Since January 1 of this year I have operated in private for gall-stones eleven times; at the Massachusetts General Hospital in the same period, five times. One private patient died at the end of a week. This was a desperate case, and the operation was undertaken with very little expectation of saving the patient, who gradually failed and finally died uremic. In one hospital case the patient died after removal of a stone from the cystic duct. There was no apparent cause.

This list includes all the fatalities that have occurred in my own experience. In all these cases, as I have already stated, there was a wide variation from the normal; it could not be truly said of any patients that they were in a state even of comparatively good health. In many cases the operation was performed as a forlorn hope. Many cases belong to that class in which the mortality must be at least 90 per cent.—to a class like that of general peritoneal infections in appendicitis. In

many of the gall-stone cases the patients were in that condition of cachexia which is seen in advanced malignant disease—a cachexia in which the simplest and briefest explorations show a very high mortality.

The results of experience, as here shown, can not but emphasize the importance of early operations. In most of the fatal cases it will be observed that the history of gall-stones had lasted over many years, a period of time during which serious complications, both local and general, had taken place. Moreover, in many cases the patients were beyond middle life, and one patient at least was of advanced age. Among the deaths were four occurring during the course of an acute cholecystitis. In some of the successful cases, too, similar serious local and constitutional complications existed, but in spite of them recovery followed.

Patients of middle age, or younger, without these complications, were all cured by operation, and thus far the cure has been permanent.

Among the serious complications were acute infections of the gall-bladder in some twenty cases. All recovered except four. In many of them there was no history of gall-stones; in several appendicitis was supposed to exist. In a few no gall-stones were found. In two the operation was undertaken as a last desperate hope.

The possibility of the occurrence of acute cholecystitis is another strong argument in favor of early operation. Though comparatively rarely seen in the acute stages, I am sure that many of the contracted gall-bladders have passed through successive mild infections.

What are the indications then for operation on gall-stones? In my opinion the indication is the diagnosis of gall-stones in the gall-bladder. When this diagnosis has been made, the gall-bladder should be explored if there is no contraindication in other viscera.

A single attack of gall-stone colic, after which a faceted stone is found in the stools, indicates operation, but a single attack after which a single non-faceted stone is found does not. Repeated attacks of severe colic, even if stones are not found in the stools, strongly indicate exploration, especially if there is tenderness in the gall-bladder, with fever, for stones are probably confined in the gall-bladder, or at its outlet, and the spasms are ineffectual efforts of the gall-bladder to expel them. All cases of acute cholecystitis demand operation if seen early, unless the symptoms are rapidly improving, and then they require operation after the subsidence of the acute attack. Repeated attacks of gall-stone colic indicate operation, even if no stones are discovered in the stools, and even if the symptoms are so mild as not to demand it.

True conservatism in the surgery of the gall-bladder—the lesions of which are purely mechanical—requires, as the only rational treatment, surgical measures which themselves are purely mechanical.

Though natural relief in gall-stones is not as impossible as in stones of the urinary bladder, the former, because of their occurrence, cause far more suffering and death than do the latter. Furthermore, the complications of gall-stones are in many instances quite as disabling as those of urinary calculi, and they often are more rapidly fatal.

A most pernicious argument against measures in gall-stone affections, as in appendicitis, is the occasional quiescence and the occasional complete recovery after severe symptoms; but in neither lesion can any man predict the probable course. Removal of the appendix that has offended, or is offending, is the only common

sense method of treatment, as most experienced operators and clinicians will admit, the chief difference of opinion being as to the safest time for the operation. So in patients who have suffered from gall-stones—who are suffering from them—it is but common sense to advise simple and safe methods of sure removal rather than the uncertain and dangerous courses of natural evolution. In both diseases early operation, at a period when everything favors speedy convalescence, can not but be regarded, in the light of experience and of common sense, as a life-saving procedure gained at a minimum of risk.

DISCUSSION ON PAPERS OF DRs. MEANS, MAYO AND RICHARDSON.

DR. JOHN A. WYETH, New York City—Dr. Richardson's paper is so unanswerable that it controverts discussion. It thoroughly expresses my own views, and I am modest enough to believe they are the views of every progressive surgeon.

DR. H. MYNTER, Buffalo—I have listened to the papers with a great deal of interest and noted several points which might be discussed. In the first place, as to the question of jaundice, we have all heard a good deal about hematogenous jaundice. All cases of jaundice depend on the inflammatory conditions present in the gall-ducts, and this is particularly dependent on the colon bacillus working its way into the gall-bladder, changing the condition of the epithelium. I want to say that in these cases if you look at the gall-stones you will find clumps of the colon bacillus in the center and around the layers of bile salts. This proves that the whole idea about hematogenous jaundice is exploded, in that the condition is dependent on inflammatory changes in the gall-ducts themselves.

As to Dr. Richardson's paper, I want particularly to call attention to the fact that he reports his fatal cases; we learn much more from these as to the necessity of early operation, which, I agree with him, is not dangerous. I have done many such operations myself, and in one case removed 565 gall-stones. In my cases of later operation I have been at times successful, and recall one such patient who had been sick for eighteen months. I lost one patient from a stone in the common duct.

Dr. Fenger raises the question of closing the common duct, which I think is a very dangerous operation.

It has been mentioned that jaundice is a symptom of stone in the gall-bladder, but I think this is a great mistake. I am sure that stones in the gall-bladder do not cause jaundice. Jaundice may be caused by a stone in the cystic duct if it is sufficiently large and presses on the hepatic duct, while stone in the common duct always causes jaundice. Jaundice may be entirely absent if the stones are in the gall-bladder itself. The most important points in the diagnosis are the continual pain and the intermittent tenderness over the gall-bladder. When I have these symptoms present I have no hesitation in making an exploratory laparotomy, as I believe this is no more dangerous than the disease itself. The diagnosis between cholecystitis and appendicitis is interesting. I remember a case on which I operated for appendicitis and found a distended gall-bladder containing 160 gall-stones. I shortly afterward operated on a woman for gall-stones who had been suffering with slight jaundice, but I found appendicitis with the appendix attached to the gall-bladder. Since that time I have been very careful.

DR. NICHOLAS SENN, Chicago—The X-ray is important in the diagnosis of gall-stones and can be relied on in demonstrating their presence when they contain phosphatic substances, but is useless when only cholesterol is present. One of the speakers has referred to a substitute for cholecystectomy and stated that the operation may be done in two stages. In my opinion, whenever possible all operations should be completed at the one sitting, and every surgeon objects to doing two operations instead of one, especially as there is much greater anxiety to the patient. Personally I am always in favor of very thorough dissection, and have found it much more difficult to remove mucous membrane when it is inflamed. If the operation is not completed at once it is a mistake and I should strongly recommend this be done. One speaker has mentioned

that the operation as he performs it requires no draining and this is somewhat similar to the method I employ in relapsing appendicitis. In cases in which the appendix is imbedded in adhesions its removal is much more risky to the adjacent viscera. In some cases I depend for successful operation in the sub-serous method of removal, splitting the appendix the whole length so that the enucleation is a matter of great ease. It may be done safely and readily where the proper care is given to the general conditions surrounding the removal. Sub-serous enucleation of the gall-bladder would be a good operation, I am sure, to try as the peritoneal surfaces can be very readily separated and there is very little risk of hemorrhage. The surface may be everted and sutured and abdominal wound closed. I wish to protest against too frequent operating on patients for gall-stone, as I fear that this will be carried to the same extreme that appendicitis operations have been. Of course we always look for complications in cases of gall-stone, and when these are present the sooner the operation is performed the better. I can give no more illustrative and convincing example of the rational course of treatment to be pursued in these cases than by referring to that of the most distinguished surgeon that the world ever knew, Kocher. He was himself a subject of gall-stones, and has been going to Carlsbad every summer instead of immediately submitting to the knife. I doubt if any member of this section, who might have gall-stones would be anxious for operation. We should be conservative, and the time has come to call a halt.

DR. F. D. GRAY, Jersey City—I recall one case of special interest bearing on this subject, on which I operated recently. The patient had evidently been suffering from impacted gall-stones, although she had never had colic until my first visit, two weeks ago. She had all the indications of impacted gall-stone when I first saw her about midnight. Where abdominal pain and tenderness exists, I always think of appendicitis, but in this case there was no pain in the neighborhood of the appendix, it all being localized about the region of the gall-bladder. The temperature was practically normal and morphin had been administered rather freely. I saw the patient the following forenoon, when the temperature was 102 and the tenderness and pain had begun to extend toward the appendix. At 1 p. m. the temperature was 103, and the pain was chiefly located over McBurney's point. The husband, who was a physician, agreed to an operation. There was then marked tenderness between the gall-bladder and McBurney's point, seeming to indicate an area of peritonitis between these two regions. The operation was performed at 4 p. m., when the gall-bladder was found greatly distended and two or three small concretions were discovered in the appendix, which was in a stage of beginning inflammation, and a certain amount of pus was floating loose between the gall-bladder and appendix. The appendix was at once amputated, and clearly showed evidence of the early stages of inflammation. I flushed the surfaces of the intestines, doing nothing with the gall-bladder, except to introduce an exploring needle and withdraw about one ounce of fluid, thus relieving tension. The fluid contents bore no resemblance to bile; although chemical examination showed a small amount to be present. I attached the surface of the gall-bladder to the upper third of the incision, closed the lower two-thirds, and allowed thirty-six hours for adhesions to form. I then opened the sac and evacuated the remainder of the mucopurulent contents. At the bottom of the gall-bladder were then found three large gall-stones with well-marked facets, and also two similar ones from the dilated mouth of the cystic duct. The condition thus resolved itself into one of impaction of the cystic duct, followed by distension of the gall-bladder by its own secretion. The peculiar feature was that though of long standing—judging from the nature of calculi—colic had never developed until a few hours before operation; and also there must have been a pin-point rupture of the bladder, causing in a short time a localized peritonitis and periappendicitis. The patient made a complete recovery, with spontaneous closure of fistula within a month.

DR. H. O. MARCY, Boston—Ten years ago I read a paper on this subject before the Surgical Section of the Association,

and reported the history of a patient from whom I had removed a stone from the common duct, sutured the common duct and the wound, and secured a rapid recovery with primary union of the wound. This was the first primary suture of the duct ever reported. The past week I saw this patient again, when I found marked jaundice present and all the evidences of biliary obstruction. Recently another gall-stone was passed, which shows very clearly that the removing of the diseased gall-bladder would have saved the recurrence. I must take exception to Dr. Senn's remarks and agree with the other speakers who state that this is an important subject and one calling for careful diagnosis. All of you have seen many fatal cases in the past that now would be saved had you operated promptly. One of the wisest diagnosticians in Boston recently advised against operation, and three days later, when I did operate, I found a decided empyema of the gall-bladder and all the attendant septic symptoms, from which the patient barely escaped with his life. I believe we often fail in not operating when it is our plain duty to do so, and the surgeon should often aid the physician by prompt interference.

DR. JOHN B. DEEVER, Philadelphia—I heard the papers by Drs. Mayo and Richardson, and would particularly call the attention of the Section to the fact that one of the most serious conditions a surgeon is called on to treat is perforative peritonitis; in addition it is one of the most fatal. One of the common causes of perforative peritonitis is perforative appendicitis, and another perforation of the gall-bladder or the common bile duct. I believe remarks like Dr. Senn's are capable of doing much harm and may be responsible for many deaths. I could stand here and call your attention to many cases of perforative appendicitis and perforative inflammation of the gall-bladder. One of the most distinguished physicians in the state of Pennsylvania died of a perforation of the common biliary duct. His physicians argued for conservatism, which is a very dangerous doctrine to promulgate at this age. I believe in operating early and I further believe that late operation will rarely save lives. Early operation is a life-saver. In the majority of instances the stone is situated in the common duct and not the gall-bladder. I do not agree with Dr. Mynter, that these operations are among the most difficult the surgeon is called on to perform, and that the majority of them do not compare with some of the cases of perforative appendicitis on which I am called to operate. Usually I find no trouble in removing the stone, and believe that the trouble is in the lack of skill of the operator rather than the pathologic condition with which we have to deal. I have yet to be able to diagnose a case of stone in the gall-bladder by means of the X-ray. This is an important method in the diagnosis of stone in the kidney I admit, but not in the case of the gall-bladder or the common duct.

DR. HAL C. WYMAN, Detroit—I believe there is considerable good derived from a cholecystostomy, and that it has a remedial value which has not been clearly brought out. The danger to which our patients are exposed when suffering from jaundice deters many from operating, as they dread to do an operation like the complete removal of the gall-bladder for fear of hemorrhage. Simple cholecystostomy, merely opening the gall-bladder, provides drainage and tends to recovery. The danger is in the profound bile intoxication, and it will be relieved by this operation. When we have to deal with a cholemia due to obstruction of cystic or common ducts we should endeavor to make the operation answer the purpose of draining the system of bile. In simple cholecystostomy we have a remedy that, in my experience, has been of great value.

DR. EDWIN RICKETTS, Cincinnati—I rise to bear testimony to all that has been said by Dr. Richardson, who has always been known as an advocate of the earliest possible surgical intervention for gall-stones. I recently had two cases in which I was compelled to open the common duct. One is dead and the other is living. I am sure that had the patient who died, and who had been suffering from biliary obstruction for ten years, been operated on sooner he would have lived. Gall-bladder surgery, done early, is one of the prettiest and easiest operations that ever befalls the surgeon. In contracted gall-bladders, opening of the common duct is one of the most des-

perate operations. Of 46 operations, two have been lost in which there was no complication of cancer, the loss in each case being the result of delay. In all cases in which cancer was present as a complication death took place. I have drained these gall-bladders from one ounce to one gallon lacking one ounce. Not one-quarter has been said in behalf of what we are to accomplish by early surgical intervention in biliary obstruction.

DR. A. J. OCTISNER, Chicago—In discussing the three papers on the subject of gall-bladder surgery, I wish to refer to one very important fact: All the cases which terminated fatally had suffered from gall-stones for a long time, and death was not due to the operation, but to the fact that the disease had advanced to a hopeless condition. All the patients who were operated on reasonably early recovered. Undoubtedly there was a time when it would have been possible to also operate successfully on the patients who died.

The reason why patients suffering from gall-stones uniformly recover after operation, if it is performed reasonably early by a competent surgeon, is very plain. The operation is simple; there are usually no important adhesions, and the operation can be performed practically without any danger of infecting the surrounding structures. At this time the contents of the gall-bladder are much less likely to be septic, consequently an infection of the peritoneal cavity is not likely to occur.

Two years ago, while visiting Dr. Mayo's hospital, I asked the Doctor how he explained the great number of gall-stone cases which came under his care for operation. His answer was exceedingly simple and undoubtedly correct. He said: "We make a diagnosis in these cases." Since that time I have operated on seven cases of gall-stones in patients whom I had previously referred to the general practitioner, because I thought they were suffering from some digestive disturbance, the cause of which I had completely overlooked. During the same time I have operated on more than thirty cases of gall-stones which had been treated for a long time for gastritis, no diagnosis of gall-stones having been made previously. In other words, the presence of gall-stones had been overlooked; as soon as they were removed the gastric disturbances disappeared.

We constantly find these patients at autopsies and imagine that the gall-stones gave rise to no symptoms, because no diagnosis had been made before death. As a matter of fact, these patients had suffered from gastric disturbances which were due to the presence of gall-stones, and would have been relieved had the gall-stones been removed.

Regarding the operation which Dr. Mayo recommends, I will say that in proper cases it can be performed with ease, and being practically an extraperitoneal operation it is certainly perfectly safe in the hands of a competent surgeon. Whatever the theoretical objections may be, I have found it an excellent operation in practice.

DR. ARTHUR D. BEVAN, Chicago—I do not believe that we can accept the dictum that we should operate on gall-stones whenever the diagnosis is made. My examination of post-mortem material and a careful analysis of the facts so gleaned would show that we can not accept this dictum. Among the dissecting-room material 16.5 per cent. of the cadavers have gall-stones, while in the post-mortem material 25 per cent. of individuals over 60 years of age have gall-stones. In a large proportion of these cases the gall-stones have simply been innocuous foreign bodies, which surely have not caused death in 16.5 per cent. and 25 per cent. of the cases respectively. In a great many cases gall-stones produce only very slight, but fairly definite, evidences of their existence. I am quite sure that the internal-medicine men would not agree with the surgical section if they were to adopt the dictum that we should operate on all cases so soon as the diagnosis is made. The internist sees the majority of these cases, the surgeon only the severe cases. Gall-stone operations have done much for the saving of life and the lessening of suffering, but I am sure that in a judicial way we can separate the surgical from the medical cases. Cases are best handled, and always will be, by the internist, while many others should be handled by

radical operation. I do not think that this section can afford to take any but a judicial view of this subject.

DR. H. H. GRANT, Louisville, Ky.—I have waited to hear the expressions of opinion on this important subject before speaking. Most of Dr. Bevan's cases seen post-mortem are those in which the gall-stones have probably never produced symptoms, and I think it is unwise to operate at any time unless symptoms are present. Where the diagnosis is correctly made these cases may be operated on safely without 1 per cent. mortality. I desire to call the attention of the Section to the fact that by an exploratory operation where the diagnosis has not been satisfactorily made or where the case has been in the hands of those who can not make a diagnosis and where the X-ray has been tried and may or may not have worked, the patient will not be in the least harmed and the slight damage done is easily remedied. The success of our efforts lies in the beginning rather than in the end of the disease. Exploratory laparotomy should be done where the symptoms are present, but are not sufficiently distinct to determine the diagnosis.

DR. J. E. SUMMERS, JR., Omaha—I would like to call attention to the occasional necessity of establishing an anastomosis between the common bile duct and the duodenum. This may be necessitated by an impermeable stricture of the lower end of the common duct complicated by the same kind of a stricture in the cystic duct or by an obliterated gall-bladder. The operation is difficult and has been done only a very few times. In my own case—the only reported one in America—it was found that after the introduction of the respective halves of a Murphy button in the common duct and the duodenum, the only method by which the two halves of the button could be pushed home was by passing the left index finger into the foramen of Winslow so as to get its palmar surface behind the common duct and push on the end of the half button introduced into this duct. The thumb and middle finger of the same hand were opposite one another and grasped the circumference of this half button through the duct walls. With this half of the button thus supported the anastomosis was readily accomplished by the usual manipulations.

Probably if an anastomosis was made between the cystic duct and the duodenum the procedure could be carried out quite as readily as when the gall-bladder is joined to the bowel, but when necessity compels the operator to select the common duct the manipulations which I have outlined are practicable and ideal. I drained the gall-bladder in my case, because I had opened it in an endeavor to overcome the stricture in the cystic duct. Only mucus discharged from the opening for about two months and I had arranged to excise the gall-bladder mucous membrane as recommended by W. J. Mayo, when bile began to discharge and after some further drainage I closed the fistula and the young woman is now perfectly well.

DR. W. J. MEANS, closing discussion—I am certain I voice the sentiments of the gentlemen who have read papers on this interesting subject, when I state I have been highly pleased with the discussion and feel that much useful information has been elicited. Replying to the covert criticisms of my friend, Dr. Mynter, I desire to state that I do not claim to have a wide experience in the operative treatment for cholelithiasis. I have operated on ten cases, as mentioned in my paper, all of which recovered. I quite agree with Dr. Mynter that fatal cases should be reported as well as successful ones, and I certainly should have done so had I been less fortunate. The Doctor evidently misunderstood the meaning of the terms "hepatogenous" and "hematogenous" as applied to jaundice. The former refers to jaundice caused from obstruction of the ducts from some source, and the latter to jaundice produced by suppression of the function of the liver cells, or when blood-destruction is in excess of the capacity of the liver to remove the products of destruction. In malignant diseases of viscera contiguous to the biliary apparatus, both types may be present, making a differential diagnosis very difficult.

It is my judgment that our text-books place too much importance on jaundice as a symptom of gall-stones. My report shows jaundice in thirteen cases out of twenty. If physicians were to discard jaundice as one of the pathognomonic signs, and were to make a diagnosis from general symptoms always

present where gall-stones have existed for some time, there would be more cases of cholelithiasis reported among the living, and fewer in the dissecting room.

I feel grateful to Dr. Senn for his very kind criticisms on my pronounced views in favor of the operative treatment. His conservatism is no doubt the product of a ripe experience and intelligent observation, and therefore entitled to our consideration. We younger surgeons, who have been his devout students for years, are loth to take issue with him; but it seems to me now that in the rapid evolution of modern surgery, as evidenced by the achievements in abdominal work, his words of warning are largely the echo of things past, and should not be the rule of to-day. I believe the rational treatment for gall-stones is surgical, and that an operation should be made as soon as a diagnosis has been reasonably determined.

My experience with the X-rays as a diagnostic aid has been limited, but negative so far as used. I am not in position, therefore, to discredit the statement of others who have found them useful.

I believe the drainage through the abdominal incision is the safest procedure. In two cases where I was positive that the common duct was open I closed the opening in the gall-bladder with Lembert sutures, and closed the incision in the abdominal wall. This is the ideal operation, but unfortunately can be made safely, in but few cases. Where there is an obstruction in the ducts from cholangitis the patency is restored after five or six weeks, the external fistula closes, and the biliary apparatus resumes its normal function. No doubt the enforced rest relieves the ducts from irritation, the exudates are absorbed from the surrounding tissues, and all evidences of inflammation disappear.

The statement that gall-stones may exist in the bladder without causing any trouble, I do not believe. That they may remain in the gall-bladder for an indefinite period and produce no serious trouble, is no doubt true. This fact, however, does not sustain the let alone theory of those who are opposed to radical treatment.

DR. W. J. MAYO, closing discussion—I did not read the whole of my paper, which perhaps accounts for the mistake Dr. Senn made in thinking I operated in two stages. Where there is a stricture in the cystic duct following a cholecystotomy which the cholecystotomy had failed to relieve, where the common duct was patent, the removal of the mucous lining of the gall-bladder is indicated. In 106 cases which I have followed up there were 8 in which drainage had failed to cure and occasionally a mucous fistula would close producing a certain amount of pain. Sometimes when you operate on these cases and remove the stone you can not tell at that time whether the cystic duct will restore itself or ulceration and stricture follow. I refer to cases in which the patient is not wholly relieved by the operation, and if you can safely remove membrane I can not see any good reason why it should not be done. Dr. Senn advocates the removal of the peritoneum, but in many cases there is no peritoneum on the inside of the gall-bladder. By stripping it from the outside you would not have any peritoneum where you most needed it, so that I can hardly understand how Dr. Senn's idea would be a good one. There is a great deal of difference between the peritoneum with and without the muscular coat. The mucous membrane strips with remarkable ease, and any one who has operated on the stomach knows this to be so.

DR. M. H. RICHARDSON, closing discussion—The first part of my paper was not read, which will explain why some of the points discussed were not mentioned by me. I believe that the appendix should be removed not only when there are direct symptoms of trouble, but also when there are any suspicious conditions present that attract attention. I believe the patient should be operated on even if there is only a faint suspicion of appendicitis.

I was very glad to hear Dr. Senn's conservative remarks, as such discussion is distinctly beneficial. I have removed gall-stones from the large intestine in a man between 60 and 70 years of age who had never had a symptom in his life.

I am quite sure that the colon bacillus and the typhoid bacillus have much to do with the infection of the gall-bladder.

MODERN EMPIRICAL INVENTIONS.*

N. C. MORSE, M.D.

ELDORA, IOWA.

I desire to call your attention to some of the so-called modern empirical or quack inventions for the cure of disease, namely, the "electropoise," the "oxydonor victory," and the "oxygenor king."

An old Indiana attorney made the assertion, many years ago, that "any proposition is good law in a justice court that is boldly asserted and plausibly maintained." What is true in a lower court of law, is, I think, equally applicable to the unthinking American people, who seem to find enjoyment in the purchase and use of every new medical "fad" or "fake" when forcibly and plausibly brought to their notice.

The wearing of medical amulets, charms, etc., from the time of the "five golden mice" (I Sam., vi-4), down to the more modern "buckeye" or stolen "potato," or still later the use of the "rabbit's" foot and electric ring, furnish now, as of old, a certain amount of inexplicable solace that seems very dear to the hearts of those who have faith in their efficacy and is but another endorsement of Ouida's statement that "superstition has fascinated and swayed mankind since history began." The average American believes what he reads. There is no law to prohibit the false statements or misrepresentation of these quacks or charlatans who depend on their power to deceive and to prey on public credulity.

For several months past a certain charlatan has been flooding the State of Iowa with his "oxydonors." A cadaverous looking individual, acting as his special agent, has sold many of these instruments in the county in which I reside, and through a liberal patronage of the press, is in a fair way to sell many more. The "electropoise" and "oxygenor king," have likewise been introduced, and, according to their agents, have performed many wonderful cures.

The first case coming under my personal observation, where one of these mysterious instruments had been used, was that of a neurotic lady of 48 years, who had unintentionally slept over night with one of these oxydonors attached to her ankle. On awakening the next morning, she found it impossible to move the hand or leg of the treated side; she was greatly alarmed and for a while thought herself hopelessly paralyzed. It is needless to say that she was easily restored to her equilibrium by simply attaching the instrument to the other leg for an equal number of hours, there being no way, that I could discover, to reverse the current.

The second case was that of a patient of mine, a gentleman of more than ordinary good judgment and intelligence. He had just recovered from a very serious attack of gall-stones. Naturally dreading another attack he was induced to try the oxygenor. He has not had a return of the old symptoms, and has given full credit therefor, through our county paper, to this instrument. We know that such a history is of frequent occurrence in these cases. He may possibly never have another attack, but if he does, he will learn to his sorrow that he can not rely on his oxydonor.

This case led me to make an investigation of these instruments or inventions, and I bring them before you, that we may dissect and study them together, that we may knowingly explain to our patrons just how and of what they are constructed, and I feel assured that you will agree with me that the autopsy will reveal no battery

or any other means of generating oxygen or electricity, and that they are absolutely without medical virtue except in so far as they act as a psychical, i. e., mental or "faith" cure.

This little instrument I first show you is called "The Electropoise." The cost price of which is \$10. It has gained much notoriety through some of the Southern states, and is supposed to cure all diseases. It is manufactured by parties at Birmingham, Ala. The cylinder, or "Polizer" as they call it, is $3\frac{1}{2}$ inches in length, and weighs about 5 ounces. It has only one wire or insulated cord, which passes through a small, movable cap at the top of the cylinder. This cord is attached to a small disc, and by means of an elastic band and buckle is intended to be placed around the wrist or ankle of the patient, or over the diseased part. I have had it sawed into sections and alas, like the goose that laid the golden egg of fable fame, there is nothing in the carcass!

The next instrument is called the "oxydonor victory." You will no doubt notice the close resemblance to the electropoise. This oxydonor has a nickel-plated cylinder called "Vocor," which is $2\frac{3}{8}$ inches in length and weighs 5 ounces. It has but one wire, a non-insulated cord, which is attached and used in the same manner as described for the electropoise. I have had this oxydonor cut into two sections. The cylinder is made of brass and the center is filled by a stick of carbon, like that used by electricians, held in place by a little sealing-wax or melted resin. The price of this instrument was formerly \$35 cash; they can now be purchased for \$10.

"The Oxygenor King" has evidently been constructed with the intent to deceive the most expert, and for this reason it seems to me would be more effective as a "faith" or "mind" cure than either of the others. It is composed of a nickel-plated, hollow brass cylinder, $5\frac{1}{2}$ inches in length and weighs 24 ounces. On removing the ends, there will be seen a small pivot or point which is supposed to make connections with the battery within. Sawing through the center reveals a gray substance, of the consistency of sand. A careful analysis proves conclusively that the mixture is composed simply of powdered charcoal and a little sulphur. One end of the cylinder connects with a copper, the other with a zinc disc, by means of insulated cords which are intended to be attached to the ankle or wrist of the patient, as shown in the wood cut of the catalogue. The price of this instrument is \$25 net cash.

The large book is sold for \$1. By reading it, you will understand at once how they reach the people.

The inventors of these "cure-alls" claim that they work on the human body, in the following manner: "The electropoise supplies the needed amount of electric force to the system and by its thermal action places the body in condition to absorb oxygen through the lungs and pores. We know this by the way it acts and its wonderful effects." . . . "The oxydonor victory generates or absorbs the oxygen from the water and forces it by the law of induction through the system, putting new life into the tissues and blood, thus proving a blessing to the sick and afflicted." . . . "The oxygenor king acts in a dual capacity. First, it forces the absorption of oxygen by the system under the polar control of the instrument; secondly, it removes all obstruction to the free flow of chyle, lymph and other juices of the body, thus giving nature a chance to perform her natural work."

Generators of oxygen! Wonderful instruments! But the most wonderful part of all, is the fact that people can be made to believe in their efficacy. Every high-

* Read before the Austin Flint Medical Society Midsummer Meeting, Clear Lake, Iowa, July 11, 1900.

school boy knows that it requires a most powerful battery to separate oxygen from water. Could anything be more ludicrous, therefore, than the claims of these inventors! Yet there are thousands of people who believe their assertions and purchase these instruments. It simply shows that the people believe what they read regardless of the absurdity of the claims. I agree with "Puck," that, "if some enterprising yankee would graft a strawberry vine to a milkweed and advertise the product to produce strawberries and cream, in a short time he could not supply the demand for the plants." This is no more absurd than many of the statements that appear in these circulars. Take the oxygenor pamphlet for instance and turn to page 4, under "Facts of great value," you will find the following: "It is the most infallible protection to life ever known to man, and it is ever ready to save the life of its possessor from the most formidable of diseases." "With the oxygenor at hand, every one is master of his own health. It is a discovery absolutely unequaled in science or the wealth of the world. No diagnosis is needed. It cures all diseases. Any one can apply it. It enables mankind to utilize one of the most remarkably beneficial laws which an all-wise Creator has put in operation." "They can

of the oxygenors, it was held by the court that "the evidence adduced in support (of the oxydonor) was insufficient to conclusively establish its validity or show that the device was in fact useful or valuable, in such sense, as to entitle it to the protection of a Court of Equity."

So much for the oxydonor, how about the electropoise and oxygenor? As to their actual value, I will read you what Dr. Hercules Sanche says. Printed in large letters, on the box containing the oxydonor, are the following words:

"Beware of frauds and impostors. All things used for treating diseases by wire or cord connection with the earth, or anything cold, in any form or by any name not plainly stamped Dr. H. Sanche, Detroit, Mich., are dangerous imitations made in total ignorance of the principles involved and without reference to any principle except fraudulent gain."

Thus the renowned Dr. Sanche pronounces judgment upon the oxygenor and the electropoise, while the United States Court of our own state has decided that Dr. Sanche's instrument of cure is not of sufficient value to entitle him to a standing in a Court of Equity.

These instruments are in no sense electrical, nor magnetic. They do not claim such powers. They contain no battery or other means of generating oxygen. They, therefore, possess no more medical virtue than a copper wire attached to a stove lid, or a tin can filled with brimstone and charcoal. Cures resulting from their use, no matter how wonderful, belong to that class known as "mind cure" or "faith cure."

It might be asked: What possible harm then can they do? We as physicians will not object if our millionaire friends want to buy them for their children to play with; they are harmless toys. But we think it wrong to have them foisted on those who are unable to buy them or on whom their purchase would entail hardships in the vain hope of curing their incurable diseases.

Again, there is the fact that so many are prone to believe what they read, and the fact also that many in their ignorance seem perfectly willing to trust to or rely on such methods of cure, even in serious or contagious diseases; it is here that the law should interfere, or prohibit the sale of these inventions.

And lastly, some of the statements of these charlatans should not be allowed to remain unchallenged, especially when they tend to lead the people astray and endanger public health.

Electropoise. Oxygenor King. Oxydonor Victory.

never wear out." "They can never exhaust themselves." "Their law of cure is based upon principles as positive and lasting as the laws of gravity," etc.

They also publish a list of "don'ts," under which appear the following:

"Don't worry, it can do no possible good, and is injurious."

"Don't hesitate to eat the seeds of grapes, figs, dates, etc., because of the fear of appendicitis."

"Don't lend the oxygenor to any one. If it is desired to treat a sick friend, take the instrument and apply it, but don't leave it." (Some one might want to examine it!)

"Don't permit any one to see this instruction book"—(Presumably for the reason it will not bear inspection, except from those who are foolish enough to invest in an instrument.)

MEDICOLEGAL ASPECT OF THESE INVENTIONS.

In correspondence with friends at Washington, who have been kind enough to examine the records at the Patent Office, I learn that the dates or patents apply to the trade-marks or names of these instruments, the instruments not being of themselves patentable.

I also learn that in a trial before the United States Court, held at Des Moines, Iowa, Dec. 19, 1899, wherein Dr. Hercules Sanche endeavored to prevent the sale

BACTERIOLOGICAL EXAMINATIONS OF OTITIS MEDIA PURULENTA AND SUPPURATIVE MASTOIDITIS.*

TALBOT R. CHAMBERS, M.D.

Consulting Ophthalmologist Orange Memorial Hospital; Surgeon in Charge Eye, Ear, Nose and Throat Departments of City and Christ Hospitals.

JERSEY CITY, N. J.

The season just passed, since last autumn, has furnished Hudson County an admirable supply for study of catarrhal and purulent inflammations of the middle ear and mastoid. The course of these diseases has been watched with unusual interest. In dispensary there have come under my personal care 107 cases of otitis media purulenta, and 35 in private practice, 142 in all. There have been 58 cases of mastoid disease, of which 28 have been aborted and 30 have been operated on.

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In 19 instances there was no opportunity to try abortive measures and the mastoid was found partially or entirely broken down. I might say two cases of drawn face were relieved by operation, and two cases of facial paralysis followed operation.¹ The tip was always thoroughly cleared out.

One death occurred after three weeks, suddenly, just as an exploratory secondary operation had been decided on. A second death from tuberculosis, one month after operation, occurred, my third and last death was in the case of a man brought into the hospital in a state of coma, who failed to recover and died five hours after operation. The others operated on were discharged cured in from ten days to four weeks, except two tuberculous cases, which have a slight aural catarrh.

Starting out with the purpose of discovering why some cases yielded to treatment by pepsin and others did not, I engaged Dr. G. E. McLaughlin, of Jersey City, to examine the discharges microscopically. In some cases the germ was only recognized after a culture had been made. Several specimens which needed a culture for identification of the germ failed to return, and hence though over sixty-five examinations were made by him, I have report of only 58. Cases accumulated so that many questions arose, some of which this paper attempts to answer.

Germ found in O. M. P.	Total Exam-ined and Microscopically.	Cured by H. W.	Cured by Enzymol.	Antiseptics.	Cured.	Unimproved.	Unimproved.	Fail to return.
Streptococcus	14	4	1		1	1	3	3
Strept. and dip. pneu. (Fraenkel)	1	1			1	1		
Strept. and ptyocyanus	1						1	1
Strept., staph. and ptyocyan.	1				1			
Strept. and staph.	4				1	1	2	2
Staphylococcus	5	1	3		4	2	1	1
Staph. prog. anrens	1				1			
Dip. pneum. (Fraenkel)	12	2	10		12			
Dip. pn. and colon bacillus	3				3			3
Ptyocyanus	3				3			
Colon bacillus	1				1			1
	58	7	16		33			13

In the first-column of the report appears the name of the germ or germs discovered in a single specimen. Column two records the number of each class of germs. The third column records such cases where a cure resulted from hot water syringing without other medication.

At the commencement of the season, the one rule was adopted whenever an otitis purulenta, acute or chronic, came under treatment. The canal was thoroughly cleansed with hydrogen peroxid. Granulations and polyps received appropriate treatment tending to their speedy removal if possible.

The same order was then given every case, namely, hot-water syringing to be followed by instillation of enzymol in the canal. If after one week no improvement was noted, the enzymol was discontinued and the hot-water syringing was changed to hot bichlorid (1 to 4000), or hot carbolie acid (10 to 20 drops to the pint), or hot Seiler's solution. The hot syringing was at a temperature of 120 F., and patients have a number of times returned with the statement: "I use 130 and it feels good." Of course, it is necessary to employ an ear-douche with outflow, which prevents burning the cheek. (A simple contrivance, costing 25 cents, is on sale in any large city.) A two-quart fountain syringe was employed and it should take from 10 to 15 minutes for the séance.

1. One has since recovered.

Where the auditory canal was swollen and the mastoid painful, leeches were applied in the early stage and then six hours later, after the bleeding had stopped, the following treatment was employed every hour for twenty-four or forty-eight hours: Ten minutes' syringing with the hot water at 120 F., ice poultice bound firmly on for fifteen minutes and a continuous application from a hot-water bag for the remainder of the hour. To this thorough treatment I ascribe the aborting of 28 out of 39 cases of acute mastoid inflammation, presenting swollen auditory canal and mastoid pain. In no acute mastoid case where this treatment was properly carried out was operation done. In a number of the cases paracentesis of the drum membrane was performed one or more times.

Measles or scarlet fever was the precursor of the ordinary number of cases, but the epidemic, if you would call it so, might be ascribed to a catarrhal condition of nose and throat accompanying la grippe. Quite a large number reported a recent attack of what their physicians had termed la grippe.

Where the hot-water syringing alone brought the cases to a state of non-discharge no medication or further treatment was employed. Where this was employed hourly there was no time for enzymol instillations. But when the acute violent symptoms had subsided the latter were employed. Thus, in the third column, 7 cures are credited to the hot water alone.

In the fourth column are noted cases which came to a state of rest without other treatment than the hot water and enzymol. The one particular fact to notice here is that, out of 12 cases with diplococci pneumoniae, two are cured by hot water and 10 by enzymol. In order to test this point, one case containing the diplococcus was ordered to be syringed with hot carbolie water. At the end of ten days he presented himself with no diminution of discharge, and in addition an eczema of the canal which made the hot syringing painful. Five days of enzymol cured the discharge and the eczema subsided.

The fifth column shows that the antiseptics or alkaline solution, also used hot, cured 6 out of 14 streptococic cases, and with the other germs combined or alone about one-half were cured. The rest proved stubborn and resisting, and time alone will tell whether they ever will be cured. Certain it is that I have given personal enthusiastic care to several cases and they are still discharging pus to-day, my local treatment being by peroxid of hydrogen and dry cotton-tipped probes for removing from every nook all dead epithelium and debris, and then using tincture of iodine, silver nitrate or zinc chlorid solutions, or trying the dry method with boracic acid powder or nosophen. If these ears should be neglected for one or two days they fill with pus. Of course, granulations and polyps receive proper attention. One may remove the polyps and curette the base, but I confess my inability to cure granulations in certain instances when the germ is not pneumococcus. Fortunately these are not frequent, perhaps 5 out of 55.

In regard to the paracentesis of the drum, if the germ present was Dip. Pn. Fr. only, I felt sure that enzymol, if it could only be given a fair chance in the middle ear, would speedily cure the case, and hence if the opening in the drum closed prematurely it was reopened, and in one case reopened four times. Finally the case came to a state of rest. When other germs were present, the opening was cauterized with chromic acid in order that the cleansing of the middle ear might be more complete and that the opening should remain patent.

Tonic, constitutional and hygienic measures suitable to the individual were in all cases taken.

It is interesting to note that out of 65 examinations the colon bacillus appeared only four times. An unidentified bacillus was found several times on the slides, but failure to get a culture left it unknown. The pyocyaneus discharge was always profuse and fetid, and if imprisoned had a green color.

To recapitulate, the great value of having a microscopical examination of the catarrhal or purulent discharge is seen in the case of diplococcus pneumoniae (Fraenkel), where one may prognosticate a speedy cure, and secondly, one may, with equal confidence, sew up the mastoid wound completely and discharge the patient in about one week, or at most not over two weeks.

With streptococcus alone, 50 per cent. come to a cure. One case of acute suppurative mastoiditis (streptococcus alone) had hot-water syringing and zinc chlorid instillation 2 per cent. in strength, and after paracentesis came to rest in two weeks. With streptococcus and pyocyaneus the chances are even of an eventual if tardy cure.

With streptococcus and staphylococcus, the chances are two to one against cure.

If staphylococcus alone, four out of nine may come to a cure.

If pyocyaneus alone, one-half may be cured and the others prove stubborn.

If coli bacillus communis be the germ it is practically incurable.

All these may prove stubborn and resisting except the diplococcus pneumoniae (Fraenkel), which yields forthwith to pepsin. About one-fifth of all the cases came in this class. It is a fair inference that many cases which failed to return were cured and were probably of this class.

There are several factors causing imperfect efforts at cleansing the middle ear, such as the construction of the individual canal, a pin-hole in the drum, a pouting drum, attic disease, granulations in recesses where possibly denuded bone exists, and last but not least, nasal, nasopharyngeal and tonsillar abnormalities. These difficulties having been conquered, the disease will sometimes come to an abrupt termination with only little or no after-treatment.

NOTE.—Oct. 22. Since this paper was presented four months and a half ago I have had only five mastoid operations. The number of acute and chronic O. M. P. and incipient mastoid cases which have been aborted, has confirmed the claim of the curative action of the very hot water syringing. It is the most satisfactory means of cure we have to-day for these poor sufferers.

TUBERCULOSIS OF THE TESTICLE.

WITH SPECIAL CONSIDERATION OF ITS CONSERVATIVE TREATMENT.

JOHN B. MURPHY, M.D.
CHICAGO.

(Continued from p. 1349.)

Orchiectomy was in vogue for many years prior to 1895, and is still advocated by many able men, as Koenig, Kocher, Terrillon, Richez and Senn, though most of them are opposed to double castration except in very exceptional instances. It would be the operation of election, because of its ease of performance and the rapid healing of the parts which usually follows, were it not for the unnecessary mutilation, the influence on general metabolism, the mental effect, and for the fact that patients will not consent to it until the

disease is very far advanced. As the glandular portion of the testis is practically never primarily involved, and very rarely seriously secondarily affected, there is no good surgical basis for its removal. The claim, which has always been made by the advocates of castration, that the operation is more radical than epididymectomy, is not proved by the results of operations, and it is for the purpose of controverting this idea that this paper has been prepared and these cases cited. In 38 cases reported by Badenheuer in which castration was performed for tuberculosis of the testicle there was recurrence of the disease in the other organ 28 times. Bazy, Routier and Mauclair have noted the same recurrence in the other testicle in many cases. These statistics form the strongest argument against castration that can possibly be brought forward, because, as the disease so frequently develops on the other side, a double castration will be inevitable, if it be true, as these authors claim, that it is the only radical operation.

Another great objection to the performance of castration is the profound mental effect which is induced in many patients, not only where both organs have been removed, but sometimes by the removal of one. Pujol, in 2 cases of unilateral castration, observed melancholia following the operation, and Fuadls, in 3 similar cases, noted the development later of grave mental symptoms. These mental changes may in part be due to psychological impression, or they may be ascribed to absence of the internal secretion of the testicle, but whatever their cause, the fact remains that they develop in a certain and rather large percentage of the cases. The secondary secretion and its importance to normal metabolism were considered in the physiology. Tillaux, in 1896, says: "I believe that the testicular substance has an important influence on the general health. The secretion is resorbed in part by the system and contributes to the vigor of the organism." Audebal also condemns castration for the same reason.

We do not consider that a surgeon is justified in removing a testicle for tuberculosis where the epididymis, or only a part of the testicle proper, is involved. Even when the seminal vesicles are diseased, it does not supply an additional indication for castration, nor is the effect on the vesical symptoms more rapid or more pronounced and permanent when castration is performed than when the epididymis alone is ablated. After orchietomy, in many cases, there is a gradual and often ultimately complete subsidence of the sexual desire, which is not the case after epididymectomy.

Curettagé and Drainage.—This is of no more effect in the treatment of tuberculosis of the testicle and epididymis than it is in the knee-joint or other tissue. It is followed by prolonged suppuration, further extension of the disease and final destruction of the organ. It has many disadvantages, and no advantages over the more radical epididymectomy. Where the testicle is much swollen and infiltrated, so that it is impossible to determine the exact condition of affairs, it is justifiable to incise and drain the infiltrated tissues, and later, after the acute infection has subsided and the exact extent of the disease ascertained, do an epididymectomy. Longuet advocates, in cases where the tubercular foci are softened and liquefied, incision into the abscess cavities, curettagé of their walls and cauterization with the thermoantery or chlorid of zinc. His results in some cases were excellent. After curettagé the wound may be packed with iodoform gauze and allowed to granulate, or it may be closed with sutures.

Excision of foci in the testicular proper was advocated by Deville in 1852, and about the same time by Syme and Malgaigne (quoted by Longuet). Reclus has performed the same operation with perfect success. S. Duplay, in 1897, recommended dissecting out tubercular foci in the testicle and closing the defect left by suturing with catgut.

Epididymectomy.—L. Longuet, in his recent excellent paper, treated very extensively the subject of conservative operations for tuberculosis of the testicle, both from the historical and technical points of view. The first epididymectomy on record was performed by Jarjavay in 1850, upon a patient 20 years of age, with tuberculosis of the right epididymis. He resected the epididymis Aug. 7, 1850, and swabbed the wound out with tincture of iodine. As mentioned before, Syme and Malgaigne, for some time previous to Jarjavay's operation, had been teaching that in fungus and carcinomatous testicular affections not involving the whole organ the diseased portion only should be removed, and Deville, in 1852, saved a testicle which was prolapsed through an ulcerating scrotum by resecting the diseased foci. In these earlier operations, however, it was not the epididymis that was removed, but rather portions of the testicle proper in which the disease had become localized.

Typical total epididymectomy was probably first performed by Bardenheuer in 1880, and in 1887 he reported 12 successful cases. Tuffier in 1883, Villeneuve in 1889, Duplay in 1890, Humbert in 1891 and Lejars in 1893, reported cases and advocated the conservative operations. Dr. Herman Mynter, of New York, in 1893, reported 2 cases in which he had performed epididymectomy one and two years previously. Both patients had remained perfectly well up to the time of the report, and there was no prospect of recurrence in either. Guyon, 1892, condemned castration where the epididymis only was involved. Longuet, during the period from 1895 to 1898, had performed 30 typical and atypical epididymectomies with most excellent results. Humbert, in 1897, published the reports of 15 resections, with good results in the majority of cases. Reclus has done a number of successful resections, but thinks the operation indicated only when the disease is distinctly localized in the epididymis.

Indications for the Operation.—Epididymectomy should be the operation of election in every case of tuberculosis of the epididymis, single or double, except under the following conditions:

1. Where there are extensive tubercular lesions elsewhere, which will shortly terminate the patient's life.

2. Where the disease has extended to and destroyed the greater part or all of the testis proper. Here castration should be done.

3. Where the scrotum is riddled with discharging sinuses. The indication is usually here also for castration. In every other case a resection, typical or atypical, should be done for the following reasons:

1. Because it is radical and removes all the diseased tissue.

2. It does not remove the healthy glandular portion of the testicle, the internal secretion being thus preserved.

3. Patients will consent to an early removal of the epididymis, thereby avoiding the disastrous results of further infection of the genito-urinary tract.

4. It has the same beneficial effect on the vesical symptoms as has orchietomy.

5. Sexual desire and potency, even to emissions, are retained; power of procreation, however, is lost.

6. It has no ill effects on the general metabolism, nor does the patient suffer from the mental distress and melancholia mentioned above.

7. It is easy of performance and entirely devoid of danger.

8. The period of convalescence is short, and the good results are permanent.

The principal objections which have been brought against the operation are:

1. That it is not radical, as the rete testis is involved in every case, even where it appears normal macroscopically. (Koenig, Fink, Dürr.)

2. That atrophy of the testicle follows the operation.
3. That, as the patient will be sterile after either epididymectomy or orchietomy, it is unwise to risk the possibility of leaving in infected tissue.

With regard to the first objection, e. g., that the operation is not radical, we have only to say that while theoretically this may be true, practically it is not. Where the rete testis is seriously involved, to such an extent that it will give rise to trouble later, it will always be possible to determine it macroscopically at the time of the operation, and excise the affected portion with the epididymis. If this is done, recurrence need not be feared, but even supposing it does take place in a small proportion of the cases, a localized focus in the rete can be excised at a subsequent operation and no harm result from the delay, for the reason that as the vas is absent, extension upward can not take place. As a precautionary measure, in order to avoid leaving infected tissue, some operators—Lejars, Koenig, Poncet, Delbet and André—have recommended an exploratory incision into the testicle, the subsequent operation, castration or epididymectomy, to be determined by the condition of affairs in the rete. In the cases which have come under our care, this has never been necessary, it always being possible to detect deposits in the rete at the time of removal of the epididymis.

The symptoms of vesical irritation subside, after resection of the epididymis, just as promptly and completely as after castration, and the healing of secondary deposits in the prostate and seminal vesicles takes place just as rapidly. Even where the tubercular process in these latter situations is far advanced, arrest, by cicatrization and encapsulation, is the rule after epididymectomy. For this reason it is never necessary to remove these organs.

The second objection, that atrophy of the testicle follows removal of the epididymis, is not founded on fact, for numerous observations and experiments have shown conclusively that when the operation is correctly performed and the spermatic vessels not interfered with, atrophy does not take place. (T. Dimetresco.) The testes not only retain their normal size, but also their natural firmness and sensitiveness. (Longuet.) Mauclair, in one case upon which unilateral epididymectomy had been performed observed that the testis on the side of operation retained its normal size, while the opposite one became hypertrophied. In Cases 4 and 5 of our series the testicle presented some atrophy, which must be accounted for by a slight injury to the vessels at the time of operation; a considerable portion of the organ, however, remains in each case.

The third objection is hardly worth considering, as the importance of the internal secretion is not recognized by those who make it. After epididymectomy the patient is sterile, but not impotent, while after castration he is both. Reynier objects to the conservative operations because he thinks that permanent sinuses

are often left. This is certainly not true if the operation is properly done. The sinuses which are occasionally formed quickly close.

The operation of epididymectomy is extremely simple and easy of performance, if the operator will first take the trouble to experiment on the cadaver. It amounts simply to an anatomical dissection, very little cutting being necessary, except in dividing the vasa efferentia where they enter the globus major.

The steps of the operation illustrated by Figs. 11, 12 and 13 are as follows:

1. Incision into the sac of the tunica vaginalis, just external and parallel to the epididymis.

2. Dissection of epididymis from testis proper, commencing below at globus minor and passing upward to mediastinum testis. From here one must proceed slowly and carefully so as not to injure the spermatic artery and veins, closely hugging the epididymis and separating it from the testis proper and spermatic vessels. Blunt dissection should be used when possible, cutting only when necessary. If a focus is discovered in the mediastinum it is to be excised in a wedge-shaped piece and the defect closed with catgut sutures.

3. When the globus major is free, the vas is to be isolated from the other structures of the cord upward, as far as the internal ring, where it is to be clasped on both sides of its circumference with hemostatic forceps, divided and the lumen of the proximal end cauterized with 95 per cent. carbolic acid in the end of a needle. The needle is to be worked upward in the lumen for one-half inch and the mucous membrane thoroughly cauterized.

4. When cauterization is complete the vas is ligated with chromicized catgut, one-quarter of an inch from its end, so as to prevent infectious material from passing backward through it into the tissues. This step is considered of great importance as previous to the use of the ligature it was not uncommon to have induration and occasionally suppuration develop near the stump of the vas. The tunica albuginea is to be sutured with catgut, if it has been opened.

5. The testicle is now replaced in the scrotal sac, and the external wound closed either with a buried subcutaneous suture of catgut, or interrupted sutures of silk-worm gut, leaving a small iodoform gauze drain in the lower angle for forty-eight hours.

6. After forty-eight hours the gauze drain is removed and provisional sutures, put in at the time of the operation, are tied.

REPORT OF CASES.

CASE 1.—Mr. E. J. B., aged 22 years. Occupation, factory-man. Unmarried. Admitted to Alexian Brothers Hospital, Sept. 9, 1894.

Present Illness.—Six months ago patient first noticed some "chafing of skin" on the left side of scrotum, and a varicocele on the same side, which had been present for several months, became larger and somewhat painful. Shortly afterward a small papule developed on the irritated skin and this was opened by patient. Cheesy material was discharged, and a small sinus, which would not close, was formed. There was at no time any marked swelling of testicle and patient suffered but little pain. Has had no urinary symptoms of any kind. Has lost considerably in weight (10 pounds). No cough.

Previous History.—Chorea several times in childhood. Before onset of present trouble patient worked in a shop where much heavy lifting was a part of his daily labor. No history of venereal infection. No direct injury to testicles.

Family History.—No tuberculosis in any members.

Examination of Patient.—Medium stature. Nourishment fair. Heart, lungs and abdomen negative. *Genitalia.*—Left

epididymis thickened, hard, nodular and slightly tender to compression. Testicle proper, normal. A small sinus leading down into nodular epididymis is present in left side of scrotum. Right testicle and epididymis normal.

Operation.—Sept. 10, 1894. Operator, Dr. J. B. Murphy, assisted by Dr. E. H. Lee. Incision into left tunica vaginalis and dissection of epididymis from testicle proper, leaving the spermatic vessels undisturbed. Vas severed from other structures of cord, ligated and amputated at internal ring. Testicle proper replaced in sac of tunica vaginalis and skin wound closed with silk-worm gut suture, leaving small gauze drain in lower angle. The night after operation some secondary hemorrhage took place and house surgeon applied a ligature to the bleeding vessel. After this the wound healed without further trouble, except at the upper angle, where a small sinus persisted. Sinus remained open for two years, when ligature was discharged and it closed. General health improved much after operation and he regained the flesh which he had lost. For ultimate results see notes under Case 5.

CASE 2.—Mr. M. Z., aged 22 years; occupation, watch-maker; unmarried. Admitted to Mercy Hospital December 14, 1895.

Present Illness. For four years previous to last April, when the organ was removed, patient had had repeated attacks of pain and swelling in the right testicle. Eight weeks ago the left testicle began to swell and a permanent nodular enlargement developed. This has been accompanied by considerable dull, aching pain, and some tenderness in the mass. Urination has been frequent and painful. Family history negative as regards tuberculosis.

Examination of Patient: Right testicle absent. In the left side of the scrotum is a firm nodular mass situated posteriorly, and having in front of it the testicle proper, which is apparently normal.

Operation, Dec. 16, 1895; Operator, Dr. J. B. Murphy, assisted by Dr. E. H. Lee. Incision into left tunica vaginalis; dissection of nodular epididymis from the testicle proper; ligation and amputation of the vas high up, and cauterization of its lumen with 95 per cent. carbolic acid. Testicle replaced in the scrotum and the wound closed with silk-worm gut sutures, a gauze drain being left in the lower angle. Cavity of the tunica vaginalis on the right side opened and a hollow oval ball of silver, the size and shape of a normal testicle, introduced and the wound closed. Convalescence was uneventful, and patient was discharged cured Dec. 25, 1895. In a letter received from him May 8, 1900, the following particulars as to his present state of health are given: His general health is excellent. He has gained ten pounds since the operation, now weighing 180. He has no vesical irritation, and has passed no blood or pus in the urine. There has been no return of the disease since the operation, though patient states that occasionally he has some slight pain in the testicle, which may be attributed to the silver ball in the right side. There has been no atrophy of the left testicle proper. He has had no cough, fever or sweats. He has been married for several months and states that the sexual desire is normal, there being some discharge during intercourse. No nocturnal emissions since operation.

CASE 3.—M. S. R. V., aged 30 years; married; occupation, electroplater. Admitted to Cook County Hospital, service of Dr. F. S. Hartman, Dec. 16, 1895.

Present Illness: About nine years ago right testicle was swollen for several weeks. Swelling gradually subsided, leaving a small, hard, painful nodule in the lower and posterior portion of organ, which has persisted until the present time. Frequent urination has been complained of lately, and he has had to void his urine every fifteen or twenty minutes without, however, having any pain during its passage. During the past two or three weeks he has had numerous hemorrhages from urethra.

Previous History: Patient claims he was never sick before, and positively denies any venereal infection. Family history entirely negative as regards tuberculosis.

Examination of Patient: Well-nourished man; heart, lungs and abdomen negative. Right testicle is enlarged, and a firm

nodular mass can be felt involving the lower and posterior portion of the organ. In the left testicle there is a hard nodule occupying the upper and posterior portion.

Urinalysis: Dark color, neutral reaction. Specific gravity 1018. Albumin; no sugar. Microscopic examination, red blood-cells and pus in moderate amount.

Operation, Dec. 17, 1895. Operator, Dr. J. B. Murphy, assisted by Drs. Besley and Champlin. Incision over nodular mass in upper and posterior part of left testicle; diseased tissue well exposed, caught with forceps, and dissected from body of the testicle, the latter being apparently normal. Iodoform gauze drain inserted and the wound closed with silk-worm gut sutures. Exactly similar operation performed on right side. Convalescence was uneventful and patient was discharged cured Dec. 31, 1895.

Examination of patient June 27, 1896, showed that there had been no return of the testicular disease, and the blood had disappeared from the urine. He had gained fourteen pounds since the operation, and sexual desire was same as before. About one year after operation, patient suddenly developed urinary suppression, which continued for twenty-four hours. Several days later he had a similar attack lasting sixty hours. At this time the left kidney became enlarged and soon afterward, the right. He died of the renal complication, probably tuberculosis of both kidneys, early in February, 1897. There was no recurrence of the trouble in the testicles, and the lungs were unaffected throughout. Tubercle bacilli were found in the urine toward the close of the disease. While the ultimate result in this case was bad, the success of the operation, as regards the disease in the testicles and the relief of bladder symptoms, was demonstrated, as there was no sign of local recurrence, and no return of urethral hemorrhages up to the time of his death.

CASE 4.—Mr. A. D. B., aged 38 years; occupation, driver. Admitted to Alexian Brothers' Hospital May 6, 1896. Present illness dates from three and a half or four years ago, at which time patient had what he calls "eczema of the scrotum." About two years ago urination began to be more frequent than normal, and he suffered from some burning pain at the base of the bladder toward the end of micturition. A short time after this he passed some blood and pus from the urethra. One year ago a perineal cystostomy was performed, and at the same time some operation on the testicles, the nature of which is unknown to the patient. After operation the urinary fistula remained open for three or four months, when it closed completely. Since closure of fistula he has been unable to hold his urine more than one and one-half hours, involuntary passage taking place after this time. He says that at the time of operation right testicle was discharging pus, but that soon after it the sinus closed. For the past one and one-half years left testicle has been gradually increasing in size, and has been the seat of considerable pain. At the present time he is obliged to urinate every hour at least. He often has pain at the base of the bladder and along the urethra. Several weeks ago a small ulcer developed on the glans penis, followed after about two weeks by a similar one on the prepuce. These are still present. The general health is good. Bowels constipated. Patient says he was never sick before. Family history negative as regards tuberculosis.

Examination of Patient: Both epididymi nodular and hard. Testicles proper show no signs of involvement. The inguinal glands on both sides very slightly enlarged. The prepuce presents on its inner surface a large shallow ulceration, which extends a short distance over the glans penis. Temperature on admission ranged from normal to 100.3 F.

Urinalysis on Admission: Straw-colored, cloudy, acid reaction, specific gravity 1018, albumin present in considerable quantities, no sugar. Microscopic examination showed pus cells, red blood-cells, a few granular and epithelial casts.

Operation, May 8, 1896. Patient circumcised for removal of preputial ulcer. Operation May 15, 1896. Operator, Dr. J. B. Murphy, assisted by Dr. Oswald. Incision into cavity of right tunica vaginalis, testicle and epididymis well exposed, and the latter dissected from the former, beginning below and passing upward. Vas was amputated high up and lumen cau-

terized. Testicle proper replaced in sac, and external wound closed by means of silk-worm sutures, leaving a small gauze drain in lower angle. Similar operation performed on the left side. Examination of epididymi showed both to contain typical caseous nodules. Patient was discharged from hospital June 4, 1896, the incision on the left side having closed by primary union. On the right side there was a small sinus at the lower angle of the wound, which was discharging a slight amount of purulent material. Urinalysis June 1 showed the same findings as on admission, except that the urine was clearer and contained less blood and pus. On the day of discharge from hospital a few pleuritic friction sounds were heard in the right side of the chest.

Examination of patient July 11, 1900: General health excellent; patient now weighs 150 pounds, which is more than he ever weighed before. Has no cough; appetite good; no symptoms referable to the genital organs, except some itching of the scrotum. Vesical irritation, which was such a marked symptom before the operation, disappeared almost entirely within a month or six weeks after it was performed, and has never returned in anything like the same degree. Occasionally he is obliged to urinate more frequently than normal, and usually has to get up two or three times during the night. Has no pain during urination and never passes blood. Sexual desire is the same as before onset of trouble, and the sensation attending intercourse is also the same, though he has no discharge of seminal fluid. It was neglected in the history to mention that for about one and a half years before the first operation there had been no seminal discharge during coitus.

Examination of the heart, lungs and abdomen negative. Genitalia: The right testicle proper is of normal size and consistency, and there is absolutely no sign of recurrence of the disease. The left testicle is very much atrophied, not being larger than the end of the middle finger. It is hard, but not at all tender, and there is no evidence of any recurrence of the tubercular trouble. Rectal examination shows the prostate and seminal vesicles to be free from disease.

Urinalysis July 11, 1900. Clear, yellow, acid reaction, no albumin, no sugar. Microscope showed no pus, blood or casts.

CASE 5.—(See Case 1). Mr. E. J. B., aged 24 years. Occupation, factoryman. Unmarried. Admitted to Alexian Brothers' Hospital Aug. 17, 1896.

Present Illness.—Left epididymis was removed for tubercular disease Sept. 10, 1894. Small sinus persisted in wound after operation and closed only a short time ago. Health has been good until about one month ago, when the right testicle suddenly became enlarged, tender and painful. He has lost some flesh, but has had no cough, fever or sweats. No urinary symptoms have been present, either during this or the previous attack. Previous and family histories given under Case 1.

Examination.—Man of medium stature. Nourishment fair. Heart, lungs and abdomen, negative.

Genitalia.—Cicatrix of former operation present on left side of scrotum. No recurrence of disease here, and testicle is of normal size and consistency. Right side of scrotum swollen. Right epididymis enlarged, hard, nodular, and very tender. Testicle proper not involved, so far as examination shows.

Operation.—Aug. 18, 1896. Operator, Dr. J. B. Murphy. Assistant, Dr. E. H. Lee. Epididymectomy performed—exactly similar to that done on left side. Drain removed after 36 hours. Wound healed by primary union and patient was discharged from hospital cured Sept. 1, 1896.

Examination of patient, April 7, 1900. Has gained thirty pounds since operation. Feels perfectly well. Has no cough, fever or sweats. No urinary symptoms. Sexual desire and sensation are the same as before onset of trouble, and patient says that seminal discharge is of the same quantity. Patient always supports testicles in a suspensory. If suspensory is not used, left testicle swells and becomes tender. No pain or tenderness when supported.

Examination: Both testicles present in scrotum and of normal consistency. No nodules present in either. Above left testis is a small firm band about three-quarters of an inch in length, not nodular, but slightly tender to compression. No hydrocele. Patient says the testicles are somewhat smaller

than before operation, and they apparently are slightly atrophied. Rectal examination shows in each seminal vesicle a small, very hard and painless nodule. The tubercular process has here been arrested and encapsulated. Discharge during intercourse, clear, looks like mucus; no spermatozoa.

(To be continued.)

AMERICAN MEDICAL JOURNALISM.*

CHARLES WOOD FASSETT, M.D.

ST. JOSEPH, MO.

The history of medical journalism in America is a story of progressiveness and success. After passing through many phases during the last century there has been evolved, during the past decade, a type of medical journal which is distinctly American, and I am inclined to think that it more nearly approaches the ideal than any other in the professional world. Our earliest lessons in journalism were taken from our French colleagues. The first medical journal published in the United States was called, *A Journal of the Practice of Medicine and Surgery and Pharmacy in the Military Hospital of France*, consisting principally of French translations.¹ The next to appear was the *Medical Repository*, begun in 1779, and discontinued in 1824.

The earliest types of American medical journalism were dignified and scholarly, and but few of them exhibited any "news" qualities until the middle of the fourth decade. The Addisonian type of essay seemed to prevail in these magazines, items of news and personalities being excluded. The American medical journal of to-day, however, has developed into a strong and modern type in which is reflected, not only the medical and surgical progress of the age, but the personal movements and work of the active members of the profession, and each issue contains a brief review, as it were, of the medical world for the week just passed. There are to-day in the United States 278 periodicals devoted to the interests of medicine and surgery, and allied sciences. These journals are classed as follows: medicine and surgery 145, nervous system 6, gynecology and obstetrics 5, pediatrics 3, genito-urinary and rectal diseases 2, eye, ear, nose and throat 10, homeopathic 23, physio-medical 3, eclectic 8, dental 15, drugs and therapeutics 22, X-ray 1, microscopy 2, and miscellaneous 31. The issue is divided as follows: 8 weeklies, 4 bi-weeklies, 258 monthlies, 8 quarterlies.

Subscription rates vary from 25 cents to \$5 a year.

The number of physicians in the United States is estimated at 125,000.

Two organizations of medical journalists in the United States have been prominent factors in extending the influence of the American medical press. The Association of Medical Editors, organized fifteen years ago, holds meetings annually, coincident with the meeting of the AMERICAN MEDICAL ASSOCIATION. A short business meeting is usually held in the afternoon, at which current topics are discussed, and at night the editors gather round the festal board, drink to one another's health, "talk shop"—a mingling of congenial spirits.

The American Medical Publishers' Association was organized in 1893, and holds meetings annually the day preceding that of the AMERICAN MEDICAL ASSOCIATION. At the session of this society papers are presented bearing on different phases of medical journal-

ism. Here the subscription and advertising questions are discussed, the methods of advertising agents are looked into, and reports are made concerning the various questions which arise to perplex the medical journalist during the year.

In the organization of the International Congress of the Medical Press is an opportunity for much good and unlimited power. It is high time that the duty line in medical journalism be drawn and universally recognized, when as a unit the medical press shall shut out the petty weaknesses that now impair its dignity and destroy its usefulness. The first of these is sensationalism—that bane of the newspaper press to-day—disguised, of course, in the physician's garb, but none the less insidious in character and all the more harmful in its influence.

The question of the protection of an author's original article is one which has not disturbed the American medical editor, as it is a common custom in this country, among the best classes of medical journals, to copy-right each issue, and even if this were not done, no medical editor would think of copying or abstracting an article or paper without giving due credit to the journal in which it first appeared. Professional etiquette requires this.

Our exchange system, which has been in use from time immemorial, has never been repudiated, save by one medical weekly in this country. A \$5-journal exchanges with a \$1-magazine without exacting any difference in the subscription price.

Treatment of Insanity in Lead-Workers.

In the treatment of a considerable number of cases of various forms of insanity observed in workers in lead, Robert Jones—*British Medical Journal*, Sept. 22, 1900, p. 794—employed mainly expectant measures. Milk with beef-tea and eggs, was prescribed as additional proteids to a fairly representative diet, such as is usually fixed to scale in public asylums. Proteids in solution are said to retard the soluble effects of the hydrochloric acid of the gastric juice on lead-compounds. Magnesium sulphate in the form of the compound draught of senna was given to relieve constipation. Regular and not exhausting exercise in the open air was customary. In some cases massage was employed, as well as the hot and the electric bath, the latter by passing the constant current through water at a temperature of 100 F., in an ordinary earthenware, large bath. The two terminals in the bath were broad copper plates, one at the head and the other at the foot of the bath, with a smooth piece of wood between them and the patients' body. Large doses—about 500 c.c.—of artificial serum—Hayem's formula: namely, sodium sulphate 5 gm., sodium chlorid 1 gm., mercuric chlorid .05 gm., and distilled water 200 c.c., under the skin of the abdomen—have been employed. The muscular pain, headache and vomiting were relieved, but no action on the paralysis was noted. Normal saline solution, sterilized, and warmed to the temperature of the body and in doses of from 600 to 800 c.c., subcutaneously, has also been recommended, in conjunction with bleeding to the extent of one-half of the amount of the injection. This treatment has been reported to be favorable in cases of convulsions, and the albuminuria disappears under it. It has been found that the administration of potassium iodid does not influence the rate of elimination of lead from the system, but that this is increased by warm baths and general massage. It has been contended that the administration of potassium iodid in large doses in severe cases, would be quickly followed by the development of coma and death. Electric baths have been recommended, traces of lead being found on the copper electrodes, but there is doubt whether this is derived from the tissues or from contamination of the skin with lead-compounds. The voltaic current should be employed to maintain the irritability and the nutrition of the muscles, while the nerves are recovering after peripheral neuritis. Amyl nitrite has been recommended for the relief of the cerebral symptoms due to increased arterial tension, and also an alcoholic solution of nitroglycerin, with an acidulated saline aperient. Subcutaneous injections of atropin or of morphin will effectively relax the spasm of colic, after which aperients may be administered.

* Abstract of Paper read at the International Congress of the Medical Press, Paris, France, July 27, 1900.

[We believe this is a mistake, and that the *Medical Repository* should take precedence as to time.—Ed.]

Subscription price: Five dollars per annum in advance

SATURDAY, DECEMBER 1, 1900.

SOME OF THE INDICATIONS FOR VASECTOMY.

The clinician, both medical and surgical, should ever bear in mind that the human body must be considered as a continuity of structure, removal of any part of which will not be without influence on the remainder. This fact is illustrated, on the one hand, by the assumption of vicarious function, but more especially by the development of certain constitutional phenomena such as have been recognized to follow extirpation or obliterative disease of the ovaries, the thyroid gland, the testicles, etc. These latter effects have been thought to be due to the withdrawal of a supposititious internal secretion, and the theory, while lacking in absolute demonstration, affords a convenient explanation for the results observed. The validity of this view is sustained in part by the important fact of its successful therapeutic application. The control of cretinism and myxedema by means of preparations of the thyroid gland is one of the best established truths in modern medicine.

It had long been known that removal of the testicles is followed in animals by certain changes in nutrition, and in human beings by alterations in growth and character, but it was not until some seven years ago that, from analogy with the atrophy of the fibroid uterus which follows removal of the ovaries, it was suggested that removal of the testicles might be followed by atrophy of the hyperplastic prostate gland, and the correctness of this conclusion was demonstrated first by experiments on animals and subsequently by observations on human beings. It has been shown that a similar condition can be brought about by division or obliteration of the vas deferens, and Harrison,¹ who has performed this operation more than one hundred times, presents some illustrations of its application in the treatment of prostatic hypertrophy. The cases are divided into three groups: 1, those in which the effects are known to have been good, sufficient and enduring; 2, those in which they have been good, but restricted to certain conditions; 3, those in which they are alleged to have been inadequate or negative.

In the first group are included cases of prostatic obstruction pure and simple, without any other structural complication. In these the bladder is in no sense secondarily implicated, and is capable, on removal of the obstacle in front of it, of holding and expelling its contents. With shrinkage of the enlarged prostate the func-

tion of micturition is speedily restored. The second group includes cases in which structural changes in the bladder have supervened on prostatic obstruction, or in which catheter-life or the necessity for it has been developed in greater or lesser degree. In these cases the prostate may be rendered, by vasectomy or similar operation, incapable of further obstruction, although the bladder may not regain its expulsive power. Thus, the reduction in the size of the prostate may render catheterization more easy, or be attended with disappearance of existing epididymitis, or facilitate the performance of litholapaxy or the control of hemorrhage resulting from difficult catheterization in connection with prostatic enlargement. Inquiry among cases in which the results are alleged to have been or seem to have been inadequate or negative, disclosed that at least symptomatic improvement had really taken place.

From his experience with litholapaxy, as illustrated in a recent series of one hundred cases, Harrison is led to believe that vasectomy has proved an important aid in preventing the recurrence of stone after operation when complicated by enlarged prostate, probably by providing a free and more independent exit from the bladder, as well as by diminishing the large amount of tenacious mucus that the enlarged prostate both provokes and helps to supply, and which lessens materially as the gland shrinks. It is, finally, pointed out that in contrast with the serious results that follow total removal of both testicles, double vasectomy properly performed is unattended with any untoward results whatever.

COOK COUNTY HOSPITAL AND POLITICS.

The Cook County Hospital, of Chicago, occupies a unique position among institutions of a similar character in that its various medical, surgical and other services are more or less equally apportioned among regular physicians, so-called homeopaths and eclectics, the basis of apportionment being the supposed relative number of each of these species of medical men in Cook County, which includes Chicago. The hospital has three distinct and separate attending staffs, regular, homeopathic and eclectic. The institution has been managed along strict political lines. The various "jobs" in the hospital constitute a goodly share of available *quid pro quo* of the political faction in power. The anomalous division of the services is the outgrowth of this pernicious system. The management is in the hands of the Board of Commissioners of Cook County; this board is an unwieldy body of fifteen, all of whom are elected by popular vote every two years. The standard of the board varies from time to time. Usually it is none too high, as might be expected, and the chief object of the average commissioner, nearly always wholly untrained for his work, is to feather his own nest rather than to place the charitable institutions of the county on a sound basis of progressive, healthy development. The recurring biennial change is accompanied always by a protracted period of

1. *Lancet*, July 14, 1900, p. 96.

unrest and strife that is detrimental to the best interests of such institutions. The frequent changes in the personnel of the administrative and medical staffs are inconsistent with healthy growth.

During the last six years the Cook County Hospital has been blessed in a singular manner by having at its head as warden, whose administrative powers are almost absolute, a man who from the medical point of view is entitled to great credit. Some effort at systematic organization of the heterogeneous staffs of the hospital has been made. The resources of the hospital have been improved greatly, and its vast material has been freely utilized for purposes of medical education. Public clinics have been given regularly by representative men, and bedside instruction again introduced on a large scale. The medical profession and the medical students owe the warden a debt of gratitude for his enlightened policy. Whether he is to continue as warden under the incoming board of commissioners is as yet wholly uncertain. That any better man could be appointed for this important position is doubtful.

Medical men should not be slow in giving a man, who, though non-medical, has shown so clearly that he has the best interests of the hospital at heart, their unqualified endorsement regardless of personal political opinion. The training of six arduous years of intelligent effort should count for something. The Cook County Hospital is an important factor in making Chicago the center for medical education it has become. The great economic advantages to the citizens from the annual influx of thousands of medical students, undergraduate and postgraduate, are furthered best by continuing the present policy of management of this hospital. That the patients of the hospital derive added benefit from the present system is self-evident; never before has there been so little complaint and such dearth of scandal.

A permanent, self-perpetuating, scientific attending staff, free from political domination, is essential for the proper development of medicine in this as in other public hospitals. At the present time there is no concerted action toward raising the scientific standard of the work of this hospital. The staff lacks the incentive. The conditions are too uncertain. There is no *esprit de corps* in the staff on account of its "mixed" composition, and it lacks all elements of proper organization. Much could be done by placing the staff under civil-service rule, imperfect and unsatisfactory as it is at the present time, but constituting at all events a beginning in the right direction, and an intelligent president of the Board of Commissioners would probably not hesitate in doing so, provided the medical profession as a body expressed itself in favor of this change. There is good opportunity now for the local profession to join in a determined effort to free the medical services of this large hospital from the ban of practical politics. Success would raise the standard of the profession of medicine in Chicago.

Can the members of the medical profession of Chicago unite for such a purpose? Will they?

THE REGISTRATION OF TUBERCULOSIS.

The Philadelphia County Medical Society, as noticed elsewhere in this issue, after listening recently to an able presentation of the subject by Dr. Hermann M. Biggs, of New York City, took a distinct step forward in recommending to the Bureau of Health of Philadelphia the placing of tuberculosis on the list of notifiable diseases and the adoption of measures looking to the suppression of the disease. Dr. Biggs demonstrated the good that has already been accomplished by registration as practiced in New York City during the past four years, and stated that the measure, while at first received with some opposition, has been gradually growing in favor and is being more generally observed. Indeed, the objections raised against it have been shown to be largely hypothetical and to have no existence in actual practice. The information given is received in confidence, and the Health Department exercises an intelligent discretion, in harmony with the wishes of the attending physician, as to what steps in education, disinfection and the like, if any, it shall take. There is no interference with personal liberty, no social ostracism, no espionage of the unfortunate victims of a disease in itself sufficiently harassing, but only a healthful watchfulness calculated to conserve the welfare of the many as opposed to the possible unbridled license of the few.

The legitimacy of registration for tuberculosis is based on the soundest and most logical hygienic grounds. It is by no one seriously denied that tuberculosis is dependent on the invasion of a susceptible individual by the tubercle bacillus—that there can be no tuberculosis without the bacillus, and that the disease is almost exclusively transmissible through matter containing the micro-organism, and, as the lungs are so generally involved, most commonly through the expectoration. The proper care of the expectorated matter, therefore, would alone go a great way in reducing the morbidity to, and the mortality from, tuberculosis.

To bring about such a result, however, will require the education of the community in the methods of disposal of sputum and of general thorough disinfection. This can not be done, of course, unless the location of the victims of the disease is known, and the large number of these, unfortunately, belong to the lower classes, unable or unwilling, by reason of poverty, ignorance, vice or indifference, to learn and to carry out the necessary prophylactic measures. At this point the Health Department steps in and meets the needs.

It has been conclusively shown that in every community foci of tuberculosis exist, which it will ever be impossible to eradicate unless some central body is informed of their existence and is clothed with authority to enforce the necessary measures to bring about the desired result. Of what these measures shall consist must vary with the individual case, and it is essential that any policy that shall be adopted should be executed with intelligent and delicate discretion. When the patient can and will, under direction of his physician, observe

the necessary hygienic rules, he will require no aid or suggestion from the Health Department. Should he for any reason fail in this direction, however, it will then become the duty of the Department to inform him by pamphlet or otherwise of the danger to which he exposes himself, as well as others, by neglect of the hygienic regulations in which he is to be instructed and which he must carry out or have carried out for him; and, especially in case of death or removal, must the premises previously occupied by the tuberculous patient be rigorously disinfected before another occupant takes possession. What applies to the private dwelling applies in even more emphatic degree to the hotel and the apartment-house, and the ordinances preventing indiscriminate expectoration on the street, in cars, carriages, steamboats, and other conveyances, and in all public or semi-public places, must be rigorously enforced.

The experimental stage of registration for tuberculosis is past. The practice has proved successful wherever tried, and its general application is bound to work an immense reduction in the prevalence and the fatality of the disease. It is to be hoped that the recommendation of the Philadelphia County Medical Society will be adopted by the Bureau of Health, and that the influence of its example will inspire other communities to institute like measures of prophylaxis.

BOGUS FOREIGN DIPLOMAS.

In a communication in this issue, Dr. A. J. D. Hughes, consul at Coburg, Germany, calls attention to certain changes in the granting of the degree of Doctor of Medicine in that country. These changes are of interest to but few in this country, but the last paragraph of the consul's letter, containing his views regarding the acceptance of foreign degrees by our state registration boards, is worthy of notice. Too often the apparently genuine foreign diploma or certificate is a fraudulent one, but is accepted even if there is a suspicion of its fraudulency because of the supposed difficulty or imaginary expense of having it verified. And yet an American consul is stationed at all the important cities to attend to just such duties as these cases require.

At its recent annual meeting one of our state societies was asked to appropriate a sum of money to investigate the genuineness of a certificate which was alleged to have been issued by a European university, and on which a pretended physician had obtained a license to practice. The holder had presented it to the licensing board, which, while suspicious that the applicant was a fraud and the certificate a bogus one, accepted both as genuine because there was no proof of the opposite and also, we presume, because they imagined that it would be too expensive to get the true facts in the case. After-developments making more evident the probability of fraud having been committed, the state society was asked to take up the matter, but the society not feeling justified in appropriating so much money as was supposed to be necessary, the matter was dropped. It did not seem to

occur to any of the parties that the American consul in the city in which the university that was alleged to have granted the certificate was located could have gotten all the facts with comparatively no expense.

The acceptance in our country of foreign diplomas is done too carelessly by many of the states. A well-educated foreign physician is welcome, but there is no need to import the other kind. The former ought not to object if he is put to some inconvenience and delay in getting his license to practice, neither will he object if he knows that it is for the purpose of bettering the profession of which he is a member.

Consul Hughes makes a suggestion that it would be well for our state boards of medical registration to follow, viz., to require a consular certification of foreign medical diplomas presented to them as evidence of qualification. They might even go further and demand an official government endorsement from the country from which they came, but a consular certificate that is not a mere formality should certainly be demanded. There are, no doubt, a large number of fraudulent foreign qualifications utilized in this country. Some of them have been from time to time brought to light, but we fear that they are too often accepted at their face value, and thus let in pretentious impostors to prey on the public. The proper application of the measures suggested, if our foreign consuls did their full duty and always made sure of the character of the documents they endorsed, would be a valuable protection to the afflicted American public and a useful measure of defense from foreign quacks.

THE DIAGNOSTIC SIGNIFICANCE OF ACID-PROOF (TUBERCULOID) BACILLI IN BUTTER AND ELSEWHERE.

Acid-proof and alcohol-proof bacilli, resembling *B. tuberculosis*, have been found in butter by Rabinowitch, Herbert, Korn and others; in grass, barn-dust and dung by Moeller; in gangrene of the lung by Rabinowitch; in the crypts of the tonsils by Marzinowsky; and in the sputum by a number of observers; also in intestinal discharges of nurslings. These organisms resemble *B. tuberculosis* tinctorially, and to some extent morphologically, but not in cultural characteristics. The lesions they produce in animals may be distinguishable only with difficulty from true tuberculosis by naked-eye examination. Georg Mayer has emphasized that the tuberculiform nodules that result from the injections of butter are due to the acid-proof bacilli and the butter acting conjointly. But the acid-proof bacillus recently isolated from butter by Otto Korn produces a tuberculiform disease in guinea-pigs and rabbits. The acid-proof bacilli consequently acquire diagnostic significance. It is no longer wholly and always sufficient for a diagnosis of tuberculosis and tubercle bacilli to obtain tubercles in the animals inoculated. The nodules must be studied histologically and cultures should be made. This holds true, among other things, with regard to the study of milk. From what we know about butter and about barn-dust, milk would seem to

offer a favorable place for the growth of acid-proof bacilli other than *B. tuberculosis*. Acid-proof tuberculoïd bacilli are nicely distributed in nature. The necessity of care in interpreting the results of experiments now much in vogue with milk is shown by Klein's work. Klein examined 100 samples of milk for tubercle bacilli by means of injections into guinea-pigs, and obtained eight instances of "pseudo-tuberculosis," and seven of genuine tuberculosis. Klein also shows that the pathogenic powers of *B. tuberculosis* are increased in milk and that young bacilli may be easily decolorized.

BACTERIOLOGIC EXAMINATION OF AIR AND WATER IN THE CENTER OF THE ATLANTIC OCEAN.

Minervini¹ examined the number of bacteria in the air and in the water of the middle of the Atlantic Ocean. As expected, the air was found much purer than that of the continent, the number of bacteria being relatively smaller. Not rarely the air was free from bacteria. The bacterial flora was found to contain fewer varieties than are usually present in the air inland; in none of the experiments were any of the usual pathologic forms discovered; and, commonly, fungi are more numerous than bacteria. The number of bacteria in the air of the ocean varies with the atmospheric conditions and it becomes smaller after rains. The rain-water is also relatively poorer in bacteria, the fungi predominating. Out in the ocean, the sea-water contains less bacteria than near the shore, but the condition is not materially different from that usually observed a few miles from land. In sea-water bacteria are more numerous than fungi; relatively few species are found, the number of vibrios being greater than that of other forms.

THE SURGICAL TREATMENT OF PLAGUE.

In our last issue² there was published a brief note on the surgical treatment of the plague at Rio de Janeiro, by Professor Terni, as reported by Acting Assistant-Surgeon Havelburg, of the Marine-Hospital service. The theory advanced in favor of this method is that at a certain stage of the disease it is arrested in the lymphatic glands, which form a rational protective rampart against its infection of the blood. It is only in these glands that it settles, develops and produces its toxin, and if the reactive inflammation produces suppuration so as to check the development of germs, the disease is localized, otherwise the toxins produced, together with the corpuscular substance of the bacilli themselves, will enter the circulation and the infection become general. With this view of the progress of the disease the suggestion of a surgical therapeutics was a natural one and Dr. Havelburg reports in the latest Public Health Report that experiments in this direction at the Rio de Janeiro isolation hospital have impressed the local physicians favorably. They believe that the early extirpation of the infected glands have been followed in their observations by improvement, the temperature curve descends, which they interpret as the result of the removal of the focus of toxic infection. Microscopic examination of the removed glands also favors

this view by showing that the disease proceeds in them centrifugally. The operation is a simple one, as the glands are superficial and easily enucleated. Of course, in the pneumonic or interstitial types of the disorder this method is impracticable, since the deeper glands are inaccessible, but in the ordinary early bubonic form with the implication of only the inguinal, axillary or cervical lymphatics it seems to be hopeful. At least that is the impression of the Brazilian physicians, who think they have had better results after this surgical procedure than was formerly the rule.

