

INAUGURAL DISSERTATION:

AN

BEING AN

ATTEMPT

TO DISPROVE THE DOCTRINE OF THE PUTREFACTION OF THE BLOOD

O F

LIVING ANIMALS.

SUBMITTED TO THE EXAMINATION OF THE

Rev. JOHN EWING, S. T. P. PROVOST;

THE TRUSTEES, AND MEDICAL PROFESSORS OF THE UNIVERSITY OF PENNSYLVANIA,

FOR THE DEGREE OF DOCTOR OF MEDICINE;

On the \$th. day of May, A. D. 1793.

BY ADAM SEYBERT, OF PHILADELPHIA;

Honorary Member of the Philadelphia, and Member of the American, Medical Societies.

"FOR THE LIFE OF THE FLESH IS IN THE BLOOD.

PHILADELPHIA:

L'exiticus.

PRINTED BY T. DOBSON, AT THE STONE-HOUSE, NO. 41, SOUTH SECOND-STREET.

M,DCC,XCIII.

For John Reamon oxe with the Compliments of the author.

TO THE REVEREND

JUSTUS HENRY CHRISTIAN HELMUTH, D. D.

PROFESSOR of the GERMAN LANGUAGE in the

UNIVERSITY OF PENNSYLVANIA, &c. &c. &c.

A S a fmall tribute of gratitude for his care and attention, in directing and fuperintending my ftudies, whilf under his tuition, at the Univerfity,

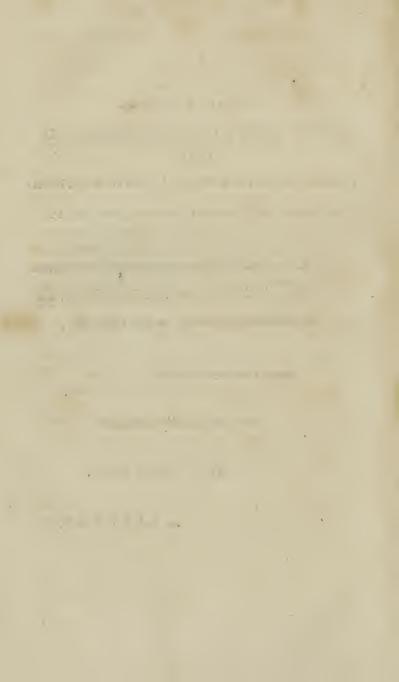

THIS DISSERTATION IS,

399790

Very respectfully infcribed,

By his obliged friend,

A. SEYBERT.

TO CASPAR WISTAR, M. D.

ADJUNCT PROFESSOR OF ANATOMY, SURGERY, AND MID-WIFERY IN THE UNIVERSITY OF PENNSTLVANIA.

SIR,

IN addreffing this Inaugural Differtation to you, every body that knows you will readily admit the peculiar propriety of the tribute. Your juftly acknowledged abilities leave no room to doubt that I have an intereft in making this offering. But, whilft I candidly admit this, I feel and confefs profound obligations of gratitude to a beloved mafter, for his very beneficial inftructions, and his many courtefies and attentions. To whom can the following production, with more evident propriety, be inferibed, than to him who planted the Seed of Knowledge, and, with anxious folicitude, fuperintended the growth ?--To you, Sir, I am indebted for whatever progrefs I may have made in Medical Science; and I am ambitious, that the firft fruits of my labors fhould be prefented to the world under the adorning fanction of your patronage.

The cordiality of your friendship has naturally inspired me with fentiments of effeem and attachment, which it will ever be my pride, as it is my duty and interest, to cherist.

Believe me, Sir, nothing can ever obliterate from my mind the mingled fentiments of gratitude and efteem with which I remain

Your obliged friend and Pupil,

A. SEYBERT.

INTRODUCTION.

THE Opinion, that the blood became putrid in many Difeafes, is of ancient date. It has been embraced, with various modifications by moft of the fects in Medicine. It particularly engaged the attention and belief of the learned Boerhaave, who publicly taught it in the celebrated fchool of Leyden. Under the imposing authority of his name, and by means of his industry, it was diffused throughout almoss the whole globe. It became the theme of the vulgar; and at this day has many great and illustrious names to fupport it.

There have been, however, at different times, a few Medical Philofophers, who, although they adopted it in fome inftances, feem to have had doubts refpecting the truth of the doctrine, and to have rejected it in their explanations of many difeafes. In this clafs may be reckoned the celebrated Hoffmann, who explained the phænomena of many diforders without any regard to the flate of the blood : He was followed in this by the great Cullen, who, in his fyftem, attends lefs to the flate of the fluids in difeafes than any of his predeceffors. The doctrine has of late been wholly denied by the very ingenious Dr. Milman in his treatife on the Scurvy ; and entirely rejected by the late fagacious Dr. Brown of Edinburgh, from his Syltem of Medicine. Many phyficians appear to have adopted the fentiments of thefe gentlemen ; fo that at prefent there

is

is a diverfity of opinion among medical philosophers respecting the Putrefaction of the Blood of *Living Animals*.

On examining the fubject, I found that it had never been put to the teft of fair experiment; but, that fpeculative reafoning (too often delufive at beft) and a few indecifive facts, were the chief fupports of the argument on both fides. With thefe data, the refult was neither fatisfactory nor convincing. I then determined to contribute my mite towards inveftigating the matter by experiment. In the profecution of this attempt, my attention has been directed to the advancement of Science; and, in the detailing of the Experiments which I have made with this view, truth fhall be my polar ftar.

I have been induced from reflection and experiment to adopt a politive belief on this fubject, and to deny the truth of the doctrine which I have juft noticed. I am, therefore, neceffarily led into an oppolition to the opinions of many celebrated men. But, I truft, I have obferved a decent regard and veneration for thole from whom I diffent, without being at all deprefied by the weight of their authority. Having viewed nature *attentively*, I fhall endeavour to communicate *accurately* what I have obferved. I will not facrifice truth to the luftre of great names, but, with confidence adopt the fentiment of Cicero—" Mea fuit femper hec in hac re voluntas et fententia, quemvis ut hoc mallem de iis, qui effent idonei, fufcipere quam me : me, ut mallem quam nemincm."

INAUGURAL DISSERTATION.

T will be proper, before I enter upon the confideration of the Putrefaction of the Blood of living Animals, to take a brief view of *Putrefaction in general*; for, this is, indeed, the only method by which we can be prepared for an examination of the circumftances neceffary to induce that ftate of the blood in living animals.

Though Chemistry is much improved, and numerous difcoveries are made almost every day, by different philosophers, *Putrefaction* is, at this moment confidered as the fame difficult subject, that it was in the days of the celebrated *Lord Bacon*.

This last stage of Fermentation, in the days of Stahl, was supposed to be a mere confequence of the vinous and acetous stages; but, modern difcoveries teach us the contrary; for we find, that while some substances undergo only the last stage, others suffer the three successive changes in a regular manner: thus mucilages, &c. become acid without undergoing the vinous fermentation, and the glutinous matter of vegetables will putrefy before it undergoes either of the other changes.

Obfervation,

Obfervation, the grand parent of difcovery, has taught us, that no fubftance is capable of undergoing a change by the putrefactive fermentation, except it be animal or vegetable; and that the numerous claffes of the productions of nature, comprehended under the title of the Mineral Kingdom, are excluded. It is alfo an opinion, generally eftablifhed, and proved by experiment, that the fluid and fofter parts of those bodies, putrefy much fooner than the harder and more folid parts. It has likewise been observed, "That the flesh of younger animals is fomewhat more prone to putridity, than that of older animals."*

Animal and vegetable matters cannot putrefy in every fituation or condition in which they may exist; for it is neceffary that a living animal or vegetable should undergo a confiderable change, before it can be rendered capable thereof: It must even be deprived of life, or the vital principle. No one has ever feen an entire animal or vegetable putrefy whilft alive; and Beccher, on this fubject, beautifully observes : "Causa putrefactionis primaria defectus spiritus vitalis balfamini est." And, indeed, in all refearches into those kingdoms which are the fubjects of fermentation, it is of fo great confequence to keep this univerfal actuating principle in view, that by neglecting it, we may commit great miftakes, and look to other caufes than the true ones for its palpable effects; infomuch that the learned Chaptal, when regretting the imperfect fuccefs which Chemistry has met with, in the analysis of animal matters, cannot help obferving it. "All (fays he) have mistaken or overlooked that principle of life which inceffantly acts upon the folids and fluids, modifies, without cealing, the impression of external objects; impedes the

* Medical Commentaries, Vol. II. p. 142.

[11]

the degenerations which depend on the confliction itfelf; and prefents to us phænomena which chemistry never could have known or predicted by attending to the invariable laws obferved in inanimate bodies."*

The prefence of that invisible elastic fluid, which we term vital air, is fo neceffary to putrefaction, that a body cannot putrefy without being in contact with it; and may be preferved found and pure for years if the communication between them be destroyed. It is a well known fact that a body will not putrefy *in vacuo*: This has been noticed by an ingenious author in the following words: "How much the air contributes to putrefaction, is evident hence, that bodies buried deep under the earth, or in water, out of the reach of air, shall remain for ages entire; which yet, being exposed to the open air, shall foon rot and moulder away." †

It appears that too great a degree of moifture, or a total want of it, retards the process of putrefaction. In order, therefore, that a body may putrefy, it is necessfary that it be only duly moistened. Thus it happens, that after an animal or vegetable fubstance has been made perfectly dry, it may be preferved, in that state, for many years after. It has been observed by the immortal Beccher, that too great a degree of moisture prevents putrefaction: These are his words: "Nimia quoque humiditas a putrefactione impedit, prout nimius calor; nam corpora in aqua potius gradatim confumi quam putrefcere, fi nova femper affluens fit, experientia docet: unde longo tempore integra

> * Chaptal's Chemistry, Vol. III. p. 280, † Frewen's Physiologia, p. 128.

integra interdum fubmersa prorfus a putrefactione immunia vidimus; adeo ut nobis aliquando speculatio occurreret, tractando tali modo cadavera anatomiæ subjicienda, quo diutius a fœtore et putrefactione immunia forent,"*

That all enlivening principle, heat, which, in a certain degree; is neceffary to life, is no lefs neceffary to the bringing on of the diffolution of a body. Temperature has been found to have great influence in promoting and retarding putrefaction.

I have now mentioned the most effential circumstances necessary to promote the inception of putrefaction; to which we may fubjoin Reft; for bodies do not putrefy while in continual motion. In proportion as these circumstances take place the process will advance with greater or lefter rapidity.

Certain fubftances, as well known to the vulgar as to the philofopher, by the name of Ferments, when added to a fermentable mafs, are found to haften the procefs in a manner truly aftonifhing; though both the peafant and the philofopher ftand on an equal footing with regard to a knowledge of the principle by which their application produces a fpecific operation. "We are told indeed (fays the ingenious Mr. Henry) that a vinous ferment induces the vinous, that a ferment of an acetous kind brings on the acetous fermentation, and a putrid one, that fermentation which ends in putrefaction. But we receive no more information, relative to the manner in which they produce those effects, than we do with regard to fermentation itfelf."

I will

* Phyf. Sub. lib. 1. f. 5. cap. 1. p. 277. † Manchefter Memoirs, Vol. II. p. 259. I will now proceed to examine, whether, in becoming putrid, a body undergoes any confiderable change; and, whether it be poffible to remove putrefcency after it has taken place.

The very meaning of the word *putrefaction* conveys the idea that an effential change muft have taken place in any fubfiance which has acquired a putrid flate.

Putrefaction reduces both animals and vegetables to the fame principles, for, it caufes an entire and complete decomposition of them, infomuch that it is difficult, and indeed impossible, to distinguish between a putrefied mass of animal and one of vegetable matter. The former characteristics of each are at an end. Colour, texture, and every fenfible quality of the body, are thereby deftroyed. It reduces the animate part of the Creation to an indifcriminate level with inanimate matter. There is abundance of truth in the observation, that bodies, in this process, undergo a new combination, as well as feparation of their conftituent parts. Putrefaction caufes the fweetest fubstances to become the most offensive and difagreeable to the fmell; and, inftead of a vegetable acid, at length produces a volatile alkali-bodies poffeffing very oppofite principles.

