## ENGINEERS' AND MECHANICS' POCKET-BOOK.

#### CONTAINING

UNITED STATES AND FOREIGN WEIGHTS AND MEASURES; TABLES OF AREAS AND CIRCUMFERENCES OF CIRCLES, CIRCULAR SEG-MENTS AND ZONES OF A CIRCLE;

> SQUARES AND CUBES, SQUARE AND CUBE ROOTS; LENGTHS OF CIRCULAR AND SEMI-ELLIPTIC ARCS; AND RULES OF ARITHMETIC.

#### MENSURATION OF SURFACES AND SOLIDS;

THE MECHANICAL POWERS:

GEOMETRY, TRIGONOMETRY, GRAVITY, STRENGTH OF MATERIALS, WATER WHEELS, HYDRAULICS, HYDROSTATICS, PNEU-MATICS, STATICS, DYNAMICS, GUNNERY, HEAT, WINDING EN-GINES, TONNAGE, SHOT, SHELLS, &C.

#### STEAM AND THE STEAM-ENGINE;

COMBUSTION, WATER, GUNPOWDER, CABLES AND ANCHORS, FUEL, AIR, guns, &c, &c.

TABLES OF THE WEIGHTS OF METALS, PIPES, &c MISCELLANEOUS NOTES, DIMENSIONS OF STEAMERS, MILLS, MOTION OF BODIES IN FLUIDS, ORTHOGRAPHY OF TECHNICAL TERMS, &c., &c.

> EIGHTH EDITION. \_\_\_\_\_

## BY CHAS. H. HASWELL, MARINE ENGINEER.

An examination of facts is the foundation of science.

## HON. WILLIAM S. MILLER,

OF NEW YORK,

IN TOKEN OF HIS EMINENT SERVICES, AS A MEMBER OF THE HOUSE
OF REPRESENTATIVES OF THE UNITED STATES, IN OBTAINING THE
PASSAGE OF THE ACT PROVIDING FOR THE CONSTRUCTION OF
UNITED STATES MAIL STEAMERS, AND OF THE AUTHOR'S
APPRECIATION OF HIS GREAT PUBLIC AND
PRIVATE WORTH.

NEW YORK, February 10, 1853.

Entered, according to Act of Congress, in the year 1853, by

HARPER & BROTHERS,

In the Clerk's Office of the Southern District of New York

## PREFACE.

THE following work is submitted to the Engineers and Mechanics of the United States by one of their number, who trusts that it will be found a convenient summary, for reference to Tables, Results and Rules connected with the discharge of their various duties.

The Tables comprising the Weights of Metals, Iron and Leaden Balls, Cast Iron and Copper Pipes, &c., were calculated expressly for this work, and from specific gravities of the different materials taken for the purpose.

The want of a work of this description in this country has long been felt, and this is peculiarly fitted to supply that want, in consequence of the adaptation of its rules to the metals, woods, and manufactures of the United States.

Having for many years experienced inconvenience for the want of a compilation of tables and rules by a Practical Mechanic, together with the total absence of *units* for the weights and strengths of American materials, I was induced to attempt the labour and the experiments necessary to furnish this work.

The proportions of the parts of the steam-engine and boilers will be found to differ in most instances materially from the English authorities; but as they are based upon the actual results of the most successful experience, I do not hesitate to put them forth, being well assured that an adherence to them will ensure both success and satisfaction.

The principal sources of information from which I have compiled are Adcock, Grier, Gregory, the Library of Use-

ful Knowledge, and the Ordnance Manual; and to the labours of the authors of these valuable works I freely acknowledge my indebtedness.

In my own efforts, I have been materially assisted by the officers of the West Point Foundry Association, who liberally furnished me with the means of making such experiments as were considered necessary; and to the Engineer of that establishment, Mr. B. H. Bartol, and also to Mr. Chas. W. Copeland, I am indebted for much valuable information and assistance.

To the Young Engineer I would say, cultivate a knowledge of physical laws, without which, eminence in his profession can never be securely attained; and if this volume should assist him in the attainment of so desirable a result, the object of the author will be fully accomplished

We have seen a proof copy of HASWELL'S Engineers' and Mechanics' Pocket Book, and approve of its design, which in extent exceeds that of any of its class: a work of this description has long been wanted, and we are satisfied of its usefulness and application.

December, 1843.

We concur in the above, having used a copy of Haswell's Engineers' and Mechanics' Pocket Book.

WILLIAM MAYNADIER, Captain Ordnance Corps, U. S. A.
WILLIAM J. TOTTEN,
JOSEPH TOMLINSON,

Pittsburg, Penn.

August, 1844.

We concur in the above.

JOHN ERICSSON, C. W. COPELAND, SAMUEL HUMPHREYS, J. R. ANDERSON, Civil Engineer, N. Y.
Principal Engineer, U. S. N.
Chief Naval Constructor, U. S. N.
Foundry and Steam Engine Manufactory, Richmond, Va.

March, 1846.

We concur in the above.

Francis Grice, Chief Naval Constructor, U. S. N. Frederick E. Sickels, Steam Engineer, N. Y.

September, 1847.

JOHN FARON, JR.,

A. MEHAFFEY,

JABEZ CONEY,

Segment From Works, Va.

Steam Engine Manufacturer, Boston, Mass.

We take pleasure in adding our names to the list of recommendations of Haswell's Engineers' and Mechanics' Pocket Book, which we consider the best of the kind.

1. P. Morris & Co., Steam Engine Manufacturers, Philadelphia, Penn.

With much pleasure we add our testimony to the value of Haswell's Engineers' and Mechanics' Pocket Book, which we are gratified to learn is about to be published in a fifth edition, as each succeeding issue contains valuable additions to the preceding.

There are several valuable English works of this description, but the peculiarities and differences in this country render his a far more useful book; we consider it, in fact, an almost indispensable pocket companion.

MURRAY & HAZLEHURST, Vulcan Works, Baltimore, Md.

We concur in recommending Haswell's Engineers' and Mechanics' Pocket Book, and consider it a very useful and valuable work.

A. & C. Reeder, Steam Engine Manufacturers, Baltimore, Md.

In the daily use of Haswell's Engineers' and Mechanics' Pocket Book, we concur in the recommendation of it as one of very general reference and great utility; it is an indispensable pocket companion.

REANEY, NEAFIE & Co., Penn Works, Kensington, Phila. August, 1848.

Propellers and Iron Hulls 289	ORTHOGRAPHY OF TECHNICAL TERMS 309

## EXPLANATIONS OF THE CHARACTERS USED IN THE FOLLOWING TABLES AND CALCULATIONS.

- = Equal to, as, 12 inches = 1 foot, or  $8 \times 8 = 16 \times 4$ .
- + Plus, or more, signifies addition; as, 4+6+5=15.
- Minus, or less, signifies subtraction; as, 15-5=10.
- $\times$  Multiplied by, or into, signifies multiplication; as,  $8 \times 9 = 72$ .
- $\div$  Divided by, signifies division; as,  $72 \div 9 = 8$ .
- : Is to :: so is to 16.
- $\checkmark$  Prefixed to any number signifies that the square root of that number is required; as,  $\checkmark$ 16=4; that is,  $4\times4=16$ .
- 3/ Signifies that the *cube root* of that number is required; as,  $\sqrt[3]{64} = 4$ ; that is,  $4 \times 4 \times 4 = 64$ .
- <sup>2</sup> added to a number signifies that that number is to be squared; thus, 4<sup>2</sup>, means that 4 is to be multiplied by 4.
- 3 added to a number signifies that that number is to be cubed; thus, 4<sup>3</sup>, is = 4×4×4=64. The power, or number of times a number is to be multiplied by itself is shown by the number added; as, 2<sup>3</sup> 4<sup>5</sup>, &c.
- The bar signifies that the numbers are to be taken together; as, 8-2+6=12, or  $3\times 5+3=24$ .
  - Decimal point, signifies when prefixed to a number, that that number has a unit (1) for its denominator; as, .1 is  $\frac{1}{10}$ , .155 is  $\frac{155}{1000}$ , &c.
- Signifies difference, and is placed between two quantities when it is not evident which of them is the greater.
- o Degrees, 'minutes, " seconds, " thirds.
- < Signifies angle.
- a=1, a=2, a=3, &c., denote inverse powers of a, and are equal to  $\frac{1}{a^1}$ ,  $\frac{1}{a^2}$ ,  $\frac{1}{a^3}$ , &c.
- 7 Is put between two quantities to express that the former is greater than the latter; as, a7b, reads a greater than b.
- $\angle$  Signifies the reverse; as,  $a \angle b$ , reads a less than b.
- ... Signifies therefore.
- · · · Signifies because.
- () Parentheses are used to show that all the figures within them are to be operated upon as if they were only one; thus,  $(3+2)\times 5=25$ .
- p is used to express the ratio of the circumference of a circle to its diameter = 3.1415926, &c.
- A A' A" A" signifies A, A prime, A second, A third, &c.
- $a \times d$ , a.d, or ad, signifies that a is to be multiplied by d.

Note. The degrees of temperature used in this work are those of Fahrenheit.

## NOTATION.

1 = I. 2 = II. As often as a character is repeated, 3 = III. so many times is its value repeated. 4 = IV5 = V. A less character before a greater 6 = VIdiminishes its value, as IV = I from (V, or 1 subtracted from 5 = 4.7 = VII.8 = VIII.9 = IX. A less character after a greater increases its value, as XI = X+I, or 10 = X. 10+1=11.20 = XX. 30 = XXX. 40 = XL. 50 = L. 60 = LX. 70 = LXX80 = LXXX. 90 = XC. 100 = C. For every O annexed, this be-500 = D, or IO. comes 10 times as many. For every C and O, placed one at 1,000 = M, or CIO. each end, it becomes 10 times as many. 2,000 = MM. $5,000 = \overline{V}$ , or IOO.  $6,000 = \overline{VI}$ .  $10,000 = \overline{X}$ , or CCIOO. A bar, thus -, over any  $50,000 = \overline{L}$ , or IOOO. number, increases it 1000  $60.000 = \overline{LX}$ times.  $100,000 = \overline{C}$ , or CCCIOOO.  $1,000,000 = \overline{M}$ , or CCCCIDDDD.  $2,000,000 = \overline{MM}$ . Examples.—1840, MDCCCXL. 18560, XVIIIDLX.

#### UNITED STATES' WEIGHTS AND MEASURES.

## Measures of Length.

10	inches	== 1 foot.	1	Inches.	Feet.	Yards.	Rods.	Furl.
	*******	= 1 yard.	ı	36=	3.			
. 3			- 1					
$5\frac{1}{2}$	yards	= 1  rod.			$16\frac{1}{2} =$			
40	rods	= 1 furlong	ŗ.	7920 =	660 =	220 =	<b>40.</b>	
8	furlongs	= 1 mile.		63360 = 8	5280 =	1760 =	: 320	=8.

The inch is sometimes divided into 3 barley corns, or 12 lines. A hair's breadth is the 48th of an inch.

#### Gunter's Chain.

7.92 inches = 1 link.

100 links = 4 rods, or 22 yards.

#### Ropes and Cables.

6 feet = 1 fathom.

120 fathoms = 1 cable's length.

## Geographical and Nautical Measure.

1 degree of a great circle of the earth = 69.77 Statute miles.
1 mile . . . . . . = 2046.58 yards.

### Log Lines.

1 knot = 51.1625 feet, or 51 feet  $1\frac{3}{4}$  + inches.

1 fathom = 5.11625 feet, or 5 feet  $1\frac{1}{3}$  + inches.

Estimating a mile at  $6139_{\frac{1}{2}}$  feet, and using a 30" glass. If a 28' glass is used, and eight divisions, then

1 knot = 47 feet 9 + inches.

1 fathom = 5 feet  $11\frac{5}{8}$  inches.

The line should be about 150 fathoms long, having 10 fathoms between the chip and first knot for stray line.

Note.—Bowditch gives 6120 feet in a sea mile, which, if taken as the length, will make the divisions 51 feet and 5 1-10 feet.

#### Cloth.

1 nail =  $2\frac{1}{4}$  inches =  $\frac{1}{10}$ th of a yard.

1 quarter = 4 nails.

5 quarters = 1 ell English

#### Pendulums.

6 points = 1 line. 12 lines = 1 inch.

#### Shoemakers'.

No. 1 is  $4\frac{1}{8}$  inches in length, and every succeeding number is  $\frac{1}{3}$  of an inch.

There are 28 divisions, in two series of numbers, viz., from 1 to 13, and 1 to 15.

#### Circles.

60 seconds	=	1 min	ute.	1	. 11
60 minutes	= ;		3600 = 60		
360 degrees	== ]	circl	e.		1296000 = 21600.
1 day is .					.002739 of a year.
1 minute is					.000694 of a day.

#### Miscellaneous.

1 palm $=$ 3 inches.	1  span  = 9  inches.
1 hand $= 4$ inches.	1  metre = 3.28174  feet.

The standard of measure is a brass rod, which, at the temperature of 32° Fahrenheit, is the standard yard.

## Measures of Surface.

144 square inches = 1 square foot. | Inches. 9 square feet = 1 square yard. | 1296

#### Land.

40	square yards square rods	=1  so	luare rod. luare rood.	Yards. 1210.	Rods.	Roods.
10	square roods square chains	=1 ac	ere.	4840 =		05.00
640	acres	= 1  sc	quare mile.	3097600 ==	102400 :	= 2500.

Note. -208.710321 feet, 69.5701 yards, or 220 by 198 feet square = 1 acre.

## Paper.

24  sheets = 1  qu	nire.   Sheets.
20  quires = 1  re	am. 480.

## Drawing Paper.

Cap .	13 $\times$ 16 inches.	Columbier .	$33rac{3}{4} imes$	23 inches.
Demy .	$19\frac{1}{2} \times 15\frac{1}{2}$ "	Atlas	$33 \times$	26 "

Elephant	$27\frac{3}{4} \times 22\frac{1}{4}$ "	Uncle Sam .	48 ×	120 "

## Measures of Capacity.

## Liquid.

4	gills	=	1	pint.	1 .	Gills.	Pints.
2	pints	=	1	quart.	-	8.	
4	quarts	==	1	gallon.		32 =	= 8.

The standard gallon measures 231 cubic inches and contains

8.3388822 avoirdupois pounds, or 58372.1754 troy grains of distilled water at 39° 83 Fahrenheit; the barometer at 30 inches.

The gallon of the State of New-York contains 221.184 cubic inches, or 8 pounds of pure water at its maximum density.

The Imperial gallon (British) contains 277.274 cubic inches.

#### Dry.

2 pints = 1 quart.	Pints. Quarts Gallons.
4 quarts = 1 gallon.	8.
2 gallons = 1 peck.	16 = 8.
4 pecks = 1 bushel.	64 = 32 = 8.

#### U. S. Standard Bushel.

The standard bushel is the *Winchester*, which contains 2150.42 cubic inches, or 77.627413 lbs. avoirdupois of distilled water at its maximum density.

Its dimensions are  $18\frac{1}{2}$  inches diameter inside,  $19\frac{1}{2}$  inches outside, and 8 inches deep; and when heaped, the cone must not be less than 6 inches high, equal 2747.70 cubic inches for a true cone.

The bushel of the State of New-York contains 80 lbs. of pure water at its maximum density, or 2211.84 cubic inches.

1728 cubic	inches	===	1	foot.	Inches.
27 cubic	feet	=	1	yard.	46656.

## Miscellaneous.

# 1 chaldron = 36 bushels, or 57.25 cubic feet. 1 cord of wood 128 cubic feet. 1 perch of stone 24.75 cubic feet.

## Measures of Weight.

## Avoirdupois.

16 drachms = 1 ounce.	Drachms. Ounces. Pounds.
16 ounces = 1 pound.	256.
112 pounds $= 1$ cwt.	28672 = 1792.
20  cwt. = 1  ton.	573440 = 35840 = 2240.
1  lb. = 14  oz	. 11 dwt. 16 gr. troy.

The standard avoirdupois pound is the weight of 27.7015 cubic inches of distilled water weighed in air, at the temperature of the maximum density (39°.83), the barometer being at 30 inches.

#### Troy.

24 grains 20 dwt. 12 ounces	= 1 dwt. = 1 ounce. = 1 pound.	Grains. 480. 5760 ==	Dwt. 240.
in cances	r pound.	1 01.00	WTU.

## Apothecaries.

	grains				Grains.	Scruples.	Drachms.
o	scruples		1	uraenin.	60.		
8	drachms	=	1	ounce.	480 =	= 24.	
12	ounces	==	1	pound.	5760 =	= 288 =	= 96.

#### Diamond.

1 cord Virginia pine		=2	700	"	-
1 cord Southern pine		=3	300	."	
1 stone			14	66	

Coals are usually purchased at the conventional rate of 28 bushels (5 pecks) to a ton =43.56 cubic feet.

## Measures of Value.

```
1 eagle = 258 troy grains.
1 dollar = 412.5 "
```

The standard of gold and silver is 900 parts of pure metal, and 100 of alloy, in 1000 parts of coin.

## Relative Mint Value of Foreign Gold Coins,

## By Law of Congress, August, 1834.

	Coin.				Weight. Dwt. Gr.		Value.	
BRAZIL.	1 Johannes				18		\$17.068	
	1 Dobraon .				34 12		32.714	4
	1 Dobra .				18 06		17.305	
	1 Moidore .				6 22		6.560	
	1 Crusado .				164		.638	
ENGLAND.	1 Guinea .				5 9 3		5.116	
	1 Sovereign				$5 \ 3\frac{7}{4}$		4.875	
FRANCE.	1 Double Louis	(1786)	)		10 11		9.694	
	1 Double Napol				8 7		7.713

## Measures of Capacity.

BRITISH. The Imperial gallon measures 277.274 cubic inches, containing 10 lbs. avoirdupois of distilled water, weighed in air, at the temperature of 629, the barometer at 30 inches.

For Grain. 8 bushels = 1 quarter.

1 quarter = 10.2694 cubic feet.

Coal, or heaped measure. 3 bushels = 1 sack.

12 sacks = 1 chaldron.

Imperial bushel = 2218.192 cubic inches. \*Heaped bushel,  $19\frac{1}{2}$  ins. diam., cone 6 ins. high = 2815.4872 cub. ins.

1 childron = 58.658 cubic feet, and weighs 3136 pounds. 1 childron (Newcastle) = 5936 pounds.

FRENCH. New System.—1 Litre = 1 cub. decimetre, or 61.074 U. S. cub. ins. Old System.—1 Boisseau = 13 litres = 793.964 cub. ins., or 3.43 galls 1 Pinte = 0.931 litres, or 56.817 cubic inches.

Spanish. 1 Wine Arroba = 4.2455 gallons.

1 Fanega (common measure) = 1.593 bushels.

AUSTRIAN				1	46				: 1.2		66		
PRUSSIAN			-	1	46					333	"		

Note.—In the new French system, the values of the base of each measure, viz., Metre, Litre, Stere, Arc, and Gramme, are decreased or increased by the following words prefixed to them. Thus,

Milli exp	resses th	ne 1000th part.	Hecato	express	es 100	times the val	ue
Centi	"	100th "	Chilio	- 16	1000	. "	
Deci	44	10th "	Myrio	"	10000	"	
Deca	44	10 times the value.					

## Table showing the relative value of $Foreign\ Weights$ compared with British.

Places.	Weights.	Number equal to 100 avoir- dupois pouds.		<b>W</b> eights.	Number equal to 100 avoir- dupois pounds.
Aleppo	Rottoli Oke Rottoli " Pound " Catty Seer Pound " " Rottoli " Catty Oke Pound " " Rottoli " " Rottoli " " " " " " " " " " " " " " " " " " "	20.46 35.80 107. 84. 91.8 96.75 112.6 76.78 53.57 96.8 125.3 90.93 97.14 105. 85.9 75.45 35.55 90.80 131.72 19.07 25.28 133.56 82.35 92.86	Japan Leghorn Leipsic Leyons Madeira Mocha Morea Naples Rome Rotterdam Russia Sicily Simyrna Sumatra Sweden Tangiers Tripoli Tunis Venice Vienna Warsaw	Pound Catty Pound " (common) " (silk) Maund Pound Rottoli Pound " " " " " " " " " " " " " " " " " " "	98.81 143.20 33.33 90.79 50.91 133.69 91.80 110.86 142.85 36.51 35.56 106.67 120.68 94.27 89.28 90.09

## Scripture Long Measures.

	Feet.	Inches.	1	Feet.	Inches.
A digit	$\cdot = 0$	0.912	A cubit .	=1	9.888
A palm	$\cdot = 0$	3.648	A fathom .	=7	3.552
A span	=0	10.944	i		

## Grecian Long Measures.

	Feet.	Inches.		Feet.	Inches.
A digit .	=0	Inches. 1 1 0.75541 6	$\mathbf A$ stadium	= 604	4.5
A pous (foot)	=1	0.0875	A mile .	=4835	
A cubit .	=1	1.59848			

A Greek or Olympic foot = 12.108 inches. A Pythic or natural foot = 9.768 "

## Jewish Long Measures.

A cubit = 1.824	A mile = 7296
A Sabbath day's	A day's journey . = 175104
journey $\cdot = 3648$ .	(or 33 miles 864 feet).

## Roman Long Measures.

Feet.	Inches.	Feet.	Inches.
A digit $\cdot \cdot \cdot = 0$	.72575	A cubit $\cdot = 1$	5.406
An uncia (inch) $= 0$	.967	A passus . = 4	10.02
A pes (foot) $\cdot = 0$	11.604	A mile = 4835	

### Miscellaneous.

	Feet.	1	Feet.
Arabian foot .	= 1.095	Hebrew foot	= 1.212
Babylonian foot	= 1.140	" cubit	= 1.817
Egyptian	= 1.421	" sacred cubit	= 2.002

Note .- The above dimensions are British.

## Table for finding the Distance of Objects at Sea, in Statute Miles.

	, , ,		,				
Height in feet.	Distance in miles.						
*.582	1.	11	4.39	30	7.25	200	18.72
1	1.31	12	4 58	35	7.83	300	22.91
2	1.87	13	4.77	40	8.37	400	26.46
3	2.29	14	4.95	45	8.87	500	29.58
4	2.63	15	5.12	50	9.35	1000	32.41
5	2.96	16	5.29	60	10.25	2000	59.20
6	3.24	17	5.45	70	11.07	3000	72.50
7	3.49	18	5.61	80	11.83	4000	83.7
8	3.73	19	5.77	90	12.55	5000	93.5
9	3.96	20	5.92	100	13.23	1 mile.	96.1
10	4.18	25	6.61	150	16.20		

\* 6.99 inches.

The difference in two levels is as the square of the distance Thus, if the height is required for 2 miles,

 $1^2:2^2::6.99:27.96$  inches; and if for 100 miles,  $1^2:100^2::6.99:1.103+$  miles.

For Geographical miles, the distance for one mile is 7.962 inches

EXAMPLE.—If a man at the foretop-gallant mast-head of a ship, 100 feet from the water, sees another and a large ship (hull to), how far are the ships apart?

A large ship's bulwarks are, say 20 feet from the water.

Then, by table, 100 feet . . . . 
$$= 13.23$$
  
 $= 5.92$   
Distance . .  $= 13.23$   
 $= 5.92$ 

Note,  $-\frac{1}{13}$  should be added for horizontal refraction.

## To Reduce Longitude into Time.

Multiply the number of degrees, minutes, and seconds by 4, and the product is the time.

EXAMPLE.—Required the time corresponding to 50° 31'.

$$\frac{50^{\circ} 31'}{4}$$
 $h.3 22' 4'' Ans.$ 

If time is to be reduced, then

$$\frac{4) \ 3}{50} \ \frac{22}{31} \ \frac{4}{4ns}$$

Or, multiplying by 15: thus,

Degrees of longitude are to each other in length, as the cosines of their latitudes.

For every 50 they are as follows:

		Miles.			Miles.
Equator		60.	50°		38.57
5°		59.77	55°		34.41
10°		59.09	60°		30.
15°		57.96	65°		25.36
20°		56.38	70°		20.52
25°		54.38	75°		15.53
30°	•	51.96	80°		10.42
35°		49.15	85°		5.23
40°		45.96	90°		0.00
45°		42.43			

. . . . . .

#### VULGAR FRACTIONS.

A Fraction, or broken number, is one or more parts of a Unit.

Example.-12 inches are 1 foot.

Here, 1 foot is the unit, and 12 inches its parts; 3 inches, therefore, are the one fourth of a foot, for 3 is the quarter or fourth of 12.

A Vulgar Fraction is a fraction expressed by two numbers placed one above the

other, with a line between them; as, 50 cents is the ½ of a dollar.

The upper number is called the *Numerator*, because it shows the number of parts used. The laws maniver is called the Denominator, because it denominates, or gives

name to the fraction.

The Terms of a fraction express both numerator and denominator; as, 6 and 9 are the terms of  $\frac{6}{9}$ .

A Proper fraction has the numerator equal to, or less than the denominator; as, 1, &cc.

An Improper fraction is the reverse of a proper one; as,  $\frac{2}{1}$ , &c.

A Mixed fraction is a compound of a whole number and a fraction; as,  $5\frac{7}{8}$ , &c.

A Compound fraction is the fraction of a fraction; as, ½ of ½, &c. A Complex fraction is one that has a fraction for its numerator or denominator, or

both; as,  $\frac{1}{2}$ , or  $\frac{5}{3}$ , or  $\frac{1}{2}$ , or  $\frac{31}{6}$ , &c.

A Fraction denotes division, and its value is equal to the quotient obtained by di viding the numerator by the denominator; thus, 12 is equal to 3, and 21 is equal to 41.

## REDUCTION OF VULGAR FRACTIONS.

To find the greatest Number that will divide Two or more Numbers without a Remainder.

RULE .- Divide the greater number by the less; then divide the divisor by the remainder; and so on, dividing always the last divisor by the last remainder, until nothing remains.

Example.—What is the greatest common measure of 1908 and 936?

So 36 is the greatest common measure.

To find the least Common Multiple of Two or more Numbers.

RULE .- Divide by any number that will divide two or more of the given numbers without a remainder, and set the quotients with the undivided numbers in a line beneath.

Divide the second line as before, and so on, until there are no two numbers that san be divided; then the continued product of the divisors and quotients will give the multiple required.

Example. -- What is the least common multiple of 40, 50, and 25?

Then  $5\times5\times2\times4=200$  Ans.

To reduce Fractions to their lowest Terms.

RULE .- Divide the terms by any number that will divide them without a re mainder, or by their greatest common measure at once.

**EXAMPLE.**—Reduce  $\frac{720}{960}$  of a foot to its lowest terms.  $\frac{720}{960} \div 10 = \frac{7}{96} \div 8 = \frac{9}{12} \div 3 = \frac{3}{4}$ , or 9 inches.

To reduce a Mixed Fraction to its equivalent, an Improper

Note.—Mixed and improper fractions are the same; thus,  $5\frac{1}{2} = \frac{1}{2}$ . For illustration, see following examples:

RULE .- Multiply the whole number by the denominator of the fraction, and to the product add the numerator; then set that sum above the denominator.

**EXAMPLE.**—Reduce  $23\frac{2}{6}$  to a fraction.

$$\frac{23\times 6+2}{6} = \frac{140}{6}$$

EXAMPLE.—Reduce  $\frac{123}{6}$  inches to its value in feet.  $123 \div 6 = 20\frac{3}{6}$ ; that is, 20 feet and  $\frac{3}{6}$  or  $\frac{1}{2}$  of a foot.

To reduce a Whole Number to an equivalent Fraction having a given Denominator.

Rule.-Multiply the whole number by the given denominator, and set the product over the said denominator.

Example.—Reduce 8 to a fraction whose denominator shall be 9.  $8 \times 9 = 72$ ; then  $\frac{7}{9}$  the answer.

To reduce a Compound Fraction to an equivalent Simple one.

 $R_{\rm ULE}.-Multiply$  all the numerators together for a numerator, and all the denominators together for a denominator.

Note .- When there are terms that are common, they may be omitted.

Example.—Reduce ½ of ¾ of ¾ to a simple fraction.

$$\frac{1}{2} \times \frac{3}{4} \times \frac{2}{3} = \frac{6}{24} = \frac{1}{4}$$
 Ans.

Or,  $\frac{1}{2} \times \frac{3}{4} \times \frac{2}{3} = \frac{1}{4}$ , by cancelling the 2's and 3's.

Example.—Reduce  $\frac{1}{2}$  of  $\frac{3}{4}$  of a pound to a simple fraction.  $\frac{1}{2} \times \frac{3}{4} = \frac{3}{8}$  Ans.

To reduce Fractions of different Denominations to equivalent ones having a common Denominator.

RULE.—Multiply each numerator by all the denominators except its own for the new numerators; and multiply all the denominators together for a common denominator

Note .- In this, as in all other operations, whole numbers, mixed, or compound fractions, must first be reduced to the form of simple fractions.

Example.—Reduce 
$$\frac{1}{2}$$
,  $\frac{2}{3}$ , and  $\frac{3}{4}$  to a common denominator.  
 $1 \times 3 \times 4 = 12$   
 $2 \times 2 \times 4 = 16$   
 $3 \times 2 \times 3 = 18$   
 $2 \times 3 \times 4 = 24$   
 $2 \times 3 \times 4 = 24$ 

The operation may be performed mentally; thus, Reduce  $\frac{1}{8}$ ,  $\frac{3}{2}$ ,  $\frac{6}{8}$ , and  $\frac{5}{2}$  to a common denominator.

$$\frac{3}{2} = \frac{12}{8}$$
.  $\frac{1}{8} = \frac{1}{8}$ .  $\frac{6}{8} = \frac{6}{8}$ .  $\frac{5}{2} = \frac{20}{8}$ .

To reduce Complex Fractions to Simple ones.

RULE.—Reduce the two parts both to simple fractions; then multiply the numerator of each by the denominator of the other.

Example.—Simplify the complex fraction  $\frac{2^2_3}{4^4_4}$ .

$$2\frac{3}{3} = \frac{8}{3}$$
  $8 \times \frac{5}{3} = \frac{40}{72} = \frac{5}{9}$  Ans.  $4\frac{4}{3} = \frac{2}{5}$ 

## ADDITION OF VULGAR FRACTIONS.

RULE.—If the fractions have a common denominator, add all the numerators together, and then place the sum over the denominators.

NOTE.—If the prepared fractions have not a common denominator, they must be reduced to one. Also, compound and complex must be reduced to simple fractions.

EXAMPLE. - Add & and & together.

$$\frac{1}{4} + \frac{3}{4} = \frac{4}{4} = 1$$
 Ans.

**Example.**—Add  $\frac{1}{2}$  of  $\frac{3}{4}$  of  $\frac{6}{10}$  to  $2\frac{1}{8}$  of  $\frac{3}{4}$ .

$$\begin{array}{l} \frac{1}{2} \times \frac{3}{4} \times \frac{6}{10} = \frac{18}{80}. \\ 2\frac{1}{8} \text{ of } \frac{3}{4} = \frac{17}{8} \times \frac{3}{4} = \frac{51}{32}. \quad \text{Then, } \frac{18}{80} + \frac{51}{32} = 1\frac{131}{100}. \text{ Ans.} \end{array}$$

### SUBTRACTION OF VULGAR FRACTIONS.

Rule.—Prepare the fractions the same as for other operations, when necessary; then subtract the one numerator from the other, and set the remainder over the common denominator.

Example.—What is the difference between \$\frac{5}{6}\$ and \$\frac{1}{6}\$?

$$\frac{5}{6} - \frac{1}{6} = \frac{4}{6} Ans.$$

Example.—Subtract  $\frac{6}{8}$  from  $\frac{3}{9}$ .

$$\begin{cases}
6 \times 9 = 54 \\
3 \times 8 = 24 \\
8 \times 9 = 72
\end{cases} = \frac{54}{72} - \frac{24}{72} = \frac{30}{72} \text{ Ans.}$$

## MULTIPLICATION OF VULGAR FRACTIONS.

Rule.—Prepare the fractions as previously required; multiply all the numerators together for a new numerator, and all the denominators together for a new denominator.

Example.—What is the product of  $\frac{3}{4}$  and  $\frac{3}{9}$ ?  $\frac{3}{4} \times \frac{3}{9} = \frac{9}{36} = \frac{1}{4} Ans.$ 

Example.-What is the product of 6 and 2 of 5?

$$\frac{6}{3} \times \frac{2}{3}$$
 of  $5 = \frac{6}{3} \times \frac{10}{3} = \frac{60}{3} = 20$  Ans.

### DIVISION OF VULGAR FRACTIONS.

Rule.—Prepare the fractions as before; then divide the numerator by the numerator, and the denominator by the denominator, if they will exactly divide; but if not, invert the terms of the divisor, and multiply the dividend by it, as in multiplication.

Example.—Divide 
$$\frac{25}{9}$$
 by  $\frac{5}{3}$ .
$$\frac{25}{9} \div \frac{5}{3} = \frac{5}{3} = 1\frac{2}{3} \text{ Ans.}$$

To find the Value of a Fraction in Parts of a whole Number.

Rule.—Multiply the whole number by the numerator, and divide by the denominator; then, if anything remains, multiply it by the parts in the next inferior denomination, and divide by the denominator, as before, and so on as far as necessary, so shall the quotients placed in order be the value of the fraction required.

Example.—What is the value of ½ of 2 of \$9?

$$\frac{1}{2}$$
 of  $\frac{2}{3} = \frac{2}{6} \times \frac{9}{6} = \frac{18}{6} = $3$  Ans.

EXAMPLE.—Reduce & of a pound to avoirdupois ounces.

pound to avoirdupois
$$\frac{3}{1}$$
4)  $\overline{3}$  (0 lbs.
$$\underline{16} \text{ ounces in a lb.}$$
4)  $\overline{48}$ 
 $\overline{12} \text{ ounces, } \mathcal{A}ns.$ 

**Example.**—Reduce  $\frac{3}{10}$  of a day to hours.

$$\frac{3}{10} \times \frac{24}{10} = \frac{72}{10} = 7\frac{2}{10}$$
 hours, Ans.

To reduce a Fraction from one Denomination to another.

Rule.—Multiply the number of parts in the next less denominator by the numerator if the reduction is to be to a less name, but multiply by the denominator if to a greater.

EXAMPLE.—Reduce & of a dollar to the fraction of a cent.

$$\frac{1}{4} \times \frac{100}{1} = \frac{100}{4} = \frac{25}{1}$$
, the answer.

EXAMPLE.—Reduce & of an avoirdupois pound to the fraction of an ounce

$$\frac{1}{6} \times \frac{1}{1} = \frac{1}{6} = \frac{8}{3}$$
, the answer-

Example.—Reduce  $\frac{2}{3}$  of a cwt. to the fraction of a lb.

$$\frac{2}{7} \times \frac{4}{1} \times \frac{28}{1} = \frac{224}{7} = \frac{32}{1}$$
, the answer.

EXAMPLE.—Reduce \(^2\_3\) of \(^3\_4\) of a mile to the fraction of a foot.

$$\frac{2}{3}$$
 of  $\frac{3}{4} = \frac{6}{12} \times \frac{5280}{1} = \frac{31680}{12} = \frac{2640}{1}$ , the answer.

Example.—Reduce 4 of a square foot to the fraction of an inch.

$$\frac{1}{4} \times \frac{144}{1} = \frac{144}{4} = \frac{36}{1}$$
 Ans.

For Rule of Three in Vulgar Fractions, see page 29.

## DECIMAL FRACTIONS.

A Decimal Fraction is that which has for its denominator a unit (1), with as many ciphers annexed as the numerator has places; it is usually expressed by setting down the numerator only, with a point on the left of it. Thus,  $\frac{4}{10}$  is .4,  $\frac{3.5}{10.5}$  is .85,  $\frac{0.015}{10.000}$  is .0075, and  $\frac{1.25}{10.0000}$  is .00125. When there is a deficiency of figures in the numerator, prefix ciphers to make up as many places as there are eithers in the denominator.

Mixed numbers consist of a whole number and a fraction; as, 3.25, which is the same as  $3.\frac{2.5}{10.0}$ , or  $\frac{3.2.5}{10.0}$ .

Ciphers on the right hand make no alteration in their value; for .4, .40, .400 are

Ciphers on the right hand make no alteration in their value; for .4, .40, .400 are decimals of the same value, each being  $\frac{4}{1.0}$ , or  $\frac{2}{5}$ .

#### ADDITION OF DECIMALS.

Rule.—Set the numbers under each other according to the value of their places, as in whole numbers, in which state the decimal points will stand directly under each other. Then, beginning at the right hand, add up all the columns of numbers as in integers, and place the point directly below all the other points.

Example.—Add together 25.125, 56.19, 1.875, and 293.7325.

25.125 56.19 1.875 293.7325 376.9925 the sum.

#### SUBTRACTION OF DECIMAL FRACTIONS.

RULE.—Place the numbers under each other as in addition; then subtract as in whole numbers, and point off the decimals as in the last rule.

Example:—Subtract 15.150 from 89.1759.

89.1759 15.150 74.0259 Rem.

#### MULTIPLICATION OF DECIMALS.

Rule.—Place the factors, and multiply them together the same as if they were whole numbers; then point off in the product just as many places of decimals as there are decimals in both the factors. But if there be not so many figures in the product, supply the deficiency by prefixing ciphers.

EXAMPLE .- Multiply 1.56 by .75.

1.56 .75 780 1092 1.1700 Prod.

#### BY CONTRACTION.

To contract the Operation so as to retain only as many Decimal places in the Product as may be thought necessary.

Rule.—Set the unit's place of the multiplier under the figure of the multiplicand whose place is the same as is to be retained for the last in the product, and dispose of the rest of the figures in the contrary order to what they are usually placed in. Then, in multiplying, reject all the figures that are more to the right hand than each multiplying figure, and set down the products, so that their right hand figures may fall in a column straight below each other; and observe to increase the first figure in every line with what would arise from the figures omitted; thus, add 1 for every result from 5 to 14, 2 from 15 to 24, 3 from 25 to 34 from 35 to 44, &c., &c., and the sum of all the lines will be the product as required.

EXAMPLE.—Multiply 13.57493 by 46.20517, and retain only four places of decimals in the product. 13.574 93

71 502.64 54 299 72 8 144 96+2 for 18 271 50+2 " 18 6 79+4 " 35 14+1 " 5 9+2 " 21 627 23 20

Example.-Multiply 27.14986 by 92.41035, and retain only five places of decimals. Ans. 2508.92806.

#### DIVISION OF DECIMALS.

RULE.—Divide as in whole numbers, and point off in the quotient as many places for decimals as the decimal places in the dividend exceed those in the divisor; but if there are not so many places, supply the deficiency by prefixing ciphers.

EXAMPLE.-Divide 53.00 by 6.75. 6.75) 53.00 (= 7.851 + ...

Here 3 ciphers were annexed to carry out the division.

#### BY CONTRACTION.

RULE.—Take only as many figures of the divisor as will be equal to the number of figures, both integers and decimals, to be in the quotient, and find how many times they may be contained in the first figures of the dividend, as usual.

Let each remainder be a new dividend; and for every such dividend leave out one figure more on the right-hand side of the divisor, carrying for the figures cut off as in Contraction of Multiplication.

Note .- When there are not so many figures in the divisor as are required to be in the quotient, continue the first operation till the number of figures in the divisor be equal to those remaining to be found in the quotient, after which begin the contraction.

Example.—Divide 2508.92806 by 92.41035, so as to have only four places of decimals in the quotient.

EXAMPLE. - Divide 4109.2351 by 230.409, retaining only four decimals in the quotiont Ans. 17.8345.

#### REDUCTION OF DECIMALS.

To reduce a Vulgar Fraction to its equivalent Decimal.

Rule.-Divide the numerator by the denominator, annexing ciphers to the numerator as far as necessary.

EXAMPLE.—Reduce 4 to a decimal.

To find the Value of a Decimal in Terms of an Inferior Denomination.

RULE .- Multiply the decimal by the number of parts in the next lower denomination, and cut off as many places for a remainder, to the right hand, as there are places in the given decimal.

Multiply that remainder by the parts in the next lower denomination, again cutting off for a remainder, and so on through all the parts of the integer.

EXAMPLE.-What is the value of .875 dollars ?

$$\begin{array}{c} .875 \\ 100 \\ \text{Cents,} & \overline{87,500} \\ \underline{10} \\ \text{Mills,} & \overline{5.000} \end{array}$$

Ans. 87 cents 5 mills.

Example.—What is the content of .140 cubic feet in inches?

 $\frac{1728}{241.920}$  cubic inches in a cubic foot.

Ans.  $241.\frac{920}{1000}$  cubic inches.

EXAMPLE.—What is the value of .00129 of a foot?

Ans. .01548 inches.

Example.—What is the value of 1.075 tons in pounds?

Ans. 2408.

To reduce Decimals to equivalent Decimals of higher Denomina-

Rule.—Divide by the number of parts in the next higher denomination, continuing the operation as far as required.

EXAMPLE.—Reduce 1 inch to the decimal of a foot.

EXAMPLE.—Reduce 14 minutes to the decimal of a day.

Example.—Reduce 14" 12" to the decimal of a minute.

NOTE .- When there are several numbers, to be reduced all to the decimal of the highest.

Reduce them all to the lowest denomination, and proceed as for one denomination.

Example.—Reduce 5 feet 10 inches and 3 barlevcorns to the decimal of a vard.

#### RULE OF THREE IN DECIMALS.

RULE.—Prepare the terms by reducing the vulgar fractions to decimals, compound numbers to decimals of the highest denomination, the first and third terms to the same name; then proceed as in whole numbers. See Rule, page 31.

Example.—If \( \frac{1}{2} \) a ton of iron cost \( \frac{3}{4} \) of a dollar, what will .625 of a ton cost ?

$$\begin{array}{c}
1 = .5 \\
4 = .75
\end{array}$$

$$\begin{array}{c}
.5 : .75 : .625 \\
.626 \\
.5 : .46875 \\
.9375 \text{ dollars, } Ans.
\end{array}$$
C 2

#### DUODECIMALS.

In Duodecimals, or Cross Multiplication, the dimensions are taken in feet, inches, and twelfths of an inch.

Rule.—Set down the dimensions to be multiplied together, one under the other, so that feet may stand under feet, inches under inches, &c.

Multiply each term of the multiplicand, beginning at the lowest, by the feet in the multiplier, and set the result of each immediately under its corresponding term, carrying 1 for every 12, from one term to the other. In like manner, multiply all the multiplicand by the inches of the multiplier, and then by the twelfth parts, setting the result of each term one place farther to the right hand for every multiplier. The sum of the products is the answer.

EXAMPLE. - Multiply 1 foot 3 inches by 1 foot one inch.

PROOF.—1 foot 3 inches is 15 inches, and 1 foot 1 inch is 13 inches; and  $15\times13$  = 195 square inches. Now the above product reads 1 foot 4 inches and 3 twelfths of an inch, and

1 foot 
$$=$$
 144 square inches.  
4 inches  $=$  48 "  
3 twelfths  $=$  3 "

**Example.**—How many square inches are there in a board 35 feet  $4\frac{1}{2}$  inches long and 12 feet  $3\frac{1}{3}$  inches wide?

EXAMPLE.—Multiply 20 feet 62 inches by 40 feet 6 inches.

By duodecimals, Ans. 831 feet 11 inches 3 twelfths equal 831 square feet and 135 square inches.

Table showing the value of Duodecimals in Square Feet, and Decimals of an Inch.

Application of this Table.

What number of square inches are there in a floor  $100\frac{1}{2}$  feet broad and 25 feet 6 inches and 6 twelfths long?

Ans. 2566 feet 11 inches 3 twelfths equal 2566 feet 135 inches.

#### RULE OF THREE.

The Rule of Three teaches how to find a fourth proportional to three given numbers.

It is either DIRECT OF INVERSE.

It is Direct when more requires more, or less requires less. Thus, if 3 barrels of flour cost \$18, what will 10 barrels cost? Or, if 300 lbs. of lead cost \$25.50, what will 10 lbs. cost?

In both of these cases the Proportion is Direct, and the stating must be, As 3:18 :: 10:

As 3:18 ::10: Ans. 60. 300:25.50::10: Ans. .85.

It is Inverse when more requires less, or less requires more. Thus, if 6 men build a certain quantity of wall in 10 days, in how many days will 8 men build the like quantity? Or, if 3 men dig 100 feet of trench in 7 days, in how many days will 2 men perform the same work?

Here the Proportion is Inverse, and the stating must be,

As 8:10::6: Ans. 7½.
2: 7::3: Ans. 10½.

The fourth term is always found by multiplying the 2d and 3d terms together, and dividing the product by the 1st term.

Of the three given numbers necessary for the stating, two of them contain the supposition, and the third a demand.

RULE.—STATE the question by setting down in a straight line the three necessary numbers in the following manner:

Let the 2d term be that number of supposition which is of the same denomination as that the answer, or 4th term, is to be, making the demanding number the 3d term, and the other number the 1st term when the question is in Direct Proportion, but contrarivise if in Inverse Proportion, that is, let the demanding number be the 1st term.

Then multiply the 2d and 3d terms together, and divide by the 1st, and the product will be the answer, or 4th term sought, of the same denomination as the 2d term.

Note.—If the first and third terms are of different denominations, reduce them to the same. If, after division, there be any remainder, reduce it to the next lower denomination, and divide by the same divisor as before, and the quotient will be of this last denomination.

Sometimes two or more statings are necessary, which may always be known by the nature of the question.

EXAMPLE 1 .- If 20 tons of iron cost \$225, what will 500 tons cost?

Tons. Dolls. Tons. 20: 225:: 500

2|0) 11250|0

5625 dollars, Ans.

EXAMPLE 2.—If 15 men raise 100 tons of iron ore in 12 days, how many men will raise a like quantity in 5 days?

Days. Men. Days. As 5:15::12

5) 180

36 men, Ans.

EXAMPLE 3.—A wall that is to be built to the height of 36 feet was raised 9 feet high by 16 men in 6 days: how many men could finish it in 4 days at the same rate of working?

Days. Men. Days. Men. 4:16::6:24 Ans.

Then, if 9 feet require 24 men, what will 27 feet require?
9: 24::27:72 Ans.

EXAMPLE 4.—If the third of six be three, what will the fourth of twenty be?
Ans. 74.

#### COMPOUND PROPORTION.

COMPOUND PROPORTION is the rule by means of which such questions as would require two or more statings in simple proportion (Rule of Three) can be resolved in one.

As the rule, however, is but little used, and not easily acquired, it is deemed preferable to omit it here, and to show the operation by two or more statings.

EXAMPLE.—How many men can dig a trench 135 feet long in 8 days, when 16 men can dig 54 feet in 6 days?

Feet. Men. Feet. Men. First As 54: 16:: 135: 40 Days. Men. Days. Men. As 8:40:: 6:30 Ans. Second.

Example.—If a man travel 130 miles in 3 days of twelve hours each, in how many days of 10 hours each would he require to travel 360 miles?

Miles. Days, Miles. Days First As 130: 3::360:8.307Hours. Days. Hours. Days As 10: 8.307:: 12: 9.9684 Ans.

EXAMPLE.—If 12 men in 15 days of 12 hours build a wall 30 feet long, 6 wide, and 3 deep, in how many days of 8 hours will 60 men build a wall 300 feet long, 8 wide, and 6 deep? Ans. 120 days.

#### INVOLUTION.

INVOLUTION is the multiplying any number into itself a certain number of times. The products obtained are called Powers. The number is called the Roor, or first power.

When a number is multiplied by itself once, the product is the square of that number; twice, the cube; three times, the biquadrate, &c. Thus, of the number 5.

5 is the Root, or 1st power.

 $5 \times 5 = 25$ Square, or 2d power, and is expressed 52. "  $5 \times 5 \times 5 = 125$ Cube, or 3d power, and is expressed 53. "

 $5\times5\times5\times5=625$ Biquadrate, or 4th power, and is expressed 54. The little figure denoting the power is called the INDEX or EXPONENT.

EXAMPLE. - What is the cube of 9?

Ans. 729.

EXAMPLE. - What is the cube of 3?

Ans.  $\frac{27}{64}$ .

EXAMPLE. - What is the 4th power of 1.5?

Ans. 5.0625.

#### EVOLUTION.

EVOLUTION is finding the Root of any number.

The sign  $\sqrt{\text{placed before any number, indicates the square root of that number is required or shown.}$ 

The same character expresses any other root by placing the index above it. Thus,  $\sqrt{25} = 5$ , and  $4+2 = \sqrt{36}$ . And,  $\sqrt[3]{27} = 3$ , and  $\sqrt[3]{64} = 4$ .

Roots which only approximate are called Surd Roots.

TO EXTRACT THE SQUARE ROOT.

RULE .- Point off the given number from units' place into periods of two figures each.

Find the greatest square in the left-hand period, and place its root in the quotient; subtract the square number from the left-hand period, and to the remainder bring down the next period for a dividend.

Double the root already found for a divisor; find how many times the divisor is contained in the dividend, exclusive of the right-hand figure, place the result in the quotient, and at the right hand of the divisor.

Multiply the divisor by the last quotient figure, and subtract the product from the lividend; bring down the next period, and proceed as before.

Note .- Mixed decimals must be pointed off both ways from units.

EXAMPLE. - What is the square root of 2?

EXAMPLE. - What is the square root of 144?

EXAMPLE.—What is the square root of 12?

Ans. 3.464101.

#### SQUARE ROOTS OF VULGAR FRACTIONS.

RULE.—Reduce the fractions to their lowest terms, and that fraction to a decimal, and proceed as in whole numbers and decimals.

Note.—When the terms of the fractions are squares, take the root of each and set one above the other; as,  $\S$  is the square root of  $\frac{2.5}{3.8}$ .

Example.—What is the square root of  $\frac{9}{12}$ ?

Ans. 0.86602540.

To find the 4th root of a number, extract the square root twice, and for the 8th root thrice, &cc., &cc.

#### TO EXTRACT THE CUBE ROOT.

RULE.—From the table of Roots (page 99) take the nearest cube to the given number, and call it the assumed cube.

Then say, as the given number added to twice the assumed cube is to the assumed cube added to twice the given number, so is the root of the assumed cube to the required root, nearly.

And, by using in like manner the root thus found as an assumed cube, and proceeding as above, another root will be found still nearer; and in the same manner as far as may be deemed necessary.

EXAMPLE.—What is the cube root of 10517.9 ?

Nearest cube, page 99; 10648, root 22.

To extract any Root whatever.

Let P represent the number,

n " the index of the power,
A " the assumed power, r its root,
R " the required root of P.

Then say, as the sum of  $n+1\times A$  and  $n-1\times P$  is to the sum of  $n+1\times P$  and  $n-1\times A$ , so is the assumed root r to the required root R.

Example.—What is the cube root of 1500?

The nearest cube, page 99, is 1331, root 11.

P = 1500, n = 3, A = 1331, r = 11;

 $n+1 \times A = 5324, n+1 \times P = 6000$  $n-1 \times P = 3000, n-1 \times A = 2662$ 

8324 : 8662 :: 11 : 11.446+ Ans.

## ARITHMETICAL PROGRESSION.

ARITHMETICAL PROGRESSION is a series of numbers increasing or decreasing by a constant number or difference; as, 1, 3, 5, 7, 9, 15, 12, 9, 6, 3. The numbers which form the series are called *Terms*; the first and last are called the *Extremes*, and the others the *Means*.

When any three of the following parts are given, the remaining two can be found, viz.: The First term, the Last term, the Number of terms, the COMMON DIFFERENCE, and the SUM of all the terms.

When the First Term, the Common Difference, and the Number of Terms are given, to find the Last Term.

Rule.—Multiply the number of terms less one, by the common difference, and to the product add the first term.

EXAMPLE.—A man travelled for 12 days, going 3 miles the first day, 8 the second, and so on; how far did he travel the last day?

12-1×5+3=58 Ans.

When the Number of Terms and the Extremes are given, to find the Common Difference.

RULE.—Divide the difference of the extremes, by one less than the number of terms.

EXAMPLE.—The extremes are 3 and 15, and the number of terms 7; what is the common difference?

 $15-3\div(7-1)=2$  Ans.

When the Extremes and Number of Terms are given, to find the Sum of all the Terms.

RULE.-Multiply the number of terms by half the sum of the extremes.

Example.—How many times does the hammer of a clock strike in 12 hours ?  $12 \times (13 \div 2) = 78$  Ans.

When the Common Difference and the Extremes are given, to find the Number of Terms.

RULE.—Divide the difference of the extremes by the common difference, and add one to the quotient.

EXAMPLE.—A man travelled 3 miles the first day, 5 the second, 7 the third, and so on, till he went 57 miles in one day. How many days had he travelled at the close of the last day?

 $57-3\div2+1=28$  Ans.

To find two Arithmetical Means between two given Extremes.

Rule.—Subtract the less extreme from the greater, and divide the difference by three, the quotient will be the common difference, which, being added to the less extreme, or taken from the greater, will give the means.

Example.—Find two arithmetical means between 4 and 16.

 $16-4 \div 3 = 4 \text{ com. dif.}$  4+4 = 8 one mean.16-4 = 12 second mean.

To find any Number of Arithmetical Means between two Extremes.

RULE—Subtract the less extreme from the greater, and divide the difference by one more than the number of means required to be found, and then proceed as in the foregoing rule.

## GEOMETRICAL PROGRESSION.

GEOMETRICAL PROGRESSION is any series of numbers continually increasing by a constant multiplier, or decreasing by a constant divisor.

As, 1, 2, 4, 8, 16, and 15,  $7\frac{1}{2}$ ,  $3\frac{3}{4}$ . The constant multiplier or divisor is the RATIO.

When any three of the following parts are given, the remaining two can be found, viz.: The First term, the Last term, the Number of terms, the Ratio, and the Sum of all the Terms.

When the Ratio, Number of Terms, and the First Term are given, to find the Last Term.

Rule.—Write a few of the leading terms of the series, and place their indices over them, beginning with a cipher. Add together the most convenient indices to make an index less by one than the number of the term sought.

Multiply together the terms of the series or powers belonging to those indices, and the product, multiplied by the first term, will be the answer.

NOTE. - When the first term is equal to the ratio, the indices must begin with a unit.

EXAMPLE.—The first term is 1, the ratio 2, and the number of terms 23; what is the last term?

Indices. 0 1 2 3 4 5 6 7 Terms. 1, 2, 4, 8, 16, 32, 64, 128. 1+2+3+4+5+7=22. 128×32×16×8×4×2=4194304×1=4194304 Ans.

EXAMPLE.—If one cent had been put out at interest in 1630, what would it have amounted to in 1834 if it had doubled itself every 12 years?

When the First Term, the Ratio, and the Number of Terms are given, to find the Sum of the Series.

Rule.—Raise the ratio to a power whose index is equal to the number of terms, from which subtract 1; then divide the remainder by the ratio less 1, and multiply the quotient by the first term.

EXAMPLE.—If a man were to buy 12 horses, giving 2 cents for the first horse, 6 cents for the second, and so on, what would they cost him?

 $3^{12} = 531441 - 1 = 531440 \div (3-1) = 2 = 265720 \times 2 = $5.314.40$  Ans.

By another Method, the greater Extreme being known

 $\frac{\text{(Greater extreme} \times \text{ratio)} - \text{less extreme}}{\text{Ratio } - 1} = \text{Sum of the Series.}$ 

Thus

$$\frac{354294 \times 3 - 2 = 1062880}{3 - 1} = $5.314.40, Ans., as above.$$

### A TABLE OF GEOMETRICAL PROGRESSION,

Whereby any questions of Geometrical Progression proceeding from 1, and of double ratio, may be solved by inspection, if the number of terms exceed not 50.

cocu	100 00.						
1	1 1	1 8 1	128	15	16384	22	2097152
$\tilde{2}$	2	9	256	16	32768	23	4194304

## PERMUTATION.

PERMUTATION is a rule for finding how many different ways, any given number of things may be varied in their position.

RULE .- Multiply all the terms continually together, and the last product will be the answer.

Example.—How many variations will the nine digits admit of?  $1\times2\times3\times4\times5\times6\times7\times8\times9=362880$  Ans.

## COMBINATION.

Combination is a rule for finding how often a less number of things, can be chosen from a greater.

RULE.—Multiply together the natural series, 1, 2, 3, &c., up to the number to be taken at a time. Take a series of as many terms, decreasing by I, from the number out of which the choice is to be made, and find their continued product. Divide this last product by the former, and the quotient is the answer.