GONORRHEAL ARTHRITIS.

Although gonorrhea is a local infectious disease, an increasing experience has taught that it may be attended with serious and even disastrous extension and metastasis. In women, metritis, salpingitis and peritonitis are not uncommon complications, and in both men and women cystitis, pyelitis and nephritis may readily result. There may be also invasion of one or more joints; and gonorrheal conjunctivitis, resulting from conveyance of infectious pus, is with reason to be greatly feared. More recently endocarditis, myocarditis, myelitis, pleuritis and iritis have been reported as complications of gonorrhea. In many instances gonococci have been discovered in the secondary lesions. The bodies of dead gonococci have been shown to contain an active poison, to which some of the bad effects of gonorrheal infection are attributable. Rubinstein,¹ in a recent communication, discusses the articular complications of gonorrhea, of which four varieties have been described, namely, hydrops, serofibrinous arthritis, purulent arthritis, and phlegmonous arthritis. The last is by far the most dangerous, and its treatment will require incision and irrigation with 1 to 1000 solution of mercuric chlorid, and tamponade. Gonorrheal hydrops is a comparatively benign condition. It will require rest, counter-irritation with iodine and cantharides, applications of guaiacol-vasogen, and of creosote-vasogen. If the effusion is considerable, puncture should be practiced. An injection of a 15 per cent. solution of carbolic acid may be made. The same treatment may be directed against serofibrinous arthritis, that is, rest, immobilization, elevation, splints, plaster-of-paris, an ice-bag, extension, and repeated applications of tincture of iodine. If the pus ruptures into adjacent structures incision should be practiced, with drainage and possibly resection. Subsequently active and passive movement may be undertaken and when pain has disappeared massage and warm baths. Dry heat also may be employed, even in the acute stage. Artificial stasis may be induced, and an absorbent dressing applied, to which alcohol can be constantly added, and which is covered by some impermeable material.

INTESTINAL SAND OR GRAVEL.

The intestinal tract, like the urinary and the biliary, may be the seat of either calculi or sand or gravel, whose expulsion may be attended with great pain, and this may lead to examination of the stools and the detection of the foreign matter. Coproliths are designated true or false, accordingly as they are constituted of inspissated fecal matter or of earthy precipitate. The occurrence of in-

1. *Zeitschr. f. Hyg. u. Infektionskr.*, 1900, xxxiv, 166-194.

2. P. 1357.

1. *Berliner Klin. Wochenschr.*, 1900, No. 37, p. 822.

testinal sand would seem to be exceedingly rare, inasmuch as there are but few references to the subject in the literature, and Eichhorst,¹ in the course of a large clinical and pathological experience, has encountered but two cases. Both of these occurred in neurotic women exposed to emotional strain, who were habitually constipated and were from time to time seized with attacks of severe abdominal pain in the course of the descending colon, attended with the discharge from the intestines of shreds or casts of membrane, which on disintegration precipitated a sandy substance of a finely granular appearance, and from a grayish-yellow to a light-brown color. On microscopic examination the granules were found to be variable in size and spheroidal in shape, with sharp processes. When shaken in a test-tube, they yielded the same sensation and sound as sand. They proved to be as hard as stone, and they could be crushed only with considerable force. They were insoluble in water, alcohol or ether, but they became swollen and gave off gas-bubbles when exposed to the action of mineral acids. They were thus shown to be composed of a mineral and of an organic portion, the former consisting of calcium carbonate, and the latter of a mucoid or albuminoid substance, and of fat. All of the granules contained bacteria, principally resembling the bacterium coli, and some also micrococci. Some contained hemoglobin. Intestinal sand is to be distinguished from biliary sand, from urinary, and from the indigestible remains of food or foreign bodies in the intestinal contents. The association of the disorder with membranous enteritis suggests its dependence on innervation disturbances and changes in the intestinal secretion, together with inflammatory alterations in which bacteria may take part. The affection is rather obstinate and its treatment includes regulation of the diet, together with massage of the abdomen, irrigation of the bowel with physiologic saline solution, and the administration of an aperient water.

A THERAPEUTIC PARADOX.

Medicine, like other departments of human activity, is full of curious contradictions which cause the thoughtful physician always to be chary of dogmatizing. Thus, the eating of indigestible food frequently at first produces constipation, but a little later diarrhea. It is customary to say that the preliminary constipation is due to irritation of the intestines, while the diarrhea is its secondary effect; yet we know that some irritating matters, when administered, promptly cause a diarrhea without any previous constipation. From observation of these apparently antipodal phenomena, and especially from our methods of their treatment, has arisen an analogous contradiction in therapeutics. Thus, in the case of an individual who habitually overeats or who eats improper food, there is usually found during the greater part of the time constipation. The even course of the constipation, however, is interrupted at intervals by sharp attacks of diarrhea, for which the physician is frequently asked to prescribe. As in most of these cases, bacterial infection of the retained intestinal contents is known to be a factor in the production of the succeeding diarrhea, it is now customary to administer an antiseptic,

of which there are many good ones. The action of one of them is very interesting in this respect, although the same thing is true of others of the group. Bismuth salicylate is most efficient in combating gastric and intestinal infection, and in soothing the irritated mucous membrane of the alimentary canal. This drug thus relieves the diarrhea quite promptly, but a number of physicians and patients have observed that, if its use is persisted in it tends also to ameliorate the constipation. Of course, it does this through its antiseptic action in preventing the formation of bacterial products, which primarily paralyze the bowel and cause the constipation. While this apparently paradoxical action of bismuth salicylate and other similar internal antiseptics at first glance appears to be merely one of the curiosities of medicine, it really is a practical fact in therapeutics well worth the careful attention of every physician who is not already aware of it. Many persons who suffer from constipation become discouraged with the difficulty of finding permanent relief and, by force of circumstances, drift into the "physic habit." They rarely consult their physicians, except for a severe intercurrent diarrhea. Then arises the opportunity for the physician to administer a remedy that is at once soothing and antiseptic, the patient being encouraged to continue its use after the diarrhea has ceased. The result, in many instances, will be at least a partial relief of the chronic constipation.

Medical News.

CALIFORNIA.

THE SHASTA COUNTY HOSPITAL at Redding was formally accepted by the board of supervisors, November 13. It will be thoroughly equipped and will be ready to receive patients about December.

THE OAKLAND COLLEGE OF PHYSICIANS AND SURGEONS, the incorporation of which was noted in THE JOURNAL, November 3, has completed its organization and elected the following officers and faculty: Dr. Frank L. Adams, professor of clinical surgery and president; Dr. Carl R. Krone, professor of pathology and secretary; Dr. Joseph S. Eastman, Berkeley, professor of the principles and practice of medicine and president of the faculty; Dr. Dennis D. Crowley, professor of principles and practice of surgery and clinical surgery; Dr. Hayward G. Thomas, professor of ophthalmology and otology; Dr. Samuel H. Buteau, professor of gynecology; Dr. W. F. B. Wakefield, professor of clinical gynecology; Dr. Robert T. Stratton, professor of nervous diseases and cerebral surgery and registrar; Dr. Edward N. Ewer, professor of obstetrics; Dr. William S. Porter, professor of surgical anatomy; Dr. Joseph L. Milton, professor of anatomy, and Dr. Oliver D. Hamlin, professor of visceral anatomy.

DISTRICT OF COLUMBIA.

DR. JOSEPH BAUDOT, charged with practicing medicine without registration in Washington, pleaded not guilty and was released on bail.

THE BOARD OF EDUCATION of Washington has recommended that eleven medical inspectors of schools be appointed, one for each school division, at a salary of \$500 per annum, and has instructed a committee to urge this recommendation on Congress.

THE ANNUAL REPORT of the Government Hospital for the Insane, Washington, shows 2070 patients in the hospital, an increase of 135. Of the inmates, 958 were from the army, navy and marine-hospital service, and during the past year 256 were received from these branches of the service.

GEORGIA.

THE GEORGIA LEGISLATURE has been memorialized by the Woman's Suffrage Association to appoint women on the staff of physicians at the State Sanatorium at Milledgeville.

1. Deutsches Archiv f. klin. Medizin, B. lxxviii, 1 u. 2, II., p. 1.

DR. GEORGE H. NOBLE, Atlanta, has been sued by a patient on whom he operated, for sewing up "a piece of surgical gauze over a foot long" in her body. She claimed damage to the extent of \$10,000. This "piece of rag" she avers, caused her much pain and suffering until it was removed. The jury rendered a verdict for the defendant.

REPRESENTATIVE SYMONS, of Glenn County, introduced a bill into the house of representatives which provides "that the State Medical Society shall choose from its members by ballot four members and the governor of the state shall appoint five other persons, one of whom shall be a sanitary engineer, and they shall constitute the Board of Health of the State of Georgia."

ILLINOIS.

THE SANITARY OFFICER of Canton reported 8 cases of scarlet fever on November 20.

THE BIENNIAL REPORT of the Illinois Western Hospital for the Insane at Watertown, shows that the capacity of the institution has increased from 360 to 600, that new buildings have been erected, that there have been no contagious diseases and that \$200,000 is needed for the ensuing year.

Chicago.

THE HEALTH DEPARTMENT warns against influenza. The bacillus is being found in increasing numbers, and 4 deaths were reported from the disease last week.

DR. GEORGE S. PHILLIPS, who was held by a coroner's jury in connection with the death of a woman patient, has been freed, as the grand jury found no evidence on which to indict.

THE CHICAGO MEDICAL SOCIETY and Physicians' Club have adopted resolutions favoring the re-appointment of Dr. James A. Egan, Springfield, as secretary of the State Board of Health.

TYPHOID FEVER continues below the average, and the increase in the death-rate is only the usual autumnal increase. Nearly 19 per cent. of the fatal cases were contracted outside of Chicago.

DR. N. SENN will give a course of lectures on "Military Surgery," at the University of Chicago, beginning next fall. He has been announced as professorial lecturer on Military Surgery at the University.

DR. W. D. CHRISTOPHER, who has done so much for the physical well-being of the school-children of Chicago, has resigned from the Board of Education on the ground of urgent professional duties.

THE DEATHS for the week ended November 24 are 33 in excess of those of the previous week, and the increase is due to exposure and excitement, with a disproportionate death total among the aged—92 out of 448 deaths being of individuals more than 60 years of age.

CHICAGO'S MORTALITY for the week ended November 24 was 448, or at the rate of 13.75 per 1000 per annum. Consumption caused 53 deaths; pneumonia, 54; bronchitis, 18; heart disease, 42; diphtheria, 23; typhoid fever, 10; scarlet fever, 2; suicide, 12 and violence, 20.

WESLEY HOSPITAL has received a donation of \$25,000 from Thomas Kent, toward its building fund. This brings the total of the fund to \$185,000. The other chief contributors are William Deering, \$50,000; H. P. Taylor, \$40,000; Physicians' Fund, \$30,000; G. F. Swift, \$10,000, and N. W. Harris, M. H. Wilson and Dr. R. D. Sheppard, each \$5,000.

DR. CHRISTIAN FENGER has donated to the library of Rush Medical College a collection of books which represents the German surgical literature of the last fifty years. This collection includes the library of Professor Luecke, of Strassburg, and several thousand inaugural dissertations collected by Thiersch. Among the books are many which are rare and can not be duplicated, such as "Lebert's Atlas."

INDIANA.

THERE WERE 2933 deaths in Indiana during October, corresponding to a death-rate of 13.7 per 1000 per annum.

MUNCIE now has about 500 cases of measles, according to the report of Dr. Hugh A. Coving, county health officer.

AN ATTEMPT was made November 20, to assassinate Dr. Peter Drayer, Hartford City, late president of the Indiana State Medical Society. As he was returning home, late in the evening, two men, hidden in an alley, shot at him and fled.

KENTUCKY.

COMPULSORY VACCINATION has been ordered by the Ashland Board of Health, which has now under discussion the establishment of quarantine against Russell and Collettsburg.

DR. ROBERT WINX, Winchester, formerly acting-assistant surgeon, has passed his examination for the medical depart-

ment of the army, and has been ordered to report for duty at Fort Riley, Kas.

MARYLAND.

Baltimore.

AT THE annual banquet of the Hebrew Benevolent Society on November 21, \$10,180 was subscribed for charity.

DR. C. IRWIN HILL, son of Dr. Charles G. Hill, the attending physician to Mt. Hope Retreat, has returned from Berlin, where he has been attending a special course of lectures. Dr. Dr. H., Jr., is assistant-surgeon of the Fourth Maryland Regiment and is connected with the staff of the Maryland General Hospital.

THE MORTALITY for the week ending November 24 was 195, being a mortality for the whites of 15.83 and for the colored of 36 per 1000. There were 3 deaths from typhoid fever, 2 from scarlet fever, 7 from diphtheria, 24 from tuberculosis, 8 from cancer, 19 from pneumonia, 4 from bronchopneumonia, and 8 from Bright's disease; 104 births were reported.

AT THE meeting of the Johns Hopkins Medical Society held November 5, Dr. Louis Hamburger spoke on the diagnosis of certain tumors of the bone from the presence of a peculiar proteid in the urine. The test was that of Bence-Jones, recently noted in THE JOURNAL. By means of it alone he had been able to make the diagnosis of bone myeloma, and he also exhibited a negro woman, about 55 years old, with tender soft tumors on each clavicle, on the occiput and on the right thigh-bone in which the test was present. His observations will appear in the *Bulletin* shortly. Dr. Welch said he met with this test at his laboratory in New York, and Dr. Osler said he also had met with it, but neither recognized its significance.

AT THE meeting of the same society, November 19, Dr. Arthur Dare, of Philadelphia, exhibited a new hemoglobinometer. It consists of two plates or layers in close proximity, between which the drop of blood drawn from the finger is allowed to permeate, when by means of a suitable device the quality of the blood as to its coloring matter can be readily determined. The examination can be made in a few minutes and the instrument is said to be very accurate. It costs \$15.

MASSACHUSETTS.

DR. ARTHUR G. GRIFFIN has been elected a member of the staff of the Malden Hospital, vice Dr. J. Langdon Sullivan, deceased.

DR. JOHN F. COUCH, who is obliged to leave his home in Somerville and go South, on account of poor health, was given a banquet on November 17, by his professional and lay friends in Somerville.

LYNN PHYSICIANS are alleged to be up in arms against the new rule of the local board of health, which requires two negative examinations by the city bacteriologist before fumigation will be made and quarantine removed.

THE BOSTON CITY HOSPITAL had 8457 patients, 7071 discharges and 929 deaths in the last fiscal year. In the infectious department, 3045 were treated, and in the out-patient department, 26, 288. The expenditures during the year were \$407,505. The maximum number of patients at any one time was 533, and the minimum, 363.

MICHIGAN.

THE STATE PRISON at Jackson has 22 cases of typhoid fever under treatment.

KALAMAZOO will have a new hospital in a short time. An association has been formed with a capital stock of \$60,000 by Drs. Harris B. Osborne, Rush McNair, Edwin H. VanDeusen, Oliver A. La Crone, and others.

DR. J. W. BARNES, Detroit, a diplomate of the Independent Medical College, Chicago, was fined \$80, with the alternative of 90 days' imprisonment, November 20, for practicing medicine without a license. This case was the first one tried.

LUDINGTON PHYSICIANS have very properly combined and refused to accept the position of health-officer at the salary of \$75 per annum offered by the common council. Their action has compelled the council to raise the salary to \$300 per annum.

DR. B. D. HARRISON, secretary of the State Board of Examination and Registration, was in Detroit last week conferring with Drs. Bell and Lodge, the local members, and with the prosecuting attorney. Since the law went into effect the board has had 6000 applications for registration; of these about 2000 have been rejected, of which at least 75 per cent. have left the state, the greater part supposedly for Texas.

MINNESOTA.

DR. NELLIE S. SHELFAN, Minneapolis, has been commissioned by the Presbyterian Board of Home Missions as its first woman medical missionary in Puerto Rico.

ST. PAUL had 111 deaths in October, an annual death-rate of 8.07 per 1000. Tuberculosis caused 12 deaths; typhoid fever and pneumonia each 7; violence, 14, and cancer 5.

A "MESSAGE ARTIST" of Minneapolis, who was charged with practicing medicine unlicensed, was found not guilty by a jury, November 20, because it could not be proved that he received pay for giving medicine which it was admitted he practiced at the "earnest solicitation of the patient."

MISSOURI.

THE CASE of the Government against Dr. I. N. Love, who was indicted for sending certain matter through the mails, the alleged impropriety being that he published in the *Medical Mirror* a poem by Dr. C. A. L. Reed, Cincinnati, entitled "The Dying Speech of Meamoun," was dismissed by the district attorney, November 20, at the instance of the Attorney-General of the United States.

THE ST. LOUIS MEDICAL SOCIETY has decided to hold its meetings at the Odeon, corner of Grand and Finney Avenues, abandoning quarters at the St. Louis Board of Education building, with which it has been associated almost since its beginning. The new quarters are at Thirty-sixth street, and consequently will be much more convenient for the majority of the members. It is believed that this will tend to increase the attendance largely and the new quarters are in every way suitable.

FOLLOWING comparatively closely on the consummation of the union of the Missouri Medical College and the St. Louis Medical College, comes the preliminary announcement of the consolidation of the Beaumont Hospital College and the Marion Sims College of Medicine. This will not become effective until May 1, 1901. The faculties of the two colleges will be merged, giving the new college a very strong faculty indeed. The clinical facilities afforded by each college will then be at the service of the students in the new college, affording a great abundance of clinical material. The governing faculty has not been entirely decided on, but it is believed that the members of both faculties will be needed and that the instructors will be continued in their respective fields of work. This move recommends itself strongly to the general profession of the city, and will serve to greatly strengthen St. Louis as a medical center.

NEBRASKA.

A STUDENT of Omaha Medical College was seriously injured in a row between medical and dental students, November 6, and injuries may prove fatal.

DR. J. P. LORD, professor of surgery in Creighton Medical College, Omaha, expects to leave immediately after the holidays, for Europe, where he will spend several months, going first to Naples.

MORE THAN 100 cases of smallpox are said to exist in and around Decatur, Onawa, Iowa, on the other side of the Missouri river, has quarantined against Decatur in consequence.

AN OSTEOPATH of Broken Bow, was fined \$50 for practicing medicine without a license, but has appealed his case.

NEW JERSEY.

DR. ANDREW F. McBRIDE was re-elected president of the Paterson Board of Health, November 13, and Dr. Bryan C. Magennis, health officer.

DR. E. L. B. GODFREY, secretary of the State Board of Examiners has asked THE JOURNAL to state the other side of the case of Dr. George B. Fletcher, Atlantic City. By a typographical error, Dr. Fletcher was named as a graduate of "Harvard" instead of Howard University. Dr. Godfrey states that Dr. Fletcher has appeared before the board for examination on four different occasions, and was rejected each time, viz., July 1892, October 1892, April 1893 and October 1900, because of failure to obtain the total average percentage necessary to secure a license. The statement that "the charges against him are inspired by spite and jealousy" is without foundation. During the greater part of the interval between his rejection in 1892 and 1900, Dr. Fletcher has practiced medicine at Atlantic City, N. J., as stated under oath in his application for examination, without a license from the board and in violation of the medical law of the state, in consequence of which, his case has been referred to the legally constituted authorities of Atlantic City for their consideration and action.

NEW YORK.

DR. THOMAS A. KILLIP, Rochester, has been appointed co-ordinator of Monroe County to succeed Dr. Wallace L. Sibley, deceased.

DR. ALBERT S. ZABRISKIE, Suffern, was given a reception November 8, at the residence of Mr. William W. Snow, 1111-

burn, by many of his friends, among whom he had done faithful practice for 45 years.

FOR MANY MONTHS past there has been a sharp contest in Utica for the control of the health board. Taking advantage of the temporary absence of the mayor, the acting-mayor appointed a new health board, and the new members were immediately sworn in. This action is supposed to be preliminary to securing a garbage-removal contract.

New York City.

A NEW HOSPITAL is to be erected by the New York Department of Charities on Lenox avenue, near 136th street.

THE NEW SITE for St. Francis' Hospital is a plot of 32 lots on Brock avenue, extending from 142d street to 143d street.

THE GERMAN HOSPITAL is in a precarious financial condition, owing to the demands made on it by the poor and the lack of support from the wealthy. Its capital has diminished nearly \$18,000 since January 1, and the trustees have issued an earnest appeal for assistance.

THE new electric automobile ambulances of the Roosevelt and Presbyterian Hospitals took advantage of a late trip from Bellevue Hospital to have a speed contest. Both vehicles covered the distance, about three miles, in thirteen minutes.

THE CLASS of 1890 of the College of Physicians, New York, celebrated its decennial anniversary, November 15, by a dinner at the New York Athletic Club. There were 49 members present. Dr. H. Beattie Brown acted as toastmaster, and the following officers were re-elected: Dr. James F. McKernon, chairman; Dr. A. Ernest Gallant, secretary, and Dr. William Whitehead Gilfillan, treasurer.

THE PHYSICIANS of Kings County Hospital were surprised to discover on November 22, a case of smallpox in the hospital. The health department promptly removed the patient. Eleven physicians at once began the task of vaccinating the 2500 inmates, and completed their task in forty-eight hours.

A DRESSMAKER has sued Dr. Morris Manges and Dr. Julius Rosenberg to recover \$60,000 damages, alleging that on May 13, 1897, they gave her chloroform and operated for the removal of a tumor against her wishes and protests. The defendants have entered a general denial, contending that the operation was necessary, and that the plaintiff consented to it.

ALTHOUGH the Gouverneur Hospital continues to be little more than a death-trap, the many appeals to the authorities to persuade them to open and make use of the new hospital building built in the previous administration seem to fall on deaf ears. They have now devised a new pretext for delay, and inform the long-suffering public that the law compels them to use prison-made furniture, and the latter is not yet forthcoming. In this connection, Dr. Albert T. Weston makes the very sensible and practical suggestion that the new building be opened and fitted up temporarily with the furniture now in use in the old building.

THE RIGHT of hospital physicians and attendants to vote has just been decided by three test cases from Bellevue Hospital. Dr. Albert Sellenings, two trained nurses and two hired helpers at this hospital were held by Magistrate Deuel on the charge of illegal registration, having given their residence as Bellevue Hospital. Justice Andrews, in the Supreme Court, subsequently sustained the writs of habeas corpus, and in his decision says: "I am at a loss to understand how either of these classes of persons is disqualified from voting by reason of the provision of the Constitution found in Article II. The term 'kept' as used in the provision of the Constitution evidently refers to paupers, patients and other persons who are maintained at the expense of the public. It can not be truthfully said that the physicians, hired helpers, or pupil nurses are supported by the public. The physicians render most valuable services to the patients in the hospital and are allowed to lodge and eat there, not as a matter of charity, but as a matter of convenience and almost of necessity, owing to the nature of the duties which they are at all times called on to perform." This decision sustains the right to vote of 143 persons in Bellevue Hospital, and of 413 in other city institutions.

Buffalo.

THE SISTERS OF CHARITY are about to erect an emergency hospital as a down-town branch of the Sisters' Hospital.

ACTIVE WORK has begun for the erection of the New York State laboratory for the investigation of cancer. It is to be situated directly opposite the Buffalo General Hospital.

DR. E. L. SHURLEY, Detroit, discussed the relation of laryngeal and pulmonary tuberculosis before the Buffalo Academy of Medicine, laryngological section, November 19.

THE NEW GERMAN HOSPITAL has been opened for the inspection of the general public. Before the admission of patients

a bazaar will be held in the building during the next two weeks, in which all the German societies will participate for the purpose of increasing the available funds.

The water-supply of the city is affected at the present time by the recent gales on Lake Erie. Because of the increase of the number of cases of typhoid thus far reported this month, as compared with the same period for the past few years, the health authorities have advised that all water for drinking purposes be boiled.

THE PHYSICIANS at Williamsville, a suburb of Buffalo, are involved in a controversy, the matter at issue being whether a disease there prevalent is scarlet-fever or German measles. Meanwhile the public schools have been closed as a matter of precaution.

OHIO.

REPORTS OF 60 cases of diphtheria and 19 of smallpox were made to the Cleveland health office last week.

FRONTON has quarantined against Russell and Catlettsburg, Ky., where smallpox exists, and has ordered compulsory vaccination.

THE NEW BUILDING for the Cleveland College of Physicians and Surgeons was dedicated with appropriate ceremonies, November 22, and formally transferred to the Ohio Wesleyan University.

DR. JOHN E. GRIEWE, clinical director of the City Hospital, Cincinnati, has appointed the following physicians on his staff: Alfred Friedlander, William H. Crane, Horace J. Whitacre, James W. Rowe, Frank E. Fee and Albert B. Devers.

DR. CHARLES F. H. WILGONS, Doylestown, celebrated his ninety-seventh birthday anniversary, November 21. He has lived and practiced in Doylestown for more than sixty years, and is probably the oldest physician in active practice in the United States.

PENNSYLVANIA.

A GIRL, aged 15 years, of Lancaster, on November 22, died, it is said, from the effects of an overdose of belladonna which had been prescribed by a local druggist.

AT THE last meeting of the State Board of Charities and Corrections, held in Pittsburg on November 22, it was decided to ask the legislature at its next meeting to establish state institutions for the treatment of consumptives and epileptics.

A LARGE number of cases of diphtheria have been reported from the town of Mt. Joy. At a recent meeting of the council it was decided to purchase a sufficient amount of antitoxin; 15 new cases were reported within a few days. Up to November 19, two deaths had occurred.

SO WIDESPREAD has the epidemic of typhoid become at Allentown that the state authorities are making an investigation. On November 17 Dr. Benjamin Lee, secretary of the State Board of Health, and Dr. W. D. Heller, state quarantine officer of Philadelphia, left for the infected locality. While there are only a few hundred inhabitants in the town, about 160 cases of typhoid have been reported. Both the water and milk have been ordered to be boiled.

Philadelphia.

AN ADDRESS was given before the Charles K. Mills Neurological Society (Univ. Pa.) by Dr. S. Weir Mitchell, on the evening of November 19.

THURSDAY November 29 has been set aside by a number of the principal hospitals as a special day for donation. Among these may be mentioned the University Hospital, Presbyterian Hospital, Jefferson Maternity Hospital, Episcopal Hospital, St. Christopher's Hospital for Children, and many others.

DIPHTHERIA, which has been so widespread over the northern part of Pennsylvania and New Jersey, also shows an increase in this city. The Board of Health has quarantined all the infected houses in the Pensanken neighborhood and has placed a sanitary officer in charge to see that no one leaves the infected houses. Considerable feeling has arisen over one case which had to be detained at a police station several hours before an ambulance could be obtained.

THE NUMBER of deaths which occurred for the week ending November 24 was 426, a decrease of 13 as compared with the previous week, and an increase of 40 as compared with the corresponding period of last year. The principal causes of death were: Apoplexy, 17; nephritis, 35; cancer, 13; casualties, 13; cerebrospinal meningitis, 2; tuberculosis, 41; diabetes, 1; heart disease, 39; bronchitis, 5; pneumonia, 64; septicaemia, 5; suicide, 3; tetanus, 1; diphtheria 112 cases, 15 deaths; scarlet fever, 57 cases, 1 death; typhoid fever 43 cases, 5 deaths.

GENERAL.

CLARENCE F. CRABBE, a former student of Sacramento, Cal., has recently been elected senator to the Hawaiian legislature.

THE officials of the Pennsylvania railroad system are endeavoring to improve the conditions on locomotives influencing the sight and hearing of the engineers and firemen. With this end in view they purpose sending a special oculist and aurist to ride in the engine cab, study defects and suggest improvements consistent with the nature of the machinery and work.

THERE are 23,778 students, it is said, in the medical colleges of the United States; less than half as many in the law schools, and only about a third in the theological seminaries. More young persons are studying medicine and theology in Illinois than in any other state, though New York leads in the number of law students.

THE TITLES, with short abstracts, of the papers intended to be read at the Pan-American Medical Congress at Havana should be sent as soon as possible to the secretary of the Congress, Dr. Thomas V. Coronado, Predo 105, Havana, Cuba. For further particulars, apply to the respective secretaries of sections for this country; their names and addresses are given in THE JOURNAL of November 24, page 1357.

A DECISION AGAINST OSTEOPATHS.

A test-case against osteopaths, which has been in the courts of Nebraska for more than a year, has just been decided in the Supreme Court, the decision being against osteopathy. The only point on which the Supreme Court was asked to decide was whether the practice of osteopathy is the practice of medicine within the meaning of the act. Chief Justice Norval, in rendering his opinion, says: "The writer is not deeply versed in the theory of the healing art, but he apprehends that all physicians have the same object in view, namely, the restoring of the patient to sound bodily or mental condition, and whether they profess to attack the malady or its cause, they are 'treating' the ailment as the word is popularly understood. We can, therefore, see no good reason why the practice of osteopathy does not fall within the provisions of the statutes under which defendant was prosecuted, as clearly so as do ordinary practitioners."

THE BERTILLOU CLASSIFICATION.

THE Surgeon-General of the Marine-Hospital Service has received a number of letters from the health officers throughout the United States asking him to have the Bertillon classification of the causes of death translated and published. Accordingly, he is having it translated now by a medical officer of the Service and will have it published for the information of those who are interested in such matters. There seems to be a growing demand for the adoption of a uniform system throughout the world. At present the various governments are expending large amounts in collecting these statistics, adopting various systems, while some have adopted no system at all. It can be readily seen of how much more value such statistics would be should the civilized nations adopt this or any good system of the kind and adhere strictly to it.

CANADA.

THE OTTAWA CLINICAL SOCIETY met for the first time this season on the 16th inst., and elected the following officers for the current year: President, Dr. Scott; first vice-president, Dr. Eehlin; second vice-president, Dr. Minnes; third vice-president, Dr. McElroy; secretary, Dr. Royce; treasurer, Dr. Maybury, curator, Dr. Pratt; librarian, Dr. Rowles; executive committee, Drs. Cooke, Webster, Klock, and Robinson.

THE ONTARIO DRUGGISTS have become much aroused over the German bill, details of which have already appeared in the columns of THE JOURNAL. A mass meeting of the Toronto druggists and representatives from the outside towns and cities was held last week and a strong feeling appears to be developing among the drug fraternity that they throw the "patent medicine men" over entirely, as they claim that there is now very little to be made in handling those preparations.

THE MONTHLY report of the Ontario Board of Health shows a considerable increase from deaths from typhoid fever during October, the total number for the month of fatal cases being 117, as against 88 in October a year ago. Consumption shows a falling off, 160 being recorded, as against 194 in October of last year.

THE MEDICAL men of that portion of the province of Quebec known as the Eastern Townships, at the quarterly meeting of their medical association, known as the St. Francis District Medical Association, took steps to form a medical defence union. Copies of the rules will be at once sent to all medical men in that district for their signatures, when the organization will seek the endorsement of the Canadian Medical Association. The association also decided to accept and adopt the

Ontario code of ethics. Hereafter the society will meet every two months, on the second Wednesday of the month.

ONTARIO'S VITAL STATISTICS.

The apparent decrease in the birth-rate of the province of Ontario in 1898 was thought to be attributable to defective returns, but in spite of the fact that stricter precautions have been taken in this regard, even to the extent of prosecutions and fines for neglect to register, the birth-rate of this province still continues to go down. Marriages have increased, but the births have decreased. In 1899 there were 16,514 marriages, as against 15,375 in 1898, an increase of 1139. Of births, there were 44,705 in 1899, as against 46,599 in 1898, a decrease of 1894. The deaths for 1899 number 28,607, as compared with 26,370 in the preceding twelve months. In Toronto alone, although the population has increased by 5000, the births show a decrease of 116. In Hamilton they have decreased by 156 in 1899.

THE INSANE OF ONTARIO.

The Ontario government has recently been receiving some pretty severe criticism for failing to provide proper and full accommodation for the lunatics who are confined in the common goals of the province. Toronto especially is taking active steps to have this abuse immediately removed. In the goal of that city no less than 49 insane people are confined like other criminals, awaiting transference to government asylums, but as there is no accommodation for them, they continue on in their present quarters. The medical health officer, Dr. Sheard, and Dr. Richardson, the goal surgeon, have been appointed a committee to lay this matter before the provincial secretary, seeking to have the wrong remedied. The government claims that it is hurrying on the work at the old Victoria College at Cobourg, which, when completed, will accommodate 200 patients.

MONTREAL GENERAL HOSPITAL.

The work of this hospital is increasing in a manner altogether out of proportion to its revenues, and the present state of affairs is causing some anxiety to the committee of management. At the quarterly meeting of the board of governors last week, it was decided to make a vigorous canvass of the city for funds to carry on the work in a proper manner. The report of the medical superintendent shows that the average number of patients per day has been 178, as against 160 last year, an increase of 13 per day, but the hospital days this year count up 15,863, as against 14,686 last year. The out-door patients the past quarter are 11,043, as against 9470 last year, and it is this constantly increasing strain, as at the present time the current expense account is a debtor to capital account of \$22,850, that is causing the anxiety. The greatest number of typhoid patients at one time present was 87. The life governors will be increased to 1000, and as the minimum subscription of these is \$12 per year, this work at least mean \$12,000. The number of governors is now 598.

FOREIGN.

The death is announced of Dr. L. Acconci, professor of gynecology at Genoa, and that of Dr. G. Buelau, of Hamburg, the inventor of aspirating drainage of purulent pleurisy.

The Gesellschaft der Aerzte, of Vienna, has presented the triennial Goldberger prize of 1500 kroner to Dr. H. Hering, of Prague, for his work on "Centripetal Ataxia in Tabes."

The *Archives Orientales* states that very strict orders have been promulgated by the authorities at Constantinople to put an end to the illegal practice of medicine, pharmacy and dentistry throughout the entire Ottoman empire.

Two professors of the Lyons faculty of medicine and Prof. F. Vidal, of Paris, have been sent to Syria by the French minister of public instruction to preside over the examining board of the free medical school at Beyrouth.

A new pavilion for stomatology and dental surgery has been completed in connection with the Hospital Saint Louis, at Paris, the first complete service organized in any of the hospitals there, we are told.

THE QUESTION whether to exclude the Latin language from the course at the St. Petersburg Military-Medical Academy, which has been much discussed, has been decided in the negative. The committee reported that it would be dangerous to allow the students to graduate without a knowledge of Latin, but it is not necessary to devote as much time to it as heretofore. Ability to read and write it correctly should be the standard.

THE TWENTY-FIFTH anniversary of the accession of the Sultan to the throne was celebrated at Constantinople by laying the corner-stone of several buildings in which the profession is interested, the bacteriologic institute at Chichli, the section of surgery in the Greek colony, the inauguration of the Hebrew

hospital at Galata, and of the new buildings of the Imperial University.

FROM VIENNA comes a report of the cure of a case of alopecia areata of three years' standing by the Roentgen rays. After six sittings of fifteen minutes each, the spot exposed to the rays, it is alleged, became covered with normal hair, while there was no change in the bald patches not exposed to the rays. Kienboeck, who exhibited the patient two months later, states that "soft" tubes have been much more effective than "hard" ones in his experience.

MEDICAL DEFENSE IN GERMANY.

A strike of medical men engaged in club practice is threatened in Germany. The clubs are there official institutions, membership being compulsory for working people, and they are in the habit of treating their medical employees badly and appointing them on humiliating terms. This condition has lasted a long time and it is now proposed to organize the profession and to raise a general defense fund and generally to give the members of the workmen's sick-clubs a dose of the same medicine which they have so often administered through their trade-unions. The *Lancet* correspondent thinks the movement will hardly succeed and says that it has been rather coldly received by the medical journals, especially those of Berlin, which think there may be a better way to bring about the desired end.

MEDICAL ATTACHES TO EMBASSIES.

Some Berlin papers, in view of the prevalence of the plague throughout the world, have proposed that medical attachés should be appointed to the German embassies abroad to study hygienic conditions and inform their government as to the occurrence of cases of infectious disease. In this way it is suggested that international arrangements could be better made to prevent the spread of epidemics and timely notification of danger be assured. The Berlin correspondent of the *Lancet*, from which this information is obtained, says that there is ample precedent for this course, as there have frequently been other than diplomatic appointments on embassies and the duties of the medical appointees would be altogether analogous to those of the other technical attachés.

Correspondence.

German Medical Degrees.

COBURG, GERMANY, Nov. 6, 1900.

The ministers of the several German federal governments have recently promulgated the following rules regarding promotion to the degree of Doctor of Medicine: 1. The Ministers of Instruction have agreed that the following rules must be taken into consideration in the new regulations for the promotion to the degree of Doctor of Medicine. 2. The full meaning of these regulations is to be laid down in the rules for promotion in the various medical faculties. But it must be kept in mind, that only minimum requirements are here set forth, and that it is left to the discretion of the various faculties to lay out more stringent rules to be observed by the candidates for medical degrees. 3. Prospectus showing the regulations that have been issued and the names of those receiving the degrees are to be published half yearly in the *Imperial German Advertiser* (*Reichsanzeiger*). For this purpose the ministries in question will have to fill up the necessary forms, and send in those of the summer semesters by December 1, and those of the winter semester by June 1, of every year, to the *Reichsanzeiger*, whose business it will be to collect the same and publish them as soon as possible.

The regulations agreed on are as follows: The degree of Doctor of Medicine can only be conferred, after a thesis has been printed and published and a verbal examination. A *promotio in absentia* will not be allowed under any circumstances. By this thesis the candidate must prove that he is able to work independently on scientific lines (*selbstständig wissenschaftlich zu arbeiten*). The thesis must be written in German, but the use of another language may be allowed by the faculty. A biography of the candidate must be appended to the thesis. The verbal examination (*Mündliche Prüfung*) consists, as the case may be, either of a simple questioning (*colloquium*) or of an *Examen rigorosum*. German subjects can not receive the degree, before obtaining the permission from the government to practice within the German Empire.

Deviations from this rule may be granted in particular cases by a unanimous vote of the faculty, and with the permission of the supervising board. Foreigners who have received the government permission to practice medicine within the German Empire are subjected to the same regulations regarding their promotion to the degree of Doctor of Medicine, as those laid down for German subjects. Foreigners who do not possess the practicing physicians' permit for the German Empire and who desire to be promoted must lay before the faculty proofs of the following facts.

1. That they have had the necessary schooling (Vorbildung), which in their own country is required for passing the medical examination and for receiving the degrees of a Doctor of Medicine; if in their own country fixed rules with regard to this matter do not exist, they will have to show certificates from home, which in case of need can or will be supported by certificates acquired in Germany, in which proof is given that their schooling, at the least, is equal to the scholarship which is required for obtaining the matriculation certificate at a German Realgymnasium. 2. That, after having acquired the thus stipulated degree of general scholarship, they have passed through well-regulated medical studies before a regularly organized medical faculty, for as many semesters as are required in Germany for admittance to the regular medical examinations; and that at least one of those semesters must have been spent at the German University at which they wish to receive their degree. But this latter rule, with the permission of the supervising board, may be exceptionally suspended, if the candidate be well known to the faculty. The printed thesis, which must be produced before obtaining the permission to appear for the degree examination, may, at the faculty's discretion, be replaced by a scientific work of the candidate which has already been printed and published.

To avoid the use of, and presentation for registration, in the different States of the Union of bogus German diplomas, or those not recognized by the Imperial German Government, I would respectfully suggest to the different State Medical Societies that all German diplomas before being accepted as bona fide, should be required to be certified to as genuine by the United States Consul, in whose Consular District the University granting the degree, is located.

As American degrees are not in reality recognized in Germany, why should every German degree be accepted by our State Medical Boards, or at least by most of them? Medicine and surgery stand to-day on a higher plane in America than here. Consequently we should be just as discriminating toward Germany as her laws are to our medical graduates. Very respectfully,

OLIVER J. D. HUGHES, M.D.
Consul of the United States.

The Discoverer of Anesthesia.

TULSA, I. T., Nov. 15, 1900.

To the Editor: I noticed a communication from James McManus, D.D.S., of Hartford, Conn., in the November 10 issue of THE JOURNAL in which he refers to the action taken by THE AMERICAN MEDICAL ASSOCIATION and other well-known associations wherein they have gone on record that it is their belief that Dr. Horace Wells, of Hartford, Conn., was the discoverer of modern anesthesia. Did these associations so commit themselves? If so, what facts had they for such an action?

Dr. McManus must have been blinded by professional loyalty and civic pride, for from the facts in the case he is not justified in claiming this imperishable honor for Dr. Wells. The most incontrovertible facts and best authenticated details as to its prior discovery by Crawford W. Long, M.D., of Athens, Ga., March 30, 1842, two years and eight months before Dr. Wells even claimed to have discovered it, are available to any one who desires to accord honor to whom honor is due.

This is a golden opportunity for the judges in the Hall of Fame to perpetuate their own names as long as civilization endures, by selecting that of Crawford W. Long as one of the immortals, not from the medical profession alone, but from among modest men—who desired no greater glory or glittering gold for his incomparable discovery than to be "a benefactor of mankind." Yours truly,

FRED. S. CLINTON, M.D.

Estimation of Amount of Hemoglobin.

ST. PAUL, MINN., Nov. 20, 1900.

To the Editor: I was much interested in Dr. Allen Staples' letter in the last issue of THE JOURNAL, on "Medical Study in Helsingfors," and, particularly in his allusion to Tallquist's method of estimating the amount of hemoglobin by means of a color scale, because Tallquist's original article on this subject was published in the *St. Paul Medical Journal* for May, 1900, together with the color scale which was made for us in Helsingfors under his direction. Possibly some of your readers who are interested in this matter may be glad to know where this article can be found. The price of the *Journal*, with the color scale is fifty cents.

BURNSIDE FOSTER, M.D.,
Editor *St. Paul Medical Journal*.

Connell's Suture; A Question of Priority.

TROY, N. Y., Nov. 21, 1900.

To the Editor: In November, 1896, I had the privilege of assisting Professor Thomas H. Manley, of New York, in a case of gangrenous strangulated hernia, necessitating a resection and lateral enterorrhaphy. The gangrenous loop measured 27 inches, and more than 3 inches of both free ends of gut were also excised, in all about 30 inches. In this instance the lateral enterorrhaphy was done by the "Connell" method, the patient making a prompt recovery. This was the first case of intestinal resection for gangrenous hernia by the "Connell suture" on record; but I am informed that the same surgeon again employed the same suture successfully in August last, after the excision of 19 inches of mortified intestine; here again uneventful recovery followed.

I venture to intrude on your kindness in this matter, especially for two reasons: 1, to call attention to the "Connell," the simplest and most effective of all intestinal sutures; and 2, in order to bestow credit on whom credit is due, and to show that though the procedure is an invention of the mighty West, it was a native Eastern surgeon who first tested its practical value, in mortified intestine on living human being; and successfully at that, in the only cases where it was tested. I am yours, etc.,

A. D. DAVIDSON, M.D.

Marriages.

JOHN TURNER, M.D., to Miss Frances Mabel Wentz, both of Baltimore, November 19.

C. MERWIN BRANCH, M.D., to Miss Erna Bass, both of Richmond, Va., November 14.

WALTER MADDEN, M.D., to Miss Annie Metzler, both of Trenton, N. J., November 14.

ROBERT EDWARD WILSON, M.D., to Miss Grace Cunningham, both of St. Louis, November 21.

HUGH NELSON LEAVELL, M.D., to Miss Hattie Rodman, both of Louisville, Ky., November 7.

WILLIAM G. CAMERON, M.D., Staples, to Miss Mabelle Davis, of Brainerd, Minn., November 14.

ROBERT MINOR WILEY, M.D., to Miss Ellen Edmundson Blair, both of Salem, Va., November 15.

JOHN MILES GIBBON, M.D., Seranton, Pa., to Miss Kathleen Coghlin, of Montreal, November 15.

EVERETT M. HURST, M.D., Cloverdale, Ind., to Miss Eliza M. Herod, of Greencastle, Ind., September 23.

ROSCOE C. DANFORD, M.D., Pana, Ill., to Miss Monta McLaughlin, of Bloomington, Ill., November 14.

MICHAEL J. KENEFFICK, M.D., Algona, Iowa, to Miss Edith May Lusk, of Milwaukee, Wis., November 15.

HENRY F. TATUM, M.D., Meridian, Miss., to Miss Ruth Featherstun, of Brookhaven, Miss., November 8.

WILLIAM H. BODENSTAB, M.D., New Salem, N. D., second vice-president of the North Dakota State Medical Society, to Miss Zetta Morgan, of Glen Ullin, N. D.

Deaths and Obituaries.

ROMAINE J. CERTIS, M. D., University of Cincinnati, 1864, for many years professor of bacteriology and pathology in the College of Physicians and Surgeons, Chicago, a veteran of the Civil War, and noted in years past as a lecturer and writer, at his home, Joliet, Ill., November 20, aged 58.

FREDERICK CORNELL DE MUND, M.D., College of Physicians and Surgeons, N. Y., 1855, at his home, Brooklyn, N. Y., November 20. He was born at Millstown, N. J., and practised in the old town of New Utrecht, Long Island, from 1859 till 1895.

WILLIAM F. MAHNEKE, M.D., University of Würzburg, 1868, thereafter surgeon in the Franco-German War, and for twenty-five years a resident of Pennsylvania, at his home, Pittsburgh, November 18, after an illness of ten weeks, aged 50.

ALEXANDER C. STREATOR, M.D., Western Reserve University, Cleveland, Ohio, 1882, at the home of his brother in Washington, Pa., from diabetes, November 16, aged 53.

JOHN H. FREEMAN, M.D., Jefferson Medical College, 1836, who practiced for nearly 40 years in Lexington, Va., at his home in that city, November 12, aged 84.

THOMAS A. QUAYLE, M.D., Tulane University, New Orleans, 1891, professor of pharmacy in the university, at his home in New Orleans, November 16, aged 31.

MARK P. BURLESON, M.D., Kentucky School of Medicine, Louisville, 1891, shot and killed in his office at Richland Springs, Texas, November 16.

WILLIAM A. WEST, M.D., University of Nashville, Tenn., 1870, after a long illness, at his home, Indian Mount, Tenn., November 15, aged 73.

BENJAMIN T. MOSELEY, M.D., Charity Hospital Medical College, New Orleans, 1875, at his home in Alexandria, La., November 14, aged 51.

ROBERT ACTON, M.D., Harvard, 1899, at Presbyterian Hospital, New York City, from an overdose of morphin, November 22, aged 32.

JOHN SWAN, M.D., Bowdoin College, Brunswick, Me., 1866, at his home in Westbrook, Me., after a long illness, November 17, aged 60.

EDWARD E. WAGGONER, M.D., Washington University, St. Louis, 1868, at his home in Shelbyville, Ill., November 20, aged 71.

FRANK W. PATTEN, M.D., College of Physicians and Surgeons, New York, 1877, suddenly, in Boston, November 17.

J. R. SHINN, M.D., Memphis Hospital Medical College, 1896, at Sanderson, Texas, of consumption, November 15.

GEORGE W. SPARKS, M.D., Jefferson Medical College, 1865, at his home in Philadelphia, November 17, aged 56.

O. P. BRASHEAR, M.D., Jefferson, at New Haven, Pa., after an illness of three years, November 3, aged 60.

ROBERT B. BROWN, M.D., University of Pennsylvania, 1846, at Phillipsburg, N. J., November 13, aged 76.

LOYD DORSEY, M.D., University of Maryland, 1854, at his home, Washington, D. C., November 13.

WILLIAM H. ROSS, M.D., University of Georgetown, D. C., 1869, in New York City, November 20.

JOHN WERNER, M.D., Detroit Medical College, 1875, at Hillsdale, Mich., from paralysis, November 22.

Association News.

The Exhibit of the American Medical Association at the St. Paul Meeting.

A museum of medical and surgical instruments, apparatus and dressings, pharmaceutical preparations, food and drink for the sick and for infants, utensils for chemical, microscopical and biological laboratories, sanitary and hygienic appliances and devices, ambulances, hospital and office furniture, and of the literature of the medical and allied sciences, has for

many years been held in connection with the annual meeting of the AMERICAN MEDICAL ASSOCIATION.

This medical bazaar should be one of the most interesting features of the meetings, where every member can see the newest instruments, and the most recent additions to the pharmacopeia; where he can inspect books, and place his orders for any professional supplies he may be in need of. The time devoted to a careful study of such an exhibition is always profitably spent, as something must be seen which is new to every one. The exhibitor can not find anywhere a means of advertising his wares which will bring them under the most favorable conditions to the attention of so many medical men from all parts of the United States, at an equal cost. If visited in his office by an agent, the practitioner's only wish is to see the back of his unwelcome guest, but while strolling through the exhibit he is just in the humor to examine anything that is of interest.

The privileges offered at each meeting to those whose business it is to supply the profession with its manifold professional needs were gradually encroached on by those whose chief occupation is to destroy legitimate medicine by scattering broadcast over the land patented and secret specifics, drugs and apparatus, for every human ill. These intruders, with the effrontery of quackery, than which earth knows nothing more brazen, forced their way into this exhibit hoping to find weak brethren, who would blow their trumpets for them and defend them in the lists if need be, because forsooth they had been endorsed by the AMERICAN MEDICAL ASSOCIATION. Whereas the truth of the matter is, that the Association has never exercised any control over the exhibit, which has always been in the hands of the local committee, to whom it has been a source of considerable income. The money derived from the sale of space has been a very grateful financial assistance to the committee charged with the important and costly duty of properly entertaining the Association. Hence the temptation has always been strong to increase the revenue obtained from the exhibit, even at the cost of lessening its value and dignity, by selling space to concerns that had no business there. This sort of thing could go on only to a certain extent when reaction was certain to follow; and it has come in complaints from members of the Association and in threats from houses doing an open and ethical business, that they will not in the future patronize the exhibit unless it be cleansed of this very undesirable element.

If the members of the Association know that all the exhibitors are worthy of their confidence and that everything in the exhibit has been carefully scrutinized by the committee, then it will receive much more attention from the members, and be correspondingly more valuable to the exhibitors than it ever has been. The exhibit at the St. Paul meeting is to be of this character. Nothing can be exhibited here which can not be advertised in THE JOURNAL OF THE ASSOCIATION or in the *St. Paul Medical Journal*. The editor of the *Journal* has consented that all applicants to the local committee for space can be referred to this office, where they will be passed upon, and if rejected there the committee in St. Paul have agreed to abide by his decision. This arrangement is final and it will guarantee to the Association an exhibit without an objectionable feature, and to the exhibitors that they will not find themselves in bad company.—*St. Paul Medical Journal*.

Societies.

- Indian Territory Medical Association, Muscogee, Dec. 4-5.
- Seaboard Medical Association of Virginia and North Carolina, Weldon, N. C., Dec. 13.
- Pan-American Medical Congress, Havana, Cuba, Dec. 26-28.
- Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

THE TENNESSEE VALLEY MEDICAL ASSOCIATION, whose membership is to consist of the physicians of Northern Alabama, is in process of organization.

THE MASON COUNTY (KY.) MEDICAL SOCIETY, at its last meeting passed resolutions appropriate to the death of the late Dr. Samuel Pangburn, Maysville.

THE KEOKUK COUNTY (Iowa) MEDICAL ASSOCIATION met at Sigourney and elected Dr. William H. McLaughlin, Webster, president, and Dr. Charles A. Trumbauer, Harper, secretary.

THE FLOYD COUNTY (Ind.) MEDICAL SOCIETY held a special meeting at New Albany, November 8, and adopted resolutions of regret for the death of its late member, Dr. William A. Clapp.

THE MISSISSIPPI GULF COAST MEDICAL SOCIETY met at Seranton, Miss., November 14, and elected Dr. Benjamin F. Duke, Pascagoula, president, and Dr. J. A. Tabor, Seranton, secretary and treasurer.

THE CARROLL COUNTY (Ill.) MEDICAL SOCIETY was organized November 13, with the following as officers: Dr. Joseph Haller, Lamark, president; Dr. Frederick H. Snow, Chadwick, vice-president, and Dr. Henry S. Metcalf, Mount Carroll, secretary and treasurer.

THE PETERSBURG (Va.) MEDICAL FACULTY, at its annual meeting, November 16, elected Dr. Daniel W. Lassiter, president; Drs. John Mann and Robert H. Jones, vice-presidents; Dr. Hugh Stockell, corresponding secretary, and Dr. Joseph D. Osborne, recording secretary and treasurer.

THE MIDDLE TENNESSEE MEDICAL ASSOCIATION met in Pulaski, Tenn., November 15 and 16. The following officers were elected: Dr. Kirby S. Howlett, Franklin, president; Dr. Reginald Stonestreet, Nashville, vice-president, and Dr. Paul Clements, Cross Bridges, secretary and treasurer.

THE SCHUYLKILL COUNTY MEDICAL ASSOCIATION, at its meeting, November 14, elected Dr. A. L. Gillan, Pottsville, president; Dr. Joseph P. Morris, St. Clair, vice-president; Dr. David Taggart, Frackville, treasurer, and Dr. George W. Farquhar, Pottsville, secretary, and nominated delegates to the AMERICAN MEDICAL ASSOCIATION.

THE SOUTHEASTERN IOWA MEDICAL ASSOCIATION held its annual meeting at Ottumwa, November 15, at which the following officers were elected: Dr. John F. Herrick, Ottumwa, president; Drs. Samuel K. Davis, Libertyville, and Florence De W. Patrick, Burlington, vice-presidents, and Dr. William S. Lesenger, Mount Pleasant, secretary and treasurer.

THE MARYLAND LARYNGOLOGICAL ASSOCIATION has elected the following officers for the ensuing year: Dr. Samuel K. Merrick, president; Dr. Jacob H. Hartman, vice-president; Dr. John R. Winslow, treasurer; Dr. Hughlett Hardestack, secretary. The above, with Drs. Samuel Johnston and John N. Mackenzie, all of Baltimore, constitute the council.

THE ST. LOUIS MEDICAL SOCIETY, at its November 10 meeting, listened to a paper by Dr. G. Wiley Broome, entitled, "The Recent Cases of Pelvic Surgery, with a Criticism of Prevailing Methods of Drainage," which elicited much discussion. Drs. E. W. Lee, A. H. Meisenbach, John Young Brown, A. R. Keifer, and others, developed the discussion from every surgical standpoint.

THE WASHINGTON COUNTY (Md.) MEDICAL SOCIETY met at Hagerstown, November 13, and elected the following officers: Dr. D. C. R. Miller, State Line, president; Drs. Japhtha C. Pit-nogle, Hagerstown, and Charles D. Baker, vice-presidents; W. Baker Morrison, Hagerstown, recording secretary; Dr. W. Preston Miller, Hagerstown, corresponding secretary, and Dr. Christian R. Scheller, Hagerstown, treasurer.

THE SOUTHERN COLORADO MEDICAL SOCIETY was organized at Pueblo, November 15, with a membership of 75. The following officers were elected: Dr. Tighlman B. Moore, Canon City, president; Drs. Will B. Davis and Pembroke R. Thoms, Pueblo, vice-presidents; Dr. Cyrus F. Taylor, Pueblo, secretary, and Dr. John A. Black, Pueblo, treasurer. The organization was perfected and the society adjourned to meet in Pueblo in May, 1901.

THE CLINICAL SOCIETY OF MARYLAND elected the following officers at its first meeting: Dr. William J. Todd, Mount Washington, president; Dr. H. Barton Jacobs, vice-president; Dr. Henry O. Reik, recording secretary; Dr. Nathan Ilberman, corresponding secretary, and Dr. J. Frederick Crouch, treasurer, all of Baltimore. Dr. William Osler gave an account of the centennial celebration of the Royal College of Surgeons in London last summer.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY MUTUAL AID ASSOCIATION elected the following officers: Dr. John B. Roberts, president; Drs. John B. Turner and John H. Musser, vice-presidents; Dr. Joseph S. Neff, treasurer; and Dr. Michael O'Hara, Jr., secretary. This association, organized twenty-two years ago, has been of great value in relieving the distress among the families of deceased members. A legacy of several

thousand dollars was left to this organization by Dr. Albert Frichs, who died a few months ago.

THE ST. LOUIS ACADEMY OF MEDICAL AND SURGICAL SCIENCES, at its meeting, Nov. 13, listened to a paper on "Appendiceal Abscesses," by Dr. Augustus C. Bernays. His observations were based on nearly 1000 cases, of 492 of which he had complete records. He called attention to six localities in which these abscesses are ordinarily found. Dr. Carl Fisch exhibited sections of various organs taken from a case of "Schaumorgan" (foam organs). Dr. A. H. Ohmann-Dumesnil showed several rural syphillids removed post-mortem.

THE VANDERBURGH COUNTY (Ind.) MEDICAL SOCIETY held a special meeting at Evansville, November 20, at which papers were presented by Dr. William Wishard, Indianapolis, on "Local Anesthesia in Genito-Urinary Surgery"; Dr. Hugo O. Pantzer, Indianapolis, on "Peritonitis"; Dr. James B. Herrick, Chicago, on "Treatment of Gastric Ulcer"; Dr. Hugo Summa, St. Louis, on "The Floating Tenth Rib"; Dr. Albert H. Meisenbach, St. Louis, on "Operations for Gall-Stones," and Dr. Archibald Dixon, Henderson, Ky., on "Obstruction of the Bowel."

THE MAINE ACADEMY OF MEDICINE AND SCIENCE held its forty-first regular meeting at Portland, November 12. Dr. Galen M. Woodcock, Bangor, was elected vice-president of Section 6, of Public Health, Legal Medicine and Medical and Vital Statistics, after which the nominating committee reported as follows: Dr. Samuel J. Bassford, Biddeford; president; Dr. Addison S. Thayer, Portland, corresponding and statistical secretary; Dr. Daniel Driscoll, Portland, recording secretary; Dr. Herbert F. Twitchell, Portland, treasurer, and Hon. E. B. Winslow, Portland, trustee for seven years.

THE CLINTON COUNTY (Pa.) MEDICAL SOCIETY, at its meeting, November 16, adopted the report of the committee appointed to devise a more perfect system of collecting accounts. The suggestions were to send out bills every three months; with old accounts to send a notice warning the delinquents that if not settled within a reasonable length of time their names will be handed to the society; if not then paid, that the names of such delinquents be placed on the dead-head list and that their physicians would not be required to attend, but would not be prohibited from attending the delinquents and their families.

BUFFALO ACADEMY OF MEDICINE.—At a recent meeting of the medical section of the Academy a very interesting paper was presented by Dr. W. G. Spiller, Philadelphia, on the involvement of the nervous system in malaria, in which he reported a case presenting the symptoms of disseminated sclerosis and presented microscopic slides of the nervous tissue. In the microscopic examination of his case, which gave symptoms of marked intention-tremor of the left arm, marked ataxia of the left leg, transitory hemiparesis, diplopia, marked vertical nystagmus, distinctly scanning speech and exaggerated tendon-reflexes on the right, every capillary of the central nervous system was found plugged with pigmented malarial parasites of the estivo-autumnal form. There was also found an area of sclerosis in the outer part of the middle third of the left crista, also the right crossed-pyramidal tract. This sclerosis followed a small hemorrhage due to the presence of the malarial parasites. The case shows that symptoms of disseminated sclerosis occurring from malaria probably are the result of vascular lesions.

THE CALIFORNIA NORTHERN DISTRICT MEDICAL SOCIETY held its tenth annual meeting at Sacramento, November 13. After the presentation of papers, Dr. Wallace A. Briggs, Sacramento, introduced the following resolution: "Resolved, That it is the profound conviction of the California Northern District Medical Society that the State Board of Health of California should immediately and officially recognize the existence of bubonic plague in the city of San Francisco, and should exert its utmost power to limit the spread of the disease and to stamp it out at the earliest possible moment." This resolution evoked considerable discussion. It was claimed that some who had been quoted as not believing in the existence of plague in San Francisco had not derived their information from actual observation and that either they were not bacteriologists or had made no bacteriological investigation in regard to the matter. Despite remarks made against the resolution it was adopted without a dissenting vote. The following officers were elected: Dr. Walter E. Bates, Davisville, president; Drs. Andrew M. Henderson, and William J. Hanna, Sacramento, and Clarence W. Kellogg, Lakeport, vice-presidents; Dr. Elmer E. Stone, Marysville, secretary, and Dr. Oscar Stansbury, Chico, treasurer.

Southern Surgical and Gynecological Association.

Thirteenth Annual Meeting, held in Atlanta, Ga.,

Nov. 13-15, 1900.

(Continued from p. 1361.)

REMOVAL OF PELVIC INFLAMMATORY MASSES BY THE ABDOMEN AFTER BISECTION OF THE UTERUS.

DR. HOWARD A. KELLY, Baltimore, recently pointed out the great advantages which accrue from bisection of the myomatous uterus in an abdominal enucleation in certain complicated cases. In previous contributions he had described his method of enucleation by a continuous transverse incision from left to right, or from right to left. He now called attention to the great value of a somewhat similar procedure in certain cases of pelvic inflammatory diseases. The steps of the operation are these: If the uterus is buried out of view, the bladder is first separated from the rectum and the fundus found. Then, if there are any large abscesses, adherent cysts, or hematomata, they are evacuated by aspiration or by puncture. The rest of the abdominal cavity is then well packed off from the pelvis. The right and left cornua uteri are each seized by a pair of stout museau forceps and lifted up, the uterus is now incised in the median line in an antero-posterior direction, and as the uterus is bisected, its cornua are pulled up and drawn apart. With a third pair of forceps the uterus is grasped on one side of its cut surface, as far down in the angle as possible, including both anterior and posterior walls. The museau forceps of the same side is then released and used for grasping the corresponding point on the opposite cut surface, when the remaining museau forceps is removed. In this way two forceps are in constant use at the lowest point. He commonly applies them three or four times in all. As the uterus is pulled up and the halves become everted, it is bisected farther down into the cervix. If the operator prefers to do a panhysterectomy, the bisection is carried all the way down into the vagina. The uterine canal must be followed in the dissection, if necessary, using a grooved director to keep it in view. The museau forceps are now made to grasp the uterus well down in the cervical portion, if it is to be a supravaginal amputation, and the cervix is bisected on one side. As soon as it is divided and the uterine and vaginal ends begin to pull apart, the under-surface of the uterine end is caught with a pair of forceps and pulled up, and the uterine vessels, which can now be plainly seen, are clamped or tied. As the uterus is pulled still farther up, the round ligament is exposed and clamped, then finally a clamp is applied between the cornu of the bisected uterus and the tubo-ovarian mass, and one-half of the uterus is removed. The opposite half of the uterus is also taken away in the same manner. The pelvis now contains nothing but rectum and bladder, with right and left tubo-ovarian masses plastered to the sides of the pelvis and the broad ligaments, affording abundant room for investigation of their attachments, as well as for deliberate and skilful dissection. The wide exposure of the cellular area over the inferior median and anterior surfaces of the masses offers the best possible avenue for beginning their detachment and enucleation. The operator will sometimes find on completing the bisection of the uterus that he can just as well take out each tube and ovary together with its corresponding half of the uterus, reserving for the still more difficult cases, or for a most difficult side, the separate enucleation of the tube and ovary after removal of the uterus.

The advantages of a bisection and enucleation of the uterus as a preliminary to a complete enucleation of uterine tubes and ovaries for pelvic inflammatory and other diseases by the abdominal route were briefly recapitulated: 1. Additional space for handling adherent adnexa, afforded by the removal of the uterus. 2. Great increase in facility for dealing with intestinal complications. 3. Better access by new avenues from below and in front to adherent lateral structures. 4. Elevation of structures to or above pelvic brim, or even out into the abdomen, bringing them within easy reach of manipulation and dissection. 5. Some advantage in approaching both uterine vessels by cutting from cervix out toward the broad ligament as is secured in approaching one of them in the continuous transverse incision. In general, the time of the operation is

shortened; its steps are conducted with greater precision; surrounding structures are far less liable to be injured. In this way, there are fewer troubles and sequelae, and the mortality is lessened.

DR. WILLIS G. MACDONALD said his experience in bisection of the uterus, had been very largely associated with tumors deeply situated in the pelvis, attended with great tension on both broad ligaments. It has been his custom to follow the method improved by Dr. Kelly, and the only objection to the operation lay in a certain class of cases in which the tumor is deeply situated in the lower segment of the uterus, or extends to one side or the other in the broad ligament, or is associated with microcystic and adherent ovaries, so that when the operator lifts the tumor out of the abdomen to begin preliminary ligation on one side or the other, he causes considerable tension on the broad ligament, and when the ligature is placed on one or the other ovarian artery there is more or less danger of its giving way when the tension is released. He had seen many cases in his own practice, and that of other surgeons, in which this accident had occurred.

DR. J. WESLEY BOVEE, Washington, D. C., said he had occasionally removed the body of the uterus previous to the removal of the appendages in pus cases, also in fibroid tumors of the uterus, but in some instances he had followed the method of Kelly, since he read his paper before the Washington meeting of the Association on the removal of fibroids of the uterus by going down on one side, as he had described it, and going up on the other. He had recently modified this plan in dealing with pus cases, namely, to cut off the tube and ovarian ligaments from the uterus on one side, clamp the round ligament, going down to the cervix, clamping the uterine artery, cutting through the cervix and uterine artery on the other side, going up and removing the appendage on the other side with the uterus.

DR. W. E. B. DAVIS, Birmingham, Ala., expressed the opinion that the method outlined by Kelly would be of great assistance in the severe cases of inflammatory pelvic disease. The removal of the uterus for inflammatory disease had its origin in the difficulties which beset French surgeons in removing the appendages by the vaginal method, so that it became necessary for them to remove the uterus in order to have a route by which they could reach the adnexa. Dr. Kelly, therefore, had accomplished by operating from above what French surgeons had so frequently done through the vagina.

DR. GEORGE J. ENGELMANN, Boston, considered the method a step in advance, and said it was really amazing that no one had thought of doing this work by the abdomen before it had been done by the vaginal route.

VESICOVAGINAL FISTULA.

DR. M. C. MCGANNON, Nashville, read a paper on this subject, in which he referred to the work of Sims, Emmet, Mackenrodt and others, in this field of surgery. He has applied the principle of Mackenrodt in six cases, during the last two years, with primary union and complete closure of the fistula in every case. The technique in each case was the same, and this the author outlined at considerable length.

A CASE OF OSTEOFIBROMA OF THE UTERUS.

DR. GEORGE BEN JOHNSON, Richmond, Va., narrated a case of a woman, aged 30, the mother of three children, the youngest 3 years old. About two years after the birth of the youngest child she noticed an enlargement of the abdomen, and at times experienced difficulty in voiding her urine. An examination disclosed a tumor, which filled the pelvic cavity, growing from the posterior wall of the uterus, and so displacing the uterus forward that it pressed on the bladder. Six months later she missed her menstrual period, and by this time her size had greatly increased and her ability to void urine normally was almost lost. About the middle of March, 1900, she passed a fetus of six or eight weeks' development; but her size did not reduce and the pressure symptoms continued. Examination revealed two tumors, one a large fibromyoma, situated posteriorly and to the right of the uterus; the other a small tumor, anterior and to the left. Complete hysterectomy was performed April 10. The smaller tumor was found to be intra-

mural and situated at the junction of the body and the neck. On liberation the tumor was about the size of a small orange, and of firm consistency. Held between the thumb and fingers it gave the sensation that is produced by pressing a hard-boiled egg, the shell of which has been broken. Plates, apparently of bone, surrounded the surface, and on opening it a substance resembling medullary tissue was found. This was unfortunately lost, so that no subsequent histological study of it could be made. Attached to the lower part of the osseous tumor was a small fleshy mass, which contained a body about an inch in length resembling a pear in shape. On opening the uterus a recent placental site was found near the uterine opening of the right Fallopian tube. The tumor was covered by a fibrous capsule, scattered through which were plates, rounded nodules, and irregular jagged masses, which, when decalcified, proved to be dense laminae of bone, with their included bone cells. These bone cells were not so numerous as in normal bone, while the lamellae were irregular in their arrangement, although showing a general tendency to lie parallel to frequent openings in the bony tissue. These openings were larger and more irregular in shape than the Haversian canals of normal compact bone, and were filled with a connective-tissue stroma supporting blood-vessels. The softer parts of the tumor were found to be compound of involuntary muscle fibers arranged in groups and bundles, which were supported by loose connective tissue. Dense masses of fibrous tissue occurred throughout the tumor, independently of the muscular tissue. Microscopic examination of the tumor verified the diagnosis made macroscopically—osteofibroma. Patient recovered.

DR. HOWARD A. KELLY said he would be loath to accept diagnoses that had been made twenty-five years ago in regard to tumors of this kind, when the nature between calcified tumors and teratomata was not clearly understood, and even pathology itself was in a vague condition. Of 562 myomec-tomies, he had met with 27 calcified myomata.

APPENDICITIS IN THE FEMALE.

DR. F. W. McRAE, Atlanta, referred to an article by Edebohls as to the relative frequency of appendicitis in the two sexes; also to the work of Einhorn, who had found in 18,000 successive autopsies perforating appendicitis in 55 per cent. of males, and 57 per cent. of females. Robinson, in 123 autopsies, found evidences of past peritonitis in or about the appendix in 68 per cent. of females, and 56 per cent. of male bodies. Clinically, Edebohls finds that 4 per cent. of all women have appendicitis. On the contrary, Deaver believes that 80 per cent. of all cases occur in males. Of 1577 cases of appendicitis collected from the annual reports of the city hospitals of Berlin, 949 were males, and 628 females.

The speaker quoted eminent authorities to show the divergence of opinion as to the relative frequency of the disease in the male and in the female. In practically all of the cases that had come under his observation in females, mistakes in diagnosis had been made either by himself or by the attending physician. Almost all of the attacks had occurred at or about the menstrual term, and most of them had been diagnosed "inflammation of the tube or ovary." In two cases of his own series the appendix and the right tube and ovary were involved; in two others the appendicular trouble was complicated with diseased kidneys. Two patients suffered with recurrent appendicitis, and attacks of renal colic before or after operation for the removal of their appendices. He had records of 49 cases of appendicitis seen within the last sixteen months, 29 of them being males, and 20 females. During this period he had operated on 17 males, and 14 females. The author then detailed 13 cases.

DR. J. B. S. HOLMES, Atlanta, detailed three interesting cases of appendicitis in females, which illustrated forcibly the necessity of always examining the appendix, when the abdomen of a woman is opened for any cause.

DR. HAL C. WYMAN, Detroit, cited a case of extrauterine pregnancy in which he removed a fetus that had apparently died at about the end of the seventh month of pregnancy. The operation was done thirteen months after the appearance of the first symptoms of pregnancy. The appendix was found intimately blended with the fimbria of the right tube. The

right Fallopian tube was involved with the appendix by dense inflammatory adhesions, and it occurred to him that in consequence of that blending the impregnated ovum had escaped. With this experience we might just charge some of the cases of extrauterine pregnancy possibly to adhesions between the fimbriae and the appendix.

DR. HOWARD A. KELLY stated that for four years past he has made it a rule at the Johns Hopkins Hospital to have stated on a slip the exact condition of the appendix. During this period he has removed 150 appendices. Of this number 60 were involved in pelvic inflammatory disease. He found the appendix adherent to myomata in 12; adherent to ovarian tumors in 9. He found carcinoma of the appendix secondary to ovarian carcinoma, without any traceable macroscopic relation in one case, and primary carcinoma in one other case. He found tuberculosis of the appendix secondary to tuberculosis in the tubes and ovaries in three cases; in the remainder of the cases calculi, cystic diseases, and uncomplicated appendicitis. If, in opening the abdomen for any pathological condition, the incision is sufficiently large, he would examine the appendix.

DR. LEWIS S. McMURTY mentioned a case in which he had enucleated an ovarian cyst in a woman of 30. She had had a typical acute perforative appendicitis, followed by septic symptoms, which was quite limited in the area of peritoneal involvement. When the abdomen was opened, it was found that the appendix, instead of perforating the general peritoneal cavity, pierced the ovarian cyst, in that manner limiting the infection to the ovarian cyst and saving the life of the patient.

DR. WILLIS F. WESTMORELAND, Atlanta, spoke of the practicability of stitching the kidney back through the same incision after the manner described by Dr. McRae in one of his cases.

DR. WILLIAM P. NICOLSON, Atlanta, called attention to the coincidence of disease of the appendix and uterine adnexa, and cited cases in which symptoms for years had been ascribed to uterine or ovarian trouble, but operation disclosed the fact that the appendix was solely at fault.

DR. GEORGE BEN JOHNSTON expressed the conviction that chronic appendicitis is quite as frequent in the female as in the male. He believes, however, we see fewer cases of the fulminating form of the diseases in the female than in the male. He has seen many cases of chronic appendicitis associated with movable kidney in females, and it is sometimes difficult to determine which is the cause of distress for which the patient consults a surgeon, the diseased appendix or movable kidney, or both. The coexistence of the two conditions is so frequent in his practice that oftentimes he keeps patients under observation for days, perhaps weeks, to determine which is the more distressing condition.

DRAINAGE IN ABDOMINAL SURGERY.

DR. J. W. LONG, Salisbury, N. C., said that the chief purposes for which drainage is employed are to drain away existing septic material; to afford an exit for the sepsis when the operator fears he has possibly infected his patient; to provoke adhesions and thereby wall off weak spots from the remainder of the abdominal contents; to keep the peritoneal cavity free of blood and other fluids; to allow of a more certain knowledge of the conditions present in the abdomen. Gauze drains are sometimes employed as tampons to control hemorrhage. The objections to drainage were then considered.

DR. MANNING SIMONS, Charleston, said there are some surgeons who would not admit that draining in suppurative cases is an evidence that something has been left which ought to have been removed, or that the surgeon had done something that he ought not to have done. There are many cases in which suppuration is not confined to the tubes, but has diffused itself more or less over the pelvic and abdominal cavities. The surgeon's conscience would scarcely, in such a case, prompt him to close up all avenues for the escape of reaccumulated fluid from the cavity. Drainage is applicable to such cases.

DR. HOWARD A. KELLY believes that there is a tendency on the part of the profession to drain entirely too many cases.

Dr. W. E. B. DAVIS referred to drainage in general septic peritonitis, and said it was impossible to lay down any fixed or definite plan of treatment because results were uniformly fatal. Reports in the past showed the percentage of recoveries to have been small. Much good can be accomplished by first using hydrogen peroxid in the abdomen in this class of cases, and following it with infusion of normal salt solution, injecting say a quart under the skin every three hours. This accomplishes even more than multiple drainage in cases of general septic peritonitis.

Dr. BEVERLY MACMONAGLE called attention to drainage in connection with surgery of the gall-bladder and gall-ducts. When the gall-bladder is opened, it is absolutely essential to drain it.

ATRESIA OF THE VAGINA.

Dr. GEORGE H. NOBLE, Atlanta, described a flap operation for the relief of this condition, saying that he had operated successfully in several cases by the plan he had outlined.

(To be continued.)

Philadelphia County Medical Society.

Regular Meeting, held November 14, 1900.

President Dr. John H. Musser, in the chair.

REGISTRATION OF TUBERCULOSIS.

Dr. H. M. BIGGS, of the Board of Health of New York City, delivered an address on this subject. The speaker referred to certain English writers who had argued against the registration of tuberculosis, among whom Thorne opposed such an idea. To the speaker it seemed incomprehensible to say that a tuberculous person should be permitted to live in a crowded work-room where he would be a menace to all about him. As to the manner of registration and its influence on the public mind, he did not believe that tuberculosis should be classed with such contagious diseases as smallpox and diphtheria. Tuberculosis, while it is a highly infectious disease, in his opinion, should be put in a class by itself.

As to the means of limiting its spread some have advocated that isolation hospitals be erected in cities and that other similar institutions be constructed in the country, to which places these persons could be sent. This seems a most rational plan. As to the spread of the disease there could be no doubt that it was by means of the specific micro-organism, which can not multiply outside of the body of some animal. Therefore it is a preventable disease. The best plan is compulsory notification and registration. Because the disease is so common and so widespread should be no reason why it should not be lessened if possible. If the tuberculous person is taken from the infected home it lessens the danger to the immediate family. The speaker had come to the conclusion that it was always best for the attending physician to tell the patient that he was suffering from tuberculosis. It might not be well borne by some at the outset, but in the long run he believed the majority would profit by it. He had known instances in which the physicians had not done this, and the patient had gone to another physician who had informed him of the condition, thus causing animosity toward the first named.

Some persons believe that if a city has compulsory registration the affected individual will become socially ostracised. This is not the case. Others contend that it is a disease of very long duration, therefore it is not well to have an institution where they would be housed. These institutions, however, prove the advantage of such a plan. Others contend that the people at large are not in favor of compulsory registration, therefore the law would do but little good. The means must be a graduated one. He deprecates the idea that the disease should be classed as a contagious one. The New York Board of Health had not classed it as a "contagious" disease, but as a communicable disease. When a report comes in to this department, notices are at once sent out to the physician and to the patient, giving proper instruction as to preventive measures. Another important thing is that it is not necessary for the general public to be aware that a tuberculosis has been

reported to the board of health. The records are simply for the use of this special department. It was from fear of this that a strong protest was made against compulsory registration in New York. At this time in New York, where there is compulsory registration, about 10,000 cases are reported annually, excluding duplicates. It has been found that a man suffering with the disease goes from institution to institution, thus being reported often as many as 15 or 20 times. City hospitals for advanced cases, and country hospitals for incipient cases, seem to be the ideal plan.

The speaker, by means of the stereopticon, demonstrated how he had arranged and classified infected houses and districts throughout the city. What seemed striking was that as many as 22 cases of tuberculosis had been reported from only one tenement house, while in other houses in the immediate neighborhood no case had developed. In one district or block with a population of 1165 persons, 104 cases of tuberculosis had been reported. In another quarter, with a population of 2100, there had been 206 cases reported. He had found that those who opposed compulsory registration never had anything better to offer. In New York since 1866 there had been a reduction in the number of cases of 35 per cent, and with compulsory registration properly carried out he believed that within the next five years the number of cases will be reduced at least one-third.

Dr. A. C. ABBOTT, of the Philadelphia Health Department, endorsed all the views of the speaker. He believed that the object of compulsory registration was not generally understood by the public nor by physicians. What the health department wanted mainly to find out is where these cases live so that proper instruction could be given. He could see no reason why any one should oppose compulsory registration.

Dr. J. C. WILSON had not previously come to any definite idea as to the practicability of compulsory registration of cases of tuberculosis. On this question he believed that there was a great diversity of views. He believed, however, that if such measures as advocated by the speaker were adopted good would result to the patient and public.

Dr. A. V. MEIGS spoke in opposition to compulsory registration. He did not believe in the infectiousness of the disease as was generally taught. He believed, however, that he was on the side of the minority. He quoted from English authorities who also doubted the specificity of the disease. If such a law were enacted it would not have the sanction of the public at large and hence would be avoided. As to the plan of placarding houses in cases of diphtheria and scarlet fever it doubtless leads to secreting them from the public.

Dr. J. M. ANDERS believed in compulsory registration, though at first the measures adopted must be mildly administered.

Dr. L. W. FLICK stated that if those who opposed this plan would come in contact with the poor classes they would soon be convinced of their error. He believed that the foci of the disease were at the homes of the tuberculous, and that compulsory registration would prevent many cases from occurring.

Dr. LAMBERT OTT spoke in favor of compulsory registration. He had been able to trace the contagion even before the specific micro-organism had been discovered. In certain instances he had warned families against moving into an infected house, some of whom had subsequently become tuberculous.

Dr. W. M. L. COPLIN, as a laboratory worker advocated compulsory registration. He thought that the plan was best for the patient, for the family, and for the community at large.

Dr. WM. WOONS spoke in opposition to such a measure; in his opinion harm would result. He referred to the commonness with which the disease was widespread among the lower animals, and even fishes.

Dr. SIMON FLEXNER thought that the last speaker had furnished the missing link in the chain of evidence of the value of compulsory registration.

Dr. ALFRED STENGL was in favor of the measure, as was Dr. SENECA EGBERT.

Dr. GUY HINSDALE offered a resolution to the effect that the Philadelphia County Medical Society sanction compulsory registration in tuberculosis. This was carried with only one dissenting voice.

Books and Pamphlets.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

BOOKS.

INTERNATIONAL CLINICS. A Quarterly of Clinical Lectures and Specially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattel, A.M., M.D., Philadelphia, U. S. A., with the collaboration of John E. Murphy, M.D., of Chicago; Alexander D. Blackder, M.D., of Montreal; H. C. Wood, M.D., of Philadelphia; T. M. Rotch, M.D., of Boston; E. Landolt, M.D., of Paris; Thomas G. Morton, M.D., of Philadelphia; and Charles H. Reed, M.D., of Philadelphia, with Regular Correspondents in Montreal, Paris, Leipzig, and Vienna. Volume III, Tenth series, 1900. Cloth; pp. 301. Price, \$2.25. Philadelphia: J. B. Lippincott Co. 1900.

A MANUAL OF MATERIA MEDICA AND PHARMACOLOGY. Comprising all Organic and Inorganic Drugs which are and have been official in the United States Pharmacopoeia, together with Important Allied Species and Useful Synthetics, Especially designed for Students of Pharmacology and Medicine, as well as for Druggists, Pharmacists, and Physicians. By David M. R. Culbreth, Ph.D., M.D., Professor of Botany, Materia Medica, and Pharmacology in the Maryland College of Pharmacy. Second Edition, Enlarged and Thoroughly Revised. With 464 Illustrations. Cloth; pp. 885. Price, \$4.50 net. Philadelphia and New York: Lea Brothers & Co. 1900.

OBSTETRIC CLINIC. By Deauslow Lewis, Ph.C., M.D., Professor of Gynecology in Chicago Polyclinic. A Series of Clinical Lectures on the Subjects of Interest to Students and Practitioners, at the Cook County Hospital, Chicago. Together with Remarks on Criminal Abortion, Infanticide, Illegitimacy, the Restriction of Venereal Diseases, the Regulation of Prostitution and other Medico-Sociological Subjects. Cloth; pp. 652. Price, \$3.00. Chicago: E. H. Colegrove.

DISEASES OF THE THROAT, NOSE AND EAR. A Clinical Manual for Students and Practitioners. By P. McBride, M.D., F.R.C.P., Ed., Fellow of the Royal Society of Edinburgh. Third Edition, Enlarged and Thoroughly Rewritten. With 744 Illustrations and Original Drawings. Cloth; pp. 744. Price, \$7.00. Edinburgh and London: Young J. Pentland. Philadelphia: P. Blakiston's Son & Co. 1900.

URIC ACID AS A FACTOR IN THE CAUSATION OF DISEASE. A Contribution to the Pathology of High Blood Pressure, Headache, Epilepsy, Menstrual Diseases, Patulous Renal Hemoglobinuria and Anemia, Bright's Disease, Diabetes, Gout, Rheumatism, and other Disorders. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P., Physician to the Metropolitan Hospital. Fifth Edition. With 75 Illustrations. Cloth; pp. 846. Price, \$5.00. Philadelphia: P. Blakiston's Son & Co. 1900.

A MANUAL OF HYGIENE AND SANITATION. By Seneca Egbert, A.M., M.D., Professor of Hygiene and Dean of the Medico-Chirurgical College of Philadelphia. Second Edition, Enlarged and Thoroughly Revised. Illustrated with 77 Engravings. Cloth; pp. 435. Price, \$2.25. Philadelphia and New York: Lea Brothers & Co. 1900.

CANCER OF THE STOMACH. A Clinical Study. By Wm. Osler, M.D., and Thomas McCrae, M.B. (Tor.), of the Johns Hopkins Hospital, Baltimore. With Illustrations. Cloth; pp. 157. Price, \$1.25. Philadelphia: P. Blakiston's Son & Co. 1900.

A HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT. By Helen B. Swanzy, A.M., F.R.C.S. L. Examiner in Ophthalmology to the University of Dublin. Seventh Edition. With 165 Illustrations. Cloth; pp. 607. Price, \$2.50. Philadelphia: P. Blakiston's Son & Co. 1900.

PAMPHLETS.

ANNUAL REPORT OF THE DEPARTMENT OF PUBLIC HEALTH. City of Newark, N. J. 1899. Paper; pp. 128.

A BULLET IN THE POPULATED SPACE. A CASE OF DILATED COLICUS, SHOWING A MILD, BUT NOT A SEVERE, INFLAMMATION AND IN THE SAME TIME THAT IN THE FIRST CASE THEY WERE MISLEADING. A CASE OF APPENDICITIS IN WHICH THE APPENDIX BECAME PERMANENTLY SOLDERED TO THE BLADDER, LIKE A THIRD RECTUM PRODUCING A URINARY FECAL FISTULA. Miscellany.

MARINE-HOSPITAL NOTES.

SOME OF THE WORK OF THE SERVICE FOR THE YEAR ENDED JUNE 30, 1900.

MARINE-HOSPITAL DIVISION.—There are now 21 U. S. Marine Hospitals and 115 additional relief stations maintained by the Marine-Hospital Service. A new hospital was opened at Dutch Harbor, Alaska, and relief stations established at San Juan and Ponce, Porto Rico, and at Honolulu, Hawaii. Patients to the number of 12,904 were treated in hospital and 1380 operations were performed. Aid was extended to other branches of the government service, as follows: To the Life-Saving Service, in the physical examination of 1467 surfmen and the examination of 360 claims of surfmen for relief benefits; to the Revenue-Cutter Service, in the examination of 977 applicants for enlistment; to the Steamboat-Inspection Service, in the examination of 2437 applicants for pilots' licenses; to the Coast-Survey and Lighthouse Service, in the examination of 9 applicants for enlistment; and to the Immigration Service, in the medical inspection of 488,572 immigrants.

DOMESTIC QUARANTINE DIVISION.—There are now 13 fully equipped quarantine stations, employing 27 medical officers, 7 stewards, and 150 attendants; and 12 maritime inspection stations, employing 12 medical officers. During the year 4917 vessels were inspected and 597 disinfected. On the border of Texas three inspection stations are maintained, at the following places: Laredo, Eagle Pass and El Paso. At these stations 1521 trains, carrying 35,316 passengers, were inspected; of these passengers 213 were detained and 482 refused entry.

FOREIGN QUARANTINE DIVISION.—Maritime quarantine has been conducted in Cuba, Porto Rico, Hawaii and the Philippines. There are 19 quarantine stations in Cuba, 9 in Porto Rico, 3 in the Philippines, and 4 in Hawaii.

ARMY NOTES.

The tabulations of the cases of suicide and homicide which occurred in the army during the years 1898 and 1899 are compared in the annual report of Surgeon-General Sternberg with the cases which occurred during the ten years 1888-97. Contrary to the general anticipation it is found that there were among the troops during the past two years relatively fewer homicides than during the years of the previous decade and that the mean annual ratio of suicides per 1000 men was about two and one-half times greater during the decade of peaceful garrison life than during the recent period of active military service. The following figures show the rates for three years:

Year.	Suicides.		Homicides.	
	Mean Strength	Ratio per thousand.	Number.	Ratio per thousand.
1888	26,739	8	30	5
1889	27,206	21	77	5
1890	26,684	16	69	7
1891	26,460	22	83	8
1892	26,861	22	82	5
1893	27,659	22	80	5
1894	27,674	18	65	10
1895	27,326	19	70	1
1896	27,183	12	44	4
1897	27,374	10	37	5
Mean of decade	27,116	17	63	5.5
1898	147,795	38	26	19
1899	105,546	30	28	23

Therapeutics.

VOMITING.

Vomiting may be caused by various pathological conditions of the stomach. It may be due to some spinal or brain trouble, organic in nature or arise reflexly from diseased conditions of the other organs, such as involvement of the upper air-passages or digestive apparatus—the palate, pharynx, larynx, esophagus—or from disturbances of the liver, organs of reproduction, dislocated kidney. It may also originate from functional disturbances of the nervous system, which include neurasthenia, hysteria, juvenile and periodic or cyclic vomiting. The process of vomiting relieves the stomach of its contents through the esophagus and mouth. The mechanism includes the contraction of the abdominal muscles and of the diaphragm, which compresses the abdominal cavity and causes the contraction of the walls of the stomach, the simultaneous closure of the pylorus and the opening of the cardia. The epiglottis protects the larynx while the soft palate guards the entrance to the posterior nares, leaving a free and unobstructed passage from the stomach to the mouth. Below are given prescriptions adapted to some of the forms of vomiting.

VOMITING IN PREGNANCY.

Bacon states that proper intracranial circulation should be maintained by assuming the horizontal position, which is the most important of all things in treating vomiting due to this cause. This position must be persistently maintained. Keep the head lower than the feet and give nourishment without raising the head. During the attacks of vomiting the patient may be turned on the side, but for no reason should she be raised.

1. Rest in bed.
2. A cup of strong coffee, without sugar or cream, in the morning before rising.
3. Liquid diet, milk with lime-water added, egg albumin, somatose, beef-juice.
4. It is sometimes advisable to wash out the stomach—lavage.
5. Rest the stomach and give rectal alimentation.

SEVERE HYPEREMESIS.

The *Atlanta Med. Journal* contains the following extracts from an article written by Twombly, who quotes authorities for and against radical interference in severe hyperemesis.

Klein states: "In hyperemesis of the third degree the artificial induction of labor is occasionally required."

Bacon: "Induction of abortion is never indicated."
Leclerc: "Good results from simple cauterization of the cervix."

Lusk: "There remains as an ultimate resource the artificial induction of abortion."

Jewett: "Evacuation of the uterus is often too long delayed."

And, according to the *Atlanta Medical Journal*: "The indications for emptying the uterus are: 1, inability to retain any food by the mouth; 2, intolerance of rectal enemata; 3, more or less albuminuria; 4, progressive emaciation; 5, constant headache; 6, frequent and feeble pulse."

PERSISTENT VOMITING.

Dr. Mitchell, in *Med. Summary*, states that he has succeeded in overcoming persistent vomiting by the aid of cold compresses, by wringing towels out of iced water and placing them over the epigastric region and changing them every minute until vomiting ceases. He states that in this way he can check vomiting in fifteen or twenty minutes.

Can Not Testify as to Sobriety of Patient.—The Supreme Court of Iowa apparently sanctions the rule that a physician may state the fact of his attendance upon a patient, but not his condition, even as regards sobriety. For example, in the personal injury case of Finnegan vs. the City of Sioux City, the plaintiff had said that he was not treated for delirium tremens at the time of treatment for his injury. His attending physician was called as a witness by the defendant, and it was sought to be shown by him that the plaintiff at this time had delirium tremens. But this testimony was excluded by the trial judge, and the supreme court holds properly. The matter asked for, it says, was in the nature of a confidential communication, privileged under section 4608 of the Iowa code. Facts learned by a physician while in the discharge of his duties as such, it declares, are within this section.

Accident Insurance Covering Death by Sunstroke.—The Court of Appeals of Kentucky says, in the case of the Railway Official & Employees Accident Association vs. Johnson, that if it were to go to the adjudicated cases bearing on the subject, or to reason the case out, to determine whether death caused by sunstroke should be considered accident, much might be said one way or the other. But it finds itself relieved of the necessity of deciding that question here by the terms of the contract of insurance. The policy itself expressly provided that disability or death caused by or contributed to by sunstroke or freezing while the insured, a railway employee, was not in the line of his duty as such employee, should reduce the liability to one-fourth. And this, the court holds, certainly meant that if the sunstroke was received while in the discharge of his duty there would be full liability; otherwise, one-fourth liability.

Attaches Pecuniary Value to Physical Training.—In the case of Hoadley vs. the International Paper Company, the Supreme Court of Vermont points out that the law shows that it not only recognizes a pecuniary value in intellectual and moral training because of the provisions it has made for it, but that it also recognizes the pecuniary value of physical training in including elementary physiology and hygiene among the studies to be taught in the common schools of the state. Continuing, the court says that it needs no argument to prove that physical training is as necessary for the well-being of a child as mental and moral nurture. The experience of everyday life emphasizes this fact. It is equally apparent, it declares, that such training has a pecuniary value. Besides, it is convinced that the training of the child mentally, morally, and physically by the parent may be, and often is, more effective and lasting for good than any instruction received in schools and colleges. Wherefore, it in this case holds that the loss in this respect of the minor children of the man whose death was the subject of the action was proper to be considered in determining their pecuniary loss resulting from their father's untimely death, which was attributed to the negligence of the defendant.

Proper and Improper Expert Evidence in Rape Case.—The Supreme Court of California holds, in the case of People vs. Benc, a prosecution for rape, that the testimony of a physician as to the condition in which he found the sexual organs of the prosecutrix some four to six days after the alleged rape was admissible in evidence. The jury, it states, were the judges of its probative force. Moreover, it says that it has been held that the condition of the hymen six months after the alleged rape may be shown, the remoteness of the evidence going merely to its probative force. Then, a medical witness was asked, in this case: "As a physician, having knowledge of the strength and physical condition and development of a man and of women, do you think it possible for a man to have forcible intercourse with a girl well developed, and weighing 138 pounds, without her consenting to the performance of such sexual act?" But, without stopping to inquire if the proposition involved in this question was admissible at all, the court holds that it was not a subject for expert opinion. The jury, it declares, were as competent to answer the question

as a physician would be. It also holds incompetent and improper as evidence in such a case a statement made by a physician that medical authorities place the proportion of town to false charges of rape as one true charge to twelve false ones.

Registry Essential to Recovery of Fees.—In the case of *Acetia vs. Zupa*, an action brought to recover for professional services, the defendant denied that the plaintiff was duly qualified, registered, and authorized to practice medicine as a physician in Kings county, New York. The plaintiff proved that he was admitted to practice and graduated in the University of Naples, and had passed an examination in the University of the State of New York, was licensed in 1896, and had practiced medicine since that time. Now, after proof that the plaintiff was a regular physician, the defendant was bound, the second appellate division of the Supreme Court of New York holds, to sustain the allegation that the plaintiff was not licensed and authorized to practice in Kings county. In other words, it holds that the plaintiff was not bound, in the first instance, to prove that he was a regularly licensed physician, the burden of proof in the matter, in such a case, being on the defendant. Next, it holds that, counsel for the defendant having for this purpose offered the Register of Physicians and Surgeons of Kings County, volume 2, to show that at the time of the rendition of the services in question the plaintiff was not a registered or licensed physician in Kings county, the exclusion of the record was error. It adds that if the plaintiff had desired to raise a question as to its being a public record, his objection should have been specific, and the defendant would then have been called upon to prove the authenticity of the volume by showing the source of its production and that it was kept by authority. But an objection that it was incompetent, immaterial, and irrelevant, it holds, was not sufficient to raise that question. Nor does the court consider that the evidence was irrelevant and immaterial. It holds that registry was essential to a recovery, under the provisions of the New York public health law, which make it a misdemeanor, punishable by fine and imprisonment, to practice medicine without registration.

Town Should Pay for Attendance on Poor Person.—By section 1512 of the Revised Statutes of Wisconsin it is provided that when any person not having a legal settlement therein shall be taken sick, lame or otherwise disabled in any town, city, or village, or for any other cause shall be in need of relief, as a poor person, the supervisors or other proper authorities shall provide such assistance as they may deem just and necessary, and shall make such an allowance for medical aid, etc., as they shall deem just and shall order the same to be paid out of the town, city or village treasury, and the expense so incurred shall be a charge against the county, the account of the town therefor to be audited by the county board and paid out of the county treasury. At the same time, it makes it the duty of the authorities to notify the county clerk within ten days after such a person so becomes a public charge, whereupon the county authorities may take charge of such poor person and remove him to the county poor farm or relieve him in such other manner as they may see fit. But, in the case of *Ebert vs. Langlade County*, the chairman of a town notified the county clerk of such a poor person in the town who became suddenly in need of medical treatment, and those two officials employed a physician to render the required medical treatment, and agreed that he should file his claim for services with such county clerk, to be paid by the county. The claim was in due time filed pursuant to such agreement, and a taxpayer brought this action to enjoin the county from issuing a county order on the audited bill for medical services. With the taxpayer the Supreme Court of Wisconsin agrees that the course pursued in this instance was clearly wrong. It holds that under the statute the town became the debtor of the physician; that he did not have any legal or equitable demand enforceable against the county, and that the latter had no legal right to allow or pay his claim. The claim, it continues, should have been presented to and audited by the auditing board of the town and paid out of the town treasury like any other town liability, and

a claim should then have been presented by the town to the county for reimbursement. Yet, while the supreme court holds that the statutes should be strictly followed at every step in incurring public liabilities and in the disbursement of public moneys, as the county was ultimately liable for the amount, it does not consider it a case for an injunction.

2. **Endothelioma of Bone.**—The case reported by Brandt was published in the previous number of the *New York Medical Journal*, and he discusses in this issue the origin of the growths and reviews the literature. He remarks that most of these growths have their origin in the blood-vessels, but doubts that an irritating substance in the blood causes a proliferation of the endothelium as suggested by Koenig. The growth is one of extreme malignancy and, if recognized in its early stages, may be relieved by prompt operation. Heredity seems to be lacking, but it predominates in the male sex. It occurs more in people past middle life, and is nearly always preceded by a history of trauma. Swelling is noticed first, this gradually increases and then is accompanied with pain sometimes quite intense and perhaps radiating. With these a distinct pulsation is seen and a bruit heard over the tumor. The skin remains normal and the periosteum seems to be uninvolved. Unless removal of the tumor is practiced, gradual absorption of the bone will eventuate in spontaneous fracture. The general symptoms are anemia, anorexia, emaciation, chills and fever, and, in the later stages, delirium.

4. **Etiology of Eczema.**—Bulkley reviews the various predisposing causes of eczema as: 1, inherited states, like tissue debility, eczema of parents, scrofula, gout and rheumatism, neuroses, bronchitis and asthma, and 2, acquired states, such as assimilated disorders, dyspepsia, auto-intoxication, hepatic disorder, lithemia, anemia, intestinal derangements, pulmonary disorders, etc., and then discusses the relation of neurosthenia, neuroses, cardiac disorders, faulty nutrition, dietetic errors, etc., to the disease.

5.—See Society Proceedings in this number.

6. **Delirium Tremens.**—Douglas criticizes a recent article on the treatment of delirium tremens by large doses of digitalis and restraint, and contrasts it with his own treatment by apomorphin in anodyne doses, together with the gradual withdrawal of alcohol and nourishment. He says that in delirium tremens he never uses forcible restraint, never suddenly withdraws alcohol, and has never had a death.

8. **Public Health Laboratories.**—Smith's address covers the field of the importance of laboratories for public-health purposes, their possibilities, methods, uses and dangers. He suggests that the tendency to crystallize the methods is both a safeguard and a danger since they guide us and make results homogeneous, but they also tend to routinism, to stifle discovery, and to the maintenance of stereotyped and not always most advantageous procedures. The laboratory should always be testing and devising new methods, ever having as its guide the purpose in view.

9. **Feeding in Typhoid.**—The old rule of keeping typhoid patients exclusively on a liquid diet is noticed and the experience of Moorehouse with the more general feeding detailed. He gives the details of several typhoid diets, ranging from the strict milk diet, through the liquid, including broths, etc.; the soft typhoid diet, adding some well-cooked gruels, crackers, soft eggs, etc.; the convalescent diet, including the more digestible means and vegetables; and the full typhoid diet, which is one that can be easily endured by the healthy individual. The results are detailed. In some cases there was an apparent tendency to increase of fever or what might be considered a relapse, though he does not so regard it in all cases. He thinks he has included among relapses some that would not be so considered by others. The mortality was reasonably small only 13 out of a total of 150 cases, and in all the deaths the patients were on a liquid diet though one had been put on a soft diet for a short time before; so it is apparent that the more generous diet did not have any serious effect in increasing mortality. In cases of apparent relapses, there was one death, giving a mortality of 3.3 per cent., which compares

favorably with 9.1 per cent. reported by Hare from 252 cases in the literature. The average stay in the hospital on a milk diet has been 10 days, the average time from the first order of increasing the diet to the order for the patient to be propped up in bed with a bed-rest, 18 days. These events divide the first 28 days of the average patient's stay into two periods. In the first, 9 relapses occurred and in the second, 21. The usual period of relapse is during convalescence or after complete defervescence, so it would appear that diet does not specially influence the relapse as judged by this fact. He quotes the statistics of a Russian army surgeon, Bushuyev, which were very favorable to a generous diet. Moorehouse remarks that the conclusion as to the advisability of a fuller diet will be judged by the mortality and offers his experience as a contribution toward the settlement of the question.

13. **Yellow Fever.**—Wasdin criticizes the recent article of Reed and Carroll and maintains his old position as to the part Sanarelli's bacillus plays in the production of the disease. He also criticizes their experiments regarding mosquito-transmission of the disease.

14. **Carcinoma of the Rectum.**—Deaver describes the different forms of carcinoma which may affect the rectum. The vast majority are of the cylindrical-cell type, while clinically, several varieties may be distinguished, scirrhus, the medullary or encephaloid and colloid. The symptoms, especially the early ones, appear to bear no relation to the gravity of the affection. Pain is the most frequent symptom; it is often intense, tenesmus is often distressing, and diarrhea is constant and troublesome. The prognosis depends upon the position and extent of the growth and the time which has elapsed since beginning. Ordinarily the disease is situated about 2½ to 3 inches above the anus, but it may start higher up and then the growth is more rapid as a rule, and an earlier colotomy may be necessary to relieve the pain. The characteristic "feel" and odor render the diagnosis unmistakable. The only condition that might be confused with it is indurated ulceration causing stricture. The insidious beginning of the disease makes it advisable, in Deaver's opinion, to make a rectal examination in every case of more or less continuous diarrhea. The radical measures offer the best chance of relief. His practice in dealing with carcinoma of the rectum is as follows: Where the growth involves the terminal part of the rectum and includes the anus, the operation of removal is made through the perineum; the mucous membrane of the bowel above being stitched to the skin margin of the circular perineal incision. Where the growth involves the lower portion of the rectum, exclusive of the anus, it is removed through a posterior median incision, taking away the coccyx with, in many cases, the last one or two segments of the sacrum. By this modified Kraske method, as in that for the removal of a growth occupying a higher location, the diseased portion of the bowel is excised and end-to-end union of the divided bowel made. This permits of re-establishment of the function of the bowel. Where the growth occupies the upper portion of the rectum, and to some extent the terminal portion of the sigmoid, it is removed through the posterior median incision, taking away the coccyx and the lower three or four segments of the sacrum. Here, end-to-end union of the divided bowel is practiced. Cases, reported by him in the *Transactions of the Academy of Surgery, of Philadelphia*, for the year 1900, show three successful cases with complete restoration of bowel function. The section of the sacrum is made with chisel or osteotome, and the ligaments and soft tissues cut with scissors curved on the flat and made to hug the bone, thus dividing the vessels where they are smallest and readily reached. The amount of bleeding is not great, hence shock is of minor importance. On one occasion he first opened the abdominal cavity and tied the inferior mesenteric artery. This he has never repeated, as he considers it too much surgery where less suffices. He does not consider preliminary colotomy necessary, and would practice it only when incision of the rectum is to be done later. He regrets that more radical surgery is not permissible, by which he means removal of the lymphatic glands of the mesosigmoid. If this could be done, the outcome would be more promising. When the growth occupies the rectum high up and can not be

ected by examination through the rectum and vagina he opens the abdomen in the left iliac region. The growth in the rectum can be taken out by a posterior incision; the sigmoid is divided transversely and removed with its mesentery as far as the growth, and the margins of the upper opening are stitched, closing the lower part of the incision entirely.

15.—See abstract in *THE JOURNAL*, xxxiv, p. 1416.

20. **Surgical Importance of Jaundice.**—The early theory that jaundice is always due to obstruction is noticed by Macaren, who points out its incorrectness and then reports a case illustrating his views. The diagnosis of obstructive jaundice was apparently clear, but an operation developed a perfectly normal biliary system and a large appendicular abscess. Other similar cases of jaundice are mentioned and the cause in these cases is presumed to be a toxemia. The general conditions producing jaundice are noticed, and as regards its surgical importance the author concludes: 1. That slight attacks of jaundice are of comparatively little surgical importance, and that the majority of surgical diseases of the biliary passages are no jaundice at all. 2. That persistent jaundice, especially if progressive, is usually a contraindication to operation. 3. Intermittent, deep jaundice, especially if associated with chills and a rise in temperature, denotes a stone in the common duct which urgently demands removal.

22. **Pernicious Anemia.**—The symptoms, etiology, diagnosis, prognosis and treatment of pernicious anemia are discussed by Trowbridge, who reports a case and emphasizes the following points: In cases of apparent chlorosis and primary anemia in which there is present the greenish tint of the skin, together with dyspnea, palpitation, and general malaise, one should not depend on symptoms for the diagnosis, but should let the blood examination decide whether one is dealing with either of these diseases or with a case of pernicious anemia.

24. **Diagnosis of Biliary Diseases.**—The object of Brewster's paper is to present a tabulated diagnosis-chart pointing out the different symptoms observed in the various forms of diseases of the gall-bladder and its ducts, and together with the chart he reviews the symptoms in detail. Pain is one of the three chief symptoms and repeated attacks occurring in aroxyms in the upper right quarter of the abdomen strongly suggest a lesion of the biliary passages. This suggestion is enforced if the attacks occur at night or during fasting, and are accompanied with vomiting or fever, and still more if the pain leads up toward the back and shoulder and there is an area of tenderness under the free border of the ribs. The appearance of tumor is indicative rather of cholelithiasis, and jaundice without tumor, of a lesion of the common duct. There are conditions giving rise to acute pain in the upper abdomen that have to be excluded, such as that from gastric ulcer usually without fever, but with some tenderness in the epigastrium or left hypochondrium, and appendicitis, where it is generally in the right lower quarter. Renal calculi, gastric crises of tabes, intestinal obstruction, and syphilitic hepatitis, all of which are generally more or less prominent characteristics of their own, are also mentioned, though some of them may have symptoms almost identical with those calculous diseases. The tumor which sometimes occurs, smooth, elastic, perceptibly moving with respiration just under the abdominal wall below the ribs and near the outer margin of the right rectus muscle, which cannot be made to disappear like a movable kidney, and has a certain amount of lateral motion without pain and fever, is probably the distended gall-bladder—hydrops. If with such a tumor there is a progressive jaundice, it is probable that the gall-bladder is distended with bile and that there is common-duct obstruction. If sensitive to touch and accompanied by fever it is doubtless a gall-bladder distended with pus. If the tumor is not well defined on account of muscle rigidity, and there is acute radiating pain and marked tenderness, we generally have to do with cholecystitis with local peritonitis. The presence of tumor corresponding to the above description without pain or fever and with progressive increasing jaundice and irregularity of its surface probably indicates cancer. Mild jaundice without other symptoms generally is due to catarrhal obstruction of the common ducts. Temporary jaundice with

pain suggests the passage of stone through the common duct. Intermittent jaundice with pain and fever suggests a floating stone in the common duct. Continued jaundice with chills, fever, hepatic enlargement and tenderness, splenic hypertrophy and general sepsis means infective cholangitis. Progressively increasing jaundice and enlargement of the liver with previous history of colic suggests impacted stone near the patella. Progressively increasing jaundice without pain or fever, but with tumor of the gall-bladder is indicative of common-duct obstruction from a new growth.

25. **Diabetes Mellitus.**—Stern's article is principally a tabulated analysis of the mortality from diabetes mellitus according to the month, sex, age, nationality, occupation, accompanying affections, etc., in New York City.

26. **Suprarenal Capsule.**—Floersheim reports the results of suprarenal capsule in disease of the lower air-passages, including bronchiectasis, bronchial asthma, lung congestion and edema, hemoptysis, and pulmonary tuberculosis. Seven cases are reported in which the use of the drug gave more or less relief. He orders it in the form of 3-grain capsules, chewed without water and swallowed after a few minutes. The action of the drug is apparent in from two to fifteen minutes. In the majority of the cases the action was temporary, continuing from ten minutes to six hours, but in some it was permanent.

47. **Spinal Cocainization.**—McLean describes the methods of medullary analgesia, reporting several different cases. He insists on asepsis and caution in the operation, and says he would not recommend the use of the method without caution and close observation afterward.

48. **Compound Fractures.**—Wyman pleads for the treatment of compound fracture by extension and external manipulation without putting the fingers near the wound, using only sterilized forceps and gauze to remove foreign bodies, disturbing the clot as little as possible, placing the foot and limb in a position of physiologic rest, making sure that the soft parts as well as the bone are approximated, and then sealing it all with an aseptic dressing of gauze and cotton. With this he says he is sure his cases heal with about the same results as in simple fracture. More time and more restraint will be needed, but there will be little more pain or constitutional disturbance. He fears that many doctors, in their zeal to secure an aseptic wound, sometimes fill the wound up with filth in the preliminary washing. Great care should be taken to avoid rubbing anything from the surface of the skin into the wound. Before the wound is washed, it should be effectively plugged with aseptic material.

52. **Trigeminal Neuralgia.**—Aldrich discusses the treatment of this condition, especially the strychnin treatment and mentions several cases in which he found castor-oil efficacious. Since then he has followed with better success than ever before the following treatment: The patient is put in the hospital in a quiet room under the care of first-class nurses; his mouth is carefully examined by a competent dentist—he usually finds that the incompetent dentist has drawn about all the teeth the patient had, before coming to him, sound and unsound alike—the urine is carefully examined and the quantity measured; the abdominal and pelvic organs are examined with assiduous care; the heart, and in fact the whole circulatory apparatus as well as the blood is studied, and, to use a commercial phrase, "stock is taken" of all the organs and functions of the body. The first morning the patient receives the initial dose of castor-oil, which is one ounce if the patient is not taking opiates, and two ounces if he has become an habitué or is temporarily using them. A solution of nitrate of strychnin is prepared, one minim of which should represent 1/200 grain. Of this solution he receives 20 m. four times a day as

the initial dose, with orders that the dose should be increased one drop in every twenty-four hours, being an actual increase of 4/200 grain each twenty-four hours. If the patient has been taking morphin, the least possible dose that will relieve the pain is continued for the first two or three days, after which time the dose is gradually diminished by the following method: If it requires one-half grain at each hypodermic injection to relieve pain, an ounce solution is prepared, 30 m. of which represents one-half grain; this solution is kept where it will be in the sight of the patient, and the nurse is instructed to come into the room with a syringe containing 30 m. of sterilized water, and when she prepares to give the morphia, the contents of the syringe are expelled carefully into the bottle, which should be shaken and the usual dose drawn into the syringe and administered. Any competent nurse can do this without the patient being aware that his dose is diminishing every day. If these directions are followed there will be little trouble in weaning the patient from the morphin habit, which is almost as dreadful as the disease itself. In addition to this, if arterial sclerosis is suspected he sometimes found it necessary to use nitroglycerin. This drug is very evanescent in its effects, and he was obliged to give it in full doses, as much as the patient could stand. It can be gradually increased with comparative safety. In some cases of atheromatous disease he has found thyroid with nitroglycerin to have good results, and he has failed to meet with cases where strychnia was absolutely contraindicated or where he felt there was reason for discontinuing the drug excepting when symptoms of strychnia poisoning appeared. He suggests caution in regard to this.

56.—*Ibid.*

57.—*Ibid.*

58.—*Ibid.*

61. **Heart Disease or Epilepsy.**—In this article Pearce endeavors to point out the possible existence of a great similarity between epileptoid phenomena—*petit mal*—where the cardiac action is affected primarily or where the so-called heart failure predominates in the symptomatology, and syncopal attacks independent of the epilepsy neurosis. The subject was first brought to his attention by the case of a man where skilled diagnosticians, including Dr. Da Costa, were unable to determine the nature of syncopal attacks coming on at irregular times. Consciousness was entirely preserved; there were no physiologic signs of heart disease or vascular sclerosis; urinalysis and eye-grounds were negative. Exercise and mental strain alike produced the attacks, which had no sequelae, but tended to recur in spite of dietetic, hygienic and medicinal treatment. A year later the patient developed convulsive seizures alternating with these typical syncopal attacks. A slight sunstroke several years previous was the only objective cause. The man died later of meningitis. He accounts for this case, therefore, by assuming an irritative lesion of the vagus center in the medulla, gradually rising to the motor cortex and due to an insidious meningo-cerebritis from sunstroke. A characteristic point in the syncopal attack was the slow pulse, which did not average over 54 per minute, was at times very irregular, but did not intermit. Other cases are given differing in some respects from the one given, and he concludes that there is a minority of cases of heart failure in which the true origin is difficult to discern. Organic disease of the heart is rarely the cause of convulsions, excepting when due to emboli, in which case paralysis or death usually follows. The less frequent and variable the apparent unconsciousness during an attack of syncope, the more likely the epileptoid nature. The condition in children is most difficult of diagnosis. The presence of a slow, full and irregular pulse, with or even without unconsciousness favors the epileptoid nature of the attack. Leaky skin and cold extremities are more in favor of hysterogenic cases. The absence of pain in any case eliminates angina. Cyanosis is not common, except in organic heart disease. The tendency to rigidity without convulsions favors hysteria.

63.—See abstract in *THE JOURNAL* of September 29, p. 841.

64.—*Ibid.*, October 6, p. 904.

67.—See abstract in *THE JOURNAL*, xxxiv, p. 1416.

68. **Rectal Surgery.**—The cases here described are three of congenital absence of the coccyx, closure of artificial anus of three years' duration, and stricture of the rectum in an infant eleven months old, caused by swallowing an open safety-pin.

69. **Blastomycetic Dermatitis.**—This article is a report of bacterial and cultural examinations of preparations from a case reported by Brayton in the *Indiana Medical Journal* of April, 1900, as blastomycetic dermatitis. The scrapings from the fingers were examined by Golden and two organisms found, one, a yeast, which, when tested in all the various media, as well as examined under the microscope, differed from any hitherto described species. There was also a mould, which examined similarly as to its growth on agar, gelatin, bouillon, potato, etc., also appeared to be a new type. As the work on this species is incomplete, conclusions are hardly justified as to its complete full life-history. A number of inoculation experiments were tried on dogs, rabbits and guinea-pigs which in some cases produced scabs and pustules, but in others were comparatively negative. Dr. Brayton adds a note stating that the patient recovered from his disease, which lasted one and a half years, after the diseased tissues had been removed twice under ether. A notable point is that the cultures were made from specimens that had been in a weak solution of formalin which did not seem to inhibit their growth.

70.—See abstract in *THE JOURNAL* of September 15, p. 706.

74.—*Ibid.*

76. **Spermin.**—Thelberg reports two cases in which impotence was treated with Poehl's spermin solution, 1 c.c. given daily subcutaneously, and in both cases with success.

78. **Spermin in Pulmonary Phthisis.**—Mays reports experiments of the use of spermin in phthisical patients with observation of the temperature, pulse and respiration. He finds that the hypodermic injection of 5 to 10 minims of Krieger's spermin diminished the temperature somewhat and reduced the pulse and respiration. There was a feeling of warmth and well-being for a short time, sometimes followed by a disposition to sleep. There was no gain in flesh and he concludes that the injections are of no special value in phthisis.

79. **Testicular Extract.**—McCarthy has used the Brown-Séquard serum in tabetic and neurasthenic patients. The only conclusion he deduces is that in tabes and some other parasphyllitic affections, where the testicular function is deranged, it acts as an excellent tonic, and in association with exercises is attended with beneficial results.

80. **Nuclein.**—Aulde recommends nuclein therapy in various conditions in connection with other measures, especially a light, nutritious diet. He claims that it is non-toxic and antiseptic, an almost constantly normal product of the polymorphous white blood-corpuses and is increased or diminished in accordance with the demands of the system through increased functional activities of these bodies. Increase always attends a leucocytosis, provided the system is in a favorable condition. When the production is defective in quality or quantity, the nutrition is correspondingly reduced, but this may be overcome by the introduction of an artificial product, providing the body-cells have not too long been deprived of their necessary pabulum. The corpuscles themselves normally produce this complex substance from the daily food-supply of the individual. It is curative directly and indirectly, through its influence on cell-metabolism increasing oxidation, favoring elimination, and through its manifest virtues as an antiseptic, as shown in the case of leucocytosis. As regards the bacterial infection, it is not claimed that it does more than to create and maintain conditions hostile to growth and multiplication of micro-organisms, and for this purpose the remedy should be administered hypodermically in full doses. It does not supplant other recognized methods of treatment, neither does it interfere with them excepting in so far as they tend to suspend or arrest cell-metabolism. It is claimed, however, that the addition of nuclein medication not only shortens the ordinary period of illness and lessens its severity, but also prevents complications and creates a feeling of well-being that renders

much of the usual routine practice needless. He gives illustrations of its good effects, immediate mitigation of the symptoms in tonsillitis, rapid arrest of chronic catarrh, etc., and maintains that it offers a most promising treatment in tuberculosis. Scarlet fever is also a disease which he claims is specially amenable to nuclein medication.

89.—See abstract in *THE JOURNAL* of October 20, p. 1050.

96.—See *THE JOURNAL*, XXXV, p. 1086.

99. **Pseudo-Pertussis in Influenza.**—Foreheimer's paper discusses the subject of pertussoid cough connected with influenza. He first notices the definition of influenza and adopts a clinical rather than an exclusively bacteriologic one. In his cases he found streptococci and not the Pfeiffer bacillus. The peculiarities of the cough are that it always moved in epidemics and that it was decidedly contagious. If it broke out in a family, few or none of the family were spared, irrespective of age. The servants who came in contact with the patients were attacked, and in three instances he has seen patients attacked who had previously had whooping-cough. The onset was that of an ordinary attack of influenza. In children there was fever and principally the form of respiratory or gastro-intestinal type of influenza. These symptoms would pass over in possibly two to four days, and then would begin a cough. If the type had been originally respiratory the cough would immediately develop into the characteristic cough, which is described below. If the original attack had been originally gastro-intestinal, all the symptoms would disappear, and then the peculiar cough would develop. This cough is characteristic; it usually first develops at night, but not so distinctly as in whooping-cough, as the attacks would appear during the daytime as well. The cough is that of a whooping-cough except that the peculiar whoop is not so characteristic as in pertussis; however, sufficiently so as to be recognized as a whoop, and in some instances as well-marked as we find it at any time in whooping-cough. It is accompanied by the ordinary congestive symptoms of whooping-cough, is followed by vomiting and expectoration, and in every respect like whooping-cough. The mouth in some respects differs from whooping-cough in that the peculiar blue color of the mucous membrane and of the tongue is absent. This is to be ascribed to the fact that the attacks of coughing are more numerous, but not so long in duration as those in whooping-cough. As to ulcer of the frenulum, his observation has shown that it not only is present, but if anything is better-marked than in whooping-cough. The duration of the trouble varies; left to itself, the disease lasts from six to eight weeks, but in most cases it can be aborted by treatment. He infers from observations that to produce the symptoms of whooping-cough there must be a certain anatomical location of the cause, and this not necessarily the specific cause of whooping-cough. The diagnosis is usually easily made by the fact of the epidemic appearance of this cough connected with epidemic influenza; and that former attacks of croup, pertussis, etc., did not prevent it. As regards treatment, he thinks that a full dose of quinin materially reduces the duration of the disease. Phenacetin and antipyrin afford great relief, but do not materially affect the duration. In some cases belladonna failed, in some its effects were gratifying. When symptoms of septicemia are present, unguentum Crede or even injections of antistreptococcus serum may be of great benefit.

100. **Epidemic Paralysis in Children.**—An interesting epidemic occurred during the summer of 1899 at Poughkeepsie, N. Y. Seven cases were seen by Chapin, in consultation with Dr. Sheedy. The peculiarity of the epidemic appeared to be the existence of severe pain in the parts affected by the paralysis. Two cases are reported, in one of which there was a peripheral neuritis. The most of the patients recovered in from one to four months; but three had paralysis and atrophy, with typical after-appearance of poliomyelitis. The author concludes that the disease was epidemic and that in some cases the infection attacked the anterior horns of the cord, in others, the peripheral, nervous system, and in some, possibly both.

101. **Malarial Coma in Children.**—Acker has had two cases of coma connected with malarial fever in children, which

he thinks were due to the malarial parasite, and reports them in detail with temperature charts. He finds little in the literature about this type and remarks that it is somewhat peculiar that malaria does not produce more disturbances of the nervous system than it does, considering the unstable condition of the latter in poorly-nourished infants. In the first case he thinks there is little doubt as to the malarial nature of the case. In this case lumbar puncture was followed by decided improvement. In the second case there was a complicating nephritis which leaves some little doubt as to the malaria being the sole cause of the coma.

102 and 103. **The Amount of Diphtheria Antitoxin Required.**—In summing up the study of 93 cases, Park says that the local condition in children in markedly severe cases did not clear up as rapidly with one thousand as with two thousand units and in two or three cases he believes death would have been prevented by larger doses. In several other cases, better results would have been obtained by 3000 to 5000 units. Very large and repeated doses of antitoxin somewhat increase the liability to serum complication, but he thinks it correct to say that the increase in serum-effects from very large doses is much less than is generally believed. In his second paper he concludes that antitoxins are, in all probability, substances having the properties of globulin. They can not, with our present knowledge, be separated from that portion of the blood-serum which in susceptible persons produces disagreeable effects. The fact, however, that the antitoxic serum from some horses is scarcely at all deleterious, leads us not to give up the attempt of procuring a serum either by selection of animals or by the treatment of serum itself, which, while antitoxic, is not to any important degree deleterious. For routine practice at present we can scarcely do better than to follow the general plan of using the serum from all healthy animals which have remained healthy during their period of immunization and which have in their blood a sufficient concentration of antitoxin. This should not be less than 200 units in each c.c.

109. **Astereognosis.**—Dereum describes the condition and findings as regards this symptom seen by him in a considerable number of patients and concludes from his studies: 1. That the loss of impairment of the spacing sense is the most important factor in determining astereognosis. It must be remembered, however, that astereognosis may exist, though the spacing sense be preserved. In the single case of hemiplegia in which this was the case, there was, however, a loss of location, a loss of the knowledge of the position of the fingers and marked secondary contracture. 2. Next in importance to the spacing sense appears to be the knowledge of the position of the fingers and ataxia of movement. 3. The mere preservation of the ability to perceive tactile impressions and the preservation of the pressure, temperature and pain senses is insufficient to prevent stereognostic loss. The question whether there are any conclusions of clinical value to be drawn is taken up and he recognizes that in many cases the symptom is undoubtedly of cortical origin. If it is at times cortical and at times peripheral, he asks if there is any means by which the symptom can be made of differential value. While our present knowledge prevents a positive answer he thinks there is a possibility that it may be so employed. Given cases in which the various factors known to be important to stereognostic perception are well preserved and astereognosis nevertheless exists, it may be advisable to infer that the origin of the symptom is cortical. Again if with the astereognosis there are specific or isolated losses, such as the loss of the sense of weight, or position of the fingers or ataxic movement without signs of peripheral nerve or cord disease, it would, other things being equal, justify the inference of brain or cortical involvement. It would indicate not merely cortical involvement but would point directly to a special area of the posterior portion of the superior parietal lobe.

112. **Brain Pressure Following Injury.**—Bullard reports experiments at the Physiologic Laboratory of the Harvard Medical School to determine the cause of brain pressure from various injuries. He finds that the uninjured brain of an

etherized cat will bulge out through the opening left after removal of the bone and the dura unless pressure is applied to keep it in place; the pressure necessary to prevent bulging varied in a typical case from 8 cm. to 16.9 cm. of water, according to the degree of etherization. The more ether given, the greater the pressure until the anesthetic is pushed too far, when it begins to fall. Every factor increasing the general blood-pressure has a direct influence on the brain-pressure, crying, muscular movements, stimulation of the sciatic nerve, etc., all demand a stronger pressure to keep the brain level. Pulsations of the brain are much more extensive after hemorrhage, while the pressure necessary to keep the brain from bulging is less, and after heavy blows on the skull the pressure needed to prevent the brain from bulging is gradually increased. Experiments thus far fail to show when there is any increase of arterial pressure to account for the brain-pressure after injuries. No observations have as yet been made to ascertain if the increase is to any degree dependent upon cerebral venous pressure. These observations confirm those of Kramer, Polis, and Horsley that the respiratory center is the first to be affected after a blow on the head. Many times after respiration has ceased, artificial respiration for a few minutes has been followed by normal breathing, which has continued for hours.

123. Common Food Adulterations.—Excepting a short notice of the adulteration of jellies which are sometimes made with gelatin and flavored with coal-oil products and which should by law be required to be labeled as imitations, the chief part of Leuf's article is given to the subject of oleomargarin. He maintains, and quotes numerous authorities to show, that it is a wholesome article of food and that the "anti-oleo" crusade is largely an interested movement of butter-makers and sellers and politicians anxious to get their votes. The reason why he recommends this is that it is practically identical with butter, it is more wholesome, free from germs, can not be made from spoiled fats, keeps better than butter, would entirely displace renovated butter which is unwholesome, brings within the reach of all the equivalent of a high-grade butter, benefits the masses of the people, though at the expense of a small class, and lastly that it is the only proper thing to do. The remedy consists in having every package properly labeled, and then the people would understand perfectly well what they were buying and also it would be necessary to have them educated as to its food value and wholesomeness.

133 and 134. Obesity.—Dunn reports the case of a man who had taken the Kissengen-Vichy treatment of obesity at first with such effects that he became enthusiastic over it, but later it caused a serious nervous irritability and a marked degree of arterial tension which suggested organic disease of the kidneys. Purgatives and nitroglycerin, however, failed to give results. The author does not attempt to explain how it produced these results. Other cases were treated in a similar way, and one man had to relinquish his work and take to the woods for a while for relief.

Brand's article offers the case of a street-car conductor who weighed 223 pounds on May 30 and reduced his weight to 169 pounds by the middle of August. The treatment which he followed was the taking of but one meal a day, which would seem to be effective, and refraining from all liquids at the time and for two hours later, but afterward drinking water freely. Previous to taking this treatment he suffered from indigestion, but now he says he is well, and is the picture of perfect health. The treatment might be suitable for one individual, but would hardly do for everyone.

139. Goiter.—The general subject of goiter and its treatment is the theme of Beck's paper. He first notices the distribution of the disease and is inclined to attribute it to local causes; the question whether it is of bacterial origin is noticed, but there is no positive evidence as yet. The different types of the condition are mentioned, and the author remarks that generally the diagnosis is easy, though there may be conditions that will sometimes give trouble, such as the attachment of the gland to the upper trachea, etc. The Roentgen rays offer a method of diagnosis not heretofore available when calcareous

concretions exist. In the treatment he mentions the use of iodoforn and ether injections, and remarks on the advantages and difficulties of the method. The misfortune of entering a large vessel is a possibility, but if one injects only into the middle of the tumor, or rather its lobes, this is not likely to occur. Local treatment has no special influence on the fibrous and cystic forms of goiter, and he recommends the use of iodoforn combined with the local treatment in cases where the latter is advisable. The surgical treatment is less dangerous with modern asepsis than formerly. Proper ligation of the great vessels and careful operating have notably lessened the danger of hemorrhage. He does not advise the complete removal of the gland, but would rather prefer the injection treatment for this reason. He concludes his paper with the mention of a case of follicular goiter associated with Addison's disease in which he was able to produce a decided diminution of the tumor by iodoforn injections. Exploratory laparotomy showed tuberculosis of the right suprarenal body and the injection treatment of the goiter undertaken after the operation caused a diminution of the growth to one-third its original circumference and general improvement of the patient in other ways, which must be ascribed to the operation.

Progressive Pernicious Anemia with Spinal Symptoms. DYE DUCKWORTH.—In this clinical lecture based on a case thoroughly reported, Duckworth considers the subject of pernicious anemia in its general aspects briefly. He remarks that it can not be considered as a primary anemia, because there may possibly be more than one source for the toxins which induce it. Our knowledge is as yet imperfect in regard to this point, but the evidence of the toxic origin is very strong. In the cases reported no possible cause was ascertained, but gastric enteric symptoms were especially noted. The diagnosis of the condition is not difficult; it should be suggested in every case of profound anemia that comes on insidiously in this climate. Cancer of the stomach is the disease which most closely resembles it, but the extreme wasting and gastric symptoms are generally more prominent. Chlorosis may simulate pernicious anemia, but age and sex help here and the condition of the blood is somewhat different; there is a much greater deficiency of hemoglobin and much less diminution of red globules, and poikilocytosis is rare. In splenic anemia the enlarged spleen is a marked feature. There is a form of grave endemic anemia secondary to parasitic infection, the presence of *ankylostomata* or *hæmorrhoides* in the intestines. If there is any suspicion of their presence the feces should be examined for ova and treatment directed accordingly. Duckworth's experience confirms the benefits from the use of arsenic and red ox-marrow, together with good diet and wine in this condition. He mentions the suggestion of Hunter of the use of the antistreptococci serum, but says we have too little experience with it. When any measure of improvement is secured by any method it is best to continue treatment for a long period and not rest satisfied that the disease is overcome.

Enteric Fever in the Army in South Africa, with Remarks on Inoculation. HOWARD H. TOOTH.—The writer reviews the facts as regards the cases of typhoid fever in South Africa, and assuming that the water is the chief derivative considered in spreading the disease, he says, this by no means leaves the question in a satisfactory state for the sanitarian. The soldiers when thirsty will drink whatever is convenient, and filters are at best imperfect resources where muddy streams exist. Certain other factors completely beyond control are dust and flies, and he mentions a special species of flies which seem to prefer enteric cases, and are in vast numbers and ubiquitous. Inoculations with enteric toxin had only a partial test in South Africa, and yet what was done was suggestive of its value. He thinks it is not unlikely that the reaction of the individual to injection may offer information as regards the nature of immunity or liability. The constitutional reaction was very variable; some showed considerable general disturbance, others had very little except at the site of puncture,

and he asks may not this be some measure of the degree of immunity possessed by the individual. As a rule the more severe cases of typhoid among the inoculated were in the men who had suffered more or less severely at the time of inoculation, while the slight or abortive cases were among those who showed little constitutional reaction. If this is correct those who suffered the most severely would require a second inoculation if any did and would be the least willing to undergo it.

Enteric Fever in South Africa: Effective Sterilization of Excreta. H. A. CUMMINS.—During the epidemic of typhoid at Bloemfontein in the British Army, Cummins used a method of sterilizing the excreta, which he found to be at once effective. He used the boiling process, adding considerable carbolic solution, 1 in 20, with the boiled excreta. The result was that the process was thorough and produced no serious odor or disturbance. He says this simple and cleanly process is one that might be adopted with benefit in hospitals, and the cost is very small.

The Lancet, November 10.

The Urinary Pigments in their Pathologic Aspect. ARCHIBALD E. GARROD.—The writer believes that urobilin is formed in the intestines and is of bacterial origin. The various theories are reviewed and the objections considered. The question whether there are some sources in the body other than the intestines is discussed, and he does not give a positive opinion, though he notices an observation by Gerhardt as rendering it necessary if accepted, to admit of a second source. The clinical aspects of urobilin are briefly mentioned. An excretion of the pigment, as shown by the spectroscope, is a very common phenomenon of disease and may occur temporarily in febrile disturbance of almost any kind. In liver disease it is usually persistent, and in diseases attended with excessive hemolysis and during the absorption of extravasated blood there is apt to be conspicuous urobilinuria without any corresponding increase of the other coloring matters unless complications are present. It affords a diagnostic sign of real value in pernicious anemia and indicates the progress of the case. Hematoporphyrin, with its pathologic significance is a comparatively new field. The author concludes that hematoporphyrin is an intermediate product of metabolism which, normally to a large extent, and still more so in morbid conditions, escapes further change and is excreted as such, or else that it is a by-product of metabolism which may be formed in undue amount in the place of some other hemoglobin derivative such as its isomer bilirubin. Whatever be the process, it is one which is constantly active to some extent in health, and even in intrauterine life. It seems probably *a priori* that the liver is the organ in which it is formed. We are not in a position, however, to assume that the liver is in a disordered condition in all cases in which hematoporphyrin is in excess in the urine. The evidence as a whole is strongly in favor of the view that this disturbance plays the chief part in bringing about this result. The spleen may be excluded, as it is not altered by its extirpation or affected by its disease. In those cases due to sulphonal, or those rarer ones in which it occurs apart from taking this drug, there is somewhat more than mere exaggerated excretion, and, as Hammarsten has pointed out, the peculiar color of the urine is almost wholly due to other abnormal pigments as yet not studied. The removal of hematoporphyrin from such urines causes little or no reduction of the color. The condition is a serious one. Various profound disturbances of pigment metabolism and fatty degeneration of the liver have been observed in sulphonal cases. Intestinal hemorrhages have been observed. Where it occurs in cases not due to sulphonal the symptom is not of apparently so grave a significance and pathologic data are wanting. In no two of the few recorded instances have the morbid conditions been alike. As regards urochrome and uroerythrin, Garrod says our knowledge is yet too imperfect to allow of the framing of definite theories of their modes of origin and the conditions which control their excretion. He reviews, however, the literature of the subject as far as known to him and notices the conditions in which uroerythrin may appear, such

as especially disturbances of the hepatic functions, even functional ones in the slightest degree. The study of urinary pigment is a matter that, as the author has pointed out, in some cases may furnish very valuable diagnostic data not obtained in other ways and, therefore, is worthy the attention of the physician.

The Physiology and Pathology of Inheritance, or What do We Inherit from Our Parents? THOMAS OLIVER.—The conditions of heredity are noticed by Oliver, who illustrates them by the facts observed in breeding of animals and the inheritance of diseases as shown by statistics, especially in the insurance statistics. He holds that there is no doubt as to the individual and family susceptibility to phthisis. He says in conclusion: I would say from a pathologic point there is considerable evidence to show that mental, not less than physical qualities are transmitted, that pathologically such a disease as hemophilia is inherited, and that where there is a family history of phthisis and cancer there is, especially as regards phthisis, a greater liability to the disease than where a family shows no such record. I believe that the influence of inheritance, however, has been exaggerated. Tuberculous disease is inherited, but only in the same sense as other diseases that are due to microbes. It is in the form of an enfeebled resistance on the part of the tissues. Pulmonary phthisis seems to exhibit a kind of inheritance that is particularly its own; but on scrutiny this is found to be largely due to the domestic character of the malady, which is encouraged by our home life, insanitary dwellings, overcrowding of the poorer working classes, infection, Britain's changeable climate, dusty occupations, and ill-assorted marriages.

On the Influence of Fatigue on the Minute Structures of the Kidney and Liver. GUIDO GUERRINI.—The influence of fatigue on the minute structures of the kidney have been the study of Guerrini, who gives his results in this preliminary note as follows: In the *kidney*, the grossest modifications of structure are in the cells of the convoluted tubules and of the ascending part of the loop of Henle. The corpuscles of Malpighi and the collecting tubes are nearly always normal. In the affected cells the modifications of structure are, naturally, in relation with the degree of fatigue undergone by the animal. The more fatigued the dog was, the more profoundly altered were the cells. In animals already much fatigued the following appearances may be observed. The protoplasm loses its usual aspect and becomes homogeneous and granular. It appears that the cellular body enlarges, sometimes little, sometimes so much that in a transverse section all the openings of the canals seem to be closed by the swollen cells. The edge between the cells become uncertain and sometimes disappears altogether. In animals still more fatigued the minute modifications of the cells of the convoluted tubules are much greater. It is seen, in fact, that the borders of the cells which surround the openings of the canals fray out and break, and that the cellular protoplasm shows here and there rarefied points, vacuoles and cracks, and finally crumbles away into a fine detritus which collects in the opening of the tubules. In the midst of this detritus normal nuclei are sometimes found, sometimes lumps or granulous masses which stain like the nuclei. This degenerative process almost always attacks a certain number of cells, but sometimes it is seen only in a group of a few diseased cells which are in the midst of several normal ones. In the *liver*, the minute modifications of structure of the cells are much less than are those of the kidney cells, and they appear conspicuously only in the liver of those dogs in which the modifications of structure are the greatest. They are as follows: From the beginning all the cellular body enlarges and the edge between the cells becomes uncertain and sometimes disappears altogether. Sometimes the little biliary canals are evidently compressed, whereupon the protoplasm of the liver cells appears rarefied, full of knots, spongy, and very dark from biliary pigment.

The Practitioner, November.

The Practitioner's Duty in the Treatment of Acute Intestinal Obstruction. A. ERNEST MAYLARD.—The duty of the average practitioner in cases where acute intestinal ob-

structive disease is shown by sudden excruciating pain, rapid and small pulse, pinched and drawn face, temperature varying between subnormal and a little above, and painful abdomen and vomiting, are pointed out by Maylard. The point especially noticed is that intervention is indicated in the early stages, as it is only in these that acute obstruction can be best met. The mere fact that the patient is suffering from peritonitis is sufficient to determine the proper course; the abdomen must be opened, and if it is possible to determine beforehand some clue as to its cause, so much easier is the operation and more direct the procedure, but it is useless for the practitioner to attempt to discover this in *prima facie* obscure cases, as experienced surgeons may fail in such. The first duty is to recognize the gravity of the initial symptoms irrespective of the cause, and lose no time in operation. If all men were skilled hospital surgeons or had a properly equipped nursing home at hand the question would be easy to answer what should be done, but such is not the case and the difficulties for a man to undertake operative work without proper facilities are very great. If the case be one of acute obstruction following on a history of chronic obstructive trouble the colon should be opened in the left lumbo-iliac region when the obstruction is known to be in the rectum, and in the right iliac region when the obstruction is known to be in the right bowel between the rectum and cecum. The operation is a simple one and can easily be done with local anesthesia. The longitudinal muscular bands on the surface of the colon will serve to distinguish the large gut from the small, and if possible the loop should be withdrawn and some rigid rod or tube passed through the mesentery, so as to secure the loop from receding into the abdominal cavity. Stitches to secure the bowel to the edge of the wound are only needed when it can not be sufficiently withdrawn. A small incision is made and the contents allowed to escape. If the practitioner has made a medial incision, by this procedure subsequent treatment of the artificial anus can be left for the operative surgeon in the course of ten days or so, as the patient can be removed. In case of acute intestinal obstruction from some cause that is not easy to determine, the practitioner's duty is equally clear. There is no need for general anesthesia and the subsequent injection of cocaine along the line of incision will suffice. The operation is the old classical one of Nélaton, which consists in making an oblique incision about two inches long through the abdominal parietes in the right iliac or inguinal region. The distended coil of intestine which presents is carefully secured by stitches to the edge of the parietal wound and bowel opened by a small incision. There is much to encourage the practitioner in the performance of this operation, for numerous cases have occurred where not only the immediate situation of gravity has been successfully tided over, and the patient has made a complete and permanent recovery. The relief of distention of the bowel and other congested parts brings about sometimes a reduction of an internal hernia, untwists a volvulus, or unravels intussusception or dislodges an impacted gall-stone. No medical man should hesitate to make such a simple operation, however isolated or devoid of surgical facilities. In regard to a supposed case of perforation of the stomach, it is almost impossible to expect the right thing can be done, and yet we are encouraged from time to time by hearing that some case of perforated gastric ulcer has been successfully dealt with under most unfavorable conditions. Maylard does not consider it possible to lay down simple directions for the practitioner in dealing with these cases. He must be prepared to open the abdomen to the required extent and to deal with the case radically, which may be an incision from the ensiform cartilage to the pubes, or a vertical incision succeeded by a transverse one, and then be guided by what he finds. The most unmistakable signs of gastric ulcer often prove to be from a perforated appendix, or a perforated appendix turns out to be a perforation in the jejunum. If the case of intestinal or abdominal trouble has progressed beyond the initial stage, Maylard recommends the washing out of the stomach and colon before operation, as having a very excellent effect on the patient's general condition, and relieving the patient of the poisonous material in these viscera. On opening the abdomen a distended bowel at

once presents, the loop of which should be withdrawn and placed in the charge of an assistant who holds and guards it so that as the incision is made into it the contents flow into a receptacle at the patient's side. The operator continued to withdraw the distended coils, while the second assistant guards and keeps warm with cloths soaked in hot normal saline solution. The operator then seeks for the cause of the obstruction, that is, if it is required, and returns to the everted intestines which he empties by running between his fingers and squeezing out the contents. If one incision is not sufficient, another one should be made; the object should be to completely empty the gut of the matter that is poisoning the patient. After emptying, the incision can be closed and the bowel returned. He believes in making an incision immediately after opening the abdomen to relieve tension, and it is better for the condition of the parts. Flushing of the abdomen is recommended; it can not be too freely done. Another useful measure, especially when peritonitis has set in, is the direct introduction into the bowel of one-half ounce of sulphate of magnesium in solution.

Bulletin de l'Academie de Medecine (Paris), October 30.

Success of Traction of the Tongue in Asphyxia from a Bullet Wound. MATIGNON.—This communication describes the successful resuscitation by rhythmic tractions of the tongue, of a man in syncope and commencing asphyxia due to a bullet wound through the upper air-passages, during the siege of the legations at Pekin.

Delivery of a Double Monster. PINARD.—Barette describes a maternity case he attended in 1899 in which he discovered, by introducing his hand in the vagina during the delivery, that a band connected the two fetuses, which were both dead. He writes to the Academy to inquire whether Cesarean section is imperative in such cases if the double monster is alive. Pinard comments on the extreme rarity of this experience and of a correct diagnosis, but asserts that if he were certain that it was a monophalian xiphopagus at or near term, impossible to extract by the natural route, he would perform Cesarean section. This class of double monster is viable and separable. In all other cases of dystocia from double monstrosity he would not hesitate to do embryotomy, as the fetuses are not liable to survive after leaving the uterus. He cites his statistics to prove that the generation of twins has no connection with syphilitic antecedents, a question recently raised.

Prolonged Application of Compresses of Ether on Strangulated Hernia. FIESSINGER.—The remarkable benefits derived from the prolonged application of a compress kept moistened with ether on an irreducible, strangulated hernia are detailed in this communication. In from a quarter of an hour to two hours the hernia—whether inguinal, femoral or umbilical—is reduced spontaneously with the assistance of slight digital pressure. The ether relieves congestion and induces reflex vasoconstriction. After thirty-six hours have elapsed there might be danger in reducing a possibly gangrenous herniated intestine.

Echo Medical du Nord (Lille), October 14.

Value of Surgical Intervention in Urinary Tuberculosis. V. CARLIER.—Speedy intervention in case of tuberculosis of the kidney is advocated by Carlier, but when the bladder is the site of the infection he is much more conservative. Vesical tuberculosis is usually secondary, and in many cases might have been prevented by prompt removal of the primary focus in the kidney. Medical treatment is indicated and often is surprisingly effective, combined with suitable instillations in case of microbial infection, unless they induce irritation. When the cystitis is not influenced by these measures and the patient is exhausted by the frequency and pain of micturition, Carlier resorts to cystostomy, which he prefers to perineal drainage. The relief is often so pronounced that it is equivalent to a cure. Hypogastric drainage, when once established, should be permanent.

Experimental Study of Fractures of the Upper Jaw. R. LEFORT.—The independence between the skull and face is em-

phazied, and also the fact that the pterygoid processes and the lateral masses of the ethmoid form part of the maxillary bone from the surgical point of view. On the other hand, the malar bones remain adherent to the skull in case of traumatism of the center of the face, and the plane of cleavage passes through the pyramidal process of the upper maxillary bone, the ethmoid and the root of the nose. The face tends to separate into fragments, the characteristics nearly constant, whatever the mechanism of the fracture. Guerin's transverse fracture is the most frequent. It comprehends the palatine arch, the alveolar and pterygoid processes, with sometimes an antero-posterior fissure near the median line. The malar bone may form a second fragment, nearly or quite intact, bringing with it the top of the pyramidal process of the maxillary bone or exceptionally the entire process. The ascending portion of the upper maxillary with a part of the lachrymal bone and sometimes of the bones of the nose, form a third fragment.

Nord Medical (Lille), October 1 and 15.

Reduction of Hump in Pott's Disease. PHOCAS.—In certain exceptional cases, in which the hump is dorsal or dorso-lumbar and of recent development, without an abscess or much alteration of the general health, or when there is paraplegia, extension under chloroform with very slight digital pressure may succeed in reducing the hump. The family should be warned of the dangers and the method should be appreciated at its true value. This cautious and rare procedure is all that remains of the famous forcible reduction of the hump wanted by Calot. Even with this apparently harmless procedure Phocas had the following experience: A girl of 13, with right torticollis, painful on the slightest movement, had a severe attack of la grippe ten months previously. A cervical arthritis was diagnosed and the head gently straightened under chloroform and an apparatus applied. The manipulations were all extremely gentle, but the child was completely paralyzed the next day and died the day after. The autopsy showed Pott's disease. All the ligaments had been destroyed and the spinal cord had been held erect only by the immobilization of the bones by the muscles. The moment that this immobilization ceased the bones slipped and crushed the cord. Two other patients died from meningitis seven and three months after intervention, a total of three deaths in the twenty cases in which reduction was done. The hump has recurred in all of the seven reduced according to Calot's directions. The results have been satisfactory in only one of the twenty cases, although in three the hump was more or less diminished, and recurred lower down in another. In one case, paralysis appeared three months after a gentle reduction.

The Thymus in Therapeutics. BLONDEL.—The thymus seems to have a favorable action on nutrition and growth, and administered fresh or desiccated has cured five cases of Basedow's disease and fifteen of chlorosis in Blondel's experience. He has also administered it in milk to infants with congenital debility, bringing them up to normal weight in a few days. He attributes to the thymus an antitoxic role like that of the ovary or testicle, and describes experiments which show that the latter compensate it when absent.

Incompatibility of Arsenic and Phosphorus. PHOCAS.—Serious symptoms of polyneuritis with pain and impotence of the legs, occurring after prolonged administration of creosote, have been traced to an incompatibility between the phosphorus in the creosote and the arsenic which the patients had been taking previously or simultaneously.

Presse Medicale (Paris), November 3 and 7.

Action of the Toxins of the Colon Bacillus on the Circulation. H. ROGER.—In the issue of July 4, Roger pointed out that certain varieties of dysentery are due to the bacillus coli communis. He has been injecting its toxins into rabbits and publishes the tracings of the circulation and respiration afterward. The latter is scarcely affected by the toxin, but the heart-beat becomes more vigorous and slower. The organ evidently struggles against the effect of the toxin. The intense congestion of the intestines, liver and kidneys is another

argument in favor of the compensating antagonism between the peripheral and central circulation. The myocardium does not seem to be affected by the toxin, which explains the rapid recuperation when the gastrointestinal intoxication is arrested or when the effects of the peripheral vasodilation are counteracted by artificial serum. These findings explain some of the morbid manifestations in the course of intestinal infections.

Intoxications and Infections in Mental and Nervous Affections. G. D'ABUNDO.—The doctrine of intoxication best explains the majority of nervous symptomatic manifestations, and the classification of nervous and mental affections should conform to this conception. Modern science is constantly according a more important place to chemistry, and the clinician must now work together with the expert chemist to attain the best results. Infections and intoxications represent the most frequent, sensitive and active elements in the pathogenesis of nervous affections in general. Infections and intoxications in the progenitors or in the mother during pregnancy frequently retard to a marked degree the process of myelinization of the different systems of nerve connections. Certain degenerative neuropathic types are due to organic faulty development in the brain or spinal cord, the consequence of cured, toxic, embryonal pathologic processes. Infections and intoxications of the nervous system facilitate the evolution of secondary intoxications which nourish re-enforce and complicate the clinical phenomena with concomitant and secondary poly-intoxications. The action of infectious or toxic agents may be exerted at any portion of the nervous system, originating systematic, disseminated, peripheral or central localizations, and leading to acute or chronic neuropsychoses. Mental confusion is the most frequent type of toxic-infectious action, but a toxic origin is equally probable for other psychopathic manifestations. Acute delirium should be considered a clinical picture caused by different infectious and toxic agents. The latest research on the etiology of progressive paralysis only corroborates its infectious and toxic origin. The clinical manifestations of infections and intoxications of the nervous system are the result of disturbances in nutrition, which in certain cases may subside, although the symptoms give little hope of cure. We are justified in cherishing the highest anticipations in regard to the future treatment of toxic neuropsychoses, which should be based on elimination of the toxic products and neutralizing or diminishing the effects of secondary intoxications. The author mentions instances in which very severe cases of infectious psychoses were treated with copious venesection and injections of artificial serum, thus attaining results which surpassed all expectation.

November 7.

History of Subarachnoid Anesthesia. T. TUFFER.—The three communications of Leonard Corning of New York, 1885-88, in regard to his injections of cocaine into the spinal canal for surgical purposes, found no echo, Tuffier states. Quincke six years later proclaimed the harmlessness of lumbar puncture. Franck announced in 1892 that cocaine does not permanently affect the nerve tissue. Sicaud in 1898 demonstrated that injection of an antiseptic fluid or serum into the subarachnoid space was tolerated, and in 1899 Bier applied these data to surgery, but after his first communication relapsed into silence. Although he had not experienced any serious accident, the practical process was lacking. Tuffier claims that the merit of evolving a practical technique belongs to him. As he first described it in the *Sem. Méd.* of May 16, 1900, it has been generally adopted, and the method has now a record of 1000 applications, including his 210 personal cases. The symptoms observed were invariably the same, if any occurred—headache, nausea and vomiting. He is now engaged in the study of the mechanism of this analgesia by a new, experimental technique.

Permeability of the Meninges in Cholemia, Tubercular Meningitis and Nervous Uremia.—This and the preceding number contain three articles by prominent writers describing clinical research which establishes that the permeability of the pia mater is altered in certain affections and can be tested with potassium iodid and methylene-blue. The arachnoid and pia

mater are permeable from within outward but not from without inward under ordinary circumstances. A. Gilbert found biliary salts and pigments in the cerebrospinal fluid in three cases of severe icterus with serious nervous symptoms. In fifteen other cases the fluid was normal, although the biliary salts abounded in the blood. Widal, Sicard and Monod contribute an article corroborating the delicacy and value of the potassium iodid test of meningeal permeability in the two cases of tubercular meningitis investigated, in which the presence of lymphocytes in the cerebrospinal fluid, the iodid test and the elevated freezing-point paralleled each other. J. Castaigne also found similar abnormal permeability in four cases of nervous uremia in which the cerebrospinal fluid proved toxic for guinea-pigs. Methylene-blue injected subcutaneously was found in the cerebrospinal fluid in the form of chromogen, and the fluid also gave the iodine reaction after injection of two grams of potassium iodid. These four cases terminated fatally, while of the twelve other cases in which the fluid was not toxic only two died. The toxicity of the fluid, therefore, has a bearing on the pathogenesis, prognosis and treatment of this affection. As the passage of uremic poisons into the cerebrospinal fluid is apparently fatal, we should be justified in injecting some substance to neutralize or destroy the toxin in the spinal canal.

Beiträge Z. Path. Anat. (Jena), xxviii, 2.

Growth of Carcinoma of the Skin and Mucous Membranes. H. LOHMER.—The author presents arguments in favor of the theory that the development of a carcinoma is preceded by an increase in the proliferating power of the epithelial cells. An alteration of the cells is an indispensable preliminary, whether congenital or acquired, and whether parasitic or toxic elements co-operate in the production of the carcinoma.

Specific Stain for the Hemameba. M. LOEWIT.—The disputed parasites which the author claims to have discovered in the blood take a differentiating stain with an aqueous solution of thionin and iodid. They are also differentiated from mast-cells by their shape. They have never been found except in cases of myeloma and in the blood of rabbits inoculated with the same disease.

Centralblatt F. Chirurgie (Leipsic), Oct. 27 and Nov. 3.

Sudeck's Trephining Fraise. L. HEIDENHAIN.—Doyen's drill used with Gigli's wire saw proved a great advance over previous methods of trephining, but Sudeck's new drill far surpasses them. "It solves the problem of a rapid, perfectly safe method of making even the largest Wagner flaps without hemorrhage." It consists of a fine steel drill with a cutting screw thread. A small metal plate is fastened at the point, which pushes down the dura out of the way. The instrument is introduced through a hole made with the smallest Doyen drill. It was first exhibited at the last German Congress of Surgery.

November 3.

Intracranial Removal of the Gasserian Ganglion Without Removal of the Middle Meningeal Artery. J. DOLLINGER.—The Krause-Hartley method of extirpating the Gasserian ganglion requires an hour and a half at least and the ligation of the middle meningeal artery. Dollinger has devised a new method which he has successfully applied on five patients. The operation can be made in twenty minutes and does not require ligation of the vessel. He first cuts the temple flap as Krause directs, then inserts his finger between the base of the skull and the dura as far as the middle meningeal artery, then works it forward to the second and third branches of the trigeminus and detaches the dura from them with a dull elevator. He next presses the elevator backward and inward, thus exposing the ganglion in front of the artery. It is then an easy task to detach the dura from its surface and the ganglion from the base of the skull, seize it with an artery forceps, cut the second and third branches of the trigeminus with a tenotome and extirpate the ganglion. He does not trust his assistant to retract the brain, but does it himself with a blunt elevator, 1 to 1½ cm. wide, which he holds in his left hand under the light of his head mirror. The anterior trunk of the middle meningeal artery in 55 per cent., was enclosed in a

tunnel in the front lower edge of the parietal bone, and in only 45 per cent. did it lie in an open groove. In his experience with nine cases in which he attempted the removal of the ganglion to cure rebellious trigeminal neuralgia, excessive hemorrhage occurred in two. It was controlled in one but in the other all the tissues bled like a squeezed sponge. The operation was abandoned; necrosis followed the tamponing and the neuralgia recurred. In one case scarcely a drop of blood was lost. The bleeding in Dollinger's experience was generally from the veins, and consequently it is unnecessary to expose the external carotid as a preliminary measure.

Muenchener Med. Wochenschrift, October 30 and November 6.

Artificial Oxidation of Albumin. F. N. SCHULTZ.—Oxidation of albumin occurs much more rapidly with hydrogen peroxid in the presence of an acid than with a neutral reaction. The acid also has a peptonizing effect in the presence of hydrogen peroxid lacking to the acid alone. These results of the tests communicated corroborate the multiplicity of the vital processes.

Tests of Kidney by Freezing-Point of Blood and Urine. H. KUEMMEL.—This article extols the valuable information to be derived from comparative study of the freezing-point of the blood and of the urine from each kidney withdrawn separately. If the kidney to be left after an operation shows a freezing-point above the normal—which is .56 C. below that of distilled water—Kuemmell waits until this kidney becomes normal before he ventures to remove the other. The diagnosis made from the freezing-point was invariably confirmed by the later course of events in the numerous cases in his experience.

Compensation Processes in Nervous System. A. BICKEL. The remarkably favorable results obtained of late by appropriate exercises in various affections of the nervous system, especially tabes, are explained by the mechanism of the processes of compensation observed in animals in Bickel's researches. For instance, the ataxia which occurs in dogs after division of the roots of the spinal nerves for the hind legs, soon becomes compensated. This compensation, however, is completely abolished if the sensory-motor zones of the cortex on both sides are removed. The ataxia returns as complete as after the first operation, and is never again fully compensated. This experiment among many others, shows how the cortex transformed its function to adapt it to circumstances and compensate the missing innervation.

November 6.

Therapeutic Application of a Pupil Reaction. H. KIRCHNER.—Very little attention has been paid to the contraction of the pupil as the eyelids are voluntarily closed. Many a pupil has been asserted to be absolutely rigid when on investigation as the lids are energetically closed, it will be seen contracting. The phenomenon may occur even after extinction of the convergence and accommodation-reflexes. The symptom is frequently exaggerated in the supposedly rigid pupils of tabetics and paralytics, indicating that it can not be ascribed to a purely peripheral lesion. A case of ophthalmoplegia interna, bilateral and recent on one side, is described at length, which was cured by the therapeutic application of this lid-closing reflex to exercise the paralyzed pupils. The patient was instructed to shut his eyes vigorously a certain number of times and to repeat this at intervals, with the result that he was able to resume his occupation. Kirchner attributes this reflex action to preformed tracts passing through the posterior longitudinal fibers.

Influence of Rectal Feeding on the Gastric Secretions. L. METZGER.—In numerous tests on dogs and patients, milk and egg enemata induced merely a weak reaction to the Congo test in the gastric secretions and no free hydrochloric acid was noted until one and one-half hours after the injection. On the contrary enemata of bouillon and red wine invariably induced a strongly acid secretion in half an hour, which vanished by the end of the hour.

Gazetta Degli Ospedale (Milan), October 7.

Disturbances in Respiration in Hemiplegia. BOERI AND

SIMONELLI.—A number of tracings are given illustrating the fact that in 10 out of 61 patients with hemiplegia, the excursions of the thorax were three to four times as extensive on the paralyzed as on the unaffected side. Also that the former curves slightly preceded the latter. In the other patients slight disturbances in the frequency, rhythm and synchronism were occasionally observed. These phenomena seem to favor the hypothesis of a secondary, subcortical center for the respiration, not affected by the cortical lesion, and the possibility of hyperfunction of this center from some irritative process.

Vratch (St. Petersburg), October 6, 13 and 20.

Improved Stain for Fat. I. B. LEVINSON.—The usual osmic acid test for fat has several disadvantages, among them the high price of the acid and the non-durability of the stain. By the method described in this communication the fat is stained to the minutest droplets, and specimens several months old are as bright as when fresh. No experience or skill is required and the materials are on hand in all laboratories. The specimens are first treated with Mueller's fluid for two to five weeks, next with alcohol and mounted in celloidin. They are transferred then from the alcohol to the stain, which is made by dissolving 2 gm. of hematoxylin in a small quantity of alcohol and mixing with 100 c.c. of a 2 per cent. solution of acetic acid. The specimens are kept in the stain for twelve hours at 40 C., then rinsed in water, and placed in a 1 per cent. aqueous solution of potassium permanganate for ten to fifteen minutes, then rinsed again and placed in a 2 per cent. solution of oxalic acid or in a mixture of two parts of 2 per cent. solution of oxalic acid and one part of a 2 per cent. solution of potassium sulphate, for five minutes.

October 13.

Closing Defects in Skull with a Bone Flap from the Leg. A. N. ZEMIN.—A case is described in which a large defect in the skull was closed with a periosteal-bone flap from the femur according to Scydel's method. This brings the list of these cases to nine, all treated by different surgeons and all successful.

October 20.

Resection of Kidney Tissue. A. M. DOLGOFF.—The purpose of the extensive experimental researches described was to determine the recuperative power of the kidney after incision and resection, and the effect on the vitality and performance of the organ. Dogs were the animals used, and the recuperative power of the renal tissues after incision and resection proved remarkable. Injury of the medullary portion was more serious in its effects than of the cortical. After removal of one kidney any operation on either cortical or medullary portion of the other was fatal. The experiments demonstrated that the healing power of renal tissue is so great that it offers a good field for surgical intervention, either curative or for diagnostic purposes.

Anales de Oftalmologia (Mexico), October.

Screen for Ophthalmologic Examination. P. DE OBARRIO.—In the writer's practice in Ecuador he found the heat of the lamp a serious hindrance to protracted examination of the eyes. He has devised a screen to overcome this drawback, consisting of two plates of glass with a narrow space between, the whole standing upright in a metal standard, with a spring shade attached, which can be raised or lowered. The glass box is filled with water, which arrests the heat.

Queries and Minor Notes.

MEDICAL PRACTICE LAWS.

DANA, L.L., Nov. 1, 1900.

To the Editor:—I wish to know the laws governing the practice of medicine in the Argentine Republic, and also what opportunities are in that country for an American physician. Yours truly,

G. F. T.

ANS.—We do not know how American diplomas stand in Argentina. An American physician going there to practice must at any rate have his diploma certified to by the Argentine consul in this

country, and his certificate passed on by the Argentine foreign office on arrival there. Expensive examinations in the Spanish language are necessary before permission would be given. A temporary authorization to practice may be given for six months. The conditions for non-graduates of Spanish or local schools are rather severe, and probably American physicians would not find matters easy.

To the Editor:—Would you kindly let me know through THE JOURNAL the requirements to practice medicine and surgery in South Dakota; also the name and address of the medical registrar for that state.

SUBSCRIBER.

ANS.—In South Dakota a diploma from a recognized medical college is all that is required, except that the law also specifies as conditions for license, good moral character and that the candidate shall not be a habitual drunkard. The Secretary of the Board of Health is Dr. A. E. Clough, Madison, S. D.

REMOVAL OF TATTOO MARKS.

HUNTINGTON, IND., Nov. 13, 1900.

To the Editor:—Will you please give the prescription for removal of "tattoo marks" published in THE JOURNAL not long ago. It was a short article, but the writer of the item claimed good results for the removal of "tattoo marks" made with India ink V. C. S.

ANS.—The article on the removal of "tattoo marks" noticed in THE JOURNAL was by Dr. Ohmann-Dumesnil, of St. Louis, in the St. Louis Medical Journal for October. The method consisted in using a bland solution of caroid, rubbing it over the retattooed tattoo marks. The digestive action of the caroid, it is claimed, eats away the tissue including the pigment, and the result is a crust which comes off, carrying with it the tattoo marks. We refer the querist to the original article for full particulars.

FOREIGN MEDICAL JOURNALS WANTED.

W. H. S. writes for information in regard to procuring regularly the use of leading foreign medical journals, and says that he would gladly give a liberal compensation, to any club, society or private individual for the regular fortnightly or monthly use of the important journals and pay for expressage.

If any of our readers can give information that will aid W. H. S. in his laudable desire, we shall be glad to publish such, or forward to him. We are always willing to loan special numbers from among our exchanges, and the Surgeon-General's library at Washington, also, we believe, will loan journals to responsible individuals. This, however, is not what is desired, as we understand our correspondent.

New Patents.

- Patents of Nov. 6 and 13, of interest to physicians:
- 661,433. Adjustable stirrup-bar for physicians' tables. Wm. D Allison, Indianapolis, Ind.
- 661,434. Adjustable mens for leg-rests of physicians' tables. Wm. D. Allison, Indianapolis, Ind.
- 661,437. Invalid-bed. Nelson Clement, Chicago.
- 661,145. Tip for syringes. Harlan P. Cole, Hariford, Conn.
- 661,211. Obtaining soluble albumen. Cittmar Finkler, Bonn, Germany.
- 661,402. Douche-pan. Daniel Hogan, New York City.
- 661,433. Adjustable stirrup-bar for physicians' tables. Wm. D Allison, Indianapolis, Ind.
- 661,232. Operating-table. James T. Shigley, Detroit, Mich.
- 661,390. Vapor-bath cabinet. John W. Zupkham, Evans City, Pa.
- 35,530. Design, cabinet for medical treatment. Henry A. Schmidt, Milwaukee, Wis.
- 661,682. Laryngocope. Wm. Avery and A. Burrell, Chicago.
- 661,482. Indicator for bottles. Wesley J. Barrett, Marion, N. Y.
- 661,596. Compressorolle for pill-machine. Ferdinand J. Beck, Chicago.
- 661,765. Rennet extract and making same. John A. Just, Syracuse, N. Y.
- 661,812. Surgical appliance. Thomas D. McKown and H. E. Clark, Cripple Creek, Colo.
- 661,818. Soda fountain. Samuel J. Rogers, Marlton, Ind.
- 661,836. Capsule-bottle top. Frank A. Whitot, Bridgeport, Conn.

Change of Address.

- J. A. B. Adcock, Warrensburg, to 908 Paseo St., Kansas City, Mo.
- C. F. Andrews, Clardyville, Tenn., to Bartlett, Tex.
- W. J. Baer, 3348 22nd St., to Harbor Emergency Hospital, San Francisco, Cal.
- C. A. Betts, Chicago, to Hawkeye, Iowa.
- Irvin J. Becknell, Milford to 109 S 5th St., Goehen, Ind.
- W. J. Birkofer, Kanawha, Iowa, to Gothenburg, Neb.
- John Bacon, Andalusia, to Tonessdale, Philadelphia, Pa.
- Carl Booth, 3202, to 2722 Pine St., St. Louis, Mo.
- H. B. Brashear, South Lancaster, Mass., to Atlantic City, N. J.
- D. E. Brown, Chicago, to Laramie, Wyo.
- H. R. Cotton, Fayetteville, Tenn., to Haskell, Tex.
- M. C. Cronin, Bangor, to Mt. Clemens, Mich.
- C. Cushing, San Francisco, Cal., to 1407 I St., Washington, D. C.
- C. G. Chaddock, 511 N. Garrison St., to 3750 Lindell Boul., St. Louis, Mo.
- C. R. Dewey, South Haven, to Coloma, Mich.
- J. Donnelly, 722 Washington St., to 220 Michigan St., Toledo, O.
- J. B. Dickinson, Cobham, Va., to 137 E 21st St., New York City.
- F. W. Davis, Scranton, Pa., to 28 Washington St., East Orange, N. J.
- E. G. English, La Crosse, Wis., to 98 Warren Ave., Chicago.

F. F. Fowle, S. Milwaukee, to Milwaukee Hospital for Insane, Wauwatosa, Wis.
 D. B. Frederick, Marshallville, Ga., to N. Y. Hospital. W. 15th St., New York City.
 Lawrence C. Grosh, 344 W. Woodruff Ave., to 232 Michigan St., Toledo Ohio.
 W. D. Huff, Richmond, to Williamsburg, Kan.
 F. A. Hudson, Florence, Colo., to A. A. Surgeon, U. S. A., Fort McKeanie, Wyo.
 M. B. Hutchins, Fitten Bldg., to 64 Marietta St., Atlanta, Ga.
 C. C. Jones, Brock, to 2117 Market St., Galveston, Tex.
 M. C. Johnson, Minneapolis, to Rochester, Minn.
 E. B. Johnson, Norfolk, to Madison, Neb. N. C.
 M. Kleiner, 2203 Welton St., to Barth Bldg., Denver, Colo.
 J. J. LaSalle, Toledo, Ohio, to The Anchorage, Riverside, Cal.
 J. A. Lockard, Gothenburg, Neb., to Monticello, Toledo, Ohio.
 A. B. Lewis, Hamilton, Kan., to 411 S. Carlisle St., Philadelphia, Pa.
 E. Alfred Mallette, 1206 Arch St., to 5029 Hazel Ave., Philadelphia, Pa.
 J. F. Menertrina, Iron Mountain, Mich., to 11th and Franklin Ave., St. Louis, Mo.
 W. L. Moore, Hilo, to Honolulu, H. I.
 Wm. Northrup, Clarksville, to 84 Monroe St., Grand Rapids, Mich.
 C. P. Paulding, Blue Lake, to Santa Maria, Cal.
 H. M. Pomeroy, Los Angeles, Cal., to 1 N 10th St., care R. B. Chaffin & Co., Richmond, Va.
 W. H. Prioleau, Highlands, to Asheville, N. C.
 E. B. Rierson, Greensboro, to Cooleman, N. C.
 J. J. Ritter, 1026 N. Eutaw St., to 822 Hamilton Terrace, Baltimore, Md.
 E. W. Ross, 5442 Drexel Ave., to Oxford Bldg., Chicago.
 L. N. Seaman, New York City, to Major Louis L. Seaman, Hospital Ship *Marian*, Chinese Waters, China.
 E. N. Shaaf, Chicago, to Cisco, Ill.
 J. E. Sherrard, Perrysburg, to Oakwood, Ohio.
 George E. Sherwood, Dassel, to Kimball, Minn.
 H. A. Stocum, 1427 Walnut, to 1900 Chestnut St., Philadelphia, Pa.
 W. H. Snyder, 912 Jefferson, to 211 Ontario St., Toledo, Ohio.
 R. L. B. Schoonmaker, Sayre, Pa., to 172 Benefit St., Providence, R. I.
 Wm. Stanton, Varysburg, to Webster, N. Y.
 Robert E. Swigart, 20 N Washington St., Tiffin, to 1105 Detroit St., Cleveland, Ohio.
 J. B. Taylor, Vermontville, Mich., to Racine, Wis.
 J. B. Truax, Wallace, to Camp Osborne, Idaho.
 Fred M. Tryon, 212, to 332 S. State St., Ann Arbor, Mich.
 C. B. Turner, Snickersville, to Blumenton, Va.
 F. W. Van Kirk, 25 Hazel, to 50 S. Hermitage Ave., Chicago.
 W. Wickham, 842 Superior St., to Ashley Bldg., Toledo, Ohio.