Many philofophers have gone fo far as to fay, that, by certain chemical proceffes, they were able not only to render putrid fubftances fweet again, but reftore them to the condition they were in, previoufly to their undergoing this peculiar change. This, according to them, is to to be effected by furrounding the putrefied body with an atmosphere of fixed air; to the loss of which principle, an enlightened enlightened philosopher wholly attributed the changes produced in a body by putrefaction; though the opinion has been ingenioufly refuted, and therefore needs not much confideration in this place *.

It is true, that by furrounding a putrefied body with fixed air, we shall prevent the advancement of the procefs ; yet the fixed air has no fpecific operation in this refpect, for other fubftances possels a fimilar property. After I had fuffered feveral pieces of highly putrid beef to remain completely covered with fresh pump water for feveral hours, and then washed them frequently in water feveral times renewed, I found, that by this operation the water gained a highly offenfive and putrid fmell, and that the meat had loft a great degree of its own; but its folidity was not in the least reftored. It is a common and well-known fact in domestic æconomy, that meat, which has become tainted, is very frequently washed in fresh water before it is cooked; and the reafon affigned for this process is, that the meat is thereby rendered fweeter. Thus do houfe-keepers reafon from a knowledge of the fact without any theory to bias them.

Hence it appears very clear, that to explain this fact no fpecific operation is neceffary to be recurred to, fince water, free from the combination of fixed air, had effects fimilar to those produced by fixed air itself. Mr. Chaptal, in my opinion, explains the operation of this, and of the other fubstances which are faid to have the like effect, upon very fimple and philosophical principles. When speaking of the neceffity of the prefence of vital air to putrefaction,

* Medical Commentaries, Vol. II. p. 150.

putrefaction, he fays, "We shall observe, on this subject, that the effects observed in subject in the effects observed in state effects to the Carbonic acid, Nitrogene gas, &c. are referable to a similar cause; and it appears to me that it is without sufficient proof that a conclusion has been drawn, that these fame gases, internally taken, ought to be confidered as antispetic; because, in the cases we have mentioned, they act only by defending the bodies they furround from the contact of vital air, which is the principle of putrefaction *."

To me it appears plain, that, fo great is the chemical change and decomposition which a putrid body has undergone, that no means can remedy it. On this point Fontana truly obferves, "We do not know any power, nature herfelf does not difclofe any, that can recompose an organ that is deftroyed, and entirely decomposed by putrefaction, or by the concuffions of external bodies. This is what has never yet either been accomplished or feen. We have, therefore, every possible reason not only to believe an animal that is reduced to this state dead, but likewise to believe it dead for ever †."

From the above confideration of putrefaction, as going on out of the body, it appears, that a certain degree of heat, the prefence of vital air, a certain degree of moifture, together with reft, are indifpenfably neceffary to putrefaction; and that without their prefence no body can putrefy. We alfo know, that by adding certain fubftances to bodies which are to undergo the change, the procefs is haftened in a manner furprifing to every one who has ever had occafion to notice it.

Having

* Chaptal's Chemiftry, Vol. III. p. 398.

† Fontana on Poisons, Vol. I. p. 406.

Having confidered the circumftances in which fermentation, in general, takes place, as it is conceivable that if the above circumftances be prefent in the living animal, the procefs might readily go on in it—let us examine if thefe neceffary requifites be prefent, fo as to act in a due and proper manner upon that vital fluid, *the blood*.

Several queffions occur here.—Is there any difference between dead and living matter ?—Is there not in living animals a politive power of refifting putrefaction ?— Whether the nice and inexplicable operation which is employed in converting the dull mass of the motionlefs creation into the peculiar condition of organic fensibility, acts to no purpose ?—In fact, whether the principal characteristic of death, has not been determined by physiologists to be the beginning of putrefaction in the body ?

The principle we denominate *vital*, with whofe effects we begin to be acquainted, though its nature and origin will perhaps ever be hidden from us, is found to be the chief impediment to the putrefaction of a living animal. As foon as the animal is deprived of it, putrefaction is the inevitable confequence, except the above precautions be well obferved. This may be fairly demonstrated. All the circumstances neceffary to putrefaction take place with respect to the external furface of our bodies, yet they do not putrefy while alive; but if life be by any means destroyed, they will as readily undergo the procefs as other inanimate matter.

It is to be observed, that by the living principle is understood that power which in an animal actuates its whole fystem, or from which is derived fensation, moti-

3

on,

[17]

on, and the other qualities of life. It is the caufe of the prefervation of the body from diffolution, and is capable of exifting, for fometime, under a fufpenfion of all its actions *.

We will now proceed to confider the prefence of *heat*, pure *air*, *moifture*, and *reft*, with regard to the blood; in order to determine whether we might expect a putrefaction of that fluid if the principle of life, were not alone fufficient to obviate it.

Ift. Of Heat. Though different degrees of heat are found fufficient to maintain life, in different animals, yet no animal while alive has ever been found devoid of a confiderable quantity of it; indeed, fo careful was nature in this refpect, that fhe has endowed man, and the inferior animals, with a power, whereby they are capable of generating heat;—a procefs the inveftigation of which has of late much engaged the attention of philofophers, and upon which confiderable light has been thrown. It is probable that the blood of every living animal contains a degree of heat fufficient to fupport the procefs of putrefaction.

2dly. Pure Air. That element fo neceffary to our exiftence, and which we receive into our bodies, by means of those vital viscera, the lungs, is no less necessary to the maintaining of animal life, than to the process of putrefaction. A man will no more live, than a dead body will purefy, in vacuo \dagger .

C

* Gardiner's Animal Economy, p. 3.

+ That air is a very active and powerful agent in putrefaction, is evident from the following fact, viz. Whilft pus remains that up

in

It

It was for a long time fuppofed that elaftic air exifted in the blood-veffels of living animals; but, the experiments of the ingenious Darwin clearly prove the contrary; the following is one of them. "Part of the jugular vein of a fheep, full of blood, was included between two tight ligatures, and cut out while the animal was yet alive. It was immediately put into a glafs of warm water, and placed in the receiver of an air pump. It funk at firft to the bottom of the water, and did not rife again, although the air was carefully exhaufted. After this, it was wiped dry, and laid on the brafs floor of the receiver. The air was again exhaufted, but there was not the leaft vifible expansion of the vein or its contents *."

By the experiments above referred to it is reduced to a certainty, that no air exifts, formally in the blood, while enclofed in the blood-veffels. And it is evident, that it was without fufficient grounds, that philofophers inferred, that air exifted in the blood, while enclofed in the blood-veffels; becaufe they perceived it in blood drawn from a vein, and placed in the receiver of an air pump; for during its expofure it muft have had time to abforb air from the atmosphere.

The celebrated Huxham was of opinion, that, " elaftic air is probably generated in the arterial and venous fyftems,

in a perfectly clofe cavity it will keep fweet and inodorous, but on exposure to the atmosphere, it contracts in a very fhort time a putrid fmell; the fame circumflance takes place with regard to extravalated blood.

* Medical Commentaries, Vol. VI. p. 35.

[19]

tems, in putrid fevers *," though he has no experiments to prove it. Let us then examine, whether air can exift in the blood-veffels of living animals.

With this view the ingenious Luzuriaga tried many experiments on living dogs. He injected feveral different kinds of air into the blood-veffels, and in every inftance the animals were killed, in a very fhort time. I will only mention that he twice injected inflammable air; once phlogifticated air; once fixed air; once nitrous air. I will ftate the particular circumftances that happened in the inftance, when dephlogifticated or pure air, which is the chief agent of putrefaction, was injected.—It was forced into the jugular vein of a dog, and in three minutes he died. On diffection, the blood appeared of a lively red colour, and frothy, but not grumous nor coagulated \dagger .

Thus it appears, that air does not, and cannot exift, formally, in the blood-veffels of a living animal; a circumftance which refutes the opinion, that the blood is capable of undergoing the process of of putrefaction, during the life of the animal.

3dly. Moifture. No perfon in his fenfes dares to deny the prefence of this third circumstance, as effential to putrefaction, and therefore it needs no further confideration.

4thly. We have mentioned that it was neceffary for a body, which is to undergo the putrefactive process, to be at rest. The continual motion of the blood of living animals,

* Medical Qbfervations, Vol. III. p. 36. † Luzuriaga's Inaug. Differtat. Eden. 1786, p. 26. animals, muft certainly be a great impediment to the procefs; and indeed motion has been found to be a very effectual means of preventing it; even a brifk wind has been known to retard it *.

We have found that the life of the animal, the want of air in the blood-veffels, and its circulatory motion, were great impediments to the putrefaction of the blood; we fhall now proceed to confider, whether the principle of animal life is contained in the blood.

The fituation of that principle, to which we owe our existence as living beings, is at prefent much disputed. While fome Physiologists will have it to exist wholly in the nervous system, in the form of a subtle fluid, whose prefence the best microscopes have not been able to discover; there are others, whose authority is by no means inferior, who strenuous oppose the doctrine, and perfist that blood partakes of it also. In this latter class we may rank the celebrated Hunter and Fontana.

That the life of the animal exifts in the blood, is an opinion of as ancient a date as Holy Writ itfelf: It was the favourite fentiment of many ancient philofophers; and the great Harvey, to whom we are fo much indebted, fays, "the blood is the primum vivens, and the ultimum moriens, of the animal."

This hypothefis was for fometime funk into oblivion, but was again revived and placed on a firm bafis by the able Mr. John Hunter of London; who fupports the doctrine by

* Medical Commentaries, Vol. II. p. 146.

by reafoning truly philofophical, and by experiments, in my opinion, incontrovertibly convincing. It would be needlefs for me to repeat all the ingenious arguments which are made ufe of by him on this occafion, as they may be eafily feen, by referring to the Encyclopædia, Vol. III. P. 313.

His 5th argument alone would almost fuffice to convince me of the truth of his opinion. "The blood (fays he) preferves life in the different parts of the body. When the nerves going to a part are tied or cut, the part becomes paralytic, and loofes all power of motion; but it does not mortify; if the artery be cut, the part dies, and mortification enfues. What keeps it alive in the first place? Mr. Hunter believes it is the living principle which alone can keep it alive; and he thinks that this phenomenon is inexplicable on any other fupposition, than that life is fupported by the blood"*.

This doftrine is every day gaining ground; and appears to be further fupported by the opinions and experiments, of the celebrated Fontana; who obferves, "What may lead one to fufpect, that a very active and volatile principle does really exift in the blood, is, that the vipers venom prevents its coagulation when it is drawn from the veffels, and on the contrary, produces it in the veffels themfelves. One would fuppofe (fays he) in the first cafe, that fomething had flown off from the blood, which exists in it when it is enclosed by the veffels" †.

"My experiments on animals (continues this last mentioned enlighted philosopher) in which the nerves were bit

by

^{*} Encyclopædia Loc. citat.

[†] Fontana on Poisons, Vol. II. p. 135.

by vipers, fhew that the venom is a fubftance perfectly innocent to thefe organs, that it does not occafion in them any fenfible change, and that they are not even a means or vehicle of conveying it to the animal. In a word, it appears that the nervous fyftem does not concur more to the production of the difeafes of the venom, than does the tendon, or any other infenfible part of the animal : on the other hand, all the experiments on the blood, the injection of venom into the veffels, and fo from conftantly evince that the action of the venom of the viper is on the blood itfelf. This fluid is alone changed by the venom, and this fluid conveys the venom to the animal, and diftributes it to its whole body. The action of the venom, and its effects on the blood, are almost inftantaneous."*

His experiments, in my opinion, allow this inference, that fince life was not deftroyed by the immediate application of the poifon to the bare nerves, and that the lofs of it was almost inftantaneous when the poifon was applied to the blood; there exists fome quality in the blood, that does not exist in the nerves; and as death can only be produced by deftroying the vital principle, this principle must confequently exist in the blood, and in a state different from that in which it exists in the nervous system.