Example.—How many combinations may be made of 7 letters out of 12?  $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 = 5040$ .

 $12 \times 11 \times 10 \times 9 \times 8 \times 7 \times 6 = 3991680 \div 5040 = 792$  Ans.

Example.—How many combinations can be made of 5 letters out of 10?

 $10\times9\times8\times7\times6$  $\frac{1\times2\times3\times4\times5}{1\times2\times3\times4\times5} = 252 \text{ Ans.}$ 

## POSITION.

Position is of two kinds, Single and Double, and is determined by the number of Suppositions.

#### SINGLE POSITION.

Rule.—Take any number, and proceed with it as though it were the correct one; then say, as the result is to the given sum, so is the supposed number to the number required.

Example.—A commander of a vessel, after sending away in boats 1, 1, and 1 of his crew, had left 300; what number had he in command?

Suppose he had 600. \$ of 600 is 200 \$ of 600 is 100 \$ of 600 is 150

450

150: 300:: 600: 1200 Ans.

Example.—A person being asked his age, replied, if \ of my age be multiplied by 2, and that product added to half the years I have lived, the sum will be 75. How old was he? Ans. 37% years.

#### DOUBLE POSITION.

RULE.-Take any two numbers, and proceed with each according to the condi-

tions of the question; multiply the results or errors by the contrary supposition, that is, the first position by the last error, and the last position by the first error. If the errors be too great, mark them +; and if too little, —.

Then, if the errors are altike, divide the difference of the products by the difference.

ence of the errors; but if they are unlike, divide the sum of the products by the sum

Example.—F asked G how much his boat cost: he replied that if it cost him 6 times as much as it did, and \$30 more, it would stand him in \$300. What was the price of the boat?

Suppose it cost		60			or	30	
		6 tir	mes.			6 tin	ies.
		360				180	
	a	nd 30 m	iore,		and	. 30 mc	re.
		390				210	
		300				300	
		90+				90-	
		30 Ż	d posit	ion.		60 1st	position.
	90	2700				5400	
	90	5400					
	180	) 8100 (	(45 Ar	ıs.			
		720					
		900					
		900					

EXAMPLE. -- What is the length of a fish when the head is 9 inches long, the tail as long as its head and half its body, and the body as long as both the head and Ans. 6 feet. tail?

# FELLOWSHIP.

Fellowship is a method of ascertaining gains or losses of individuals engaged in joint operations.

RULE .- As the whole stock is to the whole gain or loss, so is each share to the gain or loss on that share.

Example.—Two men drew a prize in a lottery, of \$9.500. A paid \$3, and B paid 22 for the ticket; how much is each one's share?

```
5: 9.500:: 3: 5.700, A's share.
5: 9.500:: 2: 3.800, B's share.
```

# DOUBLE FELLOWSHIP,

# Or Fellowship with Time.

RULE.—Multiply each share by the time of its interest in the Fellowship; then, as the sum of the products is to the product of each interest, so is the whole gain or loss to each share of the gain or loss.

Example.—A ship's company take a prize of \$10,000, which they divide according to their rate of pay and time of service on board. The officers have been on board 6 months, and the men 3 months; the pay of the lieutenants is \$100; midshipmen \$50, and men \$10 per month; and there are 2 lieutenants, 4 midshipmen. and 50 men. What is each one's share?

	hipmen	:	•					$\begin{array}{c} $100 = 200 \times 6 = 1200 \\ 50 = 200 \times 6 = 1200 \\ 10 = 500 \times 3 = 1500 \\ \hline 3900 \end{array}$	
eutenants								$3.076.92 \div 2 = \$1.538.46$	
idshipmen								$3.076.92 \div 4 = \$769.23$	
en .		3900	٠	1500 :	:	10.000	:	$3.846.16 \div 50 = \$76.92$	

Μi

## ALLIGATION.

ALLIGATION is a method of finding the mean rate or quality of different materials when mixed together.

When it is required to find the mean price of the mixture, observe the following

RULE.—Multiply each quantity by its rate, then divide the sum of these products by the sum of the quantities, and the quotient will be the rate of the composition.

EXAMPLE.—If 10 lbs. of copper at 20 cents per lb., 1 lb. of tin at 5 cents, and 1 lb. of lead at 4 cents, be mixed together, what is the value of the composition?

When the Prices and Mean Price are given, to find what Quantity of each Article must be taken.

RULE 1.—Connect with a line each price that is less than the mean rate with one or more that is greater.

Write the difference between the mixture rate and that of each of the simples opposite the price with which it is connected; then the sum of the differences against any price will express the quantity to be taken of that price.

Example.—How much gunpowder, at 72, 54, and 48 cents per pound, will compose a mixture worth 60 cents a pound?

$$60 \left\{ \begin{matrix} 48 \\ 54 \\ 72 \end{matrix} \right) \begin{matrix} 12, \text{ at } 48 \text{ cents} \\ 12, \text{ at } 54 \text{ cents} \\ 12+6 = 18, \text{ at } 72 \text{ cents} \end{matrix} \right\} \mathcal{A} ns.$$

Proof.  $-12 \times 48 + 12 \times 54 + 18 \times 72 = 2520 \div 12 + 12 + 12 + 12 + 6 = 60$ .

Should it be required to mix a definite quantity of any one article, the quantities of each, determined by the above rule, must be increased or decreased in the proportion they bear to the defined quantity.

Thus, had it been required to mix 18 pounds at 48 cents, the result would be 18 at 48, 18 at 54, and 27 at 72 cents per pound.

Again, when the whole composition is limited, say,

As the sum of the relative quantities, as found by the above rule, is to the whole quantity required, so is each quantity so found to the required quantity of each.

Example.—Were 100 pounds of the above mixture wanting, the result would be obtained thus:

As 
$$42:100::12:28\frac{4}{7}$$
,  $42:100::12:28\frac{4}{7}$ ,  $42:100::18:42\frac{6}{7}$ .

# COMPOUND INTEREST.

If any principal be multiplied by the amount (in the following table) opposite the years, and under the rate per cent., the sum will be the amount of that principal at compound interest for the time and rate taken.

EXAMPLE.—What is the amount of \$500 for 10 years, at 6 per cent.? Tabular number  $1.79084 \times 500 = $895.42$  .Ans.

Table showing the amount of £1 or \$1, &c., for any number of years not exceeding 24, at the rates of 5 and 6 per cent. compound interest.

Years.	5 per cent.	6 per cent.	Years.	5 per cent.	6 per cent.
1	1.05	1.06	13	1.88564	2.13292
2	1.1025	1.1236	14	1.97993	2.26090
3	1.15762	1.19101	15	2.07892	2.39655
4	1.21550	1.26247	16	2.18287	2.54035
5	1.27628	1.33822	17	2.29201	2.69277
6	1.34009	1.41851	18	2.40661	2.85433
7	1.40710	1.50363	19	2.52695	3.02559
8	1.47745	1.59384	20	2.65329	3.20713
9	1.55132	1.68947	21	2.78596	3,39956
10	1.62889	1.79084	22	2.92526	3.60353
11	1.71033	1.89829	23	3.07152	3.81974
12	1.79585	2.01219	24	3.22509	4.04893

### DISCOUNT.

The Time, Rate per Cent., and Interest being given, to find the Principal.

RULE .- Divide the given interest, by the interest of \$1, for the given rate and time.

Example.-What sum of money at 6 per cent. will in 14 months gain \$14? \$14 ÷ .07 = \$200 Ans.

The Principal, Interest, and Time being given, to find the Rate per Cent.

RULE .- Divide the given interest, by the interest of the given sum, for the time, at 1 per cent.

Example.—A broker received \$32.66 interest for the use of \$400, 14 months: what was that per cent.?

The interest on \$32.66 for 14 months, is 4.66.

32.66 -4.66 = 7 per cent. Ans.

The Principal, Rate per Cent., and Interest being given, to find the Time.

RULE .- Divide the given interest, by the interest of the sum at the rate per cent. for one year.

Example.—In what time will \$108 gain 11.34, at 7 per cent.?

The interest on \$108 for one year is 7.56.

 $11.34 \div 7.56 = 1.5$  years, Ans.

# EQUATION OF PAYMENTS.

Multiply each sum by its time of payment in days, and divide the sum of the products by the sum of the payments.

Example.—A owes B \$300 in 15 days, \$60 in 12 days, and \$350 in 20 days; when is the whole due?

 $300 \times 15 = 4500$  $60 \times 12 = 720$   $350 \times 20 = 7000$ 

710 ) 12220 (17+ days, Ans.

## ANNUITIES.

# The Annuity, Time, and Rate of Interest given, to find the Amount.

Rule.—Raise the ratio to a power denoted by the time, from which subtract 1 divide the remainder by the ratio less 1, and the quotient, multiplied by the annuity, will give the amount.

NOTE.—\$1 or £1 added to the given rate per cent is the ratio, and the preceding table in Compound Interest is a table of ratios.

**EXAMPLE.**—What is the amount of an annual pension of \$100, interest 5 per cent, which has remained unpaid for four years ? 1.05 ratio; then  $1.05^4 = 1.21550625 - 1 = .21550625 + (1.05-1).05 = 4.310125 \times 100 = 431.0125$  dollars.

## The Annuity, Time, and Rate given, to find the Present Worth.

RULE.—Find the value of it for the whole time; and this amount divided by the ratio, involved to the time, will give the answer.

EXAMPLE.—What is the present worth of a pension or salary of \$500, to continue 10 years at 6 per cent. compound interest?

\$500, by the last rule, is worth \$6590.3975, which, divided by  $1.06^{10}$  (by table, page 39, is 1.79084) = \$3680.05 Ans.

Or, by the following table, multiply the tabular number by the given annuity, and the product will be the present worth:

Table showing the present worth of \$1 or £1 annuity, at 5 and 6 per cent. compound interest, for any number of years under 34.

Years.	5 per cent.	6 per cent.	Years.	5 per cent.	6 per cent.
1	0.95238	0.94339	18	11.68958	10.8276
2	1.85941	1.83339	19	12.08532	11.15811
3	2.72325	2.67301	20	12.46221	11.46992
4	3.54595	3.4651	21	12.82115	11.76407
<b>4</b> 5	4.32948	4.21236	22	13.163	12.04158
6	5.07569	4.91732	23	13.48807	12.30338
7	5,78637	5.58238	24	13.79864	12.55035
8	6.46321	6.20979	25	14.09394	12.78335
9	7.10782	6.80169	26	14.37518	13.00316
10	7.72173	7.36008	27	14.64303	13.21053
11	8.30641	7.88687	28	14.89813	13.40616
12	8.86325	8.38384	29	15.14107	13.59072
13	9.39357	8.85268	30	15.37245	13.76483
14	9.89864	9.29498	31	15.59281	13.92908
15	10.37966	9.71225	32	15.80268	14.08398
16	10.83777	10.10589	33	16.00255	14.22917
17	10.27407	10.47726	34	16.1929	14.36613

Example.—Same as above; 10 years at 6 per cent. gives  $7.36008 \times 500 = \$3680.04 \ Ans.$ 

When annuities do not commence till a certain period of time, they are said to be in REVERSION.

# To find the Present Worth of an Annuity in Reversion.

RULE.—Take two numbers under the rate in the above table, viz., that opposite the sum of the two given times and that of the time of reversion, and multiply their difference by the annuity, and the product is the present worth.

EXAMPLE.—What is the present worth of a reversion of a lease of \$40 per annum, to continue for six years, but not to commence until the end of 2 years, allowing 6 per cent. to the purchaser?

4.37640×40 = \$175.05 Ans

For half yearly and quarterly payments, the amount for the given time, multiplied by the number in the following table, will be the true amount:

Rate per ct.	Half yearly.	Quarterly.	Rate per ct.	Half yearly.	Quarterly.
3 3½ 4	1.007445 1.008675 1.009902	1.011181 1.013031 1.014877	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	1.013567 1.014781 1.015993	1.020395 1.022257 1.024055
4½ 5	1.011126 1.012348	1.016720 1.018559	72	1.017204	1.025880

Example.—What will an annuity of \$50, payable yearly, amount to in 4 years, at 5 per cent., and what if payable half yearly?

By table, page 39,

 $1.21550 - 1 \div (1.05 - 1) = 4.310 \times 50 = $215.50$  Ans., for yearly payment, and  $215.50 \times 1.012348 = $218.16$  " half yearly do.

## PERPETUITIES.

PERPETUITIES are such annuities as continue forever.

Rule.-Divide the annuity by the rate per cent., and the quotient will be the answer.

Example.—What is the present worth of a \$100 annuity, payable semi-annually, at 5 per cent.?

 $100 \div .05 = 2000 \times 1.012348$  (from preceding table) = \$2.024.70 Ans. For Perpetuities in Reversion, subtract the present worth of the annuity for the ime of reversion from the worth of the annuity, to commence immediately.

EXAMPLE.—What is the present worth of an estate of \$50 per annum, at 5 per cent., to commence in 4 years?

\$50, for 4 years, at 5 per cent. = 3.54595 (from table)  $\times 50 = 177.29$ \$822.71 Ans.,

which in 4 years, at 5 per cent. compound interest, would produce \$1000.

# CHRONOLOGICAL PROBLEMS.

The Golden Number is a period of 19 years, in which the changes of the moon fall on the same days of the month as before.

To find the Golden Number, or Lunar Cycle.

RULE.—Add one to the given year; divide the sum by 19, and the remainder is the golden number.

NOTE .- If 0 remain, it will be 19.

EXAMPLE.—What is the golden number for 1830 ?  $1830+1 \div 19 = 96$  rem. 7 Ans.

# To find the Epact.

Rule.—Divide the centuries of the given year by 4; multiply the remainder by 17, and to this product add the quotient, multiplied by 43; divide this sum plus 86 by 25, multiplying the golden number by 11, from which subtract the last quotient, and, rejecting the 30's, the remainder will be the answer.

EXAMPLE.—Required the epact for 1830.

Centuries.  $18 \div 4 = 4.2$   $2 \times 17 = 34$ .  $4 \times 43 = 172 + 34 = 206 + 86 = 292 \div 25 = 11$ , last quotient.

Golden number, as ascertained above,  $7 \times 11 = 77 - 11$  (last quotient) = 66, rejecting 30's = 6 Ans.

Example.-What is the epact for 1839?

Ans. 15.

#### TO FIND THE MOON'S AGE ON ANY GIVEN DAY.

RULE.—To the day of the month add the epact and number of the month, then reject the 30's, and the answer will be the moon's age.

# Numbers of the Month.

February 2,	April Mav	2, 3,	July 5, August 6.	October 8, November 10.
March 1,	June	4,	September 8,	December 10.
EXAMPLE.—For 5	th February	, 1841.		

Given day  $\cdot \cdot \cdot \cdot 5$ Epact  $\cdot \cdot \cdot \cdot 7$  14, age of the moon. Number of month  $\cdot \cdot 2$ 

The Cycle of the Sun is the 28 years before the days of the week return to the same days of the month.

Table of Epacts, Dominical Letters, and an Almanac, from 1776 to 1875.

February, March, November.	February,* August.	May.	January. October.	January,* April, July.	September, December.	June.
1	2	3	4	5	6	7
8	9	10	11	12	13	14
15	16	17	18	19	20	21
22	23	24	25	26	27	28
29	30	31	}	1

. Use of the Table — To find the day of the week on which any given day of the month falls in any year from 1776 to 1875.

EXAMPLE.—The great fire occurred in New-York on the 16th December, 1835; what was the day of the week?

Against 1835 we find Sunday, and at top, under December, we find that the 13th vas Sunday; consequently, the 16th was Wednesday.

# PROMISCUOUS QUESTIONS.

1. If \$100 principal gain \$5 interest in one year, what amount will gain \$20 in 8 months?

As 12 months: 5::8 months: 3.33, the interest for 8 months. And, as 3.33::100::20:600 the answer.

2. A reservoir has two cocks, through which it is supplied; by one of them it will fill in 40 minutes, and by the other in 50 minutes; it has also a discharging cock, by which, when full, it may be emptied in 25 minutes. If the three cocks are left open, in what time would the cistern be filled, assuming the velocity of the water to be uniform?

The least common multiple of 40, 50, and 25 is 200.

Then . . the 1st cock will fill it 5 times in 200 minutes, the 2d " 4 " 200 "

or both 9 times in 200 minutes; and, as the discharge-cock will empty it 8 times in 200 minutes, then 9-8=1, or once in 3.20 hours, Ans.

3. Out of a pipe of wine, containing 84 gallons, 10 gallons were drawn off, and the vessel replenished with water; after which 10 gallons of the mixture was likewise drawn off, and then 10 gallons more of water were poured in, and so on for a third and fourth time It is required to find how much pure wine remained in the vessel, supposing the two fluids to have been thoroughly mixed!

 $\begin{array}{c} 84-10 = 74 \\ \text{As } 84:10::74 \\ 84:10::65.19048:7.76077 \\ 84:10::57.42971:6.83687 \\ \hline 6.83687 \\ \hline 50.59284 \ \textit{Ans.} \end{array}$ 

4. A traveller leaves New-York at 8 o'clock in the morning, and walks towards New-London at the rate of 3 miles an hour, without intermission; another traveller sets out from New-London at 4 o'clock the same evening, and walks for New-York at the rate of 4 miles an hour, constantly; now, supposing the distance between the two cities to be 130 miles, whereabout on the road will they meet?

From 8 o'clock till 4 o'clock is 8 hours; therefore,  $8\times3=24$  miles, performed by A before B set out from New-London; and, consequently, 130-24:=106 are the miles to travel between them after

that. Hence, as  $7=3+4:3::106:\frac{313}{7}=45\frac{3}{7}$  more miles travelled by A at the meeting; consequently,  $24+45\frac{3}{7}=69\frac{3}{7}$  miles from New-York is the place of their meeting.

5. What part of \$3 is a third part of \$2?

$$\frac{1}{3}$$
 of  $\frac{2}{1}$  of  $\frac{1}{3} = \frac{1}{3} \times \frac{2}{1} \times \frac{1}{3} = \frac{2}{9}$  Ans.

6. The hour and minute hand of a clock are exactly together at 12; when are they next together?

As the minute hand runs 11 times as fast as the hour hand; then, 11:60::1:5, min.  $5\frac{5}{11}$  sec. The time, then, is 5 min.  $5\frac{5}{11}$  sec. past 1 o'clock.

7. The time of the day is between 4 and 5, and the hour and minute hands are exactly together; what is the time?

The speed of the hands is as 1 to 11.

- 4 hours  $\times 60 = 240$ , which  $\div 11 = 21\frac{9}{11}$  min. added to 4 hours,
- 8. A can do a piece of work in 3 weeks, B can do thrice as much in 8 weeks, and C five times as much in 12 weeks; in what time can they finish it jointly?

Then, by addition,  $\frac{1}{3} + \frac{3}{8} + \frac{5}{12}$  will be the work done by them all in one week; these, reduced to a common denominator, become  $\frac{24}{72} + \frac{30}{72} = \frac{3}{12} = \frac{9}{8}$ ; whence,  $9:6:8:5\frac{1}{3}$  Ans.

9. A cistern, containing 60 gallons of water, has 3 unequal cocks for discharging it; one cock will empty it in 1 hour, a second in 2 hours, and a third in 3 hours; in what time will it be emptied if they all run together?

First,  $\frac{1}{2}$  would run out in 1 hour by the second cock, and  $\frac{1}{3}$  by the third; consequently, by the 3 was the reservoir supplied one hour.  $\frac{1}{2} + \frac{1}{3} + 1 = \frac{3}{6} + \frac{2}{6} + \frac{6}{6}$  being reduced to a common denominator, the sum of these  $3 = \frac{1}{6}$ ; whence the proportion,  $11:60:6:32\frac{3}{12}$  minutes, the time required.

10. Suppose a cubic inch of common glass weighs 1.49 ounces troy, the same of sea water .59, and of brandy .53. A gallon of this liquor in a glass bottle, which weighs 3.84 lbs., is thrown into the water. It is proposed to determine if it will sink; and if so, how much force will just buoy it up?

 $3.84 \times 12 \div 1.49 = 30.92$  cubic inches of glass in the bottle.

231 cubic inches in a gallon  $\times .53 = 122.43$  ounces of brandy.

Then, bottle and brandy weigh  $3.84 \times 12 + 122.43 = 168.51$  ounces, and contain 261.92 cubic inches, which,  $\times .59 = 154.53$  ounces, the weight of an equal bulk of salt water.

And, 168.51-154.53 = 13.98 ounces, the weight necessary to support it in the water.

11. How many fifteens can be counted with four fives? Ans. 4.

12. What is the radius of a circular acre?

(Side of a square  $\times 1.128 =$  diameter of an equal circle.) 208.710321, the side of a square acre,  $\times 1.128 = 235.50 \div 2$  (for radius) = 117.75 feet, Ans.

13. From Caldwell's to Newburg is 18 miles; the current of the river is such as to accelerate a boat descending, or retard one ascending 1½ miles per hour. Suppose two boats, driven uniformly at the rate of 15 miles per hour through the water, were to start one from each place at the same time, where will they meet?

Call x the distance from N to the place of meeting; its distance from C, then, will be 18-x.

Speed of descending boat, 15+1.5 = 16.5 miles per hour. Speed of ascending boat, 15-1.5 = 13.5 miles per hour.

 $\frac{x}{16.5}$  = time of boat descending to point of meeting. 18-x = time of boat ascending to point of meeting.

These times are, of course, equal; therefore,  $\frac{x}{16.5} = \frac{18-x}{13.5}$ .

Then, 13.5x = 297 - 16.5x, and 13.5x + 16.5x = 297, or 30x = 297. Hence,  $x = \frac{297}{20} = 9.9$  miles, the distance from Newburg, Ans.

14. A steamboat, going at the rate of 10 miles per hour through the water, descends a river, the velocity of which is 4 miles per hour, and returns in 10 hours; how far did she proceed?

Let x = distance required,  $\frac{x}{10+4} =$  time of going,  $\frac{x}{10-4} =$  time of returning.  $\frac{x}{14} + \frac{x}{6} = 10$ ; 6x + 14x = 840; 20x = 840;  $840 \div 20 = 42$ , Ans.

15. If a steamboat, going uniformly at the rate of 15 miles in an hour through the water, were to run for 1 hour with a current of 5 miles per hour; then, to return against that current, what length of time would she require to reach the place from whence she started?

15+5=20 miles, the distance gone during the hour.

Then 15-5=10 miles, is her effective velocity per hour when returning, and 20+10=2 hours, the time of returning, and 2+1=3 hours, or the whole time occupied. Ans.

Or, let d represent the distance in one direction, t and t' the greater and less times of running (in hours), and c the current or tide.

Then, 
$$\frac{d\frac{t+t'}{2}}{t \times t'}$$
 = velocity of boat through the water, and  $c = \frac{d-v \times t'}{t'}$ .

16. The flood tide wave of a river runs 20 miles per hour, the current of it is 3 miles per hour. Assume the air to be quiescent, and a floating body set in motion at the commencement of the flow of the tide; how long will the body drift in one direction, the tide flowing six hours from each point of the river?

Let x be the time required; 20x = distance the tide has run up, together with the distance which the floating body has moved; 3x = whole distance which the body has floated.

Then  $20x-3=6\times20$ , or the length in miles of a tide.

$$z = \frac{6 \times 20}{20 - 3} \times 6 = 7$$
 hours, 3 minutes,  $31\frac{7}{1000}\frac{52}{000}$  seconds, Ans.

### GEOMETRY.

## Definitions.

A Point has position, but not magnitude.

A Line is length without breadth, and is either Right, Curved, or Mixed.

A Right Line is the shortest distance between two points.

A Mixed Line is composed of a right and a curved line.

A Superficies has length and breadth only, and is plane or curved.

A Solid has length, breadth, and thickness.

An Angle is the opening of two lines having different directions, and is either Right lcute, or Obtuse.

A Right Angle is made by a line perpendicular to another, falling upon it

An Acute Angle is less than a right angle.

An Obtuse Angle is greater than a right angle.

A Triangle is a figure of three sides.

An Equilateral Triangle has all its sides equal.

An Isosceles Triangle has two of its sides equal.

A Scalene Triangle has all its sides unequal.

A Right-angled Triangle has one right angle.

An Obtuse-angled Triangle has one obtuse angle.

An Acute-angled Triangle has all its angles acute.

A Quadrangle or Quadrilateral is a figure of four sides, and has the following particular names, viz.:

A Parallelogram, having its opposite sides parallel.

A Square, having length and breadth equal. A Rectangle, a parallelogram having a right angle.

A Rhombus (or Lozenge), having equal sides, but its angles not right angles.

A Rhomboid, a parallelogram, its angles not being right angles.

A Trapezium, having unequal sides.

A Trapezoid, having only one pair of opposite sides parallel.

Note.—A Triangle is sometimes called a Trigon, and a Square a Tetragon.

POLYGONS are plane figures having more than four sides, and are either Regular or Irregular, according as their sides and angles are equal or unequal, and they are named from the number of their sides or angles. Thus:

A Pentagon has five A Hexagon "six A Heptagon "seve sides. " seven " eight An Octagon A Nonagon " nine " A Decagon ten An Undecagon " eleven A Dodecagon " twelve

A CIRCLE is a plane figure bounded by a curve line, called the Circumference (or

An Arc is any part of the circumference of a circle.

A Chord is a right line joining the extremities of an arc.

A Segment of a circle is any part bounded by an arc and its chord.

The Radius of a circle is a line drawn from the centre to the circumference. A Sector is any part of a circle bounded by an arc and its two radii.

A Semicircle is half a circle.

A Quadrant is a quarter of a circle.

A Zone is a part of a circle included between two parallel chords.

A Lune is the space between the intersecting arcs of two eccentric circles.

A Gnomon is the space included between the lines forming two similar parallelograms, of which the smaller is inscribed within the larger, so as to have one angle in each common to both.

A Secant is a line that cuts a circle, lying partly within and partly without it.

A Cosecant is the secant of the complement of an arc.

A Sine of an arc is a line running from one extremity of an arc perpendicular to a diameter passing through the other extremity, and the sine of an angle is the sine of the arc that measures that angle.

The Versed Sine of an arc or angle is the part of the diameter intercepted between Hosted by GOO the sine and the arc.

-The Cosine of an arc or angle is the part of the diameter intercepted between the line and the centre.

A Tangent is a right line that touches a circle without cutting it.

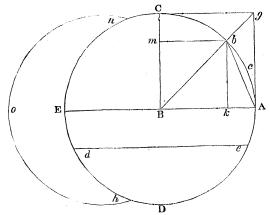

A Cotangent is the tangent of the complement of the arc

The Circumference of every circle is supposed to be divided into 360 equal parts called Degrees; each degree into 60 Minutes, and each minute into 60 Seconds, and

The Complement of an angle is what remains after subtracting the angle from 90 degrees.

The Supplement of an angle is what remains after subtracting the angle from 180 degrees.

To exemplify these definitions, let A c b, in the following diagram, be an assumed are of a circle described with the radius A B.

A c b, an Arc of the circle A C E D. A b, the Chord of that arc.

e D d, a Segment of the circle.

A Bo the Radius. A B b, a Sector.

ADEB, a Semicircle.

C B E, a Quadrant.

A e d E, a Zone.

n o h, a Lune.

Bg, the Secant of the arc A c b. do.

b k, the Sine of

A k, the Versed Sine of do.

A Prism is a solid of which the sides are parallelograms, and are of three, four, rive, or more sides, and are upright or oblique.

cot

coversin.

B &, the Cosine of the arc A c o.

A g, the Tangent of do. C B b, the Complement, and b B E, the

Bg, the Cosecant of the arc, written

m & the Coversed sine of the arc, or, by

convention, of the angle A B b; written

Supplement of the arc A c b.
C g, the Cotangent of the arc, written

A Parallelopipedon is a solid terminated by six parallelograms: thus, a four-sided prism is a parallelopipedon.

A Pyramid is a solid bounded by a number of planes, its base being a rectilinear figure, and its faces triangles, terminating in one point, called the summit or vertex.

It is regular or irregular, upright or oblique, and triangular, quadrangular, and so on, from its equality of sides, inclination, or number of sides.

A Cylinder is a solid formed by the rotation of a rectangle about one of its sides, at rest; this side is called the axis of the cylinder. It is right or oblique as the axis is perpendicular or inclined.

An Ellipse is a section of a cylinder oblique to the axis. (See Conic Sections, page 54.)

A Sphere is a solid bounded by one continued surface, every point of which is equally distant from a point within the sphere, called the contre.

The Altitude, or height of a figure, is a perpendicular let tall from its vertex to the opposite side, called the base.

The Measure of an angle is an arc of a circle contained between the two lines that

form the angle, and is estimated by the number of degrees in the arc.

A Prismoid has its two ends as any unlike parallel plane figures of the same number of sides, the upright sides being trapezoids.

A Spheroid is a solid resembling the figure of a sphere, but not exactly round, one cf its diameters being longer than the other.

A Spindle is a solid formed by the revolution of some curve round its base.

A Segment is a part cut off by a plane, parallel to the base.

A Frustum is the part remaining after the segment is cut off.

A Cycloid is a curve formed by a point in the circumference of a circle, revolving on a right line the length of that circumference.

An Epicycloid is a curve generated by a point in one circle which revolves about another circle, either on the concavity or convexity of its circumference.

An Ungula is the bottom part cut off by a plane passing obliquely through the base

of a cone or cylinder.

The Perimeter of a figure is the sum of all its sides.

A Problem is something proposed to be done.

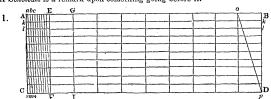

A Postulate is something required.

A Theorem is something proposed to be demonstrated.

A Lemma is something premised, to render what follows more easy.

A Corollary is a truth consequent upon a preceding demonstration.

A Scholium is a remark upon something going before it.

To construct a Diagonal Scale upon any Line, as A B-fig. 1.

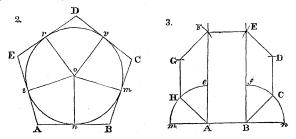

Divide the line into as many divisions as there are hundreds of feet, spaces of ter. feet, feet, or inches required.

Draw perpendiculars from every division to a parallel line C D.

Divide these perpendiculars and one of the divisions A E, C F, into spaces of ten if for feet and hundredths, and into twelve if for inches; draw the lines A 1, a 2, b

3, &c., and they will complete the scale required.

Thus: The line A B representing ten feet; A to E, E to G, &c., will measure one foot; A to a, C to 1, 1 to 2, &c., will measure 1-10th of a foot; and the several lines A 1, a 2, &c., will measure upon the lines k k, l l, &c., 1-100th of a foot; and op will measure upon k k, l l, &c., 1-10th of a foot.

To circumscribe a Pentagon about a given Circle—fig. 2.

From the centre o, draw or, ov, &c.
Through n, m, &c., draw A B, B C, &c., perpendicular to on, om, and complete the figure.

Note.—Any other polygon may be made in a similar manner, by drawing tangents to the points, first defining them in the circle.

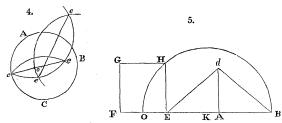

## Upon a given Line A B, to form an Octagon-fig. 3.

RULE .- On the extremities of A B, erect indefinite perpendiculars A F, B E, produce A B to m and n, and bisect the angles m A e and n B f with A H and B C.

Make A H and B C equal to A B, and draw H G, C D, parallel to A F, and equal

From G and D, as centres with a radius equal to A B, describe arcs cutting A F. B F, in F and E. Join G F, F E, and E D, and the figure is made.

## Circles and Squares.

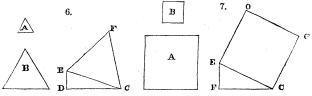

To describe a Circle that shall pass through any three given Points, as A B C-fig. 4.

RULE.—Upon the points A and B, with any opining of the dividers, describe two arcs to intersect each other, as at ee; on the points A C describe two more to intersect each other in the points ee; draw the lines ee and cc, and where these two inces intersect o, place one foot of the dividers, and extend the other to A, B, or C, and it will pass through the three given points as required.

## To make a Square equal to a given Triangle-fig. 5.

Let B d E be the triangle given. Rule.—Extend the side of the triangle B E to O, making E O equal to half the ength of the perpendicular of the triangle A d. Divide B O into two equal parts in K, and with the distance K B describe the semicircle B H O. Upon E erect the perpendicular E H, which will be the side of a square, equal to the triangle B d E.

# Triangles and Squares.

To make an Equilateral Triangle equal to two given Equilateral Triangles-fig. 6.

Let the given equilateral triangles be A and B.

RULE .- Draw a right line C D equal in length to one side of the triangle B. Erect the perpendicular D E, equal in length to one side of the triangle A.

Draw C E, and complete the equilateral triangle C E F, and it will be equal in

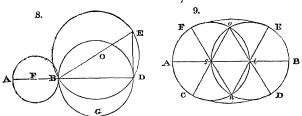

quantity to the two given equilateral triangles A and B.

To make a Square equal to two given Squares-fig. 7.

Let the two squares given be A and B.

RULE.—Draw the line C F, equal in length to one side of the largest square A. Raise the perpendicular E F, equal in length to one side of the smallest square B. Draw C E, and C E is the side of the square C E G O, which is equal in quantity to the two given squares A and B.

## Circles and Ellipses.

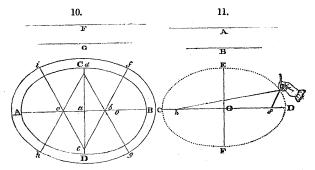

Two Circles, F and G, being given, to make another of equal quantity-fig. 8.

RULE.—Upon the diameter of the largest of the two circles at the point D, erect the perpendicular D E, equal in length to the diameter A B of the least circle.

Draw B E, and divide it into two equal parts in O; take the distance B O or O E, and describe a circle. This circle will be equal in quantity to the two given circles F and G.

To describe an Ellipse of any given length, without regard to breadth-fig. 9. Let A B be the given length.

RULE.—Divide it into three equal parts, as A si B. Then, with the radius A si describe A F oin C; and from i, the circle B D ns o E; then with n F and o C describe F E and C D, and you have the ellipse required.

To describe an Ellipse to any length and breadth given-fig. 10.

Let the longest diameter given be the line F, and the shortest G.

Rule.—Make A B equal to F, and C D to G, dividing A B equally at right angles in a.

Make A o equal to D C, and dividing o B into three equal parts, set off two of those parts from a to b and from a to c, then with the distance c b make the two equilateral triangles c d b and c e b, these angles are the centres, and the sides being continued are the lines of direction for the several arcs of the oval A C B D.

NOTE.—Carpenters, Bricklayers, and Masons are oftentimes obliged to work an architrave, &c., about windows, of this form: they may, by the help of the four centres c, d, b, e, and the lines of direction h d, e f, d g, e i, describe another line around the former, and at any distance required, as h t f g.

To describe an Ellipse to any length and breadth required, another way-fig. 11.

Let the longest diameter be A, and the shortest B.

The diameter be A and the shortest B.

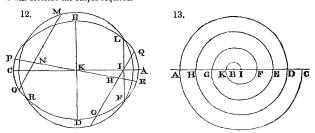

The diameter be A and the shortest B.

The diameter be A and at right angles with C D.

Take the distance C O or O D, and with it, from the point E and F, describe the arcs h and f upon the diameter C D.

ness n and y upon the diameter C.D.
Strike in a nail or pin at h and at f, and put a string around them, of such a length
that the two ends may just reach to E or F.

Introduce a pencil, and bearing upon the string, carry it around the centre O, and it will describe the ellipse required.

To find the Centre and two diameters of an Ellipse-fig. 12.

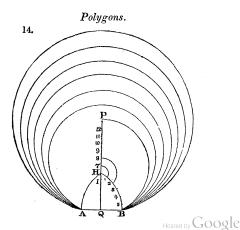

Let A B C D be the ellipse.

Rule.—Draw at pleasure two lines, Q G, M O, parallel to each other; bisect them in the points H N, and draw the line P E; bisect it in K, and upon K, as a centre, describe a circle at pleasure, as F L R, cutting, the figure in the points F L; draw the right line F L, bisect it in I, and through the points I K draw the greatest diameter A C, and through the centre K draw the least diameter B D, parallel to the line F L.

To draw a Spiral Line about a given Point-fig. 13.

Let B be the centre.

Rule.—Draw A C, and divide it into twice the number of parts that there are to be revolutions of the line. Upon B describe K I, G F, H E, &c., and upon I describe K F, G E, &c.

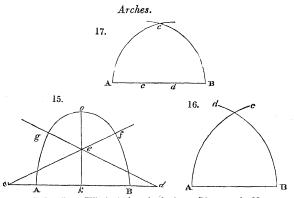

Upon a given line, to describe any Polygon beyond a Pentagon-fig. 14.

Let A B be the given line.

RULE.—Bisect the line A B in Q, and erect the perpendicular Q P. From the point A describe the arc B H, and from B the arc A H, and divide B H into equal parts, as H 1, 2, 3, 4, 5, B.

Let a pentagon be required. From the point H, with the interval H I, describe the arc I 7, and the point I will be the centre of a circle containing the given line A B five times, the interval I B being the radius thereof. Take the point H for the centre of another circle, and H B for the radius; this circle will contain the line A B six times. From the point 7, with the radius 7 B, a circle drawn will contain A B seen times. From the point H, with the interval H 2, describe the arc 2 B; and from the point 8, with the radius 8 B, draw a circle, and A B shall be the side of an octagou. From 9, with the radius 9 B, you form a nine-sided figure; from 10 a ten sided figure; and so on to 12.

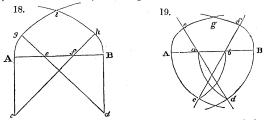

To describe an Elliptic Arch on the Conjugate Diameter-fig. 15.

RULE .- Draw the diameter A B, and in the middle at k, erect the perpendicular k o, equal to the height of the arch; divide the perpendicular k o into two equal parts at e; continue the line A B on both sides at pleasure, and from the point k, with the distance k o, define c and d; through c e, d e, draw c e f and d e g at pleasure; d and c are centres for the arcs A g and B f, and e the centre for the arc g o f, which will form the arch required.

#### To draw a Gothic Arch—fig. 16.

RULE 1 .- Take the length of the line A B, and on the points A and B describe the arcs A c and B d, and it will complete the arch required.

RULE 2, fig. 17 .- Divide the line A B into three equal parts, at c and d; take A d or B c, and describe B e or A e, and it will give an arch of another form.

RULE 3, fig. 18.—Divide the line A B also into three equal parts, e f; from the

# CONIC SECTIONS.

# Definitions.

A Cone is a solid figure having a circle for its base, and terminated in a vertex.

Conic Sections are the figures made by a plane cutting a cone

An Ellipse is the section of a cone when cut by a plane obliquely through both sides.

A Parabola is the section of a cone when cut by a plane parallel to its side.

A Hyperbola is the section of a cone when cut by a plane, making a greater angle with the base than the side of the cone makes.

The Transverse Axis is the longest straight line that can be drawn in an ellipse.

The Conjugate Axis is a line drawn through the centre, at right angles to the transverse axis.

An Ordinate is a right line drawn from any point of the curve perpendicular to either of the diameters.

An Abscissa is a part of any diameter contained between its vertex and an ordinate.

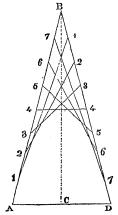

The Parameter of any diameter is a third proportional to that diameter and its conjugate.

The Focus is the point in the axis where the ordinate is equal to half the parameter.

A Conoid is a solid generated by the revolving of a parabola or hyperbola around its axis.

A Spheroid is a solid generated in like manner to a conoid by an ellipse.

To construct a Parabola-fig. 1.

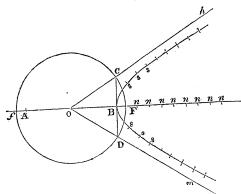

Draw an isosceles triangle, A B D, whose base shall be equal to that of the proposed parabola, and its altitude, C B, twice that of it.

Divide each side, A B, DB, into 8, or any number of equal parts; then draw lines 1 1, 2 2, 3 3, &c., and their intersection will define the curve of a parabola.

Note.—The following figures are drawn to a scale of 100 parts to an inch.

To construct an Hyperbola,\* the Transverse and Conjugate Diameters being given—fig. 2.

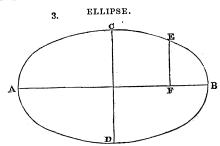

Make A B the transverse diameter, and C D, perpendicular to it,

the conjugate.

Bisect A B in O, and from O, with the radius O C or O D, describe the circle D fc F, cutting A B produced in F and f, which points will be the foci.

In A B produced take any number of points, n, &c., and from F and f, as centres, with B n, A n, as radii, describe arcs, cutting each other in s s, &c.

Through s s, &c., draw the curve s B s, and it will be the hyperbola required.

\* To describe hyperbolas by another method, see Gregory's Mathematics, p. 160.

To find the length of the Ordinate, E F, of an Ellipse, the Transverse, A B, Conjugate, C D, and Abscissa, A F and F B, being known—fig. 3.

Rule.—As the transverse diameter is to the conjugate, so is the square root of the product of the abscissæ to the ordinate which divides them.

EXAMPLE.—The transverse axis, A B, is 100; the conjugate, C D, is 60; one abscissa, B F, is 20; the other, A F, is (100-20)=80.

$$100:60::\sqrt{20\times80}:24 \ Ans.$$

The Transverse and Conjugate diameters, and an Ordinate being known, to find the Abscissa-fig. 3.

Rule.—As the conjugate diameter is to the transverse, so is the square root of the difference of the squares of the ordinate and semi-conjugate to the distance between the ordinate and centre; and this distance, being added to and subtracted from the semi-transverse, will give the abscissas required.

EXAMPLE.—The transverse diameter, A B, is 100; the conjugate, C D, is 60; and the ordinate, F E, is 24.

60:  $100: \sqrt{24^2-30^2}: 30$ , distance between the ordinate and centre; then  $100\div 2-30=20$ , one abscissa;  $100\div 2+30=80$ , the other abscissa.

When the Conjugate, Ordinate, and Abscissæ are known, to find the Transverse—fig. 3.

Rule.—To or from the semi-conjugate, according as the greater or less abscissa is used, add, or subtract the square root of the difference of the squares of the ordinate and semi-conjugate. Then, as this sum or difference is to the abscissa, so is the conjugate to the transverse.

Example.—The ordinate, F E, is 24; the less abscissa, F B, is 20; and the conjugate, C D, is 60.

$$30 - \sqrt{24^2 - 30^2} = 12$$
;  
then  $12:20::60:100$  Ans.

The Transverse, Ordinate, and Abscissæ being given, to find the Conjugate—fig. 3.

RULE.—As the square root of the product of the abscissæ is to the ordinate, so is the transverse diameter to the conjugate.

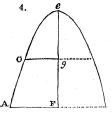

Example.—The transverse is 100, the ordinate 24, one abscissa 20, the other 80.

$$\sqrt{80\times20}:24::100:60$$
 Ans.

#### PARABOLAS.

Any three of the four following terms being given, viz., any two Ordinates and their Abscissa, to find the fourth—fig. 4.

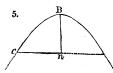

Rule.—As any abscissa is to the square of its ordinate, so is any other abscissa to the square of its ordinate.

Example —The abscissa, eg, is 50, its ordinate, eg, 35.35, required the ordinate A F, whose abscissa, eF, is 100.

 $50:35.35^2::100:\sqrt{2500}=50$  Ans.

#### HYPERBOLAS.

When the Transverse, the Conjugate, and the less Abscissa, B n, are given, to find an Ordinate, e n-fig. 5.

Note.—In hyperbolas, the less abscissa, added to the axis, gives the greater.

RULE.—As the transverse diameter is to the conjugate, so is the square root of the product of the abscissæ to the ordinate required.

When the Transverse, the Conjugate, and an Ordinate are given, to find the Abscissæ—fig. 5.

RULE.—To the square of half the conjugate add the square of the ordinate, and extract the square root of that sum.

Then, as the conjugate diameter is to the transverse, so is the square root to half the sum of the abscissæ.

To this half sum add half the transverse diameter for the greater abscissa, and subtract it for the less.

When the Transverse, the Abscissæ, and Ordinate are given, to find the Conjugate—fig. 5.

RULE.—As the square root of the product of the abscissæ is to the ordinate, so is the transverse diameter to the conjugate.

When the Conjugate, the Ordinate, and the Abscissæ are given, to find the Transverse—fig. 5.

RULE.—Add the square of the ordinate to the square of half the conjugate, and extract the square root of that sum.

To this root add half the conjugate when the less abcissa is used, and subtract it when the greater is used, reserving the difference or sum.

Then, as the square of the ordinate is to the product of the abscissa and conjugate, so is the sum, or difference above found, to the transverse diameter.

Examples.—In the hyperbola, f.gs. 2 and 5, the transverse diameter is 100, the conjugate 60, and the abscissa, B n, is 40; required the ordinate e n.

 $100:60::\sqrt{(40+100\times40)}=74.8:44.8$  Ans.

The transverse is 100, the conjugate 60, and ordinate e n, 44.8; what are the abscissæ?

Ans. 40 and 140.

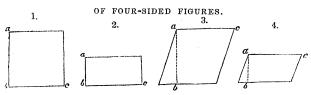

The transverse is 100, the ordinate 44.8, the abscissæ 140 and 40; what is the conjugate?

Ans. 60.

The conjugate is 60, the ordinate 44.8, and the less abscissa 40; what is the transverse?

Ans. 100.

# MENSURATION OF SURFACES.

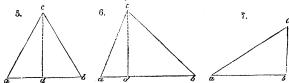

To find the Area of a four-sided Figure, whether it be a Square, Parallelogram, Rhombus, or a Rhomboid.

RULE.—Multiply the length by the breadth or perpendicular height, and the product will be the area.

#### OF TRIANGLES.

Rule.—Multiply the base a b by the perpendicular height c d, and half the product will be the area.

To find the Area of a Triangle by the length of its sides.

RULE.—From half the sum of the three sides subtract each side separately; then multiply the half sum and the three remainders continually together, and the square root of the product will be the area.

To find the Length of one side of a Right-angled Triangle, when the Length of the other two sides are given—fig. 7.

Rule.—To find the hypothenuse a c. Add together the square of the two legs a b and b c, and extract the square root of that sum.

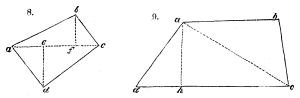

To find one of the legs. Subtract the square of the leg, of which the length is known, from the square of the hypothenuse, and the square root of the difference will be the answer.

NOTE .- For Spherical Triangles, see page 68.

#### OF TRAPEZIUMS AND TRAPEZOIDS.

To find the Area of a Trapezium—fig. 8.

RULE.—Multiply the diagonal a c by the sum of the two perpendiculars falling upon it from the opposite angles, and half the product will be the area.

To find the Area of a Trapezoid-fig. 9.

Rule.—Multiply the sum of the parallel sides a b, d c, by a h, the perpendicular distance between them, and half the product will be the area.

#### OF REGULAR POLYGONS.

Rule.—Multiply half the perimeter of the figure by the perpendicular, falling from its centre upon one of the sides, and the product will be the area.

To find the Area of a Regular Polygon, when the side only is given.

RULE.—Multiply the square of the side by the multiplier opposite to the name of the polygon in the following table, and the product will be the area.

No. of Sides.	Name of Polygon.	Angle.	Angle of Polygon.	Area.	A	В	C
3	Trigon	120°	60°	0.433012	2.	1.732	.5773
4	Tetragon	90	90	1.000000	1.41	1.414	.7071
5	Pentagon	72	108	1.720477	1.238	1.175	.8506
6	Hexagon }	60	120	2.598076	1.156	-Radius	s=l'gth of side
7	Heptagon	$51\frac{3}{7}$	$128\frac{4}{7}$	3.633912	1.11	.8677	1.152
8	Octagon	45	135	4.828427	1.08	.7653	1.3065
9	Nonagon	40	140	6.181824	1.06	.6840	1.4619
10	Decagon	36	144	7.694208	1.05	.6180	1.6180
11	Undecagon	$32\frac{3}{11}$	$147\frac{3}{11}$	9.365640	1.04	.5634	1.7747
12	Dodecagon	30	150	11.196152	1.037	.5176	1.9318

## Additional uses of the foregoing Table.

The third and fourth columns of the table will greatly facilitate the construction of these figures, with the aid of the sector. Thus, if it is required to describe an octagon, opposite to it, in column third, is 45; then, with the chord of 60 on the sector as radius, describe a circle, taking the length 45 on the same line of the sector; mark this distance off on the circumference, which, being repeated around the circle, will give the points of the sides.

The fourth column gives the angle which any two adjoining sides of the respective figures make with each other.

Take the length of a perpendicular drawn from the centre to one of the sides of a polygon, and multiply this by the numbers in column A, the product will be the radius of the circle that contains the figure.

The radius of a circle multiplied by the number in column B, will give the length of the side of the corresponding figure which that circle will contain.

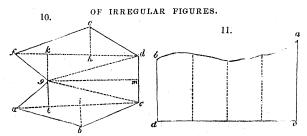

The length of the side of a polygon multiplied by the corresponding number in the column C, will give the radius of the circumscribing circle.

#### OF REGULAR BODIES.

## To find the Superficies of any Regular Body.

RULE.—Multiply the tabular surface in the following table by the square of the linear edge, and the product will be the superficies.

Number of Sides.	Names.	Surfaces.
4	Tetrahedron	1.73205
6	Hexahedron.	6.00000
8	Octahedron.	3.46410
12	Dodecahedron.	20.64573
20	Icosahedron.	8.66025

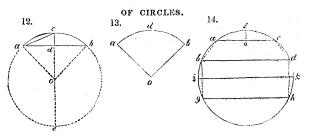

To find the Area of an Irregular Polygon, a b c d e f g-fig. 10.

Rule.—Draw diagonals to divide the figure into trapeziums and triangles; find the area of each separately, and the sum of the whole will give the area required.

# To find the Area of a Long Irregular Figure, b d c a-fig. 11.

Rule.—Take the breadth in several places, and at equal distances apart; add them together, and divide the sum by the number of breadths for the mean breadth; then multiply that by the length of the figure, and the product will be the area.

To find the Diameter and Circumference of any Circle.

RULE 1.—Multiply the diameter by 3.1416, and the product will be the circumference.

RULE 2.—Divide the circumference by 3.1416, and the quotient will be the diameter.

Rule 3.—Or, as 7 is to 22, so is the diameter to the circumference.

Or, as 22 is to 7, so is the circumference to the diameter.

Or, as 113 is to 355, so is the diameter to the circumference, &c

## To find the Area of a Circle.

Rule 1.—Multiply the square of the diameter by .7854, or the square of the circumference by .07958, and the product will be the area.

Rule 2.—Multiply half the circumference by half the diameter.

RULE 3.—As 14 is to 11, so is the square of the diameter to the area, or, as 88 is to 7, so is the square of the circumference to the area.

# To find the Length of any Arc of a Circle—fig. 12. (See Table of Areas, page 75.)

Rule 1.—From 8 times the chord of half the arc ac, subtract the chord ab of the whole arc; one third of the remainder will be the length nearly.

RULE 2.—Multiply the radius a o of the circle by .0174533, and that product by the degrees in the arc.

Rule 3.—As 180 is to the number of degrees in the arc, so is 3.1416 times the radius to its length.

When the Chord of the Arc and the Versed Sine of half the Arc are given.

Rule. — To 15 times the square of the chord ab, add 33 times the square of the versed sine cd, and reserve the number.

To the square of the chord add 4 times the square of the versed sine, and the square root of the sum will be twice the chord of half the arc.

Multiply twice the chord of half the arc by 10 times the square of the versed sine, divide the product by the reserved number, and add the quotient to twice the chord of half the arc: the sum will be the length of the arc very nearly.

When the Chord of the Arc, and the Chord of half the Arc are given.

RULE. — From the square of the chord of half the arc subtract

Note.—If the length for any number of degrees, minutes, &c., is required (see page 67 for the units, radius being 1), multiply them by the number of degrees, &c. in the arc, and the answer is the length.

the square of half the chord of the arc, and the remainder will be the square of the versed sine: then proceed as above.

NOTE .- The chord of half the arc is equal to the square root of the sum of the squares of the versed sine or height, and half the chord of the entire arc.

When the Diameter and the Versed Sine of half the Arc are given.

Rule. - From 60 times the diameter co, subtract 27 times cd the versed sine, and reserve the number.

Multiply the diameter by the versed sine, and the square root of

the product will be the chord of half the arc.

Multiply twice the chord of half the arc by 10 times the versed sine, divide the product by the reserved number, and add the quotient to twice the chord of half the arc: the sum will be the length of the arc very nearly.

Note. - When the diameter and chord of the arc are given, the versed sine may be found thus: From the square of the diameter, subtract the square of the chord, and extract the square root of the remainder. Subtract this root from the diameter, and half the remainder will give the versed sine of half the arc.

The square of the chord of half the arc being divided by the diameter, will give the

versed sine; or, being divided by the versed sine, will give the diameter.

# To find the Area of a Sector of a Circle—fig. 13.

RULE 1.—Multiply the length of the arc adb by half the length of the radius a o.

Rule 2.—As 360 is to the degrees in the arc of the sector, so is the area of the circle to the area of the sector.

Note.-If the diameter or radius is not given, add the square of half the chord of the arc to the square of the versed sine of half the arc; this sum being divided by the versed sine, will give the diameter.

## To find the Area of a Segment of a Circle—fig. 12. (See table of Areas, page 72.)

When the Segment is less than a Semicircle.

Rule 1.—Find the area of the sector having the same arc with the segment, then find the area of the triangle formed by the chord of the segment and the radii of the sector, and the difference of these areas will be the area required.

Rule 2.—To the chord a b of the whole arc, add the chord a c of half the arc, and \( \frac{1}{3} \) of it more; then multiply the sum by the versed sine c d, and .40426 of the product will be the area.

RULE 3.—Multiply the chord of the segment by the versed sine, divide the prod-

uct by 3, and multiply the quotient by 2.

Cube the height or versed sine, divide it by twice the length of the chord, and add the quotient to the former product; it will give the area nearly.

# When the Segment is greater than a Semicirle.

RULE.—Find, by a preceding rule, the area of the lesser portion of the circle, subtract it from the area of the whole circle, and the remainder is the area required.

# To find the Area of a Circular Zone—fig. 14.

(See table of Areas, page 80.)

Rule 1.—When the zone is less than a semicircle. To the area of the trapezoid  $a \ b \ c \ d$  add the area of the segments  $a \ b, c \ d$ ; their sum is the area.

RULE 2.—When the zone is greater than a semicircle. To the area of the parallelogram b g d h, add the area of the segments b i g, d k h; their sum is the area.

To find the Convex Surface of any Zone or Segment-figs. 38 and 39.

Rule.—Multiply the height cb, or bd, of the zone or segment by the circumference of the sphere, and the product is the surface.

Note.—When the diameter of the circle is not given, multiply the mean length of the two chords by half their difference, divide this product by the breadth of the zone, and to the quotient add the breadth. To the square of this sum add the square of the lesser chord, and the square root of their sum will be the diameter of the circle.

#### OF UNGULAS.

To find the Convex Surface of the Ungulas-figs. 27, 28, 29, and 30.

Rules.—For fig. 27, multiply the length of the arc line a b c of the base, by the height a d.

For fig. 28, multiply the circumference of the base of the cylinder e f g by half the sum of the greater and less lengths a e, c f.

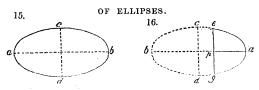

For fig. 29, multiply the sine ad, of half the arc ag, of the base acg, by the diameter eg of the cylinder, and from this product subtract the product\* of the arc agc and cosine df. Multiply the difference thus found by the quotient of the height gb, divided by the versed sine ed.

For fig. 30 (conceive the section to be continued till it meets the side of the cylinder produced), then find the surface of each of the ungulas thus formed, and their difference is the surface required

Note.—For rules to ascertain the surface of conical ungulas, see Ryan's Bonny-castle's Mensuration, page 136 (1839).

To find the Area of a Circular Ring or Space included between two Concentric Circles—fig. 54.

Rule.—Find the areas of the two circles ad, bc separately, and their difference will be the area of the ring.

To find the Circumference of an Ellipse—fig. 15.