Alexander N. Stark, captain and asst.-surgeon, U. S. A., leave of absence extended.
 Elmer S. Tenney, acting asst.-surgeon, leave of absence granted.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ended Nov. 17, 1900:
 Medical Director C. H. White, placed on the retired list of the navy, from Nov. 19, 1900, having reached the age of 62 years.
 F. A. Surgeon B. S. Blakeman, detached from the *Pensacola* and ordered to naval hospital, Mare Island, for treatment.
 Asst.-Surgeon C. S. Butler, ordered to the *Independence*.
 Surgeon W. A. McClurg, ordered to additional duty on the *Tonkee*.
 Asst.-Surgeon W. M. Carton, detached from the *Indiana* and ordered home to his orders.
 P. A. Surgeon A. R. Alfred, detached from the *Castine* and ordered to the *Culgoa*.
 P. A. Surgeon M. K. Johnson, detached from the *Celtic* and ordered to the *Brutus*.
 Asst.-Surgeon H. C. Curi, detached from the *Culgoa* and ordered to the *Castine*.
 Asst.-Surgeon E. Davis, detached from the Cavite naval station and ordered to the *Brutus*.
 Asst.-Surgeon W. L. Bell, detached from duty at Guam and ordered to the *Celtic*.
 Asst.-Surgeon B. L. Wright, detached from the naval hospital, Cavite, and ordered to the naval hospital, Yokohama, for treatment.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ended Nov. 15, 1900:
 Surgeon H. R. Carter, granted leave of absence for fifteen days from Nov. 15 on account of sickness.
 P. Surgeon J. B. Stoner, to report at Washington, D. C., for special temporary duty.
 P. A. Surgeon J. B. Greene, to proceed to Bremen, Germany, for special temporary duty.
 Acting Asst.-Surgeon J. A. Moncure, granted leave of absence for thirty days from Dec. 15.
 Hospital Steward W. F. Schlaar, to report to acting director of hygienic laboratory for duty.
 Hospital Steward E. B. Scott, granted one day's extension of leave of absence.
 Hospital Steward M. R. Mason, to proceed to San Francisco, Cal., and report to medical officer in command for duty and assignment to quarters.
 Hospital Steward L. W. Ryder, relieved from duty in the hygienic laboratory, and directed to report to medical officer in command at Washington, D. C., for duty.

BOARD CONVENED.

A board has been convened to meet at Washington, D. C., Tuesday, Nov. 13, 1900, for the examination of Asst.-Surgeon L. E. Cofer, to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: Surgeon Preston H. Faltsch, chairman; Asst.-Surgeon G. T. Vaughan, and P. A. Surgeon H. D. Geddings, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 17, 1900:

SMALLPOX—UNITED STATES.

Colorado: Total for the state, Oct. 1-31, 75 cases.
 District of Columbia: Washington, Oct. 28-Nov. 3, 1 case.
 Iowa: Des Moines, Oct. 1-31, 1 case.
 Kansas: Wichita, Nov. 3-10, 11 cases; total for the state, Oct. 1-31, 27 cases.
 Kentucky: Lexington, Oct. 28-Nov. 10, 4 cases.
 Louisiana: New Orleans, Oct. 28-Nov. 3, 2 cases.
 Massachusetts: Taunton, Oct. 28-Nov. 3, 1 case.
 Minnesota: Minneapolis, Oct. 28-Nov. 10, 6 cases.
 New York: New York, Nov. 3-10, 1 case.
 Ohio: Cincinnati, Nov. 3-10, 14 cases.
 Utah: Salt Lake City, Oct. 1-Nov. 10, 47 cases.
 Washington: Seattle, Oct. 1-31, 9 cases.
 West Virginia: Wheeling, Nov. 3-10, 1 case.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, Sept. 8-16, 33 deaths.
 Egypt: Cairo, Oct. 7-14, 4 deaths.
 England: London, Oct. 20-27, 1 case.
 India: Calcutta, Sept. 22-Oct. 13, 24 deaths; Madras, Oct. 6-12, 1 death.
 Russia: Moscow, Oct. 13-20, 3 cases; Odessa, Oct. 22-27, 1 case; 2 deaths.
 Scotland: Edinburgh, Oct. 20-27, 1 case; Glasgow, Oct. 26-Nov. 2, 26 cases, 2 deaths.

YELLOW FEVER—UNITED STATES.

Mississippi: Natchez, Feb. 18, 12 cases, 7 deaths.
 YELLO W FEVER—FOREIGN AND INSULAR.
 Brazil: Rio de Janeiro, Sept. 8-16, 2 deaths.
 Cuba: Havana, Oct. 26-Nov. 3, 13 deaths.
 Dominican Republic: Puerto Plata, Oct. 6-Nov. 3, 5 cases.
 Mexico: Tampico, Oct. 28-Nov. 4, 12 cases, 4 deaths; Vera Cruz, Oct. 26-Nov. 3, 11 cases, 12 deaths.

CHOLERA.

India: Bombay, Oct. 8-16, 17 deaths; Calcutta, Sept. 22-Oct. 13, 461 deaths; Karachi, Oct. 7-14, 1 case, 1 death; Madras, Oct. 6-12, 21 deaths.

PLAGUE—FOREIGN AND INSULAR.

Egypt: Alexandria, Oct. 1-14, 1 case.
 England: London, Oct. 30, 1 case on vessel arriving from the Philippines.
 Germany: Bremen, Nov. 6, 1 death; sailor from South America.
 India: Bombay, Oct. 8-16, 85 deaths; Calcutta, Sept. 29-Oct. 13, 197 deaths.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 8 to 14, 1900, inclusive:
 Carl E. Bentley, acting asst.-surgeon, to perform the duties of examiner of recruits at Little Rock, Ark., in addition to his duties at Fort Logan H. Root's.
 Charles B. Byrne, major and surgeon, U. S. A., from the Department of Porto Rico, to post duty at Fort Sam Houston, Tex.
 Lawrence C. Carr, major and surgeon, Vols., former orders amended so as to direct him to proceed to Washington, D. C., to report to the surgeon-general for instructions.
 Robert P. Cooke, acting asst.-surgeon, relieved from duty in the Division of Cuba, to proceed to Boyce, Va., for annulment of contract.
 David C. Cooney, acting asst.-surgeon, from the Division of Cuba, to Washington, D. C., for annulment of contract.
 Rafael Echeverria, major and surgeon, U. S. V., honorably discharged from the service of the U. S., to take effect Nov. 30, 1900.
 John S. Fogg, acting asst.-surgeon from Bideford, Me., to duty at Fort McHenry, Md.
 Vincent Gomez, acting asst.-surgeon, relieved from duty in the Division of Cuba, to proceed to Santiago, Cuba, for annulment of contract.
 William C. Gorgas, major and surgeon, U. S. A., to represent the medical department of the army at the Pan-American Medical Congress, at Havana, Cuba, Dec. 26-29, 1900.
 Timothy P. Goulding, acting asst.-surgeon, relieved from duty in the Division of Cuba, to proceed to Washington, D. C., for annulment of contract.
 Valery Havard, major and surgeon, U. S. A., to represent the medical department of the army at the Pan-American Medical Congress, at Havana, Cuba, Dec. 26-29, 1900.
 James H. Heppner, acting asst.-surgeon, from duty at the General Hospital, Fort Bayard, N. M., to Fort Caswell, N. C.
 John Van D. Hahn, major and surgeon, U. S. A., having arrived at San Francisco, Cal., in compliance with previous orders will proceed to Chicago, for duty as chief surgeon, Department of the Lakes.
 Jefferson R. Kenn, major and surgeon, U. S. V., to represent the medical department of the army at the Pan-American Medical Congress, at Havana, Cuba, Dec. 26-29, 1900.
 Willard S. H. Matthews, major and surgeon, U. S. V., honorably discharged from the service of the U. S., to take effect Nov. 30, 1900.
 Edgar A. Mearns, captain and asst.-surgeon, U. S. A., leave of absence granted on account of disability.
 Alva S. Pinto, acting asst.-surgeon, leave of absence granted; relieved from duty in Cuba and on the expiry of his present leave to proceed from Omaha Neb., to San Francisco, Cal., for duty with troops en route to Manila, P. I., and for subsequent assignment in the Division of the Philippines.
 William E. Richards, lieutenant and asst.-surgeon, U. S. A., leave of absence on account of sickness.
 Erwin L. Shores, acting asst.-surgeon, from Fort Caswell, N. C., to San Francisco, Cal., for duty with troops going to Manila and for subsequent assignment in the Division of the Philippines.

DIETETIC TREATMENT OF DIABETES.*

N. S. DAVIS, JR., A.M., M.D.

Professor of Principles and Practice of Medicine, Northwestern University,
CHICAGO.

While something can be done for diabetics by medicinal treatment, reliance must be chiefly placed on a regulated diet. The principle of diabetic diet is well understood and does not need recapitulation here. There are some details of the management of diet which are not so generally regarded as they should be and which are quite essential to successful treatment.

For convenience in discussing the diet of diabetes, cases can be grouped under three heads, first the mildest, second the moderate, third the severe cases. Acute cases, which are seen almost exclusively in childhood and early adult life, belong to the last group, as do some of those chronic from the start. Mild cases may gradually grow more severe. Not infrequently a case starts from its inception of moderate or severe type.

Those cases which can be called the mildest will cease to eliminate sugar in the urine when the ingestion of it is forbidden and the eating of starches is limited. They are usually individuals in or past middle life and are often obese and gouty. They are amenable to treatment.

The moderate cases are those from whose urine sugar can be removed, provided they are deprived of foods containing both sugar and starch. The severe cases are those from whose urine sugar can not be removed by depriving them of carbohydrate food. Sugar can be made to disappear from the urine of some of these by depriving them of carbohydrates and simultaneously limiting the amount of albuminous food. In others the same thing can be accomplished by careful diet and medicinal treatment. There are many cases, however, from whose urine the sugar can not be made to disappear by any treatment.

It is necessary to prescribe both the character and the amount of food which diabetics shall take. In order to ascertain to which of these categories a given case belongs, a patient must be placed on a diet from which sugars and starches are excluded. A strict diabetic diet, that is, one containing no carbohydrates, should not be adopted too suddenly. This is the first point on which I wish to place stress. Not infrequently coma has been precipitated by too sudden and great a change. In other cases indigestion is produced. From the beginning all sugar should be forbidden, and the amount of starchy food eaten should be diminished.

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The latter ought to be lessened day by day during the first week of treatment, so that all will be excluded, if the patient's condition permits, by the end of that time. Simultaneously with the diminution of carbohydrate food, albuminoids can be increased and especially fats. The amount of urine and the percentage of sugar which it contains should be estimated at least every second or third day.

Gerhardt's test with perchlorid of iron must be constantly made. If it gives a positive reaction, or if there is evidence of acetone or diacetic acid in the urine a greater modification of diet should be made. Indeed, it is safest to enforce Ebstein's rule that under these conditions the amount of albuminoids eaten should be lessened and the amount of carbohydrates increased. The presence of these substances in the urine signifies a great liability to coma. If the reaction is found when severe cases first come under treatment sugar only should be excluded from the diet and the amount of albuminous food should be limited. At the same time the intestines should be cleaned and albuminous indigestion—if it exists—corrected. Alkalies and alkaline mineral waters are also useful under these circumstances.

The mildest cases are discoverable by the disappearance of sugar from the urine before all carbohydrates are withdrawn, and in such cases they need not be. In most cases of diabetes a certain amount of carbohydrate food can be eaten and utilized by the tissues. What this amount is can only be determined by experimenting. The ability of individuals to utilize such food varies from time to time. It is rare that more than 100 grams—3 1/3 ounces—per day of such food can be taken safely.

Those cases which belong to more severe types of the malady, can not be so quickly classified. The effect of more rigorous dieting and often of medicinal treatment must be determined.

In the mildest cases, when it has been determined what diet will prevent glycosuria, that must be persevered with as long as possible, or at least for several weeks. When cases are very mild the dietetic limitation is often so slight as to cause the patient no discomfort and to require little self-denial. In those cases which approach the group of moderate ones persistent restriction does demand self-denial, and is not only irksome but the excess of albuminoids and fats often lessens the appetite too much and cause indigestion.

It should not be thought that because while a patient is on a restricted diet glycosuria does not return, he is cured. A genuine cure is rarely effected. A temporary recovery often is. When a restricted diet has been used for several weeks, or two or three months, if possible it can gradually be made more generous as regards carbohydrates. The mildest cases can be permitted a thin slice of bread at each meal. The amount

of this can be increased for two or three days and its effect estimated by uranalysis. If it does not cause glycosuria a baked potato can also be tried, and later a little of fruit which contains the least amount of sugar. It is rare that a full normal diet can be resumed. In a small proportion of cases it can be taken after several months of treatment. Recurrences are so usual that it is therefore necessary to inculcate perseverance in watching the urine. If it increases in amount, and especially if it produces a feeling of stickiness when it dries on any object, the patient should at once consult his physician. If appetite grows less or weight of body diminishes, he should again place himself under guidance. It is best for all who have had glycosuria to have, even after apparent recovery, a uranalysis made every four to six weeks for a year or two. In most cases recurrences take place from time to time and careful treatment is intermittently needed.

The diet which in moderate cases is necessary to prevent glycosuria can not be long maintained, and still less can it be in the severest cases, for from it all sugar and carbohydrate food must be excluded. This necessitates a diet almost exclusively of meats and fats. Such a diet soon causes a disgust of the foods permitted the patient, or dyspepsia, and often increases nitrogenous denutrition, which is already excessive. By a reasonable restriction of diet the percentage of sugar in the urine can be kept low. It must be remembered that sugar in the urine *per se* is not harmful. It is only as it indicates the degree of disturbance of nutrition which exists that it is of importance. When by suitable treatment of a moderately severe, or a severe case not more than 500 grains of sugar are voided daily, the case can be regarded as well controlled.

Another point in treatment on which I wish to place stress is that excellent results can often be had by intermittently restricting the diet closely. The advantage of this is not generally appreciated. From two to six times a year this should be done for from two to four weeks at a time. In most cases it is better on one or two days in every week to place patients on a diet which is limited in quantity and much restricted in character. For instance, if a patient is permitted a liberal amount of meats, non-amylaceous vegetables and a little bread, or occasionally a potato, it is well once from five to seven days to prescribe a day of fasting, when only a modicum of albuminous food, a little salad and possibly a small amount of nut-bread are permitted. Water should at these times especially be drunk freely. These days and the longer periods of restriction remove for a time or greatly lessen the natural stimulants of the liver. In prescribing these days and periods of fasting, what has already been said of the significance of Gerhardt's test and of disgust for food and of dyspepsia must be remembered.

To prevent too rapid nitrogenous denutrition fats must be urged on diabetics. They lessen the consumption of tissue-albumin just as carbohydrates do. Unfortunately they are not tolerated in quantities which will enable them to fully take the place of carbohydrates. Butter is well digested and should be eaten freely. Olive-oil should be used generously on salads. Fat meats, such as ham, bacon, pork and mutton should be eaten. These meats, except crisp fried bacon, can best be tolerated when eaten cold, if they must be eaten often. Many clinicians prescribe cod-liver oil also. This is not well taken by my patients. It is apt to cause indigestion and disgust. It can rarely be taken by them in quantities which make it very

useful. Many think that a small amount of alcoholic beverage which does not contain sugar, stimulates the stomach and facilitates the removal of fats from it, and therefore their more rapid digestion. I know of no experimental demonstration of this. Undoubtedly it is true that many patients can take fats and oils in considerable quantities with more relish if they take also such an alcoholic beverage. Condiments often help in the same way.

Meats can be permitted at all times, except liver, and oysters, mussels,¹ and such shell-fish as consist chiefly of liver. Meats should not be cooked with flour or bread-crumbs. Eggs are especially useful. Meat, eggs and fish must constitute the staple of a diabetic's diet. Cheese of all kinds is permissible. Some contain in an agreeable form a goodly amount of fat. Butter is the most agreeable form of all fats and can be taken in the largest amount with the greatest pleasure. It should be spread thickly on bread or its substitutes, which may be prescribed. Cream also is agreeable and can be permitted with benefit to most patients, although it contains about 3 per cent. lactose.

Devonshire cream, which is liked by many, contains less than 2 per cent. of lactose and 65 per cent. of fat. Buttermilk contains about 3.3 per cent. lactose. Koumiss contains from 1.6 to 2.8 per cent. lactose, and kephir 1.5 per cent. Milk can be permitted diabetics, except when a very strict diet is prescribed. It usually contains 4 per cent. of fat, 4.5 of lactose, and 4 of proteid. It can only be allowed in small quantities, for a pint of milk contains an ounce and a half of milk sugar.

Several substitutes for milk have been devised. I suggest the following as much the easiest to prepare: Cream contains 25 per cent. of fat, approximately 3 per cent. of sugar, and the same of proteid. If it is diluted one-fifth with water it will contain 5 per cent. of fat and approximately .5 per cent. of sugar and proteid. To the water with which it is diluted, egg-albumin should be added, so as to increase the total amount of albumin. The mixture can be sweetened with saccharin. This will make an agreeable drink, rich in fat, and containing also a small amount of albumin and about 1 dram of milk-sugar to the pint of beverage.

All sugars do not seem to be equally harmful. The same can be said of starches. When glucose is eaten it is most certain to appear at once in the urine of diabetics. Milk and cane-sugar are somewhat better assimilated, and levulose can be taken by many diabetics in considerable quantity without harm. It is, however, too expensive to be used as a substitute for sugar. Saccharin is the most available substitute. Honey must be forbidden, as must milk, cane, and grape-sugar.

Starch, although it is converted into sugar during digestion, is less certain to aggravate a glycosuria than sugar itself. It, and foods containing it, must be forbidden when a rigorous diabetic diet is prescribed and must always be limited, even if it is not forbidden. This necessitates excluding from the diet of the diabetic, flour products—bread, cake, pastry, etc.—cereal foods, rice, corn-starch, potato-starch, arrowroot, sago, tapioca, hominy, macaroni, vermicelli and farina.

Numerous substitutes for flour-products have been recommended. Bread is the most difficult of all articles of food for diabetics to abstain from. These substitutes are therefore a comfort to them. They can no

1. Klean and some others permit shell-fish; oysters contain only 2.6 per cent. of carbohydrate

are to be eaten with great freedom, for most of them contain too much of fat, nor are they relished for long when eaten steadily. They are also for the most part expensive. The following are among the best known of those substitutes: gluten, almond, sago, cocoanut, oat and Chicago Sanitary Flour. From the last and from cocoanut flour almost all trace of sugar, which is the carbohydrate present, can be removed by raising bread with yeast. The sugar can be almost as perfectly removed from almond flour by washing with acidulated water. These are the best substitutes for wheat bread. Commercial gluten bread contains half as much as, and sometimes more carbohydrate than, wheat bread. It is less palatable. It is much better to give a restricted amount of ordinary white bread than to use it. The bread made of nut-flours should be used very moderately, for it contains so much fat that it is not readily digested. The Chicago Sanitary Flour is the least objectionable on this score. Moreover, patients tire of it after a few weeks. It is well, therefore, to shift from one nut-flour to another and to make a variety of forms of bread, so that weariness of these preparations may be as long delayed as possible. The following receipt is recommended by O'Donnell as a substitute for home-made bread. It contains no starch nor sugar. It will also help to vary a diabetic diet.

Six eggs are to be beaten thoroughly; add a teaspoonful of baking-powder and a quarter as much salt; again beat the eggs. Pour the mixture into hot-waffle irons greased with butter; bake in a hot oven. Eat hot with butter or flavor with cheese or nuts.

Substitutes for home-made bread should only be used while patients are on a strict diet.

The following vegetables can be eaten by diabetics: cress, cabbage, lettuce, sprouts, endives, broccoli, spinach, celery, cucumbers, mushrooms, artichokes, green French beans,² sauerkraut, cauliflower, dandelion, sorrel, asparagus, onions, leeks, tomatoes.

Root vegetables, such as potatoes, carrots, and turnips, as well as beans, peas, and lima beans, must be forbidden to diabetics, because of the large amount of carbohydrates which they contain. When the diet is relaxed or the case is a mild one a potato can often be permitted. It is usually craved if long forbidden, and is undoubtedly much less harmful than the same amount of bread. Cranberries, strawberries, raspberries, blueberries and oranges contain from 1.5 to 6 per cent. of carbohydrates and can be permitted in mild cases. Kleen recommends peaches and apricots. All fruits should be forbidden to those who are on a strict diet. Dried fruit, preserved fruit and most dishes flavored with or garnished with fruit must at all times be prohibited. A measured amount of nuts—except chestnuts—can be allowed in mild cases.

Diabetic patients can be permitted to drink water as freely as they desire. Tea and coffee can also be allowed, providing no sugar is used in it and little cream. Cocoa and chocolate contain a considerable amount of carbohydrate and, as usually marketed, contain an additional percentage of sugar. The frequent or constant use of alcoholic beverages is undesirable, for they both irritate the liver and kidneys, which are unusually active in diabetics. Brandy, cognac, and

whisky contain no sugar, and several wines contain little, such as Swiss wine, Rhine wine, Burgundy, Bordeaux, Austrian (red). Wines should not be used, unless in the smallest quantities to flavor foods. Lemonade can be made with saccharin and is unobjectionable.

Several of the European spas are famous as resorts for diabetics. The best known of them are Carlsbad, Neuenahr and Vichy. It is doubtful if the waters in themselves influence diabetics. They may effect favorably concomitant digestive disorders and toxemia. That a short sojourn at these spas is of advantage is too well known to require a new demonstration. Benefit, however, is derived from a change of life, from an outdoor life, from exercise and a regulated diet, all of which such residence necessitates or presupposes.

Kleen,³ of Carlsbad, most frankly and justly says: "As for the glycosuria, Carlsbad and Vichy water, and doubtless, also Neuenahr water, in moderate and rational amounts recommended at present, which scarcely ever go beyond a liter a day, have no appreciable influence, or one that is extremely slight and uncertain."

Mental depression and excitement are extremely harmful for diabetics. Whenever possible they should be freed from business care, family troubles, or a life of excitement. During the last few years of widespread financial embarrassment I have frequently been able to trace the effect of sorrow and anxiety in the increasing physical trouble of my diabetic patients. Sexual excess should also be avoided by them.

The skin should be kept active by baths and friction. The patient should be carefully protected by woolen or silken underwear from sudden temperature changes. Regular exercise and, if possible, out-door exercise should be taken to ensure deep breathing, good oxygenation of the blood and vigorous metabolism.

The following menu will illustrate what should be prescribed while a strict diet is maintained. On "fast days" a limited amount of these same foods should be recommended.

Breakfast.—Tea or coffee without sugar or cream, one egg and bacon, and two or three slices of nut-bread with butter (Chicago Sanitary Flour or similar substitute for wheat flour).

Dinner.—Bouillon or broths; beef, mutton or chicken; spinach, or asparagus, or wax beans; salad of lettuce or tomatoes, with cheese; black coffee without sugar.

Supper.—Tea or coffee without sugar or cream; meat or fish, or mushrooms; a salad of tomatoes or lettuce, or chicory, etc.; two or three slices of nut-bread.

At bedtime or in the evening, an egg lemonade made with saccharin, can be given.

Use as much butter as possible on bread and oil on salads; eat by preference fat meats.

When a strict diet must be maintained, the cook should endeavor to furnish as large a variety of dishes by skilful preparation from the limited number of articles as possible.

When patients keep a "fast day" it is best to prescribe only two meals a day, one at breakfast time and one about six in the evening. At noon, if it is desired, an egg lemonade made with saccharin, can be taken. The amount of food eaten at the two meals should also be limited.

65 Randolph Street.

2. Kleen says when the seeds are developed string beans contain several per cent. of sugar and starch. They should be eaten when green. Saurkraut when well fermented contains a fraction only of a per cent. of sugar. Celery contains 10 per cent. of sugar and must be forbidden diabetics when they are on a strict diet, it is permitted by some clinicians at other times.

COMA DIABETICUM: ITS TREATMENT.*

HEINRICH STERN, Ph.D., M.D.

Professor of the Diseases of Metabolism, College of Physicians and Surgeons, St. Louis; Visiting Physician New York Red Cross Hospital; Attending Physician St. Elizabeth's Hospital; Member American Chemical Society, American Medical Association; Fellow New York State Medical Association, Etc.

NEW YORK CITY.

In a recent communication a New York writer expresses the opinion that most cases of diabetes mellitus end with coma. A research made by me of all the original death certificates of individuals who have died from diabetes mellitus in the city of New York—Manhattan and the Bronx—during 1899 revealed the fact that among a total mortality from diabetes mellitus of 202, but 60 cases, that is, about 30 per cent., terminated in coma.

The greater number of these sixty instances which were designated as "coma," it is safe to assume were not those of typical diabetic coma. Coma associated with diabetes deserves the appellation "diabetic coma" only in certain well-defined cases. A number of writers have furnished statistical data as to the frequency of coma in diabetes, but have omitted to differentiate between the typical condition and that which is the sequence of complications co-ordinate or intercurring with diabetes mellitus. Moreover, the term "coma diabeticum" is not a very specific one, as the phenomenon is by no means characteristic of diabetes alone. Naunyn,¹ after Kussmaul and Riess, suggests to substitute the designation "dyspneic coma" for "diabetic coma" on account of its greater significance and as it precludes the assumption of its occurrence in diabetes exclusively.

The characteristic symptom of typical coma diabeticum is the peculiar dyspnea, first described by Kussmaul.² The patient breathes with great exertion, although there is apparently no obstruction which either the inspired or the expired air has to overcome. Every respiratory muscle is greatly taxed; the thorax expands perfectly in all directions. The inspirations are perfect, intensely deep and long drawn. The expirations are also perfect, but of shorter duration. The respiratory movements gradually assume a greater frequency, and they may become more superficial, particularly in such instances where the patient has been unconscious for some time; at the onset the circulation remains unaffected, and cyanosis is rarely present.

In this clinical picture the singularity of co-ordination of extreme systemic asthenia with the vigorous respiratory movements is most striking.

The pulse is weak and regular, and in the beginning of the coma its frequency is not above 100. In the fully developed dyspneic coma, the extreme weakness of the pulse does not always permit ascertaining of its frequency. Sphygmo-manometric determinations of the tension of the radial artery, made by me on a patient during the prodromic stage of dyspneic coma, showed an arterial pressure equivalent to 70 mm. Hg. During the intensely deep inspiration the instrument recorded a tension equivalent to 50 mm. Hg. Later, when the respiratory movements had become more shallow, a pressure of 15 mm. Hg. was yet determinable.

The body temperature is very low from the beginning of the typical coma, and gradually declines farther as the comatose condition develops; a temperature of 31 to 33 C. (87.8 to 91.5 F.) is not unusual. An increase

in temperature, which is occasionally met with in the prodromic stage or at the onset of the coma, is invariably caused by an accompanying complication. The pupils are found dilated in most instances; occasionally, however, they are more or less contracted. Pupillary reflexes may continue to exist until the comatose condition is completely established.

The stage of somnolence is most always preceded by gastrointestinal disorders or febrile affections, headache, anxiety, mental excitement, vertigo, delirium, jactitation, pains in the abdomen or in the hypochondria, or other disturbances. Anxiety, jactitation and mental excitement may be even observed in the beginning of the comatose condition itself. Similar disturbances, though not so well pronounced, are often premonitors of the characteristic dyspnea.

The amount of the diurnal urine during the prodromic stage is rather increased; after onset of the coma the output of urine generally diminishes. A patient of mine voided 4250 c.c. of urine the day preceding dyspneic coma. The urine obtained from the same patient the second next day amounted to but 550 c.c. The urine is nearly always strongly acid; its degree of acidity, according to my observations, varies between .45 and .8. The specific gravity is neither abnormally high nor low; dextrose, which might have been eliminated in increased quantities during the week preceding the comatose condition, in my experience, is most always excreted in not only absolutely, but also relatively, diminished amounts as soon as the dyspneic symptom is well pronounced.

In about 60 per cent. of all the urines obtained by me from patients, while they were in the condition of true coma diabeticum, I found either no glucose at all or only insignificant amounts of it. The diminution or disappearance of glycosuria under these circumstances may be in part ascribed to the inane condition of the comatose diabetic.

The output of ammonia by the urine in diabetic coma is, as a general rule, excessively increased; in a few such specimens of urine, however, which I had occasion to examine, the contained ammonia seemed not excessive in amount.

Albuminous substances in small quantities are most always present in the urine just prior to and during the comatose state. Numerous casts, according to Kützle,³ are always found in the coma of true diabetes. The amount of urinary albumin does not stand in any relationship to the number of casts. These are true casts and possess a characteristic appearance; they have smooth contours, are pale, short and broad, are hyaline, or often decidedly granulated and seem to be ragged. They are rarely covered with leucocytes or kidney epithelium. They occur even frequently in the prodromal stage of the coma. Like Naunyn, I have failed to find these casts in the urine of some cases of dyspneic coma. Aceton, aceto-acetic and oxybutyric acids are frequently present in the urine of the comatose diabetic. Aceton and aceto-acetic acid I have found absent in a number of instances and the presence of oxybutyric acid could not be ascertained by me in some of the urines of patients in coma diabeticum. The urine, in most instances, assumes a deep-Burgundy red coloration with chlorid of iron, which, however, is not always indicative of the occurrence of diacetic acid.

The alkalescence of the blood seems to be somewhat diminished during dyspneic coma. Magnus-Levy,⁴ who determined the blood alkalescence, according to Loewy, found in one case of diabetic coma a diminution of blood

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

alkalinity equivalent to 217 mg. NaHO in 100 c.c. of blood. In another instance the decrease amounted to 266, and in a third case to 170. In one of my own patients, who survived, I found the blood alkalinescence, which was determined after a modification of the Loewy-Zuntz method, during the beginning of coma, to be equivalent to 266 mg. NaHO. In another of my cases, after the establishment of Kussmaul's respiration, the blood alkalinescence was equivalent to 318 mg. NaHO in 100 c.c. of blood. The exhaled air in coma diabeticum possesses a peculiar odor, likened by all observers to that of acetone. The odor, however, whether due to acetone or not, I deem not characteristic of the comatose state; a trained olfactory will often detect it in the exhalation of patients afflicted with a comparatively mild type of the affection.

The symptom-complex as described in the foregoing may even occur in apparently mild cases of diabetes. The most insignificant causes may be factors in the production of diabetic coma. Digestive disturbances, long-continued proteid diet, constipation, bodily and mental exertion, localized affections, as inflammations and formation of abscesses, chloroform anesthesia and other occurrences, predispose to coma. A patient of mine had three attacks of genuine diabetic coma which were called forth in every instance by over-eating.

There is not a single phenomenon which indicates with any degree of certainty the approach of the comatose condition. The appearance of the heretofore described coma-casts may be of diagnostic value, it is true, but I failed to find them in some cases of diabetic coma. The increased excretion of oxybutyric acid may serve as an indication of imminent danger, but v. Noorden⁹ relates a case where oxybutyric acid was repeatedly found in the urine in quantities not less than 2 per cent. and where no coma supervened. The same author mentions that Weintraud had made a similar observation. A patient of mine, a female, 24 years of age, who is affected with diabetes mellitus for over seven years, has, during the last three months, while under a rigid fat-meat diet, repeatedly excreted oxybutyric acid in appreciable quantities; at the same time, the patient improved wonderfully, gained in weight and attended to her business, which demands much mental activity. She does not complain of lassitude and experiences no paroxysms of somnolence.

The alkalinescence of the blood apparently does not furnish a clue to the threatening coma. The degree of blood-alkalinescence, to be sure, is quite low in the advanced stage of diabetes, but the diminished degree of alkalinescence, as I have frequently observed, is by no means solely characteristic of the pre-comatose state. I have observed the same low degree of alkalinescence in apparently healthy individuals and in patients afflicted with diverse disorders.

After the dyspneic coma is well developed, death generally ensues within twenty-four or forty-eight hours. Non-dyspneic coma undoubtedly forms a great percentage of the cases of coma accompanying the advanced stage of diabetes mellitus. A goodly number of the cases of coma which occurred together with diabetes and which in the certificates of death are rightfully designated as "direct cause of death," have nothing at all in common with the genuine coma diabeticum.

The coma is atypic and only pseudo-diabetic in all such instances when it is the outcome of intercurrent affections or complications. Exhausting diseases like phthisis pulmonum and hepatic cirrhosis frequently terminate in coma. When one of these maladies or a septic

infection occurs together with diabetes and death supervenes by coma, the latter, in most instances, is of the atypic, that is, the non-dyspneic, type. The coma is most always of the latter type when affections of the central nervous system concur with glycosuria or the diabetic condition.

Chronic interstitial nephritis or pyonephritis does not infrequently occur together with diabetes. Uremic coma differs from true diabetic coma in its non-dyspneic character.

The pathogenesis of diabetic coma has been made the subject of investigation by many an observer. On this occasion it is neither opportune nor to the purpose to relate the results of my own work in this direction. Of the hypotheses which have been advanced to explain the origin of dyspneic coma, I mention the following:

1. Petters⁶ was the first to advance the theory that diabetic coma is the result of an autointoxication from acetone. The same observer proved the existence of acetone.

2. Klemperer⁷ is of the opinion that as yet unknown toxic substances are produced in the course of the diabetic affection. These poisons cause a specific disintegration of the protoplasm whereby aceto-acetic, and particularly oxybutyric, acid is produced. The toxic substances, when accumulated, call forth coma by paralyzing the brain.

3. Schmitz⁸ concludes that diabetic coma is due to the action of poisons which are of intestinal origin; he bases his assumption on the fact that in the latter stage of diabetes the feces possess a very offensive odor and that it is possible to avert coma by producing free evacuation of the bowels.

Stadelmann,⁹ and with him Minkowski, Naunyn and von Jaksch, trace the origin of coma diabeticum to an acidosis, an acid intoxication. The typical diabetic coma, according to the view of these observers, is, therefore, an acid coma. The increased ammoniacal excretion by the urine in advanced grave cases of diabetes mellitus serves as an indicator of the degree of acidosis. Levorotatory oxybutyric acid is the principal factor in the production of diabetic acidosis, but aceto-acetic acid, lactic acid or fatty acids may occasionally also call forth an acid intoxication.

Stadelmann's theory of the production of coma diabeticum has more adherents at the present day than any other hypothesis which has been advanced to explain the occurrence of this phenomenon. The modern alkali therapy of dyspneic coma is based on the assumption of an acidosis.

Stadelmann¹⁰ was the first to recommend sodium carbonate for the neutralization of the oxybutyric acid in cases of acid-coma. In order to prevent localized abscesses, which are often the result of subcutaneous injections of concentrated sodium-carbonate solutions, and to speedily increase the blood alkalinescence, Stadelmann proposed to inject the antacid intravenously. A normal-salt solution in which from 3 to 5 per cent. sodium-carbonate has been dissolved will not cause any untoward effects if directly introduced into the blood-current. The intravenous injection of sodium carbonate or bicarbonate has not fulfilled the expectations entertained. It is true, in many instances, an immediate improvement takes place after the infusions, but they afford only temporary relief. The lethal termination in coma, in the vast majority of cases is only deferred from twenty-four to thirty-six hours, and but few cases are on record in which coma had definitely subsided. The introduced alkali does not seem to exert a specific influence on the

acidosis and the transitory relief afforded by the infusion appears to be due simply to the blood dilution.

Naunyn¹¹ believes that dyspneic coma, when fully developed, in all probability remains uninfluenced by the alkali infusion.

The failure of the alkali therapy, in fully developed coma diabeticum, may be due to advanced tissue-changes which have been called forth by acid-intoxication and which can no longer be counteracted by an increase of alkalinity.

The alkali therapy may be employed with better prospects of success in the prodromic stage of diabetic coma. As soon as the first symptoms of the approaching comatose state set in, sodium bicarbonate, 15 to 30 grams daily, should be administered. There are instances on record where twice and three times this dose was given. The sodium salt should be continued until all signs of threatening coma have been dispersed. Naunyn, for prophylactic purposes recommends the continued administration of sodium bicarbonate in all such cases where the urine gives a strongly positive reaction with ferric chlorid.

While, as a general rule, I have seen good results following the prophylactic administration of sodium bicarbonate, coma was not prevented by it in some cases which have been under my observation. In the fully developed coma diabeticum, the alkali therapy proved such a failure in my hands that I have now relegated it to oblivion.

I have employed precipitated calcium carbonate for the past eighteen months in a variety of glycosuric disorders. As it had answered well in some instances, I concluded to prove its efficacy also in the comatose state of diabetes. I report the following two cases of typical dyspneic coma concomitant with diabetes mellitus, in which precipitated calcium carbonate was administered:

CASE 1.—R. A., female, aged 68 years; German, fifty years in the United States, widow, mother of three children.

Anamnesis: Family history negative; patient felt well until three years ago, when the family physician diagnosed diabetes mellitus. She had lost during this period about 17 kg. in body weight. In the last three months the patient had frequent attacks of vertigo, during one of which she fell and received injuries on the right hypochondrium. She has been under a diabetic regimen from time to time.

February 6, 1900: Pronounced emaciation and weakness; somnolence; cheeks flushed; pupils dilated; heart arrhythmic; pulse, 108; tension of right radial artery, 70 mm. Hg.; left radial artery, 160 mm. Hg.; temperature (rectal), 37.2 C.; respiration deep, 20 per minute; liver apparently normal; blood alkalescence, 266 mg. NaHO; abdomen inflated, ankles edematous. Urine: total amount in twenty-four hours, 3600 c.c.; color, Vogel's scale No. 3; transparency normal, odor normal, consistency normal; reaction acid, 45 deg., specific gravity, 1023 at 15.5 C.; total solids, 192.92 grams; no deposit soon after being voided.

Salts of hydrochloric acid increased; salts of sulphuric acid increased; salts of phosphoric acid, namely, alkaline and earthy phosphates, increased; salts of carbonic acid increased; free ammonia, none; carbamid, 1.2 per cent., or 43.2 grams; uric acid, normal ratio; xanthin, traces; creatinin, appreciable quantity; hippuric acid, traces; urobilin diminished; urine indican, normal quantity; nucleo-albumin, normal amounts; serum albumin present in considerable quantity; nucleo-albumin, normal amounts; serum globulin present; biliary acids, absent; fatty matters, traces; pus, absent; glucose, 3.22 per cent., or 115.92 grams in 3600 c.c. urine; glycuronic acid combinations, absent; acetone, present in small amount; diacetic acid, present; oxybutyric acid, present in appreciable amounts.

Microscopically: Uric acid, urates, calcium oxalate, calcium sulphate, round, columnar and squamous epithelium; short hyaline casts (Külz-Aldehoff's).

Treatment: Sodium bicarbonate, 5 grams per os every hour.

February 7: Comatose condition more fully developed. Pulse, 110; pulsatory dilatation and contraction of right radial artery hardly determinable; of left radial artery, much stronger. Respiration, 28 per minute; intensely deep inspirations. There is a peculiar odor penetrating from the mouth, which, however, is not alike to that of acetone or oxybutyric acid.

Treatment: Two liters of physiologic salt-solution by enteroclysis every four hours, to be followed after evacuation of the bowels by enteroclysis of 2 grams calcii carbonas præcipitatus, suspended in one liter of water of 42 C.; strychnin camphoricum, .0005 grams, hypodermically every six hours; with exception of water, all ingesta were withdrawn.

February 8: Comatose symptoms have disappeared. The treatment is continued in the same manner. Patient is permitted to take 100 c.c. milk every hour and a half. Also water and cracked ice ad libitum.

February 9: Patient is able to sit up. The alkalescence of blood is equivalent to 373 mg. NaHO. The urine gives but a faint reaction with chlorid of iron. The enemata of salt water are continued twice daily. Precipitated calcium carbonate is ordered to be given in 2-gram doses every two hours, and strychnin sulphate in tablets of .001 each three times a day. Diet limited to milk.

February 13: Improvement continues. Urinary glucose, .75 per cent. in diurnal output. No acetone. Gerhardt's reaction negative.

Treatment: Lavage of bowel with normal salt-solution every morning. Sodium bicarbonate, 4 grams every two hours. Strychnin sulphate continued. Diet still limited to milk on account of chronic nephritis.

February 18: Urinary glucose, 1.5 per cent.; albumin diminished; a few hyaline casts. No acetone; no aceto-acetic acid, Druzs and diet continued.

February 25: Urinary glucose diminished; albumin increased; hyaline casts; no acetone, no aceto-acetic acid. Druzs and diet continued.

March 1: The patient is up and about, but is very weak and restless. Complaints of headache, tremor and vertigo. Treatment as heretofore. Strychnin is withdrawn and morphin in doses of .015 gm. substituted.

March 4: Urine, glucose, 1.25 per cent.; no acetone nor diacetic acid.

March 14: Urine, diurnal output, 1200 c.c.; acidity, .35 degrees; specific gravity, 1014; glucose, .75 per cent., or 9 grams in 1200 c.c.; albumin, .75 per cent. (Esbach); hyaline casts, no acetone, no diacetic acid.

March 23: Urine, glucose, .75 per cent.; albumin present; hyaline casts; no acetone, no diacetic acid.

March 29: Patient was able to come to my office. Heart is in better condition; bronchorrhea; arterial tension, right radial artery, 100 mm. Hg.; left radial artery, 160 mm. Hg.; arteriosclerosis. The sides of the neck are noduliferous. Liver apparently normal. Abdomen somewhat inflated. Alkalescence of blood, 373 mg. NaHO. Patient complains of the milk diet. Medicines as heretofore. Diet unrestricted.

April 7: Patient had a slight attack of hemiplegia of the right side. Aphasia present, but not complete. Treatment consists of sodium and ammonium iodid, strychnin, bicarbonate of soda. Irrigation of bowels with physiologic salt-solution.

April 10: The hemiplegic symptoms have almost totally disappeared; patient can converse as before the attack. Treatment continued as above, but hydrochloric acid is substituted for the sodium and ammonium iodid.

April 12: Patient, under the circumstances, feels comfortable, but complains of weakness and restlessness.

April 13: Attack of typical dyspneic coma resembling very much the one of February 7. Treatment, the same as in the last attack, viz., two liters of physiologic salt-solution by enteroclysis every four hours, to be followed after evacuation of the bowels by enteroclysis of 2 grams precipitated calcium carbonate suspended in 1 liter of water of 42 C. Strychnin

camphoricum .0005 grams, hypodermically every six hours. Nothing but water allowed for ingestion.

April 15: The comatose condition has completely subsided; patient is totally exhausted and near collapse, involuntary micturition and defecation. Treatment: Enteroeclysis discontinued; strychnin camphoricum as above; milk.

April 17: The patient is extremely weak, but possesses her full senses and is able to speak. Involuntary micturition and defecation.

April 18: Death by collapse.

CASE 2.—C. S., female, aged 60 years; Russian; thirty years in the United States; married, mother of three children.

Anamnesis: Family history negative. Patient is afflicted with diabetes for almost eight years. She has been repeatedly on an antidiabetic diet; she, however, did not keep it up long enough to be benefited by it. Bulimia was always present, even in her younger days, long before diabetes was recognized. Of late she complained of extreme weakness and lassitude, of attacks of drowsiness and of obstinate constipation.

March 30, 1900: Patient is lying in bed, in an apathic and somnolent condition. On being aroused she answers the questions intelligently enough, but in a peculiar drawling manner. Her countenance is flushed and she complains of pain in the occipital and umbilical regions. There had been no movement of the bowels for about twenty hours. Micturition is frequent and involuntary. Her general appearance is quite good. The odor emanating from the mouth is similar to that of acetone. The pupils are rather dilated. The tongue is not furred. Temperature, rectal, 38.6 C.; pulse, 98; pulse tension, 110 mm. Hg.; heart-beats, regular, but somewhat accelerated; respiration, labored and deep without inspiratory stridor; liver and spleen of normal caliber. There is an old umbilical hernia, which, however, causes no trouble whatsoever. Abdomen greatly inflated. No local edema anywhere. Alkalescence of blood equivalent to 266 mg. NaHO in 100 c.c. of blood. Urine, exact diurnal amount not ascertainable on account of involuntary micturition; color, yellow; transparency perfect; reaction, acid, .53 degrees acidity; specific gravity, 1026 at 15.5 C.; carbamid, .5 per cent.; ammonia in increased amount; indican, increased amount; serum albumin and serum globulin absent; glucose, 4 per cent.; acetone, present (Lieben's test); Gerhardt's reaction strongly positive; oxybutyric acid present. (Distillation, determination of melting-point of crotonic acid.)

Treatment: High irrigation of bowel with normal saline-solution; administration per os of calcii carbonas precipitatus in doses of 4 grams every three hours.

March 31 (sixteen hours later): Dyspneic coma more fully developed. Alkalescence of blood, 318 mg. NaHO; a small increase since yesterday. Temperature (rectal), 35.4 C.

Treatment: Enteroeclysis of physiologic sodium chlorid solution, 2 liters every four hours, to be followed after evacuation of the bowels by enteroeclysis of 3 grams precipitated calcium carbonate, suspended in 1 liter of water of about 42 C. Strychnin camphoricum, .0005 grams hypodermically every four hours.

April 1: Patient has been conscious repeatedly. Respiration, 32 per minute, and shallow; temperature, 36.2 C. (rectal); pulse, 120, weak and thready. Treatment continued as heretofore.

April 2: Patient has almost fully recovered from the attack of coma, but still complains of slight vertigo and headache. The urine contains nearly 2 per cent. of dextrose and still gives a decided reaction with ferric chlorid. Treatment: lavage of bowel with normal salt-solution twice daily. Calcii carbonas precipitatus by the mouth, 2 grams every hour. Strychnin sulphate, .001 grams, by the mouth three times a day. Restricted diet.

April 3: Urine, dextrose about 1 per cent. (estimated); Gerhardt's reaction positive.

April 6: Urine, dextrose, 25 per cent. Gerhardt's reaction positive.

April 7: Patient is out of bed; feels much stronger and develops again a morbid appetite. Is not satisfied with restricted diet. Treatment continued as heretofore.

April 8: Urine, dextrose, traces; Gerhardt's reaction positive.

April 9: Urine, dextrose, 1 per cent.; Gerhardt's reaction very faint.

April 10: Urine, dextrose, traces; Gerhardt's reaction very faint.

April 11: Patient is able to leave the house. Feels much stronger. Experiences hardly any dizziness. Urine is free of glucose; the ferric chlorid reaction still occurs. Medicinally, sodium bicarbonate in 3-gram doses every four hours and strychnin sulphate as above ordered to be taken. Diet: milk in small amounts and some carbohydrates permitted, meats and fats ordered to be partaken of in greatly diminished quantities.

April 18: Dyspneic coma, not completely developed, due undoubtedly to over-eating and subsequent gastrointestinal disturbances. Treatment: by enteroeclysis of normal salt-solution, to be followed by high enemas of precipitated calcium carbonate, as in previous attack. Strychnin sulphate, .001 gram, hypodermically, every five or six hours. Nothing but water allowed to be ingested.

April 20: Symptoms of coma have again subsided. Blood alkalescence equivalent to 371 mg. NaHO in 100 c.c. of blood. Urine, dextrose absent; faint reaction with ferric chlorid. Treatment: daily lavage of bowel with salt solution; precipitated calcium carbonate, 2 grams every two hours. Mixed diet.

May 3: The patient felt quite comfortable ever since the last attack of coma was dispersed. Urine: glucose, 1.5 per cent.; Gerhardt's reaction positive, but quite faint.

May 19: Patient complains of lassitude and drowsiness during the day. Restlessness during the night. Emaciation is very marked. Urine: glucose, 2 per cent.; Gerhardt's reaction decidedly positive. Treatment: lavage of bowel with physiologic salt-solution; sodium bicarbonate per os in 4 gram doses, hourly repeated. Morphine, .015 gm. at 6 p.m. and at midnight. Diet continues unrestricted.

May 21: Urine, glucose, 1.75 per cent; Gerhardt's reaction very decided.

May 24: Urine, glucose, 2.5 per cent; Gerhardt's reaction very decided.

May 25: Patient has again indulged in the pleasures of eating, and has consumed at one sitting vast amounts of delicacies. She feels nauseated and has vomited repeatedly. Constipation is present. Complete anorexia and aversion for food. Treatment: high enemas of bowel with salt-solution; sodium bicarbonate per os in 4-gram doses every hour.

May 27: The condition remains unchanged. Anorexia and aversion to food unimproved. Glycosuria scarcely noticeable. Ferric chlorid gives decided reaction.

May 28: Dyspneic coma, resembling the two previous attacks, but apparently more severe. Treatment: enteroeclysis of normal saline solution, 2 liters every three hours, to be followed by enteroeclysis of 6 grams, calcii carbonas precipitatus suspended in 1 liter of water at 42 C.

May 29 and 30: Severity of the attack has lessened. The patient continues in a semi-comatose condition. Treatment continued.

May 31: The condition of the patient is unchanged in the morning. Blood alkalescence at 8 a.m., 266 mg. NaHO. The injections are retained but for a very few minutes. The water flows back slightly discolored, but without formed masses. At 7 p.m. patient is somnolent, but gives intelligent answers. Blood alkalescence at that time, 373 mg. NaHO. Treatment continued.

June 1: Patient is still in the condition of somnolence. Urine free of glucose; gives Gerhardt's reaction. Treatment continued.

June 2: The patient's condition remains unaltered. Treatment continued.

June 4: The patient's condition has changed but little. Treatment with calcii carbonas precipitatus is continued.

Postscript: The patient died in the evening of June 4. Exitus occurred by exhaustion. No coma.

The two cases reported in the foregoing were those of undoubted typical dyspneic coma. In every case of the five instances in which an attack of coma occurred in these two patients, the phenomena characteristic of coma diabeticum soon abated.

It is true, Patient No. 1 succumbed to diabetes mellitus, but death in her case ensued by collapse, seventy days after her first and five days after her second attack of coma diabeticum. Patient No. 2 was still alive when I saw her yesterday (June 4). The first attack of diabetic coma she experienced on March 31, the second on April 18, and the third on May 28.

It may be surmised that the cessation of the comatose state in the instances mentioned may be due to a mere accident or to enterolysis per se.

The rather unusual and unailing control of the coma in every instance, however, forces one to assume that its abatement is rather the result of a specific action of the calcium carbonate. Possibly some of the precipitated chalk had reached a portion of the intestines, where, by the influence of acids upon it, carbonic acid was evolved, which in one form or the other had found entrance into the blood-channels, there neutralizing the acidosis; possibly the calcium itself, probably after the liberation of CO_2 , served as a base with which a toxic substance united to form an inert or innocuous compound. In no instance did I find the calcium output by the urine increased in any noticeable measure.

As precipitated calcium carbonate is but very slightly soluble in water, I facilitate its suspension in that medium by the addition of 25 per cent. its weight of acacia.

In submitting this preliminary communication on the use of *calci carbonas precipitatus* in true coma diabeticum, I must preclude any supposition on your part that this agent should be considered an unailing one in this condition. Still, the good services this drug and the specific mode of application have rendered will certainly induce me to prove its efficacy in other cases of diabetic coma.

DISCUSSION ON PAPERS OF DRs. DAVIS AND STERN.

DR. O. T. OSBORNE, New Haven, Conn.—I would endorse all that Dr. Davis has said on the question of when and how the dietetic treatment should be used in diabetes, and when it may be modified. The distinction is most important between glycosuria of dietetic origin and the diabetic condition in which the sugar is made from the proteids and is accompanied by wasting of the body. We all know how many persons go about in apparently good health, until it is accidentally discovered that there is more or less sugar in the urine. If they are hastily pronounced to be cases of diabetes and at once put on a restricted diet, they go down directly. It is, therefore, important to recognize not only cases in which the diabetic regimen is necessary, but also to recognize other cases in which it is not necessary and is positively harmful. I am surprised to learn that there is such a large proportion of men as compared with women—three to one. Perhaps this may be due to greater use

of alcohol by men. This leads to a consideration of the cause of diabetes. In a certain proportion of cases, the pancreas is at the bottom of the condition. I would like to believe that all cases of diabetes are directly connected with, or dependent on, the pancreas. It is not essential that there should be a gross lesion of the pancreas. It is possible to have disturbance of function of the pancreas without any actual pathological change in this organ. There may be a condition of overproduction of sugar, and a resulting glycosuria, which is analogous to functional albuminuria. Then there are conditions in which a limited portion of the pancreas may be doing all the work for the entire gland. There may be a certain amount of changed metabolism, or failure of function, which may end in glycosuria. I make the suggestion that some important function of the pancreas is at the bottom of these cases of glycosuria. If this is true, then we should be able to increase the function of the pancreas by proper remedies, just as in diseased conditions of the thyroid we obtain benefit from thyroid feeding.

DR. J. M. ALLEN, Liberty, Mo.—One question bearing on this subject we may consider settled, namely, that the function of the stomach in diabetes is well performed. We know that in order to get sugar into the blood it must be introduced through the medium of food which contains sugar or substances containing sugar. Therefore in diabetes there is a departure from the normal metabolic changes in the food which is dependent on pathologic changes in the digestive tract or perverted function of the nerve-center of the brain controlling the secretion of sugar. It is an accepted fact that this arrest of normal metabolic changes occurs below the pylorus; in my opinion in the duodenum. This portion of the digestive tract is abundantly supplied with blood and nerves. It is connected directly by its nerves with the spinal column, sympathetic nervous centers and brain center. It is the receptacle of the secretion of the liver, pancreas and its own glands. In the digestive process it performs as much work as the stomach itself. By its extensive nervous connection, in my opinion, it is the great reflex center of the gastrointestinal canal. Because of its location and physiological functions it is far more often diseased than the stomach. Chronic inflammation and ulceration of this organ is by far the most frequent cause of diabetes mellitus, either by the pathological changes arresting the metabolic changes in the food resulting in a product which can not be converted into glycogen and which by natural selection is taken up by the absorbers and passed into the blood to be deputed from it by the kidney, or by reflex irritation affecting the sugar centers of the brain, the irritation of which has been demonstrated by Bernard as resulting in sugar in the urine.

If this reflex irritation is continued long it is sufficient to produce organic changes (Brown-Séquard); then the case is hopeless. In confirmation of these facts I desire to report twenty-eight cases of diabetes mellitus which I have treated, all of which had chronic inflammation and ulceration of the duodenum. In seven of these cases I verified the diagnosis by post-mortem examination. In one the liver was slightly pale, in the remaining six the heart, liver and pancreas were perfectly normal. In support of the irritation of the sugar center, I have had two cases of pachymeningitis that during convalescence had diabetes mellitus, one case of syphilis on which I made post-mortem and found gummata at the base of the fourth ventricle of the brain. In these last three cases opium had no influence in controlling the amount of either sugar or urine. In the other cases it had a decided effect in controlling both. The conclusion I draw from this is that the only beneficial effect of opium in diabetes is in controlling reflex irritation. The dietetic list suggested by all authors, and even the essayist, points clearly to the fact that the stomach is required to do all the digestion, and food that would require functional action in the duodenum is eliminated, thereby giving this organ rest.

DR. D. R. BROWER, Chicago—I will refer briefly to the clinical history of a case of a woman, 50 years of age, who first came under my care five or six years ago, and I have seen her occasionally since then. She had passed the menopause, but had suffered with nervous symptoms for some time, which she had attributed to "change of life." On examination, I found a

large amount of sugar in her urine. Her history was that she had been treated years before for nervous symptoms which were supposed to be due to a fibroid tumor. She had been treated by Prof. Byford, and having refused operation, she had taken large doses of ergot for a long time. She improved and thought that she had recovered, but the nervous symptoms had returned shortly before applying for treatment. I found a large tumor and supposed that the former tumor had recurred. The large amount of sugar in the urine made any operative treatment out of the question. On account of constipation, she was treated by large colonic flushing; the amount of fecal matter discharged was enormous. She was put on a moderate diabetic diet and on codain. Coincidentally, with the disappearance of the fecal tumor, the sugar disappeared from the urine. A few months later, having been in good health in the interval, she returned with her former symptoms. I again recognized a fecal impaction, and again it was removed by colonic flushing. Several times during the past five years, this has had to be repeated, but she had no return of the sugar. This is a case in which the diabetes was due to fecal impaction and intoxication, and it has led me to be more careful in stating to patients, that they have diabetes merely because they have some sugar in the urine. In this case, it was the colon that was at fault.

DR. L. W. ZWIESOHN, New York City.—As stated in the paper of Dr. Stern, there are many cases in which sugar occurs in the urine, which are usually pronounced by physicians to be diabetes, and which go rapidly down when put on strict diet. I have in mind the case of a man, who was told that he had diabetes and was put on strict diet but did not improve. He went from bad to worse, lost 30 pounds in four months, had palpitation of the heart, vertigo and sinking spells; he was unable to walk from general debility. I was called to see him and found that he was not doing well; he said that he had been on strict diet for several months. There was at this time no sugar in the urine. If he had been kept on the strict diet one month longer he probably would have died. He was put on a general diet gradually. I watched the effect on the urine and found that the sugar did not return. He made an excellent recovery, improved rapidly, and within three months he has regained the 30 pounds and is attending to business as usual, for the last eight months. Therefore, if we find some sugar in the urine we should not at once tell the patient that he has diabetes, but the case should be studied while on a slightly restricted diet, but not too rigid. Patients should not be frightened by a diagnosis of diabetes, when they only temporarily have sugar in the urine.

DR. T. B. GREENLEY, Meadow Lawn, Ky.—In many cases when a patient comes under treatment for diabetes his chance for living is about the same as in tuberculosis and other diseases of a chronic character. I suggested, if the pancreas is the site of the disease, we should use pancreatin or the pancreas itself in the treatment of diabetes, just as we use the thyroid treatment for myxedema.

DR. E. T. SHELLY, Atchison, Kas.—I have a case in which the glycosuria occurs during some disturbance of the general health. Recently the patient had an attack of erysipelas, and at that time the urine was found to be loaded with sugar; in two days he had an attack of profound diabetic coma. He recovered from this and, in two weeks, he had another attack of erysipelas, and for a few days again had sugar in his urine; two days later it had again disappeared under restricted diet. One point of importance in uranalysis may be mentioned. Occasionally in examining urine with Haines's solution, there occurs no immediate change in color, but on standing for a time, it will precipitate the red oxid. Is this tardy reaction due to the presence of a small quantity of sugar or to something else?

DR. A. C. LYONS—As regards testing for traces of sugar with the copper solution, it is very difficult in such a complex fluid as the urine, because sugar is not the only substance which will precipitate the copper. There are many cases, the urine of which is perfectly normal, but which will precipitate the copper oxid on standing for several hours. However, when there is enough sugar to be of any consequence, it can always

be readily recognized by the usual tests, and when it disappears sufficiently to make it doubtful to determine whether it is present or not by the tests, the patient will be greatly improved. The laboratory tests for small quantities of sugar are not applicable to clinical use by physicians generally.

DR. E. H. BARTLEY, New York City—I wish to add my testimony to support what has been said with regard to the diet in diabetes. I am opposed to the extreme diet, and have seen it do great harm; but, on the other hand, I think some modification of the diet necessary. This idea of putting patients on almost an exclusive meat diet, or meat and water diet, is certainly harmful. While attempting to avoid one difficulty, we are almost certain to run into another one as serious. As far as the patient's general health is concerned, we can do as well, or better, with a moderately regulated diet, as by the exclusive diet. While it is admitted that, by the aid of the exclusive diet, we reduce the amount of sugar in the urine, this is not the only point to be considered; the general condition of the patient must be regarded. I have many times seen an outbreak of nervous symptoms with loss of weight, and failing health, while on a rigid, restricted diet, and as soon as it was changed to a modified diet, the patients regained their health, while the amount of sugar was not greatly increased. With regard to the question of the accuracy of the tests for sugar, I think that it is time to abandon entirely the copper test as a means of determining the presence of sugar. I prefer the bismuth test, always taking care that albumin is not present in the urine to be analyzed. There are so many things which interfere with the copper test, that it can not be relied on when small quantities only are present. Where the proportion of sugar is so great that it can be easily recognized by other means, stickiness for example, then the copper test will be liable, but for small quantities it is often misleading.

THE CHAIRMAN, DR. SOLOMON, of Louisville—I would like to emphasize one or two points in the papers just read. The first one is that man's natural diet, the food from which he derives the greatest amount of energy, will consist of about two-thirds carbohydrates, and, safely there can, as a rule, be no considerable departure from this, for any great length of time without the general health and strength showing it. We must not lose sight of the fact that it takes a certain number of calories, or units of heat (force or energy), to run a man from to-day at 6 o'clock till to-morrow at the same hour. Starch is pre-eminent in its importance to supply the required number of calories necessary to keep man alive and at work during the twenty-four hours. Along this line I wish to suggest that the gradual admission of small quantities of starch, or sugar-forming food, would enable the patient to bear the restricted diet better. It is my practice to endeavor to teach patients to do without sugar by allowing them a small cube before food, and giving a smaller piece with each meal, gradually decreasing the quantity. I can hardly agree with Dr. Davis as regards his stress on alcohol and the dangers of its use. I consider alcohol very valuable, since it produces proportionately a very large number of calories or units of heat. Alcohol I regard as an important factor in the dietetic treatment of diabetes mellitus. I fully endorse the remarks of the other speakers, as to the importance of considering the general health of the patient. It is not a question merely of removing the sugar from the urine, but of keeping up the patient's nutrition and strength and maintaining the weight of the body. The scale is a good guide.

DR. J. M. ANDERS, Philadelphia—It gives me pleasure to hear the evidence of professional change of opinion on the dietetic treatment of diabetes, and to see that we are slowly discarding a very rigid diet for a mixed one. It is surprising how small a quantity of starch is really needed to keep up the strength of our patients suffering from diabetes. I call attention particularly to the good effects of small amounts of starchy food in the dietary. When a mixed diet is used, one or two ounces of carbohydrates are often quite sufficient. The main point is to prescribe a definite amount of starchy food and watch its effects, from day to day, on the urine. I use levulose for sweetening for coffee or tea at the table, in preference to saccharose.

DR. W. W. TOMPKINS, Charleston—These cases are very unfavorable to treat because of two things: They will not carry out instructions as to diet, especially if too rigid, and when they feel a little better they discontinue treatment. My plan is to allow a certain amount of carbohydrates in the daily food. In attending the case, we should pay more attention to the general condition of the patient than to the precise amount of sugar in the urine. In fact, sometimes the patients are doing better when the quantity of sugar in the urine is rather large.

DR. HEINRICH STERN, New York City—The discussion has not brought out any points in connection with my paper on "Coma Diabeticum and its Treatment." In reply to the question as to the frequency of diabetes mellitus and its relative occurrence in both sexes, out of 1867 deaths from this affection which took place from 1889 till 1899 inclusive, 931, that is nearly 50 per cent. ensued in women. Former authors speak of a mortality of males from 2½ to 3 times as large as that of women.

Glycosuria is only a symptom of diabetes; it is not an entity per se. I have seen it following extirpation of the sublingual glands. I have seen it also occur after removal of the tonsils. Glycosuria may be the result of prolonged chloroform anesthesia. True diabetes, as I have pointed out some years ago already, is not dependent on the mere excretion of glucose. Long before dextrose is recognized in the urinary fluid, the disease has made its appearance. I have substituted for "diabetes mellitus" the designation "diabetic deterioration," for, by careful observation we may recognize a pre-glycosuric stage. The stage of toxemia, most always occurring with diminished or no output of grape-sugar, forms in reality a post-glycosuric state. I think I was the first to use the exclusive milk regimen in diabetes mellitus. My experiments date back to the year 1889. While, in my experience, many patients do very well on the exclusive milk diet, others, after the injection of but 150 or 250 c.c. excrete dextrose. This shows plainly that we have conversion of lactose into glucose in certain cases, while this transformation does not occur in other instances. In other words: chronic glycosuria is not always due to the very same underlying systemic disturbances; the causative factors of diabetes differ widely, and we should not confine ourselves to treat a mere symptom, but we should try to recognize and treat the original affection.

I fully agree with my friend, Dr. Bartley, that the copper tests, as Haines', Fehling's, Trommer's, Elliott's, etc., do a great deal of mischief in the hands of physicians and even in those of physiological chemists. A great many minor constituents, of normal or abnormal occurrence, besides dextrose, bring about copper reduction. Thus it occurs that cases have been treated for years for diabetes, where in reality diabetes never occurred.

If a total meat diet is continued for a protracted period—a period which differs as to its length materially in different subjects—diabetic cachexia with its protean manifestations is apt to be produced. It is necessary that we individualize each single case; that we study minutely the condition and systemic idiosyncrasies of every patient, and that we prescribe a diet suitable for the special case. Routine treatment in diabetes, I hesitate not to say, is responsible for just as many deaths in diabetes as is no treatment at all.

I am opposed to alcohol, as a food as well as medicine. Still, in some cases, especially where the patient was a habitual user of alcohol and where it is of the utmost importance to increase the caloric value of the food, and where a natural aversion against the diabetic diet has been produced, I was compelled to use alcohol. I have made use of alcohol in three forms: first, by ordering Moselle wine; second, by recommending diluted brandy, and third, by prescribing spits, vini rect. together with stomachics and bitter tonics.

Menstruation by Vagina and Eyelids.—A curious case is related by Dolganoff in *Wratich* of September 9, of a young woman with normal menstruation, accompanied by an oozing of blood on the external surface of the eyelids, appearing in minute droplets like sweat. The eyes are otherwise normal.

PROLONGED FEVERS OF OBSCURE ORIGIN.*

R. B. PREBLE, M.D.

CHICAGO.

There are a considerable number of organisms that normally, or at least frequently, cause prolonged fevers, which may be called obscure, only when the localization of the organism is unusual, or the disease appears in portions of the country in which the disease is exceptional. For example, the tubercle bacillus is a common cause of long-continued fevers, but the nature of the disease is usually manifest; the malarial organisms cause cases of prolonged fevers of obscure origin in portions of the country where malaria is not endemic. It is not my intention to consider these cases, nor do I plan to mention such obscure conditions as the chronic recurrent fever (Ebstein), commonly called pseudoleukemia, but to limit this paper to that very common and wonderfully polymorphous disease or group of diseases which Leube so aptly calls "kryptogenetic sepsis." Sepsis is too commonly considered a condition within the exclusive province of the surgeon, and from the conspicuous absence of this subject from most of the text-books upon medicine, one might believe that it is a disease which the medical man is not called upon to treat. This idea, however, is erroneous, and I fully believe that the more serious forms of sepsis are more common in medical than in surgical practice; this is certainly true if I am correct in including under this head a considerable number of diseases at present described as morbid entities. In the present state of our knowledge a concise definition of sepsis, septicemia, septicopyemia, is difficult. It is a combination of infection and intoxication of the organism as a whole by any one of a large number of bacteria and their chemical products, and is characterized by the great irregularity of its clinical course, and by the multiplicity and varying intensity of its manifestations. In addition to this, the infection atrium is unknown during life, and often undiscovered after death.

Etiology. A large number of bacteria have been found in cases of this class, but not all with equal frequency. The various pus cocci are most often found, probably the pneumococcus comes next in order of frequency, and then come such organisms as the gonococcus, bacillus pyocyaneus and bacillus coli communis.

These bacteria may enter through any broken surface, cutaneous or mucous, and because the atrium is often small, or hidden, or has already healed and been forgotten before constitutional symptoms develop, it is impossible clinically and often also at the autopsy to discover it. In many cases we may infer something as to its location; for example, symptoms of an angina often precede the constitutional symptoms; in other cases there are signs of a severe gastro-enteritis; in others, a bronchitis, and so forth. In still other cases the autopsy will show some old and encysted suppurative focus which has furnished, after years of quiet, the bacteria necessary for the constitutional symptoms. The demonstration of the bacteria during life is usually difficult, but is sometimes successful, as is illustrated by the cases of pneumococcus septicemia and septicopyemia reported to this Section last year. It is perhaps possible that the many failures are due to the fact that only small quantities of blood are used in the inoculation of the culture-media. For this to be successful, large numbers of the bacteria must be present, in order that each

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

drop of blood may contain bacteria. Blood for this purpose should be drawn directly from a vein.

When one considers that this disease or group of diseases may arise from a large number of bacteria, each of which shows marked variations in virulence; that the individuals infected show varying degrees of resistance to the infection, and that the bacteria may exert their influence upon the organisms as a whole or mainly upon any set of organs, it becomes at once evident that the clinical manifestations are so polymorphous that a detailed description of them is impossible in the brief time allowed, and we can refer only to the various types of cases now described as morbid entities, and leave the more complete description and illustrative cases to the paper, of which this is but an extract.

The cases may be conveniently arranged in two main groups: 1. The systemic group, in which the organism as a whole suffers. 2. The focal group, in which some organ or set of organs furnishes the bulk of clinical symptoms. Among these cases we recognize the following subgroups: *a*, cardiac cases; *b*, pulmonary cases; *c*, gastro-intestinal cases; *d*, hepatic cases; *e*, renal cases; *f*, osteal and articular cases; *g*, dermal cases; *h*, hemolytic cases; *i*, nervous cases.

THE SYSTEMIC TYPE.

The onset may be gradual, resembling that of typhoid, with depression, malaise, anorexia, headache, myalgia, and a temperature; but usually the onset is sharp, with single or repeated chills, followed by rise in temperature, and the constitutional disturbances common to acute fevers. The type of the temperature is oftentimes markedly irregular, and interrupted by chills at varying intervals; but there are many variations from this rule, and the temperature may be perfectly regular and continuous at any level, like the temperature of a typhoid; it may be regularly intermittent like that of a typical malaria, or it may be absent altogether. Such temperature may continue for days or weeks.

The pulse is usually rapid for the temperature, even from the onset, a point which may have differential value when the case resembles typhoid, but cases are seen in which the pulse is slow throughout the course.

The patient is much depressed and weakened from the onset; is manifestly ill, although examination shows no demonstrable change in any organ except an enlarged spleen, such as is seen in most infectious diseases. The blood suffers a rapid loss in hemoglobin and red blood-corpuses. The number of leucocytes may be increased, but are often normal in number or even decreased. These blood-changes may be so marked as to overshadow all other symptoms. Examination for a bacterium is usually without result. The Widal reaction is absent. The diazo-reaction in the urine is frequently present and marked.

The diagnosis of such cases, while simple in surgical practice where some gross infection atrium is present, is difficult when such atrium is lacking. The diagnosis is based mainly upon the exclusion of the more typical infective processes, and in many cases subsequent localization upon some organs removes all doubt as to the diagnosis. It is in the diagnosis of this group of cases that the greatest progress has been made of recent years; many cases formerly classed as typhoid, typhomalaria and malaria are now readily recognized. This improvement is due to the more careful examination of the blood and the discovery of specific serum reactions. Repeated failure to demonstrate the plasmodium malariae excludes malaria. Persistent absence of the Widal reac-

tion, especially when the diazo-reaction is also absent, excludes a typhoid.

THE FOCAL TYPE.

Localization Upon the Heart.—Here we must place the cases generally included under the heading of malignant endocarditis, which I believe, with Leube, is merely a localized sepsis. Most will agree to his proposition, but many may be unwilling to place here the cases of so-called simple or verrucose endocarditis, so frequently appearing in the course of acute articular rheumatism; but most will agree that the simple and the malignant endocarditis differ in degree but not in kind.

The constitutional disturbances with the endocarditis are such as briefly described above; the recognition of the endocardial process must be delayed often for weeks until the changes in the valves of the heart have led to physical signs. Great care must be exercised in the diagnosis for, because of the anemia and changes in the heart secondary to it, the commoner valvular defects, notably the mitral insufficiency, are frequently simulated. The appearance of diastolic murmurs is of great value in the diagnosis, for they are not often accidental, although I have once heard a persistent diastolic murmur over the heart of a patient dying of sepsis, and found the heart valves normal at the autopsy.

Gastrointestinal and Liver Cases.—Gastrointestinal symptoms not infrequently initiate the clinical course, and this, with the violence of the symptoms, sometimes suggests that the infection atrium is here. The symptoms consist of nausea, vomiting, purging, pain. To these are added the constitutional symptoms, fever, chills, etc., and in a considerable number of cases jaundice, with acute swelling of the liver. Here, perhaps, we should place such cases as have been described under the name of Weil's disease, and here also belong some of the cases which present themselves clinically as acute yellow atrophy, cases which are in reality diffuse systemic infections, with especial localization in the liver.

Articular Cases.—A considerable number of the cases of sepsis show bone and joint symptoms exactly resembling those usually described under the heading of acute articular rheumatism. This last disease is, to quote Sahli, "a faded mirror image of pyemia," and transition cases from manifest pyemia to ordinary acute articular rheumatism have been seen by you all, the transition being so gradual that it is impossible to say where one leaves off and the other begins. For the present, at least, we must consider them as the same condition, the only difference between them being one of degree.

The frequent association of joint pains with hemorrhages into the skin brings us into contact with the *peliosis rheumatica*, another septic condition which can not be separated from the simple purpura, and the *morbus maculosus Werlhofii*, just as the latter can not be sharply separated from the scurvy.

We have, then, in the cryptogenetic sepsis, a wide group of cases which border upon, if they do not cover, a number of diseases now described as morbid entities; the malignant endocarditis, the Weil disease, and possibly the more intense acute yellow atrophy, the acute articular rheumatism, and the various forms of primary purpura, including the scurvy. In the present state of our knowledge, it is well for us to remember that while these various diseases are described separately, they may all be various manifestations of the same underlying condition, and I believe that this thought will lend clearness to our general conception of this puzzling group of diseases.

In closing, I must mention briefly the general lines of treatment. Having no specific treatment, we can but treat symptoms, and our efforts are directed mainly to supporting the strength of the patient. Hydrotherapy, quinin, iron, strychnia, salicylates, guaiacol, mercurials, and various nuclein preparations are all used. Mention should also be made of the Credé ointment, the anti-streptococcus serum, the bleeding and subsequent intravenous injection of salt solution, all of which at times seem to yield results.

DISCUSSION.

DR. WILLIAM KRAUSS, Memphis, Tenn.—I have observed a number of times, particularly in the autumn, a number of cases of fever neither malarial, typhoid nor tuberculous, which, upon blood examination, showed only leucocytosis. The paper of Dr. Preble was very instructive to me, and I shall follow up those lines and try to verify the observations made.

DR. LOUIS FAUCERES BISHOP, New York—We often have cases in which we fail in making a diagnosis, because we insist upon putting them in long-established groups. I have been impressed with the thought that there should be a group of cases that, in popular parlance, we might call blood-poisoning. Such are the patients who run a long course of irregular temperatures after we exclude every possible disease that can be diagnosed by the microscope or by physical examination and about which we can not arrive at any definite conclusions. But such a group must not be made a dumping-place for undiagnosed cases. The suggestion of Dr. Preble that some of these are cases of typhoid is a good one. I was called in consultation to see a case in New Jersey a few months ago. The patient was a woman, of middle life, who had a great deal of pelvic trouble. She was a chronic pelvic invalid. A very clever gynecologist who examined her said there were many adhesions, but no pus in the pelvis. The woman was sick for a long time running this irregular temperature. Then it was thought it might be tuberculosis. I examined the chest and found only a slight amount of dullness at the base of the right lung; I suspected there might be pus there, but the needle introduced at that point did not show any. A careful restudy of the case led me to suspect typhoid fever which had attacked a person already an invalid. I then took some of the blood and got a very good Widal reaction. The case was entirely atypical. It was simply a chronic invalid who had commenced to run an irregular temperature. On that reaction, without symptoms of typhoid, I made the diagnosis of typhoid fever and gave a good prognosis. The woman recovered after prolonged nursing and treatment.

DR. N. S. DAVIS, JR., Chicago—The obscure cases which are difficult to diagnose and difficult to describe are made much clearer by what Dr. Preble has said regarding them. There is one point that I wish to emphasize, i. e., the liability in certain cases of infection through the gastrointestinal tract. This important point has been impressed upon my mind by several instances. I will call attention to two in the paper which I am to read here to-morrow. Another point is the frequency with which, in these cases, cardiac symptoms arise. In prolonged fevers of obscure origin we should watch for an endocarditis. And yet, when we ultimately discover the existence of a cardiac lesion we are not justified in concluding that we have had to do from the beginning with ulcerative endocarditis, but with a septic disease, in the course of which endocarditis has developed. I speak of this particularly, because in meeting other physicians and talking over cases, especially cases of malignant endocarditis, I find that it is usually an endocarditis superimposed on a general sepsis.

DR. ROBT. B. PREBLE, Chicago—In regard to the Widal reaction, I would be unwilling to make a diagnosis upon it; nor would I be willing to exclude typhoid fever in the absence of this reaction. I believe, though, that it can be obtained in the vast majority of cases.

Iron in Eggs for Invalids.—The *Gazzetta degli Osp.* of October 18 states that Dr. Viray feeds hens with salts of iron incorporated in their food. The fowls tolerate the iron perfectly and eliminate it mostly in their eggs, which are thus delicately medicated.

ACUTE ARTICULAR RHEUMATISM—ITS ETIOLOGY AND PATHOLOGY.*

DAVID RIESMAN, M.D.

Professor of Clinical Medicine, Philadelphia Polyclinic; Visiting Physician to the Philadelphia Hospital.

PHILADELPHIA.

With the exception of a small and gradually lessening number, modern writers consider acute articular rheumatism an infectious disease. The nervous origin of rheumatic arthritis, proclaimed by the elder J. K. Mitchell¹ in 1831, and defended by Charcot, and more recently by Friedländer², who places the primary lesion in the medulla oblongata, has been abandoned. More tenacious is the lactic acid theory of Prout, Todd, Fuller, Richardson, and others, according to which rheumatism is dependent on an excess of lactic acid in the blood. I need not bring forth any arguments against this theory. As MacLagan³ says, the advocates of the lactic acid theory have taken one of the phenomena of the disease and raised it from its normal and subordinate position as a symptom to the rank and dignity of an exciting cause. Edwards,⁴ Eisemann, and lately Haig,⁵ have modified the acid theory, and replaced the lactic with uric acid, the retention of which in the system Haig considers to be the causative factor in rheumatism. He presupposes the existence of an excess of uric acid in the blood, and that this is driven into the joints, owing to a diminution of the alkalinity of the blood. But not only has he failed satisfactorily to prove that uric acid accumulates in the joints in acute articular rheumatism, he has also drawn a conclusion that is scarcely warranted even in the premise—a pre-existing "uricacidemia"—is accepted; for it is just as likely that if an excess of uric acid does occur in rheumatism, it is a consequence—a symptom, merely—and not the cause of the disease. The very fact that Haig finds uric acid retention in so many affections suggests the thought that, like fever, leucocytosis, or albuminuria, the hypobiotic "uricacidemia" is only a symptom.

There are two ways of proving that a disease is infectious: by direct evidence, that is, by the unequivocal demonstration of the causative agent; and by indirect or circumstantial evidence, which rests largely on analogy. I may say that in the case of acute articular rheumatism we are not yet in possession of direct or prima facie evidence; in other words, I do not believe that the cause has been definitely discovered. It is true that a large number of investigators claim to have found the specific micro-organism, but in no instance has indubitable proof of the causative relation of the particular organism been brought. If it were that the micro-organisms hitherto found could not be cultivated, we might, as in the cases of leprosy and malaria, rest content with the mere demonstration of their invariable presence, and not demand, for final proof, the production of the disease in the lower animals; but the organisms which have been found are, for the most part, readily cultivated, and yet it has not been possible to reproduce in the lower animals the typical picture of rheumatism as we see it in man. This fact, however, does not render invalid the proposition that acute articular rheumatism is an infectious disease. The same is true of syphilis, scarlet fever, smallpox, chickenpox, and possibly of whooping-cough and measles; and yet no one doubts their specific nature. The circumstantial evidence in favor of the infectious origin of rheumatism

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

is as strong as in the diseases which I have mentioned, although two of their important characteristics are not possessed by rheumatism, viz.: contagiousness and immunity after one attack. Regarding contagiousness, however, I may add that Wagner,⁶ of Leipsic, believed it possible, and made it his practice to isolate cases of acute rheumatism in the hospital. As for immunity, it is such a vague concept, and its duration in different diseases varies so much, that it is not out of the realm of possibility that there is a brief period of immunity after one attack of rheumatism, perhaps as long as that obtaining in diphtheria, which, as is well-known, is of comparatively brief duration.

I wish now to take up the facts which, although they do not demonstrate it absolutely, point in an unmistakable manner toward the infectious origin of acute articular rheumatism.

Fever.—While fever may be due to causes other than infection, it is most natural in the case of a continuous fever, like that of rheumatism, to look for a micro-organismal agent. The occurrence of hyperpyrexia is also strongly suggestive of the activity of toxin-producing organisms.

Chill.—At times, as I have seen in several instances, the disease is ushered in by a distinct chill or rigor. I do not mean by this the chilling of the surface which often precedes an attack of acute articular rheumatism, but the initial chill which inaugurates so many infectious diseases, and which indicates that the period of incubation is passed and invasion has begun.

The Occasional Epidemic Outbreak of the Disease.—McClymont⁷ and Newsholme⁸ have both called attention to this epidemic incidence, and Risse⁹ has reported the concurrence of an epidemic of acute articular rheumatism with one of influenza. Edlefsen,¹⁰ McClymont, and Stoll¹¹ have observed house epidemics of rheumatism, such as we occasionally find in croupous pneumonia, an unquestioned infectious disease.

The Seasonal Influence.—Malaria, typhoid-fever, pneumonia, and influenza vary in their prevalence with the time of year and with meteorologic conditions. The same has been proved to be true of acute articular rheumatism by Edlefsen, Newsholme, and many others. The first-named has shown that, as a general rule, the incidence of acute articular rheumatism increases with the diminution of the precipitation and decreases with increased rainfall. Newsholme confirms this, and finds that rheumatism is more prevalent in dry seasons, when the ground-water is low, than at other times. He found that at Croydon and at Brighton epidemics occurred at a time when the sub-soil water was very low, especially if there had been more than one year of deficient rainfall. In London a low sub-soil water and a high earth temperature are the conditions in which the rheumatic poison finds its most favorable opportunities for activity.

The Complications of Rheumatism.—They are the complications that are pre-eminently characteristic of infectious diseases—endocarditis, pericarditis, pleurisy, and hyperpyrexia. So common is the first that it may readily be considered a manifestation of the disease, rather than a complication. Acute endocarditis is certainly an infectious process under practically all the conditions in which it occurs. It may not always be due to the bacteria themselves, for it can probably be produced by bacterial toxins. In rheumatism it sometimes happens, especially in the case of children, as pointed out by Cheadle,¹² that the endocarditis precedes the rheumatic manifestations or begins simultaneously with them.

Thus, in a case of my own, a boy of 8 years, there had been pain and swelling of the knees for less than twenty-four hours when I found a well-marked systolic mitral murmur. Such occurrences strongly suggest that the endocarditis and the joint manifestations are, under these circumstances, due to one and the same cause. Phlebitis, seen in many typical infectious diseases, may also occur in rheumatism, as pointed out by Remlinger,¹³ Censier,¹⁴ and others.

Portal of Entry.—The majority of infectious diseases have a demonstrable portal of entry through which the exciting cause invades the body, and if we can prove that in rheumatism there is also a portal of entry we have strongly fortified the infectious theory of the disease. Haygarth,¹⁵ it seems, was the first to state the connection between sore-throat and rheumatism. Trousseau¹⁶ also upheld it, and since then a number of writers have referred to the subject, among others Roos,¹⁷ Bloch,¹⁸ Buss,¹⁹ Gallois,²⁰ Sacaze,²¹ Pettersohn,²² and lately Packard,²³ who has summed up the relevant literature in an admirable manner. As to the frequency with which tonsillitis or, to use the more comprehensive term, angina, precedes rheumatism, it is variously stated: Stoll¹¹ gives 5 per cent.; Lebert,²⁴ 5 per cent.; Gerhardt,²⁴ 20 per cent.; Fowler,²⁵ 30 per cent.; Whipple,²⁶ 24.12 per cent., and Stewart,²⁷ from 70 to 80 per cent. Some of these figures are unquestionably too large. They include, in many instances, attacks of angina long antecedent—in Whipple's statistics by as many as fourteen years—to the rheumatic attack.