I will now proceed to give a connected view of the reafons, which together with the experiments hereafter to be mentioned, induce me to deny the putrefaction of the blood to have ever taken place, and which confirm me in believing, that no fuch change can happen in the blood of living animals.

ift. We

* Fontana on Poifons, Vol. I. p. 396.

If. We have feen that the procefs of putrefaction cannot take place in the animal or vegetable kingdoms, until after the animal or plant be deprived of life. I think we have given fome proof of the blood's containing the principle of Animal Life, of which (whether it be convincing or not) the candid will judge. When life is once perfectly deftroyed, there are no means, at our command, by which it can be again reftored : therefore, we must infer, that all putrid cafes are neceffarily mortal, or a putrefaction of the blood cannot take place.

2dly. From viewing the process of mortification, as going on in the folid parts of animals—for the death of the part *invariably* precedes the fymptoms of putrescency, as is evidenced by the want of fensibility in the part.

3dly. There is no vital air in the blood-veffels, and we know putrefaction cannot go on without it.

4thly. The blood in the living animal is in continual motion—a fmall degree of motion has been known to impede the process.

5 thly. The doctrine of ferments. For as long as a drop of this putrid blood remained in the veffels, no particle could exift in them, without being changed by it; therefore it is a neceffary confequence, that in every cafe, where putrefaction is fuppofed to have taken place in the blood, every drop of that fluid flould be drawn from the veffels, and the veffels flould undergo a perfect cleanfing before healthy blood could exift in them; confequently, if the veffels are not cleanfed, the procefs muft neceffarily continue continue for ever, and in attempting to cleanfe them, would not death be the inevitable confequence?*

6thly. We are as yet unacquainted with any means by which we are able to recover a body, when once putrid; for, according to a chemical axiom, it has undergone a perfect decomposition in the process; and, certainly, without obviating the effects of putrefaction on the blood, and reducing it to its former state, the animal cannot exist for any length of time.

7thly. In every cafe of putrefaction a great quantity of elaftic air is evolved, and no author (as far as I know) has made mention of the prefence of air in the bloodveffels of those who have died of diseafes, which were fupposed to belong to the putrid class, and whose bodies were diffected immediately after death. It has been fairly proved that air, on being injected into the vessels, kills in a very short time +.

8thly. According to the ideas of the fupporters of the putrefaction of the blood in difeafes, the procefs must be 4 different

* The difficulty of reftraining putrefaction after it has taken place, and of deftroying the putrid ferment in veffels that have contained putrid fubftances, is well known to the brewers. When their liquor becomes putrid, or as they term it, "foxed," the veffels which contained it become fo contaminated, that they will excite the fame fermentation in any frefh liquor that may be put into them, even after they are wafhed. It is only by whitewafhing or fcouring them with lime that they can be thoroughly cleanfed. I have heard of a brewer, who was fo much embarraffed by a putrid ferment in his veffels, that he was about giving up his bufinefs, when he fortunately learned the ufe of lime.

+ Vide ante Page 19.

different in Typhus, &c. from what it is in fcurvy; fince, in the former cafe, bark and wine, together with other flimuli, are the only true remedies; whereas, according to them, thefe remedies are found to be of little or no fervice in the latter, and fresh vegetables are its only remedies. For the blood, they fay, is putrid in both inftances; and fince putrefaction going on in the fame fubflance would appear to be always the fame, we might, with propriety fuppofe, that, what retards and corrects it in the one inftance, would do it in the other. Who has thought of exhibiting fuch vegetables, in typhus, yellow fever, &c. and neglecting those powerful remedies, bark and wine?

othly. It is incompatible with found reafoning to fuppofe that putrefaction of the blood takes place in the plague, &c. fince we find that perfons fometimes fall down dead, immediately on being exposed to the effluvia, that have been faid to give origin to this and other difeafes of the fame clafs, as the porters, who opened bales of goods in the lazarettos of Marfeilles. Mead relates, that, "Upon opening one of the bales of wool in a field, two Turks employed in the work were immediately killed, and fome birds which happened to fly over the place, dropped down dead *." How is it peffible that the mass of blood, or any part of it, could become in the least degree putrid in those instances? For the fpace of time, before death was produced, was too fhort to allow of it. Since the poifon kills fo quickly, can we with reafon fuppofe that an animal can live while the fountain of life is impregnated with it ? If a fmall portion of fuch effluvia produces difeafe, when its action

D

may,

Mead's Works, p. 198.

may, exclusively, be supposed to be merely on the external surface of the body, Is there not strong ground for believing that instant death would follow if the blood were in the least tainted by it ?

rothly. Experiments feem to prove, that the blood is peculiarly qualified to excite motion in the heart and arteries, and that no other fluid will anfwer the fame purpofe.—That even milk, and other bland liquors, when injected into the veffels of living animals, kill. We know it is an eftablifhed truth, that by putrefaction bodies undergo a complete decomposition and diffolution of their of their conftituent parts, and are rendered totally different from what they were before—How then can we imagine that life can be kept up whilft the blood is in a putrid ftate in the veffels ?

For thefe reafons I concluded that a putrefaction of the blood could not take place in the living body: but the importance of the fubject induced me to engage in a feries of Experiments which might enable me, with more indifputable certainty, to decide the queftion, Whether the blood of living animals can be rendered putrid ?

And this I fuppofe, if poffible, would be afcertained by the following circumftances, viz.

I. By Starvation.

II. By a putrid Diet.

And, III. by injecting putrid and other fubftances into blood-veffels.

[27]

Ift. Of Starvation. When we confider the many and various actions performed by man and other animals, we plainly fee why a certain quantity of aliment is neceffary to be taken by them. Phyfiology teaches, that by every action man fuffers a lofs of the folids, and that by every fecretion the blood becomes lefs in quantity.

The blood being the fountain from whence all the folid parts derive their fupport, and the fluids their origin, it must naturally have been fupposed to be affected by flarvation, as it is immediately prepared from the aliment we take in.

If the cafe be as above flated, is it not furprifing that man can live for a length of time without taking any nourifhment at all? There are inflances related where men have lived for fix, twelve, and even fourteen days, or longer, without receiving any aliment *.

Drink is found to be no lefs neceffary to the maintaining of animal life than the folid matters of our food. The neceffity of this article was fuppofed to be merely in recruiting, blunting, and correcting the acrimony of the blood which would take place if we did not ufe them. And it has been found by experiment, that life may be fupported a much longer time by water than it could without it. Rhedi, who made experiments to afcertain how much longer life might be fupported by the ufe of drink, without the ufe of any other article of diet, than when the animal was totally deprived of all food, found, that fowls to whom he gave no drink lived until the ninth day; whereas

* Manchester Memoirs, Vol. II. p. 467. and feq.

whereas one who was allowed water, lived more than twenty days *.

Though man may live for a confiderable length of time, without taking in any nourifhment, yet his fituation is not agreeable; for, he not only fuffers pain, but all the functions, as well bodily as mental, are in confequence affected; his fenfations are ftrange, his ideas confufed, his fight deceptive and deranged, his countenance becomes pale and fallow, his weight decreafes confiderably, though the excretions are fparing or none at all, the refpiration fuffers, the action of the heart decreates in proportion, till at laft no pulfation can be felt, debility by degrees overpowering life, death approaches and puts an end to his fufferings.

If after having fasted a length of time, the perfon recover, he becomes melancholy, hysterical, effeminate, stupid, &c. +

The functions performed by the fluids and folids of an animal, being fo nearly connected the one with the other, have occafioned this queftion, Does flarvation operate by inducing difeafe in the folids or fluids ? Moft phyfiologifts are in favour of an opinion, that the fluids are particularly affected, and that by flarvation the animal fuffers from the quality, rather than from the deficient quantity of the blood. They fuppofe it to become acrid and even putrid.

To determine whether it was the blood that fuffered, I performed the 2d. and 3d. following Experiments, and alfo

> * Manchefter Memoirs, Vol. II. p. 575. † Hallerig Elementa Phyfiologiæ.

alfo examined the phænomena prefented by the blood of an healthy dog, the better to judge of the flate of that fluid in all the fucceeding Experiments. And let me here obferve, that the Experiments I fhall have occasion to relate, were made in the prefence, and with the affiftance of way worthy friends, Meffrs. Jeffe Thomfon, John Andrews my fellow graduate, and Jacob Wagner, junior. They were witneffes to all the phænomena; and I take this public method of acknowledging my obligations to them for their kind affiftance.

EXPERIMENT I.

September 6th. 1792. An ounce of blood was drawn from one of the crural veins of an healthy dog, at 15 minutes after 2 o'clock, P. M. it was coagulated at 20 minutes after 2; feparation into ferum and craffamentum was evident at 34 minutes after 2. Serum did not change the colour of a piece of paper stained with a vegetable blue.*

EXPERIMENT II.

A young dog was kept for the purpole of flarvation, and the phænomena were as I shall now relate.

I there-

* The vegetable blue was made ufe of as a teft, with the view of afcertaining whether the ferum of an healthy animal contained any alcaline falt in a formal flate, as it is a well effablished fact that the volatile alcali is produced by putrefaction; and the production of it is one of the characteriflic circumflances of that process; the fame teft was made ufe of in the fublequent experiments, to afcertain whether ferum gained any alkaline properties by the different treatment which the feveral animals fuffered. I thought it not unneceffary to weigh him, at different times. I shall therefore mention the weight, as observed at those feveral periods.

July the 8th. he weighed 5³/₄ lb. July 29th. 7³/₂lb.

Food was given him the last time, in the afternoon of the 29th. of July.

August 3d. he weighed $6\frac{1}{2}$ lb.

August 12th. he weighed 5lb. At 2 minutes before 12 o'clock an ounce of blood was drawn from one of the crural vessel. The blood flowed freely, but by misfortune an artery was opened instead of a vein. The colour and fmell of the blood were quite natural, being highly florid like arterial blood. It was coagulated at 3 minutes after 12—fcparation into ferum and crassifiamentum was evident at 13 minutes after 12. The ferum and crassimentum appeared perfectly natural. A piece of the blue stained paper was dipped into the ferum, and no change of colour was produced. To prevent a further hæmorrhage, as he was much weakened by the bleeding, the wound was well closed, and a piece of spunge bound tightly over it. The leg became paralytic.

August 13th. the leg was much fwolen below the ligature, and when handled, did not appear to give him any pain. The ligature was fomewhat loofened.

August 14th. weighed 4¹/₂lb.

August 15th. 'This morning at 8 o'clock I found him dead.

During

E 31]

During the above management the dog had very few evacuations by ftool or urine, till the two laft days of his life, when the urine dropped continually from the urethra.

His eyes were feveral times examined, and no alteration in them was evident.

He did not appear to fuffer pain till the 3d. of August, at which time he cried very much, gaped frequently, and appeared very weak; weakness continuing daily to increase till his death.

I did not perceive that refpiration was much affected; but the action of the heart became fo feeble, that I could fcarcely perceive its beating for fome days previous to his death, though I applied my hand to the part where its ftroke is generally felt.

The abdomen was much contracted, and the fore-part of it was drawn up to the fpine.

The body was examined immediately on finding him dead, when appearances were as follow :

The flomach contained a confiderable quantity of a whitifh fluid, its texture was perfectly natural. The intestines were of a greenish cast. The other viscera appeared in a found and natural state.

At 39 minutes after 8 o'clock, blood was caught in a tumbler from an opening made into the heart; colour and fmell natural. It was coagulated at 45 minutes after 8. It began to feparate into ferum and craffamentum at 51 minutes after 8. Coagulum and ferum perfectly natural. Serum did not change the paper ftained blue.

E 32]

EXPERIMENT HI.

April 15th 1793, a dog was kept for the purpose of farvation.

April 20th. Blood was, drawn from him at 15 minutes paft 3 o'clock. The colour and fmell were natural—it coagulated at 20 minutes after 3—and feparated into ferum and craffamentum at 35 minutes after 3—The ferum was not in the leaft acrid to the tafte.

April 26th. Blood was drawn at 33 minutes paft 3 o'clock—The colour and fmell were natural—It coagulated at 38 minutes paft 3—and feparated into ferum and craffamentum at 53 minutes paft 3—The coagulum and ferum were natural—The ferum was not in the least acrid to the tafte.

