increase their produce, by assuming this as a principle, viz. '*That with the given power it is rather by a great quantity of air thrown into the furnace, with a moderate velocity, than by a less quantity thrown in with a greater velocity, that the greatest benefit is derived, in the smelting of iron stones, in order to produce pig-iron.*' However, it is by experiment alone, perhaps, that we can be enabled to find out the exact relations of power, velocity, and quantity of air requisite to produce a *maximum* of effect (1)."

In order to illustrate what is said above, a ground plan of the air vault and furnaces of the Devon Iron Works is given in Plate CCXXVI.; of which the explanation follows.

Explanation of Fig. 11.

Fig. 11.

A, The air vault, formed by a mine driven in the solid rock of coarse-grained freestone.

B, The blowing cylinder.

C, The pipe that conveys the air from the blowing cylinder to the air vault.

D, The reduction pipe that carries the air from the air vault to the iron wind-chest.

E, The iron wind chest (about $2\frac{1}{2}$ feet cube), in which is inserted a wind-gage, represented in fig. 12.

FF, The two blow-pipes for each furnace, which terminate in apertures of $3\frac{1}{4}$ inches diameter at the tuyeres of the furnaces.

GG, The two blast furnaces, placed in two pits sunk in the solid rock.

HH, The tymps of the furnaces from whence the cast iron is run off into the casting room, LL.

O, The door to give occasional admittance into the air vault.

M, The excavation, in which is placed the blowing machine.

B, The end that is inserted in the iron wind chest, and exposed to the pressure of the condensed air of the air vault.

Description of an air furnace.

To Mr Mushet we are also indebted for the following account of air furnaces, which are employed in iron founderies for the purpose of casting large pieces of ordnance, and other heavy articles.

These furnaces, he observes, "are employed for melting pig iron with the flame of pit coal. Furnaces of this kind are constructed of various sizes according to circumstances. The small sizes will run down from

seven

(1) "If Q be the quantity of a fluid, issuing in a given time through an aperture of the diameter D, V its velocity, and P the power by which it is forced through the aperture: then the area of that aperture being as D^2, the quantity of the fluid issuing in the given time will be as VD^2, or $VD^2=Q$.

"Again, this quantity multiplied into its velocity, will be as the *momentum* of the fluid expelled, or as the power by which it is expelled, that is, $V^2 D^2=P$, or $VD=\sqrt{P}$.

"Here, therefore, if D is given, V is as $\sqrt{P}$, as Mr Roebuck affirms. Also, because $V=\frac{Q}{D^2}$, and also $V=\frac{\sqrt{P}}{D}$, $Q=D\sqrt{P}$, so that, while P remains the same, Q will increase as D increases, and V will diminish in the same ratio.

"The problem, therefore, of throwing the greatest quantity of air into the furnace, with a given power, strictly speaking, has no *maximum*, but the largest aperture of which the engine can admit must be the best. It is probable, however, that there is a certain velocity with which the air ought to enter into the furnace; this will produce a limitation of the problem, which, as Mr Roebuck suggests, is not likely to be discovered but by experiment." *Note by Mr Playfair.*

Furnace. seven to ten hundred weight, and are used in small founderies for what the trade call *jobbing*.

Plate CCXXVI. fig. 13. "Fig. 13. (Plate CCXXVI.) a ground plan of two large air furnaces, and chimney for melting pig or cast iron with the flame of pit coal.

"The letters ABCD point out the exterior dimensions of the stalk or chimney, which is first erected, leaving two openings or arches into which the fore-part of the furnaces are afterwards built. The breadth of the chimney at the particular place which the plan exhibits is 16 feet from A to B, and from A to D or from B to C six feet six inches. The plan is drawn at that elevation where the flame enters the chimney by the flue or throat, narrowed on purpose to throw back part of the flame, and keep the furnace equally hot throughout, as may be more particularly viewed in the vertical section, fig. 14.

"EE, the furnace bars on which the coals rest, and where the combustion is maintained.

"FF, openings called teasing holes, by which the coals are introduced to repair the fire.

"GG, fire brick buildings called bridges. These are meant to concentrate the flame, that it may act as violently on the metal as possible. Upon the height of the bridge much depends in fusing the metal speedily, and with little loss. The height of this may be seen in the vertical section, fig. 14. G.

"HH, the charging doors, by which the metal is introduced in the shape and state of pig iron, lumps, scraps, &c. &c. The iron generally occupies the furnace across to I, called the back wall, and is never meant to approach the bridge nearer than the dotted line, lest the metal in melting should run back into the grates, in place of descending into the general reservoir or cavity below. The corners or notches, *h*, *h*, *h*, *h*, receive a stout cast iron frame lined with fire bricks. This is hung by means of a chain and pulley, and can be raised and depressed at pleasure. This frame is, properly speaking, the charging door, and is always carefully made air tight by means of moistened sand.

"KK, the flues or openings by which the flame enters the chimney. These are 15 inches by 10. On maintaining these openings of a proportionate size to the other parts depend in a great measure the powers and economy of the furnace.

"LL, lading doors, by which ladles are introduced, in the case of small furnaces, to lift out the metal and distribute it to the various moulds.

"MMMM, binding bolts to limit within proper bounds the expansion which takes place in the building when the furnace is highly heated.

Fig. 14. "Fig. 14. vertical section of one of the furnaces, and its appropriate stalk or chimney.