Rule.—Square the axes a b and c d, and multiply the square root of half their sum by 3.1416; the product will be the circumference.

To find the Area of an Ellipse—fig. 15.

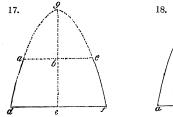

RULE.—Multiply the diameters together, and their product by .7854.

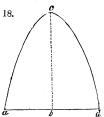

\* When this product exceeds the other, add them together, and when the cosiné is 0, the product is 0.

## To find the Area of an Elliptic Segment, a eg-fig. 16.

Rule.—Divide the height of the segment ap by the axis ab, of which it is a part, and find in the table of circular segments, page 72, a segment having the same versed sine as this quotient; then multiply the segment thus found and the two axes of the ellipse together, and the product will give the area.

#### OF PARABOLAS.

To find the Area of a Parabola-fig. 17.

 $R_{\text{ULE}}$ .—Multiply the base df by the height ge, and  $\frac{2}{3}$  of the product will be the area.

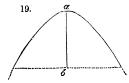

# To find the Area of a Frustrum of a Parabola—fig. 17.

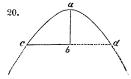

Rule.—Multiply the difference of the cubes of the two ends of the frustrum acdf by twice its altitude bc, and divide the product by three times the difference of the squares of the ends.

# To find the Length of a Parabolic Curve cut off by a Double Ordinate—fig. 18.

RULE.—To the square of the ordinate ab add  $\frac{4}{3}$  of the square of the abscissa cb; the square root of that sum, multiplied by 2, will give the length of the curve nearly.

#### OF HYPERBOLAS.

To find the Area of a Hyperbola-fig. 19.

Rule.—To the product of the transverse and abscissa add  $\frac{5}{4}$  of the square of the abscissa ab, and multiply the square root of the sum by 21. Add 4 times the square root of the product of the transverse and abscissa to the product last found, and divide the sum by 75.

Divide 4 times the product of the conjugate and abscissa by the transverse, and this last quotient, multiplied by the former, will give the area nearly.

## To find the Length of a Hyperbolic Curve-fig. 20.

Rule.—As the transverse is to the conjugate, so is the conjugate to the parameter. To 21 times the parameter of the axis add 19 times the transverse, and to 21 times the parameter add 9 times the transverse, and multiply each of these sums by the quotient of the abscissa b a, divided by the transverse. To each of these two products add 15 times the parameter, and divide the former by the latter; multiply this quotient by the ordinate, and the product is the length of half the curve nearly.

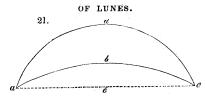

#### OF CYLINDRICAL RINGS.

To find the Convex Surface of a Cylindrical Ring-fig. 54.

Rule.—To the thickness of the ring  $a\,b$  add the inner diameter  $b\,c$ ; multiply this sum by the thickness, and the product by 9.8696, and it will give the surface required.

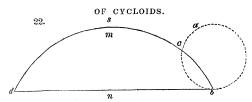

# To find the Area of a Circular Ring-fig. 54.

 $R_{\text{ULE}}$ .—The difference of the areas of the two circles will be the area of the ring.

To find the Area of a Lune-fig. 21.

Rule —Find the areas of the two segments  $a\,d\,c\,b$ ,  $a\,b\,c\,e$  from which the lune is formed, and their difference will be the area required.\*

To find the Area of a Cycloid-fig. 22.

 $R_{\text{ULE}}$ .—Multiply area of generating circle  $a\,b\,c$  by 3, and the product is the area.

<sup>\*</sup> If semicircles be described on the three sides of a right-angled triangle as diameters, two lunes will be formed, their united areas being equal to the area of the \*ri angle.

#### OF CYLINDERS.

To find the Convex Surface of a Cylinder-fig. 25.

RULE.—Multiply the circumference by the length, and the product will be the surface.

#### OF CONES OR PYRAMIDS.

To find the Convex Surface of a Right Cone or Pyramid—figs. 31 and 33.

RULE.—Multiply the perimeter or circumference of the base by the slant height, and half the product added to the area of the base will be the surface.

To find the Convex Surface of a Frustrum of a Right Cone or Pyramid—figs. 32 and 34.

RULE.—Multiply the sum of the perimeters of the two ends by the slant height or side, and half the product will be the surface.

#### OF SPHERES.

To find the Convex Surface of a Sphere or Globe-fig. 37.

 $R_{\mathtt{ULE}}$  —Multiply the diameter of the sphere by its circumference, and the product is the surface.

#### OF CIRCULAR SPINDLES.

To find the Convex Surface of a Circular Spindle-fig. 45.

Rule.—Multiply the length fc of the spindle by the radius oc of the revolving arc; multiply the said arc fac by the central distance oc, or distance between the centre of the spindle and centre of the revolving arc. Subtract this last product from the former, double the remainder, multiply it by 3.1416, and the product is the surface.

Note.—The same rule will serve for any zone or segment, cut off perpendicularly to the chord of the revolving arc; in this case, then, the particular length of the part, and the part of the arc which describes it, must be taken, in lieu of the whole length and whole arc.

#### BY MATHEMATICAL FORMULÆ.

LINES.

#### CIRCLE

Ratio of circumference to diameter, p = 3.1416.

Length of an arc =  $\frac{8c'-c}{3}$  nearly; c the chord of the arc, and c'

the chord of half the arc.

Length of 1 degree, radius being 1, = .0174533 " 1 minute, = .0002909 " 1 second, = .0000048

#### ELLIPSE.

Circumference =  $\frac{199}{200}p\sqrt{\frac{1}{2}(a^2+b^2)}$  nearly, a and b being the axes.

PARABOLA.

Length of an arc, commencing at the vertex,  $=\sqrt{\left(\frac{4a^2}{3}+b^2\right)}$  nearly, a being the abscissa, and b the ordinate.

#### QUADRILATERALS.

Half the product of the diagonals  $\times$  the sine of their angle.

#### CIRCLE.

 $pr^2$ ; or diam.  $^2 \times .78539816$ ; or circum.  $^2 \times .0795774$ .

#### CYLINDER.

Curved surface = height  $\times$  perimeter of base.

#### SPHERICAL ZONE OR SEGMENT.

2prh; or, the height of the zone or segment  $\times$  the circumference of the sphere.

#### CIRCULAR SPINDLE.

 $2p(rc-a\sqrt{r^2-4c^2})$ ; a being the length of the arc, and c its chord, or the length of the spindle.

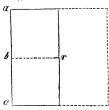

#### SPHERICAL TRIANGLE.

 $pr^2 \frac{s-180^{\circ}}{180^{\circ}}$ ; s being the sum of the three angles.

#### ANY SURFACE OF REVOLUTION.

 $2pr \times l$ ; or, the length of the generating elem in  $\times$  the circumference described by its centre of gravity.

ILLUSTRATIONS.—Let a b c be the side of a cylinder, b r the radius; then a b c is the generating element, b the centre of gravity (of the line), and b r the radius of the circle described by a b c.

Then, if a b c = 10, b r = 5;  $10 \times (5+5 \times 3.1416) = 314.16$ .

Parabola.

 $ac \times (2br \times p)$ , p being in this and all other instances = 3.1416, b the centre of gravity, and br the radius of its circumference.

Or, take a uniform piece of board or thick pasteboard, and cut out the figure of which the area is required; weigh both pieces together, and then the figure separately, and say, as the gross weight is to the entire surface, so is the weight of the figure to its surface.

#### CAPILLARY TUBE.

Let the tube be weighed when empty, and again when filled with mercury; let w be the difference of those weights in troy grains, and l the length of the tube in inches.

Diameter = 
$$.019252\sqrt{\frac{w}{l}}$$
.

#### USEFUL FACTORS,

## Examples in Illustration of the foregoing Rules.

Required the area, 1. Of the rhombus, fig. 3, ac 12 feet 6 inches, and its height ab, 9 feet 3 inches.

Ans. 115.625 feet.

- 2. Of the triangle a b c, fig. 5, a b being 10 feet, and c d 5 feet. Ans. 25 feet.
- 3. Of the triangle abc, fig. 7, its three sides measuring respectively 24, 36, and 48 feet.

  Ans. 418.282.
- 4. In the right-angled triangle  $a\,b\,c$ , fig. 7, the base is 56, and the height 33; what is the hypothenuse? Ans. 65.
- 5. If the hypothenuse of a triangle be 53, and the base 45, what is the perpendicular? Ans. 28.
- Required the area of the trapezium, fig. 8, the diagonal ac 84, the perpendiculars 21 and 28.

  Ans. 2058.
  - 7. Of the trapezoid, fig. 9, a b 10, d c 12, and a h 6 feet.
  - 8. Of an octagon, the side being 5.  $5^2 = 25 \times 4.828427 = 120.710675$  Ans.

Ans. 66.

- 9. The length of a perpendicular from the centre to one of the sides of an octagon is 12; what is the radius of the circumscribing circle?
  - $12 \times 1.08$  (table, page 60) = 12.96 Ans. 10. The radius of a circle being 12.96, what will be the length of one side of an
- Inscribed octagon? 12.96 $\times$ .765 (page 60) = 9.914 Ans. 11. The length of the side of a decagon is 10; what is the radius of the circumscribing circle? 10 $\times$ 1.618 (page 60) = 16.18 Ans.
- 12. The chord ab, fig. 12, is 48, and the versed sine cd 18; what is the length of the arc?
- By Rule 4, twice the chord of half the arc is 60, then  $60 \div 2 = 30$ , chord of half the arc, and  $30 \times 8 = 240 48 = 192 \div 3 = 64$  Ans.
- 13. The diameter  $c \, \theta$ , fig. 12, is 50, and the versed sine  $c \, d \, 18$ ; what is the length of the arc?
  - By rule 6 . . .  $50 \times 60 + 18 \times 27 = 2514 \sqrt{50 \times 18} = 900 = 30$ .

Then  $30 \times 2 = 60 \times 10 \times 18 = 10800 \div 2514 = 4.2959 + 30 \times 2 = 64.2959$  Ans.

- 14. The diameter of a circle is 50, and the chord of half the arc 30; what is the length of the arc?  $\textit{Ans.} \ 64.2959.$
- 15. What is the area of a sector, the chord of the arc being 40, and the versed sine 15?

  Ans. 558.125.
- 16. The radius of a sector o b, fig. 13, is 20, and the degrees in its arc 22; what is the area?

  Ans. 76.7947.
- 17. The radius oc is 10, and the chord ac 10; what is the area of the segment acbd, fig. 12? Ans. 52.36.
- 18. The greater chord, b d, fig. 14, is 96, the lesser, a c, 60, and the breadth 26; what is the area of the zone?

  Ans. 2136.75.
- 19. The sine of half the arc, fig. 29, is 7, the diameter of the cylinder 15, the cosine on eg, at the intersection of ac, 2.7, the versed sine 4.8, and the height, bg, 12; what is the convex surface?
- 20. The height, ap, of an elliptic segment, fig. 16, is 10, and the axes 25 and 35 respectively; what is the area? 10+35=2857 tabular versed sine, and segment =  $.185153\times35\times25=162.008$

 $10 \div 35 = .2857$  tabular versed sine, and segment  $= .105135 \times 35 \times 25 = 102.0000$  Ans.

21. In the parabolic frustrum, acdf, fig. 17, the ends ac and df are 6 and 10, and the height bc is 5; what is the area?

$$\frac{10^3 - 6^3}{10^2 - 6^2} = \frac{784}{64} = 12.25 \times \frac{2}{3} \text{ of } 5 = 40.8 \text{ Ans.}$$

- 22. The abscissa  $c\,b$ , fig. 18, is 12, and its ordinate  $a\,b$  6; what is the length of  $a\,c\,d$ ?
- 23. The transverse and conjugate diameters of a hyperbola, fig. 19, are 100 and 60, and the abscissa  $a\ b$  60; what is the area?
  - 24 What is the curve a c d of the hyperbola, fig. 20, the abscissa a b 40?

    Ans. 59.8

- 25. The chord ac, fig. 21, is 19, the heights ed 6.9, and eb 2.4; what is the area of the lune?  $\mathcal{A}ns.$  65.3.
- 26. The generating circle  $a\,b\,c$ , fig. 22, is 4 inches diameter; what is the area of the cycloid  $b\,c\,d$ ?

  Ans. 37.6992.
- 27. The base of a cone, fig. 31, is 3 feet, and the slant height 15 feet; what is the convex surface? &2.85 . 70.686.
- 23. The thickness of a cylindric ring, fig. 54, is 3 inches, and the inner diameter 12 inches; what is the convex surface?

  Ans. 444.132.
  - 29. What is the convex surface of a globe, fig. 37, 17 inches in diameter?

    Ans. 6.305 square feet.
- 30. What is the surface of the circular spindle, fig. 45, the length fc 14.142, the radius oc 10, and the central distance oe 7.071 inches?

  Ans. 190.82 inches.
  - 31. What is the surface of an octahedron, the linear side being 2 inches?  $2^2 \times 3.46410$  (tabular surface) = 13.85640 Ans.
- 32. What is the convex surface of a cylinder, fig. 25, the diameter of the base  $a\ b\ 10$ , and the height  $b\ c\ 10$  inches?

Table of the Areas of the Segments of a Circle, the diameter of which is Unity, and supposed to be divided into 1000 equal Parts.

## USE OF THE ABOVE TABLE.

# To find the Area of a Segment of a Circle.

Rule.—Divide the height or versed sine by the diameter of the circle, and find the quotient in the column of versed sines. Take the area noted in the next column, and multiply it by the square of the diameter, and it will give the area required.

EXAMPLE.—Required the area of a segment; its height being 10, and the diameter of the circle 50 feet.

 $10 \div 50 = .2$ , and .2, per table, = .11182; then .11182 $\times 50^2 = 279.55$  Ans.

Table of the Lengths of Circular Arcs.

To find the Length of an Arc of a Circle by the foregoing Table

Rule.—Divide the height by the base, find the quotient in the column of heights, and take the length of that height from the next right-hand column. Multiply the length thus obtained by the base of the arc, and the product will be the length of the arc required.

Example.—What is the length of an arc of a circle, the span or base being 100 feet, and the height 25 feet ?

 $25 \div 100 = .25$ , and .25, per table, gives 1.1591; which, being multiplied by 100 = 115.9100, the length.

Note. - When great accuracy is required, if, in the division of a height by the base, there should be a remainder.

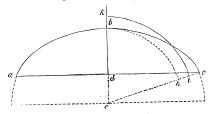

Find the lengths of the curves from the two nearest tabular heights, and subtract the one length from the other. Then, as the base of the arc of which the length is required is to the remainder in the operation of division, so is the difference of the lengths of the curves to the complement required, to be added to the length.

EXAMPLE.—What is the length of an arc of a circle, the base of which is 35 feet. and the height or versed sine 8 feet?

 $8 \div 35 = .228 \frac{20}{5.5}$ , .228 = 1.1333, .229 = 1.1344,  $1.1333 \times 35 = 39.6655$ ,  $1.1344 \times 35$ = 39.7040, 39.7040 - 39.6655 = .0385, difference of lengths.

Hence, as 35: 20::.0385:.0220, the length for the remainder, and .0220+ 39.6655 = 39.6875, and  $.6875 \times 12$ , for inches = 84, making the length of the arc 39 feet 81 inches.

# To find the length of an Elliptic Curve which is less than half of the entire Figure.

Geometrically.—Let the curve of which the length is required be a b c. Extend the versed sine bd to meet the centre of the curve in e.

Draw the line ce, and from e, with the distance eb, describe bh; bisect ch in i.

and from e, with the radius ei, describe ki, and it is equal half the arc abc.

# To find the length when the Curve is greater than half the entire Figure.

RULE .- Find by the above problem the curve of the less portion of the figure, and subtract it from the circumference of the ellipse, and the remainder will be the length of the curve required.

G 2

Table of the Lengths of Semi-elliptic Arcs.

To find the Length of the Curve of a Right Semi-Ellipse.

Proceed with the foregoing table by the rule for ascertaining the lengths of circular arcs, page 76.

Example.—What is the length of the curve of the arch of a bridge, the span being 70 feet, and the height 30.10 feet?

 $30.10 \div 70 = .430 = per table$ , 1.4627, and 1.4627 $\times$ 70 = 102.3890, the length required.

# When the Curve is not that of a Right Semi-Ellipse, the height being half of the Transverse Diameter.

Rule.—Divide half the base by twice the height; then proceed as in the foregoing example, and multiply the tabular length by twice the height, and the product will be the length required.

Example.—What is the length of the profile of arch (it being that of a semi-ellipse), the height measuring 35 feet and the base 60 feet?

 $60 \div 2 = 30 \div 35 \times 2 = .428$ , the tabular length of which is 1.4597.

Then,  $1.4597 \times 35 \times 2 = 102.1790$ , the length required.

Note.—When the quotient is not given in the column of heights, divide the difference between the two nearest heights by 5; multiply the quotient by the excess of the height given and the height in the table first above it, and add this sum to the tabular area of the least height. Thus, if the height is 118,

.115, per table, = 1.0567.120, " = 1.0618

 $0.0051 \div .5 = .00102 \times (118 - 115) = .00306$ , which, added to 1.0567 = 1.05976, the length for 118.

# To find the Area of a Zone by the above Table.

RULE 1.—When the zone is greater than a part of a semicircle, take the height on each side of the diameter of the circle, of which it is a part; divide the heights by the diameter; find the respective quotients in the column of heights, and take out the areas opposite to them, multiplying the areas thus found by the square of the diameter or chord, and the products, added together, will be the area required.

Note.—When the quotient is not given in the column of heights, divide the difference between the two nearest heights by 5, and multiply the quotient by the excess between the height given and the height in the table first above it, and add this sum to the tabular area of the least height. Thus, if the height is .333,

 $.30416 - .30790 = .00374 \div 5 = .000748 \times 3$  (excess of 333 over 330) = .002244 + .30416 = .306404, the area for 333.

Example.—What is the area of zone, the diameter of the circle being 100, and the heights respectively 20 and 10, upon each side of it?

 $20 \div 100 = .200$ , and 200, per table, =  $.19453 \times 100^2 = 1945.3$ .  $10 \div 100 = .100$ , and 100, per table, =  $.09933 \times 100^2 = .993.3$ . Hence, .1945.3 + .993.3 = .2938.6 Ans.

 $\mathtt{Rule}.-\mathit{When}$  the zone is less than a semicircle, proceed as in rule 1 for one height.

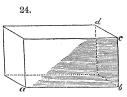

EXAMPLE.—What is the area of a zone, the longest chord being 10, and the height 4?

 $4 \div 10 = .400 = .35182 \times 10^2 = 35.182$  Ans.

## MENSURATION OF SOLIDS.

#### 23 OF CUBES AND PARALLELOPIPEDONS.

To find the Solidity of a Cube-fig. 23.

RULE.—Multiply the side of the cube by itself, and that product again by the side, and this last product will be the solidity.

To find the Solidity of a Parallelopipedon-fig. 24.

RULE.—Multiply the length by the breadth, and that product by the depth, and this product is the solidity.

### OF REGULAR BODIES.

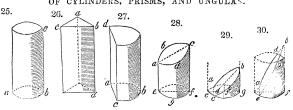

To find the Solidity of any Regular Body.

RULE.—Multiply the tabular solidity in the following table by the cube of the linear edge, and the product is the solidity.

Table of the Solidities of the Regular Bodies when the Linear Edge is

Number of Sides.	Names.	Solidities.
4	Tetrahedron.	0.11785
6	Hexahedron.	1.00000
8	Octahedron.	0.47140
12	Dodecahedron.	7.66312
20	Icosahedron.	2.18169

## OF CYLINDERS, PRISMS, AND UNGULAS.

To find the Solidity of Cylinders, Prisms, and Ungulas—figs. 25, 26, and 27.

RULE.—Multiply the area of the base by the height, and the product is the solidity.

To find the Solidity of an Ungula, fig. 28, when the section passes obliquely through the cylinder, a b c d.

Rule.—Multiply the area of the base of the cylinder by half the sum of the greater and less heights ae, cf of the ungula, and the product is the solidity.

When the Section passes through the base of the Cylinder and one of its sides—fig. 29, a b c.

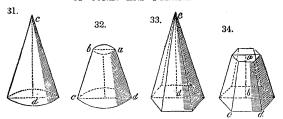

Rule.—From  $\frac{2}{3}$  of the cube of the right sine  $a\,d$ , of half the are  $a\,g$  of the base, subtract the product of the area of the base, and the cosine  $d\,f$  of said half arc.\* Multiply the difference thus found by the quotient of the height, divided by the versed sine, and the product is the solidity.

When the Section passes obliquely through both ends of the Cylinder, a d c e—fig. 30.

Rule.—Find the solidities of the ungulas  $a\ d\ c\ e$  and  $d\ b\ c$ , and the difference is the solidity required (conceiving the section to be continued till it meets the side of the cylinder).

NOTE.—For rules to ascertain the solidity of conical ungulas, see Ryan's Bonny-castle's Mensuration, page 136 (1839).

## OF CONES AND PYRAMIDS.

To find the Solidity of a Cone or Pyramid-figs. 31 and 33.

Rule.--Multiply the area of the base by the height cd, and  $\frac{1}{2}$  the product will be the content.

To find the Solidity of the Frustrum of a Cone-fig. 32.

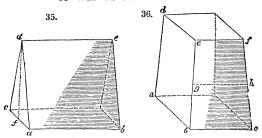

Rule.—Divide the difference of the cubes of the diameters  $a\,b, c\,d$  of the two ends by the difference of the diameters; this quotient, multiplied by .7854, and again by  $\frac{1}{3}$  of the height, will give the solidity.

To find the Solidity of the Frustrum of a Pyramid-fig. 34.

Rule.—Add to the areas of the two ends of the frustrum the square root of their product, and this sum, multiplied by  $\frac{1}{3}$  of the height ab, will give the solidity.

\* If the height of the base be less than radius, otherwise add them-

#### OF WEDGES AND PRISMOIDS.

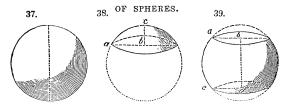

To find the Solidity of a Wedge-fig. 35.

RULE.—To the length of the edge of the wedge dc add twice the length of the back ab; multiply this sum by the height of the wedge df, and then by the breadth of the back ca, and  $\frac{1}{6}$  of the product will be the solid content.

# To find the Solidity of a Prismoid-fig. 36.

**RULE.**—Add the areas of the two ends abc, def, and four times the middle section gh, parallel to them, together; multiply this sum by  $\frac{1}{h}$  of the height, and it will give the solidity.

To find the Solidity of a Sphere-fig. 37.

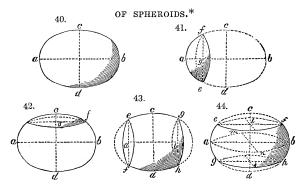

Rule.—Multiply the cube of the diameter by .5236, and the product is the solidity.

# To find the Solidity of a Spherical Segment—fig. 38.

RULE.—To three times the square of the radius of its base a b, add the square of its height c b; then multiply this sum by the height, and the product by .5236.

# To find the Solidity of a Spherical Zone or Frustrum-fig. 39.

RULE.—To the sum of the squares of the radius of each end ab, cd, add  $\frac{1}{3}$  of the square of the height bd of the zone; and this sum, multiplied by the height, and the product by 1.5708, will give the solidity.

To find the Solidity of a Spheroid—fig. 40.

RULE.—Multiply the square of the revolving axis cd by the fixed axis ab; the product, multiplied by .5236, will give the solidity.

To find the Solidity of the Segment of a Spheroid—figs. 41 and 42.

Rule.—When the base of is circular, or parallel to the revolving axis  $c\,d$ , fig. 41. Multiply the fixed axis  $a\,b$  by 3, the height of the segment  $a\,g$  by 2, and subtract the one product from the other; then multiply the remainder by the square of the height of the segment, and the product by .5236. Then, as the square of the fixed axis is to the square of the revolving axis, so is the last product to the content of the segment.

Rule.—When the base ef is perpendicular to the revolving axis cd, fig. 42. Multiply the revolving axis by 3, and the height of the segment cg by 2, and subtract the one from the other; then multiply the remainder by the square of the height of the segment, and the product by .5236. Then, as the revolving axis is to the fixed axis, so is the last product to the content.

To find the Solidity of the Middle Frustrum of a Spheroid—figs. 43 and 44.

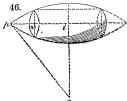

Rule.—When the ends ef and gh are circular, or parallel to the revolving axis cd, fig. 43. To twice the square of the revolving axis cd, add the square of the diameter of either end, ef or gh; then multiply this sum by the length ab of the frustrum, and the product again by .2618, and this will give the solidity.

Rule. — When the ends of and g h are elliptical, or perpendicular to the revolving axis c d, fig. 44. To twice the product of the transverse and conjugate diameters of the middle section ab, add the product of the transverse and conjugate of either end; multiply this sum by the length lk of the frustrum, and the product by .2618, and this will give the solidity.

<sup>\*</sup> Spheroids are either *Prolate* or *Oblate*. They are prolate when produced by the revolution of a semi-ellipse about its transverse diameter, and oblate when produced on an ellipse revolving about its conjugate diameter.

# OF CIRCULAR SPINDLES.

To find the Solidity of a Circular Spindle—fig. 45

Rule.—Multiply the central distance oe by half the area of the evolving segment acef. Subtract the product from  $\frac{1}{3}$  of the cube fe of half the length; then multiply the remainder by 12.5664 (or four times 3.1416), and the product is the solidity.

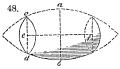

# To find the Solidity of the Frustrum, or Zone of a Circular Spindle—fig. 46.

Rule.—From the square of half the length hi of the whole spindle, take  $\frac{1}{3}$  of the square of half the length ni of the frustrum, and multiply the remainder by the said half-length of the frustrum; multiply the central distance oi by the revolving area\* which generates the frustrum; subtract the last product from the former, and the remainder, multiplied by 6.2832 (or twice 3.1416), will give the solidity.

47.

## OF ELLIPTIC SPINDLES.

To find the Solidity of an Elliptic Spindle—fig. 47.

Rule.—To the square of the greatest diameter  $a\,b$ , add the square of twice the diameter  $e\,f$  at  $\frac{1}{4}$  of its length; multiply the sum by the length, and the product by .1309, and it will give the solidity nearly.

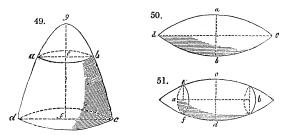

# To find the Solidity of 2 Frustrum or Segment of an Elliptic Spindle—fig. 48.

Rule.—Proceed as in the last rule for this or any other solid formed by the revolution of a conic section about an axis, viz.: Add together the squares of the greatest and least diameters, ab, cd, and the square of double the diameter in the middle, between the two; multiply the sum by the length ef, and the product by .1309, and it will give the solidity.

NOTE.—For all such solids, this rule is exact when the body is formed by the conic section, or a part of it, revolving about the axis of the section, and will always be very near when the figure revolves about another line.

<sup>\*</sup> The area of the frustrum can be obtained by dividing its central plane into segments of a circle, and triangles or parallelograms.

#### OF PARABOLIC CONOIDS AND SPINDLES.

To find the Solidity of a Parabolic Conoid\*-fig. 49.

RULE.—Multiply the area of the base dc by half the altitude fg and the product will be the solidity.

NOTE.—This rule will hold for any segment of the paraboloid, whether the base be perpendicular or oblique to the axis of the solid.

To find the Solidity of a Frustrum of a Paraboloid-fig. 49.

Rule.—Multiply the sum of the squares of the diameters ab and dc by the height ef, and the product by .3927.

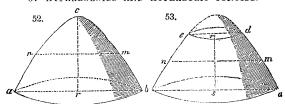

To find the Solidity of a Parabolic Spindle—fig. 50.

Rule.—Multiply the square of the diameter ab by the length dc, and the product by .4188, and it will give the solidity.

To find the Solidity of the Middle Frustrum of a Parabolic Spindle—fig. 51.

Rule.—Add together 8 times the square of the greatest diameter cd, 3 times the square of the least diameter ef, and 4 times the product of these two diameters; multiply the sum by the length ab, and the product by .05236, and it will give the solidity.

#### OF HYPERBOLOIDS AND HYPERBOLIC CONOIDS.

To find the Solidity of a Hyperboloid-fig. 52.

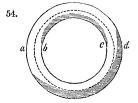

RULE.—To the square of the radius of the base ab, add the square of the middle diameter nm; multiply this sum by the height cr, and the product again by .5236, and it will give the solidity.

\* The parabelic conoid is  $= \frac{1}{2}$  its circumscribing cylinder.

To find the Solidity of the Frustrum of a Hyperbolic Conoid—fig. 53.

Rule.—Add together the squares of the greatest and least semi-diameters as and dr, and the square of the whole diameter nm in the middle of the two; multiply this sum by the height rs, and the product by .5236, and it will give the solidity.

#### OF CYLINDRICAL RINGS.

To find the Solidity of a Cylindrical Ring-fig. 54.

RULE.—To the thickness of the ring ab, add the inner diameter bc; then multiply the sum by the square of the thickness, and the product by 2.4674, and it will give the solidity.

## BY MATHEMATICAL FORMULÆ.

FRUSTRUM OF A RIGHT TRIANGULAR PRISM. The base  $\times \frac{1}{3}(h+h'+h'')$ , h being the heights.

FRUSTRUM OF ANY RIGHT PRISM.

The base x its distance from the centre of gravity of the section.

#### CYLINDRICAL SEGMENT.

Contained between the base and an oblique plane passing through a diameter of the base, twice the height  $\times$  the quotient of the square of the radius  $\div 3$ ; or  $\frac{2}{3}hr^2$ , r being the radius and h the height

#### SPHERICAL SEGMENT.

 $\frac{ph}{6}(3r^2+h^2)$ , r being the radius of the base, and h the height of the segment.

#### SPHERICAL ZONE.

 $\frac{ph}{c}(3R^2+3r^2+h^2)$ , Rr being the radii of the bases.

#### SPHERICAL SECTOR.

 $r \times$  the surface of the segment or zone.

#### ELLIPSOID.

 $\frac{pa^2b}{6}$ , a being the revolving diameter, and b the axis of revolution.

#### PARABOLOID.

+ area of the base × the height.

#### CIRCULAR SPINDLE.

 $p(\frac{1}{6}c^3-2s\sqrt{r^2-4c^2})$ , s being the area of the revolving segment, and c its chord.

### ANY SOLID OF REVOLUTION.

2prs: or, the area of the generating surface  $\times$  the circumference described by its centre of gravity.

Note.-If bounded by a curved surface, find the area by the rule for irregular plane figures.

To find a Cylinder of a Given Solidity (b) with the Least Surface.

Let a = altitude, and d = diameter of base.

Then 
$$\frac{pd^2a}{4} = b$$
, and  $\frac{pd^2}{2} = \text{sum of bases.}$ 

Convex surface . 
$$= pda$$
, or  $\frac{4b}{d}$ .

Therefore 
$$\frac{pd^2}{2} + \frac{4b}{d} = a$$
 minimum.

#### CASK GAUGING.

Casks are usually comprised under the following figures, viz.:

- 1. The middle frustrum of a spheroid.
- The middle frustrum of a parabolic spindle.
   The two equal frustrums of a paraboloid.
- 4. The two equal frustrums of a cone,

and their contents can be computed by the preceding rules for these figures.

# To find the Content of a Cask by four Dimensions.

Rule.—Add together the squares of the bung and head diameters, and the square of double the diameter taken in the middle between the bung and head; multiply the sum by the length of the cask, and the product by .1309.

Or, l.1309 ( $d^2+D^2+\overline{2M}^2$ ), l being the length, d D the head and bung diameters, and M a diameter midway between them.

Or, 
$$l(\frac{d+D+M}{3})$$
,  $dDM$  being the areas of the diameters.

Or, 
$$l \times \text{area of } \frac{2D+d}{3}$$
.

#### ULLAGE CASKS.

When the Cask is standing.  $l \times \left(\frac{d+\mathrm{D+M}}{2}\right)$ , l being the height of the fluid.

### When the Cask is on its bilge.

RULE .- Divide the wet inches by the bung diameter, and opposite to the quotient in the column of versed sines, page 72, take the area of the segment; multiply this area by the content of the cask in inches or gallons, and the product by 1.25 for the ullage required.

Example.—What is the ullage of a cask that contains 25689 cubic inches, and has 8 inches of liquor on its bilge, the bung diameter 32 inches?

# Examples in Illustration of the foregoing Rules.

- 1. The side of a cube a b c, fig. 23, is 5 inches; what is the solidity?
- 2. The length of a parallelopiped on a b, fig. 24, is 8 inches, its depth bc and breadth cd 4 inches; what is the solidity? Ans. 128.
- 3. The base of a cylinder a b, fig. 25, is 30 inches, and the height b c 50 inches; what is the solidity? Ans. 20.4531 cubic feet.
- 4. The sides of a prism a b, b c, fig. 25, are each 5 inches, and the height b d 10
- inches; what is the solidity?  $\frac{5+5+5}{6} = 7.5$ ; then  $7.5-5 \cdot 7.5-5 \cdot 7.5-5 = 2.5 \cdot \sqrt{7.5 \times 2.5 \times 2.5 \times 2.5} \times 10 =$ 108.6 Ans.
- 5. The base of an ungula, fig. 27, is a semicircle, the radius 5 inches, and the height of the figure 25 inches; what is the solidity? Ans. 981.75.
- 6. The base of an ungula, fig. 28, is a circle, the radius 8 inches, and the heights of the sides 2 and 4 inches; what is the solidity? Ans. 603.180.
- 7. The base of a cone, fig. 31, is 20 inches, and the height cd 24; what is the Ans. 2513.28. solidity?
- The diameter of the greater end c d of the frustrum of a cone, fig. 32, is 5 feet, the less end ab 3 feet, and the perpendicular height 9 feet; what is the solidity? Ans. 115.4538.
- 9. What is the solidity of the frustrum of a hexagonal pyramid, fig. 34, a side c d of the greater end being 4 feet, and one of the lesser end 3 feet, and the height ab 9 feet? Ans. 288.3864.
- 10. How many solid feet are there in a wedge, fig. 35, the base ab is 64 inches long, ca 9 inches, de 42 inches, and the height df 28 inches? Ans. 4.1319.
- 11. What is the solidity of a rectangular prismoid, fig. 36, the base being 12 by 14 inches, the top 4 by 6 inches, and the perpendicular height 18 feet? Ans. 10.666.
  - 12. What is the solidity of the sphere, fig. 37, the diameter being 17 inches? Ans. 2572.4468.
- 13. The segment of a sphere, fig. 38, has a radius ab of 7 inches for its base, and its height bc is 4 inches; what is the solidity? Ans. 341.3872.
- 14. The greater and less diameters of a spherical zone, fig. 39, are each 3 feet, and the height db 4 feet; what is the solidity in cubic feet? Ans. 61.7843.
- 15. In the prolate spheroid, fig. 40, the fixed axis ab is 100, and the revolving axis cd is 60; what is the solidity? Ans. 188496.
- 16. The segment of a spheroid, fig. 41, is cut from a spheroid, the fixed axis of which, a b, is 100 inches, the height of the segment a g is 10, and the revolving axis 60; what is the solidity of it? Ans. 14660.8.
- 17. The fixed axis cd, fig. 42, is 60, the revolving axis 100, and the height of the segment cg 8 inches; what is its solidity? Ans. 9159.509.
- 18. What is the solidity of the middle frustrum of a spheroid, fig. 43, the middle diameter cd heing 60, ef and gh each 36, and the length ab 80?

- 19. In the middle frustrum efgh, fig. 44, an oblate spheroid, the diameters of the ends are 40 by 24 inches, the middle diameters are 50 and 30, and the height lh is 18 inches; what is the solidity?

  Ans. 18661.104
- 20. What is the solidity of a circular spindle, fig. 45, the distance o e 7.07 inches, the length fe 7.07 inches, and the radius o e 10 inches?

  Ans. 210.96.
- 21. The length of an elliptic spindle ab, fig. 47, is 85, its greatest diameter cd 25, and the diameter ef, at  $\ddagger$  of its length, 20 inches; what is its solidity?

  Ans. 24756.4625.
- 22. What is the solidity of the parabolic conoid, fig. 49; its height gf is 60, and the diameter dc of its base 100 inches?
- 23. What is the solidity of the parabolic frustrum  $a\,b\,c\,d$ , fig. 49, its diameters  $d\,c$  58,  $a\,b$  30, and height  $e\,f$  18 inches?  $\mathcal{A}ns.$  30140.5104.
- 24. What is the solidity of the parabolic spindle, fig. 50,  $a\,b$  being 40, and  $c\,d$  100 inches?  $\mathcal{A}ns.$  67008.8.
- 25. The middle frustrum of a parabolic spindle, fig. 51, has  $a\,b$  60,  $c\,d$  40, and ef 30 inches; what is its solidity? Ans. 63774.48.
- 26. In the hyperboloid, fig. 52, the height cr is 10, the radius ar 12, and the middle diameter n m 15.8745; what is the solidity?

  Ans. 2073.454691.
- 27. The frustrum of the hyperbolic conoid, fig. 53, has rs 12, ab 10, de 6, and nm 8.5 inches; what is the solidity?

  Ans. 667.59.
- 28. The thickness a b, fig. 54, of a cylindric ring is 3 inches, and the inner diameter c b 8 inches; what is the solidity?

  Ans. 244.2726.
  - 29. Required the solidity of an icosahedron, its linear edge being 2?

    Ans. 17.45352.
- 30. Required the content of a cask, the length being 40, the bung and head diameters 24 and 32, and the middle diameter 28.75 inches.

  Ans. 25689.125.

Additional use of this table can be made by the aid of the following Rules:

To find the Square of a Number above 1000 — when the Number is divisible by any Number without leaving a Remainder.

RULE .-- If the number exceed by 2, 3, or any other number of times, any

Hosted by GOOgle

number contained in the table, let the square affixed to that number in the table be multiplied by the square of 2, 3, 4, 5, or 6, &cc., and the product will be the answer.

Example.—Required the square of 1550.

1550 is 10 times 155, and the square of 155 in the table is 24025. Then  $24025 \times 10^2 = 2402500$  Ans.

#### When the Number is an Odd Number.

Rule.—Find the two numbers nearest to each other, which, added together, make that sum; then the sum of the squares of these two numbers, as per table, multiplied by 2, will give the answer, exceeded by 1, which is to be subtracted, and the remainder is the answer required.

EXAMPLE. - What is the square of 1345?

The nearest two numbers are 
$$\begin{cases} 673 \\ 672 \end{cases} = 1345$$
.

Then, per table, 
$$\begin{cases} 673^2 = 452929 \\ 672^2 = 451584 \end{cases}$$

 $904513 \times 2 = 1809026 - 1 = 1809025$  Ans.

# To find the Cube of a Number greater than is contained in the Table.

Rule.—Proceed as in squares to find how many times the number exceeds one of the tabular numbers. Multiply the cube of that number by the cube of the number of times the number sought exceeds the number in the table, and the product will be the answer.

EXAMPLE.—What is the cube of 1200?

1200 is 3 times 400, and the cube of 400 is 64000000.

Then  $64000000 \times 3^3 = 1728000000$  Ans.

# To find the Squares of Numbers following each other in Arithmetical Progression.

Rule.—Find the squares of the two first numbers in the usual way, and subtract the less from the greater. Add the difference to the greatest square, with the addition of 2 as a constant quantity; the sum will be the square of the next number.

Example.-What are the squares of 1001, 1002, 1003, 1004, and 1005?

# To find the Cubes of Numbers following each other in Arithmetical Progression.

Rule.—Find the cubes of the two first numbers, and subtract the less from the greater; then multiply the least of the two numbers cubed, by 6; add the product.

with the addition of 6, to the difference, and continue this the first series of differ-

For the second series of differences, add the cube of the highest of the above numbers to the difference, and the sum will be the cube of the next number.

Example.-What are the cubes of 1001, 1002, and 1003?

#### First Series. Cube of 1000 = 1000000000Cube of 999 = 9970029992997001 Difference. $999 \times 6 + 6 =$ 6000 3003001 Difference of 1000. 6000 +6 =6006 3009007 Difference of 1001. 6006 6012 3015019 Difference of 1002.

#### Second Series.

Cube of 1000 . Difference for 1000,	== 1000000000 3003001
Difference for 1001,	$\frac{1003003001}{3009007} = $ Cube of 1001.
Difference for 1002,	$\frac{1006012008}{3015019} = $ Cube of 1002.
	1009027027 = Cube of  1003.

### To find the Cube or Square Root of a higher Number than is contained in the Table.

RULE .- Find in the column of Squares or Cubes the number nearest to that number whose root is required, and the number from which that square or cube is derived will be the answer when decimals are not of importance.

Example.—What is the square root of 562500?

In the table of Squares, this number is the square of 750; therefore 750 is the square root required.

Example.—What is the cube root of 2248090?

In the table of Cubes, 2248091 is the cube of 131; therefore 131- is the cube root required, nearly.

# To find the Cube Root of any Number over 1000.

RULE .- Find by the table the nearest cube to the number given, and call it the assumed cube. Multiply the assumed cube and the given number respectively by 2; to the product of the assumed cube add the given number, and to the product of the given number add the assumed cube.

Then, as the sum of the assumed cube is to the sum of the given number, so is the root of the assumed cube to the root of the given number.

Example.—What is the cube root of 224809 ?

By table, the nearest cube is 216000, and its root is 60.

 $216000 \times 2 + 224809 = 656809$ And  $224809 \times 2 + 216000 = 665618$ .

Then, as 656809: 665618:: 60: 60.804+

# To find the Sixth Root of a Number.

RULE.-Take the cube root of its square root.

Example.-What is the 5/ of 441?

 $\sqrt{441} = 21$ , and  $\sqrt[3]{21} = 2.7589$  Ans.

Hosted by Google

# TO FIND THE CUBE OR SQUARE ROOT OF A NUMBER CONSIST-ING OF INTEGERS AND DECIMALS.

RULE.—Multiply the difference between the root of the integer part and the root of the next higher integer by the decimal, and add the product to the root of the integer given; the sum will be the root of the number required.

This is correct for the square root to three places of decimals, and in the cube root to seven.

EXAMPLE.—What is the square root of 53.75, and the cube root of 843.75?

$$\begin{array}{c|ccccc} \checkmark & 54 = & 7.3484 & 3/844 & = & 9.4503 \\ \hline & 53 = & 7.2801 & 3/843 & = & 9.4466 \\ \hline & .0683 & .75 & .051225 \\ \hline \checkmark & 53 = 7.2801 & 3/843 & = & 9.4466 \\ \hline \checkmark & 53.75 = 7.331325 & 3/843.75 = 9.449375 \end{array}$$

When the Number is a Root of any of the Numbers from 1 to 1000, as in the preceding Table.

Find in the column of Square Root or Cube Root the number for which the Square or Cube is required, and opposite, in their respective columns, is the square or cube required.

### TO FIND THE ROOT OF A NUMBER EXCEEDING 1000.

By an Inversion of the preceding Table.

Look in the column of Square or Cube, according to the root required, for the number for which the root is required, and opposite, in the column of number, is the root.

Or, when the number is divisible by 4, twice the square root of the quotient is its square root.

Table of the Sides of Squares—equal in Area to a Circle of any Diameter, from 1 to 100.

#### USE OF THIS TABLE.

To find a Square that shall have the same Area as a Given Circle.

Example.-What is the side of a square that has the same area as a circle of

By table of Areas, page 93, opposite to 73.25 is its area, 4214.1; and in the above table, page 121, is 64.916, the side of a square that has the same area as a circle of 731 inches in diameter.

Example.—What should be the side of a square that would give the same area as a board that is 18 inches wide and 10 feet long?

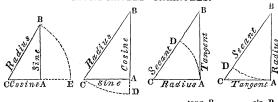

18 inches is  $\begin{array}{c} 1.5 \text{ feet.} \\ \hline 10 \\ \hline \hline 15.0 \text{ feet.} \\ 144 \text{ square inches in a foot.} \\ \hline 600 \\ 150 \\ \hline 2160.0 \text{ inches area.} \\ \end{array}$ 

By table, page 92, 2164.75 inches area have a diameter of 52.5 inches, which in the above table gives an equal side of 46.526, which is the answer very nearly.

# PLANE TRIGONOMETRY.

A B C the three angles (A the right angle); abc the three sides respectively opposite to them; R the tabular radius (1 or 1000000); S the area of the triangle, and p half its perimeter  $= \left(\frac{a+b+c}{2}\right)$ .

#### RIGHT-ANGLED TRIANGLES.

$$a=\sqrt{b^2+c^2},\ b=\sqrt{(a^2-c^2)},\ c=\sqrt{(a^2-b^2)},\ b=c\,\frac{\mathrm{tang.}\ \mathrm{B}}{\mathrm{R}},\ \mathrm{also}=a\,\frac{\mathrm{sin.}\ \mathrm{B}}{\mathrm{R}}.$$

GIVEN. To find B A and B C.

 $\begin{array}{l} \textbf{A.C.,} \\ \textbf{and Angles.} \\ \left\{ \begin{array}{l} R:AC:: tan.\ C:B\ A, \\ R:AC:: sec.\ C:B\ C, \\ or\ sin.\ B:AC:: R:B\ C. \end{array} \right. \end{array}$ 

GIVEN. To find Angles and A C.

Hyp. B C,  $\{\,B\,C:\,R::\,B\,A:\sin.\,C,\,whose\ comp.\ is\ B.\ and\ leg\ B\,A.\,\}\,R:\,B\,C::\sin.\,B:\,A\,C.$ 

GIVEN. To find Angles and BC.

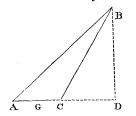

Note. - By sin. or tan. B or C is meant the sine or tangent of the angle B or C.

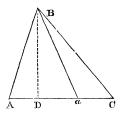

Let A B C be a right-angled triangle, in which A B is assumed to be radius; B C is the tangent of A, and A C its secant to that radius; or, dividing each of these by the base, we shall have the tangent and secant of A respectively to radius I. Tracing the consequences of assuming B C and C each for radius, we obtain the following expressions:

$$\begin{array}{ll} \underline{\text{perp.}} \\ \underline{\text{base}} \\ \underline{\text{tan. angle A.}} \\ \underline{\text{hyp.}} \\ \underline{\text{base}} \\ \underline{\text{esc. angle A.}} \\ \underline{\text{hyp.}} \\ \underline{\text{perp.}} \\ \underline{\text{esin. angle A.}} \\ \underline{\text{hyp.}} \\ \underline{\text{base}} \\ \underline{\text{hyp.}} \\ \underline{\text{sin. angle C.}} \\ \underline{\text{hyp.}} \\ \underline{\text{hyp.}} \\ \underline{\text{tan. angle C.}} \\ \underline{\text{hyp.}} \\ \underline{\text{tan. angle C.}} \\ \underline{\text{hyp.}} \\ \underline{\text{tan. angle C.}} \\ \underline{$$

#### OBLIQUE-ANGLED TRIANGLES.

GIVEN, the Angles and Side AB, to find BC and AC.

Sin. C: AB:: sin. A: BC. Sin. C: AB:: sin. B: AC.

GIVEN, two Sides A B, B C, and the Angle C, to find Angle A and B and Side A C.

AB: sin. C:: BC: sin. A, which, added to C, and the sum subtracted fror 180°, will give B.

Sin. C: AB:: sin. B: AC.

GIVEN, A.C., A.B., and the included Angle A, to find Angles C and B and Side B.C.

Subtract half the given angle A from 90°; the remainder is half the sum of the other angles. Then, as the sum of the sides A C, A B is to their difference, so it the tangent of the half sum of the other angles to the tangent of half their difference, which, added to and subtracted from the half sum, will give the two angles B and C, the greatest angle being opposite to the greatest side.

Sin. B: A C::  $\sin A : B C$ .

### GIVEN, all three Sides, to find all the Angles.

Let fall a perpendicular B D opposite to the required angle; then, as A C: sum of A B, B C: their difference: twice D G, the distance of the perpendicular from the middle of the base; hence A D, C D are known, and the triangle A B C is divided into two right-angled triangles B C D, B A D; then, by the rules in right-angled triangles, find the angle A or C.

54	1.3764	63	1.9626	72	3.0776	81	6.3137	90	Infinite.

To find the Sine or Cosine of any Angle exceeding 45°, by the foregoing Table.

Subtract the angle given from 90, look in the table for the remainder, and opposite to it take out the sine for the cosine, and the cosine for the sine of the angle given.

Example.—What is the sine and the cosine of 85°?

 $85^{\circ}-90^{\circ}=5^{\circ}$ , and opposite to  $5^{\circ}$  in the table is 08716 and 99619, which are respectively the cosine and sine of  $85^{\circ}$ .

The sine of  $90^{\circ}$  is 100000, cosine 0.

The sine of an arc, divided by the cosine, gives the natural tangent of that arc.

# To compute Tangents and Secants.

Cos.: sin.:: rad.: tangent.
Cos.: rad.:: rad.: secant.
Sin.: cos.:: rad.: cotangent.
Sin.: rad.:: rad.: cosecant.

# To find the Secant of an Angle.

Divide 1 by the cosine of that angle.

Example.—The cosine of 21° 30' is .93041;

$$\frac{1}{.93041}$$
 = 1.07479.

To find the Cosecant of an Angle.

Divide 1 by the sine of the angle.

Example.—The sine of 21° 30' is .36650;

$$\frac{1}{.36650} = 2.72951.$$

To find the Versed Sine.

Subtract the cosine from 1.

Example.—The cosine of 21° 30′ is .93042; 1-.93042 = .06958.

# To find the Coversed Sine.

Subtract the sine of the angle from 1.

Example.—The sine of  $21^{\circ} 30'$  is .36650;

$$1 - .36650 = .6335.$$

To find the Chord of any Angle.

Take the sine of half the angle and double it. Example.—The chord of 21° 30′ is required.

Sine of 
$$\frac{21^{\circ} 30'}{2} = .18652 \times 2 = .37304$$
.

# MECHANICAL POWERS.

Power is a compound of weight, or the expansion of a body, multiplied by its velocity: it cannot be increased by mechanical means.

The Science of Mechanics is based upon Weight and Power, or Force and Resistance.

The weight is the resistance to be overcome, the power is the requisite force to overcome that resistance. When they are equal no motion can take place.

The Powers are three in number, viz., Lever, Inclined Plane, and Pulley.

Note.—The Wheel and Axle is a continual or revolving lever, the Wedge is a double inclined plane, and the Screw is a revolving inclined plane.

# LEVER.

When the Fulcrum (or Support) of the Lever is between the Weight and the Power.

RULE.—Divide the weight to be raised by the power, and the quotient is the difference of leverage, or the distance from the fulcrum at which the power supports the weight.

Or, multiply the weight by its distance from the fulcrum, and the power by its distance from the same point, and the weight and power will be to each other as their products.

EXAMPLE.—A weight of 1600 lbs. is to be raised by a force of 80 lbs.; required the length of the longest arm of the lever, the shortest being 1 foot.

$$\frac{1600 \times 1}{80} = 20$$
 feet, Ans.

Proof, by second rule.

$$1600 \times 1 = 1600.$$
  
 $80 \times 20 = 1600.$ 

Example.—A weight of 2460 lbs. is to be raised with a lever 7 feet long and 300 lbs.; at what part of the lever must the fulcrum be placed?

 $\frac{2460}{300}$  = 8.2; that is, the weight is to the power as 8.2 to 1; there-

fore the whole length  $\frac{7 \times 12}{8.2 + 1} = \frac{84}{9.2} = 9.13$  inches, the distance of the fulcrum from the weight.

EXAMPLE.—A weight of 400 lbs. is placed 15 inches from the fulcrum of a lever; what force will raise it, the length of the other arm being 10 feet?

$$\frac{400 \times 15}{120}$$
 = 50 lbs., Ans.

Note.-Pressure upon fulcrum equal the sum of weight and power.

When the Fulcrum is at one Extremity of the Lever, and the Power, or the Weight, at the other.

RULE.—As the distance between the power or weight and fulcrum, is to the distance between the weight or power and fulcrum, so is the effect to the power, or the power to the effect.

EXAMPLE —What power will raise 1500 lbs., the weight being 5 feet from it, and 2 feet from the fulcrum?

$$5+2=7:2::1500:428.5714+Ans.$$

EXAMPLE.—What is the weight on each support of a beam that is 30 feet long, supported at both ends, and bearing a weight of 6000 lbs. 10 feet from one end?

30: 20: 6000: 4000 lbs. at the end nearest the weight; and 30: 10: 6000: 2000 lbs. at the end farthest from the weight.

Note.—Pressure upon fulcrum is the difference of the weight and the power.

The General Rule, therefore, for ascertaining the relation of Power to Weight in a lever, whether it be straight or curved, is, the power multiplied by its distance from the fulcrum, is equal to the weight multiplied by its distance from the fulcrum.

Let P be called the power, W the weight, p the distance of P from the fulcrum, and w the distance of W from the fulcrum; then

$$P: W:: w: p, \text{ or } P \times p = W \times w;$$

and

$$\frac{\mathbf{W} \times \mathbf{w}}{p} = \mathbf{P}. \qquad \frac{\mathbf{P} \times \mathbf{p}}{\mathbf{w}} = \mathbf{W}.$$

$$\frac{\mathbf{W} \times \mathbf{w}}{\mathbf{P}} = \mathbf{p}. \qquad \frac{\mathbf{P} \times \mathbf{p}}{\mathbf{W}} = \mathbf{w}.$$

If several weights or powers act upon one or both ends of the lever, the condition of equilibrium is

$$P \times p + P' \times p' + P'' \times p''$$
, &c., =  $W \times w + W' \times w'$ , &c.

In a system of levers, either of similar, compound, or mixed kinds, the condition is

$$\frac{\mathbf{P} \times p \times p' \times p''}{w \times w' \times w''} = \mathbf{W}.$$

Let P = 1 lb., p and p' each 10 feet, p'' 1 foot; and if w and w' be each 1 foot, and w'' 1 inch, then

$$\frac{1\times120\times120\times12}{12\times12\times1} = \frac{172800}{144} = 1200 \; ; \; \; \text{that is, 1 lb. will balance}$$

1200 lbs. with levers of the lengths above given.

Note.—The weights of the levers in the above formulæ are not considered, the centre of gravity being assumed to be over the fulcrums.

If the arms of the lever be equally bent or curved, the distances from the fulcrum must be measured upon perpendiculars, drawn from the lines of direction of the weight and power, to a line running horizontally through the fulcrum; and if unequally curved, measure the distances from the fulcrum upon a line running horizontally through it till it meets perpendiculars falling from the ends of the lever.

# WHEEL AND AXLE.

THE power multiplied by the radius of the wheel is equal to the weight multiplied by the radius of the axle.

As the radius of the wheel is to the radius of the axle, so is the effect to the power.

When a series of wheels and axles act upon each other, either by belts or teeth, the weight or velocity will be to the power or unity, as the product of the radii, or circumferences of the wheels, to the product of the radii, or circumferences of the axles.

EXAMPLE.—If the radii of a series of wheels are 9, 6, 9, 10, and 12, and their pinions have each a radius of 6 inches, and the weight applied be 10 lbs., what weight will it raise?

$$\frac{10 \times 9 \times 6 \times 9 \times 10 \times 12}{6 \times 6 \times 6 \times 6 \times 6} = 75 \text{ lbs. weight.}$$

Or, if the 1st wheel make 10 revolutions, the last will make 75 in the same time.

Note.—For a fuller treatise on wheels, see Grier's Mechanic's Calculator, pages 130 to 136.

RULE.—Divide the product of the driven teeth by the product of the drivers, and the quotient is the relative velocity, which, multiplied by the length of the winch and the force in lbs., and divided by the radius of the barrel, will give the weight that can be raised.

EXAMPLE.—A force of 18 lbs. is applied to the winch of a crane, the length being 8 inches; the pinion having 6, the wheel 72 teeth, and the barrel 6 inches diameter.

$$\frac{6}{72}$$
 = 12×8×18 = 1728÷3 = 576 lbs. weight.

Let w represent length of winch, r " radius of barrel, P " force applied, Wr = vwP. v " velocity, v " weight raised. v " weight raised. v " v

EXAMPLE. —A weight of 94 tons is to be raised 360 feet in 15 minutes, by a force the velocity of which is 220 feet per minute; what is the power required?

$$\frac{360}{15}$$
 = 24 feet per minute.  
 $\frac{24 \times 94}{220}$  = 10.2542 tons.