2dly. Of Putrid Diet. The neceffity of our taking aliment being fully eftablished, Nature, with her usual wifdom, has given man and the other animals an appetite for it. She has also provided different kinds of aliment in the different climates, in a proper quantity, fo that each might have what was most fuitable and agreeable to his particular condition.

To this purpofe the appetites of the inhabitants of the different regions vary; while fome prefer a vegetable, others according to the fituation, with more pleafure and benefit to their health, derive their chief fupport from the fame clafs of beings to which they themfelves belong, though of different genera and fpecies.

I

Animals are styled herbivorous, carnivorous, and omnivorous, from the particular kind of aliment they make ufe of : Thus fheep live wholly on a vegetable diet, while the wolf and other animals of the fame fpecies are found to fupport themfelves best by a diet which is entirely animal; and man, from the peculiar structure of his teeth, appears to be defined to take in all kinds of alimentary matter, and thus he is found to live beft on a diet, composed of animal and vegetable fubstances. Experiments would feem to prove that an animal, who is naturally herbivorous, may be made to live entirely on flesh, although not fo conveniently. A mixed diet, as already mentioned, best fuits the appetite and peculiar state of man, but there are instances where he entirely lives on vegetables; and on the contrary, he has, in other fituations, been found to live wholly on the inferior animals. While the mixed diet renders him placid and fit for every purpole, for which nature formed him, one entirely animal renders him ferocious as the brute, and that altogether vegetable renders him weak and feeble.

Among civilized nations, aliment, before it is eaten, always undergoes fome kind of preparation, whereby it is rendered more or lefs fit to be fubject of digeftion.

Aliment, after being received into the ftomach, remains there for fome time, and undergoes a confiderable change, before it quits that vifcus; for it thereby becomes fitted for the forming of the chyle, from which the blood itfelf is immediately prepared.

The flate of the chyle and confequently that of the blood, is by many fuppofed to be much influenced by the aliment

we

we take; thus a putrid and bad diet, is fuppofed to produce vitiated and putrescent chyle, and confequently in their opinion the blood is tainted in the fame manner. This opinion probably took its rife from the flefh of certain animals tafting fimilar to the food they eat; thus fea-fowls, we know, have a fifhy tafte; pidgeons who have fed on poke-berries for fometime have their flesh tinged with the colouring matter of that vegetable; and the flefh of the pheafant who has lived upon laurel-berries is capable of communicating the deadly effects of that active poifon to the human fystem. Thefe, and perhaps other like circumftances, were the means of giving rife to the opinion, that the blood of animals must be affected differently by different articles of diet, and that corrupted or putrid food would be the means of producing a putrefaction of the blood. As long fince as the days of Hippocrates, phyficians have been of opinion that water and corrupted meat were the true caufes of putrid difeafes. In this manner was the plague, fcurvy, &c. thought to have been produced ; but the fentiment of many moderns is, "That fourvy arifes from the want of a due quantity of alimentary matter in the food of those who are afflicted with the difeafe." This opinion is fupported by the two cafes of fcurvy related in the Medical Transactions by Dr. Milman, and alfo by Dr. Stark's Dietetic Experiments *.

To convince myself whether, the state of the blood was affected by a putrid diet, the following experiments were performed.

EXPE-

* Vide Blane on Seamen's Difeafes---Medical Transactions---and Surk's Works.

[35]

EXPERIMENT IV.

July 29th 1792. A dog was put upon a diet of putrid meat and putrid water, and continued to feed thereon till the 27th day of August following. The meat was beef, and never given to him till it was highly putrid: the drink was clear pump water, rendered putrid by fuspending a piece of putrid beef in it, and exposing it to the action of the fun.

August the 12th his eyes were examined, and the pupils of both appeared much contracted. They were watry. At 20 minutes passed 120'clock an ounce of blood was drawn from one of the crural veins. Its colour and smell were perfectly natural—it was congulated at 25 minutes after 12feparation into ferum and crassamentum was evident at 30 minutes after 12; the congulum and ferum were perfectly natural—the ferum did not change the colour of a piece of paper, stained with a vegetable blue.

August 19th. he appears weak and very fick. For these few days past, he has had a disrelish for the putrid meat. His eyes appear fore and inflamed. I washed them with cool pump water. The action of the heart was regular though feeble. Blood was drawn at 4 minutes before 11 o'clock—the colour and smell were perfectly natural it was coagulated at 11—separation into ferum and crassian mentum was evident, at 6 minutes after 11. The ferum and coagulum were perfectly natural—The ferum did not change the colour of the paper stained blue.

August

August 20th his eyes appear much better-washing them with cold water continued. He appears weak.

August 22d. his eyes appear quite well. Strength fomewhat recovered. Appetite appears also to be encreased.

August 24th blood was drawn at 20 minutes after 5 o'clock. Its colour and fmell were perfectly natural. It was coagulated at 24 minutes after 5—feparation into ferum and craffamentum was evident at 31 minutes after 5. The coagulum and ferum were natural. The ferum did not change the colour of the paper stained with the vegetablue.

He in general ate and drank a fufficient quantity; but ate more in the beginning than towards the latter end of the experiment. He was reduced by the diet. The excretions were not evidently affected. The action of the heart was regular as has been mentioned, and refpiration appeared to be performed in a natural and eafy manner.

EXPERIMENT V.

A dog was kept fasting from September the 10th 1792, till the 14th of the fame month.

During his fafting he did not appear uneafy till the evening of the 13th, when he cried. He continued in this ftate till the morning of the 14th, when at 15 minutes after 9 o'clock highly putrid broth was given him, he fwallowed it greedily, belched feveral times afterwards, but did not vomit. The action of the heart which before was frequent and feeble, now became flower and fuller; he appeared

[36]

[37]

peared very lively and full of play. At 3 o'clock P. M. he was fed again with putrid broth.

September 15th. At 2 o'clock, he received fome more of the putrid broth. The action of the heart in every refpect natural, except that it was little feeble.

. September 16th. At three o'clock he was fed again with putrid broth which he took in heartily.

September 17th. At 33 minutes after 9 o'clock blood was drawn from one of the crural veffels. Its colour and fmell were natural. It was coagulated at 39 minutes after 9. It began to feparate into ferum and craffamentum at 50 minutes after 9. The ferum and coagulum were perfectly natural. The ferum had no effect in changing the colour of the paper flained blue.

EXPERIMENT VI.

A bitch was kept under the fame circumstances as the dog last mentioned, and the phœnomena were alike in both instances.

September 17th. At 12 minutes before 10 o'clock', blood was drawn. Its colour and fmell were natural. It was coagulated at 6 minutes before 10. It began to feparate into ferum craffamentum at 3 minutes after 10. The ferum and coagulum were perfectly natural. The ferum did not change the colour of the paper ftained blue.

From these experiments, it is evident, that the fensible qualities of the blood are not, in the least, affected by a putrid diet. The question then must certainly be, How does does a putrid diet operate upon the fystem? I answer, by inducing debility from the little nourifhment it contains; and that from hence the folids fuffer. This I hope to prove by an experiment performed on the dog, the fubject of the 19th experiment, which will be related under the head of injections of putrid matters into the blood-veffels.

The procefs of *digeflion* is one of the moft curious operations of nature. It acts wonderfully and powerfully upon our aliment, changes the properties of animal and vegetable matters, reduces them both to a fubftance poffeffing like properties, and operates upon the hardeft as well as the moft fluid fubftances —All this is faid to be performed by a fluid we call the gaftric juice.

If fuch are the effects of digeftion on our aliment, is it not reafonable to fuppofe, that the properties of putrid matters taken into the ftomach may be alfo changed ? Let us examine whether putrid food undergoes a change of properties in the ftomach.

That great Italian Philosopher, Spallanzani, was I belive, the first who made experiments to this purpose. He performed them on birds, cats, dogs, and even went fo far as to swallow putrid meat himself. He found that the meat, in every instance, loss its putrid smell *.

I repeated his experiments on dogs, with the like fuccefs, and fhall now relate them.

EXPERIMEN'T VII.

September 17th 1792. Three ounces of highly putrid beef were given to a bitch. She retained it. Three hours

and

* Spallanzani's Differtations, Vol. I. p. 284 and feq.

and a half after, the contents of the flomach were examined. The meat was found furrounded by the gaftric-fluid; its putrid fmell was entirely deftroyed, and its colour appeared more natural than it was before the animal had fwallowed it.

EXPERIMENT VIII.

September the 17th. 1792. Highly putrid broth was given to a dog. The ftomach retained it : and three hours after, its contents were examined, fome of the broth was remaining together with fome of the folid matters that were mixed with it. The putrid fmell was found to be abundantly diminished.

I shall now proceed to the confideration of my 3d. head, which has for its object of enquiry, Whether the blood be materially changed and rendered putrid, by the injection of putrid and other fubstances into the bloodvessels?

Many centuries have elapfed fince phyficians first began to be afraid of the access of the least particle of contagious matter into the blood-vessels, for, that it excited a fermentation therein, contaminated the whole mass of blood, and caused it to partake of its contagious properties.

If (fay they) by adding a fmall quantity of a ferment to a maß of flour, or other fermentable matter, we are able to bring on a fermentation in it, and convert it into the nature of the ferment, why fhould not the blood, in like manner, be affected, if by chance or otherwife a putrid or other ferment should get into the vessels and mix with it? Thus they supposed the small-pox, measles, and other eruptive difeases to be produced.

These men always overlooked the vital principle, which exists in the one substance, and not in the other; and here in my opinion the material difference lies; for we know that if the other requisite circumstances be duly obferved, it is only necessfary to destroy life, in order to bring on a putrefaction in the animal. I think, from what I have stated, there is ground for believing that the blood cannot putrefy in the living animal; but the deductions of reason, however just and true, the inferences are not to be solely relied upon, when the better evidence of substantial facts—and of facts more immediately in point than the preceding ones, can be had.

To afcertain beyond a doubt whether the blood could be excited to a putrid fermentation, by injecting putrid matters into the blood-veffels, became an important and effential defideratum. With this view I made the following Experiments, which were performed on healthy Dogs.

The operation of injection was always executed on one or the other of the extremities of the animal. An incifion was made, and the vein was laid bare, which was for fome diftance diffected free from connection with the adjacent parts. An opening was then made into its cavity, fufficiciently large to admit a curved tube, which was retained in it by means of a ligature paffed round the veffel. The tube was made fo as to forew on the mouth of a common pewter fyringe.

EXPE.

[41]

EXPERIMENT IX.

Was performed July 29th. 1792, on a Bitch, two months old in good health.

About 5 drachms of putrid ferum were injected into one of her femoral veins. The ferum was obtained from the blood of an healthy dog; and exposed in an open phial, for one week; and had a fmell fimilar to that of rotten eggs.

Some difficulty attended the introduction of the pipe, by which the matter was injected, owing to its large fize, and the fmallness of the vein-The vein, when laid bare and touched with any inftrument, contracted confiderably, its diameter being thereby much diminished-During the operation, she lost but a very inconsiderable quantity of blood, yet she feemed very weak and languid, probably owing to the pain she endured-Whilft I was injecting the ferum into the vein, she had two convulsive paroxysms, and appeared to be in great pain, which the expressed by feveral loud cries .- The mufcles of her whole body feemed affected with these convulsive motions; that they were not owing to the irritation produced by introducing the pipe into the vein is certain, becaufe no fuch fymptoms appeared before the injection of the ferum, though it was introduced twice or thrice .- After the injection was finished, she was placed on the floor, and attempted to walk, but was fo weak that the fell down. The action of the heart was very frequent, though weak and feeble; refpiration was anxious and difficult. She feemed not at all inclined

inclined to move, and was quiet, except that at different intervals, fhe groaned and fighed, and afterwards vomited fome of the food fhe ate at noon, in an indigefted flate, together with about two ounces of a yellowifh green coloured fluid.—Continuing in this fituation, fhe was frequently affected with convulfive motions of the abdominal mufcles and lower jaw, fhe became weaker and weaker. At 15 minutes paft 7 o'clock, about an hour and an half after the experiment was performed, all her mufcles were in a relaxed flate, and fhe appeared motionlefs. At half paft 7 fhe was dead.