"E, the grates.

"F, the teasing hole.

"G, the bridge.

"H, the charging door.

"K, the flue or opening into the chimney.

"L, the lading door.

"MM, the binder or binding bolt.

"N, the interior of the stalk or chimney, 30 inches square.

"OO, the fire brick work, nine inches thick.

"PP, space of two inches for stuffing with sand.

"QQ, common brick building.

"RR, cast iron lintels, over which are thrown double nine inch arches, so that at any time the inferior building can be taken down to make repairs, without shaking or in the least injuring the chimney.

"S, The dotted lines here are meant to represent what is called the tapping hole. When a large piece of goods is to be cast, lifting the metal with ladles would be impracticable. A sharp-pointed bar is driven up this opening. The iron then flows freely out into a large bason of sand made for its reception. It is then conducted, by collateral channels, into the mould.

"The space under the curved dotted lines from G to L, by S, is filled with a mixture of sand and ashes. When the surface is prepared to melt, the whole of the bottom receives a stratum of sharp clean sand about two inches thick. This is broken up at night, and fresh sand is substituted for it before the fire is kindled in the morning.

"Fig. 15. is a horizontal section of the chimney or stalk, taken where the flues assume a perpendicular direction. The letters in this figure correspond to those in the vertical section, fig. 14. The height of the chimney ought not to be less than 45 feet: if 50 feet, the effect will be sooner and of course better produced. Fig. 15.

"The effect wished to be produced in air furnaces is the fusion of a certain portion of pig or cast iron, for the purpose of being poured or run into moulds to form articles of almost every description.

"The preparation previous to melting is as follows: After the bottom of the furnace is laid, and smoothed with fresh sand, and all the openings made air tight, the furnace man introduces a kindling at the teasing hole, accompanied with new pit coal. In a few minutes a considerable volume of dark flame mixed with smoke is produced. The fire quickly gathers strength; more coal is introduced; and the furnace now becomes filled with a yellow-coloured flame. By continuing this operation for an hour, or an hour and a quarter, the furnace and flame will have become completely white; the latter steady, and at times apparently without motion. The furnace man now judges the bottom to have been sufficiently hardened for receiving the pig iron without any risk of sinking. The charging door is now opened, and the pig metal thrown carefully and regularly upon that part of the bottom formerly described as being appropriated for its reception. The door is again closed and made air tight, and the operation of firing continued with unremitting care and attention. Preparation of furnace.

"The time of melting depends entirely upon the quantity of metal introduced. The furnaces described above are capable of melting from 50 to 60 hundred weight of metal each, and when there is a moderate circulation of air they will perform this work in $2\frac{1}{2}$ or 3 hours. In half an hour after the metal is introduced it assumes a blackish red colour. It then begins to brighten with every additional fire, and in about one hour appears white, and begins to lose shape, and resemble a wreath of snow.

"An eye accustomed to such heats will now discern the metal beginning to drop, and run down the inclined plane in very beautiful streamlets resembling quicksilver. Eight or ten of these are visible at a time, and after proceeding half way down begin to form junctions with

 with each other, and flow connected into the general cavity or reservoir. By-and-by this becomes filled, and literally forms a beautiful molten mirror, in which sometimes part of the interior furnace is reflected.

"The furnace man, by searching at the bridge with his fire-iron or teaser, judges when the metal is nearly all gone. Of this he is certain by looking up from the peep-hole of the lading door. If the streamlets of the running metal have ceased, then the whole is melted, and ready for running out.

Circumstances to be attended to during the operation.

"In the operation of melting, the three following circumstances ought to be particularly attended to: the thinness or hotness of the metal; the waste or loss sustained in melting; and the quantity of coals employed.

"The first is of the utmost importance, as many articles in the foundery business require the metal in a state of the greatest division; otherwise they will be found imperfect when taken from the sand, and unfit for sale. The furnace man, therefore, is always on the watch to replace the fire as it decays, and keep a large and sharp volume of flame constantly passing over the metal.

"The waste or loss of real metal is also an object of great importance. This always bears a relation to the quality of the iron, the strength and cleanness of the coals, and the judgment and attention of the melter. Strong iron is found always more difficult to fuse; this necessarily exposes it for a long period in contact with the flames. The reverse happens with metal that is more fragile, and easier broken in the pig. The length of the exposure in fusing depends on this; and other circumstances being alike, the loss or waste of metal will also be in the same ratio.

"There are, however, other facts not unworthy of notice. N° 1. pig iron, or richly carbonated metal, when run from an air furnace, will be found in point of quality little better than N° 2. or carbonated iron. This is owing to a quantity of its carbone being destroyed during the fusion. The loss in melting N° 1. iron, therefore, chiefly consists of carbone; and the deficiency of metal ought never, with a clean bottom, to exceed 1 cwt. in 20.

"Carbonated or N° 2. iron also becomes deprived of a considerable portion of its carbonaceous mixture in fusion; and when run from the air furnace is seldom better than N° 3. metal. The loss sustained in melting may be averaged at $7\frac{1}{2}$ per cent.

"N° 3. pig iron is, after melting in an air furnace, found whitish or mottled. It is seldom susceptible of the same nice degree of division as the superior qualities, and loses in fusion a much larger proportion of metal, seldom under 10 per cent. and frequently $12\frac{1}{2}$ or 15.