In a wheel and axle, where the axle has two diameters, the condition of equilibrium is

W: P:: R: 
$$\frac{1}{2}(r-r')$$
;  
or, P×R = W× $\frac{1}{2}(r-r')$ ;

that is, the weight is to the power as the lever by which the power works, is to half the difference of the radii of the axle;

R representing radius of wheel, r "radius of large axle, r'" radius of less axle.

# INCLINED PLANE.

RULE.—As the length of the plane is to its height, so is the weight to the power.

EXAMPLE.—Required the power necessary to raise 1000 lbs. up an inclined plane 6 feet long and 4 feet high.

As 6:4::1000:666.66 Ans.

To find the Length of the Base, Height, or Length of the Plane. when any two of them are given.

RULE. — For the length of the base, subtract the square of the height from the square of the length of the plane, and the square root of the remainder will be the length of the base.

For the length of the plane, add the squares of the two other dimensions together, and the square root of their sum will be the length required.

For the height, subtract the square of the base from the square of the length of the plane, and the square root of the remainder is the height required.

EXAMPLE.—The height of an inclined plane is 20 feet, and its length 100; what is its base, and the pressure of 1000 lbs. upon the plane?

 $\sqrt{20^2-100^2} = 9600 = 97.98$  the base.

As 100:20::1000:200 lbs. necessary power to raise the 1000 lbs., and  $\frac{1000\times97.98}{100}$  = 979.8 the pressure upon the plane.

If two bodies on two inclined planes sustain each other by the aid of a cord over a pulley, their weights are directly as the lengths of the planes.

EXAMPLE.—If a body of 50 lbs. weight, upon an inclined plane, of 10 feet rise in 100, be sustained by another weight on an opposite plane, of 10 feet rise to 90 of an inclination, what is the weight of the latter?

As 100: 90:: 50: 45, the answer.

When a body is supported by two planes, and if the weight be represented by the sine of the angle between the two planes. The pressures upon them are reciprocally as the sines of the inclinations of those planes to the horizon, viz.:

The weight,
The pressure upon one plane,
The pressure upon the other plane,
Sine of the angle of one plane.
Sine of the angle of one plane.

Thus, if the angle between the planes was 90°, of one plane 60°, and the other 30°—since the natural sines of 90°, 60°, and 30° are 1, 866, and .500—if the body weighed 100 lbs., the pressure upon the plane of 30° would be 86.6 lbs., and upon the plane of 60°, 50 lbs. = the centre of gravity being in the centre of the body.

When the power does not act parallel to the plane, draw a line per-pendicular to the direction of the power's action from the end of the base line (at the back of the plane), and the intersection of this line on the length will determine the length and height of the plane

Note.-When the line of direction of the power is parallel to the plane, the power is least.

The space which a body describes upon an inclined plane, when descending on the plane by the force of gravity, is to the space it would freely fall in the same time, as the height is to the length of the plane; and the spaces being the same, the times will be inversely in this proportion.

Example.-If a body be placed upon an inclined plane 300 feet long and 25 feet high, what space will it roll down in one second by the force of gravity alone?

As 300: 25:: \*16.08: 1.33 feet, Ans.

If a body be projected down an inclined plane with a given velocity, then the distance which the body will be from the point of projection in a given time will be  $t \times v + \frac{h}{l} \times 16.08 t^2$ ; but if the body be

as the leight of the plane bears of its length, that is, the too which as a body down an inclined plane is that fractional part of the force of gravity which is represented by the height of the plane divided by its length. Let k represent the height of the plane, l its length, t the time in seconds, s the space which a body will move through in a given time, v the velocity, and i the

angle of inclination 
$$\left(\sin i = \frac{h}{t}\right)$$
.

 $s = \frac{16.08 \, ht^2}{l}$ , or  $\frac{tv}{2}$ , or  $\frac{tv^2}{64.3h}$ , or  $\frac{v^2}{64.3 \, \sin i}$ , or  $\sin i \times 16.08t^2$ .

 $v = \frac{2s}{t}$ , or  $\frac{32.16 \, ht}{l}$ , or  $\sqrt{\frac{64.3 \, hs}{l}}$ , or  $\sin i \times 32.16t$ , or  $\sqrt{\sin i \times 64.3s}$ .

 $t = \frac{2s}{v}$ , or  $\frac{lv}{32.16 \, h}$ , or  $\sqrt{\frac{ls}{16.08 \, h}}$ , or  $\frac{v}{32.16 \, \sin i}$ , or  $\sqrt{\frac{s}{16.08 \, \sin i}}$ .

 $\frac{h}{l}$ , or  $\sin i = \frac{v}{32.16 \, t}$  or  $\frac{s}{16.08 \, t^2}$ , or  $\frac{s}{64.3 \, s}$ .

<sup>\*</sup> The distance a body will freely fall in one second by the force of gravity.

The force of an inclined plane bears the same proportion to the force of gravity as the height of the plane bears to its length; that is, the force which accelerates

The accelerating force on the plane is to the accelerating force of gravity as  $v^2$ is to  $64.3 \times s$ .

If  $\sin i = \frac{1}{2}$ , it shows that the length of the plane is twice its height, or  $\frac{1}{2} = 30^{\circ}$ . If the proportion which the length of the plane bears to the height be given, substitute these proportions for the length and height in the above rules, and the conclusions will be equally true.

projected upward, then the distance of the body from the point of projection will be  $t \times v - \frac{h}{i} \times 16.08t^2$ .

#### WEDGE.

When two Bodies are forced from one another, in a direction Parallel to the back of the Wedge.

Rule.—As the length of the wedge is to half its back, so is the resistance to the force.

Example.—The length of the back of a double wedge is 6 inches, and the length of it through the middle 10 inches; what is the power necessary to separate a substance having a resistance of 150 lbs.?

When only one of the Bodies is Movable.

Rule.—As the length of the wedge is to its back, so is the resistance to the power.

Example.—What power, applied to the back of a wedge, will raise a weight of 15,000 lbs., the wedge being 6 inches deep, and 100 long on its base.

As 100: 6:: 15000: 900 lbs., Ans.

Note.-As the power of the wedge in practice depends upon the split or rift in the wood to be cleft, or in the body to be raised, the above rules are only theoretical where a rift exists.

#### SCREW.

As the screw is an inclined plane wound round a cylinder, the length of the plane is found by adding the square of the circumference of the screw to the square of the distance between the threads, and taking the square root of the sum, and the height is the distance between the consecutive threads.

RULE.—As the length of the inclined plane is to the pitch or height of it, so is the weight to the power.

When a wheel or capstan is applied to turn the screw, the length of the lever is the radius of the circle described by the handle of the wheel or capstan bar.

Let P represent power,

length of lever,

w " weight,

l " length of the inclined plane,

" p pitch of screw or height of plane,

M

 $\boldsymbol{x}$ effect of power at circumference of screw,

" radius of screw. Then, by the above rules,

```
As l:p::W:P,
   \begin{array}{c} l:W::p:P,\ W:l::P:p, \end{array}
    p:l::P:W, P:W, P:W::p:l,
    P:x::r:R
```

Example.—What is the power requisite to raise a weight of 8000 lbs. by a screw of 12 inches circumference and 1 inch pitch?

$$12^2+1^2=145$$
, and  $\sqrt{145}=12.04159$ .  
Then,  $12.0416:1:8000:664.36$  lbs., Ans.

And if a lever of 30 inches length was added to the screw,

$$12 \div 3.1416 = 3.819 \div 2 + 30 = 31.9095$$
, length of lever.

Then, as  $31.9095 \times 2 \times 3.1416 : 12.0416 : 664.36 : 39.9$  lbs. Ans. Or, let C represent the circumference described by the power, and we have

$$P:W::p:\mathfrak{G},$$
  
 $C:p::W:P,$   
 $P\times C=W\times p;$ 

When a hollow screw revolves upon one of less diameter and pitch (as designed by Mr. Hunter), the effect is the same as that of a single screw, in which the distance between the threads is equal to the difference of the distances between the threads of the two screws.

If one screw has 20 threads in an inch pitch, and the other 21, the power is to the weight as the difference between  $\frac{1}{20}$  and  $\frac{1}{21}$ , or  $\frac{1}{420}$ = 1 to 420.

In a complex machine, composed of the screw, and wheel, and axle, the relation between the weight and power is thus:

Let x represent the effect of the power on the wheel,

R. the radius of the wheel, the pitch of the screw,

p the radius of the axle, r

 $\mathbf{C}$ the circumference described by the power.

Then, by the properties of the screw,

$$P \times C = x \times p;$$

and of the wheel and axle.

$$x \times R = W \times r$$
.

Hence we have

$$P \times C \times x \times R = x \times p \times W \times r$$
.

Omitting the common multiplier, x,

 $P \times C \times R = W \times p \times r$ ; or  $P:W::p\times r:C\times R$ , and  $p \times r : C \times R :: P : W$ .

EXAMPLE.—What weight can be raised with a power of 10 lbs. applied to a crank 32 inches long, turning an endless screw of 3½ inches diameter and one inch pitch, applied to a wheel and axle of 20 and 5 inches in diameter respectively?

Circumference of 64 = 201.

1:201::10:2010.

Radii of wheel and axle, 10 and 2.5.

2.5 : 10::2010 : 8040 lbs., Ans.,

or  $2.5 \times 1 : 201 \times 10 : 10 : 8040$ .

And when a series of wheels and axles act upon each other, the weight will be to the power as the continued product of the radii of the wheels to the continued product of the radii of the axles;

thus, 
$$W : P :: R^3 : r^3$$
; or,  $r^3 : R^3 :: P : W$ ,

there being three wheels and axles of the same proportion to each other.

EXAMPLE.—If an endless screw, with a pitch of half an inch, and a handle of 20 inches radius, be turned with a power of 150 lbs., and geared to a toothed wheel, the pinion of which turns another wheel, and the pinion of the second wheel turns a third wheel, to the pinion or barrel of which is hung a weight, it is required to know what weight can be sustained in that position, the diameter of the wheels being 18, and the pinions 2 inches?

$$p \times r^3$$
:  $C \times R^3$ :  $P : W$ ;  
or  $.5 \times 1^3$ :  $125.6 \times 9^3$ : : 150;

which, when extended, gives

.5: 91562.4:: 150: 27468720 lbs., Ans.

NOTE.—The diameter of a screw is not a necessary element in determining the weight it will support, when the point at which the power is applied is given.

### PULLEY.

When only one Cord or Rope is used.

RULE.—Divide the weight to be raised by the number of parts of the rope engaged in supporting the lower or movable block.

EXAMPLE.—What power is required to raise 600 lbs. when the lower block contains six sheaves and the end of the rope is fastened to the upper block, and what power when fastened to the lower block?

$$\frac{600}{6\times2} = 50 \text{ lbs., 1st } Ans.$$

$$\frac{600}{6\times2+1} = 46.15 \text{ lbs., 2d } Ans.;$$
or W =  $n \times P$ ,

n signifying the number of parts of the rope which sustain the lower block.

### When more than one Rope is used.

In a Spanish burton, where there are two ropes, two movable pulleys, and one fixed and one stationary pulley, with the ends of one rope fastened to the support and upper movable pulley, and the ends of the other fastened to the lower block and the power, the weight is to the power as 5 to 1.

And in one where the ends of one rope are fastened to the support and the power, and the ends of the other to the lower and upper blocks, the weight is to the power as 4 to 1.

In a system of pulleys, with any number of ropes, the ends being fastened to the support,

 $W = 2^n \times P$ ,

n expressing the number of ropes.

EXAMPLE.—What weight will a power of 1 lb. sustain in a system of 4 movable pulleys and 4 ropes?

$$1\times2\times2\times2\times2=16$$
 lbs., Ans.

When fixed pulleys are used in the place of hooks, to attach the ends of the rope to the support,

$$W = 3^n \times P$$
.

Example.—What weight will a power of 5 lbs. sustain with 4 movable and 4 fixed pulleys, and 4 ropes?

$$5\times3\times3\times3\times3=405$$
 lbs., Ans.

When the ends of the rope, or the fixed pulleys, are fastened to the weight,

$$W = (2^n - 1) \times P,$$

and  $W = (3^n - 1) \times P$ ,

which would give, in the above examples,

$$1 \times 2 \times 2 \times 2 \times 2 = 16 - 1 = 15$$
 lbs.,  $5 \times 3 \times 3 \times 3 \times 3 = 405 - 1 = 404$  lbs.

### CENTRES OF GRAVITY.

THE CENTRE OF GRAVITY of a body, or any system of bodies connected together, is the point about which, if suspended, all the parts are in equilibrio.

If the centres of gravities of two bodies BC be connected by a line, the distances of B and C from the common centre of gravity A will be as the weights of the bodies;

thus, B : C : : C A : A B.

#### SURFACES.

1. To find the Centre of Gravity of a Circular Arc.

 $\frac{\text{Radius of circle} \times \text{chord of arc}}{\text{length of the arc}} = \text{distance from the centre of the circle.}$ 

2. Of a Parallelogram, Regular Polygon, Circle, or Ellipse.

The geometrical centre of these figures is their centre of gravity.

3. Of a Triangle.

On a line drawn from any angle to the middle of the opposite side, at  $\frac{2}{3}$  of the distance from the angle.

4. Of a Trapezium.

Draw the two diagonals, and find the centres of gravity of each of the four triangles thus formed; join each opposite pair of these centres, and the intersection of the two lines will be the centre of gravity of the figure.

5. Of a Trapezoid.

On a line a, joining the middle points of the two parallel sides B b, the distance from  $B = \frac{a}{3} \times \left(\frac{B+2b}{B+b}\right)$ .

6. Of a Sector of a Circle.

 $\frac{2 \times \text{chord of arc} \times \text{radius of circle}}{3 \times \text{length of arc}} = \text{distance from the centre of}$ 

the circle.

7. Of a Semicircle.

 $\frac{4 \times \text{radius of circle}}{3 \times 3.1416} = \text{distance from centre.}$ 

8. Of a Segment of a Circle.

 $\frac{\text{Chord of the segment }^3}{12 \times \text{area of segment}} = \text{distance from the centre.}$ 

9. Of a Parabola.

Distance from the vertex,  $\frac{3}{5}$  of the abscissa.

# 10. Of any Plane Figure.

Divide it into triangles, and find the centre of gravity of each, connect two centres together, and find their common centre; then connect this and the centre of a third, and find the common centre of these, and so on, always connecting the last found common centre to another centre till the whole are included, and the last common centre will be that which is required.

11. Of a Cylinder, Cone, Frustum of a Cone, Pyramid, Frustum of a Pyramid, or Ungula.

The centre of gravity is at the same distance from the base as that of the parallelogram, triangle, or trapezoid, which is a right section of either of the above figures.

12. Of a Sphere, Spherical Segment, or Zone.

At the middle of their height.

#### SOLIDS.

1. Of a Sphere, Cylinder, Cube, Regular Polygon, Spheroid, Ellipsoid, Cylindrical Ring, or any Spindle.

The geometrical centre of these figures is their centre of gravity.

2. Of a Right Ungula, Prism, or Wedge.

At the middle of the line joining the centres of the two ends.

3. Of a Prismoid, or Ungula.

At the same distance from the base as that of the trapezoid or triangle, which is a right section of them.

4. Of a Pyramid, or Cone.

Distance from the base, 1 of the line joining the vertex and centre of gravity of the base.

Of a Frustum of a Cone, or Pyramid.

Distance from the centre of the smaller end, 
$$= \frac{1}{4} \text{ height} \times \frac{(R+r)^2 + 2R^2}{(R+r)^2 - Rr};$$

R and r radii of the greater and less ends in a cone, and the sides of a pyramid.

6. Of a Paraboloid.

Distance from the vertex,  $\frac{2}{3}$  of the abscissa.

7. Of a Frustum of a Paraboloid.

Distance on the abscissa from the centre of the less end,

$$\frac{1}{3} h \frac{2R^2 + r^2}{R^2 + r^2}$$
, h being the height.

8. Of a Spherical Segment.

Distance from the centre,

 $\frac{3.1416\,v^2\left(r-\frac{v}{2}\right)^2}{2}$ , v being the versed sine, s the solid contents of the

segment, and r the radius of the sphere.

# 9. Of a Spherical Sector.

Distance from the centre,  $\frac{3}{4}\left(r-\frac{v}{2}\right)$ .

10. Of any System of Bodies.

Distance from a given plane,

 $= \frac{BD+B'D'+B''D''+, &c.}{B+B'+B'', &c.}, B \text{ being the solid contents or weights,}$ 

and D the distances of their respective centres of gravity from the given plane.

# GRAVITATION.

In bodies descending freely by their own weight, the velocities are as the times, and the spaces as the square of the times.

The times, then, will be 1, 2, 3, 4, &c.;

The velocities, then, will be 1, 2, 3, 4, &c.;

The spaces passed through as 1, 4, 9, 16, &c.;

And the spaces for each time as 1, 3, 5, 7, 9, &c.

A body falling freely will descend through 16.0833 feet in the first second of time, and will then have acquired a velocity which will carry it through 32.166 feet in the next second.

Table exhibiting the Relation of Time, Space, and Velocities.

Seconds from the begin- ning of the descent.	Velocity acquired at the end of that time.	Squares.	Space fallen through in that time.	Spaces.	Space fallen through in the last second of the fall.
1	32.166	1	16.08	1	16.08
2	64.333	4	64.33	3	48.25
3	96.5	9	144.75	5	80.41
4	128.665	16	257.33	7	112.58
4 5 6	160.832	25	402.08	9	144.75
6	193.	36	579.	11	176.91
7	225.166	49	788.08	13	209.08
8	257.333	64	1029.33	15	241.25
9	289.5	81	1302.75	17	273.42
10	321 666	100	1608.33	19	305.58
1.1	353.832	121	1946.08	21	337.75
12	386.	144	2316.	23	369.92

and in the same manner the table might be continued to any extent.

To find the Velocity a Falling Body will acquire in any Given Time.

RULE.—Multiply the time in seconds by 32.166, and it will give the velocity acquired in feet per second.

EXAMPLE. -- Required the velocity in 12 seconds.

 $12 \times 32.166 = 386$  feet, Ans.

To find the Time which a Body will be in falling through a Given Space.

RULE.—Divide the space in feet by 16.083, and the square root of the quotient will give the required time in seconds.

Example.—How long will a body be in falling through 402.08 feet of space ?

$$\sqrt{402.08 \div 16.083} = 5$$
, Ans.

To find the Space through which a Body will fall in any Given Time.

Rule.—Multiply the square of the time in seconds by 16.083, and it will give the space in feet.

Example — Required the space fallen through in 5 seconds.  $5^2 = 25 \times 16.083 = 402.08$  feet, Ans.

To find the Velocity a Body will acquire by falling from any Given Height.

Rule.—Multiply the space in feet by 64.333, and the square root of the product will be the velocity acquired in feet per second.

Example.—Required the velocity a ball has acquired in descending through 579 feet.

 $\sqrt{579 \times 64.333} = 193$  feet, Ans.

Or, when the time is given, multiply the time in seconds by 32.166. Thus, the time for 579 feet is 6 seconds; then,  $6 \times 32.166 = 192.996$ , Ans.

To find the Space fallen through, the Velocity being given.

 $\mathbf{Rule}$ .—Divide the velocity by 8.02, and the square of the quotient will be the distance fallen through to acquire that velocity.

Example.—If the velocity of a cannon ball is 579 feet per second, from what height must a body fall to acquire the same velocity?  $579 \div 8.02 = 72.2^2 = 5212.84$  feet, Ans.

To find the Time, the Velocity per Second being given.

RULE.—Divide the given velocity by 32.166, and the quotient is the answer.

EXAMPLE.—How long must a bullet be falling to acquire a velocity of 800 feet per second?

 $800 \div 32.166 = 24.87$  seconds, Ans.

Let s represent the space described by any falling body, t the time, and v the velocity acquired in feet.

Then 
$$s = 16.08 \ t^2$$
, or  $\frac{tv}{2}$ , or  $\frac{v^2}{64.3}$ .  
 $t = \sqrt{\frac{s}{16.08}}$ , or  $\frac{v}{32.16}$ , or  $\frac{2s}{v}$ .  
 $v = 2\sqrt{16.08} \ s$ , or  $32.16 \ t$ , or  $\frac{2s}{t}$ .

The distance fallen through in feet is very nearly equal to the square of the time in fourths of a second.

Example.—A bullet being dropped from the spire of a church, was 4 seconds in reaching the ground; what was the height?

 $4\times4\times16=256$  feet, Ans.

EXAMPLE.—What is the depth of a well, a bullet being 2 seconds in reaching the bottom?

 $2\times4\times8=64$  feet, Ans.

Or, more correctly, as in case 2,

 $4 \times 4 \times 16.0833 = 257.33$  feet, and  $2 \times 2 \times 16.0833 = 64.33$  feet.

By Inversion.

In what time will a bullet fall through 256 feet?  $\sqrt{256} = 16$ , and  $16 \div 4 = 4$  seconds, Ans.

Ascending bodies are retarded in the same ratio that descending bodies are accelerated.

To find the Space moved through by a Body projected upward or downward with a Given Velocity.

# If projected downward.

Rule.—Multiply the square of the time in seconds by 16.083, the velocity of the projection in feet by the number of seconds the body is in motion, and the sum of these products is the answer.

# If projected upward.

Then the difference of the above products will give the distance of the body from the point of projection.

Or,  $t \times v \pm 16.083 \times t^2$ .

EXAMPLE.—If a shot discharged from a gun return to the earth in 12 seconds, how high did it ascend?

The shot is half the time in ascending.

 $12 \div 2 = 6$ , and  $6^2 \times 16.08^3 = 579$  feet, Ans.

Or,  $6^{\circ} \times 16.083 - \overline{192.96 \times 6}$ .

Example.—If a body be projected upward with a velocity of 30 feet per second, through what space will it ascend before it begins to return?

30÷32.166=.9326=the time to acquire this velocity.

Then,  $.9326^2 \times 16.083 = 13.98$ , and  $30 \times .932 = 27.96$ , and 27.96 = 13.98 = 13.98 feet, Ans.

Or,  $30 \div 8.02 = 13.98$  feet, Ans.

Example.—If a body be projected upward with a velocity of 96.5 feet per second, it is required to find the place of the body at the end of 10 seconds.

 $96.5 \div 32.166 = 3$  seconds, the time to acquire this velocity, and  $3^2 \times 16.083 = 144.747$ , the height the body reached with its initial velocity.

Then, 10-3=7 seconds left for the body to fall in.

Hence, by rule 3 (140),  $7^2 \times 16.083 = 788.067$ , and 788.067 = 144. 747 = 643.32 feet below the point of projection.

Or,  $10^2 \times 16.083 = 1608.3$  feet, the space fallen through under the effect of gravity, and  $96.5 \times 10 = 965$  feet, the space if gravity did not act. Hence 1608.3 = 965 = 643.3 feet.

To find the Velocity of a Falling Stream of Water per Second (the perpendicular distance being given) at the End of any Given Time.

NOTE.—The space through which a body will descend on an inclined plane is to the space through which it would fall freely in the same time as the height of the plane to its length.

If a body descend in a curve, it suffers no loss of velocity.

If two bodies begin to descend from rest, and from the same point, the one on an inclined phane, and the other falling freely, their velocities at all equal heights below the surface will be equal.

Then, To find the velocity in feet per second, proceed as directed by Rule 4 (page 140).

To find the space fallen through, the velocity being given, proceed as directed by Rule 5 (page 140).

To find the distance descended, the velocity being given.

Example.—What is the distance a stream of water will descend on an inclined plane 10 feet high, and 100 feet long at the base, in 5 seconds?

 $5^2 \times 16.083 = 402.08$ , and 100:10::402.08:40.20 feet, Ans.

Experiments, made by the author in 1852, show that the momentum of a falling body is equal to the continued product of 4.426 times its weight and its velocity

Or, 
$$M = 4.426 \ wv$$
.

Where v = velocity at end of fall in feet per second, and w =weight of body in pounds.

Consequently, to obtain the weight,  $\frac{M}{4.426 \ v} = v$ .

Example.—If a weight of 4500 lbs. fall through 10 feet, with what force does it strike?

$$\sqrt{10 \times 64.33} = 25.35 = \text{velocity}.$$
  
Then  $4.426 \times 4500 \times 25.35 = 504895.95 \text{ lbs.}$ , Ans.

#### PROMISCUOUS EXAMPLES.

1. A ball is 1 min. in falling, how far will it fall in the last second? Space fallen through equal the square of the time; then 1 minute =60 seconds.

$$60^2 \times 16.083 = 57898$$
 distance for 60 seconds,  
 $59^2 \times 16.083 = 55984$  " "  $59$  " "  $4ns$ .

2. Find the time of generating a velocity of 193 feet per second and the whole space descended.

$$193 \div 32.166 = 6 \text{ seconds}, \ Ans.$$
 $6^2 \times 16.083 = 579 \text{ feet}, \ Ans.$ 

The velocity acquired at any period is equal to twice the mean velocity during that period.

3. Then, if a ball fall through 2316 feet in 12 seconds, with wha velocity will it strike?

## GRAVITIES OF BODIES.

THE gravity of a body, or its weight above the earth's surface, decreases as the square of its distance from the earth's centre in semi-diameters of the earth.

Example.—If a body weigh 900 lbs. at the surface of the earth, what will it weigh 2000 miles above the surface?

The earth's semi-diameter is 3993 miles (say 4000).

Then 2000+4000=6000 or  $1\frac{1}{2}$  semi-diameters,

and  $900 \div 1.5^2 = 400 \text{ lbs.}$ , Ans.

Inversely, if a body weigh 400 lbs. at 2000 miles from the earth's surface, what will it weigh at the surface?

 $400 \times 1.5^2 = 900$  lbs., Ans.

Example.—A body at the earth's surface weighs 360 lbs.; how high must it be elevated to weigh 40 lbs.?

 $\sqrt{360 \div 40} = 3$ , or 3 semi-diameters from the earth's surface, Ans.

EXAMPLE.—At what height must a body be raised to lose half its weight?

 $\sqrt{4000^2 \times 2} = 5656 - 4000 = 1656$  miles, Ans.

If the diameters of two globes be equal and their densities different, the weight of a body on their surfaces will be as their densities.

If their densities be equal and their diameters different, the weight of

them will be as their diameters.

If the diameters and densities are both different, the weight will be as their products.

Example.—If a body weigh 10 lbs at the surface of the earth, what will it weigh at the surface of the sun? their densities being 392 and 100, and their diameters 8000 and 883000 miles.

 $883000 \times 100 \times 10 \div 8000 \times 392 = 281.5$  lbs., Ans.

# SPECIFIC GRAVITIES.

THE specific gravity of a body is the proportion it bears to the weight of another body of known density, and water is well adapted for the standard; and as a cubic foot of it weighs 1000 ounces avoirdupois, its weight is taken as the unit, viz., 1000.

To find the Specific Gravity of a Body heavier than Water.

RULE.—Weigh it both in and out of water, and take the difference; then, as the weight lost in water is to the whole weight, so is 1000 to the specific gravity of the body.

EXAMPLE.—What is the specific gravity of a stone which weighs 15 lbs., but in water only 10 lbs.?

15-10=5. '5:15::1000:3000, Ans.

When the Body is lighter than Water.

RULE.—Annex to it a piece of metal or stone, weigh the piece added and the compound mass separately, both in and out of water,

find how much each loses in water by subtracting its weight in water from its weight in air, and subtract the less of these differences from the greater; then,

As the last remainder is to the weight of the light body in air, so is 1000 to the specific gravity of the body.

EXAMPLE.—What is the specific gravity of a piece of wood that weighs 20 lbs. in air; annexed to it is a piece of metal that weighs 24 lbs. in air and 21 lbs. in water, and the two pieces in water weigh 8 lbs.?

$$\begin{array}{r} 20+24-8=36 \\ 24-21 = 3 \\ \hline 33:20::1000:606, Ans. \end{array}$$

Of a Fluid.

Rule.—Take a body of known specific gravity, weigh it in and out of the fluid; then, as the weight of the body is to the loss of weight, so is the specific gravity of the body to that of the fluid.

EXAMPLE.—What is the specific gravity of a fluid in which a piece of copper (s. g.=9000) weighs 70 lbs. in, and 80 lbs. out of it?

80:80-70::9000:1125, Ans.

To find the Proportions of two Ingredients in a Compound, or to discover Adulteration in Metals.

RULE.—Take the differences of each specific gravity of the ingredients and the specific gravity of the compound, then multiply the gravity of the one by the difference of the other; and, as the sum of the products is to the respective products, so is the specific gravity of the body to the proportions of the ingredients.

Example.—A body compounded of gold (s. g.=18.888) and silver (s. g.=10.535) has a specific gravity of 14; what is the proportion of each quantity of metal?

```
\begin{array}{c} 18.888 - 14 = 4.888 \times 10.535 = 51.495 \\ 14 = -10.535 = 3.465 \times 18.888 = 65.447 \\ 65.447 + 51.495 : 65.447 : 14 : 7.835 \ \mathrm{gold}, \\ 65.447 + 51.495 : 51.495 : 14 : 6.165 \ \mathrm{silver}, \\ \end{array} \right\} Ans.
```

To find the Weights, that of the Compound being given.

Rule.—As the specific gravity of the compound is to the weight of the compound, so are each of the proportions to the weight of its material.

EXAMPLE.—The weight, as above, being 28 lbs.

$$14:28:$$
 {  $7.835:15.67 \text{ gold,} \\ 6.165:12.33 \text{ silver.}$ 

# Proof of Spirituous Liquors.

A cubic inch of *proof spirits* weighs 234 grains; then, if an inch cube of any heavy body weigh 234 grains less in spirits than air, it shows that the spirit in which it was weighed is *proof*.

If it lose less of its weight, the spirit is above proof; and if it lose more, it is below proof.

ore, it is below proof.

Hosted by Google

EXAMPLE.—What is the weight of a cube of Italian marble, the sides being 3 feet?

 $3^3 \times 2708 = 73116$  oz.  $\div 16 = 4569.7$  lbs., Ans.

Or, of a 2 inch sphere of cast iron,  $2^3 \times .5236 \times .260$  weight of a cubic inch =1.089 lbs., Ans.

Comparative Weight of Timber in a Green and Seasoned State.

Timber.					Weight of a	Cubic Foot.
	Timbe				Green.	Seasoned.
					lbs. oz.	lbs. oz.
English Oak					71.10	43. 8
Cedar .					32.	28. 4
Riga Fir .					48.12	35. 8
American Fir					44.12	30.11
Elm					66. 8	37. 5
Beech .					60.	53. 6
Ash					58. 3	50.

Note.—The average weight of the timber materials in a vessel of war (English) is about 50 lbs. to the cubic foot, and for masts and yards about 40 lbs.—Edye's  $\mathcal{N}$ . C.

Given the Diameter of a Balloon to find what Weight it will raise.

RULE.—As 1 cubic foot is to the specific difference between atmospheric air, and the gas used to inflate the balloon, so is the capacity of the balloon to the weight it will raise.

EXAMPLE.—The diameter of a balloon is 26.6 feet, and the gas used to inflate it is hydrogen; what weight will it raise?

Sp. gr. of air. Grains. Sp. gr. of hydr. Grains.

1.000 : 527.04 : : .070 : 36.89 wt. of 1 cubic foot of hydrogen.

Then 1:  $527.04 - 36.89 : : 26.6^3 \times .5236 : 4830293$ . grains,  $\div 7000$  (grains in a lb.), = 690.04 lbs., Ans.

Given the Weight to be raised to find the Diameter of a Balloon.

By inversion of the preceding rule. The weight to be raised is 690.04 lbs.; what is the diameter?

 $499.15 = (527.04 - 36.89) : 1 :: 699.04 \times 7000 : 9854.725$  cubic feet,  $\div$  .5236, the cube root of the quotient, is 26.6 feet, Ans.

## STRENGTH OF MATERIALS.

#### TENSILE STRENGTH.

Tensile strength is that force by which the fibres or particles of a body resist separation, and it is therefore proportional to the number of fibres in the body, or to the area of its section.

TABLE OF THE TENSILE RESISTANCE OF METALS, &c.

Weight or Force necessary to tear as under 1 Square Inch, in Avoirdupois pounds.

# To find the Tensile Strength.

RULE. — Multiply area of transverse section in inches by the weight given in the preceding tables, and the product is the strength in lbs.

Example. - In a square bar of ordinary wrought iron, of 2 inches, what is the resistance?

 $2 \times 2 \times 60000 = 240000$  lbs., Ans.

Also, in a rod of cast steel  $\frac{1}{2}$  inch diameter, area of  $\frac{1}{2} = .1963 \times$ 120000 = 23556 lbs., Ans.

The absolute strength of materials, pulled lengthwise, is in proportion to the squares of their diameters.

# The Lateral or Transverse Strength

Of any beam, or bar of wood, &c., is in proportion to its breadth, multiplied by its depth squared, and in like-sided beams as the cube of the side of a section. Or, one end being fixed, and the other projecting, is inversely as the distance of the weight from the section acted upon, and the strain upon any section is directly as the distance of the weight from that section.

The strength of a projecting beam is only one fourth of what it would be if supported at both ends, and the weight applied in the middle.

The strength of a projecting beam is only one sixth of one of the same length, fixed at both ends, and the weight applied in the mid-

The strength of a beam to support a weight in the centre of it, when the ends rest merely upon two supports, compared to one, the ends being fixed, is as 2 to 3.

### MISCELLANEOUS.

Cast Iron.—Square bar, side 2 inches, length 12 inches, supported at both ends, broke with 22728 lbs. applied in the middle.

Cylinder 3 inches diameter, length 8½ inches, broke with 17110 lbs. applied at one end.

White Pine.—Cylinder  $\frac{7}{8}$  ins. diameter, length 12 inches, broke with 68 lbs. applied at the end.

Yellow Pine.—1 inch square, and 15 inches in length, broke with 125 lbs. applied at the end.

Hickory and White Oak.—1 inch square, and 12 inches in length, required 82 lbs. to deflect them ½ an inch, the weight suspended from the end.

The above and preceding experiments were made by the author in December, 1840.

<sup>\*</sup> From the West Point Foundry Association at Cold Spring, Putnam county, N. Y. Specific gravity, 7210.

Specific gravity. 7210.
† From the Ulster Iron Company, Saugerties, N. Y. A fine specimen of machinery iron.

This specimen broke with the greatest weight here given, when filed through the top to the depth of a ½ of an inch, and the fracture showed but very little fibre.

Mean Result of several Experiments by English Authors on Cast Iron.

Square bar, 1 inch by 32, resting upon two supports, broke with 840 lbs. suspended in the middle.

Square bar, of 1 inch, projecting 32 inches from a wall, broke with 278 lbs. applied; and one, 2 inches deep by  $\frac{1}{2}$  an inch, required 543 lbs. to break it.

Square bar, 1 inch by 32, the ends fixed in walls, required 1170 lbs. suspended from the middle to break it.

#### TO FIND THE TRANSVERSE STRENGTH.

When a Rectangular Bar or Beam is Fixed at one End, and Loaded at the other.

RULE.—Multiply the Value in the preceding table by the breadth, and square of the depth, in inches, and divide the product by the length in feet; the quotient is the weight in pounds.

Note.—When the beam is loaded uniformly throughout its length, the result must be doubled.

EXAMPLE.—What are the weights a cast and a wrought iron bar, projecting 30 inches in length, by 2 inches square, will bear?

$$2 \times 2^2 \times 400 \div 2.5 = 1280$$
 lbs., Ans.  $2 \times 2^2 \times 300 \div 2.5 = 960$  lbs., Ans.

OR, if the Dimensions of a Beam be required, to support a Given Weight at its End.

Rule.  $-\frac{\text{Weight} \times \text{length}}{\text{value in table}} = \text{product of breadth, and square of the depth.}$ 

EXAMPLE.—What is the depth of a wrought iron beam, 2 inches broad, necessary to support 960 lbs. suspended at 30 inches from the fixed end?

$$\frac{960 \times 2.5}{300} = 8$$
, and  $8 \div 2 = 4$ , and  $\sqrt{4} = 2$ , Ans.

When the Bar or Beam is Fixed at both Ends, and Loaded in the

RULE.—Multiply the Value in the preceding table by six times the breadth, and the square of the depth, in inches, and divide by the length in feet.

Note.—When the weight is laid uniformly along its length, the result must be doubled.

Example.—What weight will a bar of cast iron, 2 inches square and 5 feet in length, support in the middle, when fixed at the ends?  $400 \times 6 \times 2 \times 2^2 \div 5 = 3840 \text{ lbs.}. \text{ Ans.}$ 

When the Bar or Beam is Supported at both Ends, and Loaded in the Middle.

RULE.—Multiply the Value in the preceding table by the square of

the depth, and four times the breadth, in inches, and divide the product by the length in feet.

Note.—When the weight is laid uniformly along its length, the result must be doubled.

Example.—What are the weights a cast and a wrought iron bar, 60 inches between the supports, and 2 inches square, will bear?

$$400 \times 2^2 \times \overline{2 \times 4} \div 5 = 2560$$
 lbs., Ans.  $300 \times 2^2 \times \overline{2 \times 4} \div 5 = 1920$  lbs., Ans.

OR, if the Dimensions be required to Support a Given Weight.

 $Rule. - \frac{Weight \times length}{value \text{ in table}} = product \text{ of four times the breadth.}$  and square of the depth.

EXAMPLE.—What is the side of a square cast iron beam 2 feet ir length, between supports, that will support 6400 lbs. in the centre?

$$\frac{6400\times2}{400}$$
  $\div 4\times1 = 8$ , and  $\sqrt{8} = 2.828$ , Ans.

When the Breadth or Depth is required.

Divide the product obtained by the preceding rules by the square of the depth, and you have the breadth; or by the breadth, and the square root of the quotient is the depth.

Example.—If 128 is the product, and the depth 8,  $128 \div 8^2 = 2$ , the breadth;

And  $\sqrt{(128 \div 2)} = 8$ , the depth.

When the Weight is not in the Middle between the Supports.

 $\frac{\text{Distance from nearest end} \times \text{weight}}{\text{whole length}} = \text{pressure upon support}$  farthest from the weight.

 $\frac{\text{Distance from farthest end} \times \text{weight}}{\text{whole length}} = \text{pressure upon support}$ nearest the weight.

When a Beam, supported at both Ends, bears two Weights at unequal Distances from the Ends.

Let D = distance of greatest weight from nearest end,

d =distance of least weight from nearest end,

 $\mathbf{W} =$ greatest weight,  $\mathbf{w} =$ least weight,

L = whole length, l = length from least weight to farthest end.

l' = distance of greatest weight from farthest end 0.00

Then 
$$\frac{D \times W}{L} + \frac{l \times w}{L} = \text{pressure at } w \text{ end},$$
  
and  $\frac{d \times w}{L} + \frac{l' \times W}{L} = \text{pressure at } W \text{ end}.$ 

In cylindrical beams or bars, the lateral strength is as the cube of the diameter.

The strength of a hollow cylinder is to that of a solid cylinder, of the same length and quantity of matter, as the greater diameter of the former is to the diameter of the latter; and the strength of hollow cylinders of the same length, weight, and material, is as their greatest diameters.

To find the Diameter of a Solid Cylinder, Fixed at both Ends, to support a Given Weight in the Middle.

RULE.—Multiply the length between the supports in feet by the weight in pounds; divide by the value, and the cube root of one sixth of the quotient is the diameter in inches.

EXAMPLE.—What should be the diameter for a cylinder 2 feet in length between the supports, to bear 21000 lbs.?

$$\sqrt[3]{\frac{21000\times2\div300}{6}} = 2.85+, Ans.$$

To find the Diameter of a Solid Cylinder, to support a Given Weight in the Middle, between the Supports.

Rule.—Multiply the weight in pounds by the length in feet; divide by the Value, and the cube root of \( \frac{1}{4} \) the quotient is the diameter in inches.

EXAMPLE.—What is the diameter of a cast iron cylinder, 8 inches long between the supports, that will support 60000 lbs. suspended in the middle?

$$\sqrt[3]{\frac{60000 \times .66 \div 240}{4}} = 3.45$$
, Ans.

To find the Diameter of a Solid Cylinder when Fixed at one End, the Load applied at the other.

RULE.—Multiply the length of the projection in feet by the weight to be supported in pounds; divide by the given *Value*, and the cube root of the quotient is the diameter.

Example.—What should be the diameter of a cast iron cylinder 8 inches long, to support 15000 lbs.?

8 inches is .66 feet,  $\sqrt[3]{(15000 \times .66 \div 240)} = 3.45$  inches, Ans.

EXAMPLE.—What should be the diameter for 216000 lbs., at 12 inches from the end?

$$\sqrt[3]{(216000 \times 1 \div 240)} = 9.65, Ans.$$
Hosted by Google

# To find the Diameter of a Beam or Solid Cylinder when the Load is uniformly distributed over its Length.

RULE.—Proceed as if the load was suspended at the end or in the middle until the *quotient* is obtained; then,

If one end is fixed; if the ends rest upon supports; or if the ends are fixed, the cube root of half the quotient is the diameter.

Notes.—The values or units of 400, 240, and 300 are for iron of great strength; when an inferior article is to be used, they must be decreased to correspond.

Thus, 400 represents a weight of 4000 lbs. upon the end of a bar of cast iron 2 inches square and 1 foot in length, and 215 upon a

bar of like dimensions is equal to a weight of 2150 lbs.

240 represents a weight of 8000 lbs. upon the end of a cylinder of cast iron 3 inches in diameter and 1 foot in length, and 130 upon a cylinder of like dimensions is equal to 4333 lbs.

The strength of an equilateral triangle, an edge up, compared to a square of the same area, is as 45 to 28.

The strength of a cylinder, compared to a rectangular beam of the same depth as its diameter, is as .585 to 1.

# To ascertain the Relative Value of Materials to resist a Transverse Strain.

Let V represent this value in a beam, bar, or cylinder one foot in length and one inch square, side or in diameter.

1. Fixed at one end. Weight suspended from the other.

$$V = \frac{lW}{bd^2}$$

2. Fixed at both ends. Weight suspended from the middle.

$$V = \frac{lW}{6bd^2}$$
.

3. Supported at both ends. Weight suspended from the middle.

$$V = \frac{lW}{4bd^2}.$$

4. Supported at both ends. Weight suspended at any other point than the middle.

$$V = \frac{mnW}{lhd^2}$$
.

5. Fixed at both ends. Weight suspended at any other point than the middle.

$$V = \frac{2mnW}{3/bd^2}$$
:

W representing the weight, l the length, b the breadth, d the depth, m the distance from one end, and n the distance from the other.

From which the value of any of the dimensions may be found, by the following formulæ:

1. 
$$\frac{Vbd^2}{l} = W \cdot \frac{Vbd^2}{W} = l \cdot \frac{lW}{Vd^2} = b \cdot \sqrt{\frac{lW}{bV}} = d.$$

In square beams, &c., b and 
$$d = \sqrt[3]{\frac{lW}{V}}$$
.

2. 
$$\frac{6bd^2V}{l} = W \cdot \frac{6bd^2V}{W} = l \cdot \frac{lW}{6d^2V} = b \cdot \sqrt{\frac{lW}{6bV}} = d.$$

In square beams, &c., b and 
$$d = \sqrt[3]{\frac{lW}{6V}}$$
.

3. 
$$\frac{4bd^2V}{l} = W \cdot \frac{4bd^2V}{W} = l \cdot \frac{lW}{4d^2V} = b \cdot \sqrt{\frac{lW}{4bV}} = d.$$

In square beams, &c., b and 
$$d = \sqrt[3]{\frac{lW}{4V}}$$

4 
$$\frac{lbd^2V}{mn}$$
 = W  $\cdot \frac{mnW}{bd^2V}$  =  $l \cdot \frac{mnW}{ld^2V}$  =  $b \cdot \sqrt{\frac{mnW}{lbV}}$  =  $d$ .

In square beams, &c., b and 
$$d = \sqrt[3]{\frac{mnW}{lV}}$$
.

b 
$$\frac{3lbd^2V}{2mn} = W \cdot \frac{2mnW}{3bd^2V} = l \cdot \frac{2mnW}{3ld^2V} = b \cdot \sqrt{\frac{2mnW}{3lbV}} = d.$$

In square beams, &c., b and 
$$d = \sqrt[3]{\frac{2mnW}{3lV}}$$

When the weight is uniformly distributed, the same formulæ will apply, W representing only half the required or given weight.

# " of Pitch Pine . DEFLEXION OF RECTANGULAR BEAMS.

- 1. The deflexions of the same beam, resting on props at each end, and loaded in the middle with weights, are as those weights.
- 2. The deflexion is inversely as the cube of the depth; also, the depth being the same, the deflexion is inversely as the breadth.
  - 3. The deflexion is directly as the cube of the length.

Mean Specific Gravity of Yellow Pine

Let l represent the length of a beam, b its breadth, d its depth, and W the weight with which it is loaded; then the deflexion will vary as  $\frac{e^{-it}}{hd^3}$ ; and if the deflexion is represented by e, then,

When the Beam is Fixed at one End, and Loaded at the other,

$$\frac{l^3W}{bd^3e} = C, a constant quantity.$$

When uniformly loaded .  $\frac{3l^3W}{8hd^3e} = C$ .

$$\frac{3l^3W}{8hd^3e} = C$$

Hosted by Google

558

When Supported at both Ends, and Loaded in the Middle,

$$\frac{l^3 W}{32 b d^3 e} = C.$$

When uniformly loaded .  $\frac{5}{8} \times \frac{l^8 W}{32 h d^3} = C$ .

Hence it follows, that, to preserve the same stiffness in beams, the depth must be increased in the same proportion as the length, the breadth remaining constant.

The deflexion of different beams arising from their own weight, having their several dimensions proportional, will be as the square of either of their like linear dimensions.

Of three equal and similar beams, one inclined upward, one inclined downward at the same angle, and the other horizontal, it has been determined that that which had its angle upward was the weakest, the one which declined was the strongest, and the one horizontal was a mean between the two.

Barlow furnishes the following as some of the results obtained by him upon the deflexion of beams:

		Length.	Depth.	Breadth.	Lbs.	Deflexion in ins.
Fir	•	6 feet	2 inches	11 inches	180	1.
Fir Fir	:	3 " 6 "	2 " 1½ "	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	120 180	2.

#### WROUGHT IRON.

Supported at each end. The average of a number of experiments gave, for bars 33 inches in length, 1.9 inches broad, and 2 inches deep, a deflexion for every half ton of .024 inches.

## CAST IRON.

Supported at both ends. Bars 33 inches in length, 1.3 inches in breadth, and 0.65 inches deep, deflected 0.27 inches with 162 lbs. applied.

#### WOODS.

Fir battens. Supported at each end, 15 inches in length, and 1 inch square, broke with a weight of 440 lbs.; 30 inches in length, and 1 inch square, broke with 240 lbs.

Oak battens. Supported at each end, 2 feet long,  $1\frac{1}{2}$  inches deep, and  $\frac{1}{2}$  inch in breadth, deflected 1.1 ins., and supported 408 lbs.

Ash battens. Fixed at one end, 2 feet long, 2 inches deep, and 1 inch in breadth, deflected 6 inches with a weight of 434 lbs.

Fir battens. Fixed at one end, same dimensions as last piece, deflected 3.9 ins. with 276 lbs.

Note 1.—When a weight is uniformly distributed over the length of a beam, the leftexion will be three eighths of the deflexion from the same weight applied at the attremity.

2. If the beam be a cylinder, the deflexion is 1.7 times that of a square beam, ther things being equal.

3. If the load is uniformly distributed over the length, the deflexion will be five sighths of the deflexion from the same load collected in the middle.

 ${}_{\text{Hosted by}}Google$ 

# Torsional Strength.

The resistance to torsion, of any square beam or bar, is as the cube of its side, and of a cylinder it is as the cube of its diameter.

Table of the Torsional Strength of various Materials.

EXPERIMENTS MADE BY MAJOR WILLIAM WADE FOR THE ORDNANCE DEPARTMENT, U. S. A.

# To find the Torsional Strength of Shafts, &c.

RULE.—Multiply the Value in the preceding table by the cube of the side or of the diameter of the shaft, and divide the product by the distance from the axis in feet at which the power is applied; the quotient is the weight in pounds.

EXAMPLE.—What is the resistance of a cast iron shaft 2 inches in diameter, to which a weight is applied 2 feet from its axis?

$$125 \times 2^3 = 1000$$
 and  $1000 \div 2 = 500$  lbs., Ans.

To find the Diameter of a Shaft to resist Torsional Strain.

Rule.—Multiply the extreme of pressure on the crank pin, or at the pitch line of the pinion, that the shaft is at any time liable to be subjected to, by the length of the crank or radius of wheel in feet; divide their product by the *Value* in the preceding table, and the cube root of the quotient is the diameter of the journal in inches.

EXAMPLE.—What should be the diameter for the journal of a wrought iron water-wheel shaft, the pressure on the crank pin being 59400 lbs., and the crank 5 feet in length?

$$\sqrt[3]{\frac{59400 \times 5}{125}} = 13.5$$
 inches, Ans.

EXAMPLE.—The pressure on a crank pin is 123.680 lbs., and the length of crank 5 feet.

$$\sqrt[3]{\frac{123680\times5}{125}} = 17+$$
, Ans.

When two Shafts are used, as in Steam Vessels with one Engine.

Rule. 
$$-\sqrt[3]{\left(\frac{\text{diameter for one shaft }^3 \times 3}{4}\right)} = \text{diameter in inches.}$$

Example.—The area of the journal of a single shaft is 113 inches; what should be the diameter if two shafts are used?

Diameter for area of 113 = 12 inches.

$$\sqrt[3]{\frac{12^3 \times 3}{4}} = 10.9$$
, Ans.

The examples above given are deduced from instances in successful practice; where the diameter has been less, fracture has almost universally taken place, the strain being increased beyond the ordinary limit.

# Relative Values of Cast and Wrought Iron.

When cast iron shafts of less diameter than 12 inches are required, the *Values* here given must be reduced from  $\frac{1}{20}$  to  $\frac{1}{10}$ , according to the quality of the iron and the diameter of the shaft to be used; but when they exceed this diameter, the Values must be increased in a like manner. The necessity of this arises in consequence of the strength of a wrought iron shaft decreasing as its diameter increases.

Grier makes the difference between cast and wrought iron for all diameters as .963 to 1.000.

# Relative Values of Cast Iron, Oak, and Pine.

The Value for cast iron being 125, that for oak is 280, and that of white pine 257.

Grier, in his Mechanics' Calculator, gives the following rule:

For Cast Iron Shafts of second and third Movers.

The diameters for second and third movers are found by multiplying the diameter for a prime mover by .8 and .793 respectively.

# Torsional Strength of Hollow Cylinders.

Relative Torsional Strength of Cast Iron Shafts of different Forms, having equal Areas of Cross Sections.

From Major Wade's experiments, on shafts having sections of 1, 2, and 3 square inches.

Solid Cylin-	Solid Square	Hollow Cylinders, where interior and exterior diameters were in the proportion of								
der.		4 to 10.	5 to 10.	6 to 10.	7 to 10.	8 to 10.				
1.000	.8750	1.2656	1.4433	1.7000	2.0864	2.7377				

Formula of Lieutenant Rodman, U. S. A., deduced from the above experiments, modified to introduce the element V, and the length in feet in preference to inches.  $\frac{V}{D}\frac{D^4-d^4}{Dl}=W.$ 

$$\frac{V D^4 - d^4}{Dl} = W.$$

W = the weight which a shaft will sustain in pounds (independent of its own weight), D d the exterior and interior diameters in inches, and l the distance from the axis in feet at which W is applied.

# GUDGEONS AND SHAFTS.

To find the Dimensions of a Gudgeon.

$$0.30\sqrt[3]{(wl)} = d$$

 $\boldsymbol{w}$  representing the stress in 100 lbs.,  $\boldsymbol{l}$  the length in inches, and  $\boldsymbol{d}$  the diameter in inches.

If a Cylindrical Shaft has no other lateral stress to sustain than its own weight, and is Fixed at one End,  $d = .000024l^2.$ 

Let the stress supposed to be in the middle be n times the weight of the shaft; then,

When supported at both Ends,

If the weight of the shaft be not taken into account,

$$d = \sqrt[3]{.00012 \ nl^2}$$

If the weight of the shaft is taken into account,  $d = \sqrt[3]{.00012(n+1)l^2}$ .

When a Hollow Shaft is supported at each End,

 $d = \sqrt[3]{\frac{00048 \, wl}{4} + D^3}$ , w representing the stress in lbs., l the length in inches, D the interior diameter, and d the diameter in inches,

When a Hollow Shaft is Fixed at each End, and Loaded in the Middle.

$$d = \sqrt[3]{\frac{.00048 \, wl}{6} + D^3}$$
.

For hollow Cylindrical Shafts, when Supported at one End,

$$d = \sqrt[3]{.00048 \, wl + D^3}$$
.

If the hollow shaft support the weights at distances m and n from each end, and is supported at each end,

$$d = \sqrt[3]{.00048} \frac{mn}{l} w + D^3.$$

The last four formulas do not take into account the weight of the shaft.

The above is for Cast Iron.

For Cylindrical Shafts of Cast Iron to resist Torsion. (Buchanan.)
Let P be the number of horses' power, and R the revolutions of
the shaft in a minute; then

 $\sqrt[3]{\frac{240 \text{ P}}{R}} = d.$ 

For Wrought Iron, multiply this result by .963; for Oak, by 2.238; for Pine, by 2.06.

If a shaft has to sustain both lateral stress and torsion, then, For east iron.

$$\sqrt[3]{\left(\frac{240 \text{ P}}{\text{R}} + \frac{wl^2}{2}\right)} = d.$$

# TEETH OF WHEELS.

### To Construct a Tooth.

DIVIDE the pitch into 10 parts. Let 3.5 of these parts be below the pitch line, and 3.0 of them above.

The thickness should be .47 of the pitch.

The length should be .65 of the pitch.

The Diameter of a wheel is measured from the pitch line.

The wood used for teeth is about \(\frac{1}{4}\) the strength of cast 1100, therefore they should be twice the depth to be of equal strength.

To find the Diameter of a Wheel, the Pitch and Number of Teeth being given.

$$\frac{\text{Pitch} \times \text{number of teeth}}{3.1416} = \text{diameter.}$$

Note.—The pitch, as found by this rule, is the arc of a circle; the true pitch required is a straight line, and must be measured from the centres of two contiguous teeth.

To find the Pitch, the Diameter and Number of Teeth being given.

$$\frac{\text{Diameter} \times 3.1416}{\text{number of teeth}} = \text{pitch}.$$

Note.—The pitch, as found by this rule, is the arc of a circle; the true pitch required is a straight line, and must be measured from the centres of two contiguous teeth.

To find the Number of Teeth, the Diameter and Pitch being given.

$$\frac{\text{Diameter} \times 3.1416}{\text{pitch}} = \text{number of teeth.}$$

To find the Diameter when the true Pitch is used. Number of teeth  $\times$  pitch  $\times$  .32 = diameter.

# Dimensions of Wheels in operation.

Diameter.	Breadth.	Pitch.	Length of teeth.	Thickness of teeth.	Velocity per second.	Pressure.
Feet. Ins.	Inches.	Inches.	Inches.	Inches.	Feet.	Lbs.
10	7.	2.8	1.625	1.3	3.	1100 <b>0</b>
6	12.	4.2	2.25	1.9	6.6	20000
7 10	4.5	1.9	1.125	.875	1.1	3300
14 4	8.	3.	1.75	1.4	1.87	9000

# VELOCITY OF WHEELS.

THE relative velocity of wheels is as the number of their teeth.

To find the Velocity or Number of Turns of the last Wheel to one of the first.

RULE.—Divide the product of the teeth of the wheels that act as drivers by the product of the driven, and the quotient is the number.

EXAMPLE.—If a wheel of 32 teeth drive a pinion of 10, on the axis of which there is one of 30 teeth, acting on a pinion of 8, what is the number of turns of the last?

$$\frac{32}{10} \times \frac{30}{8} = \frac{960}{80} = 12$$
, Ans.

To find the Proportion that the Velocities of the Wheels in a train should bear to one another.