I recently saw a case with Dr. T. R. Currie, of Philadelphia, which seemed to illustrate the pharyngeal origin of rheumatism. The patient was a man aged 31 years, who had had an attack of acute articular rheumatism of seven weeks' duration at the age of 19, and another at 21, which lasted only a few days. Two weeks before I saw him he had been taken ill with sore-throat, and this was followed by an attack of rheumatism of most severe type. In addition to the involvement of the joints, he had an acute pleurisy on the right side and was bathed in the most profuse sweats that I have ever seen in rheumatism. There was no evidence of endocardial or pericardial involvement, but the poor heart-action suggested myocardial changes.

Packard is strongly of the opinion that rheumatic polyarthritides, as well as other manifestations of what Cheadle has called the rheumatic group, may be brought about through the medium of the tonsils; but infection may also enter through other channels. Gradenigo²⁴ and Bloch¹⁸ have each recorded cases of acute articular rheumatism following otitis media, and recently a case was reported by Kronenberg²⁸ in which an attack of acute articular rheumatism followed an operation on the nose. Bloch cites instances of rheumatism following felon, furuncle, fistula in ano, and vaccination, and in a case of Sacaze's²¹ the attack occurred in a patient who had an infected wound of the foot.

It might be averred that the arthritis in these cases was not rheumatic, but pyemic. In some instances, no doubt, this was true, but hardly in all of them. The course of rheumatism and the influence of the salicylates generally serve to distinguish the disease from the ordinary pyemia. Moreover, the latter has a tendency to lead to suppuration, while rheumatism scarcely ever has; indeed Iluë²⁹ states that no true case of suppuration in rheumatism is on record. He found a total of forty-four alleged cases, but in all of them he discovered internal evidence that made it improbable that they were examples of rheumatism. Körte,³⁰ in 1880, de-

scribed six cases of suppuration in rheumatism, all occurring in women. It seems strange that one observer should see so many examples of what must be considered a complication of maximum rarity.

There is another possible source of infection in rheumatism—the intestinal tract. I have no evidence to offer in proof of this point, but I believe that careful attention to it may yield some interesting results. That the intestines may at times be the infection atrium has also been suggested by Chvostek.³¹

Direct Transmission from Mother to Offspring.—This, if proved, would be a powerful argument in favor of the infectious nature of rheumatism. Two rather convincing instances are on record—those of Poccock and Schaeffer, which are quoted by Singer.³²

Contagion.—I have already referred to the subject of contagion. One indubitable example would be decisive, but there are so many possibilities of error in interpreting cases of contagion in rheumatism that we must look upon reports of such an occurrence with scepticism.

BACTERIOLOGY.

I want now to dwell briefly on the bacteriology of acute articular rheumatism. Diligent search has been made for a micro-organismal cause. Some, as MacLagan³ and Kahler,³³ have thought that this would be found in a miasm allied perhaps to that of malaria, but it seems to me that the resemblance between malaria and rheumatism is very slight.

Bacteriologists have examined the blood, the joints, the urine, the cerebrospinal fluid, and the lesions of the heart, pleura, pericardium, etc. Organisms were found by earlier observers, such as Guttman,³⁴ Wilson,³⁵ Mantle³⁶ and Bouchard and Charrin.²¹

Guttman found the staphylococcus aureus; Wilson found a bacillus in the pericardial fluid; Mantle, a bacillus and a micrococcus in the joints in seven cases, and in the blood in sixteen, both in acute and chronic and in gonorrhoeal rheumatism. Bouchard and Charrin discovered the staphylococcus albus, but only in subacute and chronic cases. Anyone who has made cultures from the living body knows how difficult it is to eliminate the possibility of contamination, and I am inclined to think that the observers I have named, whose studies were made before the present more exact methods were in vogue, dealt with accidental germs. This is the view also taken by St. Germain.³⁷

The observations of Sahli,³⁸ made in 1892, attracted much attention. He found the staphylococcus citreus in the synovial membrane, pericardial exudate, endocardial vegetations, blood, and bronchial glands of a case of articular rheumatism, but not in the fluid of the joints. He concluded that rheumatism was an abortive form of pyemia.*

Very painstaking studies were made by Singer,³⁹ of Vienna, who, distrusting the examination of the joints and believing that if the organism were in the blood it would be present in such small numbers that it might escape observation when culture was made, examined the urine, hoping that the bacteria at work in the body would be in part eliminated through the kidneys. The elimination of micro-organisms by the kidneys has been abundantly proved—experimentally by Biedl and Kraus⁴⁰; clinically, by Singer, Gwyn⁴¹ and others. Singer's examinations yielded positive results in 59 out of 84 cases of acute articular rheumatism. He found the different forms of staphylococcus and the streptococcus pyogenes, and believed with Sahli that

rheumatism is an attenuated form of pyemia. Chvostek³¹ took exception to Singer's observations on the ground that organisms eliminated through the urine might have entered accidentally through the mucous membranes, and might have no bearing whatever on the primary disease. His own bacteriologic studies were entirely negative.

Wassermann⁴² quite recently, in a case of rheumatic chorea, found a streptococcus which he thinks differs from the streptococcus pyogenes. It grows best in a strongly alkaline medium, which the ordinary streptococcus scarcely tolerates, and is most easily cultivated in hog bouillon containing 2 per cent. of peptone. The observation was carefully made in a single case, but no animal experiments were undertaken to test the virulence of the germs, and I think that we must keep our opinion under advisement.

Riva,⁴³ on a serum made from horses' joints and synovial fluid, obtained the growth of a polymorphic, spore-bearing organism in eight cases, cultures being made from the joints, the pleural fluid, and the blood. It did not grow on ordinary media. As far as I can determine, no animal or other control experiments were made, yet Riva concludes that he has found the cause of rheumatism. I think that we must adopt the same attitude in this case as in that of Wassermann's discovery.

More important than any of the preceding is the observation of Achalmé,⁴⁴ who, as far back as 1891, discovered an anaerobic bacillus at autopsy in the body of a man who had died of cerebral rheumatism on the fourth day of a second attack of acute rheumatic polyarthritis. In a second case of rheumatism examined six years later he found the same organism, and subsequently discovered it in the blood of the living patient in six cases—four times pure and twice associated with a micrococcus. The best culture-medium was found to be milk or a mixture of equal parts of milk and bouillon. Animal inoculation produced, among other changes, a marked edema, the effects being the more intense the younger the animal. Guinea-pigs died in from twenty to thirty-six hours, but when inoculated with some of the edematous fluid they perished in ten hours. Achalmé does not state whether or not any joint symptoms were present in the animals.

An anaerobic bacillus had been found in 1892 by Lucatello,⁴⁵ who seemed to be unaware of the prior work of Achalmé. The latter's observations were confirmed in 1897 by Thiroloix,⁴⁶ who found the organism in the blood *intra vitam* in five cases of rheumatism; also in one case in the pleural fluid, as well as in the blood. He noted no changes in the joints after intravenous injection in rabbits, but intra-articular inoculation produced marked edema of the joints and of the entire extremity. With the edematous fluid from guinea-pigs he obtained in rabbits, arthritis, pericarditis, and pleurisy. The blood from the human subject had no agglutinating action on the organism; that from the infected guinea-pig had at times such an action. The growth of the organism was markedly retarded by the addition to the culture-medium of salicylates in doses smaller than those necessary to check the growth of other bacteria.

Reports of the discovery of the same bacillus in rheumatism have since been made by Petit and Achalmé,⁴⁷ Papillon,⁴⁷ and Carrière,⁴⁸ and recently also by Sawtchenko,⁴⁷ The latest observations are those of Pic and Lesieur,⁴⁷ who isolated the organism during life from a case of cerebral rheumatism. They found that it grew best in sterile milk, but only under strictly anaerobic conditions. It did not grow on gelatin, but developed

*Der Rheumatismus ist eine Staphylocoekenkrankheit." Stewart had expressed the same view as early as 1881.

in secondary culture on bouillon. It is a long, slender bacillus, slightly motile, and stains by Gram's method. It is pathogenic for guinea-pigs, rabbits, and mice. In guinea-pigs it produces dyspnea, tachycardia, slight fever, and at the moment of death generally a sub-normal temperature. Suppuration does not occur. At the point of inoculation a gelatinous edema, poor in leucocytes, but rich in bacilli, develops. There is also pericarditis, but no arthritis. Injection of the edematous fluid into rabbits is fatal in ten hours, the principal lesions being focal necrosis of the liver, edema of the lungs, pleurisy, and pericarditis. The liquid products of the micro-organism seem devoid of toxic properties, but after their injection the animals appear to be immune to otherwise lethal doses of the bacteria. The bacillus is not agglutinated by the serum of patients suffering from acute articular rheumatism or chorea.

Triboulet and Coyon⁴⁹ in eleven cases isolated a diplococcus which was associated with Achalmé's bacillus in two cases. While not asserting that the diplococcus is the cause of rheumatism, they deny the specificity of the bacillus of Achalmé, believing that the latter is present only in complicated cases.

Of the various micro-organisms that have been discovered in rheumatism, the bacillus of Achalmé has apparently the strongest claims to be considered the cause, but I do not think the time is ripe for a definitive opinion. In the first place, the various experimenters have not succeeded in producing a disease in animals comparable to articular rheumatism in man; secondly, the organism has not been found with sufficient constancy. Thus, Pic and Lesieur failed to find it in seven instances out of the eight examined by them.

Summing up the bacteriologic evidence then, it may be said that the cause of rheumatism is not definitely determined.

We may consider rheumatism etiologically from two points of view; either as a group of diseases having a multitude, or at least a variety, of causes, which is the view taken by Singer, Chvostek, and others; or we may hold that there is a distinct form of acute polyarthritis, to which the term rheumatic may be properly applied, which has a single cause. The latter seems to me the more correct attitude. I believe that we may have in the case of joint affections a condition somewhat analogous to the pseudomembranous inflammations of the throat. Formerly these were nearly all classed together under the name diphtheria, but now we know that there is only one disease diphtheria—that due to the Klebs-Loeffler bacillus; nothing else deserves the name. With improved methods of investigation we shall no doubt find the organism which is the specific cause of rheumatic polyarthritis.

PATHOLOGY.

I have taken so much time in the consideration of the phases of the subject hitherto discussed that I must make my remarks concerning the pathology of rheumatism very brief.

Joint Inflammation.—In a majority of instances the fluid has been found sterile and the synovial membrane and the periarticular tissues free from germs.* This

*Since reading this paper I aspirated the ankle-joint in a young colored woman who was suffering from typical acute articular rheumatism. Only a few drops of fluid were obtained and these were at once placed into a mixture of milk and bouillon (two tubes) and glucose agar (one tube). The glucose agar had been previously melted. After inoculation it was quickly solidified and overlaid with an equal bulk of fluid glucose agar, which was then also congealed. This placed any bacteria present under moderately anaerobic conditions. No growth was obtained on the glucose agar, and of the milk-bouillon tubes one remained sterile. In the other a few diplococci, the result of contamination, developed.

leads us to the conclusion that the joint changes are probably toxic in origin, a view emphasized by Chvostek, who points out the resemblance of the rheumatic changes to the occasional joint swellings seen after the injection of diphtheria antitoxin. However, anaerobic cultures have not often been made and might lead to different results from those hitherto obtained. The synovial membrane in acute cases is swollen and injected and at times somewhat ecchymotic, and may be covered with a fibrinopurulent exudate. The fluid is more watery than the synovia and is reddish or yellowish in color. Ollivier and Ranvier⁵⁰ found proliferation of the cartilage cells and capsular and circumscribed ulceration.

Rheumatic Nodules.—These were first clearly described by Jaccoud and later by Troiser,⁵¹ although they may have been recognized long ago by Fropier. They usually occur in children, but also in adults, as multiple, pin-head or pea-sized bodies—sometimes a little larger—are situated under the skin and are tender on pressure. Microscopically they show a necrotic focus with round-cell infiltration, dilatation of the lymphatics, and thrombosis of the small arteries. Riess⁵² believes that they have an embolic origin.

Endocarditis.—You are familiar with the small vegetations that dot the valves, usually just behind the free edge at the lines of contact, and little need be said regarding their general structure. Recently, however, Achalmé⁵³ has made a contribution to the subject of their minute anatomy that merits attention. He divides rheumatic endocarditis into three phases: 1. The edematous microbial phase. 2. The proliferative phase. 3. The cicatricial phase.

The naked-eye appearance of the first stage in one case that came to autopsy a few hours after death consisted in a thickening of the valves to five times their normal thickness; the auricular surface of the valve had lost its polish, and there were slight elevations a few mm. above the free border. The myocardium was softened and of a dead-leaf color. Microscopic examination revealed an edema of the interstices of the tissue of the valve, together with an enormous bacterial invasion and an extensive transformation of the connective-tissue cells into Ehrlich's mast-cells. The edema occupied the entire valve, but predominated at certain points. Least affected was the fibrous expansion of the ring, but the cellular tissue extending from it into the auricle was markedly infiltrated, and the elements almost completely dissociated. The elastic tissue of the auricular layer of the valve was much thickened by the edema and had lost its homogeneous aspect. This was also true of the elastic layer at the free border of the valve. The bacterial invasion with Achalmé's bacillus was greater than that seen in any other disease. There might have been some growth after death, although one autopsy was made four, and the other twenty-five, hours post-mortem. The transformation of the connective-tissue-cells into the cells of Ehrlich is the most characteristic feature of rheumatic endocarditis. It is much more marked than is seen in any other affection. I have myself observed these cells in rheumatic pericarditis and found them penetrating deeply into the myocardium. The granules which they contain, and which are splendidly brought out by thionin, are often so large as to resemble micrococci.

The proliferative phase is distinguished by a proliferation of the flat cells of the superficial elastic layer. All the space previously distended with fluid becomes filled with mononuclear cells which displace the elastic

bundles. The latter become granular and indistinct and their affinity for orcein is lessened. New blood-vessels form, the walls of which are friable and are apt to rupture at the base of the vegetations, leading to minute hemorrhages. The characteristic feature of the second period of the second phase is the appearance of vegetations. According to Ziegler, the primary process in their formation is the deposit of fibrin on the valves. According to Achalmé, the first change is an alteration in the tissue of the valve, consisting in a dissociation of the superficial elastic tissue and the formation of a prominence on which fibrin is subsequently deposited. The next step consists in a proliferation of the endothelium of the blood-vessels leading to a narrowing of the lumen. Proliferation of the cells then ceases and cicatrization begins, and brings about the well-known results: stenosis and insufficiency of the valvular orifice. As the earliest changes in the valve do not produce a murmur, we may infer that endocardial lesions are more common than is clinically demonstrable. It is probable that the muffling of the heart-sounds noticed so often is due to edema of the heart-valves, and indicates the earliest organic changes.

As to the cause of the endocarditis and of the inflammation of other serous surfaces, as the pleura, the pericardium, and possibly the peritoneum, it is probably the same as that giving rise to the joint inflammation, but it is conceivable that under the damaging influence of the toxins of the rheumatic germ the heart-valves become prepared for the reception and activity of the common micro-organisms of mixed infection—the streptococci, staphylococci, and pneumococci. This would be in keeping with what we know of other diseases, such as typhoid fever and diphtheria, in which endocarditis may be due to specific organism of the disease, but is more often caused by secondary infection, the toxins bathing the valves having facilitated the invasion of pyogenic bacteria.

Rheumatic Pneumonia.—This has been described, but I have never seen an instance. Lebert⁵⁴ found only 2 in 140 cases, although Valliard⁵² makes the proportion very much greater; Stoll¹¹ gives the percentage as 1.1.

Nephritis occurs occasionally, but presents nothing characteristic. I have already referred to the occurrence of *phlebitis*, to which attention has recently been drawn by Censier.¹⁴

Cerebral Rheumatism.—The pathology of so-called cerebral rheumatism is unknown. In a case reported by Soques,⁵⁴ in which there was also hyperpyrexia, the blood and cerebrospinal fluid at autopsy were sterile, and injection of the latter fluid into animals was without effect. Soques believes that the cerebral localization of the disease is favored by a neuropathic taint.

Changes have been described in the spinal-cord—rheumatic myelitis—but the cases hitherto reported are in no way convincing.

CONCLUSIONS.

The following conclusions, based on what has been said before, seem to me to be warranted:

1. Acute articular rheumatism is a specific infectious disease.
2. It is not an attenuated form of pyemia in the sense that it is due to pyogenic organisms of reduced virulence.
3. Its true cause has not been definitely discovered, although the bacillus of Achalmé may prove to be the long-sought micro-organism.
4. A number of joint affections resemble acute articular rheumatism, just as certain pseudomembranous in-

flamations of the throat resemble diphtheria, and various diseases of the lung resemble typical lobar pneumonia.

5. These joint diseases should, wherever possible, be separated as *rheumatoid* or *pyemic* affections.

6. They are best designated according to their cause, as streptococci, staphylococci, gonococci, or pneumococcal arthritis.

COLOSTOMY FOR PERMANENT FECAL FISTULA.*

JOHN A. WYETH, M.D.
NEW YORK CITY.

The operation I desire to demonstrate deals entirely with those inoperable lesions which cause occlusion of the rectum or lower portion of the sigmoid flexure of the colon. Its chief feature is the formation of a very considerable loop of that portion of the colon which is immediately above the artificial anus, making what might be called an artificial sigmoid flexure or store-

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

house capable of holding a large amount of fecal matter, which may be discharged at long intervals, thus preventing the frequent soiling of the dressings, which are so common in the ordinary operations for fecal fistula.

After making the incision through the abdominal wall, in the left inguinal region, the large intestine is drawn through the wound and strong traction made on the lower portion so that all of the bowel between the rectum and the wound is put well on the stretch. About 4 inches of each leg of the loop should be brought out, thus exposing about 8 inches of colon through the abdominal wound. In uniting the contiguous portions of the loop I employ the method of suturing devised by my friend and former assistant, Prof. J. A. Bodine, making two parallel rows of running silk sutures 4 inches in extent and about one inch apart, one row being on either side of the mesocolon. This structure containing the vessels is caught between the two lines of sutures and adds greatly to the strength of a permanent spur. As soon as the two rows of sutures are completed, the loop is dropped back until only about one inch of the knuckle remains through the wound of incision. This should be held steadily in place by means of silk sutures passed beneath the bowel, that is, through the mesocolon just where it joins the bowel, or the glass rod may be employed to support the loop until adhesions are secured. The margin of the peri-

toneum lining the abdominal wall in the entire circumference of the wound of incision, is now carefully stitched to the intestine by the usual method. It is my practice to carry the needle well into the muscular tissue of the bowel wall—taking care not to enter the cavity—in order to get a firm hold of the bowel. Every third suture is made to include with the edge of the abdominal peritoneum the muscle and skin, in order to secure such a strong support that the bowel can not tear loose and drop back into the wound. This precaution should be taken even when the glass rod is used. When the condition of the patient will allow, it is safer to wait twenty-four to forty-eight hours before incising the bowel, for by this time the adhesions will have shut off most securely the peritoneal cavity. This can be done under cocain anesthesia, and consists in shaving off the projecting knuckle about one-half inch above the level of the skin. The fecal contents are discharged through the upper aperture of the bowel, and in the course of time the lower opening becomes contracted, and is used only for the purpose of irrigating the lower bowel, if this should be deemed necessary.

In late years many prominent surgeons prefer to perform the operation recommended by Bailey, and carried successfully into practice in a number of instances by my friend, Prof. James P. Tuttle, of New York. This consists in splitting the external oblique

muscle in the direction of its fibers and separating the fibers of the internal oblique and transversalis in the same manner that these muscular fibers are separated in the "gridiron" operation for appendicitis. The peritoneum being incised and the colon secured, it is brought through the wound. The skin at the lower portion of the incision is now dissected up for 2 or 3 inches from the abdominal wall in the direction of the groin, where it is a second time incised. The knuckle of bowel is drawn beneath this raised strip of integument and out at the lower wound, where it is held in place by the glass rod until adhesions occur. The knuckle is then incised and the artificial anus established in this manner. Wearing a truss-like pad on the skin which overlies the bowel-loop, prevents leakage when the patient is moving about. The formation of the extra pouch or loop of colon above the aperture applies equally to this operation as to any other method for the formation of an artificial anus.

REPAIR AFTER INTESTINAL RESECTION.*

WILLIAM A. EVANS, M.S., M.D.

Professor Pathology, Medical Department University of Illinois,
Milwaukee Medical College, etc.
CHICAGO.

The title of this paper is misleading, in that it gives the idea that healing in the intestine is to be fully considered. I shall discuss the question of stricture following anastomosis, and especially end-to-end anastomosis. The other points in the healing process will be treated very cursorily.

The position which the paper advocates is that the danger from secondary stricture due to development of scar tissue in the submucosa and muscular tunics is very slight. This should be removed from the list of objections to operative procedures. I have been led to this opinion by two sets of observations. I have been confirmed in it by a tone that I find in the literature—illy defined, but present.

The first observation is this: For ten years the profession has been doing anastomosis with great frequency. There has been time enough for the literature to teem with reports of secondary stricture. I have not found such abundance of reports.

The second observation is: I have examined with the unaided eye, and with the microscope, a great many specimens of intestinal union. These have been operated with the Murphy button, Frank coupler, the Connell and various other suture methods. I have not found distinct strictures. Harris says that the major amount of contraction after intestinal operations takes place during the first six months. In his case, no contraction having taken place at the end of ten months, he concluded that danger from that source was past.

As a further part of this observation, I have noted that the scar-tissue fibers occupying the region of the submucosa, muscularis and serosa are never circularly arranged. None but the circularly arranged fiber produces stricture.

Examinations of many specimens of intestines that had been resected show the following arrangement: The mucosa is commonly nearly perfectly arranged. Sometimes we find villi perfect in form directly in the line of union. Commonly the villi are not quite as symmetrical in arrangement as normal. Usually the crypts of Lieberkühn are quite natural. The surface epithe-

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

lium is generally perfect in shape and arrangement. The subepithelial mucosa is nearly normal. Occasionally a solitary lymph-gland can be distinguished. The muscularis mucosa commonly blends into the layer of scar-tissue. The submucosa forms most of the scar. The circular and longitudinal muscular layers do not participate in the process of healing. In consequence of this fact, there is usually a sulcus at the point of cicatrix. Sometimes there is a point of projection just below the zone of scar. Usually the peritoneal surface shows a slight elevation. The great interest centers in the scar. The amount of scar-tissue is always small if the healing has been uncomplicated. The fibers nearly always run in one of two directions. Sometimes they run from the mucosa to the serosa, or vice versa. More frequently they bridge the wound, running lengthwise of the intestine. Often there is some pouching. In no specimens of single healing are connective-tissue fibers found running circularly around the intestines. This is the important observation that I offer.

I find the following in Barbat's study of the subject of intestinal union: "In the Murphy button cases the submucosa forms a continuous layer, the directions of the fibers being parallel with those on each side." He adds that the results obtained with the Frank coupler are the same as those with the Murphy button. Through the courtesy of Dr. Barbat, I have had his specimens for study, and I corroborate his observation.

Let us consider the reason why the fibers do not run circularly. Thoma has enunciated the following law of pathology: "In scar-tissue the direction of the fibers is that of the tension." Biologically, this must commend itself. The connective tissues, being for the purpose of holding or retaining, must come, in time, to such an arrangement as best fulfils their function. That arrangement must be such that the fiber runs in the direction of tension.

J. B. Murphy says: "Experience shows that contraction does not take place in the cicatrix produced by this method of approximation when the viscus is in full function." This is confirmed by von Frey.¹ Dr. M. E. Connell, the deviser of the bone plate, says there is no danger of contraction in lateral anastomosis, provided the original channel is completely and permanently stopped. If, however, the old channel is open, or reopens before the new habit is established, the artificial opening will close. Full function and the use of the new channel when the old channel is closed would tend to cause the fibers to arrange themselves other than circularly.

When we come to study pathologic processes, further confirmation of the fact that fibers run in the direction of "pull" is found. When we think of the tubes that are subject to stricture, we find that those most frequently affected are the tubes in which practically the only motion is distention and contraction, for instance, the urethra, the esophagus. When there is true stricture of the intestine, it is almost always in the large intestine, rather than the small. In the statistics of Fitz, in 295 cases of intestinal obstruction 14 were due to stricture of the large intestine, and 1 to stricture of the small intestine. This is accounted for by the comparatively stationary position of the large intestine. Of the strictures of the small intestine, practically all are of tubercular origin.

As illustrating the rarity of cicatricial stricture of the small intestine from all causes, I cite the following:

In Koehler's address on "Intestinal Obstruction," to the British Medical Association, in 1898, he reported 95 cases of intestinal obstruction under his own observation. Of these 19 were due to tubercular stricture; 16 to peritoneal adhesions. None were due to ordinary cicatricial tissue in the submucosa.

Skłodowski, in a report of intestinal obstruction, reports 2 cases of cicatricial stricture, both due to tuberculosis. In Nothnagel's clinic, autopsies have been held on 343 cases of intestinal stricture. Of these, 326 were in the large intestine, and 17 were in the small intestine. These 17 were probably all either malignant or tubercular.

Prewitt says that of the chronic obstructions of the bowels, 60 per cent. are due to stricture; 25 per cent. of the strictures are in the small intestine. True stricture is the cause of obstruction in the large bowel, while "contractures" are the almost invariable cause of obstruction of the small. He uses contractures—after Fagge—as meaning peritoneal adhesions. Hofmeister was able to collect 83 cases of intestinal stricture due to tuberculosis which had been operated. He explains the reasons for tubercular stricture in the small intestine.

As showing the very small amount of stricturing, even from tuberculosis, Eisenhart reported 1000 post-mortems on tuberculous subjects. There was intestinal tuberculosis in 566; only 9 of these showed stricture. Here was a chronic ulcerative process in 566 cases and only 9 strictures—1.5 per cent. How does this compare with the results of chronic ulcerative processes in the urethra?

Troves, in 1884, collected 78 cases of stricture of intestines. Of these, 26 were in the small intestine. Of the 26, 10 were due to cancer, 4 to strangulated hernia, 2 to injury and 10 to cicatrix after ulcer. Continuing, he says: "Of the cicatricial strictures of the small intestines, the most are due to tuberculosis, primary or secondary."

Matas reported a case of multiple stricture of the small intestine, coupled with the most extensive peritoneal adhesions, all tubercular in origin. He says: "It is now recognized that notwithstanding the frequency of tuberculosis of the bowel, this condition is rarely followed by complete cicatricial stenosis. Yet, it is undeniable in the light of recent experience that tubercular ulceration in the bowel is capable of producing obstructive conditions, not so much because of cicatricial contraction, but, as Koenig, Czerny and Hofmeister have demonstrated, because deep-seated tubercular ulcer will give rise to so much secondary inflammatory thickening, edema and plastic exudation, that the lumen of the bowel will be narrowed and obstructed."

Oster, under the head of causes of intestinal obstruction, gives "simple cicatricial stenosis which results from ulceration, tuberculous or syphilitic; more rarely from dysentery, and most rarely of all from typhoid ulceration." He gives no other cause of stricture.

When we come to study the reason for strictures following tubercular ulcers, we find confirmation of the idea advanced. In tuberculosis we have to deal with an ulcerative process, chronic in character, producing local muscular paresis, and very frequently associated with local peritonitis. Adhesion bands result from this peritonitis. These adhesion bands render nugatory the efforts at pull on the part of the intestine. In consequence, the only change in the position and shape of the intestine is that which results from the

1. Beiträge f. Klin. Chir., 1895, xlv

passage of intestinal contents, and the muscular contraction which follows. Therefore, the cicatricial fibers run circularly, and stricture results. Matas calls attention to the great frequency of multiple as compared with single stricture in tuberculosis. This is confirmation along the same line as that just cited.

In this connection I call your attention to the scar-tissue of chronic interstitial myocarditis. There is an absolute lack of uniformity in the direction of the connective-tissue fibers. In the ventricular wall pull is from every direction.

In making a circular enterorrhaphy the circular muscle bundles are split lengthwise of the fiber. In consequence, as the circular muscle contracts and distends it pulls very little on the developing scar-tissue. On the other hand, the longitudinal muscle is cut across. Its fiber ends are caught in the scar. Some small portion of these fibers degenerate, to-wit, those parts separated from their governing nuclei. The remainder of the muscle remains functionally active. In consequence, every muscular contraction pulls on the scar in the direction of the long axis of the intestine. Therefore the scar-fibers run lengthwise of the intestine. We can not avoid the scar-tissue, but so long as the fibers run properly, it does no harm.

Barbat, as the result of a continued and careful study of the histology of healing after various methods of anastomosis, makes the following observations, apropos here: "Muscle cells, after being cut, will never repair in such a way as that the muscle cells will cross over the point of division; there will always be a layer of scar-tissue at the point of union."

Van Hook says that scar tissue is always found in circular enterorrhaphy, no matter by what means one performs the operation.

Lee reports a dog which was operated on with a Murphy button five months before being killed. "There is very little scar-tissue to be seen, it being most evident in the muscular coat. It was a beautiful specimen, with absolutely no contraction present."

Dr. Barbat further says: "If we follow these suture cases, we will find that the connective tissue which is formed between the approximated surfaces begins to contract, and as the amount of contraction depends on the amount of scar tissue, it necessarily follows that with the two comparatively wide surfaces which we get in all suture anastomosis, we will have considerable contraction." I may say that I can not quite agree with this point, and I do not think that his specimens would indicate great danger in this direction. I am of the opinion that exclusive peritoneal contact is not best. The more the submucosa participates in the repair process, the better the result. Barbat says: "It will thus be seen that in order to have secure anastomosis, the perineum and submucosa are the only coats which are essential, therefore the method which approximates these coats the earliest must be the best."

I quote Harris: "The error of supposing it necessary to oppose serosa to serosa was pointed out in my former paper—September, 1892—when it was shown that peritoneum unites as readily to any raw surface as it does to peritoneum." He quotes Greig-Smith's demonstration of the advantages of sero-fibrous union.

I have examined some of the cases cited as proving the possibility of secondary stricture from growth of fibrous tissue: such cases as Keen's and Abbe's. Some of them are very difficult of explanation. Some cases can be explained on the basis of an extension of the primary process, for example, malignant disease; others

on the fact that the original outlet remaining pervious, or later becoming pervious, the artificial opening tends to close. Against these we place such cases as those of Dunne and Murphy, in which the opening was larger, some time after operation, than at the time of operating.

In looking over specimens of intestines operated on many months before the animal was killed, I sometimes find great difficulty in locating the point of operation. This will be apparent to you in some of the specimens that I show, notably some of Dr. Barbat's and one of Dr. Frank's. I am certain that some of you have noticed the complete disappearance of scars after typhoid, dysentery, violent gastroenteritis, or caustic poisons. I dare say that you have often wondered what had become of the scar-tissue in cases where you have known of a most severe typhoid a few years previously. The explanation is that in areas of great functional activity, scars have a very great tendency to disappear. Especially is this true of epithelial structures. The mucosa-healing in the intestine is most complete. The muscular regeneration is least complete, and in consequence of this last fact an old scar sometimes persists as a place of thin intestinal wall.

Please do not understand that I deny the possibility of a diaphragm. Operations, such as the Czerny-Lembert, which turn in a large portion of intestine in order to accomplish a broad peritoneal contact, must result in a diaphragm. I show a cast made of such an intestine. I also show a slide showing a large amount of internal projection. I do not propose to enter on a discussion of the harmfulness of these diaphragms. Rosenthal, Goetz, Roser, Chaput, Madelung and Kunner, quoted by Harris, cite cases in which the diaphragm produced marked and sometimes symptomatic obstruction. As a general proposition, we are apt to lose sight of the fact that partial diaphragms constitute a part of the physiological arrangement of the intestine.

The conclusion that I arrive at is: The possibility of secondary stricture is not great enough to constitute a legitimate objection to end-to-end anastomosis.

I have to thank Drs. Murphy, Frank, M. E. and F. G. Connell, Barbat, Herzog, Lee and Turck for the opportunity of examining specimens.

HEMORRHAGIC GLAUCOMA.

A CLINICAL AND PATHOLOGICAL STUDY OF A CASE.*

WILLIAM CAMPBELL POSEY, M.D.

PHILADELPHIA.

Hemorrhagic glaucoma may be defined as an ocular affection characterized by an increase in the intra-ocular tension, as the result of a previous hemorrhagic iritis. Although now generally recognized as a distinct type of glaucoma, the pathology of hemorrhagic glaucoma is still obscure, so that the microscopical examination of each case is of value as serving to elucidate the precise nature of this disease. It is with this object in view, therefore, that the following case, which has been carefully studied, both clinically and pathologically, is reported.

The patient, G. W. H., aged 58 years, consulted the writer in December, 1894. He said that he had never had any trouble with his sight until the preceding August, when he noticed one morning on rising that everything appeared blue and that objects were seen

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

indistinctly. He could not remember any illness, or having subjected himself to exposure or to any unusual strain which might have accounted for this. He thinks that the eyes were not red or painful at the time. For some months prior to these ocular symptoms, he had had attacks of vertigo in the barber's chair and at stool, and had been short of breath on slight exertion. He had had piles for years, and the month before his vision failed he had bled from his nose quite freely on several occasions.

Objects still appearing blue and his vision being still clouded, he was instigated, a few weeks after the attack, to seek relief from these conditions at the Wills Eye Hospital, where he came under the care of Dr. Edward Jackson, to whom I am indebted for the following notes:

"Patient had complained of failing vision in the right eye for the last few weeks, but without inflammation or pain. Examination shows the conjunctiva of the affected eye to be injected. The cornea are clear. The pupils are 3 mm. in size, and respond actively to

Left eye.—Showing unusual dilatation and tortuosity of the retinal vessels, particularly the veins.

light stimulus. With the ophthalmoscope, the media in the eye are clear, but the disc is red and hazy, its edges being wholly obscured except at the upper margin. The retina is swollen and hyperemic and there are innumerable hemorrhages in the papillo-macular region. The retina in the left eye exhibits a similar condition, though less pronounced. Vision in the right eye equals counting fingers at 50 cm.; in the left eye 5/10. Examination of the urine showed specific gravity of 1020, and was negative regarding the presence of albumin or sugar. The patient was placed on eserin and nitroglycerin gr. 1/100, three times daily. Three weeks later the disc in the right eye was less obscured, though the retina was still very hazy. The retinal arteries were noted as being relatively very small, with their walls much thickened. Vision of the right eye now equalled counting fingers at 5 inches."

The patient employed the drops and pills which were prescribed, but did not return for further treatment as the drops made his eye painful and brought on vomiting. He then consulted several other ophthalmologists, who advised the continuance of the same treat-

ment, but as the drops still exerted the same disagreeable influence, he became disheartened and discontinued all treatment for several months. At the end of that time, he consulted the writer in the hope that the sight of the right eye, which had now failed him utterly, might be restored to him.

Examination showed the patient to be a large powerful man, but with marked evidence of faulty circulation. His hair was quite gray, his lips rather blue and his temporal vessels prominent. The right eye presented all the cardinal symptoms of absolute glaucoma; the globe being brick-red from deep ciliary congestion, the cornea steamy and needle-stuck, and the scleral vessels full. The anterior chamber appeared to be only slightly shallowed; the pupil was widely dilated and the iris was immobile to light and accommodation stimuli. There was a greenish reflex from the pupil and the tension was +2. On account of the cloudiness of the media, but a faint red glare could be obtained from the fundus. The eye was absolutely blind.

The fellow eye was almost quiet, although in addition to a faint arcus senilis above, there was a faint haze of the cornea and some congestion of the scleral vessels. The anterior chamber was of good depth; the pupil, which was 3 mm. in size, reacted well to light and accommodation stimuli; the sclera was rigid. The fundus was plainly seen, and the appearance of the optic nerve and the retinal vessels was so striking that they were thought worthy of a sketch. As seen in the sketch, the nerve was quite gray in the deeper layers, especially to the temporal side, but was markedly hyperemic and slightly swollen on its nasal half, this edge of the disc being almost hidden by the swollen nerve-fibers. There were also several minute hemorrhages on the head of the nerve, and a few corkscrew-like vessels projected from it. The outer two-thirds of the disc were embraced by a large physiological excavation, at the bottom of which the lamina cribrosa was plainly visible. The retinal veins were enlarged and very tortuous, especially on the disc, and projected into the vitreous, being twisted about one another like a cluster of angleworms. The arteries were reduced in size and their walls were thickened, presenting somewhat of a waxy appearance. The entire retina was slightly hazed, and was so swollen at the nasal edge of the disc that the distended veins were at times obscured by it. In the macular region there were several minute scattered spots of pigment. Vision equaled 5/10, and with +0.50 D. S. \ominus +0.25 D. C. ax. 90°, equaled 5/5; with +3.D. additional, type 0.50 D. was read from 12 to 20 cm. The field in the left eye was normal both for form and color.

A careful physical examination by Dr. Alfred Stengel discovered a somewhat enlarged left ventricle, and a strong high-tension pulse. The sounds over the heart were free from murmurs, but the first sound was peculiarly heavy and booming in character, while the second was sharp and accentuated, especially at the base and at the aortic region. There were faint bruits in the arteries of the neck. The vessels were everywhere stiff, but not calcareous. Dr. Stengel was of the opinion that the case was one of moderate arteriosclerosis.

An examination of the urine made by Dr. S. M. Hamill was as follows: specific gravity 1024, reaction acid; microscopically, a few cylindroids and urates, but no casts.

The patient was cautioned about overexerting himself; his diet was restricted; his bowels were kept open by salines, and his circulatory apparatus regulated by

nitroglycerin. Two drops of eserin salicylate—gr. $\frac{1}{4}$ to the ounce—were instilled into the right eye twice daily, preceded by a few drops of a 2 per cent. solution of cocain. After several weeks of this plan of treatment the eye became less painful and the circulation improved to such an extent that the outlines of a hemorrhage in the retina, slightly up and out from the disc, could be discerned. This improvement lasted for several months, when there was a recurrence of the attacks of pain in the eye, which radiated into the nose and was accompanied by profuse lachrymation. The iris gradually became vascular, the cornea more densely steamed and the globe harder, and the pain was so severe that enucleation was finally advised to avoid further discomfort. The patient's consent being obtained, this operation was performed without accident under ether, and the globe placed in Müller's fluid for examination. The socket healed satisfactorily. In order to protect the remaining eye from a glaucomatous attack, a weak solution of eserin was instilled into it, the proper correcting lenses adjusted, and a careful regimen of the patient's life insisted upon. As a result of these precautions, the patient's health improved, and there have been no untoward symptoms in his remaining eye.

Section through the angle of the anterior chamber, showing its complete obliteration by the adhesion of the base of the iris to the cornea.

An ophthalmoscopic examination, which was made a few days ago, showed that the circulation in the eye had improved, the caliber of the arteries was greater, and the veins were not so dark and full as at the time of the sketch. The intense striation of the fibers on the nasal half of the nerve still persisted, but the few pigment massings, the remains of the hemorrhage noted by Dr. Jackson, had entirely disappeared.

The enucleated globe was allowed to harden in Müller's fluid for several months preparatory to its pathological examination by the writer in the laboratory of the State Hospital for the Insane at Norristown. After the hardening process had been accomplished, the eye was frozen in a mixture of salt and ice and divided with a brain section-knife. Macroscopically, it was noted that the antero-posterior diameter of the globe was 25 mm., the horizontal 24 mm.; the lens was 9 mm. in its horizontal diameter, and 3 mm. in its posterior diameter; the anterior chamber and vitreous were filled with an albuminoid material, and the nerve-head was swollen.

MICROSCOPICAL EXAMINATION.

Cornea.—The epithelium and Bowman's membrane were intact, although the presence of tiny cavities between these two layers, as well as the increased prominence of the lines separating the individual cells, espe-

cially in the deeper tissues, gave evidence of a considerable degree of edema. The lymph-sheaths of the vessels at the periphery were much distended, and the vessels here, in common with all through the globe, showed a decided proliferation of the lining endothelial cells of the intima, thickening of the adventitia, with hyaline change, and in many places nearly complete obliteration of the lumen.

Sclera.—This coat was infiltrated in places with round cells, and was somewhat thickened posteriorly about the entrance of the optic nerve. A section across one of the anterior perforating arteries showed a hyaline thickening of its walls.

Anterior Chamber.—As shown by the sketch, the angle of the chamber was obliterated, though clinically the chamber appeared deepened. This was occasioned by the marked retraction of the entire plane of the iris with the exception of its base, which was in close contact with the cornea. The chamber was partly filled with homogeneous transudate, which extended into the posterior chamber and occupied the space between the fibers of the zonule and thence back into the vitreous, where it formed a layer on the inner surface of the retina.

Section through the head of the optic nerve, showing intense neuro-retinitis, unusual vascularity of the head of the nerve, and embolism of the central artery of the retina.

Iris.—The base was quite atrophic. The stroma was dense, and contained but few vessels, and the lumen of many of these was almost obliterated. There was a layer of organized lymph on its anterior surface, which had occasioned by its contraction a marked degree of ectropium uveæ. There was but little pigment in the membrane, except at the pupillary border, where it was found in irregular clumps, instead of the normal pigment cells. The pupil was dilated.

Ciliary Body.—The muscle fibers were atrophic; the tissue was infiltrated with fluid, the processes were pushed forward and occasioned a stretching forward and inward of the fibers of Müller of the retina. Owing to the adhesions formed by the base of the iris and the cornea and the changes in the ciliary body, the posterior chamber was greatly enlarged by a large saccular dilatation of its outer angle.

The Retina.—This membrane was covered by a sheet of organized lymph, which was blended with the disorganized internal retinal layers, and was thickest on the temporal side. Its deeper layers contained but few cells, while the more internal were freely organized. The inner surface was covered with a thick layer of mononuclear round cells, many of which had assumed a spindle form. A detachment of the retina on the temporal side had been occasioned by a contraction of the

mass. The retina was thrown into numerous folds, and in places there were large cavities between the retina and the sheet of lymph, which were filled partly with transudate and partly with fresh extravasations of blood.

The retina had been the seat of an intense inflammation, its layers being blended into a firm mass, richly infiltrated with wandering cells filled with blood-pigment. The rods and cones were broken down into irregular globules, and the space between the retina and the pigment layer, which remained attached to the choroid contained an extensive hemorrhage. Farther to the temporal side, the retina showed less inflammatory reaction, but the hypertrophied fibers of Müller were drawn out into long processes by the exudate, and by their separation allowed the formation of numerous smaller cavities, which were filled with fluid. On the nasal side of the nerve the same effect had been produced, but the cavities were smaller and there were no marked inflammatory changes. Throughout the mass there were small hemorrhages. Anteriorly, the retina showed changes due to long-standing edema; hypertrophy of the supporting fibers, cystic degeneration of the fiber layer, and disappearance of the ganglion cells. In this membrane, as elsewhere, the same vascular changes had occurred as were described above. The pigment epithelium was irregularly proliferated, especially in the papillo-maculary region, and in many places was separated from the lamina vitrea of the choroid by a faintly staining exudate.

Optic Nerve.—The excavation was .5 mm. in depth, and was filled in by the mass of organized lymph, and by the retinal fibers which had been pulled over the edge of the cup by the contraction of the newly-formed tissue. The lamina cribrosa was bent backward and the excavation occupied the entire nerve-head. The central vessels showed a marked degree of thickening of the walls and proliferation of the endothelium. The veins were full of blood, but the lumen of the main artery was partly filled with a mass of spindle cells, which was firmly filled with the proliferated endothelium. Sections of the vessel within the nerve indicated that the obliteration at the time of enucleation was, in this place, incomplete, as a small channel remained on the nasal side, which contained fresh blood-corpuscles. Sections of the temporal branch of the artery within the lymph mass, however, showed complete obliteration. The connective-tissue septa of the nerve were very much thickened, and the nerve-fibers were completely atrophic. The supravaginal space was distended.

Choroid.—This membrane was little affected beyond an enormous dilatation of its vessels, with bundles of newly-formed connective tissue scattered through it in places. There was some round-cell infiltration beneath the areas of intense retinitis.

Vitreous Chamber.—The retina and the inflammatory mass on the head of the nerve were covered with homogeneous exudate previously described in connection with that in the anterior chamber. From the center of the mass on the nerve there extended into this exudate a channel about the width of the central artery, the walls of which were at first composed of several layers of spindle-shaped cells, but were soon represented by a single layer of flattened cells. This channel was partly filled with red blood-cells, and evidently represented a new blood-vessel springing from the organized exudate, and extending into the vitreous chamber. In the homogeneous exudate surrounding it there were numerous small collections of blood-corpuscles, mononuclear cells

which showed vacuolization and disintegration of their nuclei, and cells containing absorbed pigment.

The changes which have just been described are most striking and their significance deserves careful consideration. Dr. E. A. Shumway, who kindly studied a series of the sections for the writer, has given the following explanation of them, which seems to be both pertinent and conclusive:

The finding of an occlusion of the central artery raises the interesting question: Was this the primary cause, and the subsequent changes in the nerve and retina secondary to it, or was the thrombosis dependent on the inflammation of the surrounding tissues? I think that the answer can be readily given if we compare the clinical history of the case with the pathological findings. In the first place, the process was slow in onset, and the failure in vision was not sudden, but gradual. The ophthalmoscopic examination, which was made some time subsequent to the beginning of the affection, showed a marked neuroretinitis, with numerous changes in the exudation in the nerve-head, and in the substance of the surrounding retina. There was considerable tortuosity of the venous channels, but no noticeable change in the size of the arteries. Moreover, the presence of a similar, though less-marked condition in the fellow eye, and the evident changes in the blood-vessels throughout the system, point to the fact that we are dealing here with changes due to disease of the general vascular system, and not with a mere local disturbance. The pathological examination, therefore, confirms the clinical diagnosis. As a result of the endarteritis and periarteritis of the retinal vessels, there occurred a severe inflammation of the head of the nerve and neighboring retina, with hemorrhages from the diseased vessels, an outpouring of lymph and round cells, subsequent organization of this inflammatory mass, with detachment of the retina, atrophy of the optic nerve, hemorrhage into, and round-cell infiltration of, the vitreous; glaucomatous symptoms then supervened, the filtration angle of the anterior chamber was closed by the forcing forward of the ciliary processes and lens, and as the base of the iris became adherent to the periphery of the cornea the glaucoma became absolute.

While there is still far from unanimity among pathologists regarding the changes which occur in the ocular tissues in hemorrhagic glaucoma, the majority of observers agree that the most constant lesions are found in the blood-vessels, and more especially those of the retina and optic nerve. Undoubtedly this view largely resulted from the thesis of De Bourgon, which showed, in a comprehensive review of the literature, that these tissues were the most frequently affected in the cases hitherto reported.

Thus, of 13 complete pathological examinations which had been made, all exhibited vascular lesions in the retina, such as miliary aneurysms, hyaline and amyloid degeneration, and periarteritis and sclerosis. In 7 of these cases there were lesions in the vascular system of the choroid also.

As a result of this initial general vascular disturbance it appears that a diminution in the circulation of the blood follows that favors the occurrence of hemorrhages, which are rather the result of diapedesis than of rupture of the vessel walls.

As De Bourgon has pointed out, a vicious circle is thus inaugurated: the diminution in the circulation giving rise to the hemorrhages, and the hemorrhages, in their turn, in conjunction with a fibrous transformation of the retina which occurs in the majority of the cases, contribute still further to the stasis of the blood-current. As a result of this, the hemorrhages increase in number, become more extended, and the circulation is finally so impeded that venous thrombosis ensues, in association with a dilatation of the capillaries. Serous exudation then takes place, the intraocular pressure increases and the glaucomatous attack is precipitated.

HEMORRHAGIC GLAUCOMA.*

CHARLES A. OLIVER, A.M., M.D.

PHILADELPHIA.

Frequency.—Fortunately, this almost universally fatal ocular condition, which, as Stirling says, "must be distinguished from hemorrhage into an already glaucomatous eye," is quite rare in this country. Risley's statistics of 4 in 20,000 cases are similar to mine of 8 in 40,000.

Symptoms.—Following an intraocular hemorrhage that is, as a rule, due to some gross disturbance of the vascular system, such as endarteritis or thrombosis, it is either rapidly, or even suddenly, announced by all the expressions of a subacute or an acute attack of glaucoma.

Ophthalmoscopically, if at all visible, the main retinal veins will appear engorged and tortuous, this being particularly noticeable in the larger stems as they bend into the optic nerve-head and pass through its cribriform plate. In these cases, though more particularly in the more pronounced ones, or, at times, in those eyes in which there has been a partial or a complete absorption of an intraocular hemorrhage, neuro-retinites from the veriest haze and edema to the most intense swelling and inflammation become visible. Varying grades of contraction of the arterial currents and irregular dilatations of the venous channels, with perivascular changes, are only too frequently seen. With these, both old and fresh, deeply seated and superficially situated hemorrhages will be found associated.

Should the case last sufficiently long for the gross pressure-signs to evidence themselves—though unfortunately only too frequently first determined at the post-mortem table—the nerve-head will be found deeply cupped and filled with both lymph and blood elements.

If the organ is still able to withstand these ravages on its structures, signs of further lymph-infiltration and increase of vascular exudation, with thickenings, ossifications and degenerations, will all manifest themselves until the organ is affected in its entirety; necroses in the anterior segment of the eye followed by hemorrhagic discharges appear and terminate the scene.

Pathology.—This increase of contents of an already diseased organ has offered a series of post-mortem findings to the pathologist which are quite certain. Inflammatory and degenerative changes in the vessels of the choroid and entire uveal tract have been seen by Knies, Oliver, and Randolph. Similar conditions in the iris and ciliary body have also been noted by Valude and Dubief, and Wagenmann; while the retinal series, as in the well-known cases of Hache and Pagenstecher, are the ones that at times are principally affected. The findings that are mainly seen in the vascular system of the organ consist in scleroses, hyaline changes in the vessel-walls, obstruction of the lumens by thrombi, distention of the vascular canals with blood, and ruptures. With these, the signs of more or less gross inflammatory reactions in the surrounding tissues are constantly found.

The presence of corneal bullæ, the formation of cataract, shrinkage and separation of the vitreal elements, combined with degeneration of the retinal vessels, in association with hemorrhagic extravasations into the substance of the retina, which is generally detached and cystic in places, constitute some of the main pathological

changes that may be recognized in most of the cases. In addition, there may be formations of newly organized inflammatory products throughout the entire organ, as for example, the vascular convolutions that at times are found in the cupped nerve-head and which are believed by Mauthner to be a part of the morbid processes.

In the old and extremely rare chronic cases in which the eyeball has been repeatedly attacked and escaped enucleation, the expressions of bulbar disorganization become increasingly apparent. Ulcerative processes in the cornea, more greatly pronounced degenerative changes in the crystalline lens, and loss of the true vitreous humor with the substitution of grumous and gelatinoid exudates—all become noticeable. To these more widely disseminated gross hemorrhagic extravasations and more greatly pronounced marks of inflammatory reaction are soon superadded.

In the worst and most prolonged types, both infectious and general suppurative changes with panophthalmitis will be found: while the results of hypotony and bulbar shrinkage, both with and without the appearance of gross hemorrhagic and lymphoid extravasations, may be seen.

Treatment.—General therapy must be employed in every case, though unfortunately, by the time the case is met with by the ophthalmologist, it is almost invariably in the stage or condition which requires immediate radical interference. In every case, however, the vascular system must be closely watched and constantly cared for. Sleep, betterment of surroundings, dietetic and emunctorial hygiene in combination with the treatment of any dyscrasia, particularly gout and rheumatism, as shown by Richey, and not infrequently syphilis, constitute some of the main therapeutic means in our possession. Specifically, salicylate of sodium, in large and frequently repeated doses, has, as previously demonstrated by Friedenwald, served the greatest good in two cases that were temporarily relieved by me for quite long periods of time.

Locally, I have never ventured with paracentesis of the cornea, believing that the transient relief gained at best was overbalanced by the danger of vessel-rupture from a too rapidly produced lowered support of vascular structure. With anterior scleral puncture I have not had any experience, nor do I wish to essay it in this type of cases. Sclerotomy I have both tried and seen tried, though in my experience it alone has not been productive of the least permanency in beneficial result. The duration of value of iridectomy followed by equatorial sclerotomy as proposed by Randolph, I have not yet had an opportunity to adequately study; neither have I seen any case in which Ball's suggestion of removal of the cervical sympathetic after unsuccessful iridectomy in inflammatory glaucoma, might be tried. Galezowski's crucial sclerotomy and Spencer and Watson's scleral trephining I have not as yet made any acquaintance with; while sympathectomy without the application of leeches to the corresponding temple, combined with the internal administration of ergot and sulphate of quinin as championed by Abadie, I have never employed. Stretching of the external nasal nerves and electricity can not, even hypothetically, be considered of any real use in this type of cases. In regard to excision of the related superior cervical ganglion of the sympathetic, I agree with Ball that the procedure is of more value in simple glaucoma than it is in the inflammatory type.

The value of the production of thin, breakable cystoid cataracts or the use of the formation of permanent

* Presented in discussion to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 3-8, 1900.

istulous openings is uncertain, as they seem to me to only serve to expose an already disabled organ to microbic invasion with probable septic inflammation.

In my hands, I have had the best permanent results with slowly performed iridectomies made after the patient had been properly placed under the full influence of a general anesthetic. The cases chosen were those with apparently healthy irises. As far as possible, the patient was carefully prepared. The operation was done on the bed in which the patient was to lie. The head of the bed was placed on a higher level than the foot, thus raising the patient's head higher than his feet, and reducing the chances of any increased blood-pressure while he rested. The instrument used was a properly sharpened bent keratome. The corneal incision was set far back. The knife was slowly entered and as slowly withdrawn, allowing the aqueous humor to dribble away along the sides of the instrument. A firm double figure-of-eight pressure-bandage was applied for the first twenty-four hours. The best of hygienic and constitutional measures were vigorously sought for and strenuously maintained.

As a result, three out of eight cases—37.5 per cent., a much higher percentage than in any other statistics with which I am acquainted—have been saved for periods of eight, six and four years, respectively, with almost, if not quite, normal vision in fairly large and well-shaped fields that have remained intact to the present time, an almost unprecedented result in this so universally considered hopeless disease.

Two other eyes, cared for in a similar manner, were kept in abeyance for quite long periods of time without adequate working vision—the usual result of so-called successful cases. Unfortunately, both of them, after several months' intervals, were ruined by fresh intraocular hemorrhages that were produced from slight local traumatism and undue general violence.

During any of the operative procedures that I have tried in this type of cases, I have never had the misfortune to have a hemorrhage appear, although I have seen it take place in three instances.

Two cases of hemorrhage into the interior of the fellow eye previously operated on—one with four days' and the other with two days' interval—I have seen followed by a permanently successful iridectomy on the second eye, the eye primarily operated on required removal.

In three instances in which miotics seemed to be of some temporary value in mechanically opening the filtration angle, the drugs eserin and physostigmin were usefully continued for some time, though they did not seem to act as well as they do in some of the other types of the disease.

If these measures fail—as they most generally will—however, recourse must be had to immediate removal of the globe.

Prognosis.—As can be now well understood, prognosis is almost invariably fatal, although when the local conditions have been gotten into abeyance, the general health kept constantly guarded, and the organ has resumed its functionary powers, relapses may, with a reasonable degree of certainty, not be feared, as, for example, in the 37.5 per cent. of cases in my own series—three out of eight. No rule, however, can be laid down.

From the sweeping, broad statement made by some, that all such eyes are irremediably lost, to the most sanguine views of those who, by improperly including every doubtful case in their series, have obtained data that are both uncertain and misleading, there is a mid-

dle ground that must always be occupied by the conservative and yet fearless practitioner.

The state of the patient's health, the condition of the eye, the gravity and the duration of the attacks, and the frequency of recurrence, all enter so persistently into the question of prognosis that the answer for the value of the best applied local and most judicious general therapy in each individual case becomes in large measure idiocratic in character.

DISCUSSION ON PAPER OF DR. POSEY.

DR. E. C. ELLETT, Memphis—Some years ago I had the opportunity to watch a case which from the clinical side was a very interesting and satisfactory study, but very unfortunate from the patient's point of view. The case is reported in the *Annals of Ophthalmology* for October, 1887. She was about 60 years of age when the trouble affected the left eye. When I first saw her she had a typical hemorrhagic retinitis, and I observed the development of glaucoma in spite of everything I and one or two consultants could do to control it. I finally did an iridectomy, which was followed by free hemorrhage, but with good recovery and relief of pain for the time. I finally enucleated the eye, and that was followed immediately by a hemorrhage with great infiltration of the orbital tissues. The case illustrated very well Dr. Risley's classification, dividing the course in two stages, hemorrhagic retinitis, and then confirmed glaucoma. This woman is still in good health, though she has passed through some nervous crises since that time, and the other eye is perfect. The stump of the enucleated eye, while it shows nothing abnormal to inspection, is very irritable and she has never been able to wear an artificial eye.

DR. J. E. WEEKS, New York City.—This class of cases is extremely interesting to me. The condition is due to vascular degeneration and is more frequently monocular than any other type of glaucoma, except the secondary forms due to keratoseleritis, injury or intraocular tumor. The walls of the arteries, principally, are affected but the hemorrhage takes place from the small veins and capillaries. Glaucoma seems to develop only in those patients who possess marked tendency to plastic formations. The treatment that will do most good in these cases is that which prevents the formation of fibrin, and for that reason the iodids and salicylates are apparently of the greatest value. Operative treatment is simply worthless unless we can influence the element that I have just mentioned. The condition of the blood-vessels is not one confined to the eye alone by any means; it involves the general arterial system, being often more advanced in one organ than in another.

DR. S. D. RISLEY, Philadelphia.—The Section should be grateful for Dr. Posey's paper, since it gives opportunity for the discussion of a most important subject. Perhaps no form of eye disease is so universally fatal to vision as hemorrhagic glaucoma. At the Pan-American Congress meeting at Washington I read a paper on the subject, in which I presented an abstract of the literature, gave the experience of a number of friends, secured by correspondence, and added the histories occurring in my own private practice. I could discover no instance of recovery in a well-authenticated case of the disease. It is important that hemorrhagic glaucoma should be carefully differentiated from acute or subacute glaucoma with hemorrhages. The latter, as we all know, is unfortunately frequently observed, and its course modified or assisted by treatment; while the former is fortunately rare, since no treatment is of any avail and blindness the inevitable result. It is but a local expression of the disease of the general vascular tree, and as such anticipates in blindness the fatal result which in many cases speedily follows. I am greatly pleased with the admirable statement just made by Dr. Weeks of the pathological conditions in these cases. It is important, when viewed from the medicolegal standpoint, that hemorrhagic glaucoma should not be confused with other more hopeful forms of glaucoma, since a too favorable prognosis might in that case be given. As a source of mutual protection this section should voice its opinion, as to the fatal character of this disease, in the most clear-cut and emphatic manner.

DR. J. L. THOMPSON, Indianapolis—I have seen many of

ose cases and in a great majority of instances I have had centrally to enucleate the eye. I recall one case, however, and it is the only exception, of an old gentleman now 70 years of age who came to me 10 years ago with just such a hemorrhage, and I told him of the dangers and fears of subsequent trouble. I put him on salines, used leeches and sent him to the springs. He stayed there a while and the eye began to clear up, but eventually he had glaucoma. I began the use of eserine, and glaucoma set in in the other eye. The vision in the hemorrhagic eye is still 20/70. Of course, I look for trouble yet, and I fear an iridectomy so much that I have refused to do it in either eye. It is the only case I have ever had of hemorrhagic glaucoma where I did not have to enucleate the eye subsequently.

Dr. W. C. POSEY—In closing, I wish merely to say, as I have ready stated in my paper, that the essential lesion in hemorrhagic glaucoma is vascular, both general and local. As a result of the general arterio-capillary fibrosis there is a diminution in the circulation, which affects the intraocular condition as well as that of other parts of the body. Hemorrhages occur in the eye, plastic exudates are formed, a still greater impediment is offered to the proper circulation of the blood within the eye, and more hemorrhages are the result. This vicious circle is continued until the proper exchange of the intraocular fluids is no longer possible, and glaucoma results.

I fully agree with Drs. Weeks and Risley that the treatment of this form of glaucoma should be directed to the general system, and to the lowering of the intraocular tension by local medicinal measures, for I believe iridectomy in this class of cases to be inexpedient.

IMMATURE CATARACT AND ITS TREATMENT.*

G. E. DE SCHWEINITZ, A.M., M.D.

PHILADELPHIA.

It may be asked: Why waste time on this hackneyed subject, which has so often been discussed, especially in our own country, for example, by Risley,¹ Woodward,² Alt,³ W. L. Pyle,⁴ and by others, and when we know that there is no specific treatment of incipient cataract and that all which can be done is to keep the patient in the best state of health and the affected eyes in the most perfect optical and nutritional conditions until that time arrives when the crystalline lenses may be safely extracted? While this is undoubtedly true, may it not be pertinently inquired whether a too strict adherence to this view of the case does not engender a species of unjustifiable pessimism and unwarranted therapeutic nihilism which drive patients out of legitimate consulting-rooms into the hands of irregular practitioners?

In general terms, all complicated cataracts, especially those caused by acute and chronic affections of the eye, *e. g.*, iritis, iridocyclitis, iridochoroiditis, active choroiditis, detachment of the retina, malignant myopia, glaucoma, corneal ulcers, etc., all cataracts caused by toxic agents and by direct or indirect traumatism, and those usually described under the term *juvenile* or *congenital* are excluded. So, too, it is not possible to adhere to a strictly pathological classification of lenticular lesions; but I may, for convenience sake, be permitted to describe these opacities as we usually meet with them in the consulting room, *viz.*, 1, non-progressive cortical opacities; 2, progressive cortical opacities; 3, nuclear and mixed opacities.

Non-Progressive Cortical Opacities.—Sometimes in so-called senile or simple cataract the development of the lenticular change is so slow as to justify the term "non-progressive." We see cases of this character con-

stantly, the lesions usually appearing in the form of a few equatorial streaks or tufts, the favored position being in the naso-inferior quadrant of the lens.* Dr. J. L. Thompson has particularly described them. An illustrative case is the following:

A woman, aged 68, consulted me in 1890, with the statement that, twelve years before, she had been told by two of the most competent eye surgeons of the city that she had incipient cataract. At my examination the vision of the right eye, after the correction of a slight refractive error, was 6/9 and of the left eye 6/12. In each lens downward and inward were well-marked streaks of opacity slightly fluffy on their margins. The eye-grounds were normal and the patient was in excellent health. Ten years later the findings were almost exactly the same, the vision of the right eye being 6/12 and of the left eye 6/15. The opacities, therefore, have existed for twenty-two years and have undergone practically no change. The patient has used her eyes on the finest kind of work and has never for a day ceased to do so.

At our annual meeting in Denver in 1898, Dr. Hotz quoted a similar instance, the opacities having remained unchanged for thirty years, and agreed with Dr. Jackson that cases of this kind ought not to be classified as cataract; that is to say, the patients themselves ought not to be told that they were suffering from a disease which was likely to progress and produce blindness, and they should not be debarred from a reasonable use of their eyes.

A good deal has been written to show that age itself, while a very important factor in the development of cataract, is often, as Jackson has shown in his interesting statistics, only a predisposing cause. Indeed, one of Schoen's well-known conclusions is: Simple cataract is not a manifestation of age, but frequently begins in young persons; therefore the characterization *senile* is inappropriate. Cataract, as Fuchs well puts it, "occurs very frequently in old people, but not so regularly as to be regarded as a physiological attribute of age—as the turning gray of the hair is, for example—but as a pathological process." In other words, if we wish to prove that age is the only causative factor, all other etiological processes must be excluded; that is to say, diseased processes in the patient generally or in the eye locally.

Risley has thoroughly investigated this subject, and believes that the frequent coexistence of disturbance of the choroid coat and incipient cataract indicates that, while opacity of the lens—so-called *senile*—is a condition commonly seen in advanced life, it does not in all probability depend on senile changes, but is originated in local pathological states involving the nutrition of the eye itself. This, you observe, is going a step further, and practically excludes age as a causative factor, which it seems to me is a step too far to take, because undoubtedly a certain number of incipient lenticular opacities, particularly those just described, are not associated with any pathological condition in the eye itself ophthalmoscopically demonstrable, or with any general disorder of the patient's constitution, unless age itself, as has been maintained, is a disease. They are distinctly concomitants of age, and the eyes require no treatment other than suitable optical aid. To make to such patients a solemn-faced announcement that a disease exists which will soon lead to blindness is unnecessary, cruel, and, in fact, untruthful.

True, it is difficult, if not impossible, to foretell the rate of progress such lens-changes will pursue, but careful study will, I think, often separate them from the other classes, and a definite prediction may be deferred

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

until examination reveals signs of increase, or visual acuity can no longer be maintained at a reasonable standard by suitable optical therapeutics.

Progressive Cortical, Nuclear and Mixed Opacities.—On the other hand, the large majority of cataracts, properly classified under this heading, are slowly progressive, the period of growth from incipency to full maturity varying considerably. Whether we should make a distinction between those forms of opacity which are degenerative in character, particularly the nuclear varieties, and those which partake more of the nature of an inflammation, as some of the cortical types do, a distinction which has been made by Brailey and others, is not now pertinent. What I hope to bring out in discussion is: What we shall do for the patient while the crystalline lens is passing through the stages of cataract-formation, and what measures we may employ to check the rapidity of the opacification, or to increase the patient's ocular comfort. I will hence pass at once to a consideration of:

Cases suited to Medicinal Therapeutics based on the Condition of the Choroid and the Nutritional Processes of the Eye.—At the very outset I wish to repeat distinctly what I have written and always taught, to wit: Drugs do not exist which can dissolve a growing cataract. On the other hand, I would not without qualification say, as W. L. Pyle⁴ has: "Drugs have proved absolutely valueless."

Risley has well shown that a great number of cataracts depend on alterations in the choroid coat; not alone on active choroiditis in the sense of exudations, hemorrhages, pigment heapings, etc., because I have excluded such conditions as these from this inquiry, but on changes that are best described under the vague term, "choroidal disturbances"—the nerve-head is congested, the surrounding choroid is flannel-red, woolly in appearance, and there are faint dark areas in the periphery of the eye-ground indicating the interspaces between the choroidal vessels, or the pigment epithelium has been absorbed and one sees the exposed choroidal circulation, a state of affairs when pronounced amounting practically to an epithelial choroiditis. This is a familiar picture in cases of eye-strain, and there can be no question that Galezowski, Schoen, Magnus, Risley, Jackson, and many others who have written on this subject, are entirely correct in supposing that the strain of uncorrected ametropia, particularly the neglect of proper presbyopic correction, is frequently responsible for the production of these lesions, which in their turn sufficiently disturb the nutritional processes of the eye to cause alterations in the lens-fibers, which lead to opacities.

When in the neighborhood of the 50th year, or a little later, streaks of opacity begin to appear in the lens of an eye with a choroid coat like the type described. I am convinced that properly applied therapeutic agents are of avail in checking the progress of the disease by favorably modifying the choroidal changes, although they have no influence on the opacities already formed in the lens. These agents may be classified, it seems to me, into optical therapeutics, local remedies and general medication.

The optical measures necessarily consist of glasses which absolutely correct all refractive error, both for near and far, and which should be changed as frequently as necessary to conform with the alterations in the refraction of the eye caused by the developing opacities in the lens. This of itself will reduce the hyperemia of the conjunctival and the choroidal coats, a reduction

which may be further enhanced by such local measures as the systematic application of hot water in the form of hot stupes at night or when the day's work is done—an old-fashioned but most efficient agent—and the instillation into the conjunctival sac of a weak solution of pilocarpin or eserin—gr. 1/40 to 1/20 to the ounce. Of the drugs which have given me the greatest satisfaction I may name the alternatives, particularly the iodids, especially the iodid of sodium; the bromids, most efficiently the bromid of sodium in conjunction with ergot; and some preparations of mercury, the best, it seems to me, being the biniodid. I am inclined to think that cannabis indica has a favorable influence, although I am not quite clear what its physiological action is. These remedies are of no avail unless the patients can be persuaded to take them for long periods at a time, preferably, I think, in small or broken doses. An illustrative case is the following:

A woman, aged 54 years, consulted me on June 13, 1887, for the relief of great asthenopia with well-marked striae in each lens, and fine clouding of the general lens-structure, a little more marked on the right than on the left side. The conjunctive were congested; the ciliary circle was hyperemic. There was general wooliness of the choroid coat, over-distention of the central lymph-sheaths, especially around the veins, which were unduly filled, and each disc was moderately hyperemic and the scleral rings marked. Refraction was:

O. D. +.50 C. axis 90, 5/5.

O. S. plano, 5/5. +2.25 added for near work.

January 15, 1899, or eighteen months later, the refraction was:

O. D. +.62 C. axis 105, 5/5.

O. S. +.50 C. axis 120, 5/5. +2.75 added for near work.

June 25, 1891, or thirteen months later, the refraction was:

O. D. +.75 C. axis 75, 6/6.

O. S. +.25 S. \bigcirc +.50 C. axis 105, 6/6. +2.75 \bigcirc 3 degree prism, base in, on each side added for near work. (The insufficiency of the internal recti at 30 cm. was 15 degrees.)

April 28, 1893, or two years later, the refraction was exactly the same and the vision unaltered; the presbyopic lens was slightly increased in strength.

May 15, 1898, or six years later, the refraction was:

O. D. +.50 S. \bigcirc +.75 C. axis 90, 6/9.

O. S. +.75 S. \bigcirc +.50 C. axis 105, 6/7.5.

During all this time—eleven years—only a very slight increase in the lenticular opacity had occurred. The patient was under the strictest supervision, her brother being a physician; her general health was kept in the best possible condition, and the various alterative tonics previously mentioned were administered almost continuously. She returned always when the asthenopia reappeared, and in the intervals between the changes of refraction was entirely comfortable. The appearance of the eye-ground gradually improved.

This is a type of incipient cataract very different from that described as non-progressive, in the beginning of the paper. It is the type to which Risley refers and represents a class of cases which, he demonstrated, can be, and ought to be, relieved by such lines of treatment. Naturally, we may not always or perhaps not often succeed. Doubtless we may be obliged to say, with Alt, that frequently the choroidal disturbance yields, but the formation of the cataract goes on undisturbed "in its slow and steady progress." Be it so; we have at least put the eye in the best condition possible to receive the highest benefits of future operative interference. I plead only that these patients shall have constant supervision and the benefits, whatever they may be, of the lines of treatment suggested. They must not, on the one hand, be deceived with exaggerated

promises of help, but, on the other, they ought not to be discouraged by indifference and the neglect of therapeutic trials.

Cases of Incipient Cataract Suited to Medicinal Therapeutics based on the Constitutional Condition of the Patient.—A good deal has been written on the relation of disease and of morbid conditions other than those located in the eye to the formation of cataract,⁵ but the conclusion reached by Becker that a connecting link between constitutional maladies and opacities of the crystalline lens has not been established remains in large measure true at the present time, although we know that cataracts of various types have been credited to typhus and typhoid fever, to the exanthemata, whooping-cough, malaria, influenza, gout, rachitis, syphilis, diabetes, nephritis, diseases of the heart and atheroma of the vessels, particularly the carotid. So, too, to various nervous diseases, especially epilepsy, and even to some diseases of the skin the formation of cataract has occasionally been attributed.

We may exclude at once as not likely to lead to profitable discussion all of the diseases mentioned, except diabetes, nephritis, lithemia in the widest acceptation of the term, and angiosclerosis.

While it may be true, as Mauthner once maintained, that there is reason to believe that the relationship between diabetes mellitus and the formation of cataract has been overstated, even he was unwilling to exclude this disease entirely as a causative factor, and there is no doubt that in a certain percentage of cases the excessive elimination of sugar and of water which occurs in diabetes mellitus leads to the formation of cataract. While the dietetic and medicinal treatment of the diabetes under these circumstances can not cause an absorption of the lenticular opacities, which, as we all know, are prone to rapid increase, I am inclined to think that in certain cases they may hold them in check for a time. A case in point is the following:

A woman, aged 50, who stated that she had always been slightly short-sighted, consulted me on June 15, 1895, the vision of the right eye without correction being 6/22 and of the left eye 6/60. Each lens contained large flocculent opacities, the central lenticular structure being filled with a fine haze; the maculas were normal and the general fundus was in fair condition. The urine contained 10 per cent. of sugar. After prolonged mydriasis, the following refractive result was reached:

O. D. —1.00 S. —.75 C. axis 135, 6/7.5.

O. S. —.75 S. —1.50 C. axis 15, 6/9.

The patient was referred to her family physician, who placed her upon a carefully arranged diet and prescribed various remedies which have a reputation for reducing the amount of sugar.

For seventeen months the vision and refraction remained practically stationary; then the lenticular opacity of the left eye began to increase, as did also the myopia, so that —1.50 S. —1.50 C. axis 15, was required to bring back the vision so nearly what it had been primarily, viz., 6/12.

In another year there had been no change in the vision of the right eye, but the myopia had increased 1 D. In the left eye, however, the lenticular opacity had markedly increased and the myopia had risen to 2.50 D.

Six months later, during part of which time the patient had gone to a sanitarium where cataracts are supposed to be cured by absorption, and had utterly neglected her treatment so far as the diabetes was concerned, the cataract of the left eye rapidly increased and was near maturity when she returned to decent medical supervision. On the right side, however, the vision still remained 6/12, but the myopia had again increased 1 diopter. After this the patient disappeared from view, but I know that subsequently the cataracts became complete and were extracted by surgeons abroad.

This case is interesting, as it shows that for two years nearly, by suitably changing the glasses and keeping the patient on the strictest kind of diet, there was no increase, or no material increase, in the cataractous processes. Whether the same slow rate of progress would have taken place without this general medication it is, of course, impossible to say, but it seems fair to attribute the apparent checking of the process for the time being to the measures which were employed, and it is further interesting to observe that a rapid increase in the opacity took place when for a time these measures were discontinued.

Naturally, the so-called nephritic cataracts, which it seems to me is a doubtful name, because although albumin is present in about 6 per cent. of cataract cases, the etiological relation of nephritis to the disease has certainly not been proved, would be treated, if they were not ready for operative interference, with such remedies and dietetic measures as would put the patient in the best possible condition, but certainly without the slightest hope that they would cause absorption of the cataract, or do more possibly than put off operative interference.

While it would be impossible to prove, and probably unwise to attempt to prove, that gout directly causes lenticular opacities in the sense that the opacities are gouty deposits or gouty manifestations, as these deposits and manifestations may occur in other tissues of the body, it is certainly safe to say that indirectly lithemia in the widest acceptation of the term may be a cause of lenticular opacities by affecting those portions of the eye particularly concerned in the nutrition of the crystalline lens. Naturally, it could do so by producing an iritis, cyclitis or choroiditis of active and evident manifestation, but it is possible, and I think probable, that it causes finer lesions in the uveal tract than are readily detected by the ophthalmoscope, lesions which we vaguely designate as disturbances of nutrition. Be that as it may, a careful examination of the urine and of the general constitution of many persons past middle life who come with beginning lenticular opacities will give evidence of the lithemic state, and therefore reveal an evident indication of therapeusis.

Many cases could be quoted in support of the value of treatment under these circumstances, one of the most striking being that of a woman who developed about her fiftieth year numerous gouty manifestations, such as occipital head-pain, slight alterations in the knuckles, burning and stinging of the soles of the feet, etc., and at the same time delicate streaks of opacity began to appear beneath the capsule of each lens. These opacities appeared to become stationary, or practically stationary, coincidentally with a marked improvement in the patient's general health brought about by the most scientific dietetic and medicinal treatment to alleviate the gouty manifestations, a treatment which was followed by encouraging success.

Michel once tried to establish an etiological relation between atheroma of the carotid and the formation of the so-called senile cataract. Later Becker disputed this association; at any rate, he proved that cataract was just as often unassociated as associated with alterations in the walls of the carotid. Doubtless this accurately sums up the connection of the two processes; but when that age is reached—which varies much in different subjects—when an intrusion of the lime salts may be expected, an age has also arrived when cataract formation commonly begins. Is it unreasonable to suppose that changes in the nutrient vessels of the

anterior uveal tract may also take place at this time and aid in the development of lenticular opacities? In the retina we can study ophthalmoscopically the early signs of atheroma all the more intelligently since the publication of Mr. Gunn's admirable paper; but in the uveal tract we can only surmise their presence unless, perchance, microscopic examination should become possible. Under such circumstances the patient's general condition improves with the regulation of habits of life, character of food, and the administration of such remedies as iodid of potassium, well diluted, iodid of sodium, nitroglycerin, and perhaps the chlorid of gold and sodium. I have never seen the smallest speck of opacity disappear by such treatment, but sometimes lenticular changes apparently on the increase seemed to receive a check in their rate of development. Why should it not be so? If the remedies and the diet improve the vascular conditions elsewhere in the body, is it not likely that they improve them also in the nutritive organs of the eye and therefore indirectly become of advantage to the lenticular well-being?

In this connection it is interesting to quote the theory of Magnus.⁶ The development of cataract depends on an unequal distribution of the nutritive fluid of the lens. The entrance and flow of this fluid is facilitated by the changing tension of the zonula during accommodative acts and the elasticity of the normal lens-fibers. If disturbances of the circulation (atheroma), reduction or increase of the normal play of accommodation (high myopia and hypermetropia), lessening of the elasticity of the lens-fibers (senile nuclear sclerosis), check the nutritive stream a lymph-stasis results. This shows itself either in the equatorial region and poles of the lens (which are the nutritive ports), or in the neighborhood of the sclerotic nucleus, and passes by chemical changes in the lens-fiber (un-resisting by reason of senility) to real lens-opacity.

If this hypothesis is correct, then certainly the methods thus far urged receive distinct support. True, it may be argued that the retardation of the cataractous process in diabetic, lithemic, or angiosclerotic individuals, which has apparently occurred when their constitutions were brought under the influence of such general measures as have been described, was a mere coincidence and that the lenticular changes were non-progressive from their incipency. The reply to this is that the character of the eye and of the lens-lesions in these cases is such as to indicate that the progression of opacification is to be expected, and that retardation apparently begins coincidentally with improved general conditions. What I wish to insist on is that we must first of all, as Fromaget recently said, be physicians and we should regard opacities of this character as indicating a sick eye containing a sick lens, just as much as a leaking valve in the heart indicates a sick central organ of circulation. It seems to me to be our duty, after we have fulfilled the optical therapeutic indications in the manner described, to insist that these patients shall have the treatment which is indicated by the general malady, which may or may not be the underlying cause of the lenticular changes.

Consideration of the Cases suited to Optical Therapeutics, with Special Reference to the Development of Astigmatism and Prodromal Myopia.—As has been more than once stated, the patient with incipient cataract should wear those glasses which give him the highest type of visual acuity and permit such use of the eyes which he may have with the least strain. Hence

optical therapeutics are applicable to all these cases, so long as the glasses afford any gain in visual power.

The development of prodromal myopia, or the "second-sight" of the laity, by which a patient previously emmetropic or hypermetropic owing to intumescence of the crystalline lens as the result of forming cataract, is able to lay aside his reading glasses and improve his distant vision with concave sphericals, is well known. I do not wish to detain the Section with a discussion of these cases, which recently have been reviewed and commented on by Dr. William F. Norris.⁷ I refer to the subject only because the development of the astigmatism in association with the myopia is occasionally very great, perhaps even greater than one would imagine, and a correcting lens produces the most surprising results. A striking example of what I mean is the following:

A woman, aged 64 years, who stated that cataract had begun to form ten years prior to her visit to me, on September 29, 1899, had a vision in the right eye of 3/60 and in the left eye of 3/100. Both lenses were evidently swollen, the striæ being most marked down and in, while up and out were clear areas. The pupils were small, the eye-ground was dimly seen and much distorted. Lenses did not improve the vision of the right eye, but with a -5 C. axis 90, the vision of the left eye rose to 6/25. She came to me believing that the cataracts were ready for extraction and went away almost as well satisfied as if I had performed the operation. She was seen nearly four months later with the same vision, which, so far as I am aware, has continued to the present time, now more than a year ago.

Naturally one hunts for astigmatism, particularly for changes to be made in the cylindrical glasses of patients with incipient cataract, but that such high grades are sometimes overlooked is evident from the case just detailed. This woman had often been examined by physicians and been told she had beginning cataract. For years she had lived in semi-blindness, a fate which might have been averted by a little more careful examination of refraction. This naturally leads me to

Consideration of the Cases suited to Mydriatic and Myotic Treatment.—Of course almost the first treatment that is tried in incipient cataract, particularly of the nuclear variety, when the pupil is small and glasses cease to raise the visual acuity, is mydriasis, and very frequently by permitting the patient to see through a peripheral portion of the crystalline lens there is marked improvement in vision. I would not even refer to so well known a subject were it not that we all of us now and then see cases for which mydriasis has been prescribed without a subsequent re-examination of the refraction. I can illustrate this with a case:

A woman, aged 60 years, consulted me not long ago with a nearly ripe white cataract on the right side and incipient cataract on the left, wearing a +3 S. over each eye. The opacity on the left side was encroaching on the pupil space, and with the pupil dilated her vision with the glass named was 6/22. After a number of trials, both with the retinoscope and by objective methods, +2 S. \ominus +1.50 C. axis 105 was selected, which gave a vision of 6/9. With +3 added the patient could read quite comfortably ordinary newspaper print. This glass, tinted No. 3 London smoke, combined with daily homatropin mydriasis, is giving the patient the greatest comfort while she is waiting for full maturity of the cataract on the opposite side.

It seems proper, however, when calling attention to this well-known topic, to state that it is my experience and doubtless the experience of many of those who hear me, that daily mydriasis is frequently followed by rapid increase in the lenticular opacity, acting

very much as a preliminary iridectomy does. Thus, occasionally, as in the case cited, the cataract on the side on which mydriasis has been maintained will mature more rapidly than the cataract on the opposite side, although this was originally far more advanced in its opacification. There are many illustrations of this. A good one is the following:

A woman, aged 65 years, consulted me on January 20, 1898. The vision of the right eye was 5/100; of the left, fingers at 50 cm. Each lens was filled with thick cortical striae, and on the left side, in addition, there was a dense central opacity, forbidding any view of the fundus. Mydriasis produced no effect on the vision of the left eye, nor was this benefited in any way by a glass. On the right side, with pupil dilated, —2 S. gave a vision of 6/25, and with +3.50 added, the patient could read coarse print. Very soon, however, the lenticular opacities of the right eye began to increase, and nineteen months later the cataract was fully ripe and extracted without accident and with normal healing, while that on the left side, originally more advanced than its fellow, has remained unchanged to the present time.

In a certain number of cases myosis is very efficient in sharpening visual acuity. Most frequently I have seen this either when the opacities have run across the pupil in parallel lines, leaving between them a clear space of lens-tissue, or when the lens has been fissured in several directions by striæ of refraction. The effect of the myosis under these circumstances, if there is a spot of central clear lens-tissue, is that of the ordinary pin-hole diaphragm, or of the iris diaphragm when its aperture is contracted. Sometimes I wonder whether we sufficiently often try the effect of maintaining a mild myosis, together, of course, with suitable correction. A good example is the following:

A patient in whose crystalline lenses, most marked on the left side, spicules were first discovered in 1892, was placed on the ordinary treatment described, together with proper glasses, which were changed at suitable intervals. There has been little or no change in the opacity in the equatorial region, but there has been some encroachment on the pupil space, so that the opacities cross in front of it, giving somewhat the impression of a lattice-work. The vision in the left eye dropped to 6/25, when the experiment was tried of keeping the pupil slightly contracted with a weak solution of eserine or pilocarpin. The vision, under these circumstances, rose to 6/12 and remains so unless the pupil is allowed to assume its natural form. In addition to this action, we obtain the beneficial effect of weak solutions of eserine on the congestion of the ciliary region before referred to.

