The following information has been received since the work was put to press:

TRIAL TRIP OF THE GOLDEN GATE.

Average number of Revolutions per minute,	$15\frac{1}{4}$
" Pressure of Steam,	$8\frac{1}{2}$ lbs.
" point of Cutting off,	3 feet.
Consumption of Bituminous Coal per hour,	3472 lbs.
Water Evaporated by 1 lb. of Coal,	$7\frac{7}{100}$ lbs.
Coal per hour to a square foot of Grate,	$9\frac{46}{100}$ lbs.

TRIAL TRIP OF BUCK EYE STATE.

Average number of Revolutions per minute,	16
" Pressure of Steam,	40 lbs.
Consumption of Bituminous Coal per hour,	3158 lbs.
Water Evaporated by 1 lb. of Coal,	$6\frac{18}{100}$ lbs.
Coal per hour to a square foot of Grate,	20 lbs.

The tubes in these boilers are 3 inches bore, and 15 feet long, and the natural draft is sufficient to give ample steam.

STEAMER BALTIMORE.

Average number of Revolutions per minute,	19
" Pressure of Steam,	30 lbs.
" point of Cutting off,	5 ft. 6 in.
Consumption of Virginia Pine wood per hour, $1\frac{1}{3}$ cords	3200 lbs.
Water Evaporated by 1 lb. of Wood,	$4\frac{36}{100}$

The Steamer Illinois, just finished at New York, is of the same size as the Golden Gate, and her Engines and Boilers, (constructed by the Allaire Works,) are of the same kind and dimensions.

A TREATISE

ON THE

MARINE BOILERS OF THE UNITED STATES.

The Fire Surfaces are all calculated from the top of the grate to the water line, which is taken at 12 inches above the flues.

All the boilers are drawn to a scale of $\frac{3}{16}$ of an inch to the foot. See scale on last page.

Unless noted otherwise, the draft is natural.

WESTERN RIVER STEAMERS.

The form of boiler used in the Steamer America, on Lake Erie, and here shown, is the one universally adopted on our western rivers, and will probably continue to be used so long as they remain attached to their present system of high pressure engines. One drawing is a sufficient explanation. Their proportion of boiler may be seen from the following steamer built a few years since; no change of importance has taken place in that time that I am aware of.

WHICH IS THE BEST BOILER?

Is a question that I have often been asked, and is one that is more easily asked than answered. Of the two ordinary forms of flue boilers I consider the drop flue preferable as occupying less space to produce a given effect. A good comparison may be made between these two forms by examining the boilers of the Bay and Empire State on Long Island Sound; the boats and engines being almost identical. Of tubular boilers there are two varieties, those having vertical, and those with horizontal tubes; so far as efficiency is concerned I do not think any difference would be observed where equal surface was presented to the action of the fire. Those with horizontal tubes take up less space in the length of the vessel, but more height than those having vertical tubes, unless the latter are made sufficiently high to withdraw a tube within the boiler, when its height would be as great as the former. The Miller boiler, recently brought forward by the Novelty Works in New York, has some advantages over the ordinary form of flue boilers, as it allows of increased grate and fire surface within a given space, and is somewhat lighter than the ordinary flue boiler for the same amount of fire surface.

I am of opinion that *equal* efficiency may be obtained with either of the forms of boiler (properly constructed) here shown; but there are many things, particularly in sea steamers, to be considered, and for them that boiler is the best which, *giving equal* effect, occupies the least space, always keeping in view the facilities for cleaning and repairs, two points that have been very much overlooked among us. There is one point to which I wish to draw particular attention, and that is the necessity of having an increased number of furnaces of reduced width in our boilers, and continuing the separation to the chimney if possible. The advantages to be derived from this arrangement are increased surface in immediate contact with the fire, and a very much more regular supply of steam, for it is evident that where a boiler has but two furnaces, nearly one-half of its efficiency is destroyed while our furnaces are being fired, and of course the pressure of steam is immediately reduced, and as one evil often begets another, so this has induced the use of blowers on the principle that two wrongs make one right, I suppose, for that is the only one on which it can be advocated. *Sea steamers* should *never use blowers;* when they are really necessary their boilers *are defective.* These remarks apply with equal force, so far as number of furnaces are con-

cerned, to river steamers, but with them the increased weight of the boiler to obtain sufficient steam by natural draft would often exceed the extra quantity of coal consumed on the passage, (which occupies but a few hours,) and as speed is the primary object, the blower may be as much to be desired with them, as it is to be avoided in the former.

NOTE.

The quantity of water stated to have been evaporated by a given quantity of fuel, must not be taken as *strictly* correct; but where a comparison is to be made between two steamers of the same class, it will be found sufficiently accurate for all practical purposes, in obtaining information in relation to the consumption of steam and fuel. I found that nothing authentic could be ascertained in regard to the quantity of water *blown out* in marine steamers, and I have, therefore, not considered the losses from that source, or the steam lost in valve chests and at each end of the cylinder. On the other hand, it was just as impossible to obtain the pressure of steam on the piston, from want of indicators, and I was unwilling to adopt any imaginary rule for pressure, as that which would apply to sea steamers, running with throttle valves full open, would not apply to our river boats, where they are more or less throttled off, to maintain a full working pressure in the boiler. I have, therefore, taken the *pressure* as being the same both in the boiler and on the piston, and the *quantity* of steam used as being equal to the area of the piston multiplied by the length of stroke at which the steam was cut off, and the number of revolutions. As the management of our river, lake, and sea steamers differs as regards each other, but agrees in respect to each vessel of the same class, so the calculations of fuel here given will be found sufficiently accurate to compare one river steamer with another, or one sea steamer with another, but if a comparison is to be made between a river and a sea steamer, then an allowance must be made in favor of the latter, for the water blown out.