RULE.—Subtract the less velocity from the greater, and divide the remainder by one less than the number of wheels in the train; the quotient is the number, rising in arithmetical progression from the less to the greater velocity.

EXAMPLE.—What are the velocities of three wheels to produce 18 revolutions per minute, the driver making 3 revolutions per minute?

$$18-3 = \frac{15}{3-1} = 7.5$$
; then  $3+7.5 = 10.5$ ,

and 10.5+7.5=18; thus, 3, 10.5, and 18 are the velocities of the three wheels.

To find the Number of Teeth required in a Train of Wheels to produce a certain Velocity.

Rule.—As the velocity required is to the number of teeth in the driver, so is the velocity of the driver to the number of teeth in the driven.

EXAMPLE.—If the driver has 90 teeth, makes 2 revolutions, and the velocities required are 2, 10, and 18, what are the number of teeth in each of the other two?

2d wheel, 10:90::2:18 teeth. 3d wheel, 18:90::2:10 teeth.

## STRENGTH OF WHEELS.

THE strength of the teeth of wheels is directly as their breadth and as the square of their thickness, and inversely as their length.

The stress is as the pressure.

# To find the Thickness of a Tooth, the Strain at the Pitch Line being given.

RULE.—Divide the pressure in pounds at the pitch line by 3000, and the square root of the quotient is the thickness of the tooth in inches.

Example.—The pressure is 9000 lbs., what is the thickness of the tooth required ?

$$\sqrt{\frac{9000}{3000}} = 1.732$$
 inches, Ans.

The Breadth should be 2.5 times the pitch.

Therefore, as the thickness should be 0.47 of the pitch, the pitch for the above example will be 3.685 inches, and the breadth 3.685  $\times 2.5 = 9.2125$  inches.

# To find the Horses' Power of a Tooth, the Dimensions and Velocity being given.

Thickness <sup>2</sup>×3000 = pressure.

 $\frac{\text{Pressure} \times \text{velocity in feet per minute}}{33000} = \text{horses' power.}$ 

Thickness  $\times 2.1277+$  = the pitch.

Thickness  $\times 1.5384+ =$  the length.

# To find the Dimensions of the Arms of a Wheel.

RULE.—Multiply the power at the pitch line by the cube of the length of the arms, and divide this product by the product of the number of arms and 280; the quotient will be the breadth and cube of the depth.

EXAMPLE.—If the power be 1600, the diameter of the wheel 10 feet, and the number of arms 6, what will be the dimensions of each arm?

$$\frac{1600 \times \overline{10 - 2^3}}{6 \times 280} = \frac{200000}{1680} = 119; \text{ if the breadth be 5 inches, then}$$

 $\frac{119}{5}$  = 23.8, and  $\sqrt[3]{}$  of 23.8 = 2.87, the depth.

#### GENERAL EXPLANATIONS CONCERNING WHEELS

Pitch Lines.—The touching circumferences of two or more wheels, which act upon each other.

Pitch of a Wheel.—The distance of two contiguous teeth, measured upon their pitch line.

Length of a Tooth.-The distance from its base to its extremity.

Breadth of a Tooth.-The length of the face of the wheel.

Spur Wheels .- Wheels that have their teeth perpendicular to their axis.

Bevel Wheels.-Wheels having their teeth at an angle with their axis.

. Crown Wheels.—Wheels which have their teeth at a right angle with their axis.

Mitre Wheels.-Wheels having their teeth at an angle of 45° with their axis.

Spur Gear .- Wheels acting upon each other in the same plane.

Bevel Gear .- Wheels acting upon each other at an angle.

When two wheels act upon one another, the greater is called the *spur* or *driver*, and the lesser the *pinion* or *driven*.

When the teeth of a wheel are made of a different material from the wheel, they are called cogs.

Table of the Strength of Teeth and Arms.

	l		Teeth.	With 6 Arms.

Tredgold.

# HORSE POWER.

As this is the universal term used to express the capability of first movers of magnitude, it is very essential that the estimate of this power should be uniform; and as it is customary, in Europe, to estimate the power of a horse equivalent to the raising of 33000 lbs. one foot high in a minute, there can be no objection to such an estimate here.

The estimate, then, of a horse's power in the calculations in this work, is 33000 pounds avoirdupois, raised through the space of one foot in height in one minute, and in this I am supported by the practice of a majority of the manufacturers of steam-engines in this country.

## ANIMAL STRENGTH.

#### MEN.

The mean effect of the power of a man, unaided by a machine, working to the best possible advantage, and at a moderate estimation, is the raising of 70 lbs. 1 foot high in a second, for 10 hours in a day.

Two men, working at a windlass at right angles to each other, can raise 70 lbs. more easily than one man can 30 lbs.

Mr. Bevan's results with experiments upon human strength are, for a short period.

With	a drawing-knife .				. a	force of	100	lbs
	an auger, both hands					"	100	"
	a screw-driver, one hand	1				44	84	"
	a bench vice, handle					44	72	"
	a chisel, vertical pressur	re		-		44	72	"
	a windlass		-	-	:	44	60	u
	pincers, compression	:				"	60	"
	a hand-plane	:			:	46	50	"
	a hand-saw	Ĭ	-	-	:	44	36	"
	a thumb-vice	•	•		•	"	45	"
	a brace-bit, revolving	•	•		•	44	16	"
	Twisting by the thumb and with small screw			rs on	ly, }	u,	14	46

By Mr. Field's experiments in 1838, the maximum power of a strong man, exerted for  $2\frac{1}{2}$  minutes, is = 18000 lbs. raised one foot in a minute.

A man of ordinary strength exerts a force of 30 lbs. for 10 hours in a day, with a velocity of  $2\frac{1}{2}$  feet in a second, = 4500 lbs. raised one foot in a minute, =  $\frac{1}{2}$  of the work of a horse.

A foot-soldier travels in 1 minute, in common time, 90 steps, = 70 yards. in quick time, 110 " = 86 " in double quick-time, 140 " = 109 "

He occupies in the ranks, a front of 20 inches, and a depth of 13, without a knapsack; the interval between the ranks is 13 inches.

Average weight of men, 150 lbs. each.

5 men can stand in a space of 1 square yard.

A man travels, without a load, on level ground, during 8½ hours a day, at the rate of 3.7 miles an hour, or 31½ miles a day. He can carry 111 lbs. 11 miles in a day. Daily allowance of water for a man, 1 gallon for all purposes.

A porter going short distances, and returning unloaded, carries 135 lbs. 7 miles a day. He can carry, in a wheelbarrow, 150 lbs. 10 miles a day.

The muscles of the human jaw exert a force of 534 lbs.

#### HORSES.

A horse travels 400 yards, at a walk, in  $4\frac{1}{2}$  minutes; at a trot, in 2 minutes; at a gallop, in 1 minute.

He occupies in the ranks a front of 40 inches, and a depth of 10 feet; in a stall, from  $3\frac{1}{2}$  to  $4\frac{1}{2}$  feet front; and at picket, 3 feet by 9.

Average weight = 1000 lbs. each.

A horse, carrying a soldier and his equipments (say 225 lbs.), travels 25 miles in a day (8 hours).

A draught horse can draw 1600 lbs. 23 miles a day, weight of carriage included.

The ordinary work of a horse may be stated at 22.500 lbs., raised 1 foot in a minute, for 8 hours a day.

In a horse mill, a horse moves at the rate of 3 feet in a second. The diameter of the track should not be less than 25 feet.

A horse power in machinery is estimated at 33.000 lbs., raised 1 foot in a minute; but as a horse can exert that force but 6 hours a day, one machinery horse power is equivalent to that of 4.4 horses.

The expense of conveying goods at 3 miles per hour per horse teams being 1, the expense at 4½ miles will be 1.33, and so on, the expense being doubled when the speed is 5½ miles per hour.

The strength of a horse is equivalent to that of 5 men.

Table of the Amount of Labour a Horse of average Strength is capable of performing, at different Velocities, on Canals, Railroads, and Turnpikes.

#### Force of traction estimated at 83.3 lbs.

Velocity in miles	Duration of the	Useful effect for one day in tons, drawn one mile.								
per hour.	day's work.	On a Canal.	On a Railroad.	On a Turnpike.						
Miles.	Hours.	Tons.	Tons.	Tons.						
$2\frac{1}{2}$	111	520	115	14						
3	8	243	92	12						
$3\frac{1}{2}$	$5\frac{9}{10}$	153	82	10						
4	$4\frac{1}{2}$	102	72	9.						
5	$2\frac{9}{10}$	52	57	7.2						
6	2	30	48	6.						
7	1½	19	41	5.1						
8	11	12.8	36	4.5						
9	9 10 3	9.0	32	4.0						
10	्रिल् व	6.6	28,8	3.6						

The actual labour performed by horses is greater, but they are injured by it.

## HYDROSTATICS.

Hyprostatics treat of the pressure, weight, and equilibrium of non-elastic fluids.

The pressure of a fluid at any depth is as the depth of the fluid.

The pressure of a fluid upon the bottom of the containing vessel is as the base and perpendicular height, whatever may be the figure of the containing vessel.

Fluids press equally in all directions.

The Centre of Pressure is that point of a surface against which any fluid presses, to which, if a force equal to the whole pressure were applied, it would keep the surface at rest.

The centre of pressure of a parallelogram is at  $\frac{2}{3}$  of the line (measuring downward) that joins the middles of the two horizontal sides.

In a triangular plane, when the base is uppermost, the centre of pressure is at the middle of the line, raised perpendicularly from the vertex; and when the vertex is uppermost, the centre of pressure is at  $\frac{3}{4}$  of a line let fall perpendicularly from the vertex.

#### OF PRESSURE.

The pressure of a fluid on any surface, whether vertical, oblique, or horizontal, is equal to the weight of a column of the fluid, whose base is equal to the surface pressed, and height equal to the distance of the centre of gravity of the surface pressed, below the surface of the fluid.

# To find the Pressure of a Fluid upon the Bottom of the Containing Vessel.

RULE.—Multiply area of base in feet by height of fluid in feet, and their sum by the weight of a cubic foot of the fluid.

EXAMPLE.—What is the pressure upon a surface 10 feet square, he water (fresh) being 20 feet deep?

 $10^2 \times 20 \times 62.5 = 125000$  lbs., Ans.

The side of any vessel sustains a pressure equal to the area of the side, multiplied by half the depth.

The pressure upon an inclined, curved, or any surface, is as the area of the surface, and the depth of its centre of gravity below the fluid.

EXAMPLE.—What is the pressure upon the sloping side of a pond 10 feet square, the depth of the pond being 8 feet?

 $10^2 \times {}^8 \times 62.5 = 25000$  lbs., Ans.

Or, on a hemisphere just covered with water, and 36 inches in liameter,

rea of 36 = 1017.8, centre of gravity (page 138)  $36 \div 2 \div 2 = 9$ . 9. ns. = .75 foot; then,  $\overline{.75 \times 1017.8} \div 144 = 5.3$ , which,  $\times 62.5 = 131.25$  lbs., Ans.

The pressure upon a number of surfaces is found by multiplying the sum of the surfaces into the depth of their common centre of gravity, below the surface of the fluid.

#### CONSTRUCTION OF BANKS.

A bank, constructed of a given quantity of materials, will just resist the pressure of the water when the square of its thickness at the base is to the square of its perpendicular height, as the weight of a given bulk of water is to the weight of the same bulk of the material the bank is made of, increased by twice the aforesaid weight of the given bulk of water.

Thus, if the bank is made of a stone 2 times heavier than water, the thickness of the base should be to the height, as 3 to 6.

If the height, compared to the thickness of the base, be as 10 to 7, stability is always ensured, whatever the specific gravity of the material may be.

The bottom of a conical, pyramidal, or cylindrical vessel, or of one the section of which is that of an inverted frustrum of a cone or pyramid, sustains a pressure equal to the area of the bottom and the depth of the fluid.

#### FLOOD GATES.

To find the Strain which a Fluid will exert to make it turn upon its Hinges, or open.

RULE.—Multiply \( \frac{1}{4} \) of the square of the height by the square of the breadth, and take a bulk of water equal to the product.

Example.—If the gate is 6 feet square,

$$\frac{6^2}{4} \times 6^2 = 324$$
 cubic feet, or 20250 lbs.

To find the Strain the Water exerts upon its Hinges.

Rule.—Multiply  $\frac{1}{6}$  of the breadth by the cube of the height, and take a bulk of water equal to the product.

Example.—With the same gate,

$$\frac{6}{6} \times 6^3 = 216$$
 cubic feet, or 13500 lbs.

#### PIPES.

# To find the Thickness of a Pipe.

RULE.—Multiply the height of the head of the fluid in feet by the diameter of the pipe in inches, and divide their product by the cohesion of one square inch of the material of which the pipe is composed.

By experiment it has been found that a cast iron pipe, 15 inches in diameter, and \$ of an inch thick, will support a head of water of 600 feet; and that one of oak, of the same diameter, and 2 inches thick, will support a head of 180 feet.

The cohesive power of cast iron, then, would be 12,000 lbs.; of oak, 1350 lbs.

That of lead is 750 lbs.; and wrought iron boiler plates, riveted together, is from 25 to 30,000 lbs.

In conduit pipes, lying horizontal, and made of lead, their thickness, compared to their diameter, should be,

As  $2\frac{1}{2}$ , 3, 4, 5, 6, 7, 8 lines, To 1,  $1\frac{1}{2}$ , 2, 3,  $4\frac{1}{2}$ , 6, 7 inches.

And when made of iron,

As 1, 2, 3, 4, 5, &c., lines, To 1, 2, 4, 6, 8, &c., inches.

The tenacity of lead is increased to 3000 by the addition of 1 part of zinc in 8.

## HYDROSTATIC PRESS.

To find the Thickness of the Metal to resist a Given Pressure.

Let p = pressure per square inch in pounds, r = radius of cylinder, and c = cohesion of the metal per square inch.

Then  $\frac{pr}{c-p}$  = thickness of metal.

The cohesive force of a square inch of east iron is frequently estimated at 18000 lbs., but 16000 is preferable.

A cylindrical ring, the diameters of which were 5.3 and 10.8 mehes, burst at a pressure of 9000 lbs. per square inch.

These dimensions by the above rule would give

$$\frac{9000 \times \overline{5.3 \div 2}}{16000 - 9000} = 3.4 \text{ ins.}$$
The thickness was 
$$\frac{10.8 - 5.3}{2} = 2.75 \text{ ins.}$$

# HYDRAULICS AND HYDRODYNAMICS.

Hydraulics treats of the motion of non-elastic fluids, and Hydrodynamics of the force with which they act.

Descending water is actuated by the same laws as falling bodies.

Water will fall through 1 foot in \(\frac{1}{4}\) of a second, 4 feet in \(\frac{1}{2}\) of a second, and through 9 feet in \(\frac{3}{4}\) of a second, and so on.

The velocity of a fluid, spouting through an opening in the side

of a vessel, reservoir, or bulkhead, is the same that a body would acquire by falling through a perpendicular space equal to that beween the top of the water and the middle of the aperture.

Then, by rule 4 in Gravitation,

$$\sqrt{\text{height} \times 64.33} = \text{velocity}.$$

Example.—What is the velocity of a stream issuing from a head of 10 feet?

$$\sqrt{10\times64.33} = 25.36 \text{ feet, } Ans.$$
  
Or,  $\sqrt{10\times8.02} = 25.36 \text{ feet, } Ans.$ 

If the velocity be 50.72 feet per second, what is the head?

$$\frac{50.72^{2} \div 64.33}{\text{Or}, \frac{50.72^{2} \div 8^{2}}{50.72^{2} \div 8^{2}}} = 40 \text{ feet, } Ans.$$

This would be true were it not for the effect of friction, which in pipes and canals increases as the square of the velocity.

The mean velocity of a number of experiments gives 5.4 feet for a height of one foot. The theoretical velocity is  $(\sqrt{64\frac{1}{3}})$  8.

#### OF SLUICES.

To find the Quantity of Water which will flow out of an Opening.

Rule.-Multiply the square root of the depth of the water by 5.4; the product is the velocity in feet per second. This, multiplied by the area of the orifice in feet, will give the number of cubic feet per second.

Example.—If the centre of a sluice is 10 feet below the surface of a pond, and its area 2 feet, what quantity of water will run out in one second?

$$\sqrt{10 \times 5.4 \times 2} = 34.1496$$
 feet, Ans.

Note.-If the area of the opening is large compared with the head of the water take 3 of this velocity for the actual velocity.

### OF VERTICAL APERTURES OR SLITS.

The quantity of water that will flow out of one that reaches as high as the surface is 3 of that which would flow out of the same aperture if it were horizontal at the depth of the base.

Or, velocity at bottom  $\times$  depth  $\times$  2  $\times$  breadth of slit = number

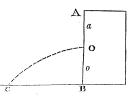

of cubic feet per second.

#### OF STREAMS OR JETS.

To find the Distance a Jet will be projected from a Vessel through an opening in the Side.

Rule.—B C will always be equal to twice the square root of AO $\times$ OB.

If o is 4 times as deep below A, as a is, o will discharge twice the quantity of water that will flow from a in the same time, because 2 is the square root of A o, and 1 is the square root of A a.

Note.—The water will spout the farthest when o is equidistant from A and B; and if the vessel is raised above a plane, B must be taken upon the plane.

The quantities of water passing through equal holes in the same time are as the square roots of their depths.

EXAMPLE.—A vessel 20 feet deep is raised 5 feet above a plane; how far will a jet reach that is 5 feet from the bottom?

$$\sqrt{15\times10}\times2=24.48$$
 feet, Ans.

When a prismatic vessel empties itself by a small orifice, in the time of emptying itself, twice the quantity would be discharged if it were kept full by a new supply.

To find the Vertical Height of a Stream projected from a Pipe.

RULE.—Ascertain the velocity of the stream by computing the quantity of water running or forced through the opening; then, by rule 5 in Gravitation, page 140, find the required height.

Example.—If a fire-engine discharges 16.8 cubic feet of water through a  $\frac{3}{4}$  inch pipe in one minute, how high will the water be projected, the pipe being directed vertically?

 $16.8 \times 1728 \div$  area of  $\frac{3}{4} \div$  inches in a foot  $\div$  seconds in a minute = 91.6, or velocity of stream in feet per second; then, by rule, page 140, 91.6 $\div$ 8 = 11.45, and 11.45<sup>2</sup> = 131.10 feet, *Ans*.

Note.—This rule gives a theoretical result; the result in practice is somewhatess.

#### VELOCITY OF STREAMS.

In a stream, the velocity is greatest at the surface and in the middle of the current.

# To find the Velocity of a River or Brook.

Rule.—Take the number of inches that a floating body passes over in one second in the middle of the current, and extract its square root; double this root, subtract it from the velocity at top, and add 1; the result will be the velocity of the stream at the bottom; and the mean velocity of the stream is equal the velocity at the surface —  $\sqrt{\text{velocity}}$  at the surface +.5.

EXAMPLE.—If the velocity at the surface and in the middle of a stream be 36 inches per second, what is the mean velocity?

$$\sqrt{36} \times 2 - 36 + 1 = 25$$
, the velocity at bottom.  $36 - \sqrt{36 + .5} = 30.5$ , Ans.

To find the Velocity of Water running through Pipes.

RULE.—Multiply the height in feet by 2500, divide this product by the product of the length in feet into 13.88 divided by the number of inches in the diameter of the pipe, and the square root of the quotient is the velocity in feet per second.

Thus, 
$$\sqrt{2500 \times h \div (l \times \frac{13.88}{d})}$$
 = velocity, when  $h$  represents the height,  $l$  the length, and  $d$  the diameter.

EXAMPLE.—The head of a reservoir is 1 foot, the diameter of the pipe 5 inches, and the length of it 100 feet; what is the velocity in feet per second?

$$2500 \times 1 \div \left(100 \times \frac{13.88}{5}\right) = \frac{2500}{277.6} = 9$$
, and  $\sqrt{9} = 3$ , Ans.

If the height is required,

$$v^2 \times \frac{13.88}{d} \times l \div 2500 = \text{height.}$$

In this, as in the annexed table, the friction is assumed to be in the ratio of the diameters.

Late and extended experiments show that this is not strictly accurate. See table, page 175.

# Quantities of Water discharged from Orifices of various forms, the Altitude being constant, at 34.642 Inches.

Nature and dimensions of the tubes and orifices.	Cubic inches discharged in a minute
1. A circular orifice in a thin plate, the diameter being	
1.7 inches	10783
2. A cylindrical tube 1.7 inches in diameter, and 5.117	
inches long	14261
3. A short conical adjutage, 1.7 inches in diameter .	10526
4. The same, with a cylinder 3.41 inches long added to	
it	10409
5. The same, the length of the cylinder being 13.65 inch-	
es long	9830
6. The same, the length of the cylinder being 27.30 inch-	
es long	9216

Results prove that the discharge of water through a straight cylindrical pipe of an unlimited length may be increased only by altering the form of the terminations of the pipe, by making the inner end of the pipe of the same form as the vena contracta, and the extremity a truncated cone, having its length about 9 times the diameter of the cylinder or pipe attached, and the aperture at the outlet to the diameter of the cylinder as 18 is to 10.

By giving this form, the discharge is over what it would be by the cylinder alone as 24 is to 10.

Table showing the Head necessary to overcome the Friction of Water in Horizontal Pipes, BY MR. SMEATON.

Look for the velocity of water in the pipe in the upper line, and in the column beneath it, and opposite to the given diameter, is the height of the column or head requisite to overcome the friction of such pipe for 100 feet in length, and obtain the required velocity.

### GENERAL RULES.

## Discharge by Horizontal Pipes.

- The less the diameter of the pipe, the less is the proportional discharge of the fluid.
- 2. The greater the length of the discharging pipe, the greater the diminution of the discharge.
  - 3. The friction of a fluid is proportionally greater in small than in large pipes.
- 4. The velocity of water flowing out of an aperture is as the square root of the height of the head of the water.

Theoretically the velocity would be  $\sqrt{\text{height}} \times 8$ . In practice it is  $\sqrt{\text{height}} \times 5.4 = \text{velocity}$  in feet per second.

## Discharge by Vertical Pipes.

The discharge of fluids by vertical pipes is augmented, on the principle of the gravitation of falling bodies; consequently, the greater the length of the pipe, the greater the discharge of the fluid.

# Discharge by Inclined Pipes.

A pipe which is inclined will discharge in a given time a greater quantity of water than a horizontal pipe of the same dimensions.

## Deductions from various Experiments.

- 1. The areas of orifices being equal, that which has the smallest perimeter will discharge the most water under equal heads; hence circular apertures are the most advantageous.
- 2. That in consequence of the additional contraction of the fluid vein, as the head of the fluid increases the discharge is a little diminished.
- 3. That the discharge of a fluid through a cylindrical horizontal tube, the diameter and length of which are equal to one another, is the same as through a simple
- 4. That the above tube may be increased to four times the diameter of the orifice with advantage.
  - 5. The velocity of motion that would result from the direct, unretarded ac-
  - tion of the column of a fluid which produces it, being a constant, or . 8
    The velocity through an aperture in a thin plate, with the same pressure, is 5.
  - Through a tube from two to three diameters in length, projecting outward, 6.5

  - Curvilineal and rectangular pipes discharge less of a fluid than rectilineal pipes.

# Discharge from Reservoirs receiving no Supply of Water.

For prismatic vessels the general law applies, that twice as much would be discharged from the same orifice if the vessel were kept full during the time which is required for emptying itself.

# Discharges from Compound or Divided Reservoirs.

The velocity in each may be considered as generated by the difference of the heights in the two contiguous reservoirs; consequently, the square root of the difference will represent the velocity, which, if there are several orifices, must be inversely as their respective areas.

## Discharge by Weirs and Rectangular Notches.

The quantity of water discharged is found by taking  $\frac{2}{3}$  of the velocity due to the mean height, using 5.1 for the coefficient of the velocity.

EXAMPLE.—What quantity of water will flow from a pond, over a weir 102 inches in length by 12 inches deep?

 $\frac{2}{3}\sqrt{1}$  foot  $\times$  5.1  $\times$  8.5 area of weir = 28.9 cubic feet in one second.

# Velocity of Water in Pipes and Sewers.

By the experiments of Mr. Rofe, of the Birmingham Waterworks, the following valuable tables are obtained:

Table of the heads of water necessary to maintain different velocities of water in 100 feet of pipe.

V represents the velocities in feet per minute, and C the constant number for these velocities.

V.		С.	V.		C.	V.		C.
60		8.62	90		17.95	140		38.90
70		11.40	100		21.56	150		44.
80		14.58	120		29.70	180		62.13

Table of the constant numbers for different diameters.

D represents the diameter of the pipe in inches, and C the constant number for their diameters.

ber for their diameters.

D. c. | D. c. | D. c. | 4 . . . .028 | 6 . . . .078 | 8 . . .134 | 5 . . .053 | 7 . . . .104 | 
$$\frac{1}{2}$$

Then, when h represents the head of water,  $\frac{C}{D+c} = H$ .

EXAMPLE.—It is required to determine what head of water would be necessary to send water through 1500 feet of six-inch pipes to an elevation of 80 feet, and at a velocity of 180 feet per minute:

 $\frac{62.13}{6+.078}$  = 10.22 inches, which  $\times$  15 (the number of 100 feet) = 153.3 inches (12 feet 9 inches). This, added to 80 feet, gives 92 feet 9.3 inches for the answer.

The time occupied in an equal quantity of water through a pipe or sewer of equal lengths, and with equal falls, is proportionally as follows:

In a right line as 90, in a true curve as 100, and in passing a right angle as 140.

## WATER WHEELS.

This subject belongs properly to Hydrodynamics, but a separate classification is here deemed preferable.

WATER WHEELS are of three kinds, viz., the Overshot, Undershot, and Breast.

The Overshot Wheel is the most advantageous, as it gives the greatest power with the least quantity of water. The next in order, in point of efficiency, is the Breast Wheel, which may be considered a mean between the Overshot and the Undershot. For a small supply of water with a high fall, the first should be employed; where the quantity of water and height of fall are both moderate, the second form should be used. For a large supply of water with a low fall, the third form must be resorted to.

Before proceeding to erect a water wheel, the area of the stream

and the head that can be used must be measured.

Find the velocity acquired by the water in falling through that height by the rule, viz.: Extract the square root of the height of the head of the water (from the surface to the middle of the gate), and multiply it by 8.

 $N_{\mbox{\scriptsize OTE}}.$  —Where the opening is small, and the head of water is great, or proportionally so, use from 5.5 to 8 for the multiplier.

EXAMPLE.—The dimensions of a stream are 2 by 80 inches, from a head of 2 feet to the upper surface of the stream; what is the velocity of the water per minute, and what is its weight?

2 feet and  $\frac{1}{2}$  of 2 inches = 25 inches = 2.08 feet,  $\sqrt{2.08 \times *6.5 \times 60}$  = 561.60 feet velocity per minute.

And  $80 \times 2 \times 561.6$  feet  $\times 12$  inches,  $\div 1728 = 624$  cubic feet,  $\times 62\frac{1}{2}$  lbs. = 39000 lbs. of water discharged in one minute.

# To find the Power of an Overshot Wheel.

RULE.—Multiply the weight of water in lbs. discharged upon the wheel in one minute by the height or distance in feet from the lower edge of the wheel to the centre of the opening in the gate; divide the product by 50000, and the quotient is the number of horses' power.

Example.—In the preceding example, the weight of the water discharged per minute is 39000 lbs. If the height of the fall is 23 feet, the diameter of the wheel being 22, what is the power of the wheel?

23 feet -8 inches clearance below =22.4 = 22.33.  $39000 \times 22.33 \div 50000 = 17.41$  horses' power, Ans.

# To find the Power of a Stream.

RULE.—Multiply the weight of the water in lbs. discharged in one minute by the height of the fall in feet; divide by 33000, and the quotient is the answer.

Example.—What power is a stream of water equal to of the following dimensions, viz.: 1 foot deep by 22 inches broad, velocity 350 feet per minute, and fall 60 feet; and what should be the size of the wheel applied to it?

$$12 \times 22 \times 350 \times 12 \div 1728 \times 62 \times 62 \times 60$$
 feet  $\div 33000 = 72.9$ , Ans.

Height of fall 60 feet, from which deduct for admission of water. and clearance below, 15 inches, which gives 58.9 feet for the diameter of the wheel.

Clearance above  $\begin{array}{cc} 3 \\ \text{below} & 12 \end{array}$  15 inches.

The power of a stream, applied to an overshot wheel, produces effect as 10 to 6.6.

Then, as 10: 6.6:: 72.9: 48 horses' power equal that of an overshot wheel of 60 feet applied to this stream.

When the fall exceeds 10 feet, the overshot wheel should be applied.

The higher the wheel is in proportion to the whole descent, the greater will be the effect.

The effect is as the quantity of water and its perpendicular height multiplied

together. The weight of the arch of loaded buckets in pounds, is found by multiplying  $\frac{4}{6}$ of their number, x the number of cubic feet in each, and that product by 40.

# To find the Power of an Undershot Wheel when the Stream is confined to the Wheel.

RULE.—Ascertain the weight of the water discharged against the floats of the wheel in one minute by the preceding rules, and divide it by 100000; the quotient is the number of horses' power.

Note.—The 100000 is obtained thus: The power of a stream, applied to an undershot wheel, produces effect as 10 to 3.3; then 3.3:10::33000:100000. When the opening is above the centre of the floats, multiply the weight of the

water by the height, as in the rule for an overshot wheel.

Example.—What is the power of an undershot wheel, applied to a stream 2 by 80 inches, from a head of 25 feet?

 $\sqrt{25} \times 6.5 \times 60 = 1950$  feet velocity of water per minute, and  $2 \times 80 = 160$  inches  $\times 1950 \times 12 \div 1728 = 2166.6$  cubic feet  $\times 62.5 =$ \*135412 lbs. of water discharged in one minute; then 135412+ 100000 = 1.35 horses' power.

Note.-The maximum work is always obtained when the velocity of the wheel is half that of the stream. Let V represent velocity of float boards, and v velocity of water; then  $\frac{(v-V)^2}{V^2}$  × force of the water, will be the force of the effective stroke.

The effect of an undershot wheel to the power expended is, at a medium, one half that of an overshot wheel.

The virtual or effective head being the same, the effect will be very nearly as the quantity of water expended.

When the fall is below 4 feet, an undershot wheel should be applied.

# To find the Power of a Breast Wheel.

Rule.—Find the effect of an undershot wheel, the head of water of which is the difference of level between the surface and where it strikes the wheel (breast), and add to it the effect of that of an overshot wheel, the height of the head of which is equal to the differ-

Hosted by GOOQIC

<sup>\*</sup> Equal  $160 \times 12 \div 1728 \times 62.5 \times 1950 =$  momentum of water and its velocity.

ence between where the water strikes the wheel, and the tail water; the sum is the effective power.

EXAMPLE.—What would be the power of a breast wheel applied to a stream 2×80 inches, 14 feet from the surface, the rest of the fall being 11 feet?

 $\sqrt{14 \times 6.5 \times 60} = 1458.6$  feet velocity of water per minute.

And  $2\times80\times1458\times12\div1728=1620$  cubic feet  $\times62.5=101250$  lbs. of water discharged in one minute.

Then  $101250 \div 100000 = 1.012$  horses' power as an undershot.

 $\sqrt{11 \times 6.5 \times 60} = 1290$  feet velocity of water per minute.

And  $2\times80\times1290\times12\div1728=1433$  cubic feet  $\times62.5=89562$  lbs. of water discharged in one minute.

 $\times 11$  height of fall  $\div 50000 = 19.703$  horses, which, added to the above, = 20.715, Ans.

When the fall exceeds 10 feet, it may be divided into two, and two breast wheels applied to it.

When the fall is between 4 and 10 feet, a breast wheel should be applied.

The power of a water wheel ought to be taken off opposite to the point where the water is producing its greatest action upon the wheel.

## BARKER'S MILL.

The effect of this mill is considerably greater than that which the same quantity of water would produce if applied to an undershot wheel, but less than that which it would produce if properly applied to an overshot wheel.

For a description of it, see Grier's Mechanics' Calculator, page 234.

Make each arm of the horizontal tube, from the centre of motion to the centre of the aperture of any convenient length, not less than  $\frac{1}{9}$  of the perpendicular height of the water's surface above these centres.

Multiply the length of the arm in feet by .61365, and the square root of the product will be the proper time for a revolution in seconds; then adapt the gearing to this velocity. Or, if the time of a revolution be given, multiply the square of it by 1.6296 for the proportional length of the arm in feet.

Divide the continued product of the breadth, depth, and velocity of the stream in feet by 14.27; multiply the quotient by the square root of the height, and the result is the area of either aperture.

Multiply the area of either aperture by the height of the head of water, and this product by 56; the result is the moving force in lbs. at the centre of the apertures.

Example.—If the fall be 18 feet from the head to the centre of the apertures, then the arm must not be less than 2 feet (as  $\frac{1}{9}$  of 18 = 2),  $\sqrt{2 \times .61365} = 1.107$ , the time of a revolution in seconds; the breadth of the race 17 inches, the depth 9, and the velocity 6 feet per second; what is the moving force?

17 inches = 1.41 feet, 9 inches = .75 feet; then  $1.41 \times .75 \times 6 \div 14.27 \times \sqrt{18 \times 18 \times 56} = 1895$  lbs., Ans.

# To find the Centre of Gyration of a Water Wheel.

RULE.—Take the radius of the wheel, the weight of its arms, and the weight of its rim, as composed of floats, shrouding, &c.

Let R represent the weight of rim,

the radius of the wheel, " A the weight of arms,

" W the weight of the water in action when the buckets are filled, as in operation.

Then  $\sqrt{(R \times r^2 \times 2 + A \times r^2 \times 2 + W \times r^2 + R + A + W \times 2)} = centre of$ gyration.

Example.—In a wheel 20 feet diameter, the weight of the rim is 3 tons, the weight of the arms 2 tons, and the weight of the water 1 ton; what is the distance of the centre of gyration from the centre of the wheel?

$$R = 3 \text{ tons } \times 10^2 \times 2 = 600$$
  
 $A = 2$  "  $\times 10^2 \times 2 = 400$ 

$$A = 2$$
 "  $\times 10^2 \times 2 = 400$   
 $W = 1$  "  $\times 10^2$  . . = 100

$$3+2+1=6\times 2=\frac{\overline{1100}}{12}=91.6$$
, the square root of which is

9.5, or 9½ feet, Ans.

Notes.—At the mill of Mr. Samuel Newlin, at Fishkill Creek, N. Y., 5 barrels of flour can be ground, and 400 bushels of grain elevated 36 feet per hour with a stream and overshot wheel of the following dimensions, viz.:

Height of head to centre of opening,  $24_5^{\circ}$  inches; opening,  $1\frac{3}{4}$  by 80 inches; wheel, 22 feet diameter by 8 feet face; 52 buckets, each 1 foot in depth. The wheel making  $3\frac{1}{2}$  revolutions, driving 3 run of  $4\frac{1}{2}$  feet stones 130 turns in a minute, with all the attendant machinery.

This is a case of maximum effect, in consequence of the gearing being well set up, and kept in good order.

At the furnace of Mr. Peter Townsend, Monroe Works, N. J., 30 to 34 tons of No 1 Iron are made per week, with the blast from two 5 feet by 5 feet 1 inch blowing cylinders. The wheel (overshot) being 24 feet diameter, by 6 feet in width, having 70 buckets of 14 inches in depth. The stream is \$\frac{1}{2}\$ by 51 inches, having a head 6\frac{1}{2}\$ feet; the wheel and cylinders each making 4\frac{1}{4}\$ revolutions per winter the stream is \$\frac{1}{2}\$. minute.

Rocky Glen Factory, Fishkill, N. Y., containing 6144 self-acting mule spindles, 160 looms, weaving printing cloths 27 inches wide of No. 33 yarn (33 hanks to a pound), and producing 24,000 hanks in a day of 11 hours, is driven by a breast

wheel and stream of the following dimensions, viz.: Stram 18 feet by 2 inches, head 20 feet, height of water upon wheel 16 feet, di-ameter of wheel 26 feet 4 inches, face of wheel 20 feet 9 inches, depth of buckets 15¾ inches, number of buckets 70.

Revolutions,  $4\frac{5}{10}$  per minute.

## PNEUMATICS.

## WEIGHT, ELASTICITY, AND RARITY OF AIR.

The pressure of the air at the surface of the earth is, at a mean rate, equal to the support of 29.5 inches of mercury, or 33.18 feet of fresh water. It is usually estimated in round numbers at 30 inches of mercury and 34 feet of water, or 15 lbs. pressure upon the square

The Elasticity of air is inversely as the space it occupies, and directly as its density.

When the altitude of the air is taken in arithmetic proportion, its

Rarity will be in geometric proportion.

Thus, at 7 miles above the surface of the earth, the air is 4 times rarer or lighter than at the earth's surface; at 14 miles, 16 times at 21 miles, 64 times, and so on.

The weight of a cubic foot of air is 527.04 grains, or 1.205 ounces

avoirdupois.

At the temperature of 33°, the mean velocity of sound is 1100 feet per second. It is increased or diminished half a foot for each degree of temperature above or below 33°.

# To compute Distances by Sound.

RULE.—Multiply the time in seconds by 1100, and the product is the distance in feet.

Example.—After observing a flash of lightning, air at 50°, it was 5 seconds before I heard the thunder; what was the distance of the cloud?

$$1100 + \frac{50 - 33}{2} \times 5 \div 5280 = 1.049$$
 miles, Ans.

To compute what Degree of Rarefaction may be effected in a Vessel.

Let the quantity of air in the vessel, tube, and pump be represented by 1, and

the proportion of the capacity of the pump to the vessel and tube by 33; consequently, it contains \( \frac{1}{2} \) of the air in the united apparatus.

Upon the first stroke of the piston this fourth will be expelled, and \( \frac{3}{2} \) of the original quantity will remain: \( \frac{1}{2} \) of this will be expelled upon the second stroke, which is equal to  $\frac{3}{16}$  of the original quantity; and, consequently, there remains in the apparatus  $\frac{9}{1.6}$  of the original quantity. Calculating in this way, the following table is easily made:

No. of Strokes.	Air expelled at each stroke.	Air remaining in the vessel.
1	4 = 4	<del>3</del> = 3
2	$\frac{3}{16} = \frac{3}{4 \times 4}$	$\frac{9}{16} = \frac{3 \times 3}{4 \times 4}$
3	$\frac{9}{64} = \frac{3\times3}{4\times4\times4}$	$\frac{27}{64} = \frac{3 \times 3 \times 3}{4 \times 4 \times 4}$
4	$\frac{27}{256} = \frac{3 \times 3 \times 3}{4 \times 4 \times 4 \times 4}$	$\frac{81}{256} = \frac{3 \times 3 \times 3 \times 3}{4 \times 4 \times 4 \times 4}$
5	$\frac{81}{1024} = \frac{3 \times 3 \times 3 \times 3}{4 \times 4 \times 4 \times 4 \times 4}$	$\frac{243}{1024} = \frac{3 \times 3 \times 3 \times 3 \times 3}{4 \times 4 \times 4 \times 4 \times 4}$

And so on, continually multiplying the air expelled at the preceding stroke by 3, and dividing it by 4; and the air remaining after each stroke is found by multiplying the air remaining after the preceding stroke by 3, and dividing it by .

# Measurement of Heights by Means of the Barometer.

Approximate Rule. For a mean temperature of 550,

x = required difference in height in feet,

h = the height of the mercury at the lower station, h' = the height of the mercury at the upper station,

 $x=55000 imes \frac{h-h'}{h+h'}$ . Add  $\frac{1}{440}$  of this result for each degree which the mean temperature of the air at the two stations exceeds 55°, and deduct as much for each degree below 55°.

# Velocity and Force of Wind.

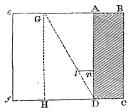

Miles in an hour.	Feet in a minute.	Pressure on a square foot in pounds avoir- dupois.	Description.
1	88	.005	Barely observable.
2	176	ړ 020.	Just perceptible.
3	264	.045 \$	Just perceptible.
4	352	.080	Light breeze.
5	440	.125 )	
6	528	.180 }	Gentle, pleasant wind.
8	704	.320 )	
10	880	.500.	Brisk blow.
15	1320	1.125 }	Drisk blow.
20	1760	2.000 }	Very brisk.
25	2200	3.125	Very brisk.
30	2640	4.500 }	High wind.
35	3080	6.125 }	riigii wilid.
40	3520	8.000 }	Very high.
45	3960	10.125 }	very mgn.
50	4400	12.500	Storm.
60	5280	18.000	Great storm.
80	7040	32.000	Hurricane.
100	8800	50.000	Tornado, tearing up trees, &c.

# To find the Force of Wind acting perpendicularly upon a Surface.

RULE.—Multiply the surface in feet by the square of the velocity in feet, and the product by .002288; the result is the force in avoirdupois pounds.

## STATICS.

#### PRESSURE OF EARTH AGAINST WALLS.

LET ABCD be the vertical section of a wall, behind which is a bank of earth, ADfe; let DG be the line of rupture, or natural slope which the earth would assume but for the resistance of the wall.

In sandy or loose earth, the angle G D H is generally 30°; in firmer earth it is 36°, and in some instances it is 45°.

The angle formed with the vertical by the earth, ADG, that exerts the greatest horizontal stress against a wall, is half the angle which the natural slope makes with the vertical.

If the upper surface of the earth and the wall which supports it are both in one horizontal plane,

Then the resultant ln of the pressure of the bank, behind a vertical wall, is at a distance D n of  $\frac{1}{3}$  A D.

In vegetable earths, the friction is  $\frac{1}{2}$  the pressure; in sands,  $\frac{4}{10}$ . The line of rupture A G in a bank of vegetable earth is = .618 of A D. When the bank is of sand, it is .677 of AD.

If of rubble, it is .414 of A D.

## Thickness of Walls, both Faces Vertical.

Brick. Weight of a cubic foot, 109 lbs. avoirdupois, bank of vegetable earth behind it, AB = .16 AD.

Unhewn stones. 135 lbs. per cubic foot, bank as before, AB = .15 AD.

Brick. Bank clay, well rammed, A B = .17 A D.

Hewn freestone. 170 lbs. per cubic foot, bank of vegetable earth, A B = .13 A D; if the bank is of clay, AB=.14 AD.

Bricks. Bank of sand, A B = .33 A D.

Unhewn stone. Bank of sand, A B = .30 A D.

Hewn freestone. Bank of sand, AB = .26 AD.

When the bank is liable to be saturated with water, the thickness of the wall must be doubled.

For farther notes, and for the Equilibrium of Piers, see Gregory's Mathematics, pages 220 to 224.

## DYNAMICS.

Dynamics is the investigation of body, force, velocity, space, and time. Let them be represented by their initial letters bfvst, gravity by g, and momentum or quantity of motion by m; this is the effect produced by a body in motion.

Force is motive, and accelerative or retardative.

Motive force, or momentum, is the absolute force of a body in motion, and is the product of the weight or mass of matter in the body, multiplied by its velocity.

Accelerative or retardative force is that which respects the velocity of the motion only, accelerating or retarding it, and is found by the force being divided by the mass or weight of the body. Thus, if a body of 4 lbs. be acted upon by a force of 40 lbs., the accelerating force is 10 lbs.; but if the same force of 40 act upon another body of 8 lbs., the accelerating force then is 5 lbs., only half the former, and will produce only half the velocity.

## Uniform Motion.

The space described by a body moving uniformly is represented by the product of the velocity into the time.

With momenta, m varies as bv.

EXAMPLE.—Two bodies, one of 20, the other of 10 lbs., are impelled by the same momentum, say 60. They move uniformly, the first for 8 seconds, the second for 6; what are the spaces described by both?

$$\frac{b}{v} = v$$
, or  $\frac{60}{20} = 3$ , and  $\frac{60}{10} = 6$ .

Then  $tv=3\times8=24=s$ , and  $6\times6=36=s$ . Thus the spaces are 24 and 36 respectively.

# Motion Uniformly Accelerated.

In this motion, the velocity acquired at the end of any time whatever, is equal to the product of the accelerating force into the time, and the space described is equal to the product of half the accelerating force into the square of the time.

The spaces described in successive seconds of time are as the odd numbers, 1, 3, 5, 7, 9, &c.

Gravity is a constant force, and its effect upon a body falling freely is represented by g.

The following theorems are applicable to all cases of motion uniformly accelerated by any constant force:

$$\begin{split} s &= \frac{1}{2} tv = \frac{1}{2} g F t^2 = \frac{v^2}{2 g F}, \\ v &= \frac{2s}{t} = g F t = \sqrt{2} g f s, \\ t &= \frac{ts}{v} = \frac{v}{g F} = \sqrt{\frac{s}{2} g F}, \\ F &= \frac{v}{g t} = \frac{2s}{g t^2} = \frac{v^2}{2 g s}. \end{split}$$

When gravity acts alone, as when a body falls in a vertical line, F is omitted, and we have,

$$s = \frac{1}{2}gt^2 = \frac{v^2}{2g} = \frac{1}{2}tv.$$
  
 $v = gt = \frac{2s}{t} = \sqrt{2}gs.$ 

<sup>\*</sup> See page 142 for notice of experiments on bodies falling freely, made by the author in 1852.

$$t = \frac{v}{g} = \frac{2s}{v} = \sqrt{\frac{2s}{g}}.$$
$$g = \frac{v}{t} = \frac{2s}{t^2} = \frac{v^2}{2s}.$$

NOTE.—g is obviously 32.166 from what has been given in rules for Gravitation, and is the force of gravity.

If, instead of a heavy body falling freely, it be propelled vertically upward or downward with a given velocity, v, then

$$s = tv \mp \frac{1}{2}gt^2$$
;

an expression in which — must be taken when the projection is upward, and + when it is downward.

## Motion over a Fixed Pulley.

Let the two weights which are connected by the cord that goes over the pulley be represented by W and w; then

$$\frac{W-w}{W+w}$$
 = F in the formulæ where F is used; so that

$$s = \frac{W - w}{W + w} \frac{1}{2} g t^2.$$

Or, if the resistance of the friction and inertia of the pulley be represented by r, then

$$s = \frac{W - w}{W + w + r} \frac{1}{2} gt^2.$$

EXAMPLE.—If by experiment it is ascertained that two weights of 5 and 3 lbs. over a pulley, the heavier weight descended only 50 feet in 4 seconds, what is the measure of r?

If r is not considered, the heavier weight would fall  $64\frac{1}{3}$  feet.

Then 
$$\frac{W-w}{W+w+r} \frac{1}{2} gt^2 = 50$$
 feet.

And, as  $5+3+r:5+3::64\frac{1}{3}:50$ ; That is  $r:5+3::14\frac{1}{3}:50$ .

Whence  $r = \frac{8 \times 14\frac{1}{3}}{50} = 2.293 \text{ lbs., } Ans.$ 

Table of the Effects of a Force of Traction of 100 lbs. at different Velocities, on Canals, Railroads, and Turnpikes.

Velocity.		Ona	Canal,	On a R	ailroad.	On a Turapike.

The load carried, added to the weight of the vessel or carriage which contains it forms the total mass moved, and the useful effect is the load.

The force of traction on a canal varies as the square of the velocity; on a railroad or turnpike the force of traction is constant, but the mechanical power necessary to move the carriage increases as the velocity.

## PENDULUMS.

THE Vibrations of Pendulums are as the square roots of their lengths. The length of one vibrating seconds in New-York at the level of the sea is 39,1013 inches.

To find the Length of a Pendulum for any Given Number of Vibrations in a Minute.

RULE.—As the number of vibrations given is to 60, so is the square root of 39.1013 (the length of the pendulum that vibrates seconds) to the square root of the length of the pendulum required.

Example.—What is the length of a pendulum that will make 80 vibrations in a minute?

As  $\sqrt{39.1013 \times 60} = 375$ , a constant number,

Then 
$$\frac{375}{80}$$
 = 4.6875, and 4.6875<sup>2</sup> = 21.97 inches, Ans.

The lengths of pendulums for less or greater times is as the square of the times; thus, for \( \frac{1}{2} \) a second it would be the square of  $\frac{1}{2}$ , or  $\frac{39.1013}{4}$  = 9.7753 inches, the length of a  $\frac{1}{2}$  second pendulum at New-York.

To find the Number of Vibrations in a Minute, the Length of the Pendulum being given.

RULE.—As the square root of the length of the pendulum is to the square root of 39,1013, so is 60 to the number of vibrations required.

Example.—How many vibrations will a pendulum of 49 inches long make in a minute?

$$\sqrt{49}$$
:  $\sqrt{39.1013}$ :: 60: number of vibrations.  
Or,  $\frac{375}{\sqrt{49}}$  = 53.57 vibrations, Ans.

To find the Length of a Pendulum, the Vibrations of which will be the same Number as the Inches in its Length.

RULE.—Square the cube root of \*375, and the product is the answer.

Example.  $-\sqrt[3]{375} = 7.211247$ , and  $7.211247^2 = 52.002$ , Ans.

The Length of a Pendulum being given, to find the Space through which a Body will fall in the Time that the Pendulum makes one Vibration.

RULE .-- Multiply the length of the pendulum by 4.93482528, and it will give the answer.

<sup>\* 375</sup> is the constant for the latitude of New-York; in any other place, multiply the square root of the length of the pendulum at that place by 60. Q 2

EXAMPLE.—The length of the pendulum is 39.1013 inches; what is the distance a body will fall in one vibration of it?

 $39.1013 \times 4.9348 = 192.9578$  inches, or 16.8298 feet, Ans.

All vibrations of the same pendulum, whether great or small, are performed very nearly in the same time.

In a Simple Pendulum, which is, as a ball, suspended by a rod or line, supposed to be inflexible, and without weight, the length of the pendulum is the distance from its centre of gravity to its point of suspension. Otherwise, the length of the pendulum is the distance from the point of suspension to the Centre of Oscillation,\* which does not coincide with the centre of gravity of the ball or bob.

## CENTRE OF GYRATION.

THE Centre of Gyration is the point in any revolving body, or system of bodies, that, if the whole quantity of matter were collected in it, the angular velocity† would be the same; that is, the momentum of the body or system of bodies is centred at this point.

If a straight bar, equally thick, was struck at this point, the stroke would communicate the same angular velocity to the bar as if the whole bar was collected at that point.

# To find the Centre of Gyration.

RULE 1.—Multiply the weight of the several particles by the squares of their distances in feet from the centre of motion, and divide the sum of the products by the weight of the entire mass; the square root of the quotient will be the distance of the centre of gyration from the centre of motion.

EXAMPLE.—If two weights of 3 and 4 lbs. respectively be laid upon a lever (which is here assumed to be without weight) at the respective distances of 1 and 2 feet, what is the distance of the centre of gyration from the centre of motion (the fulcrum)?

$$3\times1^2 = 3$$
.  $4\times2^2 = 16$ .  $\frac{3+16}{3+4} = \frac{19}{7} = 2.71$ , and  $\sqrt{2.71} = 1.64$  feet, Ans.

That is, a single weight of 7 lbs., placed at 1.64 feet from the fulcrum, and revolving in the same time, would have the same impetus as the two weights in their respective places.

<sup>\*</sup> See Centre of Oscillation.

<sup>†</sup> The angular velocity of a body or system of bodies is the motion of a line connecting any point with the axis of motion, and is the same in all parts of the same revolving system.

Rule 2.--Multiply the distance of the centre of oscillation, from the centre or point of suspension, by the distance of the centre of gravity from the same point, and the square root of the product will be the answer.

Example.—The centre of oscillation is 9 feet, and that of gravity is 4 feet from the centre of the system, or point of suspension; at what distance from this point is the centre of gyration?

$$9 \times 4 = 36$$
, and  $\sqrt{36} = 6$  feet, Ans.

The following are the distances of the centres of gyration from the centre of motion in various revolving bodies, as given by Mr. Farey:

In a straight, uniform Rod, revolving about one end; length of rod ×.5773.

In a circular Plate, revolving on its centre; the radius of the circle ×.7071.

In a circular Plate, revolving about one of its diameters as an axis; the radius

In a Wheel of uniform thickness, or in a Culinder revolving about the axis; the radius  $\times .7071$ .

In a solid Sphere, revolving about one of its diameters as an axis; the radius

In a thin, hollow Sphere, revolving about one of its diameters as an axis; the radius × .8154.

In a Cone, revolving about its axis; the radius of the circular base  $\times$  .5477. In a right-angled Cone, revolving about its vertex; the height of the cone  $\times$  .866. In a Paraboloid, revolving about its axis; the radius of the circular base  $\times$  .5773.

In a straight Lever, the arms being R and r, the distance of the centre of gyra- $(R^3+r^3)$ 

tion from the centre of motion =  $\sqrt{\frac{1}{3(R-r)}}$ 

NOTE .- The weight of the revolving body, multiplied into the height due to the velocity with which the centre of gyration moves in its circle, is the energy of the body, or the mechanical power which must be communicated to it to give it that motion.

Example.—In a solid sphere revolving about its diameter, the diameter being 2 feet, the distance of the centre of gyration is  $12 \times .6325 = 7.59$  inches.

## CENTRES OF PERCUSSION AND OSCILLATION.

THE Centres of Percussion and Oscillation are in the same point when their bodies are symmetrical with regard to the plane of their motion; or when they are solids of revolution, which is commonly the case, their properties are similar, and their point is, that in a body revolving around a fixed axis, which, when stopped by any force, the whole motion, and tendency to motion, of the revolving body is stopped at the same time.

It is also that point of a revolving body which would strike any obstacle with the greatest effect, and from this property it has re-

ceived the name of percussion.

As in bodies at rest, the whole weight may be considered as collected in the centre of gravity; so in bodies in motion, the whole force may be considered as concentrated in the centre of percussion: therefore, the weight of a bar or rod, multiplied by the distance of the centre of gravity from the point of suspension, will be equal to the force of the rod, divided by the distance of the centre of percussion from the same point.

EXAMPLE.—The length of a rod being 20 feet, and the weight of a foot in length equal 100 oz., having a ball attached at the under end weighing 1000 oz., at what point of the rod from the point of suspension will be the centre of percussion ?\*

The weight of the rod is  $20 \times 100 = 2000$  oz., which, multiplied by half its length,  $2000 \times 10 = 20000$ , gives the momentum of the rod. The weight of the ball = 1000oz., multiplied by the length of rod.  $= 1000 \times 20$ , gives the momentum of the ball. Now the weight of the rod multiplied by the square of the length, and divided by  $3 = \frac{2000 \times 20^2}{100} = 266666$ , the force of the rod, and the weight of the ball multi-

plied by the square of the length of the rod,  $1000 \times 20^2 = 400000$ , is the force of the bell, therefore the square of persussion  $= \frac{266666 + 400000}{16.66} = 16.66$  for ball: therefore, the centre of percussion = = 16.66 feet. 20000+20000

Example. -- Suppose a rod 12 feet long, and 2 lbs. each foot in length, with 2 balls of 3 lbs. each, one fixed 6 feet from the point of suspension, and the other at the end of the rod; what is the distance between the points of suspension and percus-

$$12 \times 2 \times 6 = 144, \text{momentum of rod,} \\ 3 \times 6 = 18 \quad \text{``of 1st ball,} \\ 3 \times 12 = 36 \quad \text{``of 2d ''} \\ \hline 198 \\ \hline 24 \times 144 \\ \hline 3 \times 36 = 108 \quad \text{``of 1st ball,} \\ 3 \times 36 = 108 \quad \text{``of 1st ball,} \\ 3 \times 144 = 432 \quad \text{``of 2d ball,} \\ \hline 1692 \\ \hline \end{tabular}$$

therefore the centre of percussion  $=\frac{1692}{198}$  =8.545 feet from the point of suspension.

As the centre of percussion is the same with the centre of oscillation in the non-application to practical purposes, the following is the easiest and simplest mode of

finding it in any beam, bar, &c.:

Suspend the body very freely by a fixed point, and make it vibrate in small arcs. counting the number of vibrations it makes in any time, as a minute, and let the number of vibrations made in a minute be called n; then shall the distance of the centre of oscillation from the point of suspension be  $=\frac{140850}{1000}$  inches.  $n^2$ length of the pendulum vibrating seconds, or 60 times in a minute, being 39% inch-

 $<sup>\</sup>begin{cases} \frac{\frac{1}{3}ab \times a^2 + ca^2}{\frac{1}{2}ab \times a + ac} = \text{centre of percussion.} \end{cases}$ \* a == 20 feet long, b = 100 oz. weight of a foot in length, c = 1000fixed at end,

es, and the lengths of the pendulums being reciprocally as the square of the number of vibrations made in the same time, therefore  $n^2:60^2::39\frac{1}{3}:\frac{60^2\times39\frac{1}{3}}{3}=$ 

140850  $\frac{1}{n^2}$ , being the length of the pendulum which vibrates n times in a minute, or

the distance of the centre of oscillation below the axis of motion.