Consideration of Cases Suited to Operative Interference—Optical Iridectomy and Operations for Ripening Cataract.—With a few words we may discuss these methods of treating incipient cataract. Naturally, when a practically stationary nuclear cataract directly occludes the pupillary space and mydriasis indicates that the vision can be raised to double or treble that which the patient possesses when the pupil is of its natural size, an optical iridectomy placed at the most advantageous position is a perfectly proper surgical procedure. One caution I would introduce, however, namely, that very frequently, not only in eyes with nuclear cataract, but in which, in addition to the nuclear haze, there are cortical striae and opacities, mydriasis in the office will materially improve the vision and one is tempted to make, as it were, a permanent mydriasis by means of an iridectomy. When, however, the patient is allowed, with dilated pupils, to pursue his ordinary occupation, and compare his condition with his ability to carry on this same occupation when the pupil is undilated, he will not describe any particular advantage gained during the mydriatic stage. Under

these circumstances optical iridectomy leaves the patient dissatisfied unless it is explained to him that he can not expect much gain in vision, but that it will render easier and safer the subsequent extraction of the lens. If, however, after trial of mydriasis, both in the office and outside of the office, the patient returns stating that the increased visual acuity is a comfort, optical iridectomy followed by proper correction is a very satisfactory procedure. It gives the patient a period of increased visual acuity; it renders the subsequent extraction of the lens easier, provided one does not care to wait for maturity; and it not infrequently hastens maturity without the disadvantage of actually triturating the lens.

I have elsewhere expressed my views in regard to the extraction of immature cataract and indirectly in regard to the ripening operations.⁸ "that I prefer always to wait for maturity, or for that time of life when the lens, even though immature in the ordinary sense of the term, will cleanly leave its capsule, but I prefer the extraction of immature cataracts to the performance of any operation for ripening."

Consideration of the Evidence on the Value of Electricity, Massage and Absorbents (so-called) Introduced into the Conjunctival Sac in the Treatment of Incipient Cataract.—Personally I have had no experience with electricity, but, so far as I am aware, there is absolutely no evidence that it ever has done one particle of good in the treatment of incipient cataract. I have seen a number of patients who have faithfully tried electrical treatment at the hands of reputable physicians with negative results, and I have also seen a number of patients who have purchased the so-called batteries sold by charlatans, which really contain in most instances as their active principle pieces of flannel soaked in oil of mustard, and naturally, I have never seen the slightest sign of improvement.

My personal experience with massage is too limited to make any opinion drawn from it of value, and the same may be said of the instillation of the so-called absorbents introduced into the conjunctival sac in association with massage. I have seen a number of patients who have gone to various institutions where these methods of treatment are pursued, both prior to their departure and after their return. I believe that with a single exception I am correct in stating that under these circumstances the massage and the instillations have invariably produced an increased opacity, in two instances bringing about rapid complete opacification, so that I extracted the cataracts shortly after the return of the patients from these sanitariums, without difficulty. This has led me to think that in some instances of slow-forming cataract perhaps a vigorous massage of the eyeball, particularly now that instruments are on the market by means of which the massage movements can be adapted with scientific accuracy to individual areas of the eye, might be of benefit in hastening the ripening process with less disadvantage to the patient than those ripening operations which depend for their success on the trituration of the lens-substance after evacuation of the contents of the anterior chamber.

The exception which I have noted was an old-standing traumatic cataract which certainly was absorbed, or partially absorbed, while the patient was undergoing massage treatment of the eyeball, a treatment which extended over many months and which was followed with great accuracy, so I am informed. The result was negative because of the extensive choroiditis behind the cataract. If the operator under these circumstances

had taken the trouble to investigate the light-field, he might have placed himself in possession of the data which would have assured him of the probable diseased condition of the eye-ground.

Perhaps we have permitted massage and treatment of this kind to fall too much into the hands of irregular practitioners and that it is worth while to investigate its advantages in a truly scientific spirit. We all remember that Kalish, in 1891, and again in 1899, published papers in which he advocated the treatment of uncomplicated immature cataract by a special form of manipulation and the instillation of a mixture of equal parts of glycerin and 1 per cent. solution of boric acid and rose-water. He claimed good results, but his method has not been followed, chiefly, it seems to me, because less troublesome methods are equally efficacious and because Dr. Kalish very properly gave the greatest attention to frequent correction of refractive error in his cataract patients and to keeping their general and ocular health at the highest pitch, in other words, pursuing methods such as have been advocated in this paper, and which of themselves are capable of exercising a retarding influence. Therefore, it is difficult to judge what value his method of manipulation and instillation in the conjunctival sac of itself may possess.

Now and then certain specific remedies have been advanced for the treatment of immature cataract. Perhaps the one which is best known, and to which the attention of the profession has been very much directed, is the fresh juice of the *cimeraria maritima*, a drug which, so far as we know, has in no way justified the claims that were made for it. Doubtless all have read Dr. J. Ellis Jennings' interesting research as to the value of this remedy.⁹ The extraordinary influence of the thyroid preparations, particularly in the form of thyroid extract, led me to try its effect in one or two cases of partially formed cataract. As far as I could see it did no harm; certainly it did no good.

CONCLUSIONS.

1. Certain lenticular opacities, most often situated in the naso-inferior quadrant of the lens, occasionally are practically stationary and may be designated "non-progressive." They do not handicap the patient's ocular abilities, and may with propriety be separated from the class to which the name incipient cataract is ordinarily given.

2. Certain lenticular opacities undoubtedly depend, as Risley and others have shown, on what may be designated "disturbances of the choroid" as apart from active and actual choroiditis; and their progress is sometimes apparently checked by measures—optical, local and general medicinal—which restore the choroid coat to normality. Such measures do not, however, remove from the lens the opacities which have already formed when the patient comes under treatment.

3. Certain lenticular opacities which appear in association with diabetes mellitus, nephritis, lithemia and arteriosclerosis, particularly the last two diseases, are sometimes apparently retarded, like those in No. 2, by measures which are suited to the patient's general condition in connection with local and optical therapeutics; but these measures never dissipate the lense-lesions already present.

4. Certain lenticular opacities produce not only prodromal myopia but very high degree of astigmatism, the correction of which may result temporarily in a surprising improvement in visual acuity.

5. Certain lenticular opacities cause an obscuration of vision that may be largely dissipated temporarily

by providing the patient with glasses moderately tinted which give the best visual acuity during mydriasis and maintaining this mydriasis with a mild mydriatic. Sometimes, under these circumstances, the mydriasis seems to hasten maturation; this fact should be explained to the patient.

6. Certain lenticular opacities, especially in the form of striæ of refraction, cause an obscuration of vision which is somewhat relieved by maintaining a mild myosis with weak solutions of one of the myotics.

7. If the vision of eyes suffering from incipient cataract of the nuclear type is improved by mydriasis, this is not a sufficient indication for optical iridectomy, unless the patient finds by observation that the increased visual acuity, as noted by test-type examination, is also advantageous in pursuing his ordinary occupation.

8. The extraction of unripe cataracts is preferable to any of the ordinary operations for ripening cataract.

9. There is no evidence that electricity has the slightest influence in checking the rate of progress of incipient cataract, or in dissipating the opacities which have formed.

10. If there is any evidence that massage of the eyeball favorably modifies the rate of development of cataract it is still very insufficient; there is some evidence to show that massage sometimes hastens the opacification of the lens. The subject demands further investigation.

11. There are no "specific remedies" for the treatment of cataract, and there is no reliable evidence that drugs exist which cause the absorption of partially or fully formed cataracts.

12. All lenticular opacities, unless perhaps those which belong to the so-called non-progressive group, should be regarded as indications for a thorough investigation of the patient from the general as well as the ocular standpoint, and for an employment of remedial agents—optical, local, medicinal—according to the findings.

- * Randall thinks this position depends on the frequent choroidal changes found in a corresponding area of the fundus. This is doubtless true in many cases; but these, I think, differ from the ones now under discussion, and tend to progress like other choroidal cataracts.

COMPLETE TRANSPOSITION OF VISCERA.

REPORT OF A CASE.*

S. P. DELAUP, B.Sc., M.D.

Visiting Surgeon to Charity Hospital.

NEW ORLEANS, LA.

In my work at the anatomical laboratory of the Tulane Medical College a case of complete transposition of the viscera came under my observation. Owing to the facilities of the laboratory I was able to make a thorough dissection of the viscera of the large cavities of the trunk. The subject was a negro, about 25 years of age, and fairly well developed. It presented no external abnormal signs.

On opening the thorax I found both lungs consolidated and with such adhesions as to preclude any means

* Read before the Louisiana State Medical Society, April 20, 1900.

of distinguishing the right from the left. The heart occupied the middle mediastinal space and was placed obliquely in the chest; the apex was directed downward, forward and to the right, reaching the fifth intercostal space and three inches to the right of the median line; the base was limited above by the second costal cartilage, and the left border of the heart extended to the left border of the sternum. The inherent relationship of the heart itself was changed, so that the normally right ventricle was in front and to the left, and the normally left ventricle lay to the right and posterior; that is, it was simply reversed. The venous side of the heart was toward the left, the *venæ cavæ* being on the left side and entering the left auricle (normally the right). The arch of the aorta was directed upward and slightly to the left, then backward and outward to the right, making a short curve like a Gothic arch. The innominate artery arose from the commencement of the arch of the aorta in front of the right carotid, and ascending obliquely to the upper border of the left sterno-clavicular articulation, divided into the left common carotid and left subclavian arteries. The right carotid arose from the highest part of the arch of the aorta and ascended vertically to the root of the neck. The right subclavian artery passed nearly vertically from its origin at the arch of the aorta to the inner margin of the scalenus anticus muscle. The thoracic aorta was situated on the right side of the spine, approached the median line as it descended, and at its termination lay directly in front of the column. The esophagus lay on the left side of the aorta above, then at the lower part of the thorax passed in front of the aorta and at the diaphragm was situated to its left side. The right pulmonary artery, shorter than the left, ran in front of the descending aorta and right bronchus to the root of the right lung; the left pulmonary artery passed behind the ascending aorta and superior vena cava to the root of the left lung. The right innominate vein, about two inches in length, passed from right to left, crossing the three large branches of the arch of the aorta near their origin. The left innominate vein, much shorter than its fellow of the opposite side, passed almost vertically downward and joined with it close to the left border of the sternum, to form the superior vena cava. The relations of the superior vena cava were in front, with the pericardium and sternum; behind, with the root of the left lung; on the right side, with the commencement of the innominate artery and ascending part of the aorta, and on its left side with the phrenic nerve and left pleura. The right pulmonary veins passed in front of the thoracic aorta with the right pulmonary artery; the left pulmonary veins passed behind the left auricle and ascending aorta. The right pneumogastric nerve crossed over the arch of the aorta, its recurrent branch winding behind the arch; the left pneumogastric nerve passed in front of the left subclavian artery and sent its recurrent branch behind that vessel.

On opening the abdominal cavity, the stomach was situated, for the most part, in the right hypochondriac region, beneath the liver and diaphragm and above the transverse colon; its fundus, which projected upward and to the right of the esophageal opening, touched the diaphragm, while the pyloric extremity was directed downward and to the left.

The duodenum presented its normal horseshoe curve, the convexity being directed toward the left and the concavity to the right, embracing the head of the pancreas. The common bile duct and the pancreatic duct

entered the duodenum on the inner side of its descending portion. The other divisions of the small intestine presented nothing of interest. The cecum was found in the left iliac fossa, the vermiform appendix two and one-half inches in length, and in normal relation with it. The ascending colon passed upward to the left hypochondriac region; the transverse colon was found in its normal position; the descending colon passed down on the right and terminated in the sigmoid flexure, which was somewhat shorter than usual, and situated in the right iliac fossa. The rectum originated opposite the right sacro-iliac symphysis, passed obliquely downward from right to left to the middle of the sacrum. The liver extended to the lower border of the ribs and occupied the entire left hypochondrium; the left lobe was in the epigastrium, extending to the right hypochondrium. The round ligament was to the left of the median line. The gall-bladder bore its usual relation to the liver. The spleen was normal in size and appearance and in the right hypochondriac region. The pancreas extended horizontally from left to right, the head being embraced by the concavity of the duodenum and the tail extending to the right as far as the spleen. The left kidney was a bit lower than the right; otherwise the kidneys were normal. The ureters and bladder were normal in appearance and position. The abdominal aorta presented its usual branches, but on the left side it was in relation with the inferior vena cava, which in its course upward perforated the central tendon of the diaphragm to the left of the esophageal opening. The left spermatic vein, instead of emptying into the left renal vein, emptied directly into the inferior vena cava, whereas the right spermatic vein emptied into the right renal vein instead of into the *venæ cavæ*.

Anomalies of position in various organs of the human body are occasionally observed during life, but for the most part the preternatural situations of organs are discovered in the course of post-mortem examinations or in the dissecting-room.

Entire transposition of the visceral organs is extremely rare, but a sufficient number of cases have been reported to show that this condition is not at all inconsistent with good health and longevity. This case is reported for the purpose of showing the anatomical anomaly and of suggesting an explanation for the abnormal condition.

The organs are evolved and developed in the embryo, right or left, as are the hands and feet and other parts of the body which possess right and left symmetry. Hence all true cases of transposition are congenital, and not the result of morbid processes. Therefore, transposition of the viscera, or of the viscera, can not be acquired.

We must look to embryology for the only rational explanation which can be furnished of transposition of viscera. In reviewing the scant literature on the subject, I came across the following plausible explanation in the "Reference Hand-Book of Medical Science."

"It has been observed that in the early embryo the heart is situated precisely in the median line, and that it gives off two arches, which curve to either side and unite below in a single central trunk: these are the two aortæ, and the single trunk formed by their union becomes the abdominal aorta. As the septum between the two ventricles makes its appearance, that division of the right aortic arch which constitutes the vascular portion of one of the bronchial arches becomes obliterated, disappears, and loses its connection with the abdominal aorta; a branch, however, persists during

the whole of intrauterine life, and constitutes the ductus arteriosus, and another branch is permanent, forming the pulmonary artery. During the sixth week the heart is vertical and situated in the median line, with the aorta arising from the center of its base. At the end of the second month it is raised up by the development of the liver, and its apex presents forward. During the fourth month it is twisted slightly upon its axis, and the point presents to the left."

Von Baer suggested the theory that in a few instances the embryo lies with its left side directed toward the yolk, whereas the right side is normally in this position. He considers the condition in all probability the cause of the transposition.

Ingenious as this hypothesis is, it is, unfortunately, wanting in proof, and does not appear to explain the absolute reversal.

SUBTROCHANTERIC AMPUTATION FOR DIFFUSE SKIN CARCINOMA.

EMANUEL J. SENN, M.D.

Instructor in Surgery, Rush Medical College (University of Chicago); Assistant-Surgeon, Presbyterian Hospital; Assistant-Surgeon, St. Joseph's Hospital.
CHICAGO.

The following case is of interest on account of the extent of the carcinomatous invasion and the clinical history, which gives another instance of the origin of carcinoma from post-natal embryonic tissue. The clinical examination revealed much evidence in favor of blastomycetes, and it was only after a most painstaking pathologic study by Professor Hektoen that a positive diagnosis of carcinoma was made.

Mr. W. P. R., age 23, American, had good health until 9 years of age, when he became the victim of a severe accident. While hanging on a train, he was struck on the inner side of the thigh by the sharp point of a diamond-shaped switch that caused a gaping wound of the thigh, extending below the knee. There was considerable hemorrhage at the time and the wound is said to have been closed by sixty-three stitches. After the injury there was a denuded surface on the inner aspect of the knee about the size of the palm of a hand. This was covered with skin-grafts taken from the father, mother and two sisters. The three latter are alive and in good health at the present time; the father died of pneumonia seven years ago. The whole surface healed well, except an area about the size of a dime, located just above the patella and which never healed. This ulcer was only skin deep. One year ago, there appeared six inches above this erosion, a black area in the old scar, which was exquisitely tender. The epidermis exfoliated, the base being of a deep-red color, and formed an ulcer; this rapidly extended, first along the scar tissue in a peripheral direction and later invaded surrounding healthy structures, involving almost the entire circumference of the thigh. There was a chain of enlarged glands in the groin.

The patient was in a very emaciated condition, having lost twenty-five pounds in weight during the five months previous to the operation.

Patient entered St. Joseph's Hospital Dec. 14, 1899, but on account of his weakened condition and feeble pulse, operation was not deemed advisable at this time. He was given a thorough course of supportive treatment, consisting of daily enemata of salt solution, forced feeding, alcohol, and large doses of strychnin, which

practice I always follow, if possible, as a preliminary to major operations. He gradually grew in strength, and subtrochanteric amputation was performed on Dec. 22, 1899. Immediately before the operation, the patient was given an ounce of whisky, per rectum, and 1/32 gr. of strychnin. The anesthetic was ether, by the open method. The usual orthodox amputation was performed, long anterior and short posterior flap. Hemorrhage was controlled by an Esmarch constrictor around the uppermost portion of the thigh, which was prevented from slipping by two mattress needles passed through the fleshy portion of the thigh. The operation was rapidly performed with virtually no loss of blood; nor was there any shock following, which I attribute to the rigid preliminary treatment. On account of the patient's weakened condition I deferred enucleation of the enlarged glands in the groin. The wound healed by primary intention and the patient left the hospital in the course of two weeks. He refused a second operation for removal of the lymphatic glands.

The following is the report of Professor Hektoen from the pathological laboratory of Rush Medical College:

Macroscopic Examination.—The specimen includes the left foot, leg and the greater portion of the thigh, the latter having been amputated at a little above the junction of the upper and middle thirds of the femur. The distance from the upper end

of the femur to the inner malleolus is 70 cm.; from the upper end of the femur to the lower border of the patella the distance is 27 cm. The knee is firmly ankylosed at nearly a straight angle. The tibia is longer than usual, measuring 43 cm. from the lower edge of the patella to the inner malleolus. There is also some anterior curvature in the tibia, the point of greatest convexity corresponding in front to the junction of the upper and the middle thirds.

The foot is slightly deformed, there being present some degree of talipes equino-varus. On the outer aspect of the foot, just in front of the outer malleolus, there is seen a small smooth scar about as large as a nickel and slightly depressed but unpigmented.

On the leg proper, several scars are present. These vary in size from that of a dime to that of the largest one situated on the upper half of the tibia, which extends, anteriorly and laterally, over an irregularly quadrilateral area measuring 12 by 15 centimeters. The outline of this cicatrix is irregular, and in many places the edges are decidedly pigmented.

This scar is directly continuous above the ulcer that involves the upper 2.5 cm. of the anterior surface of the tibia, the knee and the entire lower two-thirds of the thigh, being rather more pronounced on the upper and inner aspect of the thigh, where it extends down to and into the bone. The ulcer has affected the entire front of the thigh and extends laterally for a variable distance; at one point, namely, at the lower third of the thigh, it nearly encircles the limb, leaving about 8 cm. of skin surface, which although the site of an extensive scar is not now involved in the ulceration. The ulcerating surface is 30 cm. in length and measures variously from 10 to 22 cm.

width. It is thus irregularly oval in shape, the widest portion being just above the center. The borders of the ulceration are for the most part irregular and the edges in many cases are distinctly undermined.

On the lowermost portion of the thigh, the patellar region and the uppermost portion of the tibia, the ulcerating process destroyed the integument only, leaving on the floor of the ulcer the fascia and subcutaneous tissues generally; while on the upper and inner side of the thigh the subcutaneous structures have also disappeared; at one point a narrow ridge of subcutaneous tissue extends entirely across the deeper portion of the ulcer to be connected with the corresponding tissue above. This projecting line of tissue, however, is distinctly undermined and is easily separated from the deeper structures. The edges of the ulcer are indurated and thickened, while the floor is distinctly nodular. These nodules, for the most part, are small and single, generally not exceeding a large hazel-nut in size; they are fissured somewhat irregularly by sulci, which tend for a variable distance, in the median line, even down to the bone. The entire surface might well be described as resembling a cauliflower mass. The surface of the ulceration is studded in a small amount of whitish-yellow semi-fluid pus, of a slightly offensive odor; not infrequently small collections of pus or miliary abscesses are encountered; and pressure causes small drops of pus to exude from the sides of incisions.

Bacteriologic Examination.—In the cover-slip preparations of a few round, homogeneous, non-nucleated, bodies about six to twelve mikrons in diameter were seen, both when stained and unstained. Apparently budding forms were also met. These were probably degenerated epithelial cells. Numerous and extensive culture experiments failed to reveal any colonies of blastomyces. The pus contained innumerable bacteria of many kinds and there were isolated and identified, bacillus pyomyositis, bacillus subtilis, bacillus coli communis, micrococcus fragilis, staphylococcus pyogenes aureus, staphylococcus pyogenes albus, streptococcus pyogenes, and irregularly stained micrococci not stained by Gram's method.

Microscopic Examination.—Numerous sections from all parts of the ulceration and stained by various methods were examined. All present essentially the same structure. The striking feature is a rather coarse but intricate network of narrow and wider ribbons composed of cells mostly of the type of the prickly cells of the rete. Wherever the surface is covered by epithelium, narrow down-growths of this kind are seen. At frequent intervals the bands of epithelial cells present rather small bulbous and spindle-shaped enlargements and connective layers of flattened and horny cells, which stain by Gram's method. Small whorls are also found in the anastomosing cellular bands; isolated whorls, some quite large, are also present. Many of the epithelial cells are vacuolated—dropical degeneration—and many curious cell-forms are seen; in some places the nucleus refuses to stain or is very small, the protoplasm staining deeply with eosin and with methan-violet; these degenerative changes in varying degrees are scattered quite diffusely throughout the sections. The stroma is often of a rather marked fibrous character; here and there are accumulations of cells mostly of the polymorphonuclear and lymphocytic type; occasionally small abscesses are seen in the stroma, often opening on the surface of the sections. Here are found various kinds of bacteria, but no yeast-like bodies. The vessels generally have thick walls and in some are leucocytic thrombi, in other places newly-formed vessels are present. The carcinomatous tissue extends deeply into the tissues of the thigh, especially in the central parts of the ulceration, replacing the muscles, the nerves being the seat of a marked interstitial process.

I have lately examined the patient and found him in excellent health, having gained over thirty pounds in weight, and there is no sign of recurrence of the disease. The lymphatic glands in the groin were much reduced in size, showing that in all probability their enlargement was due to secondary pus infection from the eroded surface rather than carcinomatous invasion.

COLOSTOMY FOR THE CURE OF AMEBIC DYSENTERY.*

WILLIAM NORBERT SULLIVAN, M.D.
SAN FRANCISCO.

Although medical treatment of dysentery yields good results in many cases, a large number of dysenteric patients succumb in spite of careful and painstaking treatment. The unqualified success which has attended the use of colostomy in the treatment of the case which I present leads me to believe that many patients die because the application of remedies to the diseased portion of the bowel is impracticable by ordinary methods.

The pathological description, as given by Osler,¹ assists us in comprehending the difficulty which is experienced in treating some cases of dysentery. It can readily be conceived that if the ulcerated portion of the colon is situated at a distance from the rectum, i. e., if it occupies the ascending colon or the cecum, any fluid injected will have difficulty in reaching the diseased area and, if it should reach it, it will not remain long enough in contact with the affected surface to accomplish its remedial action. Furthermore, the character of the ulceration, with its sinuous tracts and undermined edges, is a feature which, in itself, renders the application of solutions difficult and impossible, at times, when indirect methods are used.

The treatment of dysentery, according to our best text-books, is restricted to dietetic measures, to remedies given by the mouth, and to remedies applied to the large intestine by means of injections into the rectum.

Rectal injections have often been attended with success, but many patients do not respond to any method of treatment, grow progressively worse and finally die.

The case which I present serves as a good example of the resistance of the disease to nearly all measures used in the treatment of dysentery, as the patient was sick a year and a quarter before I saw him and during that time had submitted to the most careful treatment by capable surgeons both in the Philippines and in San Francisco.

F. C., aged 35, enlisted in the First California Volunteers, May 4, 1898, and sailed on the transport *Pekin* for Manila, May 25. He was well until about December, 1898, when he had a slight diarrhea, which was not sufficiently severe to prevent his remaining on duty. In February, 1899, while on the firing line, he became quite sick and was given bismuth by the surgeon. On February 27 he entered the Ermita Hospital—the field hospital—and while staying there was on a dietetic and medicinal treatment. Among the remedies used were nitrate of silver injections and quinin injections. He remained either at the Ermita, or at the general hospital until May, 1899, when he was transferred to Negros Island and entered the hospital at Bocolod. He remained there until July 3, and then was consigned to the transport *Sherman* and sent home. While on the *Sherman* he passed much blood and mucus and some large membranous shreds.

On Aug. 24, 1899, he entered the hospital at the Presidio, San Francisco, and there received treatment until Oct. 11, 1899, but did not improve. From Oct. 11, 1899, till April 4, 1900, he was confined to his home in this city without methodical treatment. He could get about the streets a little, but was very weak, was having from eight to twenty passages a day, and was never sure at any moment that he would not have an evacuation. He was also suffering extreme pain in the abdomen.

On April 4, 1900, I saw him at his home and found him in a deplorable condition. He was extremely

* Read before the San Francisco Medico-Chirurgical Society.
1. Text-book on Practice of Medicine, pp. 132-133.

emaciated; he was suffering and his voice was weak. At times he endeavored to concentrate his mind on a game of cards or similar amusement, but found it impossible to do so. He lay around the house all day, not venturing to go out, and took milk and occasionally eggs as diet. If he took meat it caused great irritation and numerous watery evacuations.

I had another case of dysentery, also contracted in the Philippines, which had recovered under the use of large injections of sulphocarbolate of zinc—15 grains to the pint—and I thought it would be an easy matter to accomplish the same result in this case. But although I used these injections faithfully every day and took the greatest care with the diet, the patient became progressively worse. His stools, consisting of water, mucus and blood, numbered from ten to twenty a day. He became very weak, his voice became low and whisping and he could scarcely rise in bed.

The antiseptic solution was evidently not reaching the ulcerated patches in the upper part of the intestine, for while the local tenderness had disappeared over an area represented by the descending and the neighboring part of the transverse colon, the right portion of the transverse and the ascending colon became more tender, until the most exquisite pain and tenderness existed in this region. It was evident that while the solution was relieving the pain and inflammation as far as it penetrated, it was only aggravating the more remote region of the cecum and the ascending colon by exciting severe peristalsis.

At this juncture Dr. J. Henry Barbat suggested the feasibility of performing a right inguinal colostomy and flushing the bowel through the opening thus made. By this he expected to accomplish two things: 1. give rest to the inflamed bowel by preventing the feces from passing over it; 2. allow a large flushing irrigation of a portion of the bowel which was probably not reached by injections into the rectum.

The patient was removed to the hospital April 21, 1900, and was operated on by Dr. Barbat April 25, the bowel being brought up and attached to the abdominal wall. On April 30 the bowel was incised and a stream of pyrozone solution—half a pint to the gallon of sterile water—was passed through the large intestine and as the peristalsis operated it passed out by both outlets, the anus and the artificial anus, thus thoroughly flushing the whole of the large intestine. This treatment was continued daily.

Before the operation the patient had a temperature varying from 99 to 101 F., but on May 2, two days after the operation, it was normal. The pain, which had been excruciating and agonizing, ceased immediately after the first few days and he began to eat well of a soft diet, including fish. He gained flesh rapidly. He was kept under this treatment from April 30 until Aug. 30, 1900—four months—when the opening was closed and the bowel dropped back into the abdominal cavity. While the patient was in the hospital careful examination of the feces was made, and the ameba coli, which were found in large numbers before the operation, disappeared a few days after the operation and could not be demonstrated after. He now weighs 151 pounds, has but one or two evacuations a day, and feels well and free from pain.

This case I believe demonstrates the utility of this measure in the treatment of dysentery. The method certainly possesses two cardinal points of value: 1. it affords rest to an inflamed surface; 2. it permits direct applications of remedial solutions to a portion of the

bowel which is practically beyond the reach of injections into the rectum.

REMARKS BY DR. BARBAT.

The abdomen was opened for a distance of two inches at the external border of the right rectus muscle, and the intestines were examined as far as the fingers could reach. The small intestine appeared normal, but the cecum and ascending colon were very much thickened and of a dull gray color, the normal luster of the peritoneum being diminished. Rolling the cecum between the fingers showed that the bowel was not uniformly thickened, some spots feeling thinner than normal, but the greater portion felt about one-quarter of an inch thick and of a brittle consistency, showing all the coats to be very much infiltrated. The appendix was swollen, but not congested; it was cut off close to the cecum and the opening closed with two rows of catgut.

The colon was sutured to the peritoneum with interrupted black silk sutures, and sterile dressings applied. The gut was opened on the fourth day without anesthesia and the intestine flushed with antiseptic solutions.

The opening did not close spontaneously, and necessitated an operation, which was done four months from the first one.

The bowel was separated from the abdominal wall down to the peritoneum, which was easily found on account of the black silk sutures, which were all removed. When the abdominal cavity was opened, the fistulous tract was cut off flush with the bowel and the opening closed with fine catgut. The colon was very much thinner than at the first operation, and the bowel had a more normal appearance. The abdominal wound was closed in the usual manner and the wound healed per primam.

LUPUS HEALED WITH ROENTGEN RAYS.

REPORT OF CASE.

WM. ALLEN PUSEY, A.M., M.D.

Professor of Dermatology in the College of Physicians and Surgeons of Chicago, Medical Department of the University of Illinois.

CHICAGO.

The patient, a married woman aged 38, was referred to me May 8, 1900, by Dr. H. B. Favill, with a diagnosis of lupus and for treatment with Roentgen rays. The condition at that time is shown in the accompanying photograph, Fig. 1, which I took when I first saw her. The extent of the disease on the left side of the face and the neck is indicated in the photograph. It also extended over on the right side of the chin and up on the right cheek beyond the angle of the mouth. This entire area was covered with lupus ulcers and unhealthy scars. The ulcers were the typical flabby, soft, indolent ulcers of lupus covered with reddish-brown crusts. The scars were thick, red, band-like and very disfiguring. The scars were most marked under the chin and they were sufficiently rigid to materially interfere with motion. At many points in the scars there were recurrent ulcers. Typical "apple-jelly" tubercles of lupus were easily demonstrable in any part of the diseased area. The point of greatest activity of the lupus was an area with a diameter of perhaps two inches around the left angle of the mouth. The ulcers involved the mucous membrane of the lips at this point, but no lesions were found within the buccal cavity. There was no evidence of tubercular involvement of the deeper structures. There were no deep sinuses and no tubercular glands. The case was, in short, a lupus and not a scrofuloderma.

The disease began, the patient thinks, about four

years ago in an innocent-looking ulcer the size of a pea on the neck, and gradually spread from that point. The disease, however, was so benign in appearance that little attention was given it and no physician saw it. It is probable that it had existed some time before it attracted notice. The case had had no treatment before I saw it except the application of salves, which had had no influence on its course. It had steadily progressed from bad to worse, ulcers healing at times or new ones appearing, but more tissue constantly becoming affected.

At the time the patient appeared for treatment her general condition was considerably run down, but without evidence of other disease than the lupus. There was no indication of tubercular involvement of the lungs. She had had the usual diseases of childhood, but has had no serious illness except an attack of appendicitis about five years ago. She has never, within her

a piece of tissue taken from the border of an active ulcer. These sections show the structure of tuberculous tissue. Tubercle bacilli were found in this tissue by me, and independently in other sections by Dr. Roehr, of the Columbus Laboratory. I was fortunate in having the case seen by Dr. H. G. Anthony, professor of dermatology in the Chicago Polyclinic, when it first came to me; he agreed in the diagnosis of lupus.

The treatment which the patient has had in my hands has consisted of exposures to X-rays after the method of Schiff and Freund, of Vienna. While the lesions were freely ulcerating, the surface was covered with boric-acid vaselin, and in the morning before the treat-

memory, had an eruption except the lupus. As a young baby she is said to have had an eruption of short duration after vaccination, which was probably an impetigo. Her father died at 69, of bladder trouble. Her mother is living, aged 60, but has been blind for thirty years and has always been "scrofulous." She has a brother aged 26 and a sister aged 32, both in good health. A brother aged 23 has a chronic cough. Several brothers and sisters died in childhood.

As to the diagnosis, the presence of the pathognomonic tubercles, the indolent ulcers with soft, reddish borders, the thick band-like scars showing recurrent tubercles and ulcers, the slow course and painless character of the disease are all characteristic of lupus and serve to differentiate it from syphilis or carcinoma. That the disease is not blastomycetic dermatitis, which sometimes so closely resembles lupus clinically, is shown by the absence of blastomycetes. I have sections made from

ment by X-rays the ulcers were lightly cleaned with cotton sponges wrung out of a weak bichlorid solution. The ulcers, however, were never washed with bichlorid solution, and the case has had no other local treatment. The patient has had no internal treatment of any kind until within the last month, and then only a pill of reduced iron, arsenious acid and strychnin, t. i. d.

Treatment was begun by exposure to X-rays on May 8, and was continued daily, except Sundays, until May 26. By May 24 many of the lesions were cleaning up and beginning to heal. May 26 the exposed surfaces showed some reaction from the effects of the rays; the lupus tubercles were brighter in appearance and the borders of the ulcers redder. Treatment was discontinued until June 4, by which time the reaction had almost disappeared. The treatment was continued from June 4 until June 21, daily, as before, when considerable dermatitis developed. This dermatitis was confined

to the diseased tissue and did not involve the surrounding healthy skin which had been exposed to the rays. At this time the ulcers were healing rapidly. The treatment was discontinued until July 2, when reaction had entirely disappeared and almost all of the ulcers were healed. From July 2 till August 10 the treatments were continued, not daily, but with a few intermissions of three or four days as the condition of the face indicated. During this time there was gradual improvement in the condition, the remaining ulcers healing, tubercles being absorbed, and the entire surface becoming covered with healthy sears.

By the latter part of July the left side of the face showed few traces of the disease. The diseased area on the right side, however, which from the manner of making the exposures had received less of the effects of the rays than the left, still showed lupus nodules and open ulcers. Accordingly, additional exposures were begun directly over this area on July 30 and continued daily in a maximum amount until August 10. Under these extra exposures the lesions immediately began to improve and by August 10 had entirely healed. This observation, which is but confirmatory of similar observations made by Schiff and by Jones, leaves little room for doubt as to the positive effect of the rays.

On August 10 treatment was discontinued, because of my going away. At that time the only evidence of lupus that I could find was at the angle of the mouth, where there was still a focus of disease. On September 13 the patient returned: there was then no evidence of disease at any point except at the angle of the mouth, where the tubercles persisted. Treatment was resumed with exposures over the left angle of the mouth. September 20 the tubercles on the upper lip were breaking down and an elliptical ulcer the size of a little-finger nail had developed, which within the next few days began to heal. On October 2 some erythema over the exposed area had developed and treatment was given up until October 8. By October 8 the last lesion had disappeared. From October 8 to date the patient has had daily exposures on the left side of the chin and on the neck under the chin. These exposures have been continued for two reasons: 1, the old keloid-like sears had shown under the exposures great improvement in flexibility, softness and color, and it was desired to carry this effect as far as possible; 2, to destroy any concealed lesions still present. Since October 8-I have not been able to find any evidence of disease.

The technique of the treatment which I have used is that of Schiff and Freund. It consists of repeated exposures to a weak light of definite strength. The light is produced by a secondary current generated in an induction coil of 30 cm. spark-length, which in turn is energized by a very weak primary current. The primary current which I have used is that recommended by Freund, namely, a current of 12 volts and 1½ amperes interrupted from 800 to 1000 times per minute. The exposures are continued from five to fifteen minutes, and the distance of the tube from the surface varied from 15 to 5 cm. Adjacent surfaces are protected by lead masks. The object to be obtained by the exposures is, of course, to get the required effects of the rays without overstepping the bounds of safety.

The case is presented as one healed by exposures to Roentgen rays. The results of the treatment are indicated in photograph, Fig. 2, taken November 10. It is at once admitted that whether it is a complete cure or not can only be determined by the lapse of time. There remain now, excepting the sears, no evidences of the

disease; and even should more or less recurrence of the lupus take place, I believe the results may still be called extraordinary. Attention is called to the character of the scars. The only thick ones left are those which were in existence before the treatment began, and they have become less prominent, much softer and more pliable. The scars which have taken the place of the ulcers present when treatment began are soft, thin, flexible and white, and are as healthy-looking as they could possibly be. At the beginning the sears on the neck interfered very considerably with motion; now they interfere scarcely at all.

Certainly none of the usual methods of treatment by surgical means could produce such a result. The only other method of treatment which is comparable, as regards the cosmetic results, is Finsen's treatment by ultra-violet light, and his results are probably the same as those attained by Roentgen rays. In celerity of treatment Finsen's method does not compare with that by X-rays. Finsen's patients have about an hour's exposure daily for each 1.5 centimeter square of disease, and accordingly a cure is a matter of one or two years. In order to fortify the effects of the light, moreover, Finsen resorts to pyrogallic acid, curetting and other local adjuvants to treatment. The effects of the X-rays is sufficient without these aids.

This method of treating lupus has been in use in some German and Austrian clinics for three years. Most of the work has been done by Schiff and Freund, of Vienna, and by Kummell, of Hamburg. Single, or a few, cases of lupus cured by this method have been reported by various men in Europe. My case is, as far as I know, the third reported in the United States. P. M. Jones,¹ of San Francisco, reported a lupus cured by Roentgen rays, and another showing improvement under treatment. The second case was reported in THE JOURNAL, November 10, by Dr. J. T. Knox, of Cincinnati.

103 State Street.

TUBERCULOSIS OF THE TESTICLE.

WITH SPECIAL CONSIDERATION OF ITS CONSERVATIVE TREATMENT.

JOHN B. MURPHY, M.D.
CHICAGO.

(Concluded from p. 1411.)

CASE 6.—Mr. G. L., aged 37 years; occupation, carpenter. Admitted to Alexian Brothers' Hospital Sept. 21, 1897.

Present Illness: About one year ago patient began to cough and lose flesh. Since then he has coughed continuously, expectoration being at times quite profuse, and occasionally bloody. Loss of flesh has been marked. For some time past he has had afternoon fever, night sweats, loss of appetite and diarrhea. Three years ago he developed an empyema, which was opened and drained by Dr. Murphy. The empyema sinus is still discharging pus. Four months ago patient noticed a small nodule in the right testicle at its posterior and lower portion. This has gradually increased in size, but has caused no pain or other symptoms referable to it. Complaints of increased frequency of urination.

Previous History: No points of interest except those given above.

Examination of patient shows physical signs of the conditions recorded in the history. The nodule in the globus minor is about the size of a hickory-nut. The testicle proper is apparently not involved.

Operation Sept. 23, 1897. Operator, Dr. J. B. Murphy, assisted by Dr. Moran. Incision through the serotal coverings down to the epididymis. Epididymis picked up with forceps

and dissected from testicle proper, beginning below and passing upward, the spermatic vessels being left intact. Cord ligated high up and its lumen cauterized with 95 per cent. carbolic acid. External wound closed after first replacing testicle in serotum. Small gauze drain left in lower angle of wound for twenty-four hours. Convalescence after operation was uneventful, and patient was discharged from the hospital cured, so far as his testicular trouble was concerned, Nov. 15, 1897.

This patient later developed a tuberculosis of the spine, and died from a general miliary infection some months after the operation. No recurrence of symptoms referable to the genito-urinary organs.

CASE 7.—Mr. W. C.; nativity, Ireland. Age, 38 years; married; occupation, laborer. Admitted to Cook County Hospital Oct. 6, 1897.

Present Illness: About seven months ago patient first noticed swelling in the left side of the serotum, which swelling had appeared quite suddenly and attained a somewhat larger size than at present in the course of a few days. Its appearance was accompanied by sharp, shooting pains. The swelling remained stationary for five or six weeks, when it partially subsided. The pains decreased with the reduction in size of the testicle. About five weeks before admission to hospital a similar swelling developed in the right side of the serotum, this running a course resembling the above. He now complains of some pain in the right testicle.

Previous History: Denies syphilis and gonorrhoea. Has two children, oldest 15 and youngest 2 years of age. Family history entirely negative as regards tuberculosis.

Examination: General nourishment good. Serotum presents on the right side an ovoid mass, about 3 by 6 cm. in size, situated posterior to the body of the testicle, which is apparently uninvolved. This ovoid mass is composed of several hard nodules. The spermatic cord is negative. On the left side the epididymis answers to the same description as on the right, but here the tunica vaginalis is distended with fluid. Rectal examination shows the prostate and vesiculae seminales to be normal. Left spermatic cord normal.

Operation Oct. 29, 1897. Operator, Dr. J. B. Murphy, assisted by Drs. Simpson and Morf. Incision into serotal sac on each side down to the tunica vaginalis. Hydrocele on right side evacuated. Epididymis on both sides now removed by dissecting each from its testicle proper, carefully avoiding the spermatic arteries and veins. Testes replaced in serotum, hemorrhage controlled and external wound closed with silk-worm gut sutures; gauze drainage in each lower angle. Patient was discharged cured Nov. 12, 1897.

Unfortunately we have been unable to locate the patient since his discharge from the hospital, so can not report as to final outcome of the operation.

CASE 8.—Mr. W. L. M., aged 35 years; occupation, clerk. Admitted to Mercy Hospital, July 18, 1898.

Present illness began about one month ago with sudden painful swelling of the right testicle, the pain being quite severe and aggravated by patient being on his feet. He has had almost constant headache since the onset. Appetite is good; has no night sweats or fever. Since onset of trouble he has lost considerably in weight; bowels are constipated. Patient complains of frequent urination, it being necessary for him to get up several times every night to void urine.

Previous History: At the age of 13 years he had enlarged cervical glands, which disappeared under treatment. He has also had "scarlet fever" and "cystitis." No specific history.

Family History: One aunt died of military tuberculosis.

Examination of patient negative, except as regards sexual glands. On posterior surface of the right testicle there is a hard nodular mass, slightly tender to pressure. The testicle proper is apparently normal. A small amount of fluid is present in the cavity of the tunica vaginalis; cord not involved.

Uranalysis on Admission: Quantity in twenty-four hours, 1200 c.c.; specific gravity, 1.011; reaction, acid; color, yellow, cloudy. No albumin, no sugar. Microscopic examination, small amount of pus, no casts.

Operation, June 20, 1898. Operator, Dr. J. B. Murphy, assisted by Drs. Bick and Daly. Incision on right side of scrotum down to epididymis and into sac of tunica vaginalis. This incision was extended upward to the external inguinal ring. The nodular epididymis was dissected from the testicle proper, beginning below and passing upward, leaving the testicle and spermatic vessels intact. The vas was ligated and amputated high up, and the lumen of the stump cauterized with a red-hot needle. A few catgut sutures were introduced into the tunica albuginea to check oozing, and the testicle proper then replaced in the serotum. The fascia was sutured over the cord with buried catgut and the skin wound closed by means of a subcutaneous suture of fine catgut. Colloidin dressing.

The patient made a perfect recovery and was discharged cured Aug. 6, 1898. Urinalysis on the day of discharge from hospital showed the following: Slightly cloudy; reaction, acid; specific gravity, 1.012; no albumin; no sugar. Microscopic examination, very small amount of pus.

(For ultimate result see under Case No. 9.)

CASE 9.—Mr. W. L. M., aged 35 years. (See Case No. 8.) Admitted to Mercy Hospital Sept. 30, 1898.

Present Illness: Last July, about two months ago, patient underwent an operation for the removal of the right epididymis. Shortly after operation left testicle became swollen, slightly tender and painful, and this condition has persisted, gradually becoming more severe, until the present time. He still complains of frequent urination.

Examination shows nodular swelling of the left epididymis, adherent to the surrounding structures, very hard and slightly tender to compression. There is no sign of recurrence of trouble on the right side. Chest and abdomen negative.

Uranalysis, Oct. 1, 1898, yellow, slightly cloudy, reaction acid, specific gravity 1.015, no albumin, no sugar. Microscopic examination, small quantity of pus; no casts.

Operation Oct. 1, 1898. Operator, Dr. J. B. Murphy, assisted by Drs. Rogers, Baucus and Daly. Incision one and a half inches long parallel to raphe, near the bottom of the serotum; small amount of fluid escaped. Testicle drawn out and epididymis dissected off, leaving the vessels passing to the testicle proper intact; vas ligated, amputated and lumen cauterized. Testicle returned to serotum and skin wound closed by means of a buried suture of silk-worm gut. Small iodoform gauze drain left in lower angle of wound. Uneventful convalescence after operation. Patient discharged as cured Oct. 15, 1898.

Uranalysis, Oct. 3, 1898, quantity in twenty-four hours, 1250 c.c., pale yellow, slightly turbid, reaction neutral; specific gravity, 1.012; no albumin, no sugar.

Microscopic examination: Numbers of epithelial cells and a very few pus cells.

Examination of patient Nov. 9, 1899. General health excellent. No recurrence of tubercular trouble in either testicle, both being apparently normal. No atrophy has taken place. Patient now has no vesical irritation.

Examination March 25, 1900. Patient feels perfectly well; has gained fifteen pounds since last operation, now weighing 145. The sexual desire is the same as before the onset of the disease, and the sensation attending intercourse is unchanged. The seminal emission is less than normal, and patient now has no nocturnal emissions. The vesical irritation has entirely disappeared.

CASE 10.—Mr. S. R. A., aged 47 years; married. Admitted to Mercy Hospital Sept. 30, 1898.

Present Illness: Several months ago patient first noticed a small nodule, slightly painful and tender to pressure, on palmar aspect of right index finger. This steadily enlarged and some swelling developed along the entire length of the finger, extending into the palm. Several weeks after swelling was first noticed patient received a slight traumatism to the left testicle. Almost immediately afterward testicle became swollen and the epididymis gradually developed the hard nodular condition which is now present. Testicle is only slightly painful and tender under compression. Patient complains of some increased frequency in urination, and the

urine is cloudy. He has no cough and the general health is good. No tuberculosis in family.

Examination of the Patient: Large stature; well nourished; heart, lungs and abdomen are negative. Index finger of right hand swollen along its entire palmar aspect, the swelling extending into the palm. It is only slightly tender to pressure, the skin over it is not reddened, and along the course of the tendon several small nodules can be felt. Function is much impaired. Left epididymis is thickened, hard, nodular and adherent to the surrounding tissues. The spermatic cord is apparently not involved.

Uranalysis, Oct. 1, 1898. Quantity in twenty-four hours, 1200 c.c.; reaction acid, specific gravity, 1014; color, yellow; cloudy, trace of albumin, no sugar. A few granular casts and pus cells were found under the microscope.

Operation Oct. 1, 1898. Operator, Dr. J. B. Murphy, assisted by Drs. Rogers and Daly.

1. Finger. Esmarch on wrist. Incision on palmar surface of finger along its entire length down to tendon; numerous rice bodies escaped. Fungus granulations dissected out, hemorrhage controlled and wound closed with buried silkworm gut suture. Colloid dressing.

2. Testicle. Incision one and a half inches long near the bottom of the scrotum on the left side, into the cavity of the tunica vaginalis; small amount of hydrocele fluid escaped; testicle drawn out and diseased epididymis dissected from it, the dissection beginning below and proceeding upward. The spermatic artery and veins were left intact; the vas ligated and amputated high up and its lumen cauterized with 95 per cent. carbolic acid. One or two fine catgut sutures were used to draw together the edges of the abraded surface, left by the removal of the globus major. Testicle now returned into the scrotum and the wound closed by means of buried catgut suture, a small gauze drain being left in the lower angle of the wound.

Uninterrupted convalescence followed the operation, and patient was discharged cured Oct. 10, 1898.

(See Case No. 11 for result.)

Case 11.—Mr. S. R. A. (see Case No. 10), aged 49 years. Admitted to Mercy Hospital Feb. 13, 1900.

Present Illness: Since Oct. 1898, when patient underwent operation for the removal of the left epididymis, his health has been good. Five or six months ago some soreness developed in right epididymis, and a small hard nodule became palpable. There has been no pain in the testicle except on pressure. He complains of frequent urination, the act being accompanied by some pain at the base of the bladder. General health at present is good.

Family history and previous history given under Case No. 10.

Examination of the Patient: Nourishment good; lungs, heart and abdomen negative. Cicatrix on palmar aspect of index finger of right hand present; no recurrence of trouble here. Left epididymis absent, and the wound left by former epididymectomy now scarcely noticeable. No atrophy of left testicle and no sign of recurrence of tubercular trouble. The right epididymis is hard, nodular and slightly tender to pressure, the process being confined quite closely to the globus major. The vas is apparently uninvolved. The right seminal vesicle is slightly thickened, while the left is apparently normal.

Uranalysis Feb. 17, 1900. Color, light yellow, slightly cloudy; acid reaction; specific gravity, 1015; urea, 1.5; albumin, trace; no sugar.

Microscopic examination: A few hyaline and granular casts found. Pus cells numerous. Tubercle bacilli found in the centrifuged specimen.

Operation Feb. 14, 1900. Operator, Dr. J. B. Murphy, assisted by Drs. Lemke and Eggert. Incision two inches long into cavity of tunica vaginalis over nodular epididymis, just to the right of it. Testicle brought out of wound; tunica vaginalis incised at upper border of testes, and dissected from epididymis laterally. Epididymis now dissected from the testicle proper, leaving the nutrient vessels of the latter intact; vas clamped as high as possible, amputated and lumen cauterized

with 95 per cent. carbolic acid. Abraded surface left by removal of the epididymis now covered by flaps of tunica vaginalis and testicle returned into the scrotum. Small gauze drain introduced into lower angle and the external wound closed with silkworm gut sutures. The day after the operation irritability of the bladder had almost entirely subsided, and has not since returned. Convalescence was uneventful, and patient left hospital March 3, 1900.

Several later examinations of the urine show a small amount of albumin to persist, with a few hyaline and granular casts. In the centrifuged specimen pus cells are still found, though in smaller numbers than before operation. Tubercle bacilli have also been demonstrated on several occasions since the last operation.

Examination of patient June 20, 1900: General health excellent; has gained fourteen pounds since the last operation; appetite is good. There are no signs of recurrence of the tubercular trouble in either testicle. Vesical irritability not now present, although occasionally he is obliged to urinate somewhat more frequently than normal. No pain on urination and no blood passed. Rectal examination shows in each seminal vesicle a small, very hard nodule, which is only slightly tender to pressure. The foci in the seminal vesicles have evidently become encapsulated, as there are now no tubercle bacilli present in the urine. We believe that the seminal vesicles were the source of the bacilli which persisted so long after the last operation.

CASE 12.—Mr. P. McC., aged 30 years; married; occupation moulder. Admitted to Alexian Brothers Hospital March 11, 1900.

Present Illness: Patient has a double hydrocele, each side being as large as a goose egg. Scrotum has gradually increased in size since November, 1899. Patient complains of pain in lumbar region and scrotum; also of great weakness.

Previous History: Diseases of childhood; specific urethritis five years ago. Initial lesion of syphilis ten years ago. Inguinal adenitis in 1894. Operation for hernia in 1899.

Family History: Negative as regards tuberculosis.

Examination of Patient: Heart and lungs negative; cicatrices of hernial operation in both inguinal regions.

Genitalia: Scrotum very much enlarged, due to double hydrocele. Testicles situated below and behind the fluid sacs. Both testicles are apparently somewhat enlarged, and epididymi enlarged and nodular, especially in the region of the globus major.

Uranalysis: The urine contains some pus, and the centrifuged specimen shows tubercle bacilli.

Operation March 12, 1900. Operator, Dr. J. B. Murphy, assisted by Drs. Lee and Hess. Two incisions, one on each side of the median line of scrotum. Hydroceles exposed, sacs opened and fluid evacuated. Testicles drawn out and inspected; both epididymi nodular and thickened, the tubercular deposits extending for a short distance on to the tunica albuginea of the testicle proper. Both hydrocele sacs dissected out and removed; both epididymi and adjacent tunica albuginea removed by dissecting from the testicle proper, beginning below and passing upward, leaving the vessels of the testicle proper intact. Cords isolated, and the vas on each side clamped and ligated high up. Lumina cauterized with 95 per cent. carbolic acid. Cut edges of tunica albuginea approximated and sutured. A small gauze drain inserted at the lower angle of each scrotal incision and external wounds closed.

Microscopic examination of epididymi showed large amount of old fibrous connective tissue, with a few scattered tubercles containing giant cells.

Convalescence uneventful, and patient discharged from the hospital March 15, 1900.

We have been unable to trace this patient since his discharge from the hospital, so can not report on his present condition.

CASE 13.—Mr. J. M., aged 37 years; German; married. Admitted to Alexian Brothers' Hospital, April 1, 1900.

Present illness dates from two months ago, when patient was taken sick with high fever, pains all over the body and

other symptoms of an acute infectious disease. He had no cough or any localizing symptoms at first, but two days after the onset the left testicle suddenly became swollen, and he experienced some pain in the left inguinal region. Testicle continued to enlarge for a number of days, but was not tender, and was the seat of no pain. He did not complain of frequent urination, and never passed blood in the urine. The bowels have been constipated, and he has some pain in the rectum during defecation.

Previous History: Patient states that twelve years ago he "strained himself," and soon after had some swelling and pain in the right testicle. The symptoms subsided after a few days, but a nodule remained in the upper and posterior portion. This nodule enlarged slowly and two years ago a surgeon incised the swelling and allowed "water" to escape. No tissue was removed at that time, and the nodule is still present. One year ago patient suffered from very frequent and painful urinations, and on two occasions passed some blood in the urine. At that time he had fever, and during the six months that the trouble persisted lost twenty or twenty-five pounds in weight. He had no symptoms directly referable to the testicles at that time. After about six months the symptoms disappeared and he was in good health until the onset of the present trouble, two months ago. He denies absolutely ever having had any venereal disease. No history of injury. He is married and the father of a number of children.

Family history presents no points of interest. No tuberculosis in any of the members so far as can be ascertained.

Examination of Patient: Medium stature; nourishment poor; temperature, 98.6 F.

Heart and lungs negative. Abdomen, some slight diffuse tenderness. The edge of the liver is palpable three-quarters of an inch below the costal arch. Kidneys are not palpable. There is quite marked tenderness in the right lower quadrant of the abdomen.

Genitalia: In right epididymis there is a hard, round and slightly tender nodule in the globus major. There are defrens passes somewhat more anteriorly than normal, and the testicle is rotated so that the epididymis lies to the inner side rather than posteriorly. In the left epididymis there are numerous hard nodules massed together. The cord is thickened and tender at its lower portion.

Rectal Examination: Both seminal vesicles are enlarged, the right soft, the left nodular and tender. Urine, yellow, turbid, reaction acid. Trace of albumin. The microscope reveals pus cells and a few red cells. No tubercle bacilli found.

Operation April 12, 1900. Operator, Dr. J. B. Murphy. Incision over the left epididymis and cord, epididymis dissected from testicle proper, leaving the spermatic vessels intact. The cord was dissected from the surrounding tissues up to the internal ring, where it was ligated, amputated, and the lumen cauterized with 95 per cent. carbolic acid. Testicle proper replaced in serotum, and wound closed with subcutaneous suture, leaving a small gauze drain in the lower angle. Right epididymis not operated upon, as the process had evidently been arrested by encapsulation. Convalescence was uneventful, and the patient discharged about ten days after operation.

Since discharge from hospital, pain in the left groin has persisted. Left testicle is tender, as is also the stump of the amputated cord. Occasionally he is obliged to pass the urine oftener than normal, but has passed no blood. Complaints of some pain in the left ilio-lumbar region, which is aggravated by stooping forward. Defecation is still painful. He states that his weight is the same as before operation. Has no chills, fever or sweats. Has some burning pain in the urethra during urination. There is a small discharging sinus in the cicatrix on the left side of the serotum, and the tissues posterior to the testicle and at the stump of the cord present some inflammatory infiltration. Both seminal vesicles are in the same condition as they were when patient was admitted to the hospital. Heart, lungs and abdomen negative.

In a letter written August 25, 1900, patient states that he is at work and feeling better, but still has considerable pain in the left side and back. It was not possible for him to come to the city for examination.

I desire to express my appreciation of the valuable services rendered by Dr. J. M. Neff in the preparation of this paper.

A YOUTHFUL DECEIVER.

JOHN J. KYLE, M.D.

INDIANAPOLIS, IND.

The matron of one of our benevolent institutions, situated in the northern part of the state called my attention recently to what she regarded as a remarkable case.

A child of 10, some two years ago, contracted purulent ophthalmia, which destroyed the sight of the left eye, compelling enucleation. An artificial eye was fitted, which has been worn with comfort. Since July last, the matron tells me, there has been forming under the upper and lower lids of the right eye, three or four times a day, large lumps of a mucopurulent character, which would be discharged spontaneously, or on lifting the lids. Sometimes two lumps would be discharged at the same time. They could be seen moving and thus excited further interest in the case. Since July 1, the child has been under constant observation, making daily trips to the oculist.

When I separated the lids, a large lumpy deposit naturally excited my curiosity. On examination, the deposit was found to be fibrous bands of lint picked from the cloth given to the child to dry the eye. This would be rolled into a small ball and inserted under the lids, as stated above. When it became thoroughly saturated from discharge from the lids it would slip about, and for want of a careful examination, the child was enabled to practice this deception for a long time.

The child confessed that she did this to excite sympathy, to escape work, and to enjoy the drive into the city to consult the physician. She is now free from further inflammation of the lids.

This case is interesting in that a child so young could conceive and practice such deception, and that a foreign body could be worn in the eye without causing great pain and more destructive inflammation, and lastly as an evidence of degeneracy.

TEMPORARY RIGHT-SIDED COLOSTOMY IN CHRONIC DISEASES OF THE COLON.

On page 1475 of this issue of THE JOURNAL, is an article on "Colostomy for the Cure of Amebic Dysentery," which again forcibly illustrates the value of physiologic rest in the treatment of a diseased organ. Amebic dysentery is a serious disease. Harris, in an excellent article¹ on the subject, says that out of 78 cases reported in this country there have been 30 deaths, and that after it becomes chronic the chances of recovery, even with the best treatment, are always bad.

In view of such an unfavorable prognosis under medical treatment, temporary colostomy, as practiced by Barbat for Sullivan with such excellent results, is certainly to be commended in suitable cases. The formation of an artificial anus at the ileocecal valve in amebic dysentery was suggested some years ago by Corson,¹ but it is not shown that he ever put his suggestion into practice. His object was to permit the application of peroxid of hydrogen to the entire colon. The same procedure had already been proposed in the treatment of chronic dysentery, and Ballance² reports a case of dysentery in which he produced an artificial anus by severing the ileum close to the ileocecal valve and bringing both ends of the bowel to the surface. His intention was to wash out the colon, but his patient died from hypostatic pneumonia one week later.

Goodlee³ also reports a case of chronic dysentery in a young lady on whom he performed a left colostomy for the purpose of preventing the passage of the intestinal contents over the inflamed rectal surfaces. Marked improvement followed the operation, but unfortunately the patient died a short time thereafter from a phlebitis, which, it is said, bore no relation to the dysentery. It is not stated that these cases were due to the ameba coli, but it is quite possible that Goodlee's was due thereto, as the disease was contracted in India and was complicated by an abscess of the liver which was operated on, the patient recovering after the operation.

Right-sided colostomy has been performed for other chronic diseases of the colon with the result of curing what had otherwise proved to be intractable conditions. Keith⁴ opened the right colon in a case of chronic membranous colitis with complete success, as the symp-

ptoms were at once relieved. The artificial opening was closed eight months later and the cure continues up to the time of reporting the case.

W. Hale White and C. H. Golding-Bird⁵ report a case of right-sided colostomy for membranous colitis in a woman 30 years of age who had been afflicted for ten years. The colon was flushed simply with warm water. No antiseptics were employed, as it was feared they might irritate the bowel, and besides improvement was so rapid they were not deemed necessary. Two months later the artificial opening was closed. The patient did well for about two months, when she died rather suddenly from acute peritonitis, supposed to have been due to the rupture of an ovarian or tubal abscess.

Macpherson Lawrie⁶ reports a case of membranous colitis of ten years' standing in which he performed right inguinal colostomy with prompt recovery. The artificial anus was closed seven months later and the cure continued. Franke⁷ also reports a case of colica mucosa cured by right-sided colostomy. J. Schwab⁸ mentions Sklifasowski's case of multiple polypi of the colon in a man 51 years of age, who had suffered for seven years with diarrhea and colic and had become greatly emaciated and reduced in strength. Rapid improvement followed colostomy and in two months he was able to resume his business.

In all of these cases, with the exception of Goodlee's, the bowel was opened on the right side. In his case the sigmoid was chosen but found to be too low, as the disease extended higher up. Although right-sided colostomy will permit more thorough flushing of the colon and a direct application of the medicaments to its surface, the chief factor in bringing about recovery in these cases is undoubtedly the physiologic rest given the diseased bowel, as, in all cases, marked and rapid improvement was noted to follow at once the diversion of the intestinal contents.

The favorable results which followed this method of treatment in the above-mentioned cases indicate that temporary right-sided colostomy might oftener be employed to advantage in many of the chronic and intractable diseases of the large bowel.

SO-CALLED CHRONIC PROGRESSIVE CHOREA.

The time seems ripe for a thorough study and a careful differentiation of the numerous varieties of irregular, involuntary, incoördinate movement, to several of which the designation chorea has been applied. It would appear best, for purposes of demarcation, to restrict the use of this term to the disorder described by Sydenham, and commonly known as chorea minor, in order to distinguish it from other disorders simulating it. This affection may be considered an acute, infectious, self-limited disease, while at least some of those improperly grouped with it are dependent on

organic lesions. One of the best defined of the latter is the disorder that has been designated Huntington's, or hereditary, or chronic progressive, chorea, among the peculiarities of which are its hereditary character, its development late in life, its progressiveness of course, its complication by dementia, and the presence of degenerative changes in the brain. It is probable, however, that some of the cases that have been described as being of this nature represent other and wholly different organic disorders of the brain.

A certain similarity, both clinically and pathologically, between chronic progressive chorea and parietic dementia has been suggested. The former disorder is considered essentially hereditary, not appearing in the descendants of those free from it. It usually sets in insidiously, after the age of 35, and it is equally common in the two sexes. The movements may appear at first in the face and be attended with difficulty in articulation, and spread to the arms and legs; or they may be general from the beginning. The dementia may be contemporaneous with the twitching, or precede or follow it, although occasionally no symptoms of mental aberration appear. The disease is chronic in course, lasting from ten to twenty years, and death commonly results from exhaustion. Various lesions have been found post-mortem, namely, meningitis, hematoma, neoplasm, hyperplastic change in the vessels, in the cellular elements, and in the connective tissue of the nervous system, atrophy of cerebral convolutions, degeneration of cortical neurons and reduction in their number and connections, dilated lymph-spaces, cysts, general muscular degeneration, etc., all of which were noted in a case recently reported by Good, in which the post-mortem anatomic findings are elaborately described. The disease is clearly one with profound degenerative changes and its relations and analogies are far from being as yet satisfactorily elucidated.

An interesting contribution to the subject of chronic progressive chorea has recently been made by Kattwinkel,¹ who details the results of a histologic study of the brain of a case occurring in a man 61 years old. Macroscopically the cerebral cortex presented slight atrophy, the gyri being reduced in size and the sulci enlarged, as compared with those of a normal brain. On microscopic examination the atrophy was found to be dependent on degeneration and disappearance of the supratentorial layer of fibers and the radiating fibers, especially in the motor area. In addition, an infiltration of leucocytes was found in the region of the large pyramidal cells and in the layer of polymorphous cells. These cells lay in dilated pericellular lymph-spaces and they are surrounded in varying number, often up to eight, a single ganglion-cell, which they compressed. Further, the adventitia of the blood-vessels was thickened by strands of connective tissue surrounding the lumen of the vessels, especially in a concentric manner. The changes described do not coincide entirely with

those that have been recorded by other observers, but they are indicative of the organic basis of the disease, the lesions being situated especially in the cortex and the subcortical tissues. These alterations have been attributed to abnormal distribution of the neuroglia and also to disseminated miliary cortical and subcortical encephalitis, originating from disease of the blood-vessels. In the case reported the conditions are ascribed to infiltration of the pericellular lymph-spaces by leucocytes, giving rise to compression of the ganglion-cells, followed secondarily by atrophy of the cortex. The origin of the disorder is referred to the vascular disease demonstrable in all parts of the brain. It can be readily conceived that such infiltration by leucocytes might give rise to irritation of the motor cells and fibers. Further, the secondary atrophy of the cerebral cortex, especially of the frontal lobe, would readily explain the mental disturbances.

THE SCIENTIFIC BASIS OF ORGANOTHERAPY.

It is possible that even in the remote past there have been glimmerings of an empirical application of the principles of organotherapy, but although these principles are still far from established on a permanent basis, it is only since Brown-Séguard began the use of testicular extract and suggested its mode of action that we have come to employ glandular preparations with any degree of precision in the treatment of various morbid states. Then followed the brilliant observations with regard to the relation between disease or surgical removal of the thyroid gland, on the one hand, and cretinism, myxedema, and the cachexia strumipriva on the other hand, and their successful control by means of transplantation or administration of preparations of the gland obtained from the lower animals. The results from the use of adrenal preparations in the treatment of Addison's disease have been scarcely as striking, although those preparations have shown themselves possessed of profound physiologic activity. While destruction of the pancreas is sometimes attended with diabetes, the disorder does not yield to the administration of pancreatic preparations; and acromegaly, so often associated with disease of the hypophysis, does not respond to the administration of preparations of this organ, perhaps because the condition is already one of hypertrophy and over-action, in the same way as, and for the same reason that, exophthalmic goiter is aggravated by the administration of thyroid extract. Further, there is, as yet, no evidence justifying the employment of extracts of kidneys, liver, heart, spleen, brain, and spinal cord, in the treatment of disorders of these various organs.

What the future of organotherapy shall be it is impossible to predict, but if the therapeutic principle on which this method of treatment is based had to its credit nothing more than the successful management of cretinism and myxedema, there would be ample justification for its continued application. Some of the

¹ Deutsches Archiv f. Klin. Med., B. lxxviii, H. 1 u. 2, p. 23.

cytologic problems connected with this subject have recently been discussed in a most forceful and philo-sophic manner by David Hanseemann,¹ in an address delivered before the Association of German Naturalists and Physicians. As he points out, the therapeutic employment of glandular structures is based on the assumption that specific substances supplying some need of the body are produced in different organs. It may be accepted that every organ is necessary in the healthy body, though perhaps in varying degree. Each takes something from the circulation—and some are provided with excretory ducts—and each adds something to the circulation. This latter we have grown accustomed to designate an internal secretion, in contradistinction from the former, which may take the form of an external secretion.

Although the cellular elements of the blood are supplied essentially by the spleen, the lymph-glands and the bone-marrow, the plasma is the composite product of the metabolic energy of all the cells of the body. Consequently, any alteration in the functional activity of any organ must result in changes in the constitution of the blood, and this in turn will influence the activities of the remaining organs. The intensity and the rapidity of the resulting effects will vary with the size and importance of the organ in question. No tissue, therefore, can suffer without injury to all others and to the entire body. Each possesses a specific and important function with relation to all of the others. This peculiarity is due to a like quality of the cells by which, in turn, it is derived from the parent-cells. Organotherapy consists in supplying artificially substances by means of which the activity of diseased or absent organs can be replaced, particularly with reference to internal secretion. There is, however, no sufficient reason for believing that a gland from one animal will have the same chemical constitution or the same physiologic action as the like gland from all other animals, and it is in this connection especially that important studies need yet to be made.

EPIBRONCHIAL PRESSURE POUCHES OF THE ESOPHAGUS.

Since the classical work of Zenker and Ziemssen, dividing the esophageal diverticula according to their origin into traction and pressure diverticula, this subject has received contributions of only minor significance; these have taken the form of contentions as to the structure of the pouches or concerning the influence of pressure on the enlargement of pouches already formed by traction, or have been reports of single cases of peculiar nature or origin. These investigators located pouches, originating solely by pressure from within, at the beginning of the esophagus, or at its junction with the pharynx; it often happens that a part of the pharyngeal wall forms part of the pouch. In this region such pressure pouches form in the median line of the posterior wall or slightly to one side, and

often attain considerable size. Such diverticula, formed either by pressure from within, have rarely been observed in other parts of the canal: Brosch¹ was able to find mention of only two, and one of these—that reported by Chavasse—began four inches below the arytenoid cartilage and was large enough to contain 680 c.c.

In the examination of 300 bodies, Brosch found two diverticula that have a special interest, since they are both considered to be pressure diverticula and are intrathoracic. In both instances the diverticula projected into a region named by Brosch the *cavum broncho-aorticum*. This region, only present on the left side, is formed between the left bronchus and arch of the aorta. As the latter arching to the left and backward crosses the esophagus to lie on its left side, there is a narrow space left between it and the bronchus below, which crosses the esophagus to reach the lung. This interval is obliquely directed to the left and downward; it is bounded above and externally by the aortic arch, below and internally by the left bronchus, in front is the ductus arteriosus, and behind the left lateral wall of the esophagus for a short distance faces forward in the interval. It is obvious that a large bolus of food passing downward comes, at this level, to a place where there is less resistance in the anterolateral wall of the esophagus; the vertebrae behind are firm, likewise the aortic arch above and the bronchus below; hence the esophagus may bulge into this *cavum broncho-aorticum*.

Of the two diverticula found in this region the larger one was the size of a walnut; the wall of the pouch consisted of the mucous coat; from its appearance it could be reasonably assumed that a hernia of the mucous coat had taken place through the outer muscular coats. There were no adhesions to the surrounding structures nor were there any cicatricial lymph-glands or indurative processes of the adjacent tissues that might have initiated the process by traction.

SURE CURE FOR CONSUMPTION.

Medical matters are always of interest to the laity and never more than at the present time when the public generally may be said to be on the *qui vive* as regards everything relating to sanitation and disease. This fact has its advantages, and there is little doubt that human life has been materially prolonged by popular education in the essentials of healthy living. Once in a while, however, popular medical instruction has its disadvantages, and may even materially abbreviate human life if followed. For example, the newspapers have recently been printing an account of a new consumption cure announced by a Vienna professor; the prescription contains .1 gram—1½ grain—of arsenous acid, with three times as much cinna-mic acid, to be taken in about a teaspoonful of cognac and water after meals. Not having seen the original European authority we can not say what the actually recommended dose was, but the one printed would very likely put an end

¹ Berlin Klin. Woch., 1900, Nos. 11 and 12.

¹ Virchow's Archiv, 1880, clxii, p. 22.

to consumption and every other ailment of the patient, including "life's fitful fever," also. This is only one instance of inaccurate newspaper medicine, which however is not always so dangerous as in this particular case. Mistakes will happen even in medical journals, but their readers can recognize them as such; while they are almost the rule in newspaper medical literature and the average layman will accept them as gospel truth. The moral of the whole thing is for newspapers, if they wish to publish medical facts and do it accurately, to have a competent medical editor who will see that what goes out is approximately near the truth. There will probably be no serious result from the publication of this prescription, because the ordinary druggist would refuse to fill it.

POSTPONED PAN-AMERICAN MEDICAL CONGRESS.

A telegram received as we go to press announces the postponement of the International Medical Congress, which was to have been held at Havana, Cuba, December 26-28. The postponement is on account of the prevalence of yellow fever in and around Havana. While the disease is not understood to be spreading, or to be more prevalent than it was, at the same time the committee considered it advisable to make the postponement. The meeting will be held February 5. It is to be hoped that the postponement will make it possible for the profession of the United States to make a better showing than otherwise would have been possible.

THE FUNCTION OF THE PROSTATE.

Physiologists have differed much as to the function of the prostate. The question is reviewed carefully in Walker's recent study of the anatomy and physiology of the prostate gland.¹ It has been known for some time that the movement of the spermatozoa is markedly stimulated by the secretion of the accessory sexual glands. All anatomists state that in the testis the spermatozoa are immotile; in ejaculated semen they are all in lively motion. Artificial addition of prostatic fluid to semen taken directly from the testis induced lively motility of the organisms, continuing for twenty-one hours—Steinbach. In order to throw more light on this subject, Walker instituted a series of experiments on dogs, from the results of which it may be concluded that the immediate production of motility of spermatozoa is due to the thinning of the testicular secretion with the prostatic fluid; substances in this fluid, acting either as stimulants or as food, keep up a continued movement; unless a homogenous mixture is made of the two fluids, thick portions remain in which there is no movement. The testicular and prostatic fluids must be mixed, otherwise the organisms remain motionless; and the mixture must be homogenous; as the semen is a thick tenacious fluid, more or less mechanical means are required in order to produce a proper incorporation. Walker proceeds to show the existence of a most beautiful anatomic arrangement for this purpose: the ejaculatory ducts empty on the crest of the caput gallinaeum; the prostatic ducts converge toward the openings of the ejaculatory ducts. As the semen is poured out thirty to forty streams of prostatic fluid are sent into it. In this way

a homogenous mixture of the testicular secretion and the prostatic fluid is produced and the best conditions for establishing motility of the spermatozoa secured.

THE PHYSICIAN-DRUGGIST.

The Cincinnati daily press report an instance of a physician applying for membership in the Academy of Medicine who was finally advised to withdraw his name for fear of unpleasant discussion and of possible refusal. The sole reason given was that the applicant owned and conducted a drug store. There is a feeling that it is not proper for a physician to conduct a drug store, as it affords too great opportunity for interference with the prescriptions and practice of other physicians. This feeling appears to be particularly strong in Cincinnati. The newspapers were, however, in error when they stated that the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION contains a clause preventing physicians who conduct drug stores from becoming members of local societies in affiliation with the ASSOCIATION. The point is nowhere raised in the Code of Ethics. While a physician who is also a pharmacist rarely has a large practice, yet his competitors naturally feel that it is unfair of him to expect to fill their prescriptions at the same time that he is practicing medicine in his store. Few, therefore, send prescriptions to such a store. Of course, each society has a right to decide on the qualifications of its members, but in general there seems to be no adequate reason for refusing membership to a physician-pharmacist as such.

VOODOOISM, NORTH AND SOUTH.

In Mississippi it is said a society has recently been organized, the object of which is the suppression of voodooism and voodoo doctors. Voodooism is a sort of African "Christian Science," modified by the special theologic predilections of the race. With the savage African who originated the voodoo cult followed by some of his descendants in this country, the supernatural powers are not beneficent, and, together with those that have most influence with them, are to be placated if possible, hence the voodoo superstition. It is the belief of the negro that disease can be caused by the prayer and incantations of the voodoo doctors, who, like the C. S. D.'s, thrive on the faith of their fellows. There is no excessive difference between the two; it is only in the point of view; the practice is not specially different. The Mississippi voodoo is not, so far as known, charged with the atrocity in his ritual of infant sacrifice after the manner of his coworkers in Hayti, or as it is done through neglect by his more northern co-operators, and in that respect may be considered more respectable than either, but they come together in many points. It is said that the original African cult is spreading in the south and involves not only the blacks by many of the whites, who live in daily fear of voodoo incantations. The recent suicide of a white man, induced by this dread, has called renewed attention to the society and its objects. The civil authorities, who have been indifferent heretofore, are to be invoked, and it will be interesting to note the progress of the reform. If the movement could only extend northward and in-

1. Bull. Johns Hopkins Hospital, 1900, xi, 242-256.

cite the vigorous action of the law against passive child-murder by northern voodooists, of whatever designation, it would be a good thing.

THE PROPOSED "TRUSTEE SYSTEM" IN THE NEW YORK CITY HOSPITALS.

The physicians of New York, especially those interested in Bellevue Hospital, are discussing the proposed change of administration of that institution under the new city charter revision bill. It is proposed to change the system of management of that group of the city hospitals that lie on Manhattan Island, by removing them from the supervision of the Department of Charities and Corrections and vesting their care in a board of trustees. The seven trustees of the city hospitals will be appointed by the mayor, who, according to the charter, must consult the presidents of various philanthropic boards and institutions in the city, in preparing the list of candidates, although he may appoint some not mentioned by his advisers. This change in method of management is avowedly to remove the hospitals from the evils of practical politics, and to place them under a distinctive form of government. To this end the terms of the new charter require that the trustees shall receive no salary for their services, nor shall they hold any political office with emolument, nor be interested directly or indirectly in any contract affecting the hospital. This is in nowise a reflection on the present administration of the Department of Charities and Corrections, for the present commissioner has achieved more for the good and the reputation of the hospitals, especially for Bellevue, than was ever before done, but his efforts, and the efforts of the medical staff have been in spite of the management, and not as the result of it. One of the chief evils of the present system is the change of control and management of the city hospitals with each change in the city's administration. This, has made the possibility of scientific advance depend on the character of the commissioner. It has placed the medical staff in the unsatisfactory position of doing the best they could under the circumstances, instead of giving them the advantage of achieving the best that could be attained. The truth of this position is enforced by the example of Boston and Cincinnati, in each of which cities the city hospital was incorporated by act of legislature between thirty-five and forty years ago, to be maintained as an institution by itself, independent of all other institutions, charitable or otherwise. The contrast between the peaceable, disinterested, efficient management of these hospitals, which are in every respect as desirable places for the sick as private hospitals, and the civic management of the public hospitals of Philadelphia, New York, San Francisco, St. Louis and Chicago, with their shifting administrations and party politics, shows decidedly the benefit of the trustee system.

Acute Hydrocephalus Cured by Antisyphilitic Treatment.—Neumann recently exhibited at Berlin a babe seventeen months old, apparently normal in growth and intelligence. A year before, the child had been affected with acute hydrocephalus, the skull measuring 47 cm. in circumference, the forehead and anterior fontanelle of exaggerated size. Inherited syphilis was suspected and 25 cgm. of potassium iodid were ordered daily with mercurial inunctions, resulting in a cure.

Medical News.

ALABAMA.

DR. THOMAS W. AYRES, Anniston, has accepted a hospital appointment from the foreign mission board of the Southern Baptist Convention, and has been assigned to Hwang Hien, North China.

BILLS have been introduced into the State Senate and House of Representatives asking an appropriation of \$25,000 to relieve the insane hospital at Tuscaloosa from its present overcrowded condition. At present 1500 patients are crowded into a space intended for 1000, and halls and reception-rooms have to be used for patients.

ST. VINCENT'S HOSPITAL, Birmingham, which has just been completed at a cost of \$200,000, opened for the reception of patients on Thanksgiving Day. The hospital has a capacity of 200.

A BILL forbidding the reckless and indiscriminate sale of deadly drugs, and especially directed against cocaine, will be introduced in the legislature at the instance of the physicians of Birmingham.

CONNECTICUT.

DR. WILLIAM W. HORTON, New Haven, who was sued by a patient claiming that he had administered to her powerful drugs, as a result of which her hair and teeth fell out and her complexion was ruined, has won the suit, the costs to be recovered from the plaintiff.

A JOINT COMMITTEE of health officers and of the State Funeral Directors' Association met at New Haven, November 17, and formulated a bill to be submitted to the general assembly providing that physicians return death certificates within thirty-six hours after death, and that the physician shall certify on the death certificate to the cause of death and duration of the disease only. At present the doctor must swear to the age of the person and to the family history.

DELAWARE.

THROUGH the bequest of Elzy Wade, of Wilmington, who died a few days ago, \$1000 will be given to the Delaware Hospital for the Insane. For a number of years Wade had been employed at that institution as night watchman.

DR. JOHN PALMER, JR., Wilmington, was re-elected supreme medical examiner of the Knights of the Golden Eagle at its annual meeting at Youngstown, Ohio.

DR. PETER W. TOMLINSON, Wilmington, has been elected president of the state medical examining board, to succeed Dr. Irving S. Vallandigham, Middletown, resigned.

DR. ALEXANDER LOWBER, secretary of the State Board of Health, has been notified that the second prize of a silver medal has been awarded the board of health for its exhibit of photographs of specimens at the Paris Exposition.

GEORGIA.

THE OSTEOPATHY bill was killed in the Georgia Senate by a vote of 19 to 18, November 18.

MACON CITY HOSPITAL is about to build an annex for colored patients, to cost \$5000.

THE REPORT of the Georgia State Sanatorium shows that the increase of the insane in the state was four-fold greater than the increase in population. There are now 2495 patients in the sanatorium. During the year 49.75 per cent. of the patients suffering from acute insanity were discharged apparently cured.

ILLINOIS.

STERLING is to have a new hospital to cost \$10,000. Plans are now being prepared under the direction of P. T. Van Horne and Dr. John F. Koefer. Contributions to the amount of \$3900 toward the building fund have been received.

A STATE SANATORIUM FOR CONSUMPTIVES, state provision for the cure of epileptics, enlargement of the powers of the health authorities in enforcing penalties against those who refuse to take proper precautions to prevent the spread of contagious diseases, and provision for boards of health in counties not under township organization, are the chief recommendations in the forthcoming annual report of the State Board of Health.

Chicago.

THE CORONER-ELECT has named Dr. P. Johannes as coroner's physician.

DR. THOMAS A. WOODRUFF has been appointed professor of ophthalmology at the Post-Graduate Medical School.

DR. CHRISTIAN FENGER has given up his office-hours at his residence and has taken an office in the Reliance building.

DR. WILLIAM A. FISHER transferred to the Chicago Eye, Ear, Nose and Throat College on November 30 the property which

he recently bought at Washington and Franklin streets, which, after remodeling, will be the new abode of this post-graduate institution.

THE HEALTH COMMISSIONER estimates that he will need an appropriation of \$281,374 for 1901, an increase of \$47,724 over that required for 1900. This will provide for three additional meat inspectors, a statistician, a director of disinfection, an assistant reorderer of births, a chief of antitoxin staff and a record clerk, and for the enlargement of the public baths.

JOHN H. RANDALL, arrested in connection with the Metropolitan Medical College case, has entered a plea of "nolle contendere," which probably means that he will testify against his fellow defendants when the case is brought to trial.

DR. M. N. REGENT has been sentenced to penitentiary under the indeterminate sentence law; in addition he has been fined \$1000. He was convicted of swindling the Knights and Ladies of Security out of \$2000 by passing off a cadaver as a deceased beneficiary.

DR. HENRY B. STEHMAN, to whose persistent work and skilled and tactful management the Presbyterian Hospital owes most of its success, has been compelled by continued ill-health to resign as superintendent of the institution, to take effect before Jan. 1, 1901.

THE TERMS under which the College of Physicians and Surgeons becomes the property of the University of Illinois have recently been made public. The university is to set aside a certain amount of the profits of the college and therewith form a fund which in twenty to thirty years will be sufficient to complete the purchase without the assumption of any financial liability.

DR. FLIPP KREISSL, who was sued for malpractice a few days ago with damages of \$25,000, has filed a counter-suit, alleging that his feelings and professional reputation have been injured by the public statements that his treatment had failed to cure the patient, and claiming \$50,000 damages.

INDIANA.

THE STATE FACTORY INSPECTOR, in his report, states that the fire protection at, and means of escape from, the Central Hospital for the Insane, Indianapolis, are very inadequate, and makes recommendations that fire walls be built and the bars on windows and doors be so arranged that they can be unlocked simultaneously.

DR. CORYDON RICHMOND, Kokomo, celebrated his 92d birthday, November 22. He was the first to practice medicine in the Miami Reserve, and settled in Kokomo in 1844. Although blind for ten years, he retains his interest in matters medical and in the State Medical Society, of which he has been a member for seventy years.

THE STATE BOARD OF HEALTH reports that there are more than 6000 physicians in Indiana, and in Marion county 602 are licensed. Of these 463 are regular practitioners, 53 are eclectics, 34 homeopaths, 38 physio-medicals, 1 hygeia-therapeutic and 13 unclassified.

KANSAS.

DR. W. B. SWAN, secretary of the State Board of Health, is preparing a bill against quacks and persons holding diplomas from fake medical colleges. It will be submitted to the legislative committees of the different medical societies in the state, and will bear the stamp of approval of the reputable physicians in the state before it is presented to the legislature. It will provide for the examination of physicians and their registration. All physicians now in the state will be required to register, and all except those holding diplomas from reputable colleges will be required to take an examination. Provision probably will be made to exempt physicians who have practiced twenty years or more in the State but hold no diplomas. Legislation along these lines has been desired by reputable members of the medical profession for years, and several attempts have been made to secure the passage of acts governing the matter. The bill will have the support of all schools, and every effort will be made to secure its passage.

KENTUCKY.

DR. EDWARD M. WILEY, Lexington, formerly superintendent of the Eastern Kentucky Asylum for the Insane, has been appointed a member of the board of pension examiners, made vacant by the resignation of Dr. Waller O. Bullock.