Diffection. I did not examine the body till the 30th. at half paft 8 o'clock; fo that fhe was 13 hours dead, when the examination took place.

The abdomen was much diffended ; upon cutting into its cavity, a quantity of putrid air, of a fmell like that of rotten eggs, rufhed out. There was an effusion of a lympid fluid. The inteffines were distended with air, and contained but a finall quantity of liqued feeces. The ftomach contained little else, but a large quantity of the before-mentioned flatus, and a fluid of a yellowish colour. At its lower orifice it appeared rather preternaturally red. All the other vifcera were in a found and natural state. The veins appeared much diftended; and air, intermixed with with blood, of a dark venous colour, appeared through their coats. When I cut into the veffels, air came out in bubbles, together with the blood. The blood did not appear to be very firmly coagulated. The heart was much diftended with blood, particularly the right auricle, which contained fome air alfo .- In the heart the coagulation was more perfect than it was in the veins. The blood did not fmell in the least putrid.

EXPE-

[43]

EXPERIMENT X.

Was also performed July 29th. 1792, on a bitch in good health. About a drachm of pus, diluted with a fmall quantity of clear pump water, was injected into one of her femoral veins. The pus was obtained on the 27th. inft. from an abfcels of the intercostal muscles. This day it posseffers a putrid fmell.

During the injection of the matter, file had two very violent fits of convultion, the laft of which continued for fome time, and fhe appeared to be in great pain; refpiration was quick and irregular; the heart beat frequently, though with fome force. The pulfations were fmall and irregular, accompanied with frequent intermissions, and to all appearance fhe was dying. When fhe was placed in a cool fituation, the refpiration became lefs difficult, and the action of the heart more regular. She continued in this state and lay quiet for some time, when a mercurial thermometer was applied to the axilla, and the mercury rofe to 100°, as it did when it was applied before she underwent the experiment. After lying about twenty minutes in a cool place, fhe got up and attempted to walk, but was very weak, and did not go far before the fell down; after which she seemed again to recover. At 30 minutes paft 7 o'clock fhe was feized with twitchings of the muscles of her abdomen and lower jaw; the weaknefs encreafed; at length fhe became motionlefs; and at 15 minutes before 8 o'clock, about an hour and an half after the injection, the was dead.

Diffection.

Diffection .- The body was not examined till Monday morning the 3cth. about 14 hours and an half after the died. The abdomen was confiderably diftended, I made an incifion into it, but found that no air efcaped-about 2 oz. of a lympid fluid was found effused in the cavity. The intestines were much distended, and when an incision was made into them, air and fæces come out. The ftomach was likewife much diffended with air and half digested food. The fame preternatural redness about the lower orifice, which occurred in the former cafe, appeared alfo in this. The other abdominal vifcera appeared perfectly natural and found The heart was much diftended with blood, but no air was found in it or the blood-veffels. The blood was more firmly coagulated than that mentioned in the laft Experiment, and it had no unnatural fmell.

EXPERIMENT XI.

1 - 1 - 1 - 1 - 1 - 1 - 1

August 6th. 1792. A drachm of fluid matter, produced by highly putrid beef, was diluted with four drachms of putrid pump water, and injected into one of the femoral veins of an healthy dog.

The matter was injected at half an hour after 11 o'clock. During the injection he was much convulfed, and appeared to be in great pain. The pupils of the eyes were fomewhat dilated. The beating of the heart was now very frequent, though feeble, as it was during the injection of the matter. At 15 minutes before 12 o'clock the breathing became very frequent, accompanied with great difficulty and fighing. At this time he vomit-

ed

ed a quantity of half digested food, and appeared to be greatly relieved by it; at 12 o'clock he vomited again, which relieved him fo that he rofe, but in one or two minutes laid down again. At 4 minutes past 12 he had an evacuation of fæces-at 7 minutes after 12 heattempted to lay down, but fell, and laid in an unnatural pofture-he appeared to be very weak-his breathing became more difficult and laborious-his eyes appeared watry and funk in the orbits. At 10 minutes past 12 he had another evacuation of fæces. At 15 minutes after 12 he was raifed up on his feet-he ftood, though with difficulty, and his left hind leg became paralytic *. In a fhort time all his hind parts appeared to be more or lefs affected in this manner. At 40 minutes after 12 he became very reftlefs, turning and twifting his body every way. At 45 minutes after 12 he was again raifed upon his feet, but could not ftand, for all his mufcles appeared greatly relaxed. At 16 o'clock the pupils of his eyes were much dilated, and his fight feemed to be greatly diminished-he had an evacuation of urine. He began to groan, and the abdominal mufcles were convulfed. The convultions, after continuing fome time in those parts, extended to the muscles of his head and neck. Respiration, and the action of the heart ceasing, he died at 12 minutes paft 10 o'clock.

Diffection. The body was examined immediately after death, and nothing unufual was obferved. The blood was quite natural in every refpect.

EXPE-

* The incifion in this Experiment was made on the right thigh.

[46]

EXPERIMENT XII.

August 10th. 1792. Twelve grains of putrid blood, diluted with a drachm of clear pump water, were injected into one of the femoral veins of an healthy bitch, at thirty-five minutes paft 10 o'clock. During the injection she seemed uneasy, and had an evacuation of urine. The action of the heart became much flower, and very feeble. Respiration was somewhat difficult. She was then placed on the floor, and continued flanding -12 minutes after the had a natural motion from the rectum, and then laid down. At 11 o'clock her eyes were examined, and they did not appear any way preternatural. She feemed dull, heavy, and much inclined to fleep. At 12 o'clock I perceived that fhe had had another evacuation of urine. The eyes were now examined again, and no alteration appeared to have taken place in them. She laid quiet till half paft I o'clock, when violent efforts to vomit came on, and she brought up a quantity of the food she had eaten previously to the performing of the experiment. The heart beat very frequent and feeble-respiration was not greatly affected, but fhe continued dull and heavy. At 2 o'clock meat and drink were offered her-fhe would not even bear the fmell of meat, but rofe and drank fome water. She laid down. At half past 2 o'clock she got up again, walked about, and evacuated urine; then laid down again, and was dull and heavy as before. At 5 minutes before 5 o'clock she had another evacuation of urine. At 3 minutes before 5 she had a very copious evacuation of extremely fluid fæces, of the colour of coffee-grounds, and of a very putrid fmell. She now appeared weaker than the

the was before the evacuation, though not quite to dull. At 6 o'clock the evacuated urine again. I left her at 25 minutes after 6, when circumftances did not appear much altered. At 8 o'clock I faw her again, meat and drink were offered her—the drank, but would not eat. The heart beat very frequent and feeble—in other refpects as before.

August 11th. This morning, at 8 o'clock, I found her dead. A difagreeable odour arose from her body. The abdomen appeared somewhat distended. I perceived she had had another loose evacuation of the description above mentioned, though not so copious as the former one. There was a great deal of faliva about the mouth, and the tongue protruded through the teeth. On

Diffection, the following appearances were observed. Upon cutting into the cavity of the abdomen, no air efcaped, but I experienced a very difagreeable fœtid fmell. The fuperior parts of the intestines appeared in feveral places of a dark green colour, fpotted with fmall white fpecks, while the lower portions appeared natural. When an incifion was made into the inteffines, a quantity of putrid air rushed out, together with liquid dark green coloured fæces. The stomach appeared to be rather fmall-I made an incifion into it when fome of the like liquor flowed out. The liver was in many places of a preternatural colour, and adhered to almost all the other abdominal vifcera, particularly to the ftomach and right kidney. The gall-bladder was much diftended with a light green coloured bile; the lungs were collapfed; the right lobes were of a blackish colour, intermixed with red; the left lobes appeared natural. The red appearance at the lower orifice of the flomach, mentioned in the other cafes, was not apparent in this. The veins and heart were much diftended with blood, which was not very firmly coagulated, but its fmell was perfectly natural.

EXPERIMENT XIII.

August 14th, 1792. At, 40 minutes after 10 o'clock fix grains of putrid blood, mixed with a drachm and an half of clear pump water, were injected into one of the femoral veins of a bitch ... During the injection fhe appeared very uneafy-the action of the heart was flow and feeble-refpiration flow, and performed with difficulty. She was placed on the floor, appeared dull, and laid. down. At 10 minutes before 11 o'clock her abdominal muscles were violently convulsed. At 7 minutes before 11 she was feized with violent retchings and efforts to vomit, but did not evacuate. At 15 minutes before 3 o'clock meat and drink were offered her-fhe ate, but would not drink. At 23 minutes before 7 she had a copious evacuation of urine. At 20 minutes before 7 she ate and drank. I left her at 15 minutes before 7, when the feemed eafy. I faw her again at 8 o'clock and no alteration was evevident. the set as a set out

August 15th. This morning, at 8 o'clock, I faw her fhe appeared perfectly eafy—action of the heart nearly natural, though rather frequent. She was now fed, and ate as before. I perceived that she had had a natural evacuation of fæces. At 21 minutes after 5 blood was drawn—its colour and smell were natural—it was coagulated at 24 minutes after 5—the separation into ferum and I craffamentum craffamentum was evident at 30 minutes after 5—a piece of the paper stained blue was dipped into the ferum, and no change of colour took place—the ferum and coagulum were quite natural. I faw her again at 8 o'clock. She appeared as she did when in health.

August 16th. She was perfectly well.

EXPERIMENT XIV.

August 17th. 1792. At 15 minutes after 12 o'clock twelve grains of putrid blood, mixed with a drachm and an half of clear pump water, were injected into one of the humeral veins of the bitch last mentioned. During the injection, fhe cried violently, and appeared to be in great pain. Respiration became very frequent-action of the heart frequent and feeble. The eyes were examined, and the pupils were found to be much contracted. She was placed on the floor, walked a few steps, leaned against the wall, in a ftanding posture, and appeared very fick. At 26 minutes after 12 she had an evacuation of faces. which was rather loofe. At half paft 12 fhe laid down, appeared dull, and much inclined to fleep. At half paft 2 the abdominal muscles were affected with convulsive contractions-they did not continue long. The eyes were again examined, and the pupils appeared natural. At 3 minutes before 5 she had a copious evacuation of At 10 minutes after 6 I left her eating, and to urine. appearance eafy, though dull and languid. I faw her again at 8 o'clock, when I perceived the had had another loofe evacuation of fæces, which was copious. Pulfation of the heart frequent and feeb'e-fhe appeared eafy.

August

August 18th. Blood was drawn at 5 minutes before 6 o'clock P. M.—its colour and finell were natural —it was coagulated at 6—at 5 five minutes after 6 it feparated into ferum and craffamentum—coagulum and ferum were quite natural—Serum did not change the paper stained blue. At 8 she appeared perfectly well.

August 19th. She was perfectly well. The blood, which was drawn yesterday, had a natural odour, when it was examined this morning at 11 o'clock.

EXPERIMENT XV.

August 20th. 1792. At 4 minutes before 11 o'clock, half a drachm of putrid blood and a drachm of clear pumpwater, were injected into one of the humoral veins of the last mentioned bitch during the injection, she was very uneafy and gave feveral loud fhrieks. The heart beat very frequent and feeble. Respiration became very difficult. She was placed on the floor, and immmediately after had a copious evacuation from the ftomach. She appeared very weak, and leaned against the wall. At minutes after 11, fhe had retchings and violent efforts to vomit. but no evacuation enfued. At 32 minutes after 11, the began to groan and figh. At five minutes after 12, fhe had efforts to vomit, but nothing was thrown up. I left her at 15 minutes before 1; fhe drank, and appeared eafy, though the was very weak. I faw her again at 2 o'clock, the heart beat very frequent and feeble. Ι perceived the had had an evacuation of faces, while I was absent-it was rather loofe. Meat and drink were offered her; fhe drank, but did not eat. She appeared very fick.

[51]

. I faw her again at 8'clock, when the appeared just as the was at 2 o'clock.

August 21st. Blood was drawn at 2 minutes before 5 o'clock P. M. its colour and fmell were natural—it was coagulated at 3 minutes after 5—separation into ferum and craffamentum was evident at 9 minutes after 5 ---the coagulum and ferum-were perfectly natural---the ferum did not change the color of the paper stained blue. At 8 o'clock she appeared very well.