"The quantity of coals requisite to melt a given quantity of iron is various, as much depends upon the quality and fusibility of the metal. If the furnace goes one heat a day with N° 1. or 2. iron, the quantity of coals will be from 20 to 25 cwt. for a ton of iron. If two or three heats a day, or as many tons of iron are melted at one kindling, the proportion of coals will be nearly weight for weight of the iron melted when the coals are mixed with a fair proportion of small: with strong large splint coals, one ton of good pig iron may be completely reduced with from 12 to 15 cwt. including the previous heating of the furnace *."

* Phil. Mag. xv. 245.

Importance of blowing machinery.

In the reduction and fusion of ores, the improvement of the blowing apparatus, or the machinery contrived for the purpose of forcing a current of air into furnaces, where a high degree of temperature was necessary, has always been an important object of consideration to the manufacturer; and indeed, it appears that the history and improvement of this kind of machinery have progressively advanced, in some cases have exceeded the improvement of other departments of the manufactures of this country.

In smelting some metallic ores, as, for instance, those of lead and tin, the magnitude and powers of blowing machines have been less attended to, because the requisite temperature for that purpose is far inferior to what is necessary for the reduction of the ores of iron. Lead and tin being naturally fusible, and easily volatilized in a temperature beyond a bright red-heat, have hitherto fixed the limits with regard to the size of the furnace, and the quantity of blast. The air furnace is generally employed in the manufacture of copper, excepting in small blast furnaces, in which the precipitated oxide of this metal is received, and they are similar to the furnaces called cupolas, and used at iron founderies.

The lead mill, as it is called, or machine for the reduction of the ores of lead, is of a very simple construction. In the middle of a square building a water wheel is erected, and to the shaft of this wheel, four small wheels of cast iron, about 18 inches in diameter, are attached. Two pairs of bellows placed at equal distances, and on each side of the shaft, are supported on a strong frame of wood. During the revolution of the shaft of the water wheel, the small wheels are also carried round, and alternately depress the end of the lever, which is attached, by means of an iron chain, to an equally balanced beam. When this lever descends, the opposite end of the beam is elevated, and to this end there is attached, by another iron chain, the moveable surface of the bellows. The blast produced in this way is soft, and far inferior, either with regard to quantity or density, to the blast necessary for an iron furnace. The length of the bellows is usually about 10 feet, the breadth across the breech about five or six, and they move at the rate of about 30 strokes a minute.

Which must be of great power in the manufacture of iron.

But in the manufacture of iron, and particularly since the use of pit-coal was introduced, it is absolutely necessary to have a more powerful blowing machinery. This, however, has always been an essential requisite, and has been a constant object in this manufacture; for in proportion to the quantity of air thrown into the furnace, the produce and quantity of metal is increased. In the earlier periods of this manufacture, when the fuel employed was charcoal from wood, the process was more easily managed. Furnaces which were built of small size, and which were then called *bloomeries*, were considered of sufficient capacity to yield profit, if they produced a bloom or two of iron in the day, each bloom amounting to about 90 or 120 lbs. For smaller operations, hand bellows, and what were called fuel blasts, were deemed of sufficient power; but when the refining furnace began to be employed, and the iron manufacture branched out into the making of pig iron, and the refining

Furnace.

refining of it into bar or malleable iron, the advantage and necessity of a powerful blast were immediately seen. The first moving power introduced was that of the water wheel; and this working two or more pairs of leathern bellows, was found to produce effects sufficiently powerful for the purpose.

Progressive improvement of

Machinery constructed in this way, and set in motion by the power of water, continued to be employed for this purpose, till the principles of the steam engine were fully understood, and this powerful machine came into general use. The steam engine, besides many other advantages, could be employed in situations where the want of water prevented furnaces being erected, but otherwise commodious, in being near the necessary materials of ore and fuel. The first substitute for the leathern bellows were cylinders composed of wood, closely jointed, and strongly hooped. These in their turn gave place to cylinders of cast iron, smoothly and accurately bored; and this kind of apparatus being discovered and applied in the manufacture of iron, the blowing machine now assumed a more perfect and more manageable form.

But without attempting to describe any of the blowing machines in our own country, the power and effects of which are familiar to those to whom this knowledge is most interesting, we shall give a short description of an apparatus of this kind, which is set in motion by the pressure of a column of water, and is erected near Namur in the Netherlands. The account of this machine is given by Baillet, inspector of the mines, who observes, that its construction is simple, and not very expensive, and that it may be kept up without requiring much repair. This machine, besides, can be employed to blow several furnaces at once. It does not require any great moving power, and the consumption of water is much less than in the blowing apparatus of leather or wood. In consequence of these advantages, the number of furnaces has been greatly increased since this apparatus was first erected, and the extent of the manufacture has been doubled. This apparatus possesses another superiority over the ordinary blowing machines. The latter, to be put in motion, require a water wheel; but the apparatus which is here alluded to, is set in motion merely by the pressure of a column of water.

blowing machine by the pressure of water.