DRS. JAMES E. NEELY, James C. Catrick, and Thomas H. Kinnaird, Lexington, are defendants in a suit for \$10,000 brought by S. C. Hickerson, who claims that a broken leg was not properly set by the defendants.

MICHIGAN.

THE Upper Peninsula of Michigan seems to be saturated with smallpox. Secretary Baker, of the State Board of Health,

found nearly fifty cases in a dozen or more places in that region, the largest number of which were at Marquette.

DR. HEMAN SPALDING, who was called to Marquette to pass on a case of suspected smallpox, November 21, pronounced the case probably one of modified variola, and commended the city health department for its promptness in taking precautionary measures and quarantining the case.

DURING THE YEAR ended June 30, 1900 patients were admitted to the University Hospital at Ann Arbor, nearly 91 per cent. of whom were residents of Michigan. In the eye and ear clinic 889 cases were treated and in the pathological laboratory 621 specimens were examined and 340 cases passed on by the staff.

MINNESOTA.

DR. LEONARD F. CLAYDON, Mazeppa, returned from a six-months course of study in Europe on November 22.

THE MINNESOTA LEGISLATURE will be asked to make provision for a state sanatorium for consumptives.

ON NOVEMBER 30, the secretary of the State Board of Health reported that there were more than 300 cases of smallpox in Winona. If the disease increases quarantine will be established at St. Paul against Winona.

THE NEW PORTION of the City Hospital, Minneapolis, was opened to receive patients a few days ago. About forty patients were transferred to the wards on the ground floor of the new building.

THE HEALTH DEPARTMENT of Minneapolis announces that 208 cases of diphtheria were reported during the first twenty days of November, with 17 deaths.

THE HOSPITAL at Walker, used by the soldiers at the time of the Leech Lake Indian outbreak, has been reopened by the Walker Sanitarium and Hospital Association for the care of the lumbermen of Northern Minnesota.

MISSOURI.

DR. EDWARD C. L. RICHTER, St. Louis, physician at the House of Refuge, who contracted smallpox while in attendance on a case of the disease, is rapidly recovering and the quarantine will be raised in a short time.

THE CITY HOSPITAL, St. Louis, is said to be so cramped for funds that no money is available even for the purchase of gauze for bandages and dressing materials, and the requisitions for these necessary articles have not been filled by the city comptroller for this reason.

DR. CHESTER A. TYGART, city physician of St. Joseph, states that he has discovered in the last few weeks three unreported cases of scarlet fever. He intends to take action against the physicians who fail to make reports of contagious diseases.

NEBRASKA.

THE CITY COUNCIL OF OMAHA has appropriated \$1000 to be used by the health commission in the prevention and care of smallpox and other contagious diseases.

"CUBAN ITCH" is prevalent in Grand Island, Scott's Bluff, Minatare, Bayard, and other neighboring towns, and the State Board of Health has been asked to investigate the disease, which is thought to be modified smallpox.

FOUR TOWNS in western Nebraska, on the line of the Northwestern road, are reported to be under quarantine on account of smallpox. One of these—Valentine—has been so for some time, but only within the last few days has the quarantine been extended to the mails. Near Scott's Bluffs work on a large irrigation ditch has been suspended on account of the outbreak of variola in a surveying camp, which now has several cases. Here, as in other places, the diagnosis of smallpox is questioned by some physicians, and efforts were made to have the affection designated "Cuban itch" and to raise the quarantine. Readers of THE JOURNAL will remember that only about a year ago a similar outbreak of variola was reported in Topeka, Kas., which was diagnosed "Cuban itch." Through laxity of the authorities, and against the advice of many of the city's physicians, official quarantine was instituted only after the disease had spread extensively.

NEW YORK.

THE HEALTH OFFICER of Rome reports 8 deaths and 25 births during October. Of measles, 25 cases; of typhoid fever, 3 cases, and of diphtheria one case were reported.

THE SYRACUSE ACADEMY OF MEDICINE plans to have a staff of twelve physicians appointed for the hospital at the county house. Six of the staff are to be members of the Academy of Medicine, three from other towns in the county and three are to be homeopaths.

Buffalo.

DRS. ROSWELL PARK and Charles Cary are guests of Mr.

Frank Goodyear on a trip through the South and Mexico in his private car.

NEW FREE public bath-house No. 2 was recently opened. It is situated on the east side of the city in a region densely populated by foreigners.

THE EMERGENCY HOSPITAL now in course of construction is to be 142 ft. by 60 ft. and three stories high. There will be three operating rooms for minor surgery or preliminary examinations. On the third floor is the operating amphitheater. Another feature of the building is a roof-garden, reached by an elevator to be used as a solarium by the patients. The cost of the structure is to be \$60,000.

THE DEPARTMENT OF HEALTH has recently made a series of tests as to the percentage of good air in the rooms of the public schools, some of which have been recently constructed and are supposed to have good ventilating systems. The result shows the air inspired by the pupils to be deficient in purity and the health commissioner has called attention to the fact that in the future the plans for ventilation-construction in all public buildings should be submitted to his department for examination and approval. Because of the defects in ventilation in the newly-constructed school No. 16, the city refuses to pay, and a lawsuit is imminent, the contractors, in defense, claiming that their agreement does not specify whether the air be good or bad.

New York City.

THE WILL of R. G. Dun bequeaths \$5000 each to the Presbyterian Hospital, St. Luke's Hospital, Mount Sinai Hospital and New York Institution for the Instruction of the Deaf and Dumb.

WHILE Dr. Otto Schultze, pathologist at Cornell University Medical College, was holding an autopsy before the class, on a woman who was supposed to have died of typhoid fever, he suddenly discovered that she had been the victim of a criminal abortion. The class was dismissed and the coroner summoned. Investigation showed that the woman had at first been a ward helper in Bellevue Hospital, and had subsequently been admitted as a patient with a diagnosis of malaria. From October 27 till November 22 she was treated in the hospital for typhoid fever, and the house physician said that up to the time of her death he did not know that any operation had been performed on her.

A GENTLEMENLY appearing person, describing himself as Dr. William A. Ferguson, and as a graduate of Dublin University, has been arrested on the charge of defrauding physicians. His arrest was brought about by Drs. William M. Polk and George W. Jarman, upon whom he had called, soliciting financial aid, alleging that he was in distress because of the Galveston flood. The police say he bears a striking resemblance to Franklin J. Moses, at one time governor of South Carolina, but since known in many states as a fraud and confidence man. Dr. A. R. Shands, of Washington, D. C., is positive that this man is the one wanted in his city on a similar charge, and he is held pending extradition proceedings.

SO MUCH INDIGNATION has been aroused over the long delay in taking possession of the new building for Gouverneur Hospital that the grand jury has taken up the matter. The foreman, Mr. John P. Faure, recently commissioner of charities, took an active interest in the investigation, and asked some pointed questions of the commissioners appearing before them. The delay is apparently the result of obstinacy on the part of one of the commissioners, coupled with a lack of supervision of the work done by the contractors. When it is recalled that the building has cost \$200,000, and that \$89,000 have been appropriated for the fittings and supplies, there should not be much difficulty in getting the building ready for occupancy.

SAMPLES OF CITY WATER have been taken from various places and submitted to the chemists of the board of health for analysis. A preliminary report on these has been made public, which sets forth that there is no evidence of contamination of the water with pathogenic germs. It takes twenty-four hours for the water to travel from Croton Lake to the aqueduct station in West 135th street, and during this time nearly one-fourth of the suspended organic matter subsides. The bad color and taste of the water at present are owing to the abnormally low level of the water in the storage reservoirs. The grand jury summoned experts before it, who were all heartily in favor of the installation of a system for filtering all the city water.

A DEATH from Christian Science treatment has occurred in an exclusive and fashionable section of Brooklyn. The healers are Mrs. Parmelia J. Leonard, and her son, F. H. Leonard, who

live in a beautiful home at 160 Montague street. Mr. A. C. Hubbell, at the request of his wife, who was suffering from appendicitis, called in Mr. F. H. Leonard, and after waiting in dreadful suspense for five hours for word or sound from the sick-room, he entered, to find his wife tossing about the bed in agony while the "healer" lay in an easy chair half asleep. For this valuable service he rendered a bill for \$3, and this bill will be used as evidence against Leonard, who now denies that he attended Mrs. Hubbell. Mr. Hubbell has instructed his lawyers to proceed against the Leonards, criminally, if possible, as he intends to hold them responsible for his wife's death.

THE ANNUAL REPORT of the Children's Aid Society shows that 38,232 children have been aided in the past year. The daily average attendance at the industrial schools has been 7063, and it is interesting to note that the society has hit upon the practical plan of bringing crippled children in an omnibus to and from three of these schools. Homeless children to the number of 5163 have sought and found shelter during the year, and 1594 persons have been sent away from the city. The Emigration Department has placed 22,121 children in families, and points with pride to the fact that, so far as known, only 60 have been arrested or sent to reform schools. Nearly 14,000 sick infants and their mothers were given outings at the seashore during the past summer. Schools have been established for incorrigible truant, and by the employment of expert teachers who are able to interest these children in manual training, many of these boys, have been broken of the habit of vagrancy, and have been able to secure regular employment. The total expenditures for the year were \$382,536.78.

IN THE LAST few days the board of health has had on its hands an outbreak of smallpox, which is said to be larger than any since 1892. Up to the present, 37 cases have been reported, and as a colored man wandered through the city during the whole time he was suffering with smallpox, without consulting a physician or without the nature of his malady having been detected, it is expected that a number of other cases will necessarily develop in distant parts of the city. Nearly all of the cases have developed among colored people in a densely populated district in West 68th and 69th streets. The first cases were apparently in the kindergarten of the Rivers Association, a school having a swimming-bath attached. This school and a public school in the same neighborhood are most in danger of becoming infected. The health department is carrying out its usual practice, i. e., children from the infected houses are not allowed to go to school, and these houses are visited daily by one of the department physicians for several weeks, while the vaccinators are busily at work vaccinating all within a distance of nine blocks in all directions. On December 4 the isolation hospital on North Brother Island had 40 cases of smallpox; one new case had been reported from the "All Nations Block" on West 69th street, and two deaths occurred.

NEW JERSEY.

A RESOLUTION has been adopted in Camden that policemen of that city who find a case of contagious disease in which no physician is in attendance shall notify the board of health.

THE PERTH-AMBOY HOSPITAL plans have been accepted, and work will be commenced very soon. The building will cost \$15,000, of which \$7,000 is already available for immediate use.

THE CAMDEN COUNTY INSANE ASYLUM, Blackwood, has been remodeled and enlarged. The total amount earned during the year by the patients was \$1856, thus reducing the expense per week to \$2.27 per capita.

DOCTOR against doctor and regular against homeopath expresses the situation in the majority contest in Plainfield. Both the republican and democratic candidates are physicians, but of different schools.

BURLINGTON proposes to open a memorial hospital commemorative of the late Dr. Franklin Gauntt, who for half a century did such faithful work in that town. The scheme is to buy by popular subscription the Gauntt house and remodel and equip it as a hospital.

THE STATE HOSPITAL FOR THE INSANE, near Trenton, has treated 1435 patients during the last year. There are now 117 patients at the hospital, 84 have been discharged as recovered, 30 as improved, and 8 as unimproved, while 104 have died and 91 have been removed to other institutions. The chief causes for the insanity were general ill-health in 29 cases and alcoholism in 24.

A COMMITTEE has been appointed by the Middlesex County Medical Society to investigate the deficiencies in the state

lunacy laws, with the object of securing such amendments as may be necessary to preclude the possibility of sane people being committed to the state insane hospitals.

OHIO.

THE LATE Dr. David P. Chamberlin, Toledo, left an estate appraised at \$8659.19.

ALL OSTEOPATHS in the state have been notified to present themselves for examination at Columbus, December 10.

OF THE 104 deaths which occurred in Cleveland during the week ended November 24, 4 were due to diphtheria. There were 59 new cases of diphtheria, 22 of smallpox and 25 of scarlet fever reported for the week.

SUPERINTENDENT OF HEALTH, Dr. William D. Deuschle, has asked the law department to take action against Dr. Byron E. Baker, Milford Center, who is charged with taking a scarlet-fever patient out of quarantine in violation of the orders of the superintendent.

SIX PHYSICIANS in Cleveland vaccinated 412 persons at the workhouse in three hours. A case of smallpox developed in the workhouse, and immediate measures—fumigation, etc.—were taken by the health authorities for the protection of the other inmates.

DURING October there were 486 deaths and 550 births in Cincinnati. The death-rate per mille was 9.71 per annum. There were 325 cases of infectious diseases reported, of which 93 were consumption, with 7 deaths, and 49 of diphtheria, with 36 deaths. No cases of smallpox were reported.

PENNSYLVANIA.

AT A MEETING of the Parnassus, New Kensington and Arnold Physicians' Association, New Kensington, November 19, it was decided that each member should be compelled to withdraw his professional card from the local papers.

STATE QUARANTINE OFFICER Dr. Henry D. Heller, Philadelphia, and Dr. J. L. Forwood, Chester, have paid a visit to the Governor at Harrisburg relative to securing a tugboat, and better barracks for the quarantine station.

OWING to the development of a case of scarlet fever at the Pennsylvania Military College at Chester, the institution has been ordered closed for several weeks. The patient has been isolated and there is little fear of the further spread of the disease.

STATE INSPECTOR IRONS made an examination of a herd of very fine cattle on the Redhurst farm near Erie and ascertained that, although the milk of these animals had been sold at a higher price on account of the excellence of the breed of cattle, 95 of the animals were suffering from tuberculosis and he ordered them to be destroyed. The sum of \$1300 was paid by the state for the animals.

Philadelphia.

THE NEW HOSPITAL attached to the Home for Aged and Infirm Colored Persons will be opened in about a month. A feature of the new building will be a diet kitchen.

PRESIDENT H. B. HUEY, of the Board of Education, has submitted a report of the school medical inspectors to the sub-committee of City Council, in which it is stated that during eight months there were 5876 cases of illness, of which 3446 were contagious. He has asked for an annual appropriation of \$25,000 to pay for the service of the school inspectors.

TWO DISINFECTING BARGES, which have been reconstructed from schooners by builders of this city, are now on their way to Cuba. One will be placed at Matanzas and the other at Cienfuegos. They are in tow of the American steamer *Orion*. One is 122 feet long and 30.6 broad, and the other is 129.9 feet long and 31.2 feet broad. A fumigating barge is now being built here which will be placed at Ship Island, Miss.

AT THE last meeting of the committee on medical inspection of the Public Education Association a resolution was adopted recommending that the sum of \$500 be allowed each medical inspector for eight months' work. A similar resolution was recently adopted by the County Medical Society, and it will be considered by the College of Physicians during the next few days.

THE "COURSE IN HYPNOTISM" advertised by the American College of Sciences, which has its offices at 416-420 Walnut street, has been condemned by the members of the faculty of many different colleges, including representatives of the University of Pennsylvania, Philadelphia Polyclinic, Princeton, Yale, University of Michigan, Dartmouth, Harvard, Columbia, and the University of California. The names of representatives of these institutions had been used by this "college" as giving an implied endorsement to the course. Some of the men connected with the universities above cited are said to have consulted lawyers in regard to restraining the "College of Sciences" from using articles previously written by them and published in the

work entitled "Hypnotism and Hypnotic Suggestion." The name of the concern is not in the city directory.

SOUTH DAKOTA.

THE NEW HOSPITAL, which is being erected in Sioux Falls, at a cost of \$10,000, will be ready to receive patients some time this month.

SOUTH DAKOTA is reported to have had a death-rate for last year of only 8.22 per 1000. Consumption caused only 0.63 deaths per 1000.

THE DEATH-RATE among the Sisseton and Wahpeton Indians in South Dakota is alarming. It is reported that 56 out of 1900 Indians died last year, an annual mortality of 29.5 per 1000. Of the deaths 90 per cent. are said to be from tuberculosis.

THE SIOUX FALLS HOSPITAL has transferred its patients into the commodious new hospital building erected for it by R. F. Brown and Dr. Stephen Olney. At the meeting for re-organization of the Board of Directors, Dr. Arne Zeltitz, who has been physician-in-charge since the hospital was opened, in 1894, resigned, and Dr. Stephen Olney was elected to the position.

SMALLPOX IN SOUTH DAKOTA.

On election day, a case of smallpox was found in Lead, S. D., the patient having recently come from Valentine, Neb. The patient and his wife were at once isolated, as were also five other persons who had visited him the preceding night. The city council promptly authorized the city health officer to erect and equip a pest-house outside the city, where the patient and two of those exposed, who have since been attacked by the disease, are being cared for. As compared with Lead's action, which has doubtless resulted in confining her cases to the few mentioned, reference may be made to the lack of precautions in the neighboring city of Deadwood, three miles distant. The latter now has ten cases—five new ones during the past week—with practically no quarantine restrictions, and the city health officer has resigned, on account of failure of the county to authorize him to carry out necessary health measures. Besides Deadwood's lay press daily denies the existence of smallpox in Lead and surrounding towns, calling it an "eruptive fever," "Cuban itch," etc., but remaining silent concerning her own cases, which have exposed so many as to necessitate closing certain of the Deadwood schools, as a precautionary measure. A stone-quarry southwest of Lead, but operated by a Deadwood company, has long been in quarantine, and while the number of cases there has not been given out, two deaths have been reported. It is said that a Deadwood family recently visited near the quarry, remaining over night, and on returning to Deadwood, so stated to a physician, who advised them to say nothing about it, but the matter became public and their children were excluded from the school, and later the school closed. It is not known that they introduced the disease into Deadwood. Terry, another mining town near Lead, furnished a case the past week, the patient also recently from Nebraska. He, too has been isolated and every precaution is being taken to prevent a spread of the disease in Terry.—Later advices states that only 3 cases are at the quarry, and that Deadwood has 19.

TENNESSEE.

DR. JAMES C. BUTLER, Mountain City, who was seriously injured a short time ago in a runaway accident, has recovered and resumed practice.

THE CITY COUNCIL of Nashville has taken up and passed the bill which it rejected a few weeks ago, and which prohibits sale of cocaine except on the prescription of a physician.

NASHVILLE'S MORTALITY for October was 149, 83 white and 66 colored. The births for the month were 148, 108 white and 40 colored, 72 boys and 76 girls. Of contagious diseases 132 cases were reported with 30 deaths.

THE HEALTH OFFICER of Columbia has been ordered to vaccinate all persons not satisfactorily vaccinated within a year, to isolate all cases of smallpox, or varioloid, provide immune nurses for same and maintain strict quarantine.

TEXAS.

DR. GEORGE LARENDON, Houston, has been re-appointed county physician of Harris County.

DR. THOMAS H. STALLCUP, Jefferson, was attacked by unknown persons while in his stable and seriously injured.

GOVERNOR SAYERS will, it is said, favor the establishment of a state board of health and of a state home for indigent consumptives.

VIRGINIA.

DR. THOMAS MILLER, Fineastle, was thrown from his buggy—November 21, and severely cut and bruised.

THE ADDITION to the Central State Hospital in Dinwiddie county is now ready for occupancy. It is 185 feet long, contains 30 cells and several dormitories and has cost about \$22,000.

DR. JOHN F. WINN, professor of obstetrics at the University College of Medicine, Richmond, has appointed Drs. Charles P. White and Cheving, resident physicians at the Virginia Hospital, as his assistants.

THE MEDICAL SOCIETY OF VIRGINIA has recommended to the governor the names of physicians to compose the State Board of Health. Commissions will accordingly be issued to Drs. Paulus A. Irving and Landon B. Edwards, Richmond; Dr. Rawley W. Martin, Lynchburg; Dr. Lewis E. Harvie, Danville; Dr. Vernon G. Culpeper, Portsmouth; Dr. John T. Graham, Wytheville, and Dr. John H. Neff, Harrisonburg. The new board will serve for four years, beginning Jan. 1, 1901.

WISCONSIN.

DR. PETER H. JOBSE has returned from Cape Nome to his practice in Milwaukee.

DR. FRED. W. A. BROWN, Oshkosh, has been elected county physician of Winnebago county.

OSHKOSH SCHOOLS have been closed by the authorities on account of the prevalence of diphtheria and typhoid fever.

AN ADDITION to St. Luke's Hospital, Racine, is to be built, to cost \$7500, and of this amount a citizen of Racine has agreed to furnish \$1500.

SMALLPOX has appeared in La Crosse and many have been exposed. The State Board of Health is taking all precautions to prevent the spread of the disease.

COUNTY PHYSICIANS were elected by the Racine County board as follows: Western district, Dr. George E. Newell, Burlington; eastern district, Dr. Julian R. Sime, Racine, and middle district, Dr. William C. Hanson, North Cape.

UNDER THE NEW LAW health commissioners are compelled to certify every birth and death recorded in their respective offices and for each certification they receive 15 cents. In Milwaukee last year, the fees to Health Commissioner Schulz from this source amounted to \$1834.50.

GENERAL.

POSTPONEMENT OF THE THIRD PAN-AMERICAN MEDICAL CONGRESS.

The Committee of the Third Pan-American Medical Congress met in special session on the 4th inst., at the Marine-Hospital Bureau in Washington, and, after consultation with Surgeon-General Wyman, decided, on account of the present health conditions in Havana, to postpone the congress until February 5, next. Dr. Juan Santos Fernandez, of Havana, president of the congress, advised the postponement by cable. This delay, it is hoped, will increase the attendance and extend the work of the congress. Signed: Drs. A. Van der Veer, C. A. L. Reed, H. L. E. Johnson, Ramon Guitéras.

MAJOR JOHN VAN R. HOFF, U.S.A., chief surgeon of the Department of the Lakes, was relieved from duty in Chicago, November 30, and assigned to Washington.

ASST.-SURGEON L. L. LUMSDEN, at Angel's Island, Cal., reports to the Marine-Hospital Service that bad health conditions exist among the Chinese workers in the Alaska salmon canning industry. Last spring nearly 3000 Chinese, recruited from the poorest element, were shipped to the Alaskan country, and several deaths occurred, the nature of which is unknown, as no physician accompanied them. They are often worked eighteen hours a day, and live in barracks in utter disregard of cleanliness and sanitation.

HAVANA UNDER THE AMERICAN REGIME.

The deaths in Havana for October, 1900, numbered 507, and for the same month of last year, 497. These are the lowest figures for that month during the decade of 1891-1900. In 1896 the October deaths were 1212; in 1897, 2026, and in 1898, 2491. Major Gargas, chief sanitary officer, in his report for November, shows that 444 deaths occurred in the city from all causes, this being the lowest number for the same month during the last ten years. There were under treatment, on December 3, 37 yellow fever patients, 4 of whom are Americans.

MANILA UNDER AMERICAN RULE.

Advices from Manila state that never before has the city been so free from dangerous and epidemic diseases. But one case of plague had been reported in several weeks, and only one case of smallpox appeared in almost four months. It is now without doubt the cleanest and healthiest city in the far East, and more than ever deserves the title of "Pearl of the Orient." The credit for this sanitary condition is due to

the president of the board of health, Surgeon Guy L. Edie, and his corps of assistants, Drs. Lynch, Calvert, Gilchrist and Le Hardy. Visitors to Manila are agreeably surprised at the cleanliness of what was once a filthy and unseparably unhealthy place.

CANADA.

MONTREAL'S HYGIENIC COMMITTEE has published a statement of the expenditure in connection with the last outbreak of smallpox in that city. There were twenty-three cases of smallpox in all and the total cost amounted to \$11,675.59.

THE ONTARIO BOARD OF HEALTH has forwarded the plans for a new contagious-disease hospital to be erected at the Capital. Along with them went up an order from the lieutenant-governor authorizing the city council of Ottawa to build the institution and to expropriate any land necessary for that purpose.

NEGOTIATIONS are still in progress with regard to the amalgamation of Toronto and Trinity Universities as well as the two medical colleges. The premier of the province has recently called two meetings of representatives of the respective faculties to try to come to some definite arrangement, but so far nothing of a tangible nature has resulted.

SMALLPOX has again broken out at Nanaimo, B.C., and so far thirteen cases have been reported. The trains and boats are being inspected and all persons leaving have to be vaccinated. Forty-nine persons are quarantined on Gabriola Island, where there is one case. During the past 18 months, smallpox appeared in the Province of Ontario at twenty-five distinct points, but in each and every case it was met promptly and efficiently and thoroughly stamped out.

TORONTO ORTHOPEDIC HOSPITAL.

The medical report shows that the number of patients remaining from the previous year was 16; number admitted during the year ending Sept. 30, 205; total 221. The number discharged during the year was 198; number of deaths, 1; number remaining, 22. Collective days' stay at the hospital was 5582 and the average day's stay per patient was 25.25. Of the patients themselves, 128 were males and 93 females, and of these 114 were under and 107 over 14 years of age. The number of surgical operations performed during the year was 194. In the out-door department, there were 51 consultations. The hospital register showed that of all of the 221 patients, 51 resided in the city of Toronto, and the remainder came from 93 different towns, cities and villages of the United States and Canada.

THE HEALTH OF MONTREAL.

Scarlet fever, this time of a severe type, has again broken out in the City of Montreal, and to such an alarming extent that the Hygienic Committee is feeling somewhat uneasy. The scarlet fever wing of the Civic Hospital is filled with these patients and no more can be accommodated. There are forty-two inmates already. The cause is ascribed to the lax manner of reporting the cases and also to the want of care in patients going out too soon after an attack. The Hygienic Committee will now give special attention to the reporting of cases of infectious diseases. Trouble also has arisen with the inspection of the schools. The Catholic School Board will not permit the health officer to inspect these schools, nor will permission be granted to vaccinate unvaccinated pupils. On the other hand the Protestant school boards have sent special requests for inspection. Dr. Laberge has decided to make a test case in the courts of the action of the Catholic school boards to see whether or not they can prevent the officers of the health department entering, inspecting and vaccinating such pupils as require this operation. The health officer is determined that the by-law relating to infectious diseases shall be enforced.

PROGRESS IN TORONTO HEALTH INSPECTION.

An evidence of the care exercised in the protection of the health of the citizens of Toronto is seen in the statistics from the plumbing department under the control of the health department. The year of this department ends on October 31. During the past year there have been 7507 applications for plumbing inspection and for the previous year, 7566. The inspections made number 10,641 and 10,343 for the year before. There is an apparent increase in desire on the part of the public to have house-plumbing and house-drainage inspected. These figures appear more interesting when compared with the work done in 1897. In that year 4791 inspections were made, not quite half the number of this year. The department of public health states that the character of the plumbing in the city is greatly improving; and the people are becoming alive to

the importance of protecting themselves from disease generated through inefficient house-drainage and house-plumbing.

FOREIGN.

THE late Dr. Apostoli, of Paris, bequeathed \$4000 to the Academie de Médecine to found a prize for works on electrotherapies.

DURING the last seven years previous to his death, Professor Albert, of Vienna, published five volumes of translations from Bohemian poetry, in a historical series from the earliest to the latest times, with critical commentaries.

PROF. O. LASSAR, of Berlin, has started an international subscription for the purpose of presenting a marble portrait bust to the famous Norwegian leprologist, Prof. Armauer Hansen, of Bergen, on the occasion of his 60th birthday, July 29, next year.

ACCORDING to the *Derm. Ztg.*, the leper asylum in Iceland has proved a great blessing to the community during its two years of existence. The inmates average sixty-one. One of the patient, a boy, has been cured—at least it is so stated.

THE FRENCH authorities have offered to pay the Norwegian missionaries in Madagascar 40 francs for each leper received in the mission leper-asylum, and also to enlarge and improve the asylum.

THE SAXON government has decreed that physicians must officially report cases of tuberculosis in the cachectic stage if the patient changes his residence or becomes dangerous for his environment, either in a private residence, hotel or boarding-house.

SPAIN has now rendered the notification of infectious diseases compulsory for the physician. He has to report all cases that have fallen under his observation to the medical inspector of the district, and the latter informs the local authorities, who then take the necessary steps to prevent the spread of the disease.

SINCE the Moscow prize was awarded to Ramon y Cajal by the International Medical Congress Spain has been heaping honors on her distinguished son, appropriating funds to enlarge his laboratory and conferring a pension on him. The latest is the decoration with the grand cross of the Order of Isabel la Católica.

AMONG the deaths abroad we note that of Dr. S. Kristeller, whose name is familiar from his method of external expression of the fetus. The death of Dr. W. Basler occurred in Bavaria. His articles on "Cereals Among the Ancients," "Massage in Antiquity," etc., published in *Janus*, have attracted much attention. Although only 62 years of age, he had resigned his practice to his son in order to devote himself exclusively to historical medical research.

THE PARIS authorities have had placards posted warning the people that smallpox is assuming an epidemic form and urging vaccination and revaccination. Since the exposition has been at its height there have been 100 deaths from smallpox, while during the five previous months there were only 15, and only 4 during the entire year of 1899. There were 14 deaths during the week ending November 3, according to the *Sem. Méd.*

THE ITALIAN railroads have given orders to have all their occupied buildings protected by wire mosquito-netting, and the shelters for the workmen on the marshes are to be similarly protected. The Society for the Study of Malaria is to petition parliament for funds to generalize the application of prophylactic measures among the poor, as the tests this summer have been considered conclusive in regard to the danger of infection from mosquitoes.

A FRENCH female doctor, Mlle. Krykows, of Neuilly, has won a suit against a patient who claimed that her care of a plegmon had not been correct and hence refused to pay her bill. Brouardel testified as the expert in the case, that the operation and care had been *secundum artem* and had been successful. Mlle. Krykows at once added to her original bill a claim for damages to her professional reputation and the court decided in her favor, allowing her the original bill and ten dollars damages, as reported in the *Jour. de Méd. de Paris* of November 18.

THE RECENT German Congress of Physicians and Naturalists at Aix-la-Chapelle paid great honor to Virchow, and it was recalled that when the congress met at the same place fifty-three years ago, he read a paper on "Parenchymatous Inflammation." Professor Harless of Bonn presided and listened to the essay of the young Berlin privat-docent with consternation, finally interrupting him and putting the question to vote whether the assembly wished to hear any more of the paper as it was evident that the speaker knew nothing of his sub-

ject. The vote however was in favor of Virchow and he was allowed to continue.

PROFESSOR VAN ERMENGEM has returned from Glasgow, where he was sent by the Belgian government to study the plague. He reports that the effects of antiplague serum which he observed were extremely encouraging. In two cases at least the curative influence was marked. The fact that its efficacy was not more apparent was due to the tentative and inadequate manner in which it was administered by some of the physicians. He proclaims his convictions that the usual prophylactic measures for infectious diseases, supplemented by serotherapy, executed by an enlightened authority thoroughly prepared, armed with sufficient powers and with trained personnel, will effectively control and stamp out an outbreak of the plague, even in apparently unfavorable surroundings.

SYPHILIS IN ASIA MINOR.

Syphilis has increased to such an extent in some portions of Asia Minor that according to official reports 80 per cent. of the population are its victims, and it has seriously affected the ability to furnish the military drafts demanded by the Turkish government. Three-fifths of the young men are found unfit for service from this cause. The provinces in which syphilis is so prevalent are given as Castamoni, Bartin, Erzingian, Angora, Ismidt (Nicomedia) and Adana, the last named being only very recently added to the list. The introduction of the disease is credited to the Russian occupation of Constantinople in 1830, when a force of 30,000 men was landed on the Asiatic side of the Bosphorus. It spreads rapidly through the Moslem population, owing to their objections to medical examinations.

THE DRINKING WATER OF PARIS.

The drinking water of Paris has been under suspicion and it appears justly, for at a recent meeting of the Council of Hygiene it was developed that the Charonne reservoir has been constantly supplying unwholesome water for the past four months. Water taken from one of the filthiest portions of the Seine near Ivry is passed through gravel filters, which merely strain, and mixed at the Montmoutant reservoir with the wholesome waters of the Dhuys. When the typhoid fever reached its maximum recently the engineers shut off the Ivry supply and the mortality rapidly diminished from 18 deaths per week to about 7. The revelations have caused considerable stir in the Council of Hygiene and steps are being taken to improve matters in the future.

LONDON LETTER.

OPENING OF LABORATORIES AT KING'S COLLEGE BY LORD LISTER.

New laboratories have been opened at King's College, London, which form part of a comprehensive scheme of extension and improvement in the accommodation of the college and place its facilities for practical teaching in a foremost position in this country. The biological, architectural, anatomical, and mechanical departments have all considerably benefited by the new works. In the presence of a distinguished audience, including the lord mayor, Sir Joseph Fayrer, Prof. Clifford Albutt, Sir W. Broadbent and Baron Hayashi (the Japanese minister), Lord Lister, formally opened the new laboratories. He said the occasion marked an event of great importance in the higher education of the metropolis. Lectures were not now thought to be sufficient for the student; practical instruction was imperative. The laboratories which King's College now provided for the practical teaching of physiology were second to none in the country. The dissecting room had been almost doubled; a fine anatomical museum had been provided. The bacteriological laboratory had the very important addition made to it of a research room. The means of checking the Glasgow plague and removing the scare from London were entirely due to the kind of researches which were carried out in bacteriological laboratories.

THE SCANDAL AT THE NATIONAL HOSPITAL FOR THE PARALYZED AND EPILEPTICS.

The unseemly controversy on this subject still continues to be hotly carried on in the columns of the *Times*. For some time the medical staff have complained of grave defects in administration—insufficient food for the patients and scarcity of nurses. They requested the board to allot them two seats on their body, pointing out that such representation would be conducive to the interests of the hospital and a preventive of the evils mentioned. This very modest request the board refused. As a result the staff have appealed to the public through the columns of the *Times*, and asked for inquiry.

To this the board replied by instituting an inquiry themselves, and by means of a committee of their own members passing judgment on themselves. Obviously this was not regarded as satisfactory, and they now find themselves compelled to consent to an inquiry by an independent body. When the reputation of the eminent men who form the staff is considered—Gowers, Jackson, Ferrier, Horsley, Buzzard, Bastian and Semon—probably the most brilliant staff that ever adorned a hospital, the conclusion is inevitable that the evils must be grave which have driven them to the verge of resignation. The secretary-director of the hospital, who seems to be the main cause of the trouble, has had the discourtesy and vulgarity to use as an argument that the staff did not contribute largely in money to the support of the hospital. A letter has just been published in the *Times* supporting the very reasonable demand of the staff, signed by the senior physician and surgeon of every hospital in London.

MR. TREVES' BOOK ON THE WAR.

The distinguished surgeon, Mr. Frederick Treves, consultant to the army in South Africa, has just brought out a highly successful book, entitled "The Tale of a Field Hospital." Mr. Treves has always been known as a surgeon of distinct literary power, and this book only confirms his reputation. With graphic pen he brings home to the reader the horrors of war and the patient, pathetic heroism of the British soldier. For example, an orderly was bringing some water to a wounded man lying on the ground. He was shot through the abdomen and could hardly speak, owing to the dryness of his mouth, but he said: "Take it to my pal first; he is worse hit than me." This generous lad died next day, but his friend recovered. An instance of pluck that deserves notice was that of a soldier who was brought in from Spion Kop. He had been lying on the hill all night and had not had his clothes off for six days. He was struck in the face by a fragment of shell, that carried away his right eye and upper jaw, leaving a hideous cavity at the bottom of which his tongue was exposed. He was unable to speak, but as soon as he was settled in a tent he made signs that he wanted to write. After going through the form of wetting his pencil at what once had been his mouth, he simply wrote: "Did we win?" After a battle Mr. Treves describes the return of "the dreary ambulances, each one with a load of suffering, misery and death." "There were the very khaki-clad soldiers who had not so long ago left London spick and span, amid a hurricane of cheers, and now they were coming back to the camp silent and listless, and scarcely recognizable as men. They were burnt a brown-red by the sun; their faces were covered with dust and sweat, and in many cases blistered with heat; their hands were begrimed; some were without tunics, and their shirts were stiff with blood. All seemed dazed, weary and depressed. In this dismal scene there was one feature which can never be forgotten—the heroism with which the soldier met his ill-luck. Some were disposed to curse and a few to be jocular, but there was no whining or fear, and they were grateful for what was done for them." Of the nurses, he says: "These ill-housed women seemed oblivious to fatigue and hunger and to any need of sleep, and brought to the wounded and the dying that comfort men are unable to bestow."

THE INCREASE OF POPULATION OF THE UNITED KINGDOM.

The return issued by the registrar-general, of the births, marriages and deaths in the United Kingdom, is interesting. The population in the middle of the present year amounted to more than 40,000,000, of which 32,000,000 inhabited England and Wales, Scotland and Ireland having each a population of 4,000,000. In spite of the large amount of emigration, there is a steady increase of population. In the three months ending last September, 290,000 births and 166,000 deaths were registered. The annual birth-rate is 28 per 1000, and the death rate 16. Emigration carries off a large part of the increase. During the past quarter 60,000 people left our shores. Of these, 38,000 were English, 12,000 were Irish and 10,000 Scotch. The marriage-rate for the quarter was 16 per 1000. The death-rate is much heavier among men than women—the proportion being 117 to 100. The mortality of infants under

1 year is very heavy, 188 per 1000 born. No less than 5000 persons died from different forms of violence.

MOSQUITO THEORY OF MALARIA.

The experiments of Drs. Sambon and Low, of the London School of Tropical Medicine, have been completely successful and they have returned home in good health. It may be remembered that in order to prove the mosquito theory of malaria they volunteered to live for some months in a specially constructed mosquito-proof hut in the worst part of the fever-stricken Campagna. The requisite arrangements were carried out by the British Colonial Office. At first they were laughed at by the sceptical peasantry, who said that the "Ingesi" were healthy because they had no work to do. The doctors then went out and toiled as day laborers, getting soaked with swamp water and broiled in the sun. Then the conjecture was: "It is because the ground is not broken up about the hut." They dug up the reeking soil. Finally it was said: "You do not drink ordinary water." At considerable risk of other maladies they did so. But when the mission returned a crowd surrounded them and begged to be protected or cured; incredulity was at an end. As a result of the success of the expedition Professor Grassi has undertaken to banish malaria from Italy. He proposes, with the assistance of the government, to isolate all fever patients and to protect all dwellings in malarial districts with mosquito-proof netting. He will have a population of 2,500,000 and a district of 20,000 square miles to deal with, so that his task is no light one.

Correspondence.

Grooved Director for Vaginal Hysterectomy.

TROY, N. Y., Nov. 24, 1900.

To the Editor: It is with pleasure that I acknowledge priority for the director for vaginal hysterectomy in favor of Dr. Joseph Eastman on the statements in the letter to THE JOURNAL of November 24, p. 1359. It is only another illustration of the fact that similar ideas and needs often bring identical results. That my oversight of Dr. Eastman's previous publication is at least pardonable is shown by the fact that the "director" was exhibited at three medical meetings in large cities in the state of New York, and privately to several gynecologists of more than national reputation, and in no instance was a hint of previous knowledge given.

Having no desire for mere priority, I cheerfully give way to Dr. Eastman, whom I hold in high esteem for his personal worth and professional work.

E. D. FERGUSON, M.D.

Correction.

BOSTON, MASS., Dec. 3, 1900.

To the Editor:—In the abstract department in your issue of December 1, on page 1432, you say that in delirium tremens I recommend "the gradual withdrawal of alcohol and nourishment." As I have earnestly insisted upon the great value of nutrition in this disease, the statement that I advise the "gradual withdrawal of nourishment"—presumably to the point of total abstinence—is startling, to say the least. Whether the error is typographical or a slip of the pen is not clear, but, doubtless, what you meant to say was that I prescribe nourishment, accompanied by the gradual withdrawal of alcohol.

CHAS. J. DOUGLAS, M.D.

[The unfortunate omission of a comma after the word "alcohol" is the cause of the ambiguous reading to which our correspondent objects.—Ed.]

Marriages.

LOUIS MEYER, M.D., to Miss Blanche Lowenstein, both of Baltimore, November 20.

CHARLES A. HUGHES, M.D., Washington, D. C., to Miss Helen Bishop, of Dover, Del., November 28.

CORNELIUS C. ABBOTT, M.D., to Miss May C. Deters, both of Cincinnati, Ohio, November 28.

F. R. YARBROUGH, M.D., Victoria, Ala., to Miss Clara Dexter, of Montgomery, Ala., November 19.

JAMES W. ALLEN, M.D., Enoree, S. C., to Miss Cecilia Menke, of Charleston, S. C., November 27.

J. CLINTON POWERS, M.D., Hampton, Ia., to Mrs. Emma Haas, of Minneapolis, Minn., November 21.

MONROE G. REYNOLDS, M.D., mayor of Alco, Ill., to Miss Ella Graham, at Phillips, Wis., November 19.

HARVEY CLAY HEALD, M.D., Millard, Neb., to Miss Alberta Powell, of South Ottumwa, Ia., November 20.

CHARLES W. DOUGHTIE, M.D., Norfolk, Va., to Miss Florence Moore Willis, of Richmond, Va., November 21.

CHARLES NORTON, M.D., U. S. A., San Francisco, Cal., to Miss Bessie Spencer, Louisville, Ky., November 21.

ROBERT W. GIBBS, M.D., Columbia, S. C., to Miss Ethel Dole Andrews, of Kenosha, Wis., November 30, at Lombard, Ill.

Deaths and Obituaries.

RUFUS P. LINCOLN, M.D., Harvard, 1868, at his home in New York City, November 27, a few days after an operation for appendicitis, aged 59. He was an alumnus of Amherst College, class of 1862, and subsequently became well known as a lung and throat specialist in his residential city. He was a member of the AMERICAN MEDICAL ASSOCIATION, the American Laryngological Association, the American Climatological Association, and other scientific organizations.

ABNER SPICER WAENER, M.D., Dartmouth Medical College, 1848, who had practiced for more than half a century in Wethersfield, Conn., and had served as surgeon of the Sixteenth Connecticut Infantry in the Civil War, and later as physician to the Connecticut State Prison, at Wethersfield, November 22, aged 82.

EZRA H. BALLARD, M.D., University of Michigan, 1868, at Esterville, Iowa, November 9, aged 60. He was for eight years superintendent of schools, for five years treasurer of Emmet County, and had practiced in Esterville continuously since 1879.

GEORGE H. BRIGHT, M.D., Jefferson Medical College, 1858, an assistant-surgeon in the confederate service and a resident and practitioner of Richmond, Va., since 1867, November 20, at his home, after an illness of two months, aged 64.

CHRISTOPHER F. HARTER, M.D., Ohio Medical College, Cincinnati, 1858, suddenly from heart disease while making a professional call near his home, Akron, Ind., November 20, aged 66.

ALBERT L. A. TOBOLDT, M.D., University of Pennsylvania, 1873, and for several years professor of materia medica in his alma mater, from uremia at Philadelphia, November 23, aged 48.

W. W. ANDERSON, M.D., a venerable and popular physician of Farmville, Va., November 23, as the result of injuries received in a runaway accident a few days before, aged 84.

JOHN S. HOLSTEIN, M.D., Tulane University, New Orleans, of Steffy Island, La., at the home of his sister in Florence, La., from pernicious malarial fever, November 19, aged 28.

JESSE W. BROCK, M.D., University of Maryland, 1855, who served through the Civil War as surgeon of the Sixty-sixth Ohio Volunteers, at Leavenworth, Kas., November 26.

JAMES J. JOHNSON, M.D., University of Louisville, 1885, of Bedford, Ind., at the home of his sister in Martinsville, Ind., from Bright's disease, November 18, aged 38.

GEORGE S. GOCHENOUR, M.D., Baltimore Medical College, 1889, of Moorefield, W. Va., by an accidental gunshot wound while hunting at Wardensville, November 22.

T. B. COX, M.D., Louisville Medical College, 1891, of learned, Miss., by an accidental gunshot wound while hunting on the Sunflower river, November 17.

THEODORE J. YOUNG, M.D., University of Pennsylvania, 1868, at his home, Titusville, Pa., after an illness of nearly two years, November 22, aged 69.

GEORGE F. MAX KRIEGER, M.D., University of Freiburg, Germany, 1877, at his home, Seattle, Wash., November 18, from dropsy, aged 47.

WILLIAM F. CARSON, M.D., Starling Medical College, Columbus, O., 1880, from apoplexy, at his home in Huntington, Ind., November 26, aged 47.

ALVIN B. PETERS, M.D., University of Nashville, 1889, of Moultrie, Miss., from consumption, at Whiten Springs, Fla., November 13.

WILLIAM W. STEVENSON, M.D., University of Maryland, 1880, from meningitis, at St. Mary's Infirmary, Cairo, Ill., November 20, aged 48.

RANDOLPH N. HOWARD, M.D., Jefferson Medical College, 1879, suddenly from heart disease, November 22, at Carrington, N. D.

GEORGE S. McCOMB, M.D., University of Pennsylvania, 1892, at Williamstown, Pa., November 17, after a short illness, aged 36.

WILLIAM J. WILSON, M.D., Geneva Medical College, 1841, at his home, West Chicago, Ill., November 20, aged 83.

J. H. STIMSON, M.D., after an illness of several months, at his home, in Croton, O., November 23, aged 74.

C. FRANK TWISS, M.D., New York University, at his home in Cleveland, Ohio, November 23, aged 48.

portion of any work, on medicine an adequate consideration of treatment is, except in works more than one volume, rarely attempted. The work under consideration aims to supply this defect and it is, therefore, a supplement to other works on medicine. It deals entirely with the treatment of diseases and of symptoms, and in general this is done clearly and fully. The amount of space devoted to the different diseases, or classes of diseases, seems to be judiciously arranged, for instance, two chapters are given to the treatment of tuberculosis and about the same amount of space to the specific infectious diseases. This may seem a disproportion until we reflect that in regard to the first the average practitioner is anxious for help, whereas he is familiar with all the most approved methods of the treatment of the specific infectious diseases.

We can commend the book as up to date and a valuable addition to the busy man's library.

NETTLESHIP ON THE EYE. New Edition. Diseases of the Eye, by Edward Nettleship, F.R.C.S., Ophthalmic Surgeon at St. Thomas' Hospital, London; Surgeon to the Royal London Ophthalmic Hospital, Etc. New (6th) American from the Sixth English Edition, Thoroughly Revised by William Campbell Posey, M.D. With a Supplement on the Detection of Color Blindness, by William Thomson, M.D., Professor of Ophthalmology in the Jefferson Medical College, Philadelphia. Just Ready. In One 12mo Volume of 562 Pages, with 192 Illustrations. Selections from Snellen's Test-Types and Formulae, and 5 Colored Plates. Cloth, \$2.25, net. Philadelphia and New York; Lea Brothers & Co.

This well-known work, which has passed through the press six times in England, and as many in this country, requires words neither of introduction nor of commendation to our readers. The present edition has been revised and adapted to meet the wants of American students and practitioners. A supplement considers the practical examination of railway employees for color-perception, visual acuteness and hearing. Then follows an appendix with a selection of therapeutic formulae usually employed by American ophthalmologists. The book also gives what is required of candidates of the American public services, and closes with the method used in examining school children in some of our large cities. Many new illustrations have been inserted in this edition.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, and the Kindred Branches, with their Pronunciation, Derivation, and Definition, Including Much Collateral Information of an Encyclopedic Character. By W. A. Newman Dorland, A.M., M.D., Assistant Obstetrician in the University of Pennsylvania Hospital. Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Diplococci, Micrococci, Streptococci, Ptomaines and Leukomains, Weights and Measures; Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. With Numerous Illustrations and 24 Colored Plates. Leather, Pp. 770. Price, \$4.50. Plain, \$5.00. Index. Philadelphia and London: W. B. Saunders & Co. 1900.

The author states that it has been his aim to produce in a volume of convenient size, an up-to-date medical dictionary, sufficiently full for the varied requirements of all classes of medical men. In this he has succeeded; he has given us a word-book which is neither so unwieldy as to be too large for handy, every-day use, nor so condensed but that it can be relied on for every occasion. It contains all medical terms required by all classes of medical men and medical students, and yet it is so compact that it is as convenient in size as the ordinary abridged dictionary. While it is not encyclopedic in character, it contains a large amount of descriptive matter, together with many important tables. It is profusely and excellently illustrated. The colored illustrations are especially fine; the plates showing the arteries and veins, and those showing the transverse section of the spinal cord, are particularly worthy of notice, as are the half-tone plates on the anomalies of the placenta. The book is printed on thin Bible paper, and is bound in flexible cover, the former adding to its compactness, the latter to its convenience in handling.

Book Notices.

SYSTEM OF DISEASES OF THE EYE. By American, British, Dutch, French, German, and Spanish Authors. Edited by Wm. F. Norris, A.M., M.D., and Charles A. Oliver, A. M., M.D., of Philadelphia. Vol. iv: Motor Apparatus, Cornea, Lens, Refraction, Medical Ophthalmology. With 51 Full-page Plates and 211 Text Illustrations. Svo. Cloth. Pp. 950. Price, \$5.00. Philadelphia and London: J. B. Lippincott Co. 1899.

This volume, itself large, completes a work which, comparatively, is truly monumental—comparatively, because one would not think so much information could be gathered together concerning so small an organ. It is worthy of note, too, that such accumulated knowledge approaches very nearly the exact, for with his instruments of precision the deductions of the ophthalmologist are, to a certain extent, mathematical.

The American contributors to this volume are Drs. Norris, Oliver, Standish and De Schweinitz; among the foreign collaborators are Landolt of Paris, Suel of Liège, Haab of Zurich, Swanzy, of Dublin, and Jonathan Hutchinson, of London. The plates representing microscopic appearances are certainly instructive, particularly those illustrating pathologic conditions of the cornea and lens.

The volume is devoted largely to the consideration of general disturbances and their local effect on the eye, for instance, the influence of diseases of the circulatory and nervous systems, of the secretory and excretory organs, of that of the infectious diseases, etc. Hence, the work is valuable to the general practitioner as well as to the specialist. The "System" stands facile princeps among works of its kind in the English language.

TEXT-BOOK OF THE MEDICAL TREATMENT OF DISEASES AND SYMPTOMS. For Use of Students and Practitioners of Medicine. By Nestor Tierard, M.D., F.R.C.P., Professor of Principles of Medicine, King's College, London. Adapted to the U. S. Pharmacopoeia by E. Quin Thornton, M.D., of Jefferson Medical College, Philadelphia. Octavo. Pp. 624. Cloth. \$4.00 net. Philadelphia and New York: Lea Brothers & Co.

This book is not an ordinary work on medicine, but occupies a field which has been largely neglected. Since symptoms, etiology, diagnosis, etc., must of necessity occupy a large pro-

Miscellany.

Malaria Serotherapy.—Fifty patients with malaria were treated early in 1899 with serum from horses with the "Sterbe," a local epizootic, and the malarial infection was promptly cured. None of the patients have since contracted the infection, while many of their neighbors were affected during the rainy season. These results were attained by Dr. Kuhn, a German staff physician at Groot Fontein, in German Southwest Africa. Other experiences have confirmed the curative and preventive value of this serotherapy and Dr. Kuhn is now on his way home to present the authorities with his official report. A preliminary communication in the *Deu. Med. Woch.* of November 1 is confirmed by private advices as to the remarkable results attained in the hospitals with the serum. It transforms a chronic, relapsing malarial infection into an acute affection which runs its course in two to six weeks, with complete recovery and subsequent immunity.

German Burlesque.—The annual burlesque number of the *Muenchener Medicinische Wochenschrift* has been received and is full of fun. The "Bakers' Congress" is an amusing tragedy-comedy, dealing with the lodge question and the creation of a Tribunal of Honor for Bakers. The department-store advertisement offers medical attendance at different prices. The "lodge physicians" in the basement "imported still alive at great expense from Berlin. They will work for lower prices than are possible in any other trade, only to be secured by the extreme indigence of these gentlemen, who are not coolies, but diplomaed physicians." Professor Swindel, of Mississippi College, reports the wonderful cures of neurasthenia obtained with his serow "quietrix," which, inserted between the atlas and epistropheus, temporarily suspends the function of the cerebrum. Another communication announces the discovery of the prescribing center. Excitation of the centripetal fibers for bronchitis, for instance, invariably induces a purely reflex act; the hand writes "syr. ipecac." For organic and non-organic nervous affections, the reflex response is always: "Mixture nervina," etc. Prescribing, the writer proves, is a purely subcortical reflex action, with which the gray cortical substance has nothing to do. The report of the Medical Congress for 2001 is mainly devoted to discussion of means "to relieve the members of the profession from the overwhelming number of patients with which they are now burdened, owing to the fabulous incomes of the physicians in the colonies, which have attracted so many colleagues to foreign lands. The remedy is only to be found in reducing the standard of admission to the medical schools and shortening the course. As the curriculum now consists merely of the application of water and the administration of organs for affections in corresponding organs, we need no longer be hampered by the traditions of our ancestors. Three months at a female seminary is ample preparation for the study of medicine, or the ability to read the daily paper aloud correctly." In the "Points for Construction of a Thesis" it is advised to "always commence with Hippocrates, to describe the symptoms and food of the patient to the minutest details and fill pages on pages, to avoid original ideas, and to copy the bibliography from the latest medical journal at hand. Never condense; add as many pictures as possible, if only of the espidior or test-tubes used, and present all the old exploded theories." The "inhalator" is a new apparatus advertised, a large funnel in which a vacuum is created at the door of the office building. The passers-by are sucked into this funnel and landed in the waiting-room with some traumatism requiring immediate attention.

MARINE HOSPITAL NOTES.

ASST. SURGEON L. P. H. BAHRENSBERG, who was on duty in Liverpool during the prevalence of plague in Glasgow, has returned to New York, where he is stationed as assistant to the medical inspector of immigrants.

ON THE REQUEST of Governor Atkinson of West Virginia, Assistant-Surgeon W. C. Billings, who successfully manæged an epidemic of smallpox in Charlestown, W. Va., last summer, has been detailed to confer with Dr. Flowers, of the State Board of Health, at Clarksburg, W. Va., with reference to measures

necessary to suppress an epidemic of smallpox now existing in that place and the surrounding county.

ASST. SURGEONS Dunlop Moore, B. H. Earle, and B. J. Lloyd returned on November 28 from Dutch Harbor and Nome, Alaska, where they have been on duty during the past season, and have been assigned to duty respectively at Port Townsend quarantine, Astoria quarantine and San Francisco quarantine.

ALUM AND BACTERIAL GROWTH.

At the request of a committee of the Medical Society of the District of Columbia, of which Dr. Samuel C. Busey is chairman, the surgeon-general of the Marine-Hospital Service has directed that the hygienic laboratory of that service shall investigate the subject of the possible inhibitive effect of alum on the growth of bacteria in water, to which it may have been added as a preliminary step in purification by filtration. The experiments have been commenced, and will form the subject of observation for a period of thirty days, the alum being used in quantities varying from 3 to 6 grains per gallon, the amounts usually employed in such preliminary purification or sedimentation.

Societies.

Seaboard Medical Association of Virginia and North Carolina, Weldon, N. C., Dec. 13.

Roentgen Society of the United States, New York City, Dec. 13-14.

Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

Pan-American Medical Congress, Havana, Cuba, Feb. 5, 1901.

THE HOLYOKE (Mass.) PHYSICIAN'S CLUB met on November 21, completed its organization and elected Dr. Carl A. Allen, president; Dr. Daniel F. Donoghue, vice-president; Dr. John J. McCabe, secretary, and Dr. J. Clark Hubbard, treasurer.

THE REDWOOD COUNTY (Minn.) MEDICAL SOCIETY held its first meeting at Sanborn, November 13, and elected Dr. George W. Boot, Sanborn, president; Dr. Giles R. Pease, Redwood Falls, vice-president; and Dr. R. H. Ray, Walnut Grove, secretary and treasurer.

THE PENOBSCOT COUNTY (Maine) MEDICAL ASSOCIATION held its annual meeting and election of officers at Bangor, November 20, with the following result: Dr. Atwell W. Sweet, president; Dr. Walter L. Hunt, vice-president; and Dr. Bertram L. Bryant, secretary, all of Bangor.

THE INTER-COUNTY (Wis.) MEDICAL SOCIETY, at its annual meeting held in Eau Claire, November 20, elected Dr. William B. Lyman, Mendota, president; Drs. Frank W. Epley, New Richmond, and Charles H. Elkinton, Eleva, vice-presidents, and Dr. Joseph J. Selbach, Eau Claire, secretary and treasurer.

THE TRI-STATE MEDICAL ASSOCIATION of the Carolinas and Virginia will meet on February 26, 1901, at 10 o'clock a. m., at the Jefferson Hotel, Richmond, Va. All Fellows desiring to read papers communicate with the secretary, Dr. J. N. Upshur, 210 W. Grace street, Richmond, Va., giving title, not later than January 15, 1901.

THE DES MOINES COUNTY (Iowa) MEDICAL SOCIETY, which has been inactive for several years, reorganized at its twenty-seventh annual meeting held at Burlington, November 21, and the following officers were elected: Dr. Nathaniel M. McKitterick, president; Dr. William W. Milligan, vice-president, and Dr. George Kinney, secretary and treasurer, all of Burlington.

THE MASON COUNTY (Ky.) MEDICAL SOCIETY held its regular meeting at May's Lick, November 27. Dr. A. N. Ellis, Maysville, reported some interesting clinical experiences; Dr. Amos G. Browning, Maysville, presented a paper on "Perineal Abscesses"; Dr. Cook, Wedonia, submitted a report on typhoid fever; Dr. Edwin Matthews discussed the relation of dentistry to general medicine, and Dr. Thomas E. Pickett, Maysville, read a sketch of Dr. Daniel Drake, founder of the Medical College of Ohio and author of "The Diseases of the Mississippi Valley" which was especially appropriate, as the meeting was held at the place which a century ago young Drake left to study medicine with Dr. Goforth, of Cincinnati.

THE BURLINGTON (Vt.) CLINICAL SOCIETY held its annual meeting, November 30, and after an address by Dr. Samuel E. Maynard, the retiring president, elected the following officers: Dr. Marshall C. Twitchell, president; Dr. Frederick E. Clark, vice-president; Dr. C. K. Johnson, secretary and treasurer; Drs. Maurice J. Wilste, Bingham H. Stone and Hoyt R. Wilder, executive committee, and Drs. Donly C. Hawley and Samuel E. Maynard, special committee on program. The secretary of the Vermont State Medical Society, Dr. Donly C. Hawley was asked to explain in detail the reorganization scheme on foot in that society. At the close of his remarks, the following resolution was adopted by a unanimous vote, "Resolved, That the Burlington Clinical Society is in hearty sympathy with the re-organization plan of the Vermont State Medical Society."

THE NEW YORK STATE CHARITIES AND CORRECTION CONFERENCE.—At the meeting held in Albany on November 20, 21, and 22, Governor Roosevelt, in delivering the address of welcome, said that as the conference would discuss subjects pertaining to penology, he desired to say that the greatest blot on American civilization is lynch-law, and it flourishes most rankly in states where there is a constant miscarriage of justice. Lynch law is one form of mob violence, and should be put down at all hazards. William Pryor Letchworth, president of the conference, said that the sum expended by the state, municipalities, and counties for charitable purposes, and for reformatories and prisons, including that for buildings, during the year ended September 30, 1899, was \$9,768,515. Adding to this the \$18,517,782 expended by private charitable organizations, the total was raised to \$28,286,297. J. Graham Phelps Stokes, in discussing the University Settlement work in New York, said that it was often asserted that the three chief causes of poverty are lack of employment, vice and crime, but he felt sure that there was an underlying predisposing cause in the vast majority of cases—an undeveloped or defective personality. He thought that no efforts to reduce the world's poverty would prove successful unless they included means for reaching and developing the characters of those in poverty or on its verge. The report of the Committee on the Institutional Care of Destitute Adults gave the following as essentials to success: Competent officials, good buildings—those in which proper attention is given to fresh air, sunlight and general sanitation; proper discipline, including suitable employment, and thorough classification. The report of the Committee on Mentally Defective, presented by Dr. William P. Sprattling, of the Craig Colony for Epileptics, contained the following recommendations: To prevent insanity, epilepsy, imbecility, idioy, and feeble-mindedness as far as possible by making it impossible for them to marry; to build less expensive structures in which defective and dependent state charges shall live; to maintain at less cost the cases that are chronic and incurable, and at greater cost, to stimulate recovery, those who probably can be cured; and to give to those who ought to have it, an education that they may use, either in the institution that cares for them, that the cost of their maintenance may be lessened, or in the outer world when they leave the institution. In the discussion on Criminology, Thomas Sturgiss, New York City, chairman of the board of managers of Elmira Reformatory, read a communication on "The Treatment of the Criminal." The following conditions were considered as essential to the adoption of a true system of treatment in all penal institutions: Centralization of prisons of all kinds; taking of all prisoners out of reach of political influence; proper classification and distribution of all criminals; specializing of such institutions; such classification to be made by the head of the institution to which the prisoner is first sent; adoption of the principle that reformation and not punishment is the end sought by imprisonment, and proper application of the parole system and a constant fostering of the element of hope. The following officers were elected: Robert W. De Forest, president; T. Guilford Smith, and Simon W. Rosedale, Albany, and Thomas M. Mulry, New York, vice-presidents; Robert W. Heberder, Albany, secretary; Dr. Lee K. Frankel, New York, Miss Lucy C. Watson, Utica, and Mrs. August Falkes, Syracuse, assistant secretaries, and Frank Tucker, New York, treasurer.

THE WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.—The next annual meeting of this association, of which Dr. O. B. Campbell, Kansas City, is president and Dr. George H. Simmons, Chicago, secretary, will be held at Minneapolis, Minn., December 27 and 28. An invitation is extended to the surgeons and gynecologists of the Great West to attend this meeting and take part in its deliberations. The meetings are held during the holidays, thus enabling those to attend who

belong to the teaching faculties of medical colleges without interfering with their college duties. The following is the preliminary program:

- Anesthesia Through Cocainization of the Spinal Cord; Its Use and Limitation. Dr. J. B. MURPHY, Chicago.
 Adenoma of the Tongue. Dr. J. E. SUMMERS, JR., Omaha, Neb.
 Removal of Superior Maxilla. Dr. ALEXANDER H. FERGUSON, Chicago.
 Two Rare Tumors: (1) A Calcareous Testis Fibroma, and (2) a Fibro-Myoma of the Urethra and Anterior Vagina. Dr. J. CLARENCE WENSTER, Chicago.
 Post-Operative Fistula. Dr. H. G. WETHEBILL, Denver, Colo.
 Insanity in Women Associated with Pelvic Disease. Dr. J. R. HOLLOWHUSH, Rock Island, Ill.
 Demonstration of Gynecological Operations by Means of Casts. Dr. W. O. HENRY, Omaha, Neb.
 The Choice of Operation for Stone in the Bladder. Dr. J. CLARENCE WENSTER, Chicago.
 Traumatic Injuries of the Ureter. Dr. E. B. DAVIS, Omaha, Neb.
 Hypospadias. Dr. J. W. MACDONALD, Minneapolis, Minn.
 The Operative Management of Retro-Peritoneal Abscess. Dr. C. H. MATO, Rochester, Minn.
 Pelvic Injuries. Dr. G. G. COTTAM, Rock Rapids, Iowa.
 The Pathology of Fractures. Dr. R. HARVEY REED, Rock Springs, Wyo.
 Operative Management of Tubercular Hip Joint Disease (A Critique). Dr. LEWIS SCHOLLER, Des Moines, Iowa.
 A Further Report of a Case of Cerebral Cyst. Dr. A. F. JONAS, Omaha, Neb.
 Anatomical and Surgical Observations on Appendicidal Abscess. Dr. VAN BUREN KNOTT, Sioux City, Iowa.
 Topical Applications in Gynecological Practice; Their Use and Abuse. Dr. A. C. BERNANZI, St. Louis, Mo.
 Two Cases of Appendicitis of Unusual Course. Dr. J. W. ANDREWS, Mankato, Minn.
 A Consideration of the Different Operative Procedures in the Treatment of Retro-Displacements of the Uterus. Dr. HERMAN E. PEARSE, Kansas City, Mo.
 Dr. O. B. CAMPBELL, St. Joseph, Mo.

SYMPOSIUM ON FRACTURES.

- a. Some Observations on Compound Fractures. Dr. J. P. LORD, Omaha, Neb.
 b. Ambulatory Treatment of Fractures. Dr. D. S. FAIRCHILD, Clinton, Iowa.
 c. The Treatment of Skull Fractures. Dr. FRED. RUSTIN, Omaha, Neb.
 d. What Material Improvement in the Treatment of Fractures has Resulted from the Use of the X-Ray? Dr. J. E. DUNN, Minneapolis, Minn.
 Dr. C. E. RUTH, Keokuk, Iowa.

SYMPOSIUM ON THE SURGICAL INFECTIONS OF THE KIDNEYS AND THE CYSTOURETHROSES.

- a. Etiology and Pathology. Dr. M. L. HARRIS, Chicago.
 b. Symptomatology and Diagnosis. Dr. W. H. ALLPORT, Chicago.
 c. Treatment. Dr. L. L. McARTHUR, Chicago.

SYMPOSIUM ON SURGICAL TUBERCULOSIS.

- Tuberculosis of Fascia. J. CLARK STEWART, Minneapolis, Minn.
 Tuberculosis of Tubes, Ovaries and Peritoneum. Dr. ROLLIN E. CUTTS, Minneapolis, Minn.
 Tuberculosis of Bones and Joints. Dr. DE. KNUTE HOGSH, Minneapolis, Minn.
 Treatment of Tuberculosis of Bones and Joints. Dr. JAMES E. MOORE, Minneapolis, Minn.

Chicago Physicians' Club.

November 26, 1900.

DR. HAROLD N. MOYER in the chair.

THE PHYSICIAN AS A WRITER OF MEDICAL LITERATURE.

DR. HAROLD N. MOYER spoke of the great carelessness exhibited in medical writings. To-day medical literature is sadly in need of men who are competent to take the vast number of accumulated, and, in some cases, isolated, facts, shape them, co-ordinate them, and put them into the proper place where they belong. The services of such men are indispensable to the medical profession and to medical science.

SHOULD THE PHYSICIAN WRITE?

DR. G. FRANK LYDSTON discussed this subject. Persistent writing enables the physician to acquire a knowledge of medicine and of surgery which can not be obtained in any other manner. Many works show breadth of culture and depth of thought. According to his experience, only 25 per cent. of all medical students express themselves in good English. As models of literary style he mentioned the writings of Van Buren and Fothergill.

COMMON FAULTS OF THE WRITINGS OF MEDICAL AUTHORS.

DR. GEORGE H. SIMMONS said that most physicians write too long papers. Papers ought to be short, for two reasons, 1, because the readers desire them so, and 2, because editors would be able to present their readers with a greater variety of topics, which is impossible when two-thirds of the space in a medical journal is taken up by a long article. A long article is read by but few of the readers. Probably three-fourths of all papers published are prepared for reading before medical

societies. They are prepared hurriedly, and the subjects are not well thought out. Because such a paper sounds well when read is no reason why it would read well when printed. When one prepares a paper with the idea of placing it before thousands in its printed form he should use more care in its preparation than when it is written for the purpose of reading before a possible dozen or two in a society. Too many papers bristle with unnecessary details. Examples were given. Some writers were not able to stick to their text. Meaningless titles were dwelt on, and many examples given. The title should suggest the contents of an article. Faults in bibliographic references were pointed out; also faults in case reporting. The style which some practitioners adopt in reporting cases is to be deprecated. Several examples of involved and verbose styles were given. He urged the liberal use of central and side head-lines to guide the reader. The reckless confusion and mixing of tenses should be avoided.

HOW TO WRITE WELL.

DR. GEORGE F. BUTLER discussed this subject. A prerequisite to writing well is to think well. To cultivate a logical sequence of ideas and train the mind to precise methods of coordination and lucidity of reasoning is a hard task, yet on this systematic basis of correct ratiocination is founded the higher power of appropriate expression. As a general principle, save in cases of superior talent, the less of self injected into literary productions, the more acceptable the results. Style should be marked by the suppression of that arrant egotism which mars the works of not a few able writers and detracts from the strength and charm of their performance. Association with great minds, through diligent perusal of their works will be found in newspaper leaders of signal merit, fully equal in style to the best magazine literature, and, from the necessity of condensation, presenting admirable examples of concise, logical reasoning combined with discriminating observation of the leading events of the day.

MEDICAL WRITERS FROM THE STANDPOINT OF THE READER.

DR. HENRY F. LEWIS said the busy practitioner can only read a few medical journals, and these should be the best. Articles that appeal to the casual medical reader are scattered far and wide through medical journals. The medical writer speaks too frequently with an authority that is not his own. There is too much compilation, and not enough of the author's own observations and experience given. Too much space is devoted to what this and that man has said regarding a certain subject. Lengthy quotations of the works of others are unnecessary, because they can be found in the literature by those who are sufficiently interested to look them up. Articles are not sufficiently concise. Greater condensation is necessary. The average writer consumes too much time and space with prefatory observations, or long, windy introductions. Brevity, without vagueness, is desired. Long and involved sentences are fatal to clearness, and should be studiously avoided. Subjects should be well divided; there should be a liberal use of central and side head-lines to suggest to the reader what an article contains. He favors appending titles after the author's name, as, for instance, "Professor of the Principles of Surgery in the Squedunk Medical College," etc., but not to the extent to which it is carried by some authors. Abstracts of papers should be made by the authors themselves rather than by editors, if possible, as they can bring out the salient points more clearly. Abstracting is frequently done in a haphazard manner by many medical journals. This should be intrusted to experts in particular lines of work.

DR. HUGH T. PATRICK said that some of the very best textbooks extant on general medicine are nothing but compilations. The men who can select the good from the bad in medical literature, pick it out, and present it to the medical profession in a simple, concise, readable form are as much to be praised as are those men who discover and promulgate something new. Physicians should not write for editors, but for the readers.

DR. SNYDACKER said that every author should give a concise, terse summary of his deductions or conclusions at the end of an article.

DR. J. HOMER COULTER said that authors in preparing papers, either to be read before medical societies or for publica-

tion, should not only consider the class of readers which they intend shall read their papers, but should exercise as much care in their preparation as they would in examining and treating patients. The medical writer should compress his thoughts into the fewest possible words.

Cleveland Medical Society.

Regular Meeting, October 12, 1900.

President Dr. Henry S. Upson, in the chair.

The Committee on Necrology reported resolutions upon the death of Dr. Ralph J. Wenner, which were unanimously adopted.

UTERUS SEPTUS WITH A VAGINAL SEPTUM.

DR. FRANK E. BUNTS said his patient had been married at 22, and had a miscarriage eight months afterward. Six weeks later she was found to be in the fifth month of pregnancy and was delivered of a living child at term. Even then a diagnosis of uterus septus was not made. Later she found she had a double vagina and uterus, and thought she could tell from which side she menstruated. By digital examination no abnormality was found, but inspection showed a septum with the smaller vagina on the right and a cervix in each. She was anxious to have a child, but feared a miscarriage. An operation was agreed on and the method employed is new, so far as known. A long-bladed clamp was placed along the upper attachment of the septum and another along the lower. The septum was then excised, and the edges of membrane at each insertion stitched with running catgut suture before removing the clamps. The operation was absolutely bloodless. A laceration of the right cervix indicated that the term pregnancy had occurred on that side, and the left ovary was removed in the hope of preventing conception on that side of the uterus. Unfortunately the patient has not been seen since her prompt recovery from the operations.

DR. JOHN H. BELT had attended this case some time previously in confinement, and had not discovered the anomaly.

DR. HUNTER ROBB said that he had once examined a similar case without finding the anomaly. Only on the occasion of a later examination he accidentally found it. In this case the dividing membrane was quite thick, and there was a cervix in each compartment. A subsequent operation for ovarian disease disclosed the fact that the body of the uterus was not divided.

DR. WILLIAM H. HUMISTON said that he had examined the case reported by Dr. Bunts without finding the condition, and thought that it was a very easy mistake to make unless an anesthetic and speculum were employed.

DR. SAMUEL W. KELLEY mentioned a case which he had seen sixteen years previously, in which there had been pelvic injury from a fall. On examining for a separation of the symphysis, he found a septum in the vagina and also in the uterus. Five years later, after she had borne a child, he examined the case and found the septum had been torn, and she gave a history of having had a difficult labor.

DR. JOHN L. HESS reported a similar case in which he had discovered the anomaly by accident. In his case the septum, instead of being placed in the anterior direction, extended from one side to the other. One of the openings was not more than three-fourths of an inch in diameter, and appeared to end in a cul-de-sac.

THE PRESENT STATUS OF SUGGESTIVE THERAPEUTICS.

DR. HUBERT L. SPENCE traced the evolution of the "hypnotism" of Braid to the psychotherapy of to-day. After an experience of fifteen years he has come to regard the so-called sleep as an arbitrary and artificial phenomenon, and seldom necessary for therapeutic purposes. For the same reason all physical agencies, as revolving mirrors and objects for securing fixation of gaze, are generally superfluous. The conditions tending to mental inertia, as quietude, limitation of movement, and muscular relaxation, favor suggestibility. Post hypnotic or deferred suggestions can be made operative without preceding hypnosis. In some hysteric and neurasthenic cases with marked disintegration of personality, deep hypnosis is

needed. In this state hysteric anesthesia and other defects can be removed, and the restitution of function thus achieved may be carried over into the waking state. All hysteric and markedly nervous patients should be approached with caution. An explanation of the nature and mode of treatment gains confidence and dispels apprehension. In no instance has the speaker observed unpleasant consequences following this treatment. While functional affections, and especially the psychoneuroses, are generally amenable to suggestion, direct or otherwise, many organic diseases, or rather their nervous accompaniments may be thus greatly benefited. Obviously it behooves the physician in all cases to carefully differentiate these conditions, and, though employing psychotherapy, by no means to neglect the many other remedial measures that judgment demands.

DR. HAMILTON BIGGAR, Jr., presented specimens removed from a dermoid cyst. The tumor contained a large bunch of hair and a number of teeth, which were pretty well developed. He showed another specimen of calcification of the corpus luteum. The shell was hard and brown, and composed of lime salts, while the interior cavity was filled with a dark brown fluid.

THYROIDECTOMY WITHOUT ANESTHESIA.

DR. GEORGE W. CRILE reported an operation on a case of goiter in which the tumor interfered with breathing. It was a large one and had caused several attacks of cyanosis. Because of the exhaustion of the patient through the extraordinary effort at breathing, it seemed impossible to administer an anesthetic. He had therefore preferred to make the operation under cocaine anesthesia, and had asked the patient who had been sitting up on account of the difficult breathing, to lie down for the injection of the cocaine, when respiration practically ceased from pressure of the tumor. As the patient at once became thoroughly unconscious, he operated without an anesthetic, removing the goiter in the median line, and then commenced artificial respiration at once. The patient recovered after having been unconscious sufficiently long for the completion of the operation, of which she had no knowledge whatever.

Cincinnati Academy of Medicine.

Regular Meeting.

President C. L. Bonfield, in the chair.

FETAL MONSTROSITY.

DR. E. GUSTAVE ZINKE presented a specimen of fetal monstrosity. In January of this year he had been consulted by a young married woman, 23 years of age, suffering with obstructive dysmenorrhea. Under his advice, the cervical canal was dilated. She conceived soon afterward, the date of her last menstruation being March 23. Pregnancy at first was uneventful beyond a little gastric distress. On examination at about the sixth month he had found the abdomen as large as that at term, and was able to diagnose a large amount of amniotic fluid. Fetal movements were readily palpated, but though the child was in the first position, the fetal heart-sounds could not be detected. He then informed the husband of the possibility of multiple pregnancy or of monstrosity, but requested that this knowledge be kept from the wife. At about six and a half months abortion took place, the rupture of the membranes being accompanied by the escape of an enormous amount of amniotic fluid, the abdomen then assuming a size commensurate with the length of the pregnancy. The vertex was rapidly delivered, but as the face began to present, progress was arrested, and on examination a large mass could be felt apparently in connection with the child's face. When delivery was accomplished this mass was found to be united to the child by a pedicle attached to the junction of the hard and soft palate, and continuing well outside the mouth. In weight it was about two pounds. Examination showed it to be in all probability a second fetus that had undergone destruction.

LIMITATIONS OF THE X-RAY.

DR. N. P. DANBRIDGE thought that the other side of the question of X-ray diagnosis—those cases in which failure has

been recorded—should be discussed. He himself had several weeks previously operated on a man at the Cincinnati Hospital who had been shot in the back in the region of the spine of the left scapula. An X-ray photograph taken antero-posteriorly revealed the bullet very well, and though the foreign body was causing no trouble it was thought best on account of the ease with which its apparent position had been located, to attempt its removal. Though a large crucial incision was made and exploration continued down to the thorax, every portion of the neighboring tissue being carefully palpated with the finger, even the scapula being lifted up in the search, the bullet could not be found. He also narrated many other instances of failure in the experience of others, one notable example where a collar button had slipped down a man's back and unfortunately stopping at the lumbar region, gave a photograph of apparent renal calculus; an operation was performed and nothing found, much to the discomfiture of the operator. In fracture cases, X-ray photographs are often of the greatest importance as medico-legal testimony. Taken in lateral and perpendicular planes with the same position of the limb, or in the same plane with a different position of the limb, a fairly good or very bad result might be shown; particularly was this the case in fractures of the fore-arm. He presented several pictures in illustration of this point. Another point of some importance was that provisional callus was not shown by the X-ray photograph, and that often a fracture of some weeks' duration, but all clinical symptoms doing well, would present the appearance of non-union. Within the past few weeks, he had been greatly aided by an X-ray photograph in a case of fracture of the upper part of the humerus with dislocation of the shoulder-joint. X-ray photographs were exhibited showing the normal shoulder, the dislocated shoulder and the dislocation with fracture. In the latter case he had delayed two weeks, giving time for granulation tissue to form around the fractured ends, and then through a small open incision, drawing the head of the bone into its normal position according to the operation of McBurney. He thought delay of a few weeks in operating beneficial as liable to prevent infection between the fractured ends, and consequent non-union.

DR. E. H. SHIELDS presented a patient of about 50 years of age, female, afflicted with lichen ruber of varying appearance; on some parts of the body presenting the appearance of lichen ruber planus, in others that of lichen ruber acuminatus. She was being treated with Fowler's solution in small doses.

DR. GILES MITCHELL presented a specimen of large intra-uterine fibroid, the uterus completely surrounding the tumor and increased to many times its normal size.

CARCINOMA OF THE BREAST.

DR. P. S. CONNER dealt chiefly with the symptoms of breast cancer and the unreliability of each as diagnostic, though when taken together they made a very complete picture. He reviewed the various operative procedures and narrated instances of simple removal followed by cure, while the radical operation was very often followed by recurrence, even when performed early. Therefore, he thought every case a study and law unto itself, and he had himself experienced cases in which recovery took place even when the supraclavicular glands were extensively involved, while on the other hand all were familiar with the recurrence that often speedily follows total extirpation. Yet he was a firm believer in operation even if a very slim chance existed for the patient. The removal of a foul sore was of the greatest service if nothing else is accomplished.

The paper was discussed by Drs. W. D. Haines, Ransohoff, Freidberg, Bonfield and Hall.

California Academy of Medicine.

Meeting held Oct. 23, 1909.

President Dr. D. W. Montgomery, in the chair.

DR. PHILIP KING BROWN presented some pathological specimens from dogs. The first one was a case of tuberculosis in the heart wall and pericardium of a sky terrier, six years old

and very stout. For some weeks there had been dyspnea on exertion. In the family was a child with pulmonary tuberculosis. Autopsy showed enlargement of bronchial and mediastinal glands, and tubercles studding the pericardium. The heart itself was much enlarged, and extremely irregular in outline owing to the nodular elevations scattered over the auricular and ventricular walls. Microscopical examination showed structure of tuberculosis with large areas of caseation in the center of all the large nodules.

He next presented three skulls of dogs showing a condition of osteoporosis. The symptoms in all three cases were those of chorea of exaggerated type. No etiological factor was to be obtained. The great thickness of the skull was not noticed during life. The dogs were all of different breed, a cocker, fox terrier, and pointer. All were destroyed after various kinds of treatment were tried. The thickness of the skull was greatest in the fox terrier, the section measuring from $\frac{3}{8}$ to $\frac{1}{2}$ inch in parts ordinarily less than $\frac{1}{2}$ of an inch thick. The thickened bone was so soft that the thumb nail could be pushed well into it. The thickening was chiefly in the medullary part, the plates, however, also taking a small part in the process.

DR. WILLIAM OPHULS in referring to these last specimens presented by Dr. Brown, said that he had not been able to find any signs of inflammatory processes. He thought that they belonged to those cases of osteoporosis found in some animals, but never in human beings.

DR. D. W. MONTGOMERY said that he had assisted at an autopsy where a similar condition had been found in a human being. The bones of the head were much enlarged, as also were both clavicles and a scapula. When the outer table of the skull was cut through, it came off, leaving a red, porous, spongy mass, which looked like a granular mass. The sawing was continued and the inner plate taken off. The bones microscopically had a porous condition. He had never seen anything like it in the literature.

DR. H. J. KREUTZMANN presented a patient on whom he had two months ago operated for complete prolapse and perfect inversion of the vagina, with large cystocele and rectocele. Special stress was laid on the cure of cystocele, which the Doctor considers an essential point in curing prolapse. The operation was fully described; it consisted materially in the detaching of the bladder from the vagina and from the uterus, with the idea of dislocating the bladder from its pathological abnormal position and bringing it back to its normal habitat. Care is taken not to destroy nor to remove the layer of fascia and muscle under the vaginal mucous membrane. In women past or near the menopause vaginal fixation is done. The redundant tissue of the vaginal flaps is dissected and the incision closed, the lower part of the vaginal flap being sewed directly on the uterus. If any operation has to be done on the uterus, it is done, then posterior colporrhaphy and perineorrhaphy is made. The Doctor criticised the usual operation performed for rectocele and cystocele as illogical; muscle and fascia must be laid open and directly united; a simple excision of a piece of the vaginal mucous membrane and union will not do. It is immaterial what the shape of the incision is. He bluntly separates after making a longitudinal incision for cystocele, and a crescent-shaped one for rectocele.

DR. J. F. MCCONE said that he had examined the patient and had found physiological restoration of the perineal body and the anterior vaginal wall. He had been much dissatisfied with the described operations for cystocele, and agreed with Dr. Kreutzmann that the operation ordinarily done, that of simply denuding the mucous membrane and bringing the edges together, was insufficient. The same held good in the usual operations for rectocele.

DR. DUDLEY TAIT asked Dr. Kreutzmann what advantage he finds, where it is necessary to fix the uterus, in vaginal fixation, over abdominal. It would seem to him very logical to begin the operation above, fix the uterus, and then do what is necessary in the vagina. He thought recurrences, after these operations, may come one or two years after.

DR. KREUTZMANN said of the advantage of abdominal fixation over vaginal, that he had no faith in the former opera-

tion, unless the operator allows no space to remain between the uterus and the abdominal wall. Numerous instances are on record of hernia existing between the folds of these so-called false ligaments. He had been thoroughly satisfied with vaginal fixation in these cases.

New York County Medical Association.

Stated Meeting, October 15, 1900.

THE NEED OF BETTER ORGANIZATION IN THE PROFESSION.

DR. FREDERICK HOLME WIGGIN, on retiring from the office of president, spoke briefly on this topic, which was opportune because the State Association was on the eve of considering the plan of re-organization. Dr. Wiggin said that the readiness with which such a large and active body as the New York County Medical Association had consented to become a subordinate county association of the reorganized State Association was most significant, and to his mind was positive proof that the medical profession was reaching out for better organization. An organization managed purely for selfish interests could not be expected to achieve all that is meant by the broad use of the term "success," any more than could the selfish individual. Some of the smaller counties had objected to paying their share of the expense of organization on the ground that each county should look after its own affairs. It was just this narrow and selfish policy that had already placed the profession in such a bad light before the general public. Small county associations could not be expected to afford their members the same protection against unjust suits for malpractice as would result from a well-organized State Association taking up such a cause for all of its members. Our legislators cared little for the petitions of those appearing before them in their individual capacity, but let these persons come as the representatives of an organization having a membership of several thousand, and the result would be very different. The speaker said that he had been brought in contact with many physicians throughout the state, and knew positively, assertions to the contrary notwithstanding, that they were deeply interested in such a scheme of organized defense.