There are many situations in which bodies are placed that prevent the application of the above rule, and for this reason the following data are given, which will be found useful when the bodies and the forms here given correspond:

1. If the body is a heavy, straight line of uniform density, and is suspended by one extremity, the distance of its centre of percussion is  $\frac{2}{3}$  of its length.

2. In a slender rod of a cylindrical or prismatic shape, the breadth of which is

very small compared with its length, the distance of its centre of percussion is nearly 2 of its length from the axis of suspension.

If these rods were formed so that all the points of their transverse sections were equidistant from the axis of suspension, the distance of the centre of percussion

would be exactly  $\frac{2}{3}$  of their length.

3. In an Isosceles triangle, suspended by its apex, and vibrating in a plane perpendicular to itself, the distance of the centre of percussion is 3 of its altitude. A line or rod, whose density varies as the distance from its extremity, or the point of suspension; also Fly-wheels, or wheels in general, have the same relation as the isosceles triangle, the centre of percussion being distant from the centre of suspen sion \$\frac{3}{2}\$ of its length.

4. In a very slender cone or pyramid, vibrating about its apex, the distance of its centre of percussion is nearly \$\frac{2}{3}\$ of its length.

The distance of either of these centres from the axis of motion is found thus: If the Axis of Motion be in the vertex of the figure, and the motion be flatwise;

then, in a right line, it is \{ of its length. In an Isosceles Triangle = 3 of its height.

In a Circle = 3 of its radius.

In a Parabola = 5 of its height.

But if the bodies move sidewise, it is,

In a Circle = 3 of its diameter.

In a Rectangle, suspended by one angle,  $=\frac{2}{3}$  of the diagonal.

In a Parabola, suspended by its vertex,  $=\frac{5}{7}$  axis  $+\frac{1}{2}$  parameter; but if suspend-

In the Sector of a Circle = 
$$\frac{3 \times \text{arc} \times \text{radius}}{4 \times \text{chord}}$$

In a Cone = 
$$\frac{4}{5}$$
 axis +  $\frac{\text{radius of base }^2}{5 \times \text{axis}}$ .

ed by the middle of its base,  $=\frac{4}{7}$  axis  $+\frac{1}{2}$  parameter, but it suspended by the middle of its base,  $=\frac{4}{7}$  axis  $+\frac{1}{2}$  parameter.

In the Sector of a Circle  $=\frac{3}{3} \times \text{arc} \times \text{radius}$   $=\frac{3}{4} \times \text{chord}$ In a Cone  $=\frac{4}{5}$  axis  $+\frac{\text{radius of base}^2}{5 \times \text{axis}}$ .

In a Sphere  $=\frac{2 \times \text{radius}}{5(t \times \text{radius})} + \text{radius} + t$ , t representing the length of the thread by which it is suspended.

Example.—What must be the length of a rod without a weight, so that when hung by one end it shall vibrate seconds?

To vibrate seconds, the centre of oscillation must be 39.1013 inches from that of suspension; and as this must be  $\frac{2}{3}$  of the rod, Then 2:3::39.1013:58.6519, Ans.

Example.—What is the centre of percussion of a rod 23 inches long? 2 of 23 = 15.3 inches from the point of suspension or motion.

Example.—In a sphere of 10 inches diameter, the thread by which it is suspended being 20 inches, where is the centre of percussion or oscillation?  $\frac{2\times 5^2}{5(20+5)} + 5 + 20 = \frac{50}{125} + 25 = 25.4, \textit{Ans}.$ 

$$\frac{2\times5^2}{5(20+5)}$$
 + 5 + 20 =  $\frac{50}{125}$  + 25 = 25.4, Ans.

## CENTRAL FORCES.

All bodies moving around a centre or fixed point have a tendency to fly off in a straight line: this is called the *Centrifugal Force*; it is opposed to the *Centripetal Force*, or that power which maintains the body in its curvilineal path.

The centrifugal force of a body, moving with different velocities in the same circle, is proportional to the square of the velocity. Thus, the centrifugal force of a body making 10 revolutions in a minute is four times as great as the centrifugal force of the same body making 5 revolutions in a minute.

## To find the Centrifugal Force of any Body.

RULE 1.—Divide the velocity in feet per second by 4.01, also the square of the quotient by the diameter of the circle; the quotient is the centrifugal force, assuming the weight of the body as 1. Then this, multiplied by the weight of the body, is the centrifugal force.

Example.—What is the centrifugal force of the rim of a flywheel 10 feet in diameter, running with a velocity of 30 feet in a second?

$$30 \div 4.01 \times 7.48 \div 10 = 5.59$$
 times the weight of the rim, Ans.

Note.—When great accuracy is required, find the centre of gyration of the body and take twice the distance of it from the axis for the diameter.

RULE 2.—Multiply the square of the number of revolutions in a minute by the diameter of the circle in feet, and divide the product by the constant number 5870; the quotient is the centrifugal force when the weight of the body is 1. Then, as in the previous rule, this quotient, multiplied by the weight of the body, is the centrifugal force.

Example.—What is the centrifugal force of a grindstone, weighing 1200 lbs., 42 inches in diameter, and turning with a velocity of 400 revolutions in a minute?

$$\frac{400^2 \times 3.5}{5870} \times 1200 = 114480$$
 lbs., Ans.

The central forces are as the radii of the circles directly, and the squares of the times inversely; also, the squares of the times are as the cubes of the distances

Hence, let v represent velocity of body in feet per second,

Then 
$$\frac{v^2 \times w}{r \times 32} = c$$
, and  $\frac{v^2 \times w}{v \times 32} = r$ ;
and  $\frac{c \times 32 \times r}{r} = w$ , and  $\sqrt{\left(\frac{r \times 32 \times c}{v}\right)} = v$ .

## Dr. Brewster has furnished the following:

- The centrifugal forces of two unequal bodies, having the same velocity, and at the same distance from the central body, are to one another as the respective quantities of matter in the two bodies.
- 2. The centrifugal forces of two equal bodies, which perform their revolutions in the same time, but are different distances from their axis, are to one another as their respective distances from their axis.
- 3. The centrifugal forces of two bodies, which perform their revolutions in the same time, and whose quantities of matter are inversely as their distances from the centre, are equal to one another.
- The centrifugal forces of two equal bodies, moving at equal distances from the central body, but with different velocities, are to one another as the squares of their velocities.
- 5. The centrifugal forces of two equal bodies, moving with equal velocities at different distances from the centre, are inversely as their distances from the centre.
- 6. The centrifugal forces of two unequal bodies, moving with equal velocities at different distances from the centre, are to one another as their quantities of matter multiplied by their respective distances from the centre.
- 7. The centrifugal forces of two unequal bodies, having unequal velocities, and at different distances from their axis, are, in the compound ratio of their quantities of matter, the squares of their velocities, and their distances from the centre.

The weight of the rim of a fly-wheel for a 20 horse engine is 6000 lbs., the diameter 16 feet, and the revolutions 45; what is its centrifugal force?

33120 lbs., Ans.

SUMMARY.—Let b represent any particle of a body B, and d its distance from the axis of motion, S.

G. O. R. the centres of Gravity, Oscillation, and Gyration.

Then 
$$\frac{bd}{B} = S G$$
.  
 $\frac{bd^2}{S G B} = S O$ .  
 $\sqrt{\frac{bd^2}{R}} = S R$ .

## FLY-WHEELS.

## To find the Weight of Fly-wheels.

RULE.—Multiply the horses' power of the engine by 2240, and divide the product by the square of the velocity of the circumference of the wheel in feet per second; the quotient will be the weight in 100 lbs.

EXAMPLE.—The power of an engine is 35 horses, the diameter of the wheel 14 feet, and the revolutions 40; what should be the weight of the wheel?

$$\frac{35 \times 2240 \div 40 \times 14 \times 3.1416 \div 60}{35 \times 2240 \div 40 \times 14 \times 3.1416 \div 60}^{2} = \frac{78400}{858.5} \times 100 = 9130 \text{ lbs.}$$

The weight of the wheel in engines that are subjected to irregular motion, as in the cotton-press, rolling-mill, &c., must be greater than in others where so sudden a check is not experienced, and 3000 would be a better multiplier in such cases.

# GOVERNORS.

THE Governor acts upon the principle of central forces.

When the balls diverge, the ring or the vertical shaft raises, and that in proportion to the increase of the velocity squared; or, the square roots of the distances of the ring from the top, corresponding to two velocities, will be as these velocities.

EXAMPLE.—If a governor make 6 revolutions in a second when the ring is 16 inches from the top, what will be the distance of the ring when the speed is increased to 10 revolutions in the same time?

As  $10:6::\sqrt{16}$  inches: 2.4 inches, which, squared, is 5.76 inches, the distance of the ring from the top.

A governor performs in one minute half as many revolutions as a pendulum vibrates, the length of which is the perpendicular distance between the plane in which the balls move and the centre of suspension

## GUNNERY.

Ir has been ascertained by experiment that the velocity of the ball projected from a gun varies as the square root of the charge directly, and as the square root of the weight of the ball reciprocally.—
Hutton.

The same author furnishes the following practical rules:

To find the Velocity of any Shot or Shell.

RULE.—As the square root of the weight of the shot is to the square root of the weight of treble the weight of the powder, both taken in pounds, so is 1600 to the velocity in feet per second.

Example.—What is the velocity of a shot of 196 lbs., projected with a charge of 9 lbs. of powder?

14:5.2::1600:594, Ans.

When the Range for one Charge is given, to find the Range for another Charge, or the Charge for another Range.

RULE.—The ranges have the same proportion as the charges; that is, as one range is to its charge, so is any other range to its charge, the elevation of the piece being the same in both cases.

 $E_{XAMPLE}$ .—If, with a charge of 9 lbs. of powder, a shot range 4000 feet, how far will a charge of  $6\frac{3}{4}$  lbs. project the same shot at the same elevation?

9:6.75::4000:3000, Ans.

Given the Range for one Elevation, to find the Range at another Elevation.

RULE.—As the sine of double the first elevation is to its range, so is the sine of double another elevation to its range.

EXAMPLE.—If a shot range 1000 yards when projected at an elevation of 45°, how far will it range when the elevation is 30° 16′, the charge of powder being the same?

Sine of  $45^{\circ} \times 2 = 100000$ , Sine of  $30^{\circ} 16' \times 2 = 87064$ .

Then, as 100000: 1000::87064:870.64, Ans.

EXAMPLE.—The range of a shell at 45° elevation being 3750 feet, at what elevation must a gun be set for a shell to strike an object at the distance of 2810 feet with the same charge of powder?

As 3750:100000::2810:74934, the sine for double the elevation of  $24^{\circ}$  16', or of  $65^{\circ}$  44', Ans.

## FRICTION.

EXPERIMENTS upon the effect of this branch of mechanical science are as yet not of such a nature as to furnish deductions for very satisfactory rules.

The friction of planed woods and polished metals, without lubrication, upon one another, is about \( \frac{1}{4} \) of the pressure.

Friction does not increase with the increase of the rubbing surfaces.

The friction of metals is nearly constant; that of woods seems to increase with action.

The friction of a cylinder rolling upon a plane is as the pressure, and inversely as its diameter.

The friction of wheels is as the diameter of their axes directly, and as the diameter of the wheel inversely.

Friction is at a maximum after a state of rest; the addition is as the fifth root of the time.

The following are the results of some experiments, without lubrication, as given by Adcock:

#### FRICTION AFTER A STATE OF REST.

At a maximum, oak on oak,  $\frac{1}{2.28}$  to  $\frac{1}{2.39}$  of the weight, according to the magnitude of the surface; for oak on pine,  $\frac{1}{1.5}$ ; for pine on pine,  $\frac{1}{1.78}$ ; for elm on elm,  $\frac{1}{2.18}$  of the weight, the fibres moving longitudinally.

When they cross at right angles, the friction of oak is  $\frac{1}{3.76}$ ; for iron on oak,  $\frac{1}{5.5}$ ; for iron on iron,  $\frac{1}{3.5}$ ; for iron on brass,  $\frac{1}{6}$ , the surfaces well polished; but when larger, and not so smooth,  $\frac{1}{3.8}$ .

For iron on copper, with tallow, the friction is  $\frac{1}{11}$  of the weight; when olive oil is used, the friction is increased to  $\frac{1}{6}$ .

The Friction on a level Railroad of a Locomotive is about \( \frac{1}{3} \); that is, an engine weighing 10 tons has a tractive power of 2 tons by the friction of the surfaces of its wheels upon the rails.

#### FRICTION OF BODIES IN MOTION,

#### Without Lubrication.

When the surfaces are large, the friction increases with velocity.

When the surfaces are large, the friction in classes with verticity. For a pressure of from 100 to 4000 lbs. on a square foot, for oak on oak, the friction is about  $\frac{1}{9.5}$ , besides a resistance of about  $1\frac{2}{3}$  lbs. for each square foot, independent of the pressure. When the surface is very small, the friction is somewhat diminished. For oak on pine, the friction is  $\frac{1}{6.3}$ ; for pine on pine,  $\frac{1}{6}$ ; for iron or copper on wood,  $\frac{1}{13}$ , which is much increased by an increase of the velocity; for iron on iron,  $\frac{1}{3.55}$ ; for iron on copper,  $\frac{1}{4.15}$ ; after much use,  $\frac{1}{6}$  at all velocities.

Where the unctuous matter is interposed between the surfaces, the hardest were found to diminish the friction most where the weight was great. Tallow, applied between oak, reduced the friction to  $\frac{1}{28}$  of the pressure. When the surfaces are very small, tallow loses its effect, and the friction is increased to  $\frac{1}{17}$ ; the adhesion was about 7 lbs. per square foot.

With tallow between iron on oak, the friction is  $\frac{1}{35}$ ; with brass on oak,  $\frac{1}{47}$ ; for iron on iron, the friction is  $\frac{1}{10}$ , adhesion 1 lb. for 15 square inches; on copper,  $\frac{1}{11}$ , adhesion 1 lb. for 13 square inches; with soft grease or oil, the friction of iron on copper and brass was  $\frac{1}{7}$  and  $\frac{1}{8}$ .

On the whole, in most machines,  $\frac{1}{8}$  of the pressure is a fair estimate of the friction.

#### FRICTION ON AXES.

For axes of iron on copper,  $\frac{1}{11}$  where the velocity was small, the friction being always a little less than for plane surfaces. An axis of iron, with a pulley of gualacum, gave, with tallow,  $\frac{1}{20}$ .

#### FRICTION AND RIGIDITY OF CORDAGE.

Wet ropes, if small, are a little more flexible than dry; if large, a little less flexible. Tarred ropes are stiffer by about  $\frac{1}{6}$ , and in cold weather somewhat more.

#### FRICTION OF PIVOTS.

When the angle of the summit of the pivot is about 18° or 20°, the friction for garnet is  $\frac{1}{10008}$  to  $\frac{1}{1050}$ ; agate,  $\frac{1}{80}$ ; rock crystal,  $\frac{1}{784}$ ; glass,  $\frac{1}{570}$ ; and steel (tempered),  $\frac{1}{500}$ . At an angle of 45° the friction is much reduced, and the friction of agate and steel are then nearly equal.

Notes .- In general, friction is increased in the ratio of the weight.

Between woods, the friction is less when the grains cross each other than when they are placed in the same direction.

Friction is greater between surfaces of the same kind than between surfaces of different kinds.

The best Lubricators are, and in the following order: Tallow, Soft Soap, Lard, Oil, and Black-lead.

As a general rule, the friction of metals upon each other, with lubrication, is about ten per cent.

196 HEAT.

## HEAT.

Heat, in the ordinary application of the word, signifies, or, rather, implies the sensation experienced upon touching a body hotter, or of a higher temperature than the part or parts which we bring into contact with it; in another sense, it is used to express the cause of that sensation.

To avoid any ambiguity that may arise from the use of the same expression, it is usual and proper to employ the word *Caloric* to signify the principle or cause of the sensation of heat.

Caloric is usually treated of as a material substance, though its claims to this distinction are not decided; the strongest argument in favour of this position is that of its power of radiation. On touching a hot body, caloric passes from it, and excites the feeling of warmth; when we touch a body having a lower temperature than our hand, caloric passes from the hand to it, and thus arises the sensation of cold.

#### COMMUNICATION OF CALORIC.

Caloric passes through different bodies with different degrees of velocity. This has led to the division of bodies into conductors and non-conductors of caloric; the former includes such as metals, which allow caloric to pass freely through their substance, and the latter comprises those that do not give an easy passage to it, such as stones, gluss, wood, charcoal, &c.

197 HEAT.

#### RADIATION OF CALORIC.

When heated bodies are exposed to the air, they lose portions of their heat, by projection in right lines into space, from all parts of their surface.

Bodies which radiate heat best absorb it best.

Radiation is affected by the nature of the surface of the body; thus, black and rough surfaces radiate and absorb more heat than light and polished surfaces.

Reflection of Caloric is the reverse of Radiation, and the one increases as the other diminishes.

#### SPECIFIC CALORIC.

Specific Caloric is that which is absorbed by different bodies of equal weights or volumes when their temperature is equal, based upon the law, acknowledged as universal, that similar quantities of different bodies require unequal quantities of caloric at any given temperature. Dr. Black termed this, capacity for caloric; but as this term was supposed to be suggested by the idea that the caloric present in any substance is contained in its pores, and, consequently, the capacities of bodies for caloric would be inversely as their densities; and such not being the case, this word is apt to give an incorrect notion, unless it is remembered that it is but an expression of fact, and not of cause; and to avoid error, the word specific was proposed, and is now very generally adopted.

It is important to know the relative specific caloric of bodies. The most convenient method of discovering it is by mixing different substances together at different temperatures, and noting the temperature of the mixture; and by experiments it appears that the same quantity of caloric imparts twice as high a temperature to mercury as to an equal quantity of water; thus, when water at  $100^\circ$  and mercury at  $40^\circ$  are mixed together, the mixture will be at  $80^\circ$ , the  $20^\circ$  lost by the water causing a rise of  $40^\circ$  in the mercury; and when weights are substituted for measures, the fact is strikingly illustrated; for instance, on mixing a pound of mercury at  $40^\circ$  with a pound of water at  $160^\circ$ , a thermometer placed in it will stand at  $155^\circ$ . Thus it appears that the same quantity of caloric imparts twice as high a temperature to mercury as to an equal volume of water, and that the heat which gives 5° to water will raise an equal weight of mercury 115°, being the ratio of 1 to 23. Hence, if equal quantities of caloric be added to equal weights of water and mercury, their temperatures will be expressed in relation to each other by the numbers 1 and 23; or, in order to increase the temperature of equal weights of those substances to the same extent, the water will require 23 times as much caloric as the mercury.

The rule for finding by calculation, combined with experiment, the relative capacities of different bodies, is this:

Multiply the weight of each body by the number of degrees lost or gained by the mixture, and the capacities of the bodies will be inversely as the products.

Or, if the bodies be mingled in unequal quantities, the capacities of the bodies will be reciprocally as the quantities of matter, multiplied into their respective changes of temperature.

The general facts respecting specific caloric are as follows:

1. Every substance has a specific heat peculiar to itself, whence a change of composition will be attended by a change of capacity for caloric. Hosted by GOOGLE

R2

2. The specific heat of a body varies with its form. A solid has a less capacity for caloric than the same substance when in the state of a liquid; the specific heat of water, for instance, being 9 in the solid state, and 10 in the liquid.

3. The specific heat of equal weights of the same gas increases as the density decreases; the exact rate of increase is not known, but the ratio is less rapid than

the diminution in density.

Water

4. Change of capacity for caloric always occasions a change of temperature. Increase in the former is attended by diminution of the latter, and vice versa.

Zinc . . . .0927 | Mercury . . .0330 ILLUSTRATION.—If 1 lb. of coal will heat 1 lb. of water to  $100^\circ$ ,  $\frac{1.0000}{.0930}$  ( $\frac{1}{30}$ ) of a lb. will heat 1 lb. of mercury to  $100^\circ$ .

The term Capacity for heat means the relative powers of bodies, in receiving and retaining heat, in being raised to any given temperature; while Specific applies to the actual quantity of heat so received and retained.

When a body has its density increased, its capacity for heat is diminished. The rapid reduction of air to  $\frac{1}{2}$  of its volume evolves heat sufficient to inflame tinder.

LATENT CALORIG is that which is insensible to the touch, or incapable of being detected by the thermometer. The quantity of heat necessary to enable ice to assume, the fluid state is equal to that which would raise the temperature of the same weight of water 140°; and an equal quantity of heat is set free from water when it assumes the solid form.

If 5½ lbs. of water, at the temperature of 320, be placed in a vessel, communicating with another one (in which water is kept constantly boiling at the tempera-

ture of 212°), until the former reaches this temperature of the latter quantity, then let it be weighed, and it will be found to weigh 6½ lbs., showing that 1 lb. of water has been received in the form of steam through the communication, and reconverted into water by the lower temperature in the vessel.

Now this pound of water, received in the form of steam, had, when in that form, a temperature of 212°. It is now converted into the liquid form, and still retains temperature of 212°; but it has caused  $5\frac{1}{2}$  lbs. of water to rise from the temperature of 32° to 212°, and this without losing any temperature of itself. It follows, then, that in returning to the liquid state, it has parted with  $5\frac{1}{2}$  times the number of degrees of temperature between 32° and 212°, which are equal 180°, and 180°× $5\frac{1}{2}$ =990°. Now this heat was combined with the steam; but as it is not sensible to a thermometer, it is called Latent.

It is shown, then, that a pound of water, in passing from a liquid at 212° to steam at 212°, receives as much heat as would be sufficient to raise it through 990 thermometric degrees, if that heat, instead of becoming latent, had been Sensible.

The sum of the Sensible and Latent heat of Steam is always the same at any one temperature; thus,  $990^{\circ}+212^{\circ}=1202^{\circ}$ .

If to a pound of newly-fallen snow were added a pound of water at 172°, the snow would be melted, and 32° will be the resulting temperature.

## Latent Heat of Various Substances.

	Fluids.		1	Vapo	urs.	
Ice		 140°	Steam .			990°
Sulphur		144°	Vinegar .			875°
Lead		162°	Ammonia			860°

Zinc .		493°	Ether .	•		$302^{\circ}$

Sensible Caloric is free and uncombined, passing from one substance to another, affecting the senses in its passage, determining the height of the thermometer, and giving rise to all the results which are attributed to this active principle.

To reduce the Degrees of a Fahrenheit Thermometer to those of Reaumur and the Centigrade.

#### FAHRENHEIT TO REAUMUR.

RULE.—Multiply the number of degrees above or below the freezing point by 4, and divide by 9.

Thus, 
$$212^{\circ} - 32 = 180 \times 4 = 720 \div 9 = 80$$
, Ans.  
 $+24^{\circ} - 32 = 8 \times 4 = 32 \div 9 = 3.5$ , Ans.

#### FAHRENHEIT TO CENTIGRADE.

RULE.—Multiply the number of degrees above or below the freezing point by 5, and divide by 9.

Thus, 
$$212^{\circ} - 32 = 180 \times 5 = 900 \div 9 = 100$$
, Ans.

MEDIUM HEAT of the globe is placed at 50°; at the torrid zone, 75°; at moderate climates, 50°; near the polar regions, 36°.

The extremes of natural heat are from -70° to 120°; of artificial heat, from -91° to 36000°.

200 неат.

#### EVAPORATION.

Evaporation produces cold, because heat must be absorbed to form vapour.

Evaporation proceeds only from the surface of the fluids, and therefore other things equal must depend upon the extent of surface exposed.

When a liquid is covered by a stratum of dry air, evaporation is rapid, even when the temperature is low.

As a large quantity of caloric passes from a sensible to a latent state during the formation of vapour, it follows that cold is generated by evaporation.

#### CONGELATION AND LIQUEFACTION.

Freezing water gives out  $140^\circ$  of heat. Water may be cooled to  $20^\circ$ . All solids absorb heat when becoming fluid.

The particular quantity of heat which renders a substance fluid is called its caloric of fluidity, or latent heat.

The heat absorbed in liquefaction is given out again in freezing.

Fluids boil in vacuo with 1240 less of heat than when under the pressure of the atmosphere. On Mont Blanc water boils at 1870.

#### DISTILLATION.

Distillation is the depriving vapour of its latent heat, and, though it may be effected in vacuo with very little heat, no advantage in regard to a saving of fuel is gained, as the latent heat of vapour is increased in proportion to the diminution of sensible heat.

For temperatures of steam, see page 208.

#### FOR WARMING APARTMENTS.

Every cubic foot of water evaporated in a boiler at the pressure of the atmosphere will heat 2000 feet of inclosed air to an average temperature of 750, and each square foot of surface steam-pipe will warm 200 cubic feet of space.

## AIR.

100 Cubic Inches of atmospheric air, at the surface of the earth when the barometer is at 30 inches, and at a temperature of 60°, weighs 30.5 grains, being 830.1 times lighter than water.

Specific gravity compared with water, .0012046.

The atmosphere does not extend beyond 50 miles from the earth's surface.

The mean weight of a column of air a foot square, and of an altitude equal to the height of the atmosphere, is equal to 2116.8 lbs. avoirdupois.

It consists of oxygen 20, and nitrogen 80 parts; and in 10.000 parts there are 4.9 parts of carbonic acid gas.

The mean pressure of the atmosphere is usually estimated at 14.7 lbs. per square inch.

13.29 cubic feet of air weigh a lb. avoirdupois, hence 1 ton of an will occupy 29769.6 cubic feet.

The rate of expansion of air, and all other Elastic Fluids, for all temperatures, is uniform.

From 32° to 212° they expand from 1000 to 1376, equal to  $\frac{1}{4.70}$ \* of their bulk for every degree of heat.

Weight and Volume of Air required for the Combustion of several Materials.

Materials.		Weight in lbs. at 32°.	Volumes in at 32°.	cubic feet at 60°.
Virginia pine		4.47 4.6	55.8 57.5	59.4 61.1
Turf Bituminous coal		9.26	115.8	123.
Anthracite coal	. ,	_		
Charcoal	}	11.46	143.4	152.3
Oil Tallow	: }	15.	187.6	199.3
Wax	. )	l	-	

19 to 20 tons of air with coke or anthracite coal, and 18 tons with charcoal, are required to make 1 ton of pig iron, the ore yielding 33 per cent. of iron.

See Heat, page 201.

## LIGHT.

LIGHT is similar to caloric in many of its qualities, being emitted in the form of rays, and subject to the same laws of reflection.

It is of two kinds, Natural and Artificial; the one proceeding from the sun and stars, the other from heated bodies.

Solids shine in the dark only when heated from 600° to 700°, and in daylight when the temperature reaches 1000°.

Relative intensity of light from the burning of various bodies is, for wax, 101 parts; tallow, 100; oil in an Argand lamp, 110; in a common lamp, 129; and an ill-snuffed candle, 229.

By experiments on coal gas, it appears that above 20 cubic feet are required to produce light equal in duration and in illuminating powers to a pound of tallow candles, six to a pound, set up and burned out one after the other.

In distilling 56 lbs. coal, the quantity of gas produced in cubic feet when the distillation was effected in 3 hours was 41.3, in 7 hours 37.5, in 20 hours 33.5, and in

25 hours 31.7.

## TONNAGE.

By a law of Congress, the tonnage of vessels is found as follows:

#### FOR A DOUBLE-DECKED.

Take the length from the fore part of the stem to the after side of the sternpost above the upper deck; the breadth at the broadest part above the main wales; half of this breadth must be taken as the depth of the vessel; then deduct from the length  $\frac{3}{5}$  of the breadth, multiply the remainder by the breadth, and the product by the depth: divide this last product by 95, and the quotient is the tonnage.

EXAMPLE.—What is the tonnage of a ship of the line, measuring, as above, 210 feet on deck, and 59 feet in breadth?

 $59 \div 2 = 29.5$ , depth.  $210 - \frac{3}{5}$  of  $59 = 174.6 \times 59 \times 29.5 \div 95 = 3198.8$  tons.

#### FOR A SINGLE-DECKED.

Take the length and breadth as above directed for a double-decked, and deduct from the length  $\frac{3}{5}$  of the breadth; take the depth from the under side of the deck-plank to the ceiling of the hold; then proceed as before.

Example.—The length of a vessel is (as above) 223 feet, the breadth 39\frac{1}{2} feet, and the depth of hold 23\frac{1}{2} feet; what is the tonnage?

 $223 - \frac{3}{5}$  of  $39.5 = 199.3 \times 39.5 \times 23.5 \div 95 = 1947.3$  tons.

A ton will stow 31 bales cotton.

NOTE .- The burden of similar ships are to each other as the cubes of their like dimensions.

## CARPENTERS' MEASUREMENT.

## FOR A SINGLE-DECKED.

Multiply the length of keel, the breadth of beam, and the depth of the hold together, and divide by 95.

#### FOR A DOUBLE-DECKED.

Multiply as above, taking half the breadth of beam for the depth of the hold, and divide by 95.

# To find the Tonnage of English Vessels.

Rule.—Divide the length of the upper deck between the afterpart of the stem and the forepart of the sternpost into 6 equal parts, and note the foremost, middle, and aftermost points of division Measure the depths at these three points in feet, and tenths of a foot, also the depths from the under side of the upper deck to the ceiling at the limber strake; or, in case of a break in the upper deck, from a line stretched in continuation of the deck. For the breadths, divide each depth into 5 equal parts, and measure the inside breadths at the following points, viz.: at \(\frac{1}{2}\) and at \(\frac{2}{2}\) from the upper deck of the foremost and aftermost depths, and at \(\frac{2}{2}\) and \(\frac{2}{2}\) from the upper deck of the midship depth. Take the length, at half the midship depth. from the afterpart of the stem to the forepart of the stempost.

Then, to twice the midship depth, add the foremost and aftermost depths for the sum of the depths; and add together the foremost upper and lower breadths, 3 times the upper breadth with the lower breadth at the midship, and the upper and twice the lower breadth at the after division for the sum of the breadths.

Multiply together the sum of the depths, the sum of the breadths, and the length, and divide the product by 3500, which will give the number of tons, or register.

If the vessel have a poop or half-deck, or a break in the upper deck, measure the inside mean length, breadth, and height of such part thereof as may be included within the bulkhead; multiply these three measurements together, and divide the product by 92.4. The quotient will be the number of tons to be added to the result as above found.

For Open Vessels. The depths are to be taken from the upper edge of the upper

For Steam Vessels. The tonnage due to the engine-room is deducted from the total tonnage calculated by the above rule.

To determine this, measure the inside length of the engine-room from the foremost to the aftermost bulkhead; then multiply this length by the midship depth of the vessel, and the product by the inside midship breadth at 0.40 of the depth from the deck, and divide the final product by 92.4.

206 STEAM.

## STEAM.

 $S_{TEAM}$ , arising from water at the boiling point, is equal to the pressure of the atmosphere, which is 14.706 lbs. on the square inch.

Under the pressure of the atmosphere alone, water cannot be heated above the boiling point.

A cubic inch of water, evaporated under the ordinary atmospheric pressure, is converted into 1700 cubic inches of steam, or, in round numbers, 1 cubic foot, and gives a mechanical force equal to the raising of 2200 lbs. 1 foot high.

The force of steam is the same at the boiling point of every fluid.

The elasticity of the vapour of spirit of wine, at all temperatures, is equal to 2.125 times that of steam.

It has already been stated (see Heat) that the sum of sensible and latent heats is  $1202^\circ$ , and that  $140^\circ$  of sensible heat becomes latent upon the liquefaction of ice; also, that 1 lb. of water converted into steam at  $212^\circ$  will heat  $5\frac{1}{2}$  lbs. of water at  $32^\circ$  to  $212^\circ$ , and that the sum is  $6\frac{1}{2}$  lbs. of water.

The practical estimate of the velocity of steam, when flowing into a vacuum, is about 1400 feet in a second when at an expansive power equal to the atmosphere; and when at 20 atmospheres, the velocity is increased but to 1600 feet.

When flowing into the air under a similar power, about 650 feet per second, increasing to 1600 feet for a pressure of 20 atmospheres.

Specific gravity of steam at the pressure of the atmosphere .488, air being  $1. \,$ 

27.206 cubic feet of steam at the pressure of the atmosphere, equal 1 lb. avoirdupois.

A pressure of 1 lb. on a square inch will raise a mercurial steam gauge (syphon) 1.01995 inches.

A column of mercury 2 inches in height will counterbalance a pressure of .9804 lbs, on a square inch.

To ascertain the Number of Cubic Inches of Water, at any Given Temperature, that must be mixed with a Cubic Foot of Steam to reduce the Mixture to any Required Temperature.

Rule.—From the required temperature subtract the temperature of the water: then find how often the remainder is contained in the required temperature, subtracted from 1202°, and the quotient is the answer.

Example.—The temperature of the condensing water of an engine is 80°, and the required temperature 100°; what is the proportion of condensing water to that evaporated?

$$100-80=20$$
. Then  $\frac{1202-100}{20}=55.1$ , Ans.

Or, let w represent temperature of condensing water, t the required temperature, and h the sum of sensible and latent heats.

Then 
$$\frac{h-t}{t-w}$$
 = water required.

To ascertain the Quantity of Steam required to raise a Given Quantity of Water to any Given Temperature.

Rule.—Multiply the water to be warmed by the difference of temperature between the cold water and that to which it is to be raised, for a dividend; then to the temperature of the steam add 990°, and from that sum take the required temperature of the water for a divisor; the quotient is the quantity of steam in the same terms as the water.

Example.—What quantity of steam at 2120 will raise 100 cubic feet of water at 860 to 2120 ?

$$100 \times \overline{2120 - 80}$$

 $\frac{1}{2120+9900}$  = 13.3 cubic feet of water formed into steam, occupying (13.3× 1700) 22610.0 cubic feet of space.

To ascertain the Specific Gravity of Steam.

RULE.—Divide the constant number 829.6 (1700 x .488) by the volume of the steam at the temperature or pressure at which the gravity is required.

To ascertain the Volume of Steam under a given Pressure, the Temperature answering to that Pressure, in Steam at its Maximum Density for its Temperature being given.

$$\frac{1+.00202\times(t-32)}{1}$$
 18329=V.

When p represents the pressure of the steam in pounds per square inch, t the temperature in degrees (Fah.), and V the volume required.

To ascertain the Temperature of Steam.

From the pressure in inches of mercury subtract the constant 0.1, divide the logarithm of the remainder by 5.13, and to the quotient add the logarithm 2.132794; find the natural number of the sum of the logarithms, from it subtract the constant 51.3, and the remainder will be the temperature.

Example.—When the pressure is = 397.8 inches of mercury, what is the temperature of the steam?

Then

397.8 - 0.1 = 397.7. log. 397.7 = 2.59956.  $2.59956 \div 5.13 = 0.506737$ 

Natural number, Constant temperature,

log. 2.132794  $436. = \log. \ 2.639531$ 51.30

384.70 = temperature required.

#### HYPERBOLIC LOGARITHMS.

# To find the mean Pressure by Hyperbolic Logarithms.

Rule.—Divide the length of the stroke by the length of the space into which the steam is admitted; find in the table the logarthm of the number nearest to that of the quotient, to which add 1. The sum is the ratio of the gain.

Example.—Suppose the steam to enter the cylinder at the pressure of 40 lbs. per square inch, and to be cut off at  $\frac{1}{4}$  of the length of the stroke; what is the mean pressure, the stroke being 10 feet?

 $10 \div 2.5 = 4$ . Hyp. log. of 4 = 1.38629 + 1 = 2.38629. Then, as 4 : 2.38629 : 40 : 23.8629 lbs.

#### TABLE.

No.	Logarithm.	No.	Logarithm.	No.	Logarithm.	No.	Logarithm.

# Table of the Density of Steam under different Pressures.

Atmos- phere.	Density.	Volume.	Atmos- phere.	Density.	Volume.	Atmos- phere.	Density.	Volume.
1	.00059	1694	5	.00258	387	12	.00581	172
2	.00110	909	6	.00306	326	14	.00670	149
3	.00160	625	8	.00399	250	16	.00760	131
4	,00210	476	10	.00492	203	18	.00849	117

The volumes are not direct, in consequence of the increase of heat. For table showing the ratio of the expansion of steam, see page 275.

## STEAM-ENGINE.

It is inconsistent with the design of this work to treat of the *operation* of the steam-engine, and this article will be confined to the exhibition of some rules of *construction*, the utility of which have been fully tested in the varied purposes of Land, River, and Marine practice.

The extremes of proportions here given are for the particular requirements of variations in speed, differences in draughts of water, pressures of steam, &c., &c.

## CONDENSING ENGINE,

For a range of pressures (indicated by a mercurial gauge) of from 10 to 60 pounds per square inch.

Condenser. The capacity of it should be from  $\frac{3}{10}$  to  $\frac{4}{10}$  that of the steam cylinder.

Air-Pump. The capacity of it, exclusive of piston space, should be from  $\frac{1}{4}$  to  $\frac{1}{5}$  that of the steam cylinder.

Steam and Exhaust Valves. Let a represent area of steam cylinder in inches, s stroke of piston in inches, and r number of revolutions per minute, then the area of the valve  $=\frac{a \times s \times r}{24000}$ .

By experiment, when there were 325 square inches of valve for 290.400 cubic inches in the cylinder, with 26 revolutions, the proportion was found to be a proper one.

And 318 inches of valve for 371.000 inches in the cylinder, with 20 revolutions, has been used, and the operation, as shown by an Indicator, was held satisfactory.

Foot Valve. The dimensions of it should give an area of from  $\frac{1}{350}$  to  $\frac{1}{350}$  of the capacity of the steam cylinder in inches.

Delivery Valve. When a solid piston is used in the air-pump, its dimensions should correspond with that of the foot valve; but when an open piston alone is used, this proportion may not be obtained.

Out-board Delivery Valve. The area of it should be from  $\frac{6}{10}$  to  $\frac{8}{10}$  that of the foot valve.

Feed Pumps. Their capacity should be  $\frac{1}{150}$  to  $\frac{1}{100}$  that of the steam cylinder.

Injection Cocks. There should be two to each condenser, the area of each sufficient to supply 70 times the quantity of water evaporated when the engine is working at its maximum; and in marine engines there should be three, viz., a Side, Bottom, and Bilge

The Side and Bottom injections will require (for 20 revolutions) an area in square inches of from  $\frac{1}{10}$  to  $\frac{1}{12}$  the number of cubic feet in the steam cylinder for the for mer, and from  $\frac{1}{7}$  to  $\frac{1}{9}$  for the latter.\*

The Bilge injection is properly a branch of the bottom injection pipe, and may be of less capacity.

*Piston Rods.* Their diameter (if of wrought iron) should be  $\frac{1}{16}$  that of the cylinder or air-pump.

Cross Heads. Of wrought iron. (Steam cylinders.) For the section at their centre, let a represent area of cylinder in inches, p extreme pressure in pounds per square inch that they may be subjected to, and l their length between the centres of journals in feet; then,

$$\frac{a \times p \times l}{700} = d^2 \times w$$
, and  $\sqrt{\frac{d^2 \times w}{w}} = d$ , or  $\frac{d^2 \times w}{d^2} = w$ ,

where d represents the depth and w the width of the section.

Air-pumps,  $\frac{a \times l}{18} = d^2 \times w$ . If the sections are cylindrical, for  $l^2 \times w$  read  $\sqrt[3]{d^2 w \times 1.7}$ .

Surface Condensers. The area of their surfaces should be from to  $\frac{1}{3}$  of that of the heating surface of the boiler, when a natural lraught is employed: with a blower, or forced draught, these proportions should be increased to  $\frac{1}{3}$  and  $\frac{4}{10}$ .

With the double vacuum condenser of I. P. Pirsson, the lowest proportions bove given have been found sufficient.

<sup>\*</sup> The proportions here given will admit of a sufficient quantity of water when he engine is in operation in the Gulf Stream, where the water is at times at the emperature of 84°, and the quantity of water (when the steam is at 10 lbs. pressure) required to give it and the water of condensation a temperature of 100°, is 70 imes that of the quantity evaporated.

## NON-CONDENSING, OR HIGH-PRESSURE ENGINE,

For a range of pressures of from 50 to 130 pounds per square inch.

Steam and Exhaust Valves. Let a represent area of steam cylinder in inches, s stroke of piston in inches, and r number of revolutions per minute, then the area of the valve  $=\frac{a \times s \times r}{30000}$ .

A decrease in the capacity of the cylinder is not attended with a corresponding diminution of their area.

Thus, a 24 inch cylinder by 3 feet stroke has valves that contain 20 square inches, which is a proportion of 1 inch in every 814 inches capacity of cylinder.

A 12 inch cylinder by 4 feet stroke has 9 inches area of valve, which is 1 inch in every 600 inches capacity, and a 6 inch cylinder by 1 foot stroke has 1 inch in every 125 inches capacity.

Piston Rod. Its diameter should be from  $\frac{1}{8}$  to  $\frac{1}{5}$  that of the cylinder.

Feed Pumps. Their capacity, when the pressure of the steam is not to exceed 60 lbs., should be  $\frac{1}{75}$  the contents of the cylinder; when not to exceed 130 lbs.,  $\frac{1}{50}$ , and in a similar ratio for higher pressures.

Cross Heads. See rule under head of condensing engines, page 211.

## BOILERS.

#### INTERNAL FURNACES AND FLUES.

#### BITUMINOUS COAL, WITH A NATURAL DRAUGHT.

With a Pressure of 20 lbs. Steam per square inch, cut off at \(\frac{1}{3}\) the Stroke of the Piston, and with 20 Revolutions of the Engine.

Fire and Flue Surface.\* For every cubic foot in the steam cylinder, the length of the flues, including steam chimney, not exceeding 45 feet, there should be from 16 to 18 square feet.

Or, surface for one revolution for each cubic foot,  $\frac{85}{100}$  of a square foot.

*Grates.* Their area in square feet should be from  $\frac{7}{10}$  to  $\frac{8}{10}$  of the subic feet in the steam cylinder.

#### ANTHRACITE COAL, WITH A BLAST.

With a Pressure of 30 lbs. per square inch, cut off at ½ the Stroke, and with 20 Revolutions.

Fire and Flue Surface.\* For every cubic foot in the steam cylinder, the length of the flues not exceeding 50 feet, there should be from 12 to 14 square feet.

Or, surface for *one* revolution for each cubic foot,  $\frac{6.5}{100}$  of a square foot.

*Grates.* Their area should be from  $\frac{55}{100}$  to  $\frac{65}{100}$  that of the cubic feet in the cylinder.

Steam Room. There should be at least 5 times the space in the steam room (independent of steam pipes, &c.), that there is in the cylinder.

ANTHRACITE COAL, WITH AN EXHAUST DRAUGHT, THE FLAME RETURNED THROUGH OR PASSING BETWEEN SMALL TUBES.

With a Pressure of 50 lbs. per square inch, cut off at \(\frac{1}{2}\) the Stroke, and with 50 Revolutions.

Fire and Flue Surface.\* For every cubic foot in the steam cylinder, the passage of the flame not exceeding 30 feet, there should be from 65 to 70 square feet.

Or, surface for one revolution for each cubic foot, 1.35 square feet.

Grates. Their area in square feet should be from 2.75 to 3.25 times that of the cubic feet in the cylinder.

Steam Room. There should be at least 7 times the space that here is in the cylinder.

<sup>\*</sup> Estimated from above the grate bars, including steam chimney, and for salt water.

## EXTERNAL FURNACE, WITH INTERNAL RETURN FLUES.

WOOD OR COAL, WITH A NATURAL DRAUGHT.

For a Pressure of 100 lbs. per square inch, cut off at \(\frac{1}{3}\) the Stroke, and with 25 Revolutions.

Fire and Flue Surface. For every cubic foot in the steam cylin der, the length of the flues not exceeding 50 feet, there should be from 65 to 75 feet.\*

Or, surface for one revolution for each cubic foot, 2.8 square feet.

Grates. Their area in square feet should be from 3. to 3.25 times that of the cubic feet in the cylinder.\*

# PLAIN CYLINDRICAL, WITH EXTERNAL FURNACE AND FLUE WOOD OR COAL, WITH A NATURAL DRAUGHT.

For a Pressure of 100 lbs. per square inch, cut off at \( \frac{1}{3} \) the Stroke, and with 25 Revolutions.

Fire and Flue Surface. For every cubic foot in the steam cylinder, their length not exceeding 30 feet, there should be from 60 to 70 feet.\*

Surface for one revolution for each cubic foot, 2.6 square feet.

Grates. Their area in square feet should be from 4 to 5 times that of the cubic feet in the cylinder.\*

In the last case the range of surface is extended to meet the application of small and large engines, as the proportion of surface varies materially with cylinders of 16 and 30 inches diameter, being inversely as their capacities.

Steam Room. There should be at least 5 times the space in the boiler that there is in the cylinder.

Notes.—Four copper boilers, with a natural draught and bituminous coal, flues 46 feet in length, including steam chimney, with 14 square feet of fire and flue surface, and  $\frac{6}{10}$  of a square foot of grate surface for every cubic foot in the cylinders, furnished steam at 20 lbs. pressure, cut off at  $\frac{1}{2}$  of the stroke of the piston, for 18.5 revolutions.

The mean of four cases, with iron boilers, and anthracite coal, with a blast; flues 50 feet in length, gave, with 11.5 square feet of fire and flue surface, and  $\frac{5}{10}$  of a square foot of grate surface for every cubic foot in the cylinders, steam at 35 lbs. pressure, cut off at  $\frac{1}{2}$  of the stroke of the piston for 22 revolutions.

The space in the steam room of the boilers and chimney was about 5 times that of the cylinders in the preceding cases.

The ranges here given, of from 16 to 18, 12 to 14, &c., are for the purpose of covering the ordinary differences of construction, thickness of metal, &c.

When there are two engines, or an increased number of revolutions, these proportions of steam room must be increased.

When a heater is used, and the temperature of the feed water is raised above that obtained in a condensing engine, the proportions of surfaces may be correspondingly decreased.

For further notes of practical results, and for the dimensions and proportions of various Engines, Boilers, Mills, &c., &c., see pages 272-280.

<sup>\*</sup> These proportions are for the evaporation of fresh water; if sea water is used the surfaces must be increased  $\frac{1}{15}$ .

## GENERAL RULES.

#### ENGINES.

Steam Cylinders. When Vertical, multiply their diameter by the extreme pressure of steam in pounds per square inch that they may be subjected to, and divide by 2400; the result will give the thickness in inches. When Horizontal, divide by 2000; and when Inclined, divide as above, in a ratio inversely as the sine of the angle of inclination.

Shafts. To resist torsion. For wrought iron, multiply the extreme of pressure upon the steam piston that they may be subjected to, or the resistance to be overcome, in pounds, by the length of the erank or arm in feet; divide this product by 125, and the cube root of the quotient is the diameter of the journal in inches.

If for Cast Iron, add  $\frac{1}{10}$  to the diameter thus found.

When two shafts are to be used, as in steamers with one engine? Take the cube root of  $\frac{3}{4}$  of the cube of the diameter found as above, and the result is the diameter for each shaft.

See pages 158, 159 for other rules and notes of experiments, &c.

Journals. Their length should exceed the diameter not less than n the proportion of 10 to 9, and in some cases the proportion should be increased in the ratio of 3 to 2.

Steam Pipes. Their area should exceed that of the steam valve.

Connecting Rods. Their length should be 24 times the stroke of he piston when it is at all practicable to afford the space. When, lowever, it is imperative to reduce this proportion, it may be a little ess than twice the stroke.

The diameter of the *neck* should be the same as that of the piston

The diameter of the centre of the body is found in the following nanner:

Multiply the length of the body (between the necks) in feet, by he area of a neck, divide the product by  $\frac{3}{4}$  the stroke of the piston r the throw of the rod, and the quotient is the area of the centre, rom which the diameter may be determined.

The length of connecting links should be half of that of the stroke of the throw of their attachments.

Where a pair of connecting rods is used, as in some descriptions f engines, and with links, their necks should have an area of  $\frac{1}{6}$  of that of the attached rod.

When a second set of connecting rods or links are used, as with ir-pump connections, &c., their necks should have a diameter in ratio inversely as their throw to the stroke of the piston.

Hosted by GOOgle

Straps of Connecting Rods, Links, &c. The area of the Strap at its least section should be  $\frac{65}{100}$  that of the neck of the attached rod. The Key should be in thickness  $\frac{3}{10}$  the diameter of the neck, the width of Gib and Key combined should be 1.25 times, and the Slot should be 1.35 times that of the same diameter. The draft of keys should be from  $\frac{6}{10}$  to  $\frac{3}{10}$  of an inch per foot.

Pins. For Cranks, their area should be 1.6 times that of the attached rod, and for Air Pumps, 1.5 times.

Cranks. Of Wrought Iron. The Hub, compared with the neck of the shaft, should be 1.75 the diameter and 1.05 the depth. The Eye, compared with the pin, should be twice its diameter and 1.5 the depth. The Web, at the periphery of the hub, should be, in width,  $\frac{7}{10}$  the width, and in depth, one half the depth of that of the hub. the periphery of the eye it should be, in width,  $\frac{8}{10}$  the width, and in depth,  $\frac{6}{10}$  the depth of the eye.

The Radii for the fillets of the sides of the web should be one half of the width of the web at the end for which the fillet is designed; for the fillets at the back of the web, they should be one half of that at the sides of their respective ends.

When of Cast Iron. The diameters of the Hub and Eye should be, respectively, twice the diameter of the neck of the shaft, and 2.25 times that of the crank pin.

Beams. Their length from centres should be 1.8 the stroke of the piston, and their depth one half of their length. If strapped, the strap at its smallest dimensions should have at least  $\frac{9}{10}$  the area of the piston rod, its depth being equal to half of its breadth. The end centres should have each one, and the main centre two and a half times the area of the piston or driving rod.

This proportion for the strap is when the depth of the beam is as a crossequently, when the depth is less, the area must be increased.

Cast Iron Beams, when of uniform thickness, should have a thickness of not less than  $\frac{1}{16}$  of their depth.

To ascertain the vibration of the end centres, let L represent length of beam, and S stroke of piston.

$$\frac{L}{2}$$
  $-\sqrt{(L+2)^2-(S+2)^2}$  = vibration at each end.

 $\it Cocks.$  The angle of the sides of their plug should be from 7' to 8° from the plane of it.

Piston Rods of different materials should have their diameters in the following ratios:

Wrought Iron, 1. Tempered Steel, .8. Cast Iron, 1.6.

Safety Valves. 10 inches area of valve for every 250 square fee of fire surface is sufficient.

Fly Wheels and Governors. See rules, page 192.

#### BOILERS

Boilers—When Sca Water is used. The heating and grate surfaces should be increased about  $\frac{1}{15}$  over that for fresh water.

Furnaces—With Coal. The space over the grate bars in height should be from  $2\frac{1}{2}$  to 3 feet.

With Wood. The capacity of them above the grate bars, compared with one where coal is used, should be as 5 to 3.

The area at the bridge wall should be from  $\frac{6}{10}$  to  $\frac{7}{10}$  that of the lower flues.

Flues. The area of them should decrease with their length, and nearly in proportion with the reduction of the temperature of the heated air; their area at the base of the smoke pipe being from  $\frac{6}{10}$  to  $\frac{7}{10}$  that of immediately behind the bridge wall.

Large flues absorb more heat than small, as both the volume and intensity of the heat is greater with equal surfaces.

Grates. The spaces between the bars should be as near or frequent as possible.

Note.—The bulk of heated air at the bridge wall is about 460 cubic feet for each

pound of coal consumed on the grates.

With a blast, there will be required about 20 square inches of area at the bridge
wall for every square foot of grate, and with a natural draught about 30 inches.

Smoke Pipes, or Chimneys. Their area at the base should always exceed that of the extremity of the flue or flues.

The intensity of the draught is as the square root of the height.

#### BLOWING ENGINES. Exhausting into a Condenser.

ONE STEAM CYLINDER, WITH ONE BLOWING ENGINE.

Cylinder. The diameter of it should be 283 that of the steam cylinder, and the stroke of it  $\frac{1}{10}$ .

ONE STEAM CYLINDER, WITH TWO BLOWING ENGINES.

Cylinders. The diameter of each should be .2 that of the steam cylinder, and their stroke  $\frac{1}{16}$ .

When the stroke by this rule would be less than 10 inches, the diameter should be decreased, and the stroke of 10 inches retained.

#### BLOWERS. When driven with a Belt.

Their Width should be equal to their radius; the Opening, in their sides,  $\frac{1}{3}$  of their diameter; the Nozzle, not to exceed  $\frac{1}{6}$  and not less than  $\frac{1}{8}$  of it, and the Depth of the Fan  $\frac{1}{10}$  less than the diameter of the opening in the side.

Pulley. Its Diameter should not be less than  $\frac{1}{4}$  of that of the blower.

#### When Direct Acting.

Their Width should not exceed  $\frac{1}{3}$  of their diameter; the Opening, in their sides,  $\frac{1}{4}$ , and the depth of the Nozzle,  $\frac{1}{8}$  of it.

#### To ascertain the Pressure of a Fan.

Let r = radius of blower in feet (taken from the centre of the blade of the fan), and t = time of one revolution in seconds. Then  $\frac{5}{4} \frac{r}{t^2} =$  the height in feet of a column of air that the fan will support

NOTES.—The pressures given are intended for those indicated by the steam gauge or safety valve.

When other pressures, revolutions, and points of cutting off than those given are required, the areas of the fire and flue and grate surfaces must be proportionally increased or diminished.

The proportion, however, will not be exactly in the ratio of expansion, pressures, and revolutions, as many of the sources of losses, as radiation and leaks, may be uniform and alike in extent.

To ascertain the Areas of Fire and Flue and Grate Surfaces for a required Capacity of Cylinder, when the Pressure, Revolutions, and Point of Cutting off differ from the Units given under the several descriptions of Boilers, pages 213 and 214.

Reduce the given capacity of cylinder to conform to the appropriate units of pressures, revolutions, and point of cutting off; then multiply this capacity by the units for surfaces given, and the products will be the required areas.

EXAMPLE.—The capacity of a cylinder is 12.5 cubic feet, the pressure of steam 40 lbs. per square inch, the revolutions of the engine 50 per minute, and the point of cutting off ½ of the stroke of the piston.

Boiler to have internal furnaces and flues, and to operate with a natural draught.

Given pressure 40 lbs. mercurial gauge = 54.7 lbs. Unit pressure 20 lbs. mercurial gauge = 34.7 lbs.

$$12.5 \times \frac{54.7}{34.7} = 19.7$$
 capacity at 54.7 lbs. pressure,  
 $19.7 \times \frac{50}{20} = 49.25$  capacity at 50 revolutions,  
and  $49.25 \times \frac{3}{2} = 73.875$  capacity at half stroke.

Then  $73.875 \times 17$ . = 1255.875 square feet of fire and flue surface.  $73.875 \times .75 = 55.406$  square feet of grate surface.

#### MATERIALS FOR BOILERS.

IRON. The tensile strength of iron boiler plates ranges from 50,000 lbs. to 60,000 lbs. per square inch of section.

This strength is increased by their exposure to a moderate temperature, and reduced when the tension is crosswise to the direction of the fibres.

COPPER. The tensile strength of copper boiler plates is about 30,000 lbs. per square inch of section.

At a temperature of  $550^{\circ}$ , this strength is reduced to 22,500 lbs. and at  $817^{\circ}$ , to 15,000 lbs.

#### Construction of Boilers.

The necessary allowances for the spaces between the rivets, oxidation and the loss of elasticity by extreme tensions, reduces the measure of this strength for practical purposes as follows:

Iron . . 10,000 to 12,000 lbs. Copper . . . . . . . 7,000 lbs.

RIVETING. A double riveted joint is equal to  $\frac{7}{10}$ , and a single riveted joint is equal to  $\frac{50}{10}$  of the strength of the plate.