The following is the description of this blowing machine, as it was first erected at Marche upon the Meuse. It was invented and constructed by Janniens, proprietor of the forges, and it consists of two cylinders of three feet eight inches diameter, and of thirty inches high, placed vertically near each other. One of these cylinders is represented at fig. 16. A piston of wood covered with leather, (fig. 17.) moves in each cylinder, and forces the air through the tubes *o*, *o*, *o*, which are fitted to the upper part of the cylinders, and are conducted to the different furnaces where combustion is to be excited. The base of these tubes is furnished with valves, to prevent the return of the air. The piston is, besides, furnished with two lids or covers, *w*, *w*, (fig. 18. and 19.) which open when it descends, and shut when it rises. The piston is surrounded with a band of leather in the usual way, to make it tight.

Fig. 16.
Fig. 17.
Fig. 18. and 19.

The moving power in this apparatus, is a water wheel erected on the horizontal shaft, *s*. On this shaft are fixed the arms *t*, *t*, projecting from its circumference, which alternately elevate the stalk of the piston. The descent of the piston is regulated by the weight *f*. which acts as a counterpoise; and the spring of wood, *g*, which is balanced when the stalks of the piston are at their lowest descent, serves to retard the velocity, and to prevent any sudden or violent stroke.

Two of these cylinders, erected at one of the forges at Marche, furnish air to two furnaces, which employ charcoal from wood, and one with coke from pit-coal. The stroke of the piston is about 18 inches, and 25 strokes in a minute, and with this length of stroke and velocity, the two pistons produce nearly about 400 cubical feet of air. The consumption of water, having a fall of about 10 feet, is about 80 cubical feet.

The similar cylinders, erected at another furnace at the same place, move with the velocity of 19 strokes per minute. The length of each stroke is about 22 inches, so that it produces about 360 cubical feet of air. For this, with a fall of 10 feet, 75 cubical feet of water are necessary.

In the construction of this blowing machine, no peculiar difficulty occurs. It is not necessary that the cylinders should be accurately turned in the inside. All that is required is, to grind or polish their inner surface with sand stone. It was in this way that the cylinders and apparatus, just described, were prepared.

The piston, which is made of wood, has in the middle of it a mortise, *u*, fig. 17. and 19. to admit the stalk, *p*, which is kept in its place by four bands or straps of iron, *x*, fig. 17.

The band of leather, *z*, is about three lines in thickness, and about five inches broad. It is nailed to the piston, and ought to be raised above the groove or gutter, *v*.

The grooves *y*, *y*, are sunk in the piston, in proportion to the thickness of the leather, and their external diameter should be somewhat smaller than that of the cylinder. The large lids or covers of the piston are of wood, lined with sheep skin; and their hinges, which are made of leather, are fixed with screws to the wood: a bridle of leather limits the extent of the opening.

The small valves, which are fixed at the upper opening of the cylinders, at the end of the tubes for conducting the air, are also of wood, and covered with sheep skin.

The tubes or pipes which conduct the air are made of iron plates, or of tinned iron, and they terminate in pipes of a convenient diameter, and proportioned to the different furnaces. They should also be furnished with keys or cocks, for regulating at pleasure the quantity of the air.

The frame which supports these cylinders is of a very simple construction, as will appear by inspecting fig. 16. It is attached and secured to part of the wall of the building.

All that is necessary to keep this apparatus in order, is with a brush to cover the internal surface of the cylinders with oil once every 10 days.

The following are the dimensions of the principal parts in the old French measure.

The large valves of the piston, 8 inches by 6.
The interval between these valves, 14 inches.
Stalk of the piston, 6 inches square.
The rollers on the axis of the wheel. { Length, 12 inches. Diameter, 36 inches.

Diameter

Diameter of the cylinder, 38 inches.
Height of ditto, 26 do.

Baillet, who has given the above description, proposes a new application of the moving force to this kind of blowing machine; and he observes, that a very important advantage may be derived from these cylinders, since the simple pressure of a column of water may be substituted for the moving power. In fig. 20. the apparatus is so arranged as to shew in what way this effect may be produced.

The stalk *f*, of the cylindrical apparatus *c*, is common to the piston of the small cylinder *d*, in which it can convey the column of water *b c*. When the cock *h* is open, and that at *l* is shut, the pressure of the column must elevate the stalk *f*, and the piston of the blowing cylinder. Then the cock *h* being shut, and that at *l* being open, the water of the cylinder *d* will flow out, and the stalk *f* and the piston of the cylinder will descend. These alternate motions can be easily managed by means of levers, or regulators at *i*, fitted to the stem of the piston, and in the same way as in the steam engine. The openings at *h* and *l* may be regulated according to the velocity which is required in the motion of the piston, and the diameter of the cylinder *d* will be proportioned to the fall of water *b*, *c*, and the volume of air which is wanted.

Explanation of the Figures.

Fig. 16. exhibits a section and elevation of the blowing machine.

a, the wall of the building. *b*, the opening in the wall for the balance beam.

c, one of the two beams which receive the gudgeons on which the balance beam moves. *d*, *e*, the balance beam; *f*, the weight which acts as a counterpoise; *g*, the spring of wood.

h, a brace or strap of leather, which is attached to the curved head of the beam.

i, *k*, *l*, *m*, the frame which supports the cylinders.

n, the blowing cylinder of cast iron.

o, *o*, *o*, tubes for conveying air to the furnace.

p, stalk of the piston.

q, a knee or catch attached to the stalk.

r, the horizontal axis of the water wheel.

s, *s*, arms attached to the axis, with rollers which raise the knee or catch *q*, and the piston.

t, *t*, similar arms and rollers for moving the piston of the second cylinder.

Fig. 17. Section of the piston.