August 22d. Serum of the blood drawn yesterday, did not change the colour of the paper stained blue.

EXPERIMENT XVI.

August 22d. 1792. At 11 o'clock, a drachm of putrid blood mixed with half a drachm of clear pump water, was injected into one of the crural veins of the bitch last men-During the injection, the action of the heart betioned. came very frequent and feeble. Refpiration very laborious. She vomited. After this she was placed on the floor, and appeared very weak, yet flood for fome minutes, and then fell down gently. At 8 minutes after 11, she had an evacuation of urine and of fæces. At 14 minutes after 11, the eyes were examined; the pupils were found to be very much contracted, and her fight much diminished. At 16 minutes after 11, she had another evacuation of urine. At 10 minutes after 11, she began to cry violently, and appeared to be in very great pain. The refpiration became very laborious, and the action of the heart encreased in frequency and feebleness. At 23 minutes af-

ter

ter 11, fhe became convulfed. At 25 minutes after 11, a finger was drawn over the eye, and no contraction of the eye-lids took place. At 28 minutes after 11, fhe was dead.

and the protocol of star Plan open in the one

Diffection. The examination of the body took place at 8 minutes after 12 o'clock. All the vifcera were found in a found and natural flate, except the lungs---there a bloody effufion was difcovered, particularly in the inferior parts of the left lobes. At 20 minutes after 12, blood was obtained by opening one of the large veins; the colour and fmell were natural. When I left the blood, it was not fo perfectly coagulated, as in the other inflances, owing to its having been by accident much agitated. I returned in the afternoon, and found the coagulation complete---the coagulum and ferum were natural---the ferum did not change a piece of paper flained blue.

EXPERIMENT XVII.

The second s

August 14th. 1792: At 16 minutes after 3 o'clock, fix grains of putrid blood, diluted with a drachm of clear pump water, were injected into one of the femoral veins of an healthy dog. During the injection, he was very uneasly and gave feveral loud shrieks. The action of the heart became so feeble, that it could scarcely be felt, and was also frequent. He was placed on the floor, when he lay down. In a short time he rose up, stood sometime, and appeared very weak. Respiration became laborious, and he lay down again. At 15 minutes before 4 o'clock, he was feized with twitchings about the bottom of, and across the thorax, in a great degree resembling an hiccup.

At

At 4 minutes after 4, meat and drink were offered him; he would not drink, and feemed as if defirous to eat; but when he approached mear the meat, he drew his head from it, as if the fmell of it were offenfive to him, though the meat was fresh killed this morning. At 2 minutes before 5, he had an evacuation of urine, and rather a loofe evacuation from the rectum. At 4 minutes after 5 he had a copious evacuation from the ftomach, when the action of the heart became perceptible to the touch. At 20 minutes after 5, he had violent efforts to vomit, and brought up a quanitty of greenish coloured fluid. At 34 minutes after 5, they recurred again, with the like effect. They attacked him a third time at 3 minutes before 6; the confequence was the fame as in both the former inftances. I left him at 15 minutes before 7 o'clock; when he was eating and drinking.""He feemed eafy. The muth in mulugson ode - ange a peer of pares flained blac

perfectly natural---I faw him again at 8 o'clock, and he appeared perfectly well.

August 16th. He was perfectly well to-day.

EXPERIMENT XVIII.

August 17th. 1792. At 15 minutes after 4 o'clock, ten grains of putrid blood, mixed with a drachm of clear pump water, were injected into one of the femoral veins of the dog last mentioned. During the injection, he appeared to be in much pain, and had an evacuation of urine ; the action of the heart became frequent and feeble, but respiration was not much altered. At half past 4, the abdominal mufcles were convulfed; the convultions did not last any length of time. At 20 minutes before 5, he was feized with tremors over his whole body; they lasted about two minutes, and then went off. At 16 minutes before 5, he had an evacuation of urine. At 15 minutes after 6, I left him eating, when he appeared pretty eafy. I faw him again at 8 o'clock, and perceived he had had a motion fince I left him. The action of the heart was frequent and feeble. While I was with him he had an evacuation of urine, and appeared eafy.

August 18th. Blood was drawn at 10 minutes after 6 o'clock this morning—its colour and finell were natural —it was coagulated at 14 minutes after 6—feparation into ferum and craffamentum began to take place at 23 minutes after 6. 'The coagulum and ferum were natural. The ferum did not change the colour of the paper stained blue. At 8 he appeared to be perfectly well.

August

August 19th. He was perfectly well to-day. The blood, that was drawn yesterday, was examined this morning, and possessed no unnatural smell.

EXPERIMENT XIX.

August 27th. 1702. At 40 minutes before 10 o'clock, a drachm of putrid blood, mixed with half a drachm of clear pump-water was injected into one of the femoral veins of the dog, the fubject of the 4th. Experiment. During the injection, he was very uneafy, and evacuated urine. The action of the heart became very frequent and feeble. He was placed on the floor, and immediately after vomited. At 3 minutes before 10, he had an evacuation of natural faces. At 2 minutes before 10, he vomited again. At 10 his breathing became very laborious, and he had a loofe and fmall evacuation of natural coloured fæces. At 3 minutes after 10, he lay down. The heart beat fo feeble, that it could fcarcely be felt. At 10 minutes after 10, he role, vomited again, and then lay down. At 15 minutes after 10, the eyes were examined and no alteration in them was apparent. At 21 minutes after 10, he role again, walked about the room, flood for fometime, and then again lay down. The action of the heart became more evident. At 11 o'clock. he groaned very much. At 6 minutes after 11 the action of the heart became more frequent and feeble. The eyes were now again examined, but prefented no unnatural appearance. At 29 minutes after 11, he rofe and walked a few steps, had a sparing evacuation of chocolate-coloured, liquid fæces, then fell down, and appeared as if stimulated to evacuate again; he role and had an evacuation of urine, and again fell down. At 18 minutes before 12, his abdominal

dominal muscles became convulsed. At 4 minutes before 12, he vomited again. At 28 minutes after 12, he rofe, walked a few steps, had an evacuation of very thin chocolate-coloured faces, and appeared to be very weak; after this he walked a few steps again, and then lay down. I left him at 10 minutes before 1 o'clock, when he appeared eafy, though very weak and fick. When I returned, at 12 minutes before 3, I perceived, that during my abfence, he had had two or three evacuations of urine. The heart beat frequently and feebly. At 10 minutes before 3, he had an evacuation of urine, and afterwards vomited. At 8 minutes before three, he had an evacuation of very liquid faces, intermixed with mucus. At 5 minutes before 3, he had retchings and efforts to vomit, but did not evacuate. At 16 minutes before three, he rofe, and had another evacuation of faces fimilar to the one last mentioned. At 10 minutes after 4, he had an evacuation from the rectum, of mucus intermixed with blood. At 25 minutes after 4, putrid meat and putrid water were offered him, he drank plentifully, but did not eat. I left him at half paft 4, and faw him again at half paft 7, when I perceived he had had a very copious evacuation of urine, but had not eaten. The heart beat frequently, though not fo feebly as before. Respiration was pretty free. He feemed eafy, and appeared much better than when I left him the laft time.

August 28th. When I faw him this morning at 8 o'clock, marks of an evacuation of faces and urine were evident. I perceived he had eaten nothing. Putrid water was given him and he drank of it. The heart beat frequently and feebly. He appeared very weak; and the wound

wound put on a bad appearance. At 2 o'clock I faw him again, when I perceived that he had had two or three evacuations of urine, but that he had not eaten. I now offered him fome fresh meat, he held it in his mouth, but did not fwallow any of it, and let it drop. Putrid water was again offered to him and he drank it. Refpiration did not appear to be much affected. The action of the heart was frequent; and fo feeble as fcarcely to be felt. In my prefence he had an evacuation of urine; I caught fome of it in an earthen veffel, dipped a piece of the bluecoloured paper in it, but no change of the colour was evident. The wound appeared in a gangrenous frate. He feemed very weak, and it was with difficulty that he flood." At 8 minutes before 5; blood was drawn; the colour and finell were natural. It 'coagulated at'4 minutes' before 5; feparation into feruin and craffamentum was evident', at 7 minutes after 5; the ferum and craffmentum were perfectly natural; the ferum did not change the colour of the paper stained blue.¹ The wound appeared much worfe. In every other cafe, yet mentioned, it invariably put on a good appearancee, and healed readily. After bleeding he appeared exceedingly weak. At 35" minutes after 5, I left him very uneafy. I faw him again at 8 o'clock, and he appeared nearly in the fame condition as when I left him laft. 110 . 3 . 3

August 29th. This morning at 8 o'clock, I found him dead. The blood drawn yesterday, was now examined. No unnatural smell was evident. The ferum did not change the colour of the paper stained blue. The coagulum was so firm, that when thrown out of the tumbler on the floor, it did not break. A very difagreeable and foetid odour arose from the body.

Diffec-

Diffection. The body was examined at half paft 9 o'clock, when I cut through the fkin covering the lower ribs, the flefh below appeared gangrenous. The liver in fome places was of rather a lighter colour than natural. The inferior part of the fmall inteflines appeared inflamed. The ftomach was perfectly natural, both internally and externally; it contained mucus and a whitifh fluid. A bloody effufion was found in the lungs, particularly in the right lobes. The bladder was quite natural. The heart and veins were much diftended with blood, which was firmly coagulated in both ; the colour and fmell of it were perfectly natural.

As yeaft is well known to be a powerful ferment, and the volatile alcali a great chemical agent, and a diffolver of the blood when out of the body, the following Experiments were made, to afcertain what effect they would have on the blood, when injected into the blood-veffels.

EXPERIMENT XX.

August 14th. 1792. At 20 minutes after 11 o'olock three drachms of flock-yeast were injected into one of the femoral veins of a dog. During the injection he appeared fomewhat uneasy. Respiration became very difficult and laborious; the action of the heart irregular, intermitting, and fomewhat encreased in force. He was placed on the floor but was not able to fland. At 30 minutes after 11, he had an evacuation of urine; at 33 minutes after 11, he had an evacuation of natural fæces. The eyes being examined, did not appear evidently altered. The muscles of his whole body now feemed to be in a relaxed laxed state. At 40 minutes after 11, his eye-fight appeared to be much diminished; at 5 minutes before 12, he was dead.

Diffection. The body was examined immediately after death. Nothing preternatural was observed, except a bloody effusion in the lungs. The blood was in every respect natural.

EXPERIMENT XXI.

August 7th. 1792. At 20 minutes before 11 o'clock, 15 grains of mild volatile alcali diffolved in two drachms of clear pump water, were injected into one of the femoral veins of an healthy bitch. During the injection, she gave three or four loud cries, and feemed to be in great pain. She was placed on the floor, walked three or four fteps, and then lay down. The action of the heart was encreafed in frequency, and respiration was performed with difficulty. In other respects she feemed easy and quiet. At 11 o'clock, meat and drink were offered to her; fhe would not take of either. Refpiration now feemed to be performed with no great difficulty. The action of the heart was as before mentioned. At 35 minutes past 4, the eyes were examined, and they appeared no ways altered. At 42 minutes past 11, she began to be restless. The action of the heart feemed to have recovered fome degree of quickness; the frequency of it still continued. Respiration appeared pretty easy, though short. At 40 minutes past 12, her whole body was feized with a tremulous motion, when a thermometer was applied to the axilla, and the temperature was as when in health. Thefe tremors came on in paroxyfms, each of which lasted but

a little time, and they recurred frequently. The heart, during a paroxyfm of trembling, beat frequently and feebly. The tremors encreafed in violence, and in frequency of recurrence. At 14 minutes paft 1, she was affected with feveral violent convulfive contractions acrofs her abdomen. At half past 1, the eyes were again examined, and the pupils were observed alternately to dilate and contract frequently and confiderably. At 40 minutes after 1, fhe rofe, looked about; meat and drink were again offered her, but she refused both, and lay down again. At 10 minutes before 2, the tremors attacked her again, her breathing became more difficult and laborious, the tremors continued more or lefs violent for 5 minutes, then went off, and she appeared eafy. At 15 minutes after 2, the tremors and laborious breathing came on again; they were of short duration; when they went off she appeared eafy, and continued fo till 5 minutes after 4, when they occurred again. At 10 minutes after 4, fhe gave three or four loud cries, as if affected with much pain, then was eafy again, and remained fo till 40 minutes after 5, when I left her. At 8 o'clock I faw her again; fhe feemed perfectly eafy, the action of the heart was frequent and feeble.