#### BELTS.

Two 15 inch belts over a driver of six feet in diameter, running with a velocity of 2128 feet in a minute, transmit the power from he water-wheel at Rocky Glen Factory, the dimensions of which are given in page 179.

An 11 inch belt over a driver of 4 feet in diameter, running from 1200 to 2100 feet in a minute, will transmit the power from two 6 nch cylinders having 11 inches stroke, and averaging 125 revolutions per minute, with a pressure of 60 lbs. per square inch.

Two 6 inch belts over a driver of 5.9 feet in diameter, running 2700 feet in a minute, will transmit the power from two 9 inch cylnders having 8 inches stroke, and averaging 150 revolutions per ninute, with a pressure of 60 lbs. per square inch.

#### SATURATION IN MARINE BOILERS.

100 parts of sea water contain 3 parts of its weight in saline natter, and is saturated when it contains 36 parts; then, if the uantity in the boiler be taken as 100 parts of water, and s parts e used for steam, b parts blowed out; to fix on the degree of satuation to contain x parts of saline matter, the quantity of salt enering and the quantity leaving in the same time, will be equal

when 
$$3(s+b) = xb$$
; hence  $b = \frac{3s}{x-3}$ .

If x=30, the water in the boiler will not reach to a higher degree f saturation when  $\frac{1}{9}$  of the quantity used for steam is allowed to scape. And as it requires but about  $\frac{1}{6}$  of the quantity of fuel to oil water that is required to convert it into steam, the loss of fuel rill be  $\frac{1}{9} \times \frac{1}{6} = \frac{1}{54}$  part.—Treagold.

#### BLOWING ENGINES.

For Smelting, &c.

The quantity of oxygen in the same bulk of air is different at different temperatures. Thus, dry air at 85° contains 10 per cent. less oxygen than when at the temperature of 32°; when saturated with vapour, it contains 12 per cent. less.

Hence, if an average supply of 1500 cubic feet per minute is required in winter, 1650 feet will be required in summer.

Manufacture of Pig Iron.

Coke or Anthracite Coal. 18 to 20 tons of air are required tor each ton of pig iron.

Charcoal. 17 to 18 tons of air are required for each ton of pig iron. (1 ton of air at  $60^{\circ} = 29750$  cubic feet.)

Pressure. The pressure ordinarily required for smelting purposes is equal to a column of mercury from 3 to 9 inches.

Reservoir. The capacity of it, if dry, should be 15 times that of the cylinder or cylinders.

*Pipes.* Their area, leading to the reservoir, should be  $\frac{1}{5}$  that of the cylinder (blast).

To ascertain the Power of an Engine.

Let P represent pressure of blast in lbs. per square inch,

v velocity of the piston in feet per minute,

a area of cylinder in square inches,

f friction of pistons, and from curvatures, &c., estimated at 1.25 per square inch of piston.

Power.  $P \times a \times v \times f =$  power in lbs. to be raised 1 foot in a minute, and  $\frac{P \ a \ v \ f}{33000} =$  horses' power required.

If the cylinder is single acting, divide the results by 2.

To ascertain the Dimensions of Driving Engine.

Let \*p represent mean effective pressure upon piston of steam cylinder in lbs. per square inch,

\*f the lbs. pressure upon the piston necessary to overcome the friction of the engine,

r revolutions of engine per minute.

Cylinder. Divide the power in pounds by  $\overline{p-f}\times v$ , and the quotient is the area.

Then  $\frac{v}{2r}$  = stroke of piston.

The quantity of air at atmospheric density delivered into the reservoir, in consequence of escapes through the valves, and the partial vacuum necessary to produce a current, will be about  $\frac{V}{8}$  less than the capacity of the cylinder.

See page 288 for dimensions of Furnace, Engines, &c.

<sup>\*</sup> See page 221 for these values.

#### To find the Power of a Condensing Engine.

Let S represent velocity of cylinder piston in feet per minute,

n velocity of air-pump piston in feet per minute,

\*P mean effective pressure upon cylinder piston in lbs.,

m pressure upon cylinder piston necessary to overcome the friction of the air-pump and its gearing,

\*b the lbs. pressure upon the air-pump piston,

f the lbs. pressure upon the piston necessary to overcome the friction of the engine.

The value of m is about 2 lbs. per square inch, that of b 9.5 lbs., and f, at a fair estimate, is  $\frac{1}{5}$  of the pressure per steam gauge.

Then 
$$\frac{P-\overline{f+m} \times S-\overline{nb}}{33000}$$
 = horses' power.

EXAMPLE.—The diameter of a cylinder is 60 inches, the stroke of the piston 10 feet, the revolutions 20 per minute, the diameter of the air-pump 46 inches, and the stroke 4 feet; the pressure of the steam 20 lbs. per square inch, cut off at \( \frac{1}{4} \) the length of the stroke.

$$\begin{array}{lll} \text{Then S} = 10 \times 2 \times 20 & = 400, \\ n = 4 \times 2 \times 20 & = 160, \\ P = \text{(per rule and example, page} & = 60235.4, \\ 209) & 20.855 \times 2827.4 & = 60235.4, \\ m = 2827.4 \times 2 & = 5654.8, \\ b = \text{area of } 46 \times 9.5 & = 15788, \\ f = 20 \times .2 \times 2827.4 & = 11309.6. \end{array}$$

$$\frac{60235.4 - \overline{11309.6 + 5654.8 \times 400 - \overline{160 \times 15788}}}{33000} = 447.9 \text{ horses'}$$

power.

To find the Power of a Non-condensing Engine.

$$\frac{S \times (*P - \overline{f + 14.7})}{33000} = \text{horses' power};$$

 $f = \frac{1}{8}$  of the pressure per steam gauge.

EXAMPLE 1.—What is the power of an engine, the diameter of the cylinder being 10 inches, the stroke 4 feet, the pressure of the steam, per gauge, 60 lbs., making 45 revolutions?

$$360 \times \overline{74.7} - (7.5 + \overline{14.7}) 22.2 \times 78.54 \div 33000 = 44.98$$
, Ans.

2. The same with 30 lbs., cut off at  $\frac{1}{3}$  the stroke, and making 25 revolutions?

$$200 \times \overline{31.61} - \overline{(3.75 + 14.7)18.45} \times 78.54 \div 33000 = 6.26$$
, Ans.

<sup>\*</sup> These values are best obtained by an *Indicator*: when one is not used, refer to rule and table, page 209. In estimating the value of P, add 14.7 lbs., for the atmospheric pressure, to that indicated by the steam gauge or safety valve.

To find the Power of an Engine in the usual Methods.

$$\begin{aligned} \frac{a\times P\times S}{33000} &= \text{horses' power.} \\ \frac{(d-1)^2\times S}{5640} &= \text{nominal horses' power.} \\ \frac{d^2\times \sqrt[3]{s}}{47} &= \text{nominal horses' power.} \end{aligned}$$

When a represents area of piston, d diameter of cylinder, s stroke of piston, and P and S as in preceding page.

To find the Quantity of Water required to be Evaporated in an Engine, the Capacity of the Cylinder, Pressure of Steam, and the Number of Revolutions being given.

 $\frac{C \times 2r}{V}$ . When C represents cubic feet of steam expended in

the cylinder, r the number of revolutions, and V the volume of the steam at the pressure as shown by an indicator.

EXAMPLE.—What quantity of water will an engine require per revolution, the diameter of the cylinder being 70 inches, the stroke of the piston 10 feet, and the pressure 30 lbs. per square inch, cut off at one third of the stroke?

Area of cylinder = 3848.4 inches.  $\frac{1}{3}$  of stroke =  $\frac{120}{3}$  = 40 inches.

Then  $3848.4 \times 40 \div 1728$  . . . . . = 89.08 cubic feet. Volume of steam at the above pressure, per table, page 208, 883 cubic feet.

Hence 
$$\frac{89.08 \times 2}{883}$$
 . . . . . . . = .2017 cubic feet.

Note.—This refers to the expenditure of steam alone; in practice, however, a large quantity of water (differing in different cases) is carried into the cylinder in mechanical combination with the steam. It is also independent of any losses by waste, clearance of piston, capacity of steam chests, noziles, &c., &c.

To find the Power of an Engine necessary to raise Water to any Given Height.

 $R_{\rm ULE}$ .—Multiply the weight of the column by the velocity in feetper minute, and divide by 33000.

EXAMPLE.—It is required to raise a column of fresh water, it inches in diameter by 86 feet high, with a velocity of 128 feet perminute; what power is necessary?

86 feet  $\div 2.31$  feet, the height equal to 1 lb. per square inch = 37.2 lbs. Area of 16 inches =  $201.\times37.2$  lbs.  $\times128$  = 957081.6  $\div$  33000 = 29, horses' power. To which must be added an allowanc for friction and waste, say  $\frac{1}{6}$ .

To find the Velocity necessary to Discharge a Given Quantity of Water in any Given Time.

RULE .- Multiply the number of cubic feet by 144, and divide the product by the area of the pipe or opening.

Example.—The diameter of the pipe is 16 inches, and the quantity of water 179 cubic feet; what is the velocity?

 $179 \times 144 \div 201 = 128.2$  feet, Ans.

To find the Area, the Velocity and Quantity being given.

Rule.—Proceed as above, and divide the product by the velocity.

#### LOSS BY RADIATION.

To ascertain the Loss of Heat per Square Foot in a Second.

Let T = temperature of pipe, which is, say  $\frac{1}{20}$  less than that of the steam,

t = temperature of the air,

l = length of the pipe in feet,

d = diameter in inches,

v = velocity in feet per second,

R = radiation in degrees of heat.  $\frac{1.7l\,(\mathrm{T}-t)}{}=\mathrm{R}.$ 

Tredgold.

#### FRICTION OF ENGINES.

The side-beam Engine taken as the Standard.

The vibrating engine (oscillating) has a gain of 1.1 per cent.

The direct action engine, with slides, has a loss of 1.8 per cent.

"""" ollers, "gain" 0.8""

""" a parallel motion, has a gain of 1.3 per cent.

By experiments made in London with a non-condensing engine, it appeared that where the pressure on the piston was 12 lbs. per square inch, the friction was about 11 lbs. per square inch.

#### BLOWING OFF.

To ascertain the Loss of Heat by the blowing off of saturated Water from a Steam-boiler.

 $S-T\times E+t$  = proportion of the heat lost; and, to obtain the

loss per cent., invert this formula.

S representing the sum of the sensible and latent heats.

T the temperature of the feed water. t the difference in the temperatures of the water blowed off and supplied to the

E the quantity of water evaporated, proportionate to that blowed off, the latter being a constant quantity, and represented by 1.

Values of E at the following de  $\left\{\frac{1.5}{32} = .5 : \frac{1.75}{32} = .75 : \frac{2}{32} = 1.\frac{2.5}{32} = 1.5 : \frac{3}{32} = 2$ , &c.

The loss by blowing off at  $\frac{2}{32}$  is 11.98 per cent.

#### COMBUSTION.

COMBUSTION is one of the many sources of heat, and denotes the combination of a body with any of the substances termed Supporters of Combustion: with reference to the generation of steam, we are restricted to but one of these combinations and that is Oxygen.

All bodies, when intensely heated, become luminous. When this heat is produced by combination with oxygen, they are said to be ignited; and when the body heated is in a gaseous state, it forms what is called Flame.

No bodies appear visible, even in a faint light, below about 8700.

Carbon exists in nearly a pure state in charcoal and in soot. It combines with no more than  $2_3^2$  of its weight of oxygen. In its combustion, 1 lb. of it produces sufficient heat to increase the temperature of 13000 lbs. of water 19.

Hydrogen exists in a gaseous state, and combines with 8 times its weight of oxygen, and 1 ib. of it, in burning, raises the heat of 42000 lbs. of water  $1^{\circ}$ .

The quantity of air chemically required for the combustion of 1 lb. of bituminous coal is 150.35 cubic feet.

The bulk of the products of combustion in a furnace is about 465 cubic feet for each pound of bituminous coal burned.

An increase in the rapidity of combustion is accompanied by a diminution in the evaporative efficiency of the combustible.

#### FUEL.

With equal weights, that which contains most hydrogen, ought in its combustion, to produce the greatest quantity of heat where each kind is exposed under the most advantageous circumstances. Thus, pine wood is preferable to hard wood, and bituminous to anthracite coal.

When wood is employed as a fuel, it ought to be as dry as possible. To produce the greatest quantity of heat, it should be dried by the direct application of heat. As usually employed, it has about 25 per cent. of water mechanically combined, the heat necessary for the evaporating of which is lost.

Different fuels require different quantities of oxygen; for the different kinds of coal, it varies from 1.87 to 3 lbs. for each lb. of coal. 60 cubic feet of air is necessary to afford 1 lb. of oxygen; and making a due allowance for loss, nearly 90 cubic feet of air will be required in the furnace of a boiler for each lb. of oxygen.

#### BITUMINOUS COAL.

Accurate experiments upon the practical burning of this description of coal in a steam boiler gave an evaporation of from 6 to 9 lbs. of fresh water, under a pressure of 30 lbs. per square inch, for one pound of coal. Cumberland coal being the most, and Scotch the least effective.

Average Weight per Cubic Foot in Pounds.

Cumberland				52.844	w estern		٠	٠	٠	47.23
Virginia .				49.276	Foreign	(Eng.)		٠		49.845

#### ANTHRACITE COAL.

Experiments similar to those referred to above, gave an evaporation, with the aid of a blast, of from  $7\frac{1}{2}$  to  $9\frac{1}{2}$  lbs. of fresh water for 1 lb. of coal.

Average weight per cubic foot . . . . . . 53.5 lbs.

#### CHARCOAL.

The best quality is made from oak, maple, beech, and chestnut.

Wood will furnish, when properly burned, about 16 per cent. of coal.

A bushel of coal from hard wood weighs about 30 lbs., and from pine 29 lbs.

#### COKE.

Sixty\* bushels Newcastle coals (lumps) will make 92 bushels good coke, and 60 bushels (fine) will make 85 bushels of a similar quality.

60 bushels Newcastle and Pictou coal (one half of each) make 84 bushels inferior; 60 bushels Pictou, or Virginia coal, make 75 bushels of bad.

A bushel of the best coke weighs 32 lbs.

The production of coke by weight is about 3 that of the coal.

Coal furnishes 60 to 70 per cent. of coke by weight.

1 lb. in a common locomotive boiler will evaporate  $7^1_{\overline{\theta}}$  lbs. water at 2120 into steam.

#### WOOD.

Virginia Pine. One cord of the best description weighs about 2700 lbs.: 106.6 cubic feet being required to stow a ton.

In practical evaporating power, 24 to 23 lbs. is an equivalent to 1 lb. of the best bituminous or anthracite coals.

Western Wood. One cord of the description used by the river steamboats, is equal in evaporating qualities to 12 bushels (960 lbs.) of Pittsburgh coal.

#### MISCELLANEOUS.

One pound of anthracite coal in a cupola furnace will melt from 5 to 10 lbs. of cast iron; 80 bushels bituminous coal in an air furnace will melt 10 tons cast iron. Small coal produces about \( \frac{3}{4} \) the effect of large coal of the same species.

10 lbs, fresh water have been evaporated in a tubular boiler by  $\bar{1}$  lb. of anthracite coal.

ΓABLE showing the Weights, Evaporative Powers per Weight, and Bulk and Character of Fuels, from Report of Professor Walter R. Johnson, 1844.

Nors.—The report of Captain Mordecai embraced a greater number of specimens, and furnished other elements. A selection only has been made of such qualities of powder, results, Sc., as are considered essential for general purposes .... 14% .... DWeutsu.

Table showing the Increase of Weight in 1 lb. of various Kinds of Gunpowder, exposed to Moisture for a Period of 17 Days.

Experiments	of	Captain	Α.	Mordecai,	U.S.A.
-------------	----	---------	----	-----------	--------

Kind o	Kind of	Increase of	Kind of	Increase of
Powde	Powder.	Weight.	Powder.	Weight.
A 1 3 B 2	E 5 F F 1	Per cent. 3.55 2.09 1.91	F 2 G 6	2.95 4.42

The powders A and B were slightly caked by this exposure; E much more so; the F's were not at all caked; and the G became hard caked on the surface after 6 days' exposure.

Table showing the Relative Force, by the Musket Pendulum, of various Kinds of Gunpowder in good order, and of the same Powders dried, after Exposure to Air saturated with Moisture.

Experiments of Captain A. Mordecai, U.S.A.

of Pow-	Powder in good order.  Initial Velocity	to Moisture.	Loss of Force by the Expo- sure.	Gain of Force by the Ex-		
der.	of Ball.	sorbed.	ure retained.	of Ball.		posure.
	Feet.	Per cent.	Per cent.	Feet.	Per cent.	Per cent.
A 1	1256	20.88	.83	891	29.06	
A 4	1499	23.25	.29	1480	1.27	
A 5	1684	27.05	.31	1516	9.98	
E 5	1351	23.11	0.	1472		8.96
F 1	1404	20.83	0.	1315	6.34	
F 0	1373	22.59	.20	1143	16.75	
C 6	1856	19.53	0.	1472	20.69	

The least dense powders return nearest to their original strength. The gain by the powder E 5 arose from the circumstance that the density of it in its original state was so great as to impede its compustion; hence, the grain becoming swollen by exposure to moisture, and its density correspondingly diminished, its combustibility was increased in a greater degree than its strength was impaired by the moisture.

In a large charge, like to that of a 24-pound gun, Captain Mordecai thinks the result would not be the same.

#### Table showing the Loss of Force by Windage.

Experiments of Captain A. Mordecai, U.S.A.

#### 24-POUNDER GUN.

		Initial Velocity of Ball in Feet per second.									
Powder.	Ball.	Without Windage.	Windage, .135 Inches.	Windage, .245 Inches.	Windage, .355 Inches.						
Lbs.	Lbs.	Feet.	Feet.	Feet.	Feet.						
4	24.25	1631	1450	1332	1197						
6	24.25	1963	1702	1596	1465						

A comparison of these results shows that 4 lbs. of powder give to

a ball without windage nearly as great a velocity as is given by 6 lbs. to a ball having 0.14 inch windage, which is the true windage of a 24-pound ball; or, in other words, this windage causes a loss of nearly one third of the force of the charge.

Table showing the Loss of Force by the Vent of a Gun.
Experiments of Captain A. Mordecai, U.S.A.

#### 24-POUNDER GUN.

Powder.	Vent.	Velocity of Ball.	Powder.	Vent.	Velocity of Ball.
Lbs.	Inches.	Feet. 1251	Lbs.	Inches. closed	Feet. 1705
3	closed	1259	6	.25	1625
6	$\begin{array}{c} .25 \\ .175 \end{array}$	$1696 \\ 1702$	6	.175 closed	1627 1612

These experiments show that the loss of force, by the escape of gas from the vent is altogether inconsiderable, when compared with the whole force of the charge.

Table showing the Effect of different Descriptions of Wadding.

Experiments of Captain A. Mordecai, U.S.A.

Powe	ler.		Velocity
Kind.	Weight.	Kind of Wad.	Per Second.
	Grains.		Feet.
G 6	77	Ball wrapped in the cartridge paper, the whole crumpled into a wad	1308
4 0	l [	and inserted over the powder	1377
""	77	I felt wad on powder and I on ball .	1346
66	77	2 felt wads on powder and 1 on ball.	1482
French \	77.17	1 elastic wad on powder and 1 on }	1096
sporting (	(	ball	1169
"	77.17	2 pasteboard wads on powder	1200
. "	77.17	2 felt wads on powder	1088
G 6	77.17	2 elastic wads on powder . {	1100
		a classic wads on powder .	1079
"	77.17	2 pasteboard wads on powder.	1193
**	77.17	2 felt wads on powder	1106
"	77.17	2 felt wads on powder and 1 on ball.	1190
	77.17	Ball wrapped in the cartridge paper, as in the first experiment .	1237

The felt wads were cut from the body of a hat, weight 3 grains.

The most advantageous wads are those made of thick pasteboard, or of the ordinary cartridge paper.

The pasteboard wads were  $\frac{1}{16}$ th of an inch thick, weight 8 grains. The cartridge paper was  $3 \times 45$  inches, weight 12.82 grains.

The elastic wads were "Baldwin's indented," a little more than  $\frac{1}{10}$ th of an inch thick, weight 5.127 grains.

## Comparison of the Force of a Charge in various Arms, as determined by Experiments in Small Arms, of Rifle Calibre.

#### By Captain A. Mordecai, U.S.A.

Kind of Arm.	Lock.	Powder, A 5.	Windage.	Ball's Weight.	Velocity.
Common rifle	Percussion	Grains. 100 70	Inches. .015 .015	Grains 219 219	Feet. 2018 1755
* Hall's rifle	Flint Percussion " Flint Percussion	70 70 70 70 70 35	.000 .000 .000 .045 .015	219 219 219 219 219 218.5	1490 1240 1687 1690 947

<sup>\*</sup> Loaded at the breach.

### Practical Deductions of Captain Mordecai, suggested by his Experiments.

#### Proof of Powder.

The common eprouvettes are of no value as instruments for determining the relative force of different kinds of gunpowder.

In the proof of gunpowder a cannon pendulum should be used.

In a 24-pounder gun, new cannon powder should give, with a charge of 6 lbs., an initial velocity of not less than 1600 feet to a ball of medium weight and windage.

For the proof of powder for small arms, a small ballistic pendulum is best adapted.
The initial velocity of a musket ball (18 to the pound), of 0.05 inches windage,
with a charge of 120 grains, should be:

With new musket powder, not less than 1500 feet. With new rifle powder, not less than 1600 feet. With fine sporting powder, not less than 1800 feet.

#### Manufacture of Powder.

The powder of greatest force, whether for cannon or small arms, is produced by incorporation in the "cylinder mills."

#### Effect of Wads.

In the service of cannon, heavy wads over the ball are in all respects injurious. For the purpose of retaining the ball in its place, light grommets should be used. On the other hand, it is of great importance, and especially so in the use of small arms, that there should be a good wad over the powder for developing the full force of the charge, unless, as in the rifle, the ball has but very little windage.

#### Effect of the Size of the Grain.

Within the limits of the difference in the size of grain, which occurs in ordinary cannon powder, the granulation appears to exercise but little influence on the force of it, unless the grain be exceedingly dense and hard.

#### Effect of Glazing.

Glazing is favorable to the production of the greatest force, and to the quick combustion of the grains, by affording a rapid transmission of the flame through the mass of the powder.

#### Effect of Using Percussion Primers.

The increase of force by the use of primers, which meanly closes the vent, is constant and appreciable in amount, yet not of sufficient value to authorize a reduction of the charge.

#### BORE, WEIGHT OF CHARGES AND RANGES FOR U. S. SMALL ARMS.

Kind of Arm.	Bore.	Windage of Ball.	Powder.	l	Ball.
Musket	Inches. .69 .69 .54 .54	Inches. * .05 † .04 .525 .525 .525	110 75 35	397.5 grains. 410.2 " 218.5 " 218.5 " 218.5 "	Wad, 10.2 grains. " 10.2 " " 8.4 " " 5.5 "

\* .05679 lbs., or 18 to the pound

#### Ranges for Small Arms.

Musket. With the ball of 17 to the pound, and a charge of 110 grains of powder, sec, an elevation of 36 is required for a range of 200 yards; and for a range of 500 yards, an elevation of 30 30 is necessary, and at this distance the ball will pass brough a pine board 1 inch in thickness.

Rifle. With the charge of 70 grains, an effective range of from 300 to 350 is obtained; but as 75 grains can be used without stripping the ball, it is deemed better

to use it, to allow for accidental loss, deterioration of powder, &c.

Pistol. With the charge of 30 grains, the ball is projected through a pine board 1 inch thick at a distance of 80 vards.

#### PROOF OF POWDER.

Ordinary Proof of Powder .- One oz. with a 24 lb. ball. The mean range of new. proved at any one time, must not be less than 250 yards; but none ranging below 225 yards is received.

Powder in magazines that does not range over 180 yards is considered unserviceable.

Good powder averages from 280 to 300 yards; small grain, from 300 to 320 yards.

#### DIMENSIONS OF POWDER BARRELS.

Whole length					20.5 i	nches
Length, interior in the clear					18.	**

Franklin Institute.

#### DIGGING.

23 cubic feet of sand, or 18 cubic feet of earth, or 17 cubic feet of clay, make a ton.

18 cubic feet of gravel or earth before digging, make 27 cubic feet when dug.

#### COAL GAS.

A chaldron of bituminous coal yields about 10.000 cubic feet of gas. Gas pipes  $\frac{1}{2}$  inch in diameter supply a light equal to 20 candles.

1.43 cubic feet of gas per hour give a light equal to one good candle.

X

1.96 cubic feet equal four candles.

3. " " ten "

#### ALCOHOL

Is obtained by distillation from fermented liquors.

#### Proportion of Alcohol in 100 parts of the following Liquors:

#### CEMENT.

Ashes, 2 parts Clay, 3 " Mixed with oil, will resist the weather equal to Sand. 1 " Mixed with oil, will resist the weather equal to

#### HYDRAULIC CEMENT.

A barrel contains 300 lbs., equal to 4 struck bushels.

#### BROWN MORTAR.

One third Thomaston lime, Two thirds sand, and a small quantity of hair.

Lime and sand, and cement and sand, lessen about \( \frac{1}{3} \) in bulk when made into mortar.

#### BRICKS, LATHS, ETC.

#### Dimensions.

Common brick		8 to '	$7\frac{3}{4} \times 4\frac{1}{4} \times 2\frac{1}{2}$ inches.
Front brick .		$8\frac{1}{4}$	$\times 4\frac{1}{2}\times 2\frac{1}{2}$ "

20 common bricks to a cubic foot, when laid;

" " a foot of 8 inch wall, when laid.

Laths are  $1\frac{1}{4}$  to  $1\frac{1}{2}$  inches by four feet in length, are usually set  $\frac{1}{4}$  of an inch apart, and a bundle contains 100.

Stourbridge fire-brick,  $9\frac{1}{8} \times 4\frac{5}{8} \times 2\frac{3}{8}$  inches.

#### HAY.

10 cubic yards of meadow hay weigh a ton. When the hay is taken out of large or old stacks, 8 and 9 yards will make a ton.

11 to 12 cubic yards of clover, when dry, weigh a ton.

#### HILLS IN AN ACRE OF GROUND.

ILLUSTRATION.—If 4 inch round iron is worth \$135 per ton, then and iron is worth \$100 per ton, for 27 is to 20 as 135 to 100.

#### POWER REQUIRED TO PUNCH IRON AND COPPER PLATES.

Through an Iron Plate, with a Punch 1/2 Inch in Diameter.

.08	inches	thick					6025	bs.
.17	"	"					11950	"
.24	"	66		_	_	_	17100	44

Through a Copper Plate, with a Punch  $\frac{1}{2}$  Inch in Diameter.

.08	inches	thick				3983 lbs.
.17	"	"				7833 "

The force necessary to punch holes of different diameters through metals of various thicknesses, is directly as the diameter of the hole and the thickness of the metal.

#### To ascertain the Force necessary to Punch Iron or Copper Plates.

RULE.—Multiply, if for iron, 150000, and if for copper, 96000, by the diameter of the punch and the thickness of the plate, each in inches; the product is the pressure in pounds.

The use of oil reduces the above 8 per cent.

#### IRON.

Cast Iron expands  $\frac{1}{162000}$  of its length for one degree of heat; greatest change in the shade in this climate,  $\frac{1}{1170}$  of its length; exposed to the sun's rays,  $\frac{1}{1000}$ ; shrinks in cooling from  $\frac{1}{85}$  to  $\frac{1}{98}$  of its length; is crushed by a force of 93,000 lbs. upon a square inch; will bear, without permanent alteration, 15,300 lbs. upon a square inch, and an extension of  $\frac{1}{1200}$  of its length.

Weight of modulus of elasticity for a base of an inch square, 18,400,000 lbs.; height of modulus of elasticity, 5,750,000 feet.

Wrought Iron expands  $\frac{1}{143000}$  of its length for one degree of heat; will bear on a square inch, without permanent alteration, 17,800 lbs., and an extension in length of  $\frac{1}{1400}$ ; cohesive force is diminished  $\frac{1}{3000}$  by an increase of 1 degree of heat.

Weight of modulus of elasticity for a base of an inch square, 24,920,000 lbs.; height of modulus of elasticity, 7,550,000 feet.

Compared with cast iron, its strength is 1.12 times, its extensibility 0.86 times, and its stiffness 1.3 times.

#### WEIGHT OF SQUARE ROLLED IRON,

From 1 Inch to 12 Inches,

AND ONE FOOT IN LENGTH

	_	AND	ONE FOO	TINL	ENGTH.		
Size in inches.	Weight in pounds.	Size in inches.	Weight in pounds.	Size in inches.	Weight in pounds.	Size in inches.	Weight in pounds.
1. do de de de de de de de de de de de de de	.013 .053 .118 .211 .475 .845 1.320 1.901 2.588 3.380 4.278 5.280 7.604 8.926 0.352 1.883	— তি - বিশ্ব ক্র বিশ্ব করি করি করি করি করি করি করি করি করি করি	13.520 15.263 17.112 19.066 21.120 23.292 25.560 27.939 30.416 33.010 35.704 38.503 41.408 44.418 47.534 50.756 54.084 57.517 61.055	19-40-19-10-1-10-10-10-10-10-10-10-10-10-10-10-1	64.700 68.448 72.305 76.264 80.333 84.480 93.168 97.657 102.240 110.695 111.756 116.671 121.664 132.040 142.816 154.012 165.632 177.672	7. de de de de de de de de de de de de de	190.136 203.024 216.336 230.068 244.220 258.800 273.792 305.056 321.332 337.920 355.136 372.672 390.628 408.960 427.812 447.024 466.684 486.656

Example.—What is the weight of a bar of rolled iron 12 inches square and 12 inches long?

In column 1st find  $1\frac{1}{27}$  and opposite to it is 7.604 pounds, which is 71hs. and  $\frac{604}{1000}$ 

of a lb. If the lesser denomination of ounces is required, the result is obtained as follows: Multiply the remainder by 16, pointing off the decimals as in multiplication of decimals, and the figures remaining on the left of the point indicate the number of ounces.

Thus, 
$$\frac{604}{1000}$$
 of a lb. = .604  
 $\frac{16}{9.664}$  ounces.

The weight, then, is 7 lbs.  $9.\frac{664}{1000}$  ounces.

If the weight for less than a foot in length was required, the readlest operation is this:

EXAMPLE.—What is the weight of a bar 64 inches square and 93 inches long? In column 5th, opposite to 64, is 132.040, which is the weight for a foot in length.

$64\times12$ inches	s = 132.040
6. "	$is \frac{1}{2} = 66.020$
3. "	$\begin{array}{cccccccccccccccccccccccccccccccccccc$
.1 "	is $\frac{7}{6}$ of $3 = 5.5016$
· <del>Ī</del> "	is $\frac{1}{2}$ of $\frac{1}{2}$ = 2.7508
	2824
9.3	$=107.\frac{2824}{1000}$ pounds.

139.920 6. [116.592 Hosted by Google **EXAMPLES.**—What is the weight of a bar of iron  $5\frac{1}{4}$  in. in breadth by  $\frac{3}{4}$  in. thick? In column 4, page 250, find  $5\frac{1}{4}$ , and below it, in column 5,  $\frac{3}{4}$ ; and opposite to that is 13.307, which is 13 lbs. and  $\frac{307}{10000}$  of a lb.

For parts of a lb. and of a foot, operate precisely similar to the rule laid down for table, page 247.

#### CAST IRON.

To ascertain the weight of a cast iron Bar or Rod, find the weight of a wrought in bar or rod of the same dimensions in the preceding tables, and from the weight duct the  $\frac{2}{2\eta}$ th part; or say,

As 486.65 . 450.55 :: the weight in the table : to the weight required. Thus,

What is the weight of a piece of cast iron 4×33×12 inches?

In table, page 250, the weight of a piece of wrought iron of these dimensions is 692 lbs.

Then 486.65: 450.55:: 50.692: 46.93 lbs.

# g find the Weight of a piece of Cast or Wrought Iron of any size or shape.

By the rules given in Mensuration of Solids (see page 81), ascertain the number cubic inches in the piece, multiply by the weight of a cubic inch, and the duct will be the weight in pounds.

#### EXAMPLES.

What is the weight of a block of wrought iron 10 inches square by 15 inches in gth?

 $10 \times 10 \times 15 = 1500$  cubic inches. .2816 weight of a cubic inch.

422,4000 pounds.

Vhat is the weight of a cast iron ball 15 inches in diameter ?

By table, page 255 == 176.7149 cubic inches.

.2607 weight of a cubic inch.

460.6957 pounds.

# WEIGHT OF CAST IRON PIPES OF DIFFERENT THICKNESSES, From 1 Inch to 36 Inches Bore,

AND ONE FOOT IN LENGTH.

9.	4	28.985	18.	5	71.258	l	l i	

The above weights include the laps on the sheets for riveting and caulking.

The weights of the rivets are not added; the *number* per lineal foot of pipe depends upon the distance they are placed apart, and their szze upon the diameter of the pipe.

Hosted by Google

## COPPER.

### To ascertain the Weight of Copper.

RULE.—Find by calculation the number of cubic inches in the piece, multiply them by .32118, and the product will be the weight in pounds.

Example.—What is the weight of a copper plate  $\frac{1}{2}$  an inch thick by 16 inches square?

BRAZIER'S SHEETS. 30×60 inches, and from 12 to 100 lbs. per square foot.

SHEATHING COPPER. 14×48 inches, and from 14 to 34 oz. per square foot.

#### LEAD.

## To ascertain the Weight of Lead.

RULE.—Find by calculation the number of cubic inches in the piece, and multiply the sum by .41015, and the product will be the weight in pounds.

Example.—What is the weight of a leaden pipe 12 feet long,  $3_4^3$  inches in diameter, and 1 inch thick?

By rule in Mensuration of Surfaces, to ascertain the area of cylindrical rings,

Area of  $(3\frac{3}{4}+1+1) = 25.967$ " "  $3\frac{3}{4} = 11.044$ 

Difference,  $\overline{14.923}$ , or area of ring. 144 = 12 feet.  $\overline{2148.912} \times .41015 = 881.376$  pounds.

## BRASS.

To ascertain the Weight of ordinary Brass Castings.

Rule.—Find the number of cubic inches in the piece, multiply by .3112, and the product will be the weight in pounds.

## CABLES AND ANCHORS.

Table showing the Size of Cables and Anchors proportioned to the Tonnage of Vessels.

Tonnage of vessel.	Cables. Circumference in inches.	Chain Cables. Diameter in inches.	Proof in tons.	Weight of Anchor in pounds.	Weight of a fathom of Chain.	Weight of a fathom of Cable.

1000	24.	2.	60.	7168	208.	134.6

The proof in the U. S. Naval Service is about  $12\frac{1}{2}$  per cent. less than the above for the larger sizes, and from 25 to 30 per cent. for the smaller.

The mean results of experiments at the U.S. Navy Yard, Washington, D.C., give for the cohesive force of chain iron, per square inch, 43500 lbs.

The diameter of chain cables assigned to the tonnage of vessels as above is based upon the practice of the Merchant Service, where shorter and fewer chains are used than in the Naval Service; hence heavier chains and anchors are necessary.

A first class ship of the line has three chains 24 inches in diameter and 180 fathoms in length, and anchors of 9000 lbs. weight.

cables. 259

## To ascertain the Strength of Cables.

Multiply the square of the circumference in inches by 120, and the product the weight the cable will bear in pounds, with safety.

## To ascertain the Weight of Manilla Ropes and Hawsers.

Multiply the square of the circumference in inches by .03, and the product is the weight in pounds of a foot in length.

This is but an approximation, and yet it is sufficiently correct for many purposes.

TABLE showing what Weight a Hemp Rope will bear with Safety.

Circumference.	Pounds.	Circumference.	Pounds.	Circumference.	Pounds.
1. 14-14-11-11-11-11-11-11-11-11-11-11-11-1	200. 312.5 450. 612.5 800. 1012.5 1250. 1512.5	3.4.14-421014 4.14-421014 4.14-55	2450. 2812.5 3200. 3612.5 4050. 4512.5 5000. 5512.5	6.14-6254 6.47-7.77-6254	7200. 7812.5 8450. 9112.5 9800. 10512.5 11250. 12012.5
3. 3.	1800. 2112.5	5.4 5.3 5.3	6050. 6612.5	8.	12800.

## To ascertain the Strength of Ropes.

Multiply the square of the circumference in inches by 200, and it gives the weight the rope will bear in pounds, with safety.

## To ascertain the Weight of Cable-laid Ropes.

Multiply the square of the circumference in inches by .036, and the product is the weight in pounds of a foot in length.

## To ascertain the Weight of Tarred Ropes and Cables.

Multiply the square of the circumference by 2.13, and divide by 9; the product is the weight of a fathom in pounds.

Or, multiply the square of the circumference by .04, and the product is the weight of a foot.

For the ultimate strength, divide the square of the circumference in inches by 5; the product is the weight in tons.

## WIRE ROPE.

Table of Experiments made by the British Admiralty with Wire and Hempen Rope and Chain.

#### COMPARATIVE STRENGTH.

Circumference of Wire Rope.	Circumference of	Diameter of	Breaking
	Hempen Rope.	Chain.	Weight.
Inches.	Inches.	Inches.  1/2 13 18	Lbs.
2	5		14224
3	8		26880
4	10	$\frac{31}{32}$	43232

#### WEIGHT PER FATHOM.

Wire Rope.	Hempen Rope.	Chain.
Lbs. 3.875	Lbs. 6.	Lbs. 1.6
8.5	14.	36
14.6125	25.	53

#### Notes.

A square inch of hemp fibres will support a weight of 9200 lbs.

The utmost strength of a good hemp rope is 6400 lbs. to the square inch; in practice it should not be subjected to more than half this strain. It stretches from  $\frac{1}{2}$  to  $\frac{1}{4}$ , and its diameter is diminished from  $\frac{1}{4}$  to  $\frac{1}{7}$  before breaking.

A difference in the quality of hemp may produce a difference of ‡ in the strength of ropes of the same size.

The strength of Manilla is about 1 that of hemp.

White ropes are one third more durable.

Hosted by Google

## PILING OF BALLS AND SHELLS.

To find the Number of Balls in a Triangular Pile.

RULE.—Multiply continually together the number of balls in one side of the bottom row, and that number increased by 1; also, the same number increased by 2;  $\frac{1}{h}$  of the product will be the answer.

EXAMPLE.—What is the number of balls in a pile, each side of the base containing 30 balls?

 $30 \times 31 \times 32 \div 6 = 4960$ , Ans.

To find the Number of Balls in a Square Pile.

Rule.—Multiply continually together the number in one side of the bottom course, that number increased by 1, and double the same number increased by 1;  $\frac{1}{8}$  of the product will be the answer.

EXAMPLE.—How many balls are there in a pile of 30 rows  $^{7}$  30×31×61÷6 = 9455, Ans.

To find the Number of Balls in an Oblong Pile.

RULE —From 3 times the number in the length of the base row subtract one less than the breadth of the same; multiply the remainder by the same breadth, and the product by one more than the same, and divide by 6.

EXAMPLE.—Required the number of balls in an oblong pile, the numbers in the base row being 16 and 7?

 $16\times3-\overline{7-1}\times7\times\overline{7+1}\div6=392$ , Ans.

To find the Number of Balls in an Incomplete Pile.

RULE.—From the number in the pile, considered as complete, subtract the number conceived to be in the upper pile which is wanting.

# WEIGHT AND DIMENSIONS OF BALLS AND SHELLS.

The weights of these may be found by the rules in Mensuration; also, in the tables, pages 237, 238, and 255.

To find the Weight of an Iron Ball from its Diameter.

An iron ball of 4 inches diameter weighs 8.736 lbs. Therefore,  $\frac{8.736}{64}$  of the cube of the diameter is the weight, for the weight of spheres is as the cubes of the diameters.

Example.—What is the weight of a ball 10 inches in diameter?  $\frac{8.736}{6.0}$  of  $10^3 = 136.5$  lbs., Ans.

To find the Diameter from the Weight.

 $\mathbf{E}_{\mathbf{XAMPLE}}.$ —What is the diameter of an iron ball, its weight being 99.5 lbs. ?

 $\sqrt[3]{\frac{64}{8,736}} \times 99.5 = 9$  inches, Ans.

Or, multiply the cube of the diameter in inches by .1365, and the sum is the weight. And divide the weight in pounds by .1365, and the cube root of the product is the diameter.

## To find the Weight of a Leaden Ball.

A leaden ball of 4 inches diameter weighs 13.744 lbs. Therefore,  $\frac{18.764}{64}$  of the cube of the diameter.

 $\mathbf{E_{XAMPLE}}$ .—What is the weight of a leaden ball 10 inches in diameter?

$$\frac{13.744}{64}$$
 of  $10^3 = 214.7$  lbs., Ans.

Inversely,  $\sqrt[3]{\frac{64}{13.744}} \times \text{weight} = \text{diameter.}$ 

Or, multiply the cube of the diameter in inches by .2147, and the sum is the weight. And divide the weight in pounds by .2147, and the cube root of the product is the diameter.

## To find the Weight of a Cast Iron Shell.

Multiply the difference of the cubes of the exterior and interior diameter in inches by .1365.

 ${\tt Example.}$  —What is the weight of a shell having 10 and 8.50 inches for its diameters ?

$$10^3 - 8.5^3 \times .1365 = 52.6 \text{ lbs.}, Ans.$$
Hosted by Google

## MEASURING OF TIMBER.

SAWED OF HEWN timber is measured by the cubic foot.

The unit of board measure is a superficial foot 1 inch thick.

#### To measure Round Timber.

Multiply the length in inches by the square of \(\frac{1}{4}\) the mean girth m inches, and the product, divided by 1728, will give the contents in cubic feet.

When the length is given in feet, and the girth in inches, divide by 144.

When all the dimensions are in feet, the product is the content without a division

Or, 
$$\frac{L \times C^2}{16}$$
:144, L the length in feet, and C half the sum of the circumferences of the two ends in inches.

Or, ascertain the contents by the rules in Mensuration of Solids, page 82, and multiply by .75734.

EXAMPLE.—The girths of a piece of timber are 31.416 and 62.832 inches, and its length 50 feet; required its contents.

$$\frac{31.416+62.832}{2}$$
  $\div 4 = 11.781$ , and  $11.781^2 \times 50 \div 144 = 48.1916$  cubic feet,  $Ans$ .

Or, 
$$\frac{50 \times 47.124^2}{16}$$
  $\div 144 = 48.1916$  cubic feet.

Or, 
$$10^3 - 20^3 - 20 - 10 \times .7854 \times \frac{600}{3} = 63.632 \times .75734 = 48.1916$$
 cubic feet,  $Ans$ .

## To measure Square Timber.

Multiply the length in inches by the breadth in inches, and the product by the depth in feet; divide by 144, and the quotient is the content.

Note .- When all the dimensions are in feet, omit the divisor of 144.

#### BOARD MEASURE.

Multiply the length by the breadth, and the product is the content.

Norm.—This rule only applies when all the dimensions are in feet. When either the length or breadth are given in inches, divide their product by 12; and when all the dimensions are in inches, divide it by 144.

Pine spars, from 10 to 4½ inches in diameter inclusive, and spruce spars, are to be measured by taking the diameter, clear of bark, at ½ of their length from the large end.

Spars are usually purchased by the inch diameter; all under 4 inches are considered poles.

Spruce spars of 7 inches and less should have 5 feet in length for every inch diameter. Those above 7 inches should have 4 feet in length for every inch diameter.

Hosted by Google

#### DISPLACEMENT OF VESSELS.

## To ascertain the Displacement of a Vessel.

Rule.—Multiply the mean of the lengths of the keel and between the perpendiculars, by the area of the immersed midship section in square feet, and divide this product, if for a Ship of the Line or a full-built Merchantman, by 42; if for a Frigate or an ordinary Merchantman, by 43; if for a Sloop or a Naval Steamer, by from 44 to 47; if for a Merchant Sea Steamer, by from 45 to 50; and if for a River Steamer, by from 48 to 56.

EXAMPLE.—The lengths of a 1st class Sea Steamer, now (1847 constructing at the Navy Yard, Gosport, are as follows:

$$250+236 \div 2 = 243$$
.  
Then  $\frac{243 \times 650}{44.5} = 3547 + \text{tons}$ .

Note.—The exact displacement is 3535 tons.

Each man in a vessel requires for his own weight, clothes, &c., and stores, water, &c., for one month, a displacement of 663 lbs.

#### EXTERNAL SURFACE OF HULLS OF VESSELS.

To ascertain the Bottom and Side Surface of a Vessel.

Rule.—Multiply the length of the curve of the midship section, taken from the top of the upper or spar deck beams on one side, to the same point on the other (omitting the width of the keel), by the mean of the lengths of the keel and between the perpendiculars, and take from  $\frac{8.5}{100}$  to  $\frac{90}{100}$  of the product (according to the capacity of the vessel) for the surface required in square feet.

EXAMPLE.—The lengths of a 2d class Steamer, now (1847) constructing at the Navy Yard, Brooklyn, are as follows:

And the curved surface of the midship section is 76 feet; what is the surface?

$$210+201 \div 2 = 205.5$$
.  
Then  $\frac{205.5 \times 76 \times 87}{100} = 13,587$  square feet.

Mote.-The exact surface is 13,650 square feet.

## MISCELLANEOUS NOTES.

#### ON MATERIALS, ETC.

Wood is from 7 to 20 times stronger transversely than longitudinally.

In Buffon's experiments, b, d, and l being the breadth, depth, and length of a piece of oak in inches, the weight that broke it in pounds was  $bd^2\left(\frac{54.25}{l}10\right)$ .

The hardness of metals is as follows: Iron, Platina, Copper, Silver, Gold, Tin, Lead.

A piece spliced on to strengthen a beam should be on its convex side:

Springs are weakened by use, but recover their strength if laid by.

A pipe of cast iron 15 inches in diameter and .75 inches thick will sustain a head of water of 600 feet. One of oak, 2 inches thick, and of the same diameter, will sustain a head of 180 feet.

When the cohesion is the same, the thickness varies as the height x the diameter.

When one beam is let in, at an inclination to the depth of another, so as to bear in the direction of the fibres of the beam that is cut; the depth of the cut at right angles to the fibres should not be more than  $\frac{1}{3}$  of the length of the piece, the fibres of which, by their cohesion, resist the pressure.

Metals have five degrees of lustre—splendent, shining, glistening, glimmering, and dull.

The Vernier Scale is  $\frac{11}{10}$ , divided into 10 equal parts; so that it divides a scale of 10ths into 100ths when the lines meet even in the two scales.

A luminous point, to produce a visual circle, must have a velocity of 10 feet in a second, the diameter not exceeding 15 inches.

Tides. The difference in time between high water averages about 49 minutes each day.

In Sandy soil, the greatest force of a pile-driver will not drive a pile over 15 feet.

A fall of  $\frac{1}{10}$  of an inch in a mile will produce a current in rivers.

Melted snow produces about 1 of its bulk of water.

All solid bodies become luminous at 800 degrees of heat.

At the depth of 45 feet, the temperature of the earth is uniform throughout the year.

A Spermaceti candle .85 of an inch in diameter consumes an inch in length in 1 hour.

Silica is the base of the mineral world, and Carbon of the organized.

Sound passes in water at a velocity of 4708 feet per second.

#### SOLDERS.

For Lead, melt 1 part of Block tin; and when in a state of fusion, add 2 parts of Lead. Resin should be used with this solder.

For Tin, Pewter 4 parts, Tin 1, and Bismuth 1; melt them together. Resin is also used with this solder.

For Iron, tough Brass, with a small quantity of Borax.

#### CEMENTS.

Glue. Powdered chalk added to common glue strengthens it.

A glue which will resist the action of water is made by boiling 1 pound of glue in 2 quarts of skimmed milk.

Soft Cement. For steam-boilers, steam-pipes, &c. Red or white lead in oil, 4 parts; Iron borings, 2 to 3 parts.

Hard Cement. Iron borings and salt water, and a small quantity of sal ammoniac with fresh water.

#### PAINTS.

		Wh	ite Pe	aint.		
White-lead, gr	round ii	ı oil			Inside work. 80.	Outside work. 80
Boiled oil .					14.5	9
Raw oil .						9

---------------	-----	-------	----

Lampblack Litharge Japan varnish	•	•	28 1 1	Linseed oil, boiled Spirits turpentine	•	<b>7</b> 3
oupun furnion	•	•	- 1			

The varnish and turpentine are added last.

## Liquid Olive Colour.

Olive paste .	61.5	Dryings .		3.5
Boiled oil	29.5	Japan varnish		2.
Spirits turpentine	5.5			

## Paint for Tarpaulins (Olive).

Liquid olive colour	 100	Spirits turpentine	6
Beeswax	6		

1 square yard requires 2 lbs. for 3 coats.

Dissolve the beeswax in the turpentine, and mix the paint warm.

## LACKER for Iron Ordnance.

Black-lead, pu	lveri	zed	12	Red-lead .		12
Litharge .			5	Lampblack		5
Linseed oil	•		66			

Boil it gently for about 20 minutes, stirring it constantly during that time

# Lacker for Small Arms, or for Water Proof Paper.

Beeswax Boiled linseed oil	٠	18. 3.5	Spirits turpentine	•	80

Heat the ingredients in a copper or earthen vessel over a gentle fire, in a water bath, until they are well mixed.

## Lacker for Bright Iron Work.

Linseed oil, boiled .	80.5	Litharge	5.5
White-lead, ground in oil,	11.25	Pulverized rosin	2.75

Add the litharge to the oil; let it simmer over a slow fire for 3 hours; strain it, and add the rosin and white-lead; keep it gently warmed, and stir it until the rosin is dissolved.

# Staining Wood and Ivory.

Yellow. Dilute nitric acid will produce it on wood.

Red. An infusion of Brazil wood in stale urine, in the proportion of a lb. to a gallon for wood, be laid on when boiling hot, and should be laid over with alum water before it dries.

Or, a solution of dragon's blood, in spirits of wine, may be used.

Black. Strong solution of nitric acid, for wood or ivory.

Mahogany. Brazil, Madder, and Logwood, dissolved in water and put on hot.

Blue. Ivory may be stained thus: Soak it in a solution of verdigris in nitric acid, which will turn it green; then dip it into a solution of pearlash boiling hot.

Purple. Soak ivory in a solution of sal ammoniac into four times its weight of nitrous acid.

#### TRACING PAPER.

By weight.	Spirits of turpentine	•			в
	Resin	•	•.		1
	Boiled nut-oil			• •	1

Use with a soft brush or sponge.

Spermaceti candles.						5.352
Wax candles						5.892
		_		• • •	 ~ -	

Wax. The consumption of a wax candle is 125 grains per hour in still air; the intensity of its light is  $\frac{1}{11}$ th that of a Carcel lamp.

Six in a pound,  $\frac{3}{10}$  "  $\times$  9 " " An inch of one, 1 inch diameter, will burn for  $1\frac{1}{2}$  hours = .0277 lbs.

Spermaceti. The consumption of a spermaceti candle is .0246 lbs. per hour, and its light is  $\frac{1}{11}$ th of a Carcel lamp.

Three in a pound,  $\frac{9}{10}$  inch diameter,  $\times 15$  inches long. Four in a pound,  $\frac{8}{10}$  "  $\times 13\frac{1}{2}$  " "

Tallow. The consumption of a tallow candle is about .025 lbs. per hour, the intensity of its light is from  $\frac{1}{12}$  to  $\frac{1}{16}$  that of a Carcel lamp.

Three in a pound, 1 inch diameter,  $\times 12\frac{1}{2}$  inches long. Three in a pound,  $\frac{9}{10}$  "  $\times 15$  " " Four in a pound,  $\frac{10}{10}$  " "  $\times 13\frac{3}{4}$  " "

C. E. and A. Journal.

#### WAVES.

The undulations of waves are performed in the same time as the oscillations of a pendulum, the length of which is equal to the breadth of a wave, or to the distance between two neighbouring cavities or eminences.

#### STRENGTH OF ICE.

Ice 2 inches thick will bear infantry.

" 4 " cavalry or light guns.
" 6 " heavy field-guns.

" 8 " 24-pounder guns on sledges; weight not over 1000 lbs. to a square foot.

## DIRECTIONS FOR PREPARING AND FITTING BABBITT'S ANTI-ATTRITION METAL.

Melt 4 pounds of copper; add, by degrees, 12 pounds best quality Banca tin, 8 pounds regulus of antimony, and 12 pounds more of tin, while the composition is in a melted state.

After the copper is melted and 4 or 5 pounds of tin have been added, the heat should be reduced to a dull red, to prevent oxydation; then add the remainder of the metal as above.

In melting the composition, it is better to keep a small quantity

of powdered charcoal on the surface of the metal.

The above composition is called hardening; for lining, take one pound of this hardening, and melt with it 2 pounds Banca tin, which produces the lining metal for use. Thus the proportions for lining metal are 4 pounds of copper, 8 of regulus of antimony, and 96 of tin.

The article to be lined, having been cast with a recess for the lining, is to be nicely fitted to a former, which is made the same

shape as the bearing.

Drill a hole in the article for the reception of the metal, say half or three quarters of an inch, according to the size of it. Coat over the part not to be tinned with a clay wash; wet the part to be tinned with alcohol, and sprinkle on it powdered sal ammoniac; heat it till a fume arises from the sal ammoniac, and then immerse it in melted Banca tin, care being taken not to heat it so that it will oxydize.

After the article is tinned, should it have a dark colour, sprinkle a little sal ammoniac on it, which will make it of a bright silver colour, and cool it gradually in water; then take the *former*, to which the article has been fitted, and coat it over with a thin clay wash, and warm it so that it will be perfectly dry, heat the article until the tin begins to melt, lay it on the *former*, and pour in the metal, which should not be so hot as to oxydize, through the drilled hole, giving it a head, so that as it shrinks it will fill up.

After it is sufficiently cool, remove the former.

P.S.—A shorter method may be adopted when the work is light enough to handle quickly, viz: when the article is prepared for tinning, it may be immersed in the lining metal instead of the tin, brushed lightly in order to remove the sal ammoniac from the surface, placed immediately on the former, and lined at the same heating.

#### SOLDERING FLUID FOR SOFT SOLDER.

To 2 fluid ounces of muriatic acid add small pieces of zinc until bubbles cease to rise. Add half a tea-spoonful of sal ammoniac and 2 fluid ounces of water.

By the application of this, Iron or Steel may be soldered without being previously tinned.

#### FALL OF RAIN AND SNOW.

The average quantity of water which falls in rain and snow at Philadelphia in one year is 36 inches.

# ANGLES OF EQUILIBRIUM AT WHICH VARIOUS SUBSTANCES STAND, AS TAKEN WITH A CLINOMETER.

Table of the Diameter and Length of Gas-pipes to transmit given Quantities of Gas to Branch Pipes and Burners.—Dr. Urr.

No. of cubic feet of gas per hour.	Length of pipe in feet.	Diameter of pipe in inches.
50	100	0.40
250	200	1.
500	600	1.97
700	1000	2.65
1000	1000	3.16
1500	1000	3.87
2000	1000	4.47
2000	2000	5.32
2000	4000	6.33
2000	6000	7.
6000	1000	7.75
6000	2000	9.21
8000	1000	8.95
8000	2000	16.65

These dimensions are applicable to the mains which conduct the gas to the places where it is to be used. If they send off branches for burners, the diameter may be reduced, or the length may be greater. For example, if a pipe of 5.32 inches, which transmits 2000 cubic feet through a length of 2000 feet, gives off, in this space, 1000 cubic feet of gas, then the same diameter can continue to transmit the gas through a length of 2450 feet.

#### LIMITS OF VEGETATION IN THE TEMPERATE ZONE.

The vine ceases to grow at about 2300 feet above the level of the sea; Indian corn, at 2800; oak, at 3350; walnut, at 3600; ash, at 4800; yellow pine, at 6200; and fir, at 6700.

Perpetual Snow. Under the equator, at 15,800 feet above the level of the sea; in latitude 45°, at 8400; and in latitude 65°, at 5000.

Hempen Cords. When twisted, will support the following weights to the square inch of their section.

Hosted by GOOGLE

Practical Deductions from above and previously-given Results.

Asphaltum is the best composition for resisting moisture, and, being a slow conductor of heat, it is best adapted where economy of heat and dryness are required.