Fig. 18. The piston seen from above.

Fig. 19. View of the under surface of the piston.

Fig. 17. 18. and 19.

p, stalk of the piston.

w, *w*, lids or valves.

v, *v*, groove in the circumference of the piston.

u, mortise to receive the stalk *p*.

x, *x*, straps of iron to support the stalk *p*.

y, *y*, the band of leather surrounding the piston.

Fig. 20. *a*, a reservoir of water; *b*, *c*, a column of water.

d, a cylinder for water.

e, the blowing cylinder.

f, the stalk common to the pistons of the two cylinders, *d* and *e*.

g, the pipe for conducting the air.

h, *l*, cocks for receiving and letting out the water.

i, *i*, the regulators, for the purpose of opening and shutting the cocks.

k, a second blowing cylinder.*

* *Jour. de Mines.*

Three-blast furnace.

The following is a description by Torelli-Narci, of a three-blast furnace, which was constructed in the chemical laboratory of the French school of mines.

"This furnace (says the author) is destined for fusing different mineral substances, in order to ascertain the nature of them; and the experience of six years has shown that it answers the intended purpose. By its means a very intense heat is obtained, and it was employed by C. Clouet for repeating his experiments on the conversion of forged iron into cast steel, which were attended with full success.

"Chemists who have seen this furnace seemed desirous of being better acquainted with the construction of it: the council even transmitted drawings of it to several persons; and what has hitherto prevented a description of it from being given was a desire to ascertain its power by longer use.

"I long ago conceived the idea of a fusing furnace, in which the wind was distributed in three tuyeres placed in its circumference, and at equal distances from each other; but I had no opportunity of realizing this idea till I became attached to the council of mines.

"Nearly seven years ago a plan was in agitation for constructing in the laboratory of the school a fusing furnace capable of producing a very great degree of heat, in order to operate with facility and speed on larger quantities of mineral, and consequently to obtain more precision in the trials which might be made than had been obtained by the small furnaces before employed for docimastic experiments.

"I proposed my ideas: they were approved by the council of mines; and I was ordered to cause the furnace I am about to describe to be constructed. The principal difference between it and those before used for the same purpose is, that in the present one the wind is introduced through three tuyeres, placed at equal distances from each other in its circumference, whereas in common furnaces it enters only by one.

"This furnace is round, both outside and inside, and constructed of very refractory bricks, secured by iron hoops in such a manner that they cannot be displaced. It rests on a square base of strong mason work, raised to a sufficient height above the ground to render it easy to manage.

"The bellows are four feet in length, and the mean breadth of them is about 20 or 21 inches: they are of wood, and the joints are covered with white leather. The upper part consists of five folds and two half folds; the inferior, of two folds and two half folds. They are placed eight or nine feet (K) above a wooden box, the joints of which are covered with leather, and into which the wind

(K) "This height is arbitrary; it depends in part on the manner in which the bellows are disposed, and on the height of the chamber in which the furnace is placed."

wind as it comes from the bellows is conveyed by a copper pipe, three inches in diameter, adjusted to the upper part of the box. The box itself is supported by two iron bars built into the wall. From the lower part of this box descend, in a vertical direction, three pipes of copper, two inches in diameter, bent at right angles about 45 inches below it, to bring them into a horizontal position, and to convey the wind to the furnace, which is about six feet distant. The extremities of these pipes are fitted into three tuyeres of forged iron, fixed at equal distances around the circumference of the furnace: these three pipes are more or less curved or bent, to convey the wind into the furnace by the three apertures made for that purpose.

"About six inches below the box is adjusted, on each of the three tubes, which descend in a vertical direction, a brass cock about three inches of interior diameter: these cocks serve to intercept entirely the communication between the bellows and the furnace; and by opening them all more or less, or each of them separately, any required quantity of wind may be obtained (L).

"These cocks are well fixed to the tubes, and kept in their place by two clips of iron suited to the diameters of the tubes, and forming a kind of three collars, which by means of four screws embrace and confine them: these pieces of iron are themselves made fast to two crutches of iron, which support the box and are fixed to it by screws. The box is kept on the crutches by two straps, which embrace it at each extremity, and are fixed by female screws, which are fitted to screws on the ends of these straps after they have passed through the horizontal part of the two crutches.

To give the proper strength to this furnace, a solid square was constructed of mason-work, about a foot larger on each side than the exterior diameter of the sides of the furnace, which were from 21 to 22 inches from outside to outside. Bricks were placed on the ground in the middle of this erection for the extent of 18 inches, in order to form a bottom, and on this base were placed the sides of the furnace constructed in the manner about to be described.

"I caused to be forged two iron hoops six lines in thickness, from 2 to 2½ inches in breadth, and about 22 inches of exterior diameter; these two circles were fastened together by three bars of iron, the distance of their exterior edge being kept at about nine inches, the height of the bricks: these bars are pierced with holes towards the end rivetted on the circles, and placed at equal distances on their circumference. One of the extremes of each of these three bars is left of a sufficient length to pass beyond the lower circle about an inch, in order to make them enter into three holes formed in the brick-work which forms the bottom of the furnace, and by these means to prevent the furnace from becoming deranged.