August 8th. At 8 o'clock this morning the appeared eafy, but was very weak; and her heart beat frequently and feebly. She now ate and drank; at 2 o'clock the appeared as in the morning: I also perceived that the had had a natural evacuation from the rectum fince I faw her in the morning, which was the first that occurred fince the operation was performed. At 7 o'clock I faw her again; no alteration was evident. I found that the had had a natural evacuation of fæces this afternoon; but I did not perceive any marks of a difcharge of urine.

August

[61]

August 9th. She feemed quite well, but drank more than dogs usually do in health.

EXPERIMENT XXII.

August 10th. 1792. At 40 minutes after 11 o'clock, 25 grains of mild volatile alcali, diffolved in two drachms of clear pump-water were injected into the bitch last mentioned. During the injection, fhe was violently convulfed, and gave feveral loud cries; fhe alfo had an evacuation of urine and vomited. The heart beat very frequently, and breathing was laborious. She was placed on the floor, ran about the room, and then lay down. Her afpect was very wild. She did not lay long before the got up again ; but in a few minutes lay down. At half past one she rose, and immediately afterwards lay down again. The breathing was veryfrequent. At 2, meat and drink were offered her, but she did not take of either. I left her at 25 minutes after 6, fhe continuing to be in the fame condition. At 8 o'clock I faw her again ; meat and drink were then offered her, fhe drank, but would not eat. Her heart beat very frequently, though weak; the feemed in other respects as she was before.

August 11th. This morning at 8 o'clock she appeared to be easy, was quiet, and ate and drank. Her heart beat frequently and feebly. I faw her again at 8 in the evening; she was in the fame condition as in the morning. At 26 minutes after 8 blood was drawn—its colour and smell were quite natural—it coagulated at 32 minutes after 8 o'clock feparation into ferum and crassamentum was evident at 38 minutes

[62]

minutes after 8 o'clock—the coagulum and ferum were every way natural—the ferum did not change the colour of the paper stained blue.

August 12th. To-day she appeared perfectly well.

EXPERIMENT XXIII.

August 13th. 1792. At 15 minutes before 11 o'clock 45 grains of mild volatile alcali diffolved in two drachms and an half of clear pump water, were injected into the fame bitch. During the injection she appeared to be in great pain, and gave feveral loud cries. She was placed on the floor, ran about the room, then lay down, and was very reftlefs. The action of the heart was extremely frequent, and her afpect was wild. _ After lying a few minutes she became easy. At 35 minutes after 2 meat and drink were offered her ; fhe ate, but would not drink. At 30 minutes after 4 o'clock blood was drawn-its colour and fmell were natural-it coagulated at 35 minutes after 4-feparation into ferum and craffamentum was evident at 30 minutes after 4-the craffamentum and ferum were perfectly natural-the ferum did not change the colour of the paper stained blue. At 39 minutes after 4 more blood was drawn from the fame vein-its colour and finell were natural : As foon as it was drawn, I added 45 grains of mild volatile alcali diffolved in 3ij of clear pump water to it, when the colour became a very deep brown, nearly black. At 8 minutes before 5 o'clock it appeared to have a tendency to coagulate. At 10 minutes before 6 it was of the confiftence of mucus. At 10 minutes after 6 fhe feemed perfectly eafy, and was eating meat. Λt 8 o'clock fhe appeared in the fame eafy fituation.

August

[63]

August 14th. At 8 o'clock this morning she appeared perfectly easy. The blood last mentioned was examined, and its confistence was much as before.

From the above Experiments the following inferences refult:

If. That, contrary to the generally received opinion, the blood is neither rendered alcaline, acrid or putrid by flarvation. This I think is evinced by thefe circumflances—that the blood went through its fpontaneous changes in the regular and ufual manner—that the ferum had no effect in changing the colour of my teft—and that no fenfe of acrimony was perceptible to the tafte.

2dly. That a Putrid Diet does not operate upon the blood fo as to change its fenfible properties. This is a material part of the enquiry, fince phyficians, from Hippocrates down to the prefent day, have fuppofed various and wonderful changes to be produced in the animal œconomy by fuch food. From the above Experiments, it appears very clear, that a putrid diet had no effect whateever in changing the qualities of the blood, although the animals were strictly confined to it. We are also led to conclude from them, that a putrid diet does not change the fenfible qualities of the excretions; fince, as I have related, the urine did not alter the colour of the vegetable blue. Here it may be objected to me, that I ought merely to infer from thefe Experiments, that the blood of dogs only is not affected by this treatment-I anfwer, that the inference may, probably, be extended to the whole animal creation; for, we cannot but fuppofe that nature is, in this respect, as beneficent to the one species as she is to the

2.

other;

other; and to fubftantiate this opinion. I avail myfelf of the refult of the Experiments of the celebrated Spallanzani as above mentioned, who not only operated upon the brute creation, but went fo far as to rifk his own life for the benefit of fcience; and found, contrary to the received opinion, that vitiated food, previous to its leaving the flomach, is converted into a matter capable of furnishnishing good blood. " Men, fuch as the inhabitants about the mouth of the Orange river, in Africa, live always on animal food, fuch as whales, feals, limpets, and what fifh they can catch ; that many times their food has entered into a great degree of putrefaction, and there is no vegetable food whatever employed at the fame time; probably most of them never tasted any vegetable fubfance in their lives, excepting aromatics for feafoning; yet they are perfectly healthy and free from all putrefaction in their fluids or folids, though they are not very careful of avoiding it in the exterior parts of the body. We fee likewife' maggots live in and upon putrid maffes, while they themfelves, and all their fluids, are perfectly fweet and free from all appearance of putrefaction*." There appears to be an intimate connection between the fluid and folid parts of our bodies, but how far this connection between them' fubfifts, I will not undertake to affert. Perhaps I might, in truth, have faid that a putrid diet acts upon the folids of our machine, by its not containing alimentary matter in a proper quantity, and therefore not affording a fufficiency of blood to fupport the animal. We know that the folids derive their nourifiment from the blood ; and, in my opinion, it is fufficiently evidenced, from the mortification of the mufcular parts which enfued upon making an incifion into the thigh, as

* Fordyce on Digeftion, p. 155.

has

has been already stated—That a putrid diet does operate upon the folids.

3dly. That although the blood, or other animal, matter may be excited into a putrid fermentation out of the body, by the addition of a putrid ferment, yet that fuch a procefs cannot be excited in the living body. We have found that many grains of putrid matter exifted in the blood-veffels for fome days without changing the blood. Is it probable that a fermentation can be induced in the blood when the ferment enters the fyftem by abforption, and no fuch procefs take place by introducing a putrid ferment immediately into the blood-veffels ?

4thly. That by the introduction of putrid matter into the blood-veffels, very violent fymptoms were produced, although the quantity of the matter was fmall, and of the fame nature as the blood, except that it had become putrid*. Is it probable, then, that the animal could exift with the whole mafs of blood in a ftate of putrefaction, when fuch violent fymptoms were the confequence of the introduction of fo fmall a quantity of putrid matter as was injected in the foregoing Experiments ?

And, 5thly. That though the volatile alcali may operate upon the blood in a wonderful manner out of the body, it does not evidently affect the blood when injected into the blood-veffels.

I

From

* My reafon for making ufe of putrid ferum and putrid blood, is, that they are the fame fubftance, only altered by putrefaction. We know, from Experiments of Transfufion, that blood may be paffed from the veffels of one animal, into those of another, without any evident injury. From this circumftance we are led to infer, that it, in these inftances, acted as putrid matter. From thefe experiments it is alfo evident, that cathartic and emetic medicines, when injected into the blood-veffels, cannot operate in a fpecific manner; for in almost every inflance evacuations were the confequence of the experiments when neither cathartics nor emetics were injected. Probably any matter capable of producing a fufficient irritation, will produce those effects, when thus thrown into the animal.

I attribute the prefence of air in the veffels and heart, which occurred in one of the experiments, to the imperfect flate of the fyringe; for it confifted of one whole piece, when the two first experiments were performed.

Before I leave this part of the enquiry, I beg leave to flate the following queflions, viz.

Is there a power in the blood-veffels, or in the blood, capable of affimilating to the blood matters which are injected into the veffels? Do not the following circumftances make it probable? I could not by a minute examination diftinguish between the blood and the matter injected. The ferum of the blood, where the volatile alkali was injected did not poffers the odour of that falt, neither did it change the colour of the paper flained with a vegetable blue. Does not the doctrine of fecretion, which is now gaining ground, favour fuch an idea? I own that there are certain exceptions to this opinion.

Do not the lofs of vision, the dilated and contracted pupil, together with the convulsions which happened, denote the nervous system to be affected by the contents of the blood-vessels?

I fhall

I shall now proceed to enquire, whether there is any reafon to believe that the blood becomes putrid in any difease?

This is a queftion of confiderable importance. Extenfive experience is neceffary to decide it; and as my own has been very limited with regard to difeates fuppofed to be putrid, I must beg leave to refer the unprejudiced reader to books, which treat at large of them. Perhaps upon thorough confideration, he will believe the matter to be at least doubtful.

All I can do, will be to ftate fome objections to the inferences that have been drawn from the fymptoms and circumftances attending these difeases.

A fymptom on which great ftrefs has been laid, is, the appearance of Petechiæ, Vibices, or effusions of blood, which takes place in the last stage of Typhus, Yellow Fever, Scurvy &c. Thefe appearances are generally fuppofed to be indicative of a diffolved state of the blood, in those difeases, though in my opinion without a fufficient reason. It is conceded by all that the fystem in those difeases is very much debilitated, and of confequence the fystem of bloodveffels, and these particularly at their ultimate terminations. The effect of this debility is a relaxation of the folids; the fibres of the blood-veffels will not now be in as clofe contact as they were in health, and the mouths of the exhalents will not be as narrowly contracted. This particular flate of the veffels at their terminations, will allow the blood to tranfude, and be effufed in the cellular membrane; or the exhalents, which in health pour out a lympid fluid, may now be capable of forwarding the red

red blood itfelf. Analogy fupports the opinion. Do not the veffels of the eye in ophthalmia, through which a colourlefs lymph is circulated in health, receive in this difeafed ftate, red globules ? Do we not find in dropfy, that the veffels allow of a greater exhalation than when in health ? If in proportion as we become debilitated, we approach nearer to a ftate of death, Does not the tranfudation of bile through the coats of the gall-bladder, in dead fubjects, give additional ftrength to the idea ? Again, is it not confirmed by the circumftance, that thefe appearances take place in the laft ftage of thofe difeafes when the debility is greateft ?

If Petechiæ were true fymptoms of a diffolved and putrid ftate of the blood, we fhould certainly find that the bodies of those who die, marked with fuch fymptoms, would certainly putrefy much fooner than the bodies of others who die without any fuch marks. The contrary of this is faid to happen: And anatomists affert " that the bodies of those who die, of what are called putrid fevers, are longer before they undergo real putrefaction than of those who die of other diseafes, or who die in perfect health by violence." *

The diffections of the celebrated Lind and Rouppe, feem to prove that the blood in those difeases is not putrid. The former found it in the yellow-fever to be grumous and viscid, and covered with a yellow gluten, impenetrable to the finger unless cut by the nail †

The

* Moore's Medical Sketches.

† Lind's first paper on Fevers and Infection, p. 13. & feq.

The fame gentleman relates; "that in fcurvy, red coagulated blood is found extravafated in almost all parts of the body, not only into the tela cellulofa, but into the bellies of the muscles, particularly of the legs and thighs, which often become quite stuffed, and even distorted, with large grumous maffes *."