Slate is a very dry material, but, from its quick conducting power,

it is ill adapted for the retention of heat.

Plaster of Paris and Woods are well adapted for the lining of rooms, being the warmest substances, while Hair and lime, being a quick conductor, is one of the coldest compositions.

Fire-brick absorbs much heat, and is therefore well adapted for the lining of fire-places, furnaces, &c.; while, on the contrary, Iron, being a high conductor of heat, is one of the worst of substances for this purpose.

Common brick is not a very slow conductor of heat, it is 1.8 times higher in the scale than oak-wood, and about 1/37th lower than fire-

brick.

Hard marble absorbs more moisture than soft.

Table of Reciprocals, or Decimal Expressions, from 1 to 250.

50	.020000	100	.010000	150	.006667	200	.005000	250	.004000

Use of the foregoing Table.—In the column of reciprocals is given the decimal expression for any number from 1 to 250, which number is the denominator of a fraction.

Thus: .033333 is the decimal expression for  $\frac{1}{30}$ . Hence for  $\frac{7}{30}$  it would be .033333  $\times$  7 = .233331.

## To find the Mean Pressure of Steam on a Piston.

Rule.—Divide the length of the stroke, added to the clearance in the cylinder at one end, by the length of the stroke at which the steam is cut off, added to the clearance,\* and the quotient will express the relative expansion it undergoes.

Find in the following table, in the column of expansion, a number corresponding to this; take out the multiplier opposite to it, and multiply it into the full pressure of the steam per square inch as it enters the cylinder.†

Table showing the Mean Pressure of Steam.

Expansion.	Multiplier.	Expansion.	Multiplier.	Expansion.	Multipne.
1.0 1.1 1.2 1.3 1.4 1.5 1.6 1.7 1.8 1.9 2.1 2.1 2.2 2.3 2.4 2.6 2.7	Multiplier.  1.000 .995 .985 .971 .955 .937 .919 .900 .882 .864 .847 .830 .813 .797 .781 .766 .752 .738	3.4 3.5 3.6 3.7 3.8 4.1 4.2 4.4 4.5 4.6 4.7 4.8 9.5.1	Multiplier.  .654 .644 .634 .624 .615 .605 .597 .588 .580 .572 .564 .556 .549 .542 .535 .522 .516	5.8 5.9 6.1 6.2 6.3 6.4 6.5 6.6 7 7.1 7.2 7.3 7.4 7.5	Multiplie.  479 474 470 466 462 458 454 450 446 442 438 434 430 427 423 420 417
2.7 2.8 2.9 3.1 3.2 3.3	.738 .725 .712 .700 .688 .676	5.2 5.3 5.4 5.5 5.6 5.7	.516 .510 .504 .499 .494 .489	7.5 7.6 7.7 7.8 7.9 8.	.414 .411 .408 .405 .402 .399

Example.—Suppose the steam to enter the cylinder at a pressure of 34.7 lbs. per square inch, and to be cut off at \(\frac{1}{4}\) the length of the stroke of the piston. The stroke being 10 feet,

10 feet = 120 inches + .5 for clearance = 120.5,  
stroke 
$$\frac{1}{4}$$
 = 30 inches + .5 " = 30.5.

Then  $120.5 \div 30.5 = 3.95$ , the relative expansion, which falls between 3.9 and 4. Referring to the table, the multiplier for 3.9 is 605, and the difference between that and the multiplier for 4 is 008. Hence, multiplying 008 by .5, and subtracting the product .004 from .605, the remainder, .601, is the multiplier for 3.95. Therefore, .601 \times 34.7 lbs. = 20.855 lbs. per square inch, the mean effective pressure of the piston required.

† A pressure equal to that of the vacuum existing must be added to the pressure of the boiler, as indicated by the steam gauge.

Hosted by Google

<sup>\*</sup> When great accuracy is required, the space between the cylinder and the steam valve must be added to the clearance.

#### MARINE ENGINES.

#### NAVAL STEAMERS WITH SIDE WHEELS.

"Missouri." Length between perpendiculars, 220 feet; beam, 40 feet; depth of hold, 23.5 feet; with a displacement of 2800 tons, at a draught of water of 18.3 feet.

Immersed Section, 550 square Feet.

Cylinders. Two, each of 215 cubic feet in capacity.

Condensers. 75 cubic feet in each. Air Pumps. 50 cubic feet in each.

Force Pumps. 74 inches diameter by 46 inches stroke.

Water Wheels. 28 feet in diameter by 11 feet in width, 21 arms in each; buckets (divided both in depth and length), 14 and 16 inches.

Shafts (Wrought iron). Diameters of journals, 17×181, and 12×15 inches.

Boilers. 6000 square feet of fire and flue surface; flues 40 feet in length, including steam chimney. Grates. 260 square feet. Steam Room. 1770 cubic feet.

Pressure. Average, 10 lbs. per square inch, cut off at \( \frac{1}{3} \) of the stroke of the piston: attainable, 20 lbs.

Revolutions. From 12 to 183 per minute. Dip of Wheel. 5 feet at load-line

Consumption of Fuel. 35 to 40 tons of bituminous coal per day.

Weights. Engines, Boilers, Water Wheels, Water in boilers, Coal bunkers, Engineer's Stores, Tools, &c., &c., 490 tons of 2240 lbs.; viz.:

Engines			47 tons.
Boilers and smoke pipe		Engineers' stores, tools, &c.	7 "
Water in boilers .	82 "	Coal bunkers	23 "

HULL. Of Live Oak and copper fastened. Launching weight, 1280 tons.

Rig. Full barque.

Armament. Two 10-inch chambered guns on pivots, and eight 8-inch chambered guns on carriages.

NOTE .- The "Mississippi" and this vessel differ alone in the design of their engines; the "Missouri" having those of direct action, at an inclination of 26° 30', and the former having vertical side levers, with equal capacity of cylinders, the stroke of the piston being 7 feet.

Their hulls should have had 20 feet additional length.

"POWHATAN." INCLINED ENGINES. Length between perpendiculars, 250 feet; beam, 45 feet; depth of hold, 26.5 feet; with a displacement of 3600 tons, at a draught of water of 18.5 feet.

Immersed Section, 663 square Feet.

Cylinders. Two, of 70 inches in diameter by 10 feet stroke of piston; capacity of piston space, 534.5 cubic feet.

Air Pumps. 52.125 inches in diameter by 42 inches stroke of piston = 51.5 cubic feet in capacity.

Condensers. 95 cubic feet in each.

Feed Pumps. 8 inches in diameter = 1.2 cubic feet in each.

Water Wheels. Diameter, 31 feet; breadth of buckets, 10 feet; depth of ditto, 26 inches. Arms, 23 in each wheel. Dip of wheels at load-line (18.5 feet), 5.5 feet. A A 2

 $\it Water\ Wheel\ Shafts.$  Journals, 18.3 and 13 inches in diameter, and 20 and 15 inches in length.

Boilers. Four of copper (double return ascending flues); length, 16 feet; breadth, 15.25 feet; height, 13 feet.

Heating Surface. 8500 square feet. Grates. 354 square feet. Steam Room. 2300 cubic feet. Cross Area of lower Flues. 75.7 square feet.

Smoke Pipe. 63.6 square feet in area, and 65 feet in height above the grate level.

Pressure of Steam. 10 lbs. per square inch, cut off at one half of the stroke of the piston, throttle one quarter open.

Revolutions. 12.7 per minute. Fuel. Bituminous coal, with a natural draught. Consumption. At load line, moderate sea, and at above pressure, revolutions. &c., 3950 lbs. per hour = 42.3 tons per day.

Speed. 10 knots per hour. Coal Bunkers. 800 tons capacity.

Slip of wheels, 16.45 per cent.

HULL. Launching draught, 10.62 feet; displacement, 1585 tons. Angles of en trance at 17 feet 5 inches and at 19 feet 5 inches are respectively 48° and 54° 40′.

Average Displacement per Inch. From 18 to 19 feet draught, 22.09 tons.

Rig. Full barque.

#### Weights.

Engines and frames, flooring, &c., complete	491,282 1	bs.
Boilers (copper and brass)	324,977	46
——— (iron, lead, &c.), in appurtenances		
Coal bunkers, deck plates, &c	117,367	"
Water wheels	97,499	41
Extra pieces	50,135	"
Hoisting engine and boiler	4,569	"
Total	208,304 1	bs.

Day's work (boilers, water wheels, and coal bunkers not included, as they were made by the pound), 56.222. Turning, boring, and planing, 775.141 square inches.

Armament. Three 10-inch chambered guns on pivots, and six 8-inch chambered guns on carriages.

"Nix" and "Salamander." Oscillating Engines. Iron Hulls. Length on deck, 186 feet; beam, 26 feet; depth of hold, 11 feet 6 inches; draught of water at load-line, 6 feet 9 inches.

Immersed Section, 168 square Feet.

Cylinders. 48 inches in diameter; stroke of piston, 4.5 feet.

Boilers. Four horizontal tubular.

Revolutions. 36 to 38 per minute.

Speed. 131 knots per hour.

Fuel. Consumption, 2450 lbs. of bituminous coal per hour.

Hull. Frames,  $3.5\times3\times\frac{3}{6}$  inches, and 2 feet from centres; thickness of plates,  $\frac{1}{2}$  and  $\frac{3}{6}$ ths thick. Ceiled with teak 8 inches thick.

Weights. Engines, boilers, and coal bunkers, 179,200 lbs.

Armament. Four 68-pounder pivot guns, and two medium 32-pounders upon carriages.

### NAVAL STEAMERS WITH SCREW PROPELLERS.

## (Ericsson).

"Princeton." Semi-cylindrical Engines. Length between perpendiculars, 156.5 feet; beam, 30.5 feet; hold, 21.5 feet; tonnage, 673. \( \frac{5}{35} \), with a displacement of 1046 tons.

Immersed Section at load-line, 338 square Feet.

Cylinders. Two, each of 54 cubic feet in capacity. Pressure. 25 lbs. per square inch, cut off at  $\frac{1}{2}$  of the stroke.

Propeller. 120 square feet of surface. Pitch. 35 feet. Diameter. 14 feet. Revolutions. 36 per minute.

Shafts (Wrought iron). Diameter of journals, 12×16 inches.

Boilers. 2500 square feet of fire and flue surface. Flues 50 feet in length. Grates. 134 square feet. Steam Room. 1150 cubic feet.

Fuel. 1 ton of anthracite coal per hour (blast).

Weights. Engines . . . . 92 tons. | Water in boilers . . . . 34 tons. | Coal bunkers . . . . . 6 "

Hull. Of White Oak and tree-nailed. Launching weight, 418 tons. Sails. Area in square feet, 11,762. Surface of sails in proportion to immersed section, 84.92 square feet to 1.

#### MERCHANT STEAMERS, WITH SIDE WHEELS.

## NEW YORK AND LIVERPOOL, Collins's Line.

"Arctic." Side-lever Engines. Length between perpendiculars, 280 feet; beam, 46 feet; depth of hold, 24 feet; depth of hold to spar deck, 32 feet; with a displacement of 3724 tons, at a draught of water of 19 feet.

### Immersed Section, 685 square Feet.

Cylinders. Two, of 95 inches in diameter, with a stroke of piston of 10 feet; capacity of piston space, 984.48 cubic feet.

Water Wheels. 34 feet 5 inches in diameter by 11.5 feet in depth; width of buckets, 21.5 inches. Arms, 36 in each wheel. Dip of wheels at load-line, 6.5 feet.

Boilers. Four, of iron (vertical tubular, with double-storied furnaces); length, 20 feet 7 inches; breadth of two forward, 14 feet; of two after, 15 feet; height of each, 13 feet 8 inches.

Heating Surface. 19.484 square feet. Grates. 587.8 square feet. Steam Room. 4350 cubic feet. Cross Area of Flues. 175 square feet.

Smoke Pipe. 78.5 square feet in area, and 75 feet in height above the grate level.

Water. 392.000 lbs.

Pressure of Steam. 17 lbs. per square inch, cut off at one half of the stroke of the piston.

Average Revolutions. 14.7 per minute.

Fuel. Bituminous coal, with a natural draught, 7640 lbs. per hour.

Average Speed. 12.2 knots per hour for an entire passage.

Slip of Wheels. Average of 11 days, 18 per cent.

Weight of Hull. 1380 tons.

Displacement per Inch. At 19 feet draught, 22 tons; at 17.6 feet, 20.3 tons.

Rig. Brig.

"North Star." Vertical beam Engines. Length on deck, 269.5 feet; breadth of beam, 38 feet; depth of hold, 22 feet; depth of hold to spar deck, 29.5 feet; draught of water at load-line, 14 feet.

## Immersed Section, 496.5 square Feet.

Cylinders. Two, of 60 inches in diameter, with a stroke of piston of 10 feet.

Water Wheels. 33 feet in diameter by 8 feet in width; depth of buckets, 18 inches. Arms. 28 in each wheel. Dip of wheels at load-line, 7.75 feet.

Boilers. Four, of iron (drop-flued, with one tier of upper return flues); length, 23 feet 11 inches; breadth, 11 feet; height, 10.5 feet; height of steam chimney, 12 feet.

Heating Surface. 4892 square feet. Graves. 266 square feet. Cross Area of Flues. 31.5 square feet.

Smoke Pipes. Two, of 5 feet in diameter and 55 feet in height above the grate level.

Pressure of Steam. 20 lbs. per square inch, cut off at one half the stroke of the piston.

Revolutions. 16 per minute.

Fuel. Anthracite coal, with a natural draught.

Coal Bunkers. Capacity of 600 tons.

Weights.

Rig. Brigantine.

#### IRON HULLS.

"EUXINE." OSCILLATING ENGINES. PENS'R. & O. S. NAV'. Co.

Length on deck, 222.7 feet; breadth of beam, 29.4 feet; depth of hold, 18.5 feet; length of engine room, 74 feet; length of quarter deck, 70.3 feet, depth, 3 feet; draught of water at load-line, 9.25 feet.

Immersed Section, 252 square Feet.

Tonnage of Hull. 1096 tons. Quarter deck, 68. Total, 1164. Contents of Engine Room, 435. Register, 729, 3506.

Cylinders.  $74\frac{\pi}{8}$  inches in diameter; stroke of piston, 7 feet; least thickness, 1.5 inches. Openings, 5 by 23 inches. Stuffing boxes, 39 inches in depth.

Cylinder Trunnions. 25.5 inches in diameter, and 9 inches in length. Thickness of Metal, 2.5 inches. Packing, 6.5 inches in depth when screwed down.

Air Pumps. 42 inches in diameter.

Water Wheels. 28 feet in diameter by 8 feet 5 inches in width. Buckets, 27 inches in depth. Arms, three sets of 25 in each wheel.

Revolutions. 19.5 per minute.

Steam Pipe. 17 inches in diameter.

Piston Rods. 9 inches in diameter.

Shafts. Journals, 15×21 inches and 10.5×12 inches.

Crank Pins. 9.25×16.375 inches.

Cranks. Hub,  $25.75 \times 16$  inches. Eye,  $18.\frac{1}{8} \times 13.\frac{5}{8}$  inches. Web, 9.5 and 9,  $\times 19$ , and  $14.\frac{1}{4}$  inches.

Columns. Of Wrought Iron. 8 of 7 inches diameter. Tapered at upper end to 5.75 inches.

Engines occupy 15 feet in length.

Boilers. Four tubular: length, above, 10 feet 10.5 inches; below, 10 feet; breadth, 10.25 feet; height, 10 feet 10.5 inches. Tubes, 198 in each (792 in all), 3.25 inches internal diameter, and 6.5 feet in length. Furnaces, three in cach boiler Smoke Pines, two of 55 inches in diameter. 37 feet 7 inches in height.

HULL. Of Wrought Iron. Launching draught, 6.5 feet.

Frames. 15 and 24 inches apart from centres.

Plates. 15 strakes from keel to gunwale, \$ to \$ths of an inch thick.

#### CREW PROPELLERS.

#### BRITISH AND N. A. R. MAIL STEAM-SHIP CO.

"Andes" and "Alps." Beam Engines. Length on deck, 236.5 feet; breadth of beam, 34 feet 1 inch; depth of hold, 24 feet; draught of water at load-line, 16.75 feet.

Immersed Section, 530 square Feet.

Cylinders. Two, of 66 inches in diameter, with a stroke of piston of 4.5 feet.

Boilers. Two tubular; length, 15.5 feet; breadth, 9.5 feet; height, 14 feet. Tubies, 832 of 3.25 inches in diameter by 6.5 feet in length. Furnaces, twelve, 6.75 feet in length.

Smoke Pipe. 5 feet 11 inches in diameter by 40 feet in height above boiler.

Pressure of Steam. 10 lbs. per square inch.

Revolutions. 25 per minute.

Propeller. True screw, two blades. Pitch, 18 feet; diameter, 14 feet; geared, 2.5 revolutions to 1 of engine.

Fuel. Bituminous coal. Consumption. 2000 lbs. per hour.

Coal Bunkers. Capacity of 400 tons.

Hull. Frames, double angled iron,  $5.25 \times \frac{1}{8} \times 3$  inches; distance apart from centres, 15 inches. Keel.  $9 \times 3$  inches. Plates.  $\frac{1}{8}$  to  $\frac{7}{8}$ ths of an inch in thickness, abuted at ends; clincher built at edges, and double riveted.

Rivets. 3ths of an inch in diameter, and 3.5 inches apart.

Keelsons. Two, same dimensions as frames.

Weights.

Rig. Barque.

#### RIVER ENGINES.

#### With Side Wheels.

"NIAGARA." CONDENSING. For 123 square Feet of Immersed Section.

Length of vessel, 265 feet; beam, 28 feet 6 inches; depth of hold, 9 feet 3 inches; draught (loaded), 4 feet 9 inches.

 $Cylinder.\ 216$  cubic feet in capacity. Condenser. 88 cubic feet. Air Pump. 33.5 cubic feet.

Force Pumps. 51 inches diameter by 41 feet stroke.

Pressure. 40 to 45 lbs. per square inch, cut off at  $\frac{1}{2}$  the stroke of the piston. Revolutions. 24 per minute.

Water Wheels. 30 feet in diameter by 11 feet face. Arms. 24 in each flange. Buckets. Two, of 15 inches deep. Dip (at load line). 30 inches.

Shafts (Wrought iron). Journal, 14 inches.

Boilers. Two, of 27 feet in length by 10 feet front. Shell. 8 feet six inches in diameter. Fire and Flue Surface. 3000 square feet. Grates. 108 square feet. Steam Room. 1200 cubic feet.

Fuel. 3200 lbs. of anthracite coal per hour (maximum).

Blowers. Two, of 9 feet in diameter. Fans. Ten, of 24 inches by 3 feet face.

Blowing Engines. Two, of 10 inches diameter of cylinder by 12 inches stroke. Revolutions. 150 per minute.

Length of vessel, 250 feet; beam, 27 feet; depth of hold, 9 feet; draught (loaded), 5 feet.

Culinder. 175 cubic feet in capacity. Air Pump. 38.5 cubic feet.

Condenser. 72 cubic feet. Force Pumps. 5 inches diameter by 4 feet stroke.

Pressure. 35 to 40 lbs. per square inch, cut off at ½ the stroke of the piston.

Renolutions. 23.5 to 24 per minute.

Water Wheels. 29 feet in diameter by 11 feet face. Arms. 24 in number. Buckets. Two divisions, and 30 inches deep. Dip (at load-line). 30 inches.

Shafts (Wrought iron). Diameter of journal, 13 inches.

Boilers. Two, 27 feet in length by 9.5 in width. Fire and flue surface, 3000 square feet. Shell. 8 feet in diameter. Grates. 100 square feet. Steam Room. 1000 cubic feet.

Consumption of Fuel. 3000 lbs. of anthracite coal per hour (maximum).

Blowers. Four, 4 feet diameter by 26 inches face. 4 arms. Fans, 13 inches deep. Revolutions, 75 per minute.

Blowing Engines. Cylinder, 8 inches in diameter by 12 inches stroke.

Weight of Boilers. 62,000 lbs.

The above engines and boilers were designed and constructed at the Phoenix Foundry, New-York.

Condensing. For 160 square Feet of Immersed Section.

Length of vessel, 335 feet; beam, 35 feet; depth of hold, 11 feet 6
inches.

Cylinder. 313 cubic feet in capacity. Air Pump. 54 cubic feet.

Pressure. 38 lbs. per square inch. Revolutions. 22 per minute.

Water Wheels. 34 feet in diameter by 10 feet 8 inches face. Buckets. 38 inches deep.

Boilers. Shell.  $9\frac{1}{2}$  feet in diameter. Surface. 3660 square feet. Steam Room. 1570 cubic feet. Grates. 145 square feet.

Blowing Engines. Two cylinders, of 14 inches diameter by 14 inches stroke. Fwo blowers, 10 feet in diameter by 2 feet in width. Ten fans in each, of 26 inches n depth. Revolutions. 100 per minute.

Fuel. 3000 lbs. of anthracite coal per hour.

\*CLIFTON." VERTICAL BEAM ENGINES. CONDENSING. Length on deck, 180 feet; beam, 29 feet; depth of hold, 8.75 feet; draught of water at load-line, 3 feet.

## Immersed Section, 75 square Feet.

Cylinder. 40 inches in diameter, with a stroke of piston of 8 feet.

Air Pump. 33 inches in diameter, with a stroke of piston of 2 feet 7 inches.

Condenser. 40 inches in diameter by 4 feet in height.

Water Wheels. 26 feet in diameter by 7 feet in width; buckets, 20 inches in depth. Arms. 28 in number, 7×2.5 inches.

Dip of Wheel. 22 inches.

Boiler. One, drop-flued, 11 feet in width, 26 feet in length, and 8.75 feet in diameter of shell, back of the furnaces; steam chimney, 9.5 feet high. Grates. 7 feet in length, having an area of 69 square feet.

Frames. Moulded, 12 inches; sided, 4 inches, and 24 inches apart from centres.

Keel. 4 inches deep.

Heating Surface. 1217 square feet; upper flues, 5 of 16.5 inches in diameter.

#### IRON HULL.

#### GLASGOW AND ROTHESAY.

"Osprey." Steeple Engine. Length on deck, 196.6 feet; beam, 18.5 feet; depth of hold, 8.8 feet; draught of water (light) 4 feet 7 inches.

Immersed Section at light draught, 80.5 square Feet.

Culinder. 54 inches in diameter, with a stroke of piston of 4 feet 4 inches.

Air Pump. 24 inches in diameter, with a stroke of piston of 4 feet 4 inches.

Water Wheels. 18.5 feet in diameter by 6 feet 7 inches in width. Arms. 17 in number. Buckets. 15 inches deep.

 $\it Boilers.~$  Two tubular; length, 8 feet 3 inches; breadth, 11 feet 3 inches; depth, 7 feet 9 inches.

Furnaces. Six, 3 feet in width; 6.5 feet in length; and 3 feet in depth. Tubes. 354 of 3 inches in diameter by 6 feet in length.

Smoke Pipes. Two, of 3 feet 8 inches in diameter and 31 feet in height above grate level.

Revolutions. 32 per minute.

Pressure. 15 lbs. per square inch.

Fuel. 1792 lbs. of bituminous coal per hour.

Speed. 15 statute miles per hour.

HULL. Frames. 2.5×2.5×3ths of an inch, and 27 inches apart from centres.

**Plates.**  $\frac{3}{16}$  to  $\frac{5}{16}$ ths thick. Clincher built.

Launching Draught. 2 feet 71 inches.

#### NON-CONDENSING.

"Buckeye State." Horizontal Engines. Length of vessel, 260 feet; beam, 29 feet 4 inches; depth of hold, 7 feet 6 inches; draught (light), 3 feet 6 inches; loaded, 4 feet.

Immersed Section, 116 square Feet.

Cylinders. Two, of 29.5 inches in diameter by 8 feet stroke of piston.

 $Water\ Wheels.\ 31\ {\rm feet}\ 8\ {\rm inches}\ {\rm in}\ {\rm diameter}\ {\rm by}\ 12\ {\rm feet}\ {\rm in}\ {\rm width}.\ Buckets.\ (20)\ 2.5\ {\rm feet}\ {\rm in}\ {\rm depth}.$ 

Boilers. 5 of 42 inches in diameter and 30 feet in length, with two flues in each, 16 inches in diameter.

Heating Surface. 2394 square feet. Grate bars. 4.1 feet in length; .08 inch thick; spaces between each, .08 inch. Area, 56 feet.

Smoke Pipes. Two, of 66 inches in diameter, and 64 feet high.

Water Wheel Shafts. 17 inches in diameter.

Pressure. Average, 145 lbs. per square inch Cut off at 5 feet.

Revolutions. 18 per minute. Fuel. 4281 lbs. of bituminous coal per hour.

Hull. Keelson.  $11\times17$  inches; bilge do.,  $3\times10.5$  inches; false do.,  $3\times8$  inches; bottom plank, 4 inches; deck beams,  $3.5\times6.25$  inches; plankshear,  $2.5\times25$  inches, and deck plank, 2 inches. Frames. Throats, 7 inches; sides, 3.5 inches; distance from centre to centre, 17 inches.

Freight. 108 tons at this draught of water.

Notes.—Areas of immersed section of hull at light draught (102.7 square feet) and of cross bucket surface, are as 1 to 1.71. Areas of grate and fire-flue surface as 1 to 18. Fuel consumed upon each square feet of grate, 50 lbs. per hour. Areas of smoke pipes, 47 feet; of flues, 16.7 feet; and of bridge wall, 27 feet.

#### For 300 square Feet of Immersed Section.

Vessel 260 feet in length, 38 feet beam, and 8 feet draught when loaded.

Cylinders. Two, each 30 inches in diameter by 10 feet stroke of piston (98.3 cubic feet). Force Pumps.  $6\frac{3}{4}$  inches in diameter by 25 inches stroke.

Water Wheels. 33 feet in diameter by 15 feet in width, 19 arms in each; buckets, 36 inches deep. Shafts (Cast iron). Diameter of journals, 16 and 14 inches.

Connecting Rod. 35 feet in length. Piston Rod. Diameter, 6 inches.

Steam Valves. 50 square inches each. Exhaust Valves. 63 square inches

Boilers. 5 of 42 inches in diameter by 34 feet in length, with 2 return flues in each, 16 inches in diameter, having 2278 square feet of heating surface. Grates. 84 souare feet.

Boiler Plates. (Shells), quarter of an inch in thickness. Flues. Full quarter of an inch.

Pressure. 75 to 100 lbs. per square inch, cut off at  $\frac{3}{8}$  the stroke of the piston.

Revolutions. 16 to 21 per minute. Dip of wheel. 5 feet when loaded.

Consumption of Fuel. 2.3 cords yellow pine per hour.

Weights. Engines, 160 tons; Boilers, 9000 lbs.

Note.—32.75 square feet of fire and flue surface is the proportion for each cubic tool in the cylinders at the above given revolutions.

Stern Wheel. Horizontal Engines. Length on deck, 110 feet; beam, 14 feet (deck projecting over, 4 feet); depth of hold, 3.5 feet, draught of water at load-line, 12 inches.

Immersed Section, 10.25 square Feet.

Cylinders. Two, of 10 inches in diameter, with a stroke of piston of 3 feet.

Water Wheels. 13 feet in diameter by 8.5 feet in width. Buckets. 13 in number, and 8 inches in depth.

Revolutions. 33 per minute.

Boiler. One tubular, 100 2-inch tubes.

Fuel. 4480 lbs. in 24 hours.

Hull. Plates. Keel, No. 3; bilges, No. 4; bottom, No. 5; sides, Nos. 6 and 7 Frames.  $2.5 \times \frac{1}{2}$  inch, and 20 inches apart from centres.

# STEAM VESSELS (Marine).

"GREAT BRITAIN." Displacement at 16 Feet draught, 3000 Tons.

Length of keel, 289 feet; beam, 51 feet; depth of hold, 32 feet 6 inches

Plates.  $\frac{7}{8}$ ,  $\frac{11}{16}$ ,  $\frac{5}{8}$ , and  $\frac{3}{8}$  thick.

Frames. 18 and 24 inches apart.  $\frac{5}{8}$  thick, by 3.5×6 inches; by 2.5×6 inches and by 3×4 inches,  $\bot$ .

WEIGHT OF HULL (in iron). 1040 tons.

"MICHIGAN." Displacement at 8 Feet 8 Inches draught, 658 Tons.

Length between perpendiculars, 162 feet 6 inches; beam, 27 feet; depth of hold, 12 feet.

Plates.  $\frac{5}{8}$ ,  $\frac{1}{2}$ ,  $\frac{3}{8}$ ,  $\frac{5}{16}$ ,  $\frac{1}{4}$ , and  $\frac{3}{16}$  thick.

Frames. 2 feet apart.  $\frac{1}{2}$  and  $\frac{3}{8}$  thick, by  $4\times4.5$  inches,  $\bot$ ; and  $\frac{1}{2}$  and  $\frac{3}{8}$ , by  $4\times2.25$  inches,  $\bot$ .

Deck Beams.  $\frac{3}{6}$ , by 4.5×7 inches,  $\perp$ .

Weight of Hull, including bulwarks and berth deck, 507,387 lbs.

"SPENCER." Displacement at 9 Feet 3 Inches, 440 Tons.

Length between perpendiculars, 143 feet; beam (average), 20 feet 3 inches; depth of hold, 11 feet 6 inches.

Plates.  $\frac{3}{8}$ ,  $\frac{5}{16}$ , and  $\frac{1}{4}$  of an inch.

Frames. 20 inches apart.  $\frac{5}{8}$  thick, by 2.5×4.5 inches, L.

Deck Beams.  $\frac{5}{8}$ , by 2.87×5.5 inches, L.

#### WEIGHTS.

Plating .			125,922 lbs.	Knees					13,845 lbs.
Bulk-heads			11,663 "	Rivets					18,005 4
Kelson			3,093 "	Stanchions					
Deck beams			34,463 "	Sundries .					20,918 "
Frames					•	Гot	al		275,567 lbs.

"Foyle." Length on deck, 196 feet; beam, 25 feet; depth of hold, 16 feet.

Tonnage. 761 tons.

Draft of Water. 8.5 feet.

Plates. 13 strakes of plates from keel to gunwale, diminishing upward from  $\frac{3}{4}$  to  $\frac{1}{2}$  an inch in thickness.

Frames. 18 inches apart amidships, and 22 inches forward and aft.  $\frac{7}{16} \times 2.\frac{1}{2} \times 4$  inches L.

# Ship (Clipper). (English.)

"Typhoon." Length of keel and fore rake, 198.5 feet; breadth of beam, 32 feet; depth of hold, 20 feet; length of poop, 76 feet.

Burden. 2000 tons by measurement, or 1400 tons by weight.

Tonnage. o. m., 976. N. M., 1100.

Frames.  $5\times3\times\frac{5}{8}$ ths of an inch, and 15 inches apart from centres. Plates.  $\frac{1.3}{16}$ ths at keel, and  $\frac{5}{8}$ ths at gunwale.

Stem.  $10 \times 3$  inches, tapering to  $7 \times 3$ . Stern Post.  $10 \times 4$  inches. Keel.  $9 \times 3$  inches.

# SCHOONER. (English.)

"Shamrock." Length on deck, 82.5 feet; breadth on deck, 20 feet; depth of hold, 11.1 feet.

Tonnage. English, New Register, 133. 16 tons.

Frames. 18 inches apart.

Plates. 10 strakes from keel to gunwale, of \$ths to \$ths thick.

Draft of water. Launching, forward, 4 feet 9 inches; aft, 5 feet 84 inches; loaded, 10 feet forward and 10 feet 6 inches aft.

Clincher built and schooner rigged.

# CANAL BOAT (very full built).

Length between perpendiculars, 80 feet; beam, 14 feet; depth of hold.

7 feet.

Plates. Nos. 3 and 4, wire gauge.

Frames. 18 inches apart, and  $\frac{3}{8}$  thick, by 3 inches wide, 1

Deck and beams of wood.

WEIGHT OF HULL, 42,300 lbs.

MISCELLANEOUS NOTES.

# SUGAR MILL.

For Expressing 20,000 lbs. of Cane Juice per Day.

#### NON-CONDENSING ENGINE.

Cylinder 15 inches in diameter by 4 feet stroke.

Pressure. 50 lbs. per square inch, cut off at 1/2 the stroke of the piston.

Revolutions. 36 per minute.

Boiler. 1 of 62 inches in diameter by 30 feet in length, with 2 18 inch return flues. Grates. 36 square feet.

Rolls. Two set of 3 each, of 24 inches in diameter by 5 feet in length; geared 21 to 36 of engine, giving a speed of periphery of 151 feet per minute.

Fly Wheel. 18 feet in diameter; weight, 5 tons.

This arrangement of a second set of rolls is a late improvement; its object, that of distributing the cane over an increased surface of rolls, reducing their speed, and affording more time for the juice to run off; an increase of 20 per cent. is effected by it.

#### For a Crop of 3000 boxes of Sugar of 500 lbs, each.

A non-condensing engine with a cylinder of 11 inches in diameter by 4 feet stroke, making 46 revolutions, with a pressure of steam 60 lbs. per square inch, driving 1 set of rolls, 24 inches by 4 feet, at a speed of periphery of 36 feet per minute.

Boiler. 52 inches by 24 feet, with 2 16 inch return flues. Grate Surface. 25 square feet.

Fly Wheel. 16 feet diameter; weight, 4 tons.

# SAW-MILL.

#### NON-CONDENSING ENGINE.

Two Vertical Saws of 34 inches Stroke. Lathes, &c.

Cylinder. 10 inches in diameter by 4 feet stroke.

Pressure. 90 to 100 lbs. per square inch, full stroke. Revolutions. 35 per minute.

Boilers. 3, plain cylindrical, 30 inches in diameter by 20 feet in length.

Note.-This engine has cut, of yellow pine, 30 feet by 18 inches in one minute.

#### COTTON FACTORY.

Condensing engine. Driving 13,000 Spindles (Mules and Throstles), with 256 Looms for 3 cloth No. 30.

Cylinders. Two, 22 inches in diameter by 3 feet stroke of piston.

Pressure. 15 to 45 lbs. per square inch, cut off at one third of the stroke.

Revolutions. 50 per minute.

Condensing Engine (British). Driving 22,060 Hand-mule Spindles, with preparation, 260 Looms, and common Sizing.

Engine. Cylinder, 372 inches diameter by 7 feet stroke; indicated pressure (average), 16.73 lbs. per square inch'; revolutions, 17 per minute.

Friction of engine and shafting, indicated 4.75 lbs. per square inch of piston.

Total power, = 1. Available, deducting friction, = .717. Estimated power of en gine, 134 horses.

Notes.-Each indicated horse power will drive

305 hand-mule spindles, with preparation,

or 230 self-acting

or 104 throstle

or 101 looms, with common sizing.

Including preparation:

1 throstle spindle = 3 hand-mule, or 24 self-acting spindles.

1 self-acting spindle = 11 hand-mule spindles.

Exclusive of preparation, taking only the spindle:

1 throstle spindle =  $3\frac{1}{2}$  hand-mule, or  $2\frac{5}{0}$  self-acting spindles.

1 self-acting spindle = 13 hand-mule spindles.

The throstles are the common, spinning 34 twist for power-loom weaving: the spindles revolve 4000 per minute. The self-acting nules are, one half spinning 36's weft, spindles revolving 4800; the other half spinning 36's twist, spindles revolving 5200. The hand-mules spinning about equal quantities of 36's weft and twist. Weft spindles 4700, and twist spindles 5000 revolutions per minute.

Average breadth of looms 37 in. (weaving 37 in. cloth), making 123 picks per minute. All common calicoes about 60 reed, Stockport count, and 68 picks to the inch.

No power consumed by the sizing. When the yarn is dressed instead of sized, one horse power cannot drive so many looms, as the dressing machine will absorb from to f of the power.

# COTTON-PRESS.

Non-condensing engine. For 1000 Bales in 12 Hours.

Cylinder. 14 inches in diameter by 4 feet stroke.

Pressure. 40 lbs. per square inch, at full stroke. Revolutions. 60 per minute. Boilers. 3, plain cylindrical, without flues, 30 inches in diameter by 26 feet in length Grates. 32 square feet.

Presses. 4, geared 6 to 1, with 2 screws each of  $7\frac{1}{2}$  inches in diameter by  $1\frac{9}{8}$  in pitch.

Shaft (Wrought iron). Journal, 81 inches.

Fly Wheel. 16 feet in diameter; weight, 4 tons.

#### BLOWING OR BLAST ENGINES.

# Dimensions of a Furnace, Engines, &c.

#### At Lonakoning (Md.).

Furnace. Diameter at the boshes 14 feet, which fall in, 6.33 inches in every foot rise.

Engine (Non-condensing). Diameter of cylinder 18 inches, length of stroke 8 feet. Revolutions. 12 per minute, with a pressure of 50 lbs. per square inch.

Boilers. Five: each 24 feet in length, and 36 inches in diameter.

Blast Cylinders. 5 feet diameter and 8 feet stroke.

At a pressure of from 2 to  $2\frac{1}{2}$  lbs. per square inch, the quantity of blast is 3770 cubic feet per minute, requiring a power of about 50 horses to supply it.

#### At Mount Savage (Md.).

For Blowing four Furnaces, 14 feet in diameter, each making 100 tons of Pig Iron per week.

Engine (Condensing). Diameter of cylinder 56 inches, length of stroke 10 feet. Revolutions. 15 per minute. Pressure. 60 lbs. per square inch, cut off at 1 of the stroke.

Boilers. 6 of 60 inches in diameter, and 24 feet in length, with 1 22 inch flue in each, double returned. Grates. 198 square feet.

Blast Cylinder. 126 inches in diameter by 10 feet stroke. Revolutions. 15 per minute. Pressure of Blast. 4 to 5 lbs. per square inch.

Area of Pipes. 2300 square inches, or 1 that of the cylinder.

For Blowing two Furnaces and two Fineries, making 240 tons of Forge Pig per week.

Engine (Non-condensing). Diameter of cylinder 20 inches, length of stroke 8 feet. Revolutions. 28 per minute. Pressure. 50 to 60 lbs. per square inch (full stroke).

Boilers. 6 of 36 inches in diameter, and 28\* feet in length (without flues). Grates. 100 square feet.

Blast Cylinders. 2 of 62 inches in diameter by 8 feet stroke. Revolutions. 22 per minute. Pressure of Blast. 21 lbs. per square inch.

Area of Pipes. 3 feet, or 1 that of the cylinders.

One Blast furnace has 2 3 inch and 1 31 inch tuyeres; the other has 3 of 3 inches. One Finery has 6 tuyeres of 11 inches, and the other 4 of 15 inches.

The ore yields from 40 to 45 per. cent of iron. The temperature of the blast is 0000.

Hosted by Google

<sup>\* 40</sup> feet would have afforded much economy of fuel.

#### STEAM DREDGING MACHINE.

Non-condensing engine. For Dredging 30 feet from Water-line. Six full Buckets per Minute.

Cylinder. 12 inches in diameter by 5 feet stroke of piston.

Pressure. 60 to 70 lbs. per square inch, full stroke. Revolutions. 20 per minute, geared 30 of engine to 1 of buckets.

Boilers. 2 of 20 feet in length by 36 inches in diameter, with 1, 15 inch return flue in each.

Ways. 55 feet in length by 6 feet in width. Buckets. 10 of 28 inches in width by 58 in length, and 14 in depth.

At a depth of 18 feet, 10 buckets full of mud are discharged per minute, the engine making  $3\hat{0}$  revolutions.

Note.-This engine is geared too slow, being but 22 to 1.

Hulls. 2 of 50 feet in length, 12 feet in width, and 9 in depth each; connected on deck, space between for the ways, 7½ feet.

(C) C

### PILE-DRIVING.

Non-condensing engine. Driving two Piles.

Cylinders. Two of 6 inches in diameter by 18 inches stroke.

Pressure. 60 pounds per square inch, full stroke. Revolutions. From 60 to 80 per minute

Boiler. Tubuler. Shell 3 feet in diameter by 6 feet in length. Furnace end, 3 feet 9 inches in width, 3 feet in length, and 6 feet in height.

Rams. 1000 lbs. each, lifted 5 times in a minute.

Frame.  $8\frac{1}{2}$  feet in width by 26 feet in length. Leaders. 3 feet in width by 24 feet in height.

### HYDROSTATIC PRESS.

Non-condensing engine. 30 Bales of Cotton per Hour

Cylinder. 10 inches in diameter by 3 feet stroke.

Pressure. 50 lbs. per square inch, full stroke. Revolutions. 45 to 60 per minute.

Presses. Two, with 12 inch rams, having 42 feet stroks.

Pumps. Two of 2 inches diameter by 6 inches stroke.

# FLOUR MILLS.

At Richmond (Va.).

OVERSHOT WATER WHEELS. For 30 Barrels of Flour per Hour.

Water Wheels. Five, of 18 feet in diameter by 14 feet 6 inches face. Buckets. 15 inches in depth.

Head of Water. 2.5 feet; opening over each wheel, 2.5 inches by 14 feet.

For further and very exact notes of a Flour Mill, Blast Engine, and Cotton Mill, refer to page 179.

# MARINE BOILERS.

Table of Dimensions of several Tubular Marine Boilers in use in England.

### MOTION OF BODIES IN FLUIDS.

Table of the Weights required to give different Velocities to several different Figures.

The diameter of all the figures but the small hemisphere is 6.375 inches, and the altitude of the cone 6.625 inches.

The small hemisphere is 4.75 inches.

The angle of the side of the cone and its axis is, consequently, 25° 42' nearly.

Velocity		ne.	Whole	Cylinder.	Hemis	Small hem-

20	1.069	2.540	1.057	2.528	2.542	1.033	1.196
Propor. number	126	291	124	285	288	119	140

From this table several practical inferences may be drawn.

- 1. That the resistance is nearly as the surface, the resistance in creasing but a very little above that proportion in the greater surfaces.
- 2. The resistance to the same surface is nearly as the square of the velocity, but gradually increasing more and more above that proportion as the velocity increases.
- 3. When the hinder parts of bodies are of different forms, the resistances are different, though the fore parts be alike.
- 4. The resistance on the base of the hemisphere is to that on the convex side nearly as 2.4 to 1, instead of 2 to 1, as the theory assigns the proportion.
- 5. The resistance on the base\* of the cone is to that on the vertex nearly as 2.3 to 1. And in the same ratio is radius to the sine of the angle of the inclination of the side of the cone to its path or axis. So that, in this instance, the resistance is directly as the sine of the

<sup>\*</sup> This is a complete refutation of the popular assertion, that a taper spar will tow in water easiest when the base is foremost.

angle of incidence, the transverse section being the same, instead of the square of the sine.

6. Hence we can find the altitude of a column of air, the pressure of which shall be equal to the resistance of a body moving through it with any velocity.

Thus, let a = the area of the section of the body, similar to any of those in the table, perpendicular to the direction of motion,

R = the resistance to the velocity, in the table, and

x = the altitude sought, of a column of air whose base is a and its pressure R.

Then ax = the contents of the columns in feet, and 1.2 ax, or  $\frac{6}{5}ax$  its weight in ounces.

Therefore,  $\frac{6}{5}ax = R$ , and  $x = \frac{5}{6} \times \frac{R}{a}$  is the altitude sought in feet, namely,  $\frac{5}{6}$  of the quotient of the resistance of any body divided by its transverse section, which is a constant quantity for all similar bodies, however different in magnitude, since the resistance R is as the section a, as by article 1.

When  $a = \frac{2}{9}$  of a foot, as in all the figures in the foregoing table except the small hemisphere, then  $x = \frac{5}{6} \times \frac{R}{a}$ , becomes  $x = \frac{1.5}{4} R$ , where R is the resistance in the table, to the similar body.

If, for example, we take the convex side of the large hemisphere, whose resistance is .634, or at a velocity of 16 feet per second, then R=.634, and  $x=\frac{1.5}{4}R=2.3775$  feet, is the altitude of the column of air whose pressure is equal to the resistance on a spherical surface, with a velocity of 16 feet.

And to compare the above altitude with that which is due to the given velocity, it will be  $33^{\circ}:16:4$ , the altitude due to the velocity 16, which is near double the altitude that is equal the pressure. And as the altitude is proportional to the square of the velocity; therefore, in small velocities the resistance to any spherical surface is equal to the pressure of a column of air on its great circle, whose altitude is  $\frac{19}{27}$ , or .594 of the altitude due to its velocity.

But if the cylinder be taken, where resistance R=1.526, then  $x=\frac{1.5}{4}R=5.72$ , which exceeds the height 4, due to the velocity, in the ratio of 23 to 16 nearly. And the difference would be still greater if the body were larger, and also if the velocity were more.

If any body move through a fluid at rest, or the fluid move against the body at rest, the force or resistance of the fluid against the body will be as the square of the velocity and the density of the fluid; that is,  $R = dv^2$ .

For the force or resistance is as the quantity of matter or particles struck, and the velocity with which they are struck. But the quantity or number of particles struck in any time are as the velocity and the density of the fluid. Therefore, the resistance or force of the fluid is as the density and square of the velocity.

The resistance to any plane is also more or less, as the plane is greater or less, and therefore the resistance on any plane is as the area of the plane a, the density of the medium, and the square of the velocity; that is,  $R = adv^2$ .

If the motion be not perpendicular, but oblique to the plane, or to the face of the body, then the resistance in the direction of the motion will be diminished in the

Hosted by GOOSIE

triplicate ratio of radius to the sine of the angle of inclination of the plane to the direction of the motion, or as the cube of radius to the cube of the sine of that an gle. So that  $R = adv^2s^3$ , 1 =radius, and s =sine of the angle of inclination.

The real resistance to a plane, from a fluid acting in a direction perpendicular to its face, is equal to the weight of a column of the fluid, whose base is the plane and altitude equal to that which is due to the velocity of the motion, or through which a heavy body must fall to acquire that velocity.

The resistance to a plane running through a fluid is the same as the force of the fluid in motion with the same velocity on the plane at rest. But the force of the fluid in motion is equal to the weight or pressure which generates that motion and this is equal to the weight or pressure of a column of the fluid, the base of which is the area of the plane, and its altitude that which is due to the velocity.

- 1. If a be the area of a plane, v its velocity, n the density or specific gravity of the fluid, and  $\frac{1}{2}g = 16.0633$  feet; then, the altitude due to the velocity v being  $\frac{v^2}{2g}$ . Therefore  $a \times n \times \frac{v^2}{2g} = \frac{anv^2}{2g}$ , will be the whole resistance or force R.
- 2. If the direction of motion be not perpendicular to the face of the plane, but oblique to it, in an angle; then  $R = \frac{anv^3s^3}{2\sigma}$ .
- 3. If W represent the weight of the body, a being resisted by the absolute force R: then the retarding force f, or  $\frac{R}{v}$ , will be  $\frac{anv^2s^3}{2\sigma w}$ .

Example.—If a plane 1 foot square be moved through water at the rate of 32.16 feet per second, then  $\frac{32.16^2}{64.33} = 16.08$ , the space a body would require to fall to acquire a velocity of 32.16 feet per second; therefore,  $1 \times 62.5$  (weight of a cubic foot of water)  $\times \frac{32.16^2}{64.33} = 1005$  lbs., the whole resistance of the plane.

The resistance to a sphere moving through a fluid is but half the resistance to its great circle, or to the end of a cylinder of the same diameter, moving with an equal velocity.

 $\mathbf{R}=rac{pnv^2r^2}{4g}$ , being the half of that of a cylinder of the same diameter,  $\mathbf{R}$  representing radius.

ILLUSTRATION.—A 9 lb. iron ball, the diameter being 4 inches, when projected at a velocity of 1600 feet per second, will meet a resistance which is equal to a weight of 132.66 lbs. over the pressure of the atmosphere.

The resistance that a body sustains in moving through a fluid is in proportion to the square of the velocity.

And it is the same, whether the plane moves against the fluid or the fluid against the plane.

The following Table shows the results of experiments with a plane one foot square, at an immersion of 3 feet below the surface, and at different velocities per second.

Velocity.	Resistance.	Velocity.	Resistance.	Velocity.	Resistance.
5 feet	29.5 lbs	8 feet	71.7 lbs.	11 feet	136.3 lbs,
6 "	40. "	9 "	90.6 "	12 "	162.1 "
7 "	54.6 "	10 "	112. "	13½ "	213. "

### ORTHOGRAPHY OF TECHNICAL TERMS.

THE orthography and use of the following terms are so varied in general practice, that it is thought proper to treat of them, with a view to establishing an uniformity of expression.

Abut. To meet, to adjoin to at the end, to border upon.

Alignment. Setting to a line, a row.

Arabesque. Applied to painted and sculptured ornaments of imaginary foliage, in which there are no figures of animals. Synonymous with *Moresque*.

Ashlar. Rough stones from the quarry. When faced and squared, they are termed smooth.

Bagasse. Sugar-cane in its crushed state, as delivered from the rollers.

Baluster. A small column or pilaster; a collection of them, joined by a rail, forms a balustrade.

Bevel. A term for a plane having any other angle than 45° or 90°.

Boomkin. A short spar projecting from the bow or quarter of a vessel, to extend a tack of the fore or main sail to windward.

Buhr-stone. Mill-stone which is nearly pure silex, full of pores and cavities.

Camboose. The cooking-room of a vessel, usually confined to merchant vessels; in vessels of war it is termed Galley.

Cag. A small cask, differing from a barrel only in its size.

Calk. To stop seams and pay them with pitch, &c. To point an iron shoe, so as to prevent slipping.

Cam. An irregular curved instrument, having its axis eccentric to the shaft upon which it is fixed.

Capstan. A vertical windlass.

Caravel. A small vessel (of 25 or 30 tons burthen) used on the coast of France in herring fisheries.

Chamfer. A slope, groove, or small gutter cut in wood, metals, or stones. To chamfer is to slope, to channel, or to groove.

Chimney. The flue of a fire-place or furnace, constructed of masonry.

Chinse. To chinse is to calk slightly with a knife or chisel.

Clincher built. A term applied to the construction of vessels, when the lower edge of the bottom planks overlays the next under it.

Coamings. Raised borders around the edges of hatches.

Cog. In Mechanics, A short piece of wood or other material ler into the faces of two bodies, to impart motion one to the other. A term applied to a tooth in a wheel when it is made of a different material than that of the wheel.

Colter. The fore iron of a plow, that cuts the earth or sod.

Compass. In Geometry, An instrument for describing circles, measuring figures, &c.

Corridor. A gallery or passage in or around a building, connected with various departments, sometimes running within a quadrangle: it may be open or enclosed. In fortifications, a covert-way.

Damasquinerie. Inlaying in metal.

Davit. A short boom fitted to hoist an anchor or boat.

Dilatation. Expanding; opposed to contraction. It differs from extension; thus, a line may be extended, but a body is dilated.

Douel. To fasten two boards or pieces together, by pins inserted in their edges.

This is very similar to cogging, but is used in a diminutive sense. An illustration of it is had in the manner a cooper secures two or more pieces in the head of a cask.

Evaporation. The conversion of a fluid into vapor, specifically lighter than the atmospheric air.

Felloe. The pieces of wood forming the circumference of a carriage wheel, into which the spokes are inserted.

Flange. A projection from an end or from the body of an instrument, or any part composing it, for the purposes of receiving, confining, or of securing it to a support or to a second piece.

Frap. To bind together with a rope, as to frap a fall or vessel.

Furring. In Carpentry, Strips of board or pieces of joist to supply deficiencies of timber, or to prepare a fair surface for lathing.

Gallery. In Architecture, A covered part of a building used for walking.

Graving. Burning off grass, shells, &c., from a ship's bottom Synonymous with Breaming.

Grommet. A wreath or ring of rope.

Jib. The projecting beam of a crane from which the pulleys and weight are suspended. A sail in a vessel.

Keelson. The timber within a vessel laid upon the middle of the floor timbers, and exactly over the keel.

Lacquer. A spirituous solution of lac.

Lapsided. A term expressive of the condition of a vessel or any body when it will not float or set upright.

Mitered. In Mechanics, Cut to an angle of 45°, or two pieces joined so as to make a right angle.

Mold. In Mechanics, A matrix in which a casting is formed. A number of pieces of vellum or like substance, between which gold and silver are laid for the purpose of being beaten. Thin pieces of materials cut to curves or any required figure. In Naval Architecture, pieces of thin board cut to the lines of a vessel's timber, &c., &c.

Fine earth, such as constitutes soil. A substance which forms

on bodies in warm and confined damp air.

This orthography is by analogy, as gold, sold, old, bold, cold, fold, &c.

Molding. In Architecture, A projection beyond a wall, from a column, wainscot, &c., &c.

Mortise. A hole cut in any material to receive the end or tenon of another piece.

Ogee. A molding with a concave and convex outline, like to an S.

Peek. The upper or pointed corner of a sail extended by a gaff, or a yard set obliquely to a mast. To peek a yard is to point it perpendicularly to a mast.

Pipe. In Mechanics, A metallic tube. The flue of a fire-place or furnace, constructed of metal; usually of a cylindrical form.

Piragua. A small vessel with two masts and boom sails.

Plumber block. A bearing to receive and support the journal of a shaft.

Porch. An arched vestibule at the entrance of a building. A vestibule supported by columns. A portico.

Portico. A gallery near to the ground, the sides being open. A piazza encompassed with arches supported by columns, where persons may walk: the roof may be flat or vaulted.

Rabbet. In Mechanics, To pare down an edge of a board or a plate for the purpose of receiving another board or plate by lapping. To lap and unite edges of boards and plates. The groove in the side of a keel for receiving the garboard strake of plank.

Rarefaction. The act or process of distending bodies, by separating their parts and rendering them more rare or porous. It is opposed to condensation.

Reem. In Mechanics, To bevel out a hole.

Reeming. The opening of the seams between the planks of a vessel, for the purpose of calking them.

Rotary. Turning on an axis, as a wheel,

Shammy. Leather prepared from the skin of a chamois goat.

Sheer. In Naval Architecture, The curve or bend of a ship's deck or sides. To sheer, to slip or move aside.

Shoar. An oblique brace, the upper end resting against the substance to be supported.

Signalled. Communicated by signals.

Slue. To slue is to turn a substance on an axis within its figure.

Sponson. An addition to the outer side of the hull of a steam vessel, commencing near the light water-line and running up to the guard. Used for the purpose of shielding the guard from the shock of a sea.

Sponson sided. The hull of a vessel may be so termed when her frames have the outline of a sponson, and the space afforded by the curvature is included in the hold.

Stack. In Masonry, A number of chimneys or pipes standing together. The chimney of a blast furnace is so called.

Strut. An oblique brace to support a rafter.

Swage. To bear or force down. An instrument having a groove on its under side, for the purpose of giving shape to any piece subjected to it when receiving a blow from a hammer.

Template. A mould cut to an exact section of any piece or structure.

Templet. In Masonry, A wooden bearing to receive the end of a girder.

Tompion. The stopper of a piece of ordnance. The iron bottom to which grape-shot are secured.

Treenails. Wooden pins employed to secure the planking of a vessel to the frames.

# Supplementary.

Burden. A load. The quantity that a ship will carry. The verse repeated in a song—the chorus. Hence burdensome.

Carvel built. A term applied to the manner of construction of small boats, to signify that the edges of their bottom planks are laid to each other like to the manner of planking vessels. Opposed to the term elincher.

Coccoon. The case which certain insects make for a covering during the period of their metamorphosis to the pupa state.

Contrariwise. Conversely, opposite.

Crossways is a corruption of this word.

Draught. A representation by delineation. The depth which a vessel or any floating body sinks into water. The act of drawing. A detachment of men from the main body, &c., &c., &c.

Draft is a corruption of this word.

Edgewise. An edge being put into a particular direction. Hence, endwise and sidewise have similar significations with reference to an end and a side.

Gearing. In Mechanics, a series of teethed or cogged wheels for transmitting motion.

To gear is to prepare. To connect, as by an articulation

Newel. An upright piece of timber, around which winding stairs turn.

Plane. In Geometry and Mechanics, a surface which coincides with a right line.

Resin. The residuum of the distillation of turpentine.

Sidewise. See Edgewise.

Slantwise. Oblique; not perpendicular.

Strake. A breadth of plank.

Syphered. Overlapping the chamfered edge of one plank upon the chamfered edge of another, in such a manner that the joint shall be a plane surface.

Dø

THE END