"This kind of iron frame was filled with bricks similar to those employed for the bottom of the furnace: they were rubbed one on the other to smooth them, and the corners were a little rounded; so that, being placed upright with their broad sides applied to the iron hoops, the narrow side stood inwards. By these means all these bricks were adjusted in such a manner as to touch each other by their broadest faces, and to form the sides of the furnace, the thickness of which was equal to the breadth of the bricks, and its depth to their length. Three apertures were reserved for the tuyeres which terminate the three tubes that convey the wind, by cutting from as many bricks a portion equal to the thickness of a brick.

"These bricks thus adjusted were taken from the iron frame, and then replaced, putting between them a cement to connect them firmly and to fill up the joints. The dust produced by cutting the bricks was reserved for this purpose; and I desired the workmen to mix with it a small quantity of clay diluted in a great deal of water, in order to make a puddle for daubing over the bricks, and in particular to put between them no more than was necessary for filling the joints and the small space left between their faces in consequence of any inequality left in dressing them.

"The furnace thus constructed was then placed on its base, a stratum of the same mortar employed for filling up the joinings of the bricks being first interposed. The extremities of the three iron bars projecting beyond the lower circle were placed in the holes left in the base to receive them. The body of the furnace encircled with iron, both by its weight and the gentle blows given to the iron hoops above the bars which connected them, expelled the excess of the mortar, and caused a part of it to enter and unite with that which filled up the joints of the brick work of the circumference, which rendered it immoveable.

"The bellows is secured as usual by crutches of iron and supporters fixed in the wall and to the floor: the handle is disposed in such a manner, that the rope which makes it act may be pulled by the same person who manages the fire of the furnace, which in certain cases is necessary.

"The tuyeres of forged iron, which receive the ends of the copper tubes, are secured in their proper apertures in the circumference of the furnace by pieces of brick and mortar similar to that employed for filling up the joints; and the ends of the copper pipes introduced into these tuyeres are luted with the same mortar, a little thickened with brick dust.

"The apertures of these tuyeres towards the interior of the furnace is only nine lines in diameter; on which account,

(L) "Care must be taken, when the action of the bellows ceases, to shut the cocks, especially when coals are used in the furnace; for the hydrogen disengaged from that mineral substance ascends into the box, and when the bellows are again made to act, may inflame and cause a violent explosion, or even burst the bellows. This accident once took place in the furnace here described: the box burst with a loud noise on the first stroke of the bellows, the gas which filled them having suddenly inflamed; but by good fortune no person was hurt. The same thing happened at the house of C. Gorlier, locksmith of Paris; one of his bellows burst with a horrid explosion at the moment when they were put in motion."

Furnace. account, as the volume of air furnished by the bellows cannot pass so quick as it is produced, it becomes condensed in the box placed above the cocks. By these means a very uniform blast is obtained, which can also be regulated by opening more or fewer of the cocks.

"During more than six years, since this furnace was constructed, it has suffered no derangement: it is not even cracked. It is however worn in the inside by the violence of the heat it has experienced, which has increased its diameter about two inches. The parts round the three tuyeres have also got hollowed, so that it has need of being repaired. It is intended to make it deeper, and to have a kind of moveable muffs or linings made of fire clay, in order that its diameter may be reduced at pleasure: it is meant also to construct it in such a manner, as to deposit the rest or support for the crucible, not on the bottom of the furnace, but on bars of forged iron placed at the distance of some inches from that bottom, so as to leave below them a vacuity in which the blast of the bellows may be diffused, and from which it may rise, passing between the bars to traverse the mass of charcoal which surrounds the crucible. The blast will then produce a more uniform fire, and the flame can no longer be directed against the sides of the crucibles; so that the risk of their breaking by sudden inequalities in the heat will be much less.

"This alteration is going to be immediately carried into execution, and the method proposed for doing it is as follows:

"A round frame will be made of forged iron, in which bricks will be placed in the same manner as above described. In the lower part of the furnace an aperture will be reserved for raking out the ashes, which will be closed by means of a door of baked earth carefully luted with clay. Some inches above the bottom of the furnace will be placed a grate of forged iron, and between this grate and the bottom of the furnace the tuyeres will terminate, and the blast be introduced. Muffs or linings of very refractory earth will then be introduced, so as to descend to this grate. There will be two of them, one within the other, and both within the body of the furnace. At the lower part these muffs will be furnished with a rim, projecting outward so as to leave between the body of the furnace and the muffs, a vacuity, which will be luted at the bottom with clay, and which will be filled with pounded glass, or any other substance a bad conductor for heat.

The interior muff, or both of them, may be removed at pleasure to obtain a furnace of greater or less capacity according to the operations to be performed. It is proposed to make the muffs wider at the top than at the bottom.

Explanation of the Figures.

Plate CCXXV. fig. 21. "Fig. 21. Plan of the bellows and of the furnace. AB, the bellows made of wood, the folds of which are also of wood covered with leather on the joints. CD, the handle which serves for moving the bellows. E, a copper tube which conveys the wind of the bellows into the box FG, in which it is condensed. FG, a box of wood serving as a reservoir for the wind condensed by the bellows. HI, KL, MN, three pipes adapted to the box FG, and which convey the wind into the inside of the furnace by three tuyeres, I, L, N. OP, mason work to support the horizontal pipes. Q, the furnace properly so called, the former of which is circular, and which is placed on the square mason work R, S, T, U.