After stating that, "Some authors from a supposition of the great diffolution of the blood in petechial fevers, and from another supposition, that blisters encreased the diffolution of that fluid still more, have forbid their application in such fevers." He adds, "But the experience of the most eminent practitioners does not support those theoretical opinions +."

Rouppe, a phyfician who had great experience in the fcurvy, found that the blood was always more or lefs coagulated in thofe inftances, in which he had an opportunity of viewing it. He obferves, "If we confider, we fhall find that the blood of thofe who have a continual fever, or an inflammation, after they have loft a good deal by bleeding, is fo diffolved, that no one can find blood of a thinner confiftency even in the laft ftage of the fcurvy. Who (he juftly interrogates) has even pretended to fay thefe difeafes were owing to a diffolved or putrid ftate of the blood ‡?"

We may further obferve, that a diffolved flate of the blood is by no means a proof of its having become putrid, it merely indicates a leffened difposition to coagulate; and

do

do we not find the blood in feveral other difeafes befides the fcurvy &c. to be in a more fluid ftate than it is in health? Certainly we do.

We are informed by Dr. Lind, that the blood of fcorbutic perfons did not impart the leaft fenfe of acrimony to the tongue, any more than the white of an egg; and that the blood of fcorbutics does not become putrid fooner than other blood, which it certainly ought, cæteris paribus, if it had already begun to putrefy in the body. Nay we are moreover informed by this celebrated writer, that the ferum of the blood of fuch patients, is not fceptic but antifceptic; and would it not be abfurd and inconfiftent with the facts of chemiftry to fay, that a portion of matter which had already began to putrefy on being added to an unputrefied mafs fhould retard the procefs?

The benefit derived from the use of fresh vegetables and their acids in curing scurvy, is, in my opinion, by no means to be admitted as proof of the blood's being in a putrid state.

We must in this place notice, that it is a well established opinion, that the powers of digestion are such, as to be capable of converting all matters into one and the same kind of chyle, whether animal or vegetable, though the one may not afford it in as great proportion as the other.

The above circumftance being admitted, and it cannot be denied, we at the fame time muft allow, that those matters undergo a confiderable change in the ftomach before they go on to the formation of the blood. Confequently, if they fuffer a change, they posses no longer the properties of a vegetable, or a vegetable acid, and therefore a tertium quid quid muft be formed. What its nature and properties are I will not pretend to fay, but leave the candid to judge for themfelves; though we might equally well fuppofe it to be feptic as antifeptic*.

There are many phyficians, who fuppofed fixed air to be chiefly ufeful when injected into the inteflines in those difeases fuspected to be putrid, by acting as an antifeptic on the putrid blood; but when, thus applied, does it not rather act on the contents of the inteflines, and deftroy the bad effects produced by their offensive fmell, &c. fince it has been well observed, "that, any thing putrid is totally incompatible with the perfect well being of the animal?"

It is generally allowed, that putrid effluvia act as debilitating powers on the fyftem. Indeed putrid matters, lying for a time in the inteftines, would feem to be debilitating, as in the inftance of the dyfentery. It appears alfo that fixed air acts as a flimulant: Mr. Henry found that it inflamed an ulcer \ddagger . And Dr. Dobfon fays, that when received by the mouth into the flomach, in ten minutes, it raifed the pulfe from 71 to 77 flrokes \ddagger .

It was objected to me, that the urine, breath, and other excretions of perfons labouring under difeafes of the putrid

* I think that the following circumftance juffifies my affertion, that vegetable aliment after it has fuffered the changes produced on food in the ftomach, &c. when it is fent on to form the chyle, has more of a feptic than antifeptic quality. Fordyce on Digeftion, p. 164, mentions, that by diffillation in a retort we obtain an empyreumatic oil, volatile alkali and water, and charcoal remains in the retort, whether the fubftance diffilled be chyle, a piece of fleth, or other animal fubftance.

+ Henry's Exper. p. 127.

+ Dobfon's Commentary on Fixed Air.

trid clafs were highly foetid and obnoxious. We grant this may be the cafe ; though a question will then arife, whether these excretions contract this foctor from the blood, or become foetid after they are feparated from the general mafs? I am of the latter opinion, and think it highly probable that they become foetid in their respective refervoirs, or in fome other manner not yet explained. We know that the excretions do not by any means poffefs the properties belonging to the blood, and we also know that they may be very different in difeafe, though the blood remain the fame as when in perfect health. To this purpofe, I will quote Dr. Home's obfervation-he mentions that the blood of diabetic perfons appeared perfectly natural; that the ferum of the fame posselfes no more fweetnefs than that of other blood; though the urine of the fame patients tafted very fweet, and upon evaporation afforded a large quantity of faccharine matter.*

The cafe of a patient, who was lately under the care of my worthy preceptor Dr. Wiftar, may alfo be mentioned in confirmation of thefe fentiments. He was affected with pneumonia, and had all the ufual fymptoms; but in addition to them, an odour proceeded from him fo putrid and offenfive that no one could remain long in his room without great inconvenience, it even extended its offenfive fmell into the rooms a ftory below him. His urine had alfo an intolerable fœtor. The fymptoms of pneumonia required bleeding, and this remedy was ufed with great caution; but notwithftanding the above circumftances, the blood coagulated very firmly, and had fome inflammatory appearances on its furface.

2

The

* Homes's Clinical Experiments, p. 332.

[73]

The arguments taken from Dedier's, Couzier's, and Homes's Experiments, employed by Dr. Ferris to prove, that the bile and blood undergo a change in the plague and meafles, are by no means conclusive. We know the plague and meafles to be highly contagious difeafes, and eafily communicated to those who are in a state of predifposition to receive the infection. Dr. Ferris supposes, that as the blood or bile of one who died of the plague, when injected into the veins of a dog, produced fymptoms of that difcafe ; and as the meafles enfue after inoculating with the blood of those who labour under it, the blood and bile must have undergone changes in those difeases. In my opinion these facts prove nothing that favours fuch a conclusion; and all that we can infer from them is, that the contagious or infectious matter was diffused through the blood, or adhered to it in those instances, as it does to old buildings, cloathing, &c. Facts prove that it does to with respect to these subjects, for months, nay even years, and then is as effectual as ever in its deadly operation. We are uninformed of the appearance or ftate of the blood in those instances. In the measles, the blood appears to be no more changed or altered than in other inflammatory difeafes. How it is in the plague, I Dedier and Couzier have taken no notice of know not. any evident change-Gentlemen whofe accuracy would not have allowed them to have neglected fuch a circumfrance if it had occurred.

What confirms me in the opinion, that the contagious matter was only diffufed through the blood, or adhered to it in the fame manner as to old buildings, &c. is, that in the one inftance the plague, in the other the meafles, was produced. If the contagious matter had mixed with the blood fo as to produce a chemical change therein, neither the plague nor the meafles would have been the refult of the Experiments; as by this mixture, they would both have loft their former properties, and a new compound would have been produced by their union, not poffeffing the properties of the contagious matter or of the blood. The fixth law of the affinity of composition, reads thus: "Two or more bodies, united by the affinity of composition, form a fubflance, whose properties are very different from those of any one of the bodies before their combination."* Confequently a difease very different from the plague or measles must be produced, if a chemical union had been formed.⁺.

With refpect to Dr. Home's Experiment, I beg leave to make one or two obfervations : He fays, "I thought that I fhould get the blood more fully faturated with what I wanted, if it was taken from the cutaneous veins amongft the meafles, than if I took it from a large vein, where there was a much greater proportion of blood from the more internal parts than from the fkin. I therefore ordered a very fuperficial incifion to be made amongft the thickeft

* Fourcroy's Chemistry, Vol. I. p. 64.

† We have already proved that the blood in the veffels of living animals was not fubject to the laws of fermentation, and that no fermentation could be excited in it by the introduction of ferments; therefore if a change had been produced in the blood in the above inflances, it must have been by a chemical union, and confequently must be fubject to the laws of chemical affinity. thickeft of the meafles, and the blood, which came flowly away, was received upon fome cotton."*

The Doctor appears to be of the opinion that a fermentation of the blood, produced by the introduction of contagious matter into the fystem, was not the cause of the difeafe; for, he fays, the blood taken from the more internal parts was not as plentifully faturated with the morbillous matter as that flowing in the cutaneous veffels. Is not this inconfistent with the true and well understood courfe of the blood ? For, is not the blood of the cutaneous veffels at one moment in one part, and at another in a very different part, of the fystem ? Confequently the whole mass must have been equally affected. Again, if the motion of the blood were not itfelf fufficient to produce the change throughout the whole mafs, this would have happened from the well known laws of fermentation ; for we know that a very fmall portion of a ferment is fufficient to affimilate a very large maß of fermentable matter. Further, this experiment is not conclusive, fince the blood was obtained by a very fuperficial incifion made amongft the thickeft of the measles, and the blood alfo flowed flowly. Here certainly in making the incifion, the lancet or inftrument used must have pierced fome of the puftules from the fituation in which it was made : and as the blood flowed flowly it had time to entangle or mix with a quantity of the matter contained in the puftules; fo that this experiment is a very indecifive one. Moreover I have been told by a gentleman who fometime fince attended the Lectures of the celebrate. John Hunter, that

* Home's Medical Facts, &c. p. 268.

that Mr. Hunter informed his pupils, that he had made frequent attempts to inoculate with the blood of those who had the fmall-pox, and lues venerea, but never fucceeded in imparting the infection.

Lind's obfervations on the blood in the yellow fever fupport the opinion, that fubftances different from the blood may be diffufed through it without changing it. He relates that the ferum was of a deep yellow tinge. A perfon by curiofity tafted it, and found it bitter.*

From these facts we learn, that the bile may exist in the blood-veffels, without producing a change in the blood, or fuffering one itself, fince its fensible properties were in these cases evident. Who will affert that the properties of the blood are changed in jaundice?

We might proceed to a much greater length in proving that certain fubftances may exift in the blood-veffels of living animals unchanged themfelves, and without producing any change in the blood, as turpentine, &c. This, I believe, is a polition at prefent generally allowed by phyficians—I fhall therefore pass it over in filence.

Eruptive difeafes were, for ages, fuppofed to be owing to changes in the blood; but the following Experiment would feem to operate against the doctrine. D. Coxe, transfufed between 14 and 16 ounces of blood from the jugular vein of an old dog, who laboured under an eruptive difeafe, into the jugular vein of another dog, who was in health. This being done, the difeafed dog got well; and

" Lind's 1ft. Paper, p. 13.

and to the other, who received the blood which might probably have been fuppofed to be affected, nothing amifs happened.*

This Experiment proves clearly that the blood did not fuffer a change from the difeafe under which the dog at that time laboured. Eruptive difeafes are, I believe, for the greateft part contagious; and as the blood did not, in this inftance, communicate the difeafe, we cannot fuppofe that the contagious matter adhered to it; this, therefore, ftrengthens my opinion, and leaves room for the fuppofition, that contagion may adhere to different parts of the body in different fubjects.

If contagious difeafes are produced by the contagion operating upon the blood as a ferment, whence is it that the blood of brute animals is not fufceptible of being excited into this fermentation, fince, from Experiments, it appears to be much of the fame nature with that of the human fpecies ?

Five months after the above fheets were written, I had the good fortune to obtain a reading of Dr. Milman's very ingenious "Enquiry into the fource from whence the fymptoms of the fcurvy, and of putrid fevers, arife, &c." wherein the author difplays a great deal of ingenious reafoning. I was happy to find that we agreed in fentiment refpecting the general opinion, though we have treated of the fubject in a very different manner. For particulars I refer the reader to the book itfelf.

Thus I have fought in nature the phœnomena of my doctrine. In my own estimation, facts respond to theory, and the inferences of my Experiments to fpeculation. When I first contemplated this fubject, I was not particularly attached to any opinion respecting it; and, from this circumstance, I gained the advantage of an impartial and unprejudiced examination of facts. After collating and confidering the Experiments I had made, I drew my conclusions with a deference to reason. If, in the event, I shall have contributed to advance the interests of Medicine, and furnished any principles to aid the labors of practice—to less the horrors of putrid diseases----and to arrest, for a moment, the dreadful arm of death, I shall be more than compensated for performing my duty, and paying this tribute to humanity.

THE END.