"Fig. 22. Elevation of the furnace, the pipes which convey the blast, the cocks, the condensing box, and the bellows. AB, the bellows mounted in their place, and supported by the iron-work necessary for securing it, which is fixed in the wall and to the floor. CD, the handle which serves for moving the bellows. E, the copper pipe which conveys the blast of the bellows to the box FG in which it is condensed. At G is a hole shut by a large cork stopper, which can be opened at pleasure. This box is supported by two crutches of iron *f*, *g*, and *h*, *i*, built into the wall, and on which it is fixed by two iron stirrups *l*, *m*. Fig. 22.

"Fig. 23. One of the crutches and its stirrup are seen represented sidewise at *f*, *g*, *l*; the extremities, *n*, *o*, are built into the wall, and the two ends, *p*, *q*, of the iron piece which keeps the box on the horizontal traverse of the crutch, are tapped, and receive screws which make them fast to the crutch *f*, *g*. HI, KL, MN, are three pipes which convey the wind into the interior of the furnace. Q, R, S, T, U, mason work on which is placed the furnace Q, and which serves it as a bottom. OP, masonry which serves to support the three pipes that convey the wind to the furnace. XYZ, fig. 22. are the three cocks fixed to the three pipes which proceed from the box to convey the wind to the furnace. Fig. 23.

"In fig. 24. the dimensions of which are double those of fig. 22. may be seen the details of one of these cocks. Fig. 24.

"At *r*, *s*, *t*, the body of the cock is seen in front; the stopper being taken out shows at *r* and at *t* the two holes which receive the tubes that communicate either with the box or with the tuyeres. *u* Exhibits the body of the cock seen on one side; *v* the key with its aperture *x*, and its head *y*. This key, turned round more or less in its socket, serves to give more or less wind. 1, 2, 3, Iron clips which secure the cocks at the distance they ought to be from each other, and connect them at the same time to the iron crutches which support the air-box.

"Fig. 25. a plan of these two clips. They are bent at the places marked 1, 2, 3, to embrace the body of the three cocks, and secure them in such a manner that they cannot be deranged when they are opened or shut. Fig. 25.

"Fig. 26. and 27. represent the plan and section of the changes and additions proposed to be made when the furnace is re-constructed. At I, L, and N, are seen the extremities of the three pipes that enter the forged iron tuyeres, and convey the wind to the interior of the furnace. *a*, *b*, and *c*, indicate the thickness at the upper part of each of the muffs and of the body of the furnace, between which there are two vacuities filled with pounded glass or some other bad conductor of heat. *d*, the grate on which are deposited the rests of baked earth destined to receive the crucibles. *e*, the crucible, luted and attached with clay to a rest of baked earth (M)." Fig. 26. and 27.

Mr

(M) "The advantage arising in large founderies from the application of two or three tuyeres instead of one, is well known; but I do not believe that such an arrangement was ever adopted in small furnaces.

Furnace.

Mr Collier, in a paper communicated to the Manchester Philosophical Society, has delivered some important observations on iron and steel, with a more correct account of the process for the manufacture of the latter than has hitherto been given. To this account he has added the description of a furnace for the conversion of iron into steel. As his observations and reasonings are extremely valuable, we shall lay the whole before our readers in his own words.

Accounts of the process for making iron and steel, imperfect.

" After examining (says (Mr Collier) the works of different authors who have written on the subject of making iron and steel, I am persuaded that the accounts given by them of the necessary processes and operations are extremely imperfect. Chemists have examined and described the various compound minerals containing iron with great accuracy, but have been less attentive to their reduction. This observation more particularly applies to steel, of the making of which I have not seen any correct account.

" It is singular to observe, how very imperfectly the cementation of iron has been described by men of great eminence in the science of chemistry. Citizen Fourcroy states the length of time necessary for the cementation of iron to be about twelve hours; but it is difficult to discover whether he alludes to cast or to bar steel: for he says, that short bars of iron are to be put into an earthen box with a cement, and closed up. Now steel is made from bars of iron of the usual length and thickness: but cast steel is made according to the process described by Citizen Fourcroy, with this essential difference; the operation is begun upon bar steel and not bar iron.

" Mr Nicholson is equally unfortunate in the account given in his Chemical Dictionary. He says, that the usual time required for the cementation of iron is from six to ten hours, and cautions us against continuing the cementation too long; whereas the operation, from the beginning to the end, requires sixteen days at least. In other parts of the operation he is equally defective, confounding the making of bar with that of cast steel, and not fully describing either. In speaking of the uses of steel, or rather of what constitutes its superiority, Mr Nicholson is also deficient. He observes, that 'its most useful and advantageous property is that of becoming extremely hard when plunged into water.' He has here forgotten every thing respecting the temper and tempering of steel instruments, of which, however, he takes some notice in the same page. 'Plunging into water' requires a little explanation: for if very hot steel be immersed in cold water without great caution, it will crack, nay, sometimes break to pieces. It is, however, necessary to be done, in order to prevent the steel from growing soft, and returning to the state of malleable iron; for, were it permitted to cool in the open air, the carbone which it holds in combination would be dissipated (N).

Process at Sheffield.

" I shall, at present, confine my remarks to the operation performed on iron in Sheffield and its neighbourhood: from whence various communications have been transmitted to me by resident friends, and where I have myself seen the operations repeatedly performed.

For the reduction of the ore,

" The iron made in that part of Yorkshire is procured from ores found in the neighbourhood, which are of the argillaceous kind, but intermixed with a large proportion of foreign matter. These, however, are frequently combined with richer ores from Cumberland and other places. The ore is first roasted with cinders for three days in the open air, in order to expel the sulphureous or arsenical parts, and afterwards taken to the furnaces: some of which are constructed so that their internal cavity has the form of two four-sided pyramids joined base to base; but those most commonly used are of a conical form, from 40 to 50 feet high. The furnace is charged at the top with equal parts of coal-cinder and lime-stone. The lime-stone acts as a flux, at the same time that it supplies a sufficient quantity of earthy matter to be converted into scoriæ, which are necessary to defend the reduced matter from calcination, when it comes near the lower part of the furnace. The fire is lighted at the bottom; and the heat is excited by means of two pair of large bellows blowing alternately. The quantity of air generally thrown into the furnace is from a thousand to twelve hundred square feet in a minute. The air passes through a pipe, the diameter of which is from two inches and a quarter, to two and three quarters, wide. The compression of air which is necessary is equal to a column of water four feet and a half high. The ore melts as it passes through the fire and is collected at the bottom, where it is maintained in a liquid state. The slag, which falls down with the fused metal, is let off, by means of an opening in the side of the furnace, at the discretion of the workmen.

" When a sufficient quantity of regulus, or imperfectly reduced metal, is accumulated at the bottom of the furnace (which usually happens every eight hours), it is let off into moulds; to form it for the purposes intended, such as cannon or pig iron.

" Crude iron is distinguished into white, black, and gray. The white is the least reduced, and more brittle than the other two. The black is that with which a large quantity of fuel has been used; and the gray is that which has been reduced with a sufficient quantity of fuel, of which it contains a part in solution.

and refining iron.

" The operation of refining crude iron consists in burning the combustible matter which it holds in solution; at the same time that the remaining iron is more perfectly reduced, and acquires a fibrous texture. For this purpose, the pigs of cast iron are taken to the forge; where they are first put into what is called the refinery: which is an open charcoal fire,

" At Treibach, in Carinthia, C. Le Febre, and Hassenfratz member of the council and inspector of mines, saw about twenty years ago, a large furnace with two tuyeres; drawings of which they brought to France, and which they represented in the third plate of *l' Art de fabriquer les Canons*, by Monge: two pairs of bellows supply wind through two opposite tuyeres, and since that arrangement the daily product of metal has been double."

(N) " It is the opinion of some metallurgists, that a partial abstraction of oxygen takes place, by plunging hot metal into cold water."

Furnace. fire, urged by a pair of bellows, worked by water or a steam engine; but the compression of air, in the refinery, ought to be less than that in the blast furnace. After the metal is melted, it is let out of the fire by the workmen, to discharge the scoriæ; and then returned and subjected to the blast as before. This operation is sometimes repeated two or three times before any appearance of malleability (or what the workmen call coming into nature) takes place; this they know by the metal's first assuming a granular appearance, the particles appearing to repel each other, or at least to have no signs of attraction. Soon afterwards they begin to adhere, the attraction increases very rapidly, and it is with great difficulty that the whole is prevented from running into one mass, which it is desirable to avoid, it being more convenient to stamp small pieces into thin cakes: this is done by putting the iron immediately under the forge hammer, and beating it into pieces about an inch thick, which easily break from the rest during the operation. These small pieces are then collected and piled upon circular stones, which are an inch thick, nine inches in diameter, and about ten inches high. They are afterwards put into a furnace, in which the fire is reverberated upon them until they are in a semi-fluid state. The workmen then take one out of the furnace, and draw it into a bar under the hammer; which being finished, they apply the bar to another of the piles of semi-fluid metal, to which it quickly cements, is taken again to the hammer, the bar first drawn serving as a handle, and drawn down as before. The imperfections in the bars are remedied by putting them into another fire called the chafery, and again subjecting them to the action of the forge hammer.

"The above method is now most in use, and is called flourishing; but the iron made by this process is in no respect superior to that which I am going to describe. It is, however, not so expensive, and requires less labour.

"The process for refining crude iron, which was most common previously to the introduction of flourishing, is as follows.

"The pigs of cast iron are put into the refinery, as above, where they remain until they have acquired a consistence resembling paste, which happens in about two hours and a half. The iron is then taken out of the refinery and laid upon a cast iron plate on the floor, and beaten by the workmen with hand hammers to knock off the cinders and other extraneous matters which adhere to the metal. It is afterwards taken to the forge hammer and beaten, first gently, till it has obtained a little tenacity; then the middle part of the piece is drawn into a bar, about half an inch thick, three inches broad, and four feet long; leaving at each end a thick square lump of imperfect iron. In this form it is called ancony. It is now taken to the fire called the chafery, made of common coal; after which the two ends are drawn out into the form of the middle, and the operation is finished.

"There is also a third method of rendering crude iron malleable, which, I think, promises to be abundantly more advantageous than either of the two former, as it will dispense both with the refinery and chafery: and nothing more will be necessary than a reverberating furnace, and a furnace to give the metal a malleable heat, about the middle of the operation. The large forge hammer will also fall into disrepute, but in its place must be substituted metal rollers of different capacities, which, like the forge hammer, must be worked either by a water wheel, or a steam engine. An improved process.

"It is by the operation of the forge hammer or metal rollers, that the iron is deprived of the remaining portion of impurity, and acquires a fibrous texture.