DR. PARKER SYMS then took the chair, and delivered his inaugural address. The Doctor called attention to the successful work of Dr. Wiggin during the past year, to the new relation the New York County Medical Association bears to the State Medical Association, to the need of more thorough organization, and to the plan on which the State Medical Association has been organized.

A memorial address on the late Dr. Lewis Albert Sayre was given by Dr. John Shady, and one on the late Dr. Samuel Smith Purple was delivered by Dr. J. W. S. Gouley.

A LOVING CUP FOR DR. WIGGIN.

Immediately after the formal adjournment of the meeting of the Association, the audience was requested to remain seated, and then Dr. Wiggin was presented with a "loving cup" and an appropriate engrossed memorial, as a token of the high appreciation by the members, of his untiring and unselfish work for the Association while acting as its president.

Southern Surgical and Gynecological Association.

Thirteenth Annual Meeting, held in Atlanta, Ga., November 13-15, 1900.

(Concluded from p. 1426.)

RECENT TECHNICAL IMPROVEMENTS IN THE SURGERY OF THE STOMACH FOR CARCINOMA.

DR. WILLIS G. MACDONALD, Albany, N. Y., made reference to the early history of operations for the relief of this disease. The technique employed by Billroth in his first pylorotomy was the technique of operations done by most surgeons for a number of years, with very slight modifications. This earlier operation presented many technical difficulties in its performance. Any one, or a combination of symptoms, is a sufficient indication for operation: 1. A chronic gastritis which is progressive in character under proper dietetic, medicinal and

physical treatment. 2. A loss of gastric motility. 3. Progressive diminution of gastric peristalsis. 4. A diminution of free hydrochloric acid, progressive in character. 5. Emaciation of the patient under forced diet. 6. Reduction of the hemoglobin in the blood, progressive to 65 per cent. or under, and a moderate leucocytosis. The widest extirpation is demanded in carcinoma of the stomach. The author called attention to the careful investigation of Cuneo and Most with relation to the distribution of lymphatics and lymph nodes as associated with carcinoma of the stomach. In a complete pylorotomy, it is desirable to remove the lymphatics along both curvatures of the stomach as well as those lying behind the pylorus. As a rule, the duodenum is not extensively involved in pyloric carcinoma, although a few observers have found infiltration of Brunner's glands in the upper portion of the duodenum. There is little justification for the total extirpation of the stomach in the majority of cases, and the probability of cure will not be greater than surgical resection. The old rule of cutting 1 cm. beyond all evidences of carcinomatous infiltration is not wide enough. Personally, the author feels that the line of excision in the stomach should be at least 3 cm. from the border of the last palpable infiltration, and in the duodenum at least 2 cm. from the most dependent portion of the growth. The immediate mortality for the operation of pylorotomy is an interesting study. Ewald condemned the operation because of its great mortality, 73 per cent., and until 1888 the mortality was somewhere in the neighborhood of 60 per cent. The mortality of Billroth was 45 per cent., of Mikulicz 30 per cent., of Kronlein 25 per cent., of Maydl 16 per cent., and of Koerber 8.7 per cent. Mayo Robson, in a study of 572 cases, collected from various sources, finds an average mortality of 30.4 per cent. Guinard found that in 148 cases of pylorotomy with end-to-end anastomosis, deaths were 56, or 37.8 per cent., and in 64 cases of pylorotomy with subsequent lateral anastomosis, there were 10 deaths, or 15.6 per cent. This showing has been equally favorable in the experience of others.

MENSTRUAL CONDITION OF THE AVERAGE GIRL IN AVERAGE HEALTH.

DR. GEORGE J. ENGELMANN, Boston, presented an interesting statistical paper on this subject, and the facts presented by him were culled from the records of 4873 cases from high and normal schools, colleges and department stores, girls between 15 and 26, the majority between 18 and 22, in rather better than average health, in good health, and in numbers sufficient to admit of positive deductions as to what may be termed normal or average menstruation. In brief, the menstrual period proper is intensified by the increase of all vital energies, followed by a depression which appears with the coming of the flow. Under ideal conditions and in perfect health, the physiological status is such that this epoch, preceded by a day or two of heightened activity, is marked by a moderate lassitude, mental and physical, the flow persisting for from four to five days. It is a period of heightened susceptibility that quickly records any variation from the normal; excitement or exertion, or fatigue, mental or physical, is promptly reflected by variation in the function, and in our every-day life such disturbing elements constantly occur, so that conditions actually existing vary greatly from this ideal. The average period of the average girl in average health presents very different features: Regularity in 50 per cent. of the cases only; recurrence every twenty-eight days in 30 per cent., varying most frequently from twenty-six to forty-two days, 45 per cent. being over twenty-eight days. The duration varies from two to seven days, average, 4.6; from 66 to 70 per cent. suffer more or less, the number of sufferers varying according to age and nature of occupation, between 30 and 90 per cent. Lessened ability for exertion, mental or physical, is admitted by 60 per cent. Some few are habitually incapacitated from work, and 30 per cent. occasionally.

OPERATION FOR TREATMENT OF MARKED PROLAPSE OF RECTUM IN WOMEN.

DR. J. WESLEY BOVEY, Washington, D. C., described an operation for the relief of this condition. In his case marked prolapse of the uterus was associated with hemorrhoids and

great proctidemia of the rectum in a woman to whom the uterine appendages were of little value. No simple operation would have relieved the rectal condition while the uterus was in such a state of prolapse, and vice versa. These conditions caused him to resort to the unique radical procedure which he described by narrating the case.

CARBOLIC ACID IN SURGERY.

DR. SENECA D. POWELL, New York City, said that in 1894 he first became convinced that he could control the action of carbolic acid under all circumstances. At that time he used it in its full strength of 95 per cent. in an abscess cavity on a patient suffering from suppurative appendicitis. Since then he has extended its use to all cases where he has had to fight disease due to microbial infection, and he is now prepared to assert its safety and reliability, when properly brought in contact with an infected surface. He bases his statements on the results of treatment of hundreds of cases which have come to his clinic at the Post-Graduate Hospital, New York. The essayist quoted Phelps, of New York, as saying that to him (Dr. Powell) the profession is indebted for one of the most useful discoveries ever made in surgery, namely, the antiodotal effect of alcohol in carbolic acid. The speaker has used carbolic acid for years in the treatment of infectious and bone diseases in various parts of the body. He recommends its use likewise for crabs and abscesses. During the past six years he has treated every phase of microbial disease with this agent, and as early as 1894 hip-joint cases were treated by him with pure carbolic acid and with a large glass drainage-tube. Abscesses, wherever located, can be speedily treated by the injection of, or swabbing with, pure carbolic acid. The size of the abscess or the amount of surface covered is not a factor. Only thorough drainage and complete removal of the pyogenic membrane need be considered.

EARLY EXCISION FOR DISLOCATIONS NOT REDUCIBLE BY MANIPULATION.

DR. WILLIS F. WESTMORELAND, Atlanta, reported two cases of this condition in which he had operated successfully.

PLEA FOR THE BETTER APPRECIATION OF THE LIMITATIONS OF OPERATIVE WORK.

PRESIDENT A. M. CARLEDGE, Louisville, delivered the Address, with the above title. Every surgeon must be his own arbiter in deciding questions, and the judgment he displays will depend on his professional learning and wisdom. Methods of surgical diagnosis have undergone striking modifications within the past decade and have influenced operative work. The older surgeon made his diagnosis of abdominal and pelvic lesions slowly; his skill at that time consisting largely of a delicate sense of touch, trained eye to detect asymmetry, keen ears to differentiate sounds elicited by percussion, and methodical investigation of all symptoms, both subjective and objective. The result was, his diagnosis having been made, he next carefully, and with abundant time before him, considered the advisability of operative intervention.

In reviewing the field of abdominal and pelvic surgery, it would seem that surgical limitation is most often exceeded and mortality unnecessarily increased in operations for the following diseases: General septic peritonitis, extensive carcinoma of the ovaries, uterus and intestine, and operations on the gall-passages in long-continued and profound choleric patients without adequate preparation. He protested against the too frequent practice of operating in these affections. As to laparotomy in cases of general diffuse septic peritonitis, with irrigation and drainage, reports of such cases have appeared in literature from time to time, but the mortality up to the present time of such operations in exaggerated types of the disease is so great, in his opinion, as to make it an unwarranted procedure. He is strongly impressed with the belief that the successful cases reported have been cases of beginning general peritonitis, or of wide-extending, yet circumscribed peritonitis. In closing, the author impressed the importance of carefully preparing choleric patients before subjecting them to operation, with a view of lessening mortality. Another class of cases amenable to the same course of preliminary treatment are those of inefficient renal action.

EXCISION OF THE EXTERNAL CAROTID ARTERY IN CASES OF INOPERABLE MALIGNANT DISEASES OF THE FACE.

DR. WILLIAM P. NICHOLSON, Atlanta, reported two cases in which this operation had recently been done. The first case was a sarcoma of the nose, which began apparently as a polypus about eight months before. This was removed several times, but recurred promptly after each removal. When seen a few weeks before the operation this had extended sufficiently to completely obstruct the nose and cause great pain by constant pressure. At the time of operation this had progressed in a few weeks only so that the growth pressing under the orbit had forced the right eye out of position, and there had been also an extension on the forehead on the left side. The patient suffered intense pain, which required the constant use of morphin for its relief. The right common carotid was excised on October 3, and the wound healed promptly. The enlargement on the left side of the forehead broke down, and the large abscess was opened a few days after the operation. The pus from this, or the discharge from the nose, set up a violent ophthalmia, from which the patient suffered for a week or ten days. Two weeks from the day of the first operation the carotid on the left side was removed, and very soon the symptoms improved in every respect, the patient was relieved of suffering, and the growth not only checked, but it apparently began to recede with the prospects of a material improvement in his condition.

The second case was one of inoperable sarcoma of the upper jaw of three months' duration, and of very rapid growth. In this case the interval between the operations was longer than in the first, on account of the occurrence of a severe secondary hemorrhage on the seventh day, which was due to tying the vessel too close to the bifurcation. The first operation in this case relieved the patient of all symptoms caused by the rapidly increasing pressure, and the growth apparently subsided materially. The second operation had not been performed long enough to give much idea as to how much permanent decrease there would be in the tumor.

He had performed various operations on the external carotid artery in cases of malignant diseases, having tied the vessel twenty-six times, four of these being cases of double ligation. The operation had not been accompanied by any mortality. Little could be accomplished by simply ligating even both carotids, because the circulation was re-established so rapidly that the nutrition could not be cut off with any degree of permanence. The operation of excision, as recommended by Dawbarn, seemed to be the only procedure that offered any hope, and while this would not perhaps produce much permanent effect, yet it seemed undoubtedly true that the lives of patients could be much prolonged and their sufferings greatly lessened. The operation was one of considerable magnitude, and dealt with structures of great importance anatomically, yet the results demonstrated that there was comparatively little danger in the performance of it.

ALIMENTATION FROM RENAL INSUFFICIENCY WITH OR WITHOUT DISEASE OF THE KIDNEYS.

DR. JAMES T. JELKS, Hot Springs, Ark., for years has made it a point to examine the urinary output for twenty-four hours of every patient who consults him. This has been a revelation to him, and therapeutics based thereon has enabled him to accomplish what he described as marvelous results. Abundant evidence was adduced to show that as the result of faulty elimination by the kidneys, without the presence of disease in these organs, patients may have vertigo, contracted capillaries, cold skin, especially of the extremities, so-called sick headache, which is now recognized as uric-acid headache, melancholia, palpitation of the heart, interrupted heart-beat, various forms of skin diseases, rheumatism, gout, hysteria, epilepsy, and even genuine insanity. Among the remedies used to correct this faulty elimination are squills, milk, rectal or hypodermic injections of normal saline solution, digitalis or its derivatives, sodium phosphates, sodium salicylate, Vichy water, etc. All of these were used in connection with baths, where it was possible to give them, and the patients were ordered to drink from one-half to one gallon of hot water

daily. Twenty-five cases were detailed as having been treated along the lines mentioned, with the most gratifying results.

DR. GEORGE S. BROWN, Birmingham, made a supplementary report regarding a case of litholopaxy previously presented to the Association, and a supplementary report with reference to a case of vesico-rectal fistula.

DR. JAMES A. GOGGANS, Alexander City, Ala., reported one case of strangulated femoral hernia in a woman 40 years of age; three cases of extrauterine pregnancy; one case of thoracotomy for empyema, and one case of ovarian cyst.

SOME LIFE-SAVING MEASURES IN OBSTETRIC WORK.

DR. R. R. KIME, Atlanta—Leaving out of discussion instrumental deliveries, Cesarean section, symphysiotomy, etc., the author considered as the most important life-saving measures saline infusions, medicinal remedies, serum-therapy, hydro-therapy and drainage. All of these topics were taken up and discussed in consecutive order. In cases of placenta previa and post-partum hemorrhage saline infusions or intravenous injections are of prime importance, not only to save life, but to lessen susceptibility of infection and hasten recovery.

PSEUDO-MEMBRANOUS ENTERITIS AND ITS RELATION TO ABDOMINAL SURGERY.

DR. FRANK A. GLASGOW, St. Louis, was the author of this paper. He called attention to this very common disease, and urged physicians to study the relations of it to appendicitis.

SOLID OVARIAN TUMOR.

DR. JOHN G. EARNEST, Atlanta, reported a case of solid tumor of the ovary.

HISTOGENESIS OF OVARIAN DERMIODS.

DR. W. D. HAGGARD, JR., Nashville, gave a verbal abstract of a paper on this subject.

The following papers were likewise read and discussed: "Removal of Cystic Gall-Stones," by Dr. Howard A. Kelly, of Baltimore; "Osteo-Arthritis of the Spine," by Dr. Michael Hoke, of Atlanta; "Epi- and Hypospadias, With Special Reference to the Operative Treatment," by W. F. Parham, of New Orleans.

IRREDUCIBLE INCARCERATED RETROFLEXED GRAVID UTERUS.

DR. WILLIAM A. QUINN, Henderson, Ky., read a paper with this title, and reported the following case:

Mrs. S., a white woman, had had previously four normal labors. In her first there was a complete tear of the perineum. Her periods always had been normal and regular. She had never had a miscarriage. He saw the case about the middle of July in consultation with Dr. Dunn, the attending physician, who informed him that in his opinion it was an irreducible incarcerated retroverted gravid uterus. He stated that he and his colleague, Dr. Johnson, had carefully emptied the patient's bladder, and placed her in the knee-breast position; had exhausted their skill in efforts to replace the mass, but failed to do so. They then administered an anesthetic and tried replacement of the organ, but without success. On examining the patient, Dr. Quinn found the bladder enormously distended, reaching into the abdomen to a point about two inches above the umbilicus. It was emptied with difficulty by catheter, and a large, hard, unyielding mass, which completely filled the pelvic cavity, was found. The perineum having been previously torn, the tumor pressed down low on the pelvic floor. It was with difficulty that the index finger could be introduced into the vagina or rectum, and it was no easy matter to introduce a catheter into the bladder. The os was found flattened against the pubis and as high as the length of the vagina would let it rise, and could be reached with difficulty. The acute flexure was situated just above the internal os. The rectum was pushed against the sacrum until only soft ribbon-shaped feces could escape. The mass was found to curve very slightly from the arch of the pubis toward the promontory of the sacrum, under which it fitted snug and fast. On the most careful conjoined manipulation no elasticity or fluctuation could be made out. It seemed to be as unyielding as the hardest fibroid, and gave very much the same impression as does a large myoma which forms a perfect cast of the pelvis and becomes impacted. Medicine being of no avail, a spontaneous cure out of the question, and all efforts at relief by manipula-

tion having signally failed, resort to surgical interference was had. On August 3 a median incision was made, which exposed the uterus in extreme retroflexion, the fundus bearing hard down on the perineum, the organ resembling very much a tumor with a twisted pedicle. As the uterus could not be replaced it was lifted into the abdominal cavity. The tissues, which were softened and extremely vascular, had broken down under the operator's hands. The author concluded that if he closed and let the uterus and appendages remain with all of the necrotic tissue, the infection already existing would be increased, and death would undoubtedly ensue from septic peritonitis. Extirpation promised the best result, and this was done.

On examining the specimen the uterus was found to contain a fetus, the arrest of development of which seemed to have occurred between the fifth and sixth months of fetal life. The low fever, which had been present, continued for two or three weeks and delayed what would have been an unavoidably slow recovery, but the woman returned to her home in six weeks from the time of the operation, has since been able to attend to her household duties, and to take care of her children. He was not aware at the time of the operation that abdominal section had ever been advised or practiced before in cases of irreducible incarcerated retroflexed gravid uteri. The most recent works on obstetrics contain no mention of it.

In searching the literature the author finds that celiotomy has been done in these cases by seven surgeons, and said that to Dr. Mann, of Buffalo, belongs the credit of first doing celiotomy for this obstetric complication. Brief reports of the other cases found in literature were given.

Much to the regret of the members, Dr. W. E. B. Davis resigned the secretaryship, owing to the pressure of other duties, after having served the Association ably and efficiently from its organization to the present time. A resolution was offered and unanimously adopted, thanking Dr. Davis for his efficient services, tireless efforts, and faithful devotion to the interests of the Association during a period of thirteen consecutive years.

Officers elected for 1901: President, Dr. Manning Simons, of Charleston; vice-presidents, Drs. George H. Noble, of Atlanta, and L. C. Bosher, of Richmond; secretary, Dr. W. D. Haggard, Jr., of Nashville; treasurer, Dr. F. W. McRea, of Atlanta.

Richmond, Va., was selected as the place for holding the next annual meeting; time, third Tuesday in November, 1901.

Therapeutics.

LA GRIPPE.

Influenza is a disease that varies greatly in its effects on different individuals and which produces so many symptoms in so many different organs of the body that it is indeed difficult to formulate any special lines of treatment, and, as Yeo states, when a practitioner advertises that he has given potassium bicarbonate in five hundred cases without a death, and another that he has given salicin in one thousand cases without a death, they make statements that are worse than useless, because they are misleading. He, however, places quinin as the most deserving drug in the treatment of influenza, giving it in combination with potassium citrate and ammonia in effervescence, and in small or moderate—not large—doses, frequently repeated. Mossé, in the *Lancet*, has shown that the bacillus of influenza is unable to live in an organism in which quinin circulates.

Below are given other prescriptions as suggestions in treatment of the different complications which may arise:

R. Hydrargyri chloridi mitis.....gr. iss 109
Ft. pulveres No. vi. Sig. One powder every hour until there is a good bowel movement.

H. C. Wood, in *Philadelphia Medical Journal*, advises the following in la grippe:

R. Antipyrinigr. xv 1
Pilocarpina hydrochloratisgr. ss 103
Tinct. aconitim. iiii 2
Aque destil.ssiss 48

M. Sig. One tablespoonful, immediately followed by a hot general bath, or a footbath for ten minutes; then the patient, being covered in bed, one desertspoonful in a glass of hot

toddy, repeated, if no sweating occurs, in twenty minutes. When there is pain, if morphin does not disagree with the patient, one-sixth of a grain may be added to the mixture.

Hening, in "The American Text-Book of Therapeutics," advises the following:

R. Salipyrini3i 4
Glycerini3iiiss 14
Syrupi rubi idæi3i 32
Aque destil.3iiss 48

M. Sig. Shake well, and take a tablespoonful every fifteen or thirty minutes.

Salipyrin is obtained by the interaction between antipyrin and salicylic acid—57 parts of the former to 43 parts of the latter. It is soluble in 200 parts of cold water and 20 parts of boiling water.

LINIMENT FOR PAINS IN THE BACK AND LIMBS.

R. Spts. chloroformi
Tinct. aconiti
Spts. camphoræ, aa.....5ss 16
Olei olivæ3iiss 80

M. Sig. Apply with friction to the painful parts.

FOR THE PAIN.

R. Codeinægr. iv 25
Phenacetini3i 4
Sodii bicarb.5ss 2

M. Ft. chartulæ No. xii. Sig. One powder every four hours.

R. Quinina hydrobromatisgr. xxxvi 236
Salolgr. xxx 2
Codeinægr. iv 25

M. Ft. capsulæ No. xii. Sig. One capsule every three hours.

R. Sodii salicylatis3i-ss 6
Liq. ammon. acetatis3ii 64
Aque camphoræ, q. s. ad.5vi 192

M. Sig. One tablespoonful every three hours when the first symptoms appear.

COUGH IN INFLUENZA.

R. Sodii benzoatis3i 4
Bromformid. x 66
Syr. toluanti3i 32
Syr. factuæarii3iii 96

M. Sig. One tablespoonful every three hours.—*Med. News.*

THE FEVER IN INFLUENZA.

R. Quinina salicylatisgr. xlv 31
Phenacetinigr. xxxiv 225
Camphorægr. vi 4

M. Ft. capsulæ No. xv. Sig. One every four hours.—Bacelli.

INFLUENZA WITH NAUSEA.

R. Morphina sulphatisgr. ss 103
Acidi hydrocyanici dil.m. viii 5
Spts. chloroformi3iiss 6
Aque mentha viridis, q. s. ad.3iiss 48

M. Sig. One teaspoonful every three or four hours, where there is nausea and troublesome cough, but when the bronchitis is not severe.—*Med. Progress.*

TO RELIEVE THE MUSCULAR PAIN AND CAUSE DIAPHORESIS.

R. Sodii salicylatis3i 4
Ext. nucis vomicegr. iii 20

M. Ft. capsulæ No. xii. Sig. One capsule every four hours.

FOR THE COUGH.

R. Liq. morph. hydrochloratis
Acidi hydrobromici dil., aa.....3i 4
Spts. chloroformim. iiii 2
Tinct. limonis3i 4
Syr. simplicis, q. s. ad.3iiss 48

M. Sig. One teaspoonful for the cough, and repeat in two hours if necessary.

CATARRAL PHARYNGITIS OF LA GRIPPE.

R. Morphina sulphatisgr. vi 36
Acidi carbolic
Acidi tannici, aa.....3i 4
Glycerini3i 32
Aque destil., q. s. ad.3ii 64

M. Sig. Use as a spray night and morning.—Ingals.

PULMONARY COMPLICATIONS IN LA GRIPPE.

R. Ammonii chloridi3ii 8
Apomorphina hydrochloratisgr. i 06
Mist. glycyrrhizæ comp.
Syrupi simplicis, aa.....3iiss 48

M. Sig. A dessertspoonful every two hours.—H. C. Wood.

FOR THE CORYZA.

R. Thymol		
Menthol, āāgr. i	06
Liq. absolemeʒi	32

M. Sig. Use as a spray in the atomizer three times a day.

INSOMNIA IN LA GRIPPE.

R. Chloralamidʒi	4
Ft. chartula No. iv.	Sig. One at bedtime in cold water.	
R. Sulphonalʒi	4
Ft. chartula No. iv.	Sig. One powder in hot water two hours before going to bed.	

STOMATITIS OF LA GRIPPE.

R. Acidi lacticigr. xxxvi	2 36
Spiritus menthe pip.m. x	66
Aque destil.ʒviii	256

M. Sig. Wash the mouth twice daily with this lotion.

If there is suppuration in the tonsillar crypts apply the following:

R. Acidi salicyliciigr. x	66
Alcoholis, q. s. ad., to dissolve		
Glyceriniʒiiss	48
Aque destil.ʒiii	64

M. Sig. Use as a gargle twice daily.—*Præsse Médicale.*

INFLUENZA IN CHILDREN.

R. Sodii benzoatis		
Salol		
Acetanilidi, āāgr. xxiv	1 5
Caffeina citrategr. iv	25

M. Ft. chartula No. xv. Sig. One powder every three hours to a child 6 years of age; if the pain is severe and the child is kept awake, add 1/12 grain of codein sulphate to each powder.

If a mixture is desired, give the following:

R. Sodii benzoatis		
Antipyrini		
Liq. ammon. acetatis		
Syr. seille comp., āāʒii	8
Syr. altheæʒss	16
Aque anisi, q. s. ad.ʒii	64

M. Sig. One teaspoonful every three hours to a child of 6 years. —H. B. Sheffield.

Rigidity of the Perineum.

R. Spts. etherisʒi	32
Spts. chloroformiʒii	64
Eau de cologneʒi	32

M. Sig. For external use to the perineum.—Southworth.

To Prevent Bedsores.

R. Aluminis		
Sodii chloridi, āāʒss	16
Aque		
Alcoholis, āāOi	512

M. Sig. Apply locally night and morning. —Forbes: *Maryland Med. Jour.*

To Promote Uterine Contractions.

R. Quinina sulphatisgr. xi	2 66
Acidi sulphurici arom., q. s. ft. sol.		
Syrupi zingiberisʒi	32
Aque, q. s. ad.ʒi	64

M. Sig. Initial dose, one tablespoonful; afterward, two teaspoonfuls every four hours. —Ringer.

Epicarin in Diseases of the Skin.

The *Medical News* speaks at some length concerning this therapeutic agent. It is a combination product of kresolin and betanaphthol, and is very soluble in alcohol or ether. It is slightly yellowish in color and non-toxic in character.

Kaposi employs it in the following combination:

R. Epicarinʒiiss	10
Spts. vini galliciʒiii	96
Spts. lavandulaeʒvi	24
Glyceriniʒiiss	10

M. Sig. Use as a wash two or three times daily.

In scabies it is best applied in a 10 per cent. ointment with vaselin or lanolin. For scabies, eczema squamosum and herpes tonsurans the above combination is very applicable.

Hydrogen Dioxid in Tinea Favosa.

Dr. Simonelli states, in *Merck's Report*, that he has successfully employed hydrogen dioxid in three cases of tinea favosa. The application was made by saturating compresses in dioxid of 10 to 12 per cent. strength. Epilation was required only once and the patients made a much more rapid recovery than is usual by any other method.

Quinin in Carcinoma.

Jaboulay's experience with three patients who had inoperable carcinoma and whom he treated with hypodermic injections of .5 to 1 gm. of quinin hydrochlorate daily, indicates that possibly he is correct in his assumption that the parasite of cancer may belong to the protozoa group. As reported in the *Semaine Médicale*, the recurring neoplasms were all reduced in size, the cerebral and other complications were cured, and marked relief was experienced in each case. Insomnia that had persisted for six months was completely cured in one case.

Ichthyol in Scarlet Fever.

The *Maryland Medical Journal* contains the following from the pen of A. Seibert, in *Jahrbuch f. Kinderheilkunde*:

In fifty-six cases of scarlet fever inunctions of a 5 to 10 per cent. strength of ichthyol in lanolin have been employed with the following results:

1. The edema of the skin is relieved.
2. The itching is relieved.
3. The fissures and secondary erysipelatous infections are prevented.
4. The temperature falls after a few hours, 1 or 2 degrees.
5. Restlessness and insomnia are avoided and postscarlatinal nephritis prevented.
6. The ichthyol renders the scales less infectious.

Salol in Diabetes.

A report of the value of salol in the treatment of diabetes, by Dr. Zandy, may be found in *Merck's Report*, in which he states that when his patient was seen for the first time he was passing 250 gm. of sugar daily in three or four quarts of urine. He placed the patient on the proper diet and administered alkalies, which diminished the daily output of sugar to about 40 gm., at which point it remained stationary until he commenced the administration of salol. The patient was given four daily doses of 1 gm. each for four days, at the end of which time only a trace of sugar could be found. And a discontinuance of the drug was followed by a slight increase of sugar, after which there was complete and permanent absence of sugar in the urine, despite the gradual deviation from the restricted diet. The patient was seen nine months later and the urine contained no sugar, although he had paid no attention to diet in the meantime.

Medicolegal.

Ten Thousand Dollars for a Boy's Foot.—The Court of Appeals of Kentucky holds, in the case of the Chesapeake & Ohio Railway Company vs. Davis, that, while a verdict of \$10,000 is large for the negligent injury of a boy 9 years of age, rendering the amputation of one of his feet necessary, it is not an excessive award of damages for the pain and suffering endured and the impairment of his ability to earn money by reason of the injury.

County is Not Liable for Not Establishing Hospitals.—In the case of Bell vs. the Commissioners of Johnston County, the Supreme Court of North Carolina holds that no action for damages for personal injuries will lie against county commissioners in their corporate capacity, or, in other words, against the county, for their failure to establish hospitals, under section 707 of the state code, which empowers boards of county commissioners to establish public hospitals for the county in cases of necessity.

Risk of Frostbite Assumed.—In reversing, in the case of the Yazoo City Transportation Company vs. Smith, a judgment which a deekhand obtained for a loss of three fingers from frostbite, the Supreme Court of Mississippi declares that a laborer must be presumed to have knowledge, equal if not superior to his employer's, of the effect of cold upon his feelings and person. His own temperament is better known to him than to any one else, and his own sensations sound the alarm to himself. Men are presumed to have ordinary common sense, until the contrary is shown, and the law, the court holds, does not speculate on degrees of knowledge about weather.

Seventeen Hundred Dollars too Much for Fracture.—The Supreme Court of Wisconsin says that the evidence in the case of Collins vs. the City of Janesville tending to show permanent injury was, at best, very doubtful. The injury was a simple fracture, in a girl thirteen years of age, of the fibula,

which reunited in the ordinary course and under ordinary surgical treatment, so that, in the opinion of a majority of the medical experts, there had been a complete recovery. To this, it adds that the plaintiff walked with no limp, or, at least, with one not ordinarily perceptible, and only complained of some pain in rainy weather. The jury awarded her \$2,500 damages. The trial judge demanded that \$800 be remitted therefrom, and, this being agreed to by the plaintiff, entered judgment for \$1,700. But the supreme court holds the amount still excessive, declaring that it sees nothing to justify so large a recovery.

Can Not Ask Experts What Should be Extent of Injuries.—The Supreme Court of Illinois holds, in *Hellyer vs. People*, a homicide case, where the defense was that the deceased had been killed by being struck by a railroad train, that it was error to ask physicians who had seen the bodies of persons who had been killed by being struck by moving trains whether it would be possible, in their opinion, for the death of such person to have been caused by being struck by a train of certain weight and speed without producing other external and internal injuries than those described in the case. The supreme court condemns the evidence as being negative in character, anticipating the defense, and not being competent as opinion or expert testimony. The subject of the inquiry, it goes on to say, was a matter of common observation, upon which the lay or uneducated mind is capable of forming a correct judgment. And in regard to such matters experts, it declares, are not permitted to state their conclusions. In questions of science their opinions are received, for in such questions scientific men, it says, have superior knowledge, and generally think alike. Not so in matters of common knowledge.

Expert Testimony Based on Supposed Previous Habits.—The Court of Appeals of Kentucky says that it can perceive no error in the rulings in the homicide case of *Bishop vs. Commonwealth*, where the testimony of one physician was excluded entirely, and another one was not permitted to answer a question in regard to a hypothetical case. Each was asked if he had any experience in the treatment of persons suffering from excessive smoking of cigarettes or drinking of whisky, and responded in the affirmative. But for all that appeared in the record, neither of them had ever seen an insane person. Under these circumstances, neither doctor, the court holds, qualified as an expert upon the subject of insanity. Moreover, had the medical witnesses been qualified as experts upon the subject, the court says that it thinks that the same rule should be applied to expert testimony based solely upon a supposed case of previous habits which might tend to produce mental unsoundness as is applied to the introduction of testimony showing an ancestral taint as a fact tending to produce the same result, viz., that it can not be introduced, in the absence of other independent testimony, to show that the defendant was himself insane at the time of the killing.

Dying Declarations Not Barred by Physician's Hope.—Declarations made by one actually in a dying condition, and conscious of the fact, the Supreme Court of Georgia holds, in the case of *Wheeler vs. State*, are admissible as dying declarations, notwithstanding the fact that a physician, either before or after such declarations were made, informed the declarant that there was a chance for him to recover. For example, in this case, certain alleged dying declarations were made both before and after a physician informed the declarant that there was a chance for him to recover if an operation was performed. The evidence, however, showed that the declarant stated, at the time he made the declarations, that he was going to die, and that there was no chance for him, and that he did die within less than a day thereafter, despite the surgical operation. Under these circumstances, the court thinks that the declarations were properly admitted in evidence, as being *prima facie* dying declarations; the jury being instructed to consider them as evidence in the case only in the event that they believed the declarations were made in the apprehension and immediate prospect of death, and in the article of death.

Regulation of Sale of Proprietary Medicines.—The Supreme Court of Illinois, in *Noel vs. People*, holds unconstitutional

so much of the pharmacy act of the state as restricts the sale of patent and proprietary medicines and domestic remedies by any other person than a registered pharmacist. It is unquestionably true, it says, that the state has as much right to regulate the sale of patent and proprietary medicines and domestic remedies as it has to regulate the sale of any other kinds of medicines and remedies. But such medicines and remedies are generally put up in sealed packages, in which form they can as well be sold by any person as by a registered pharmacist. True, it was contended that registered pharmacists are more likely to know the qualities of these patent medicines than other persons who are not registered pharmacists. But the court's answer to that is that registered pharmacists will be as apt as other men to sell such patent medicines as there is a public demand for, when they are relieved of all responsibility for the character of such medicines, and are not required in any way to guarantee their character or adaptability to the cures which they claim to effect. So it concludes that the public health is not protected by limiting these sales to registered pharmacists, who make no examination of what they sell, and hence holds that the monopoly conferred on them by this portion of the pharmacy act is unconstitutional. It also condemns the act in so far as it confers upon the board of pharmacy the power, in its discretion, to issue permits to persons, firms or corporations engaged in business in villages or other localities, empowering them to sell the usual domestic remedies and proprietary medicines under such restrictions as the board may deem proper. A law which thus invests any board or body of officials with a discretion which is purely arbitrary, and which may be exercised in the interest of a favored few, the court holds, is invalid. However, while the court for these reasons holds the pharmacy act to be invalid in the respects pointed out, it yet holds it to be valid, so far as it applies to persons retailing, compound or dispensing drugs, medicines or poisons where the person so retailing has at the same time, put up or prepared or compounded the drugs or medicines, so sold by him.

Foreman Not Authorized to Employ Physician.—The Court of Appeals of Kentucky holds, in the case of *Godshav vs. J. N. Struck & Co.*, that a foreman, as for example one of workmen engaged in the construction of a building, has no implied authority to employ a physician to attend an injured workman. It says that to support a contrary contention it was referred to a number of cases decided by courts of other states, which related to the employment of a surgeon by some officer of a railroad to administer to an injured employee or passenger in certain cases, by reason of special circumstances. But it points out that railroad companies occupy a peculiar position with reference to such matters, and that it is of common knowledge that they habitually and regularly employ surgeons and physicians in connection with the conduct of their roads. Then, several cases were cited where it was sought to hold manufacturing companies liable on the same principle that the emergency would authorize it. However, in each of those cases the employment of the surgeons was made by the general business manager of the company or the general superintendent of the company, and the court does not think that such a case as this one of a foreman could be brought within the rule laid down in any of these cases. Moreover, it says that it was referred to no cases where it was held to be within the duties of the manager of a factory for either an individual or corporation to employ physicians or surgeons for employees. And it declares that it is not prepared to hold as a matter of law that the employment of physicians or surgeons for injured employees come within the scope of the duties of a general manager of an ordinary manufacturing business. In other words, it seems to it that the rule which it was sought to have applied in this case is confined exclusively to railroad companies, and, generally, in cases which involve some act of negligence on the part of the company which occasioned the injury. It also makes the point that the services sued for were not confined to the immediate emergency, but lasted during a period of several months. Besides, some importance is attached to the fact that the employers sought to be charged resided all the while in the same city, and only a short distance from where the physician

being lived, and that it would have been very easy for him to have inquired as to the alleged authority of the foreman to act for them. Nor, it holds, could there be anything like ratification by them so long as they knew nothing of the alleged employment. Usually, too, the court says, an injured employee procures and pays for his own doctor, and if his employer can be made liable for his injuries he recovers this sum, with other damages. It also remarks that in this case no necessity was shown why the employers should have selected the physician to treat the injured man during the long period of his confinement as it did not appear that he lacked friends or relatives who were both willing and able to do so for him.

AMERICAN.

1. **Conveyance of Yellow Fever Infection.**—Cobb questions the deductions of Reed as to the conveyance of yellow fever by mosquitoes and gives some facts which he thinks point to the conclusion that it may be otherwise conveyed. He is prepared, he says, to believe that not only mosquitoes, but bedbugs and fleas, may convey the disease, and he has not seen any reasonable cause for the suppression of the disease in certain sections of Georgia and South Carolina, which are practically free of mosquitoes, unless it were that this insect does convey the infection; but it is discouraging, he says, to think that the mosquito is the sole conveyor of this disorder, for we can not in that case expect to confine the disease to each infected house as we have hitherto tried to. Some infected mosquitoes would undoubtedly escape to other houses, but this does not seem to have been the experience of the Marine Hospital officers, for they have succeeded in shutting up the disease in infected dwellings.

2. **Malta Fever in Manila.**—Strong and Musgrave report a case of fever which was somewhat misleading and was thought at first to be one of typhoid without intestinal lesions. The bacteriologic cultures at first were sterile, but on the

fourth day a micrococcus morphologically and culturally like micrococcus melitensis was obtained. They have since seen another fever case where these same micrococci were found and which led to death at a later date. There were also found three cases which gave marked reaction with micrococcus melitensis in high dilution. One of these cases was diagnosed malarial remittent fever though no malarial plasmodia could be found. Neither of the cases gave the Widal reaction nor were any malarial parasites present. He suggests that there are many fevers which are difficult to place nosologically, and that this discovery may, therefore, be of advantage.

7. **Apparent Abdominal Tumors.**—The class of cases here described by Einhorn are not those due to swellings caused by prolapse of the whole liver, kidneys or spleen, but are swellings found either directly in the epigastrium or in the left or right hypochondrium and which have nothing to do with a neoplasm of any kind. The author avoided also in this class what are called "phantom tumors," due to a high degree of meteorism. The cases here described varied in size from that of a hen's egg to that of a man's fist, and light percussion always elicited a dull sound. Out of 6405 patients he found only 42 cases, 8 in men and 34 in women. Four cases are reported and nearly the whole number are tabulated briefly. They are due to an enteroptosis, and great emaciation and removal of certain abdominal organs such as the uterus, or vagina are also important factors in their development. The treatment is not to be applied to the tumor itself but to the original condition. The patient's attention must be distracted from its existence or the mind assured and sufficient nourishment must be prescribed and persisted in.

8. **Myasthenia Gravis.**—Brown reports a case in which he describes the general conditions known under this name. It is usually the result of some prostrating disease, sometimes preceding the affection, and anemia is often met with in women. The onset is usually gradual, though it may be sudden. The first symptom is usually a characteristic weakness of some of the muscles supplied by the cranial nerves, but it may begin in the extremities or in any of the functionally-grouped voluntary muscles. The most prominent symptom is the profound exhaustion on comparatively light exercise. The symptoms are generally bilateral, though there may be a variation between the two sides. Among the muscles that are affected may be mentioned those of the jaw and pharynx. Alterations of speech are almost invariably present; it becomes nasal, and the words grow more and more indistinct until the patient is forced to desist, from mere exhaustion. Inability to support the head is common, and if the respiratory muscles are involved and cannot recuperate by rest, fatal results may ensue. The symptoms may almost wholly and unexpectedly remit for a short time; the muscles react normally to electricity, but speedily become exhausted. Atrophy is never present in pure cases and the skin-reflexes and muscle-jerks are not materially disturbed. The sphincters are never disturbed and there are no trophic or sensory changes. Muscular inco-ordination has never been observed. Emotional excitement, cold weather and menstruation have been known to aggravate the condition. Though in the sixty cases referred to by Campbell and Bramwell seventeen came to autopsy, in only six was anything found which could possibly account for the symptoms. The author believes that the symptoms point to a toxic agency, and to the bodies of the peripheral motor neurons as the main point of attack of the toxin but of such a nature as to produce no demonstrable changes in the organic elements involved. Dr. Buzzard, of London, has shown that there is, in this disease, a typical temporary degeneration reaction, and this implies necessary functional integrity of the muscles and, at the same time, suspension of the functional activity of their peripheral motor neurons. The diagnosis is important; it is easy when the symptoms appear in the external ocular muscles or those of the tongue and mastication, and when the peculiarities of speech are manifest, but there is an infinite amount of hysterical conditions which give trouble. When it is far enough advanced to suggest bulbar palsy or polio-encephalitis, the course, the distribution of the weakness and the presence of muscular atrophy in these later conditions are significant. Out

of sixty cases twenty-three ended fatally. The average duration of the disease is one and one-half years. Death usually occurs from asphyxia, a fact which greatly increases the gravity of any pulmonary diseases in these cases. Some patients improve, however, for a while, and others recover permanently. Many drugs have been tried, but none have been found to have specific influence over the disease. Brown would like to see nitrate of strychnin tried hypodermically in 1/16 gr. doses. All general measures calculated to maintain the health, consistent with the symptoms, should be tried. If, finally, there is failure of muscles of deglutition and the stomach-tube has to be used it should be done with caution.

10. Carbonated Saline Baths in Gynecology.—The general effect of the bath is described by Bandler, and particularly the effects of the Nauheim baths or similar ones. They bring about, according to him, the following results: 1, slowing of the pulse and respiration; 2, increased oxidation; 3, increased diuresis; 4, a saving of phosphoric acid; 5, rest and protection for the heart; 6, regulation of the circulation and subsequent strengthening of the heart through increased tonus of the entire circulatory system, and through the removal of congestions; 7, an increase in the number of red blood-cells; 8, a building up of healthy tissue; 9, increased demand for nutrition; 10, a stimulation of the entire nervous system, especially the trophic centers; 11, the removal of congestion; 12, the resorption of exudates. Their value has been proved in amenorrhea, in insufficient development of the genitalia and muscular insufficiency of the ureters with or without chlorotic symptoms. Uterine catarrh depends on the lack of elasticity of the pelvic organs, and atony of the vessels is greatly benefited. In chronic metritis the bath induces a diminution of hyperemia, removes collateral circulatory disturbances and improves the general condition. Cases of chronic metritis after repeated abortions, or during the climacterium, should not be treated with strong saline baths, but as a rule the older the affection the more energetic the treatment. Nervous persons must be given graded treatment, and in these, as in anemic cases progress must be made slowly. As the entire energy is employed in preserving the balance between nutrition and force used in the performance of most necessary body functions, the slightest degree of over-stimulation is of decided injury. He gives briefly the results of experiments with cases, and says he believes pelvic inflammation of the adnexa curable by this method. Cases quite hypertrophic are decidedly benefited, all the patients gain in weight and strength, and in several the red blood-cells were constantly increased; the appetite, strength and general well-being were improved, as no other treatment he thinks could do it. One case of oophoritis was not either locally or generally improved. It was probably one of anatomical cystic change in which no benefit to local conditions could be expected. He says in conclusion: I believe that the results obtained justify me in claiming for the carbonated saline baths a power of resorption too valuable to be underestimated, a method which at the same time benefits the general state to a decided degree, and which acts by increasing the natural and effective functions of the body, and in toning up those pelvic structures which depend so decidedly for their elasticity and blood-supply on the condition of the body generally.

13. Physical Training for Women.—In this conclusion of his article the first part of which discusses the purposes and fundamental principles of physical training for women, Saxe describes the equipment of gymnasiums, the dress to be worn during gymnastic exercises, the poise of head and body in walking, breathing exercises, with reference also to the tone production of the voice.

14. Eczema.—Bulkeley notices the factors in the etiology of eczema, such as sedentary occupation, and such as requires long standing and confinement in bad air, the factors of disease, such as exanthemata, exhausting diseases, malaria, accidents and surgical operations, and the exciting causes which he divides under two heads: internal and external. Of the former, defective nutrition appears to be among the most important though little appreciated. Excessive and defective diet is the cause of very many diseases, both where hereditary

influences are at work and also where these are lacking. Defects also of clothing, bathing and exercise, defective assimilation and excretion, auto-intoxication and neurotic conditions are also mentioned. Of the external exciting causes he enumerates the atmospheric influences of heat and cold, especially as shown in infantile eczema, barometric disturbances, which seem to have an influence, and the seasons. Amongst mechanical irritants he mentions scratching and friction of clothing, etc. Among the chemical irritants he enumerates various anilins and other dyes, lime, arsenic, various local applications used medicinally, and among the vegetable irritants he lists poison ivy, arnica, thapsia, croton-oil, capsicum and even mustard. Disordered sweating and urine in contact with the skin will also produce eczema at times, and the parasitic causes are numerous, some of which are familiar. The influence of micro-organisms proper, in the production of eczema, has been brought forward prominently by Unna, who holds that all eczema is due to microbial infection. The conclusions in regard to this question brought out in the discussion before the International Medical Congress last year, and given in the *British Journal of Dermatology*, are here reproduced.

15. Post-Operative Hemorrhage.—The conclusions of Cordier's article are as follows: 1. In diagnosing post-operative hemorrhage, the operative history will aid much. 2. The symptoms of shock and those of hemorrhage are very similar. 3. In suspected cases the cutting of a single stitch in the incision will tell. 4. The surgery must be quick and decisive in these cases. 5. In cases in which bleeding is expected the tube should be used. 6. Large quantities of normal saline solution will save many patients. This should be used both *per rectum* and by injection into the veins. 7. Strychnin, belladonna, etc., will not control bleeding from a uterine or ovarian artery any better than from any other artery. 8. The surgeon should do what his surgical conscience tells him is right. Late researches in hematology make it appear that an internal concealed hemorrhage may be demonstrated by a careful blood-count. This, it is stated, will show a decrease in the red cells and an increase in the white. Similar symptoms accompany shock from various causes, such as internal hernia, etc., none of which produce a change in the red cells. If an operation was performed for the relief of an inflammatory process, this test would lose its value in part, as there would exist at the time of operating a leucocytosis. Saline infusions apparently increase the white cells at first.

16. Spasmodic Wry-Neck and its Treatment.—Dr. W. M. Leszynsky, of New York, reports two cases with recovery. Both patients were young married women aged respectively 24 and 36 years, in whom the condition had existed for seven months. The sternomastoid, trapezius, and splenius capitis muscles were involved. The treatment that led to a successful result was daily massage of the neck muscles, passive movements of the head and neck, and systematic voluntary exercises with and without resistance. He had resorted to the subcutaneous injection of atropin in twelve cases of clonic wry-neck, and believes that while atropin may prove exceedingly beneficial, may, even curative in some cases, it is unsatisfactory in many others, and should only be utilized as an adjunct to absolute rest and general management. In his opinion, the principal therapeutic feature in every case should be the rational use of massage and the methodical education of the muscles and their co-ordinating centers. Such measures, in conjunction with rest in bed and general tonic treatment, should be thorough and persistently carried out before surgical intervention is considered. He concludes that the most important point is to treat these patients in the manner recommended, as soon as the disease is recognized. If this could be accomplished, fewer cases would advance to such a stage as to come within the legitimate field of surgery.

17.—See abstract in THE JOURNAL of November 3, p. 1172.

18. Edema Bullosum Vesicæ.—Bierhoff describes cases in which he found the bullous edema of the vesical mucosa in cases of carcinoma, catarrhal cystitis of the vesical neck and gonorrhœal disorders. The symptoms in each of the patients were those of the original condition, cystitis or urethritis, viz.,

abnormally frequent urination, with a varying degree of pain or tenesmus. He is not inclined to ascribe decided diagnostic value to this phenomenon, as it seems to accompany many different inflammatory or infiltrative processes.

19. Ugly Ears.—This paper of Roberts is intended to call the attention of the profession to the possibility of improving many auricular deformities with modern aseptic surgery. It is more worthy of attention, he thinks, because the operative treatment is free from risk and easily done, not often requiring confinement to bed or even absence from business pursuits. A lacerated or incised ear should be subjected to thorough sterilization and carefully sutured, bringing the parts together; fine silk is probably the best suturing material. After the removal of tumors or occurrence of sloughing from burns, frost-bite or injury, much artistic skill is sometimes required, and it may be well to operate on the uninjured ear to make it correspond to its fellow. If material is needed to take the place of lost tissue it should be transferred from the neck, cheek, or transplanted from the hand, abdominal wall or thigh. Some deformities or distortions can be corrected by orthopedic means, and it has been suggested to imbed plates of platinum to give rigidity to lacerated parts. Very large ears can be reduced by excision of a wedge-shaped, or by removal of a crescentic, piece from the central portion. Sutures are then employed to sew the auricles close to the skull; bandages or spring pads are to be used to prevent tearing of the scar tissue by unexpected movements during sleep. Absent ears, from a want of development, may be represented by celluloid, papier maché or platinum constructions, or repeated plastic operations may successfully make some representation of the normal ear.

22. Tuberculosis.—The chief subject of Beard's paper is the necessity of curative resorts for consumptives under natural conditions by the reservation of parks, and especially the proposed Minnesota National Park.

23. Diphtheria in Non-Diphtheric Cases.—The occasional presence of the Klebs-Loeffler bacilli in the mouths of healthy individuals has long been known and certain authors have reported large proportions in persons where they were found. Denny has examined the cultures of 285 healthy individuals in the Brookline Board of Health Laboratory and in only seven found in the presence of diphtheria bacilli. This shows the comparative rarity of the condition in suburban communities living under good hygienic surroundings. He also examined cultures from 190 healthy boys in the Municipal School for Truants in West Roxbury, Mass., and in 16 of these had positive results. Fifteen of these 16 lived in a building where they slept in large open dormitories, and this accounts for the larger proportion, as five cases of diphtheria had occurred among the 120 boys sleeping in the dormitories. He says: 1. Diphtheria bacilli are seldom found in the throats of those who have not been exposed to diphtheria. 2. The bacilli are more frequently found in those who have been exposed, especially in persons living under poor hygienic condition or in institutions. 3. The conditions of institution life which favor the growth of the bacilli in healthy throats are the living together of a large number of persons in a limited air space. 4. Healthy individuals with virulent bacilli in their throats can spread the disease. They are just as dangerous as mild or convalescent cases of diphtheria, and ought, therefore, to be detected and isolated. 5. Cultures ought to be made among those who have been exposed to diphtheria: By physicians among the members of a family who have been exposed; by inspectors in the schools; by health officers under any circumstances when they think the disease is being or may be spread by such individuals.

24. Chronic Diffuse Interstitial Nephritis.—Enebuske gives an account of the general and special symptoms and the pathologic anatomy of this disorder with special reference also to its diagnosis and treatment. Formerly if the patient revealed a pulse of high tension with increased area of cardiac dulness, the second aortic sound accentuated with ringing quality, the urine of low specific gravity in increased amount with a trace of albumin and some few hyaline or fine granular casts it would have been justifiable to make the diagnosis of

chronic interstitial nephritis. More reliable observations of recent date have induced some reserve in drawing conclusions, and he says albumin and casts are not always present, high-tension pulse and accentuated aortic second sound have been found to exist in advanced age, without any renal lesion, and the dislocated apex-beat with increased cardiac dulness may be simply the expression of idiopathic hypertrophy. The diagnosis can not be made with certainty from any single examination or from any formula of symptoms. It requires repeated examinations during a sufficient length of time to establish the persistence of sounds and its history and etiology must also be considered. The differentiation of chronic nephritis and secondary cirrhotic kidney must not be made before a consideration of all the facts in the history of the case has been learned and the persistence of symptoms noted. The prognosis is generally admitted to be unfavorable, though under good régime the patient may live for many years without apparent disturbance. When the heart fails, weakness, dyspnea, and dropsy will appear, at first amenable to treatment, but increasing later in spite of it. Severe edema appearing well on in the disease is a serious symptom, and there is a constant danger of uremic intoxication, which is often fatal. Nevertheless, even with severe symptoms—Cheyne-Stokes respiration, persistent vomiting and edema—the patient may live for months. Cabot and White have found from the Massachusetts General Hospital records 17 complete recoveries out of over 300 cases, and cases of eight or ten years' duration are not unusual, and there have been cases recorded up to twenty or twenty-nine years. The leading indications of treatment are to avoid irritation of the kidney and overwork of the heart. The diet must be adapted to the individual, over-eating avoided generally, both starchy and nitrogenous foods restricted and fats given generously, and the skin kept active. Physical overwork and mental worry should be avoided, but moderate exercise and recreation and rest encouraged. The several symptoms must be treated as they arrive. Iodid of potassium, nitroglycerin and chloral hydrate are important for their effect in reducing arterial tension. The leading indication in the early stage is to dilate the arteries and reduce tension, later when compensation is weak the indications are: 1, to increase the systolic stroke of the heart, 2, to relieve the venous hyperemia of the abdominal organs and the lungs when such exists, and 3, to relieve the edema. Experience with regulated gymnastics, according to Swedish and Nauheim methods, has shown their advantages. The author states in general that it may be said that, 1. Dilatation of the small arteries and reduction of too high arterial tension can be obtained in many instances by kneading and stroking of the muscles of the extremities with slow strokes and gentle but rather deep pressure. 2. Increase of the strength of the systolic stroke is obtained in many instances by simple movement of the joints of the extremities with gentle resistance, provided that the exertion is limited to that which the recuperative force of the heart can respond to. 3. Edema is relieved by centripetal strokings with gradually increasing pressure. 4. The resistive movement must be given while the patient is in a restful horizontal attitude or half reclining. 5. Passive movement must be attempted with caution in persons who have not good muscular control, because otherwise the effort of the patient to inhibit co-operative or resistive action either fails, or is so great an exertion in itself that the effect of a vigorous active movement is obtained instead of the passive one which is attempted.

26. Renal Casts.—Tobie finds from the examination of 200 cases taken without selection that there was albumin with casts in 29. This was the result from examinations for very minute quantities of albumin, otherwise the proportion of cases where casts occurred without albumin would have been very materially increased. Three influences, he finds, effect urinary examinations as regards casts. 1. The season, as bearing only to the extent that diseases affecting the kidneys were more common at certain seasons, notably winter and early spring. 2. Age is a very important factor. It is not generally appreciated how commonly the kidneys approach the cirrhotic condition in advanced life. Hyaline casts are frequently present. The question arises: What is their significance? 3. The occur

rence of casts with cirrhotic constitutional diseases is very common, but the cause of their formation is not always clear, and he notices especially the frequency of hyaline casts in connection with carcinoma, and has been led to believe that some relation exists between them, and that the casts are the result of some impairment of nutrition or from poison products occurring in the cancerous formation. He says, as considering the importance attached to the kidney diseases by life-insurance companies, the means employed by their examiners is surprisingly lax, as microscopic examination is not the routine. While he would question very much the propriety of making the presence of casts the standard for refusal it should certainly constitute a reason for more searching examination regarding the eliminating functions of the kidneys.

27.—See also p 115.

28.—See abstract in THE JOURNAL of October 20, p. 1050.

29. **Gastric Carcinoma.**—Rettmann reviews the symptoms which have heretofore been supposed to be characteristic of gastric ulcer and shows that the disappearance of hydrochloric acid from the gastric secretions is not a pathognomonic sign, neither is the presence of lactic acid. He thinks also that too much devotion to laboratory methods has worked harm as regards the diagnosis of cancer, and the search for positive signs has largely prevented proper attention to clinical observations and judgment which would be sufficient for a working diagnosis. While the absence of hydrochloric acid is a most constant and reliable symptom it would not do to depend on it, and more than once he has been led to a correct diagnosis by noting the steady decline in weight and strength all out of proportion to the gastric disturbance. Any excess of nutritional disturbance is always suspicious, great loss of weight especially, and also the rapid or gradual disappearance of HCl, and when a patient suffering from any gastric disease grows suddenly worse under proper treatment it is well to be on the guard for cancer.

30. **Uterine Displacements.**—After first describing the supports of the uterus, Bonfield notices the different types of deformities, upward, downward, backward, forward or to either side. Retrocession of the uterus seems to be due to shortening of the sacro-uterine ligaments and is usually accompanied by sharp ante-flexion of both body and cervix and a slight descent of the whole organ. It may produce no symptoms or there may be those of ante-flexion or of atrophic endometritis. If the condition requires treatment, curettage with subsequent massage and tamponade, if necessary, will relieve. Prolapsus uteri is a more serious condition. The indications for treatment are to remove the weight, and resort to supports. The weight can be reduced by replacing it and holding it in position temporarily with tampons, the patient being kept in bed. Curettage, and if necessary cervical amputation, are the more radical measures. The perineum and round ligaments are the only supports that can be restored by surgery, while the tone of the others may be improved by the use of strychnin, quinin and ergot. He has seldom been able to relieve complete prolapse without ventrosuspension. Deviations of the uterus are divided into versions and flexions. A certain amount of ante-flexion is normal, and others such as posterior deviations are apt to occur where there is a hypertrophy of the organ. The surgical measures for these conditions are noticed, and he believes that Alexander's operation is as good as any. As regards retrodeviations he summarizes his views as follows: The treatment of this condition is not satisfactory; therefore, prophylaxis is of great importance. Many cases may be cured without surgery if well-recognized and time-tried methods be carefully and perseveringly used. Many more cases may be cured by a combination of these methods with repair of cervix and perineum. The Alexander operation may be done to avoid prolonged local treatment when the uterus is movable, and there is no prolapse of ovaries, or when reposition of the uterus pulls them into place. Adhesions and ovarian prolapse are best treated through an abdominal incision in the median line. When it is found necessary to remove the appendages, ventrosuspension is the operation to be done; when pregnancy is possible shortening of the round ligaments is preferable.

35. **Renal Calculi.**—The chief point made by McGuire is that the operation should be performed early where stone is found to exist in the kidney and not as a last resort. Early nephrolithotomy or incision of the healthy kidney for removal of the stone is not risky, gives permanent cure and has no tendency to mutilation. The opposite is the case with late operations involving nephrectomy or extensive removal of the diseased parts. The diagnosis of renal calculi is sometimes exceedingly difficult and they may cause death without their presence being detected. The position of the stone, of course, affects the symptoms and the passage of the calculus is, of course, of the greatest diagnostic importance. He reports four cases.

39. **Nasal Syphilis.**—Levy describes the symptoms, diagnosis, prognosis, and treatment of tertiary nasal syphilis. Its importance depends not only on local disorders it produces, but the possible implication of the important intracranial organs. The most common deformity is the perforation of the nasal septum, the cartilaginous or bony or both, but this may be caused by other factors also. The symptomatology as a rule may vary according to the nature and site of the lesion. Pain is not prominent. The diagnosis is of special importance on account of the value of early recognition and treatment. If the gummata can be absorbed before breakdown and the disorder checked before extensive ulcerative processes have occurred there is a chance to prevent the hideous consequences which are commonly observed. Three cases are reported, illustrating the difficulties of diagnosis. In some of these very striking mistakes were made by able men. If the disease is recognized early the chances for treatment are good, and mercury and potassium iodid should be actively administered, and properly constructed tubes inserted at the adhesions and the nose, if necessary supported by an artificial bridge. If necrosed bone is detached we should attempt its removal, provided it is well separated. There is some danger in too early or vigorous curetting. The sharp Volkmann spoon should, however, be used whenever necrosis has developed to such an extent that the sequestra can be removed with slight difficulty. Besides operative medicinal treatment, frequent cleansing with a warm 1 per cent. permanganate solution, the use of tincture of iodine and the insufflation of iodoform may be employed. Great importance is attached to constitutional treatment; as a general thing mixed treatment is advised. The effect of potassium iodid may be largely enhanced by the combination of other iodids. For the occurrence of deformity plastic surgery is a valuable resource in some cases.

40. **Recurring Parotitis.**—The author describes the case of his son, who has since the second year of his birth been subject to recurring attacks of swelling and inflammation of the parotid gland, apparently idiopathic, generally unilateral, appearing at intervals varying from a few months to a year and becoming less frequent as the child grows older. There has been no attendant enlargement of the lymphatics and no resulting hypertrophy. Fever has been absent. The general health has been good, no adenoids existing. Ewing reviews the literature and finds little that is parallel to this case and is inclined to consider it one of infectious disease of Steno's duct, causing swelling, by some microbe, the identity of which is unknown.

47. **Reminiscences of a Physiologist.**—The address of Sir Michael Foster before the Denver College of Medicine is an interesting account of the early experiences of this eminent physiologist and also calls special attention to the relation of physiology to medicine. He particularly mentions the embarrassment which physiology suffers from the English anti-vivisection laws and exhorts American physiologists not to allow themselves to be thus crippled. It is the duty of the whole medical profession to see that physiology is not hampered by any misdirected legislation.

49. **Contract Practice.**—Davis' article on contract practice maintains that it is a violation of ethics in a special sense; it nullifies the agreement made by local societies as regards fee bills and is a surrender of medical ethics to corporations. In a preliminary note the author states that it is a subject for

the local societies first to deal with, and until they take up the fight in earnest and prosecute it to its fullest extent only then should the AMERICAN MEDICAL ASSOCIATION take cognizance of it.

70. **Tropical Dysentery.**—The subject of tropical dysentery as considered by Flexner and his associates has been already noticed elsewhere in THE JOURNAL. The present article is the Middleton-Goldsmith lecture delivered before the New York Pathological Society, April 12, and the views expressed are largely the same as those already published.

71. **The Prostate Gland.**—This article is an elaborate discussion of the anatomy and functions of the prostate. Walker shows what varying views have been held and describes elaborately the minute anatomy of the organ. He sums up his results as regards this in the following: 1. The prostatic muscle is derived from the longitudinal coat of the urethra, and the circular layer of the bladder. 2. Every lobule is surrounded by a circular and longitudinal coat, so arranged as to expel quickly and forcibly the secretion. 3. The prostatic muscle of the full-grown animal is independent of both urethra and bladder, and is only indirectly in connection with either. 4. The muscle is not disposed as to compress the urethra, or to act as a sphincter to the bladder. 5. The connective tissue is found in nearly the same amount as in other secreting organs; and is amply sufficient to give all the needed support to the gland, independent of the muscular elements. 6. A membrana propria is present in all cases, and consists of very fine connective-tissue fibers. There is a sheath of longitudinal elastic fibers around the prostatic urethra, from which the outer fibers diverge around the prostatic ducts in a figure-of-8 manner, and thence onward into the glandular substance. 7. Outside of the above-named elastic coat is an incomplete set of similar fibers, which also pass into the glandular substance. 8. In the gland substance a rich elastic mesh-work is seen lying under the cells, with a few extremely fine fibers in the membrana propria. 9. The glandular substance forms about five-sixths of the organ. 10. The cells are disposed in one layer; tall columnar-shaped; have a large amount of protoplasm, and a well-defined nucleus. In the same lobule, areas are present where the cells are entirely inactive. 11. Adenoid tissue is scattered at irregular intervals throughout the gland. As regards the functions, Walker finds that the prostate gland secretes a substance which causes motility of spermatozoa together with thinning of the fluid and describes the method of ejaculation. The conclusions as regards the latter are as follows: 1. The verumontanum does not prevent the entrance of the semen into the bladder. 2. The semen is prevented from passing backward into the bladder by the contraction of the so-called sphincter of Henle. 3. The prostatic ducts are so arranged that they eject their fluid directly into the outpouring testicular secretion, thus producing a homogeneous mixture. 4. The longitudinal fibers of the sphincter membranacea urethra dilate the outer half of the membranous, and a portion of the bulbous, urethra; and by this means draw the semen from the prostatic portion. 5. During the last act of ejaculation, the orifices of the prostatic

and ejaculatory ducts are closed, and their respective fluids put on much tension; so that at the moment of relaxation a sufficient quantity of semen is poured in for the next emission. 6. The sphincter membranacea urethra aids, not only in carrying the semen along the urethra, but helps very materially in expelling it.

73. **Aortic Aneurysm.**—The Moore-Corradi method of treatment of aortic aneurysm is described by Hunner, and five cases reported. He remarks that while the operation was devised by an Englishman and modified by an Italian, it has been perfected and developed principally by Americans. The selection of the wire is of importance, and he finds that a silver alloy highly drawn, 75 parts of copper to a thousand, making a wire from an 8 to 27 standard gauge, is about the most satisfactory. He finds that the fibrin formation is more of a chemical than a mechanical process; silver being least resistant of all metals, transmits more of the given current for action on the blood. The sac should never receive both poles, or the current be so passed that the negative is in the sac, as this produces a friable soft structure while around the positive pole the clot is smaller, firmer and darker in color. He reviews the cases that have been published and discusses the dangers of the operation. The chance of a loop of wire entering the aorta is less than might be supposed, and the danger of an embolism breaking from the sac either during or after insertion is possible. The closing of the important vessels by the sudden filling with clot, puncture of the sac wall and the chances of failure because of the presence of a double sac are other possible or theoretic dangers among those considered. As regards the results of the method he finds that there are two cases at least where cure resulted; in many others, at least 39 per cent., there were amelioration and prolonged life, and there is one case still under observation with more or less chances of both. Clinical and post-mortem evidence point, Hunner says, to the efficacy of the method. Its great drawback is the difficulty of an accurate diagnosis. When we consider that none of the cases were selected as specially hopeful for operation, but almost all without exception considered hopeless, he believes we are forced to give the method careful consideration.

74. **Obstetrical Paralysis.**—Thomas describes and discusses the subjects of infantile and maternal obstetric paralysis, and as regards the former, it is probable that it is due to injury to the brachial plexus, and while it is difficult to explain at first sight how paralysis may result from such injury he suggests that since all the muscles receive fibers from several spinal roots their movements are represented particularly in one or two roots and that an injury of these special roots causes paralysis of those muscles most represented in them. It seems fairly well determined that the muscles affected in obstetric palsy have their chief representation in the 5th and 6th cervical roots and the experiments of Fioux and Schoemaker show that these roots are most apt to be injured during difficult labor whether it is by simple stretching of the plexus or squeezing between the clavicle and spinal column. What we need to clear up the question is careful post-mortem examination, which we at present lack. Maternal nerve injuries during labor are also discussed and the author reports two cases. Huenemann's theory that the paralysis resulting from trauma is nearly always due to pressure on the head and not to the blade of the forceps on the external popliteal nerve is modified by saying that, "The upper roots of the sacral plexus do not lie on the pyriform muscle, but against the bony wall of the pelvis, and are thus exposed to injury from pressure during certain difficult labors. It is the dorsal offsets of these roots which lie against the bone and which receive the chief injury. The external popliteal nerve is made up from these dorsal offsets, and therefore the paralysis is chiefly localized in the distribution of this nerve." Near the close of his paper he gives the classification of the puerperal neurites by Windscheid into, 1. those developing during pregnancy and probably due to some toxic action; 2. those due to peripheral infection; 3. those due to traumatic injury during labor; 4. those developing after perfectly normal labor from unknown causes, though toxic agents have been blamed. Thomas suggests the name puerperal neuritis for those cases classed in the fourth group. As re-

gards the other three groups we have only to consider the second and third, for there is no reason to distinguish the first group from cases occurring during pregnancy. For the second group he would suggest the name septic neuritis with the qualifying sub-title local and general. For the third, traumatic puerperal neuritis. He would also suggest that the cases of paralysis during labor be called obstetric paralysis and that the paralysis of the baby's arm be also qualified by the adjective infantile; thus we would have infantile obstetric and maternal obstetric paralysis.

85. **Inhalations.**—Penrose maintains that inhalation methods are the rational means for combating pulmonary affections. Internal medication should be used only as accessory. Change of air, mountain air, etc., which are in reality inhalation methods, are all right for those who can afford them, but for the masses this is practically impossible. He reports cases where he has given inhalation with steam or oxygen, and three cases where both these methods were combined. The good effects of oxygen in pulmonary disorders are raised to the maximum when combined with the heated vapors of his inhalation mixture, consisting of one dram of a mixture of creosote, oil of turpentin and compound tincture of benzoin in a pint of hot water, gradually increasing the creosote and oil of turpentin until a mixture of equal parts of each is combined, that is one ounce of each. Inhalations to be effective should last ten or fifteen minutes at least. Breathing exercises and general gymnastics are independent adjuncts. These do not upset the stomach like cough mixtures, and many can be induced to take them that would not take medicine.

79.—This article has appeared elsewhere. See THE JOURNAL of October 27, 1900, p. 1115.

91. **Gastroptosis.**—McPhedran reports ten cases of gastroptosis and notices their cause; these, as he says, are nothing extraordinary, but are types of cases constituting the bulk of those met with. He believes the common cause of all is general debility and lack of tone. The diagnosis is not usually difficult; by inflating the stomach with air or carbonic oxid its outline can usually be determined by percussion. As regards treatment he prefers diet, medicines, abdominal massage and gymnastics. Electricity may be beneficial, an intragastric electrode being used. He is in the habit of directing massage and abdominal exercise to be taken morning and night after drinking one or two glasses of water. In this way many patients can wash their stomach out into the bowel. Change of scene is especially recommended; travel with due regard to avoidance of fatigue is of great benefit. Rest without pleasure is of little advantage.

92. **Mental Sanitation.**—Smith thinks that the public should be enlightened in regard to the nature of insanity, especially the influence of heredity, and should also be taught that the disease is insidious in its origin, and family and personal history should receive early and careful attention. Then there should be full recognition of the variability of persons to stand strains and work. Smith thinks that if the condition under which many cases originate were understood, many attacks might be avoided. An all-important matter is the study of child character and the mental development during the period of growth. The burdens of life should be adjusted to the capacity of the individual, so that overstrain is avoided, and public sentiment must be enlightened before any reasonable restrictive measures can be carried out.

98. **Cocainization of the Cord.**—Morton reports his experience with the new method of anesthesia and discusses its utility. He has had no bad results in any of his cases, which number, up to the date of the paper, ten. He uses a spray of ethyl chlorid before making the puncture, which dulls the pain and helps to keep the patient quiet. He believes this is the safest, quickest, cheapest and best anesthetic, but it will take thousands of cases to demonstrate its safety as compared with other and older methods.

109. **Hysteria.**—Zenner's article treats of the association of hysteria with organic nervous disease and the necessity of recognizing this factor in the case. He says that hysteria may

be a possible complication of various serious organic troubles and may lead to unpleasant mistakes in diagnosis. There are some symptoms which are of special importance from the diagnostic point of view, for instance, the globus and concentric contraction of the visual fields in hysteria, and the hemianopsia, alterations of the deep reflexes, rigid pupils, and the reaction of degeneration for organic disease; but these are not altogether pathognomonic nor are any diagnostic tests absolutely reliable, hence the greater importance of careful and painstaking examinations in each case.

110—See abstract in THE JOURNAL.

British Medical Journal, November 17.

Varix. WILLIAM THORBURN.—The divergence of opinion in regard to varix being first noticed, the author discusses the etiology and reduces the possible common causes down to: 1, congenital enlargement of the veins, or weakness of their walls or valves; 2, obstruction to the escape of blood from the veins; 3, increase of influx of blood to the veins. From a clinical point of view we have also three main types: 1. Developmental varix in which a large trunk stands out from a limb whose tissues are otherwise healthy. This condition may be present in one or both limbs, but is often strictly unilateral and is most common in the left side. The internal or external saphena may be alone affected, or a large branch of it be selected. The special characteristic is the limitation of the disease and its selection of large channels. The subjects are often young adults, and the most marked cases occur in robust young men. Edema, eczema and ulceration are conspicuous by their absence, or if ulcers occur it is from atrophy of the skin overlying the large venous pouch, and is not of the type of the ordinary varicose ulcer. Hence almost the only secondary troubles are pain and risk of hemorrhage from injury of large veins. No external cause is discoverable. Pregnancy, constipation and the like are readily excluded, and the only factors found are heredity and the not infrequent association with varicocele, with enlargement of the veins of the arms and chest and occasionally nevus. The predominance of the male sex indicates a congenital origin. 2. We have a more common group of cases in which the varix is less sharply limited. It is bilateral excepting in its earliest appearance, and instead of single large swellings there is an almost proportionate swelling of veins of all sizes. The whole is apt to be slightly obscured in outline by some swelling around the vessels. This type is rare in the young; increases with age, and is more common in the female sex. Complications, such as edema or chronic ulceration, almost always develop ultimately, but we do not always find large thin-walled venous sacs, with their possibilities of profuse hemorrhage. In this case we can generally find a history of some obstruction; pregnancy may be referred to. The indications point to obstruction of the venous return as the prominent cause of the disease, and the term "obstructive varix" may be given to this class of cases. In the third form we find no varix of the larger trunks, but patches scattered over the surface and the venules only are enlarged and present themselves as somewhat radiating stellate or leaf-like areas of dusky-red spots. The author considers these as probably a lesion of inflammation and prolonged hyperemia and describes the different hyperemic or inflammatory appearances probably due to long-continued increase in the blood-supply. In the lower limb it is not common, but may occur in association with inflammatory conditions, such as chronic ulcerations, exposure to heat, etc. The first type is the simpler. The second is more complicated and is also the cause of the most of the common complications of varix, such as ulcerations, edema, etc. The treatment is largely by the ligation of varicose veins, which relieves the region of the vessels involved and its best results are in the first form where one or two large veins alone were affected. In the obstructive type the probability of success will largely depend on the relative etiologic importance in each case of developmental area of obstruction. Varix of the large vessels existing after the first pregnancy indicates a marked developmental area and is fairly amenable to operative treatment. Diffuse varix with tissue congestion

and slow production is far less favorable. In conclusion he insists on the fact that the essential cause of varix is in nearly all cases a congenital venous defect, that such defect may, if severe, show itself spontaneously, although in comparatively mild and uncomplicated form, but slight deficiencies are only rendered prominent by superadded causes of congestion, and they unfortunately then are liable to be accompanied by other results.

The Lancet, November 24.

The Treatment of Sprains and of Some Fractures. A. H. TUBBY.—A sprain may be defined as a momentary disturbance of the normal relation existing between the opposing joint surfaces, but varying very much in degree. In any case some stretching of the surrounding parts must take place accompanied by hemorrhage and lymphatic effusion. In some cases the injury may cause only temporary inconvenience; in others the ligaments are ruptured, and in the severest a small portion of the bone is torn away, and in this case the injury is known under the name of sprain-fracture. Tubby notices the symptoms, the severe pain occurring shortly after the accident, then being apparently quiescent for a short while and later recurring with increase of swelling. The first stage is that of the injury associated with stretching and tearing of the parts and effusion of the blood. The second stage of pain after the quiescent period is due to tension and continued effusion of the blood. A great deal of damage is often sustained by the patient when he attempts to use a sprained joint during the quiescent period. This retards the period of convalescence. It is important in severe cases to make the diagnosis as clear as possible and the X-ray may be valuable in case of sprain-fracture. Even when no fracture has taken place there are frequently found about the joints some tender spots, as at the knee, where a spot is found just below the patella, and in the ankle in front of the external malleolus. These are first noticeable during the second period of pain and last for a considerable time and are due to rupture of the ligament in the first place and later to the persistence of roughened inflamed synovial fringes. If they should persist for some weeks or months after a sprain their usual cause is the formation of bands of adhesion. There are certain predisposing causes of sprains, malformations, club-foot, ankylosis of the knee, atrophy of the muscles, etc., which cause abnormal tension of the joints. As to treatment there are two methods, the mobile and the immobile. The principal thing to remember is what to do and the right time to do it. At first, the author recommends applications of cold water for a short time during the first two or three hours after the accident. The position is important as the joint should be put in the position of least tension and the potential cavity be lessened. For instance, the knee should be placed in extension and not flexion and the ankle at a right angle. Bandaging should be done in such a way as to relieve pressure over the point where it can cause more tension and tenderness. If the sprain is seen within the first two or three hours he insists on the following treatment: apply cold vigorously for a quarter of an hour, either by pouring on cold water, applications of ice or the spirit lotion, then wrap the joint around with lint or other material soaked in cold water and put on the cotton-wool in such a way as to relieve the pressure over the prominent points and place the joint in such a position that there is the least potential cavity for effusion to be poured into, and firmly bandage the part. During the period of quiescence the same round of treatment should be followed out where there are still some quiet effusions going on, but when the second stage of the pain occurs the right thing to do is to apply heat, as hot applications exercise a permanent effect on the duration and the amount of swelling. The most important question is the duration of the period of rest. It may be said that as a rule most joints are rested too long. On an average of three or four days after the swelling has subsided movement of the joint should be commenced. The direction of the movement is an important point so as not to interfere with the healing of strained and ruptured ligaments. When the amount of swelling is very great, hot applications and rest are not sufficient, and here properly applied friction comes into play. Together with rubbing, frequent applications of hot water and

gentle movement should be carried out. If after ten days' treatment the thickening about the joints has not disappeared and there are still tender spots, use counter-irritants by blisters. In from ten days to three weeks a severe sprain ought to cease to give trouble and the patient be able to go about with comfort, but if at this time acute pain sets in with movement the only treatment is absolute rest. Six weeks is not too long a period to keep such a joint quiet. The mobile treatment of sprains can only be used in very slight cases and then with some misgivings. The author concludes his paper with the treatment of fracture about the elbow-joint and separation of the lower epiphysis of the femur.

Ten Cases of Enteric Fever in Which the Blood was Examined Periodically for Agglutinative Properties. WILLIAM G. SAVAGE.—From the results of a number of cases covering a considerable period the author finds a decided variation in the agglutinating power of the serum and in a number of cases of relapse, he notices that in all at one period or other before the relapse the blood reaction was very feeble or not at all. He says it does not follow, however, that all cases with feeble reaction, relapse, as his own experiences show, and definite rules can not be laid down, but he thinks we are perhaps justified in saying if the blood examination shows a well-marked reaction no relapse is to be anticipated, but if feeble, relapse may follow and is more liable if on previous examination the reaction was better marked. He concludes that well-marked differences of the agglutinating power undoubtedly exist between typhoid bacilli obtained from different sources, certainly when broth cultures are used and probably also, but to a less extent when cultures on solid media are employed. That such differences can not be considered sufficient to justify a differentiation into distinct varieties, but are rather to be explained as due to differences of present environment and to conditions of environments which have acted in the past on the race of bacillus, producing changes not fairly stable and permanent but liable to be again modified.

Annales de Dermatologie et de Syphiligraphie (Paris), October.

Sarcoma Caused by Foreign Body. W. DUBREUILH.—A piece of oyster-shell crushed into the right forefinger, was apparently eliminated in an abscess. A few months later a sarcoma developed at the spot requiring ablation. The microscope showed a chronic inflammatory reaction around a number of particles of oyster shell, each enclosed in a phagocyte, giant-cell or leucocyte, with no evidences of microbial action. Spitzer has related a similar case in which a sarcoma developed rapidly on the spot where a caterpillar had been crushed, with fragments of the hairs as the origin of the irritation.

Elastic Pseudo-Xanthoma. E. BODIN.—Only two other instances of this lesion have been recorded. The patient in the case described was 50 years of age and had noticed the cutaneous affection for thirty years, but it had caused no annoyance. The lesions were symmetrical, principally on the lower portion of the abdomen, in more or less confluent patches. The skin around, above and below was normal. Sections showed each lesion to be formed of small masses of granular substance, which responded to all the tests for elastic tissue, with connective tissue and large numbers of polymuclear giant-cells near the vessels and at the periphery of the lesion. Darier is inclined to consider the affection an elastoclasia or elastorhexis.

Bulletin de l'Academie de Medicine (Paris), November 6.

Large Myeloplexes in the Blood in Leukemia. CORNIL.—The autopsy disclosed that the cells present in the blood of the patient described, a girl of 17, were derived from the bone marrow. The large bone-marrow cells or myeloplexes were formed in the marrow in great numbers and passed directly into the circulation with the eosinophiles. They had accumulated in the spleen, with effusions of blood, increasing its size and weight to a remarkable extent. They were also found in the liver and in the blood contained in the cavities of the heart.

Bulletin de la Soc. de Pharmacie de Bourdeaux, October.

To Preserve Samples of Milk. A. DUBOIS.—Samples of milk can be preserved for weeks for analysis or medicolegal

tests by adding to the liter 5 c.c. of a solution of 50 gm. of carbolic acid in 10 c.c. of 95 per cent. alcohol. It does not interfere with any of the tests, while it keeps the milk from souring or deteriorating.

Bulletin de la Soc. Med. des Hopitaux de Paris,
November 1 and 8.

Pneumococcus Otitis from Contagion. E. HIRTZ.—The case reported illustrates the necessity of antiseptic prophylactic measures on the part of the attendants of a patient with pneumonia. A healthy woman became suddenly affected with a bilateral otitis media with copious discharge containing numerous pneumococci. The otitis commenced the third day of the patient's attendance on a patient with pneumonia. It was completely cured by appropriate treatment in twelve days.

Scapulothoracic Amyotrophy a Sign of Incipient Tuberculosis. E. BOIX.—Muscular atrophy of the scapulothoracic cap, the dome of flesh surmounting the apex of the lung, is frequently observed in advanced tuberculosis, but no one has called attention to it before as a sign of incipient tuberculosis. It is frequently to be noted before other symptoms are manifest. It is always more pronounced on the side more gravely affected, is unilateral if the lesion is confined to one side and proportionate in its extent to that of the lesion. Nine cases are described in detail showing the progress of the atrophy to be parallel with that of the disease, the muscles being apparently attacked by the infection from the very beginning of the bacillary invasion. It is possible, however, although not probable, that the muscles were congenitally defective and hence favored the localization of the infection.

November 8.

Acholic Icterus. A. GILBERT AND P. LEBEBoullet.—Under this term a pathologic condition is described which is characterized by a more or less pronounced icteric complexion predominating at certain points or generalized, with the constant presence of bile-pigments in the blood, but with no elimination of bile by the kidneys. It is distinguished by its familial and hereditary character, and its close kinship with other manifestations of chronic biliary infection. The hereditary predisposition seems especially marked among the Jews as is the case for autoinfections in general. Simple acholic icterus may date from early childhood or birth, but may remain latent and unnoticed. In other cases, there may be cutaneous manifestations—frequently urticaria and xanthelasma. Or it may appear with digestive disturbances. In other cases nervous symptoms predominate—somnolence, neurasthenic or hysterical symptoms. Profuse epistaxis or menorrhagia may occur, presenting the hemorrhagic variety and there is still another, the rheumatic, in which there are pains in the joints, muscles or bones. The predominance of these secondary symptoms frequently causes them to be accepted as primary, and possibly an erroneous diagnosis of chlorosis may be made. The affection can be differentiated by examination of the blood. It is probably due to some slight chronic infection of the biliary passages on a biliary diathesis, sufficient to cause the icterus and the passage of the bile-pigments into the blood, but not to lead to their elimination in the urine. The prognosis would be favorable if it were not for the inherent, peculiar predisposition to more serious chronic, biliary infectious processes—lithiasis or cirrhosis—which are liable to occur later, possibly subsequent to some intercurrent disease.

Echo Medical (Lille), November 11.

Suture of the Bladder After Suprapubic Incision. V. CARLIER.—The only condition indispensable to the success of suture of the bladder is to ensure ample drainage. The suture is invariably successful in children, almost always in women and very frequently in men. Besides hemorrhage, profound infection from a calculus or neoplasm is the only contraindication in men. Carlier prefers suturing in two tiers, both of catgut. When the mucosa is infected he does not include it, but otherwise makes the suture through the entire thickness of the bladder wall. He always leaves a small drain in the lower corner of the abdominal wound, pointing toward the cavity of Retzius but scarcely touching it. He does not consider a permanent sound a necessity in all cases, and describes two cases

in which a permanent sound became bent and closed the lumen of the urethra with consequent distension of the bladder. In all cases he has the urine drawn every three or four hours.

Simple Treatment of Strangulated Hernia with Gangrene. BRILLANT.—Jaboulay published recently an account of a case in which a gangrenous patch 3 cm. in diameter, on the small intestine was left untouched and the strangulated hernia reduced after careful antiseptics and lavage with boiled water at 40 C. The patient made an uninterrupted recovery. Brillant describes a similar case, but, instead of reducing the gangrenous loop, he sutured the longitudinal slit in it and passed a roll of gauze under the loop which he left outside the abdomen for twenty-four hours. After this interval the intestine had become of a better color and he considered himself justified in replacing it without further intervention. The patient made a complete recovery in ten days. The hernia in this case had been strangulated only twenty-one hours. The operation was performed under very unfavorable conditions at the patient's home, and he recommends this method as far preferable to the formation of an artificial anus or to any protracted operation in the homes of the poor.

Journal des Sciences Med. de Lille, November 10.

The Sanitary Bulletin of the House.—The writer states that in Paris and Rheims efforts are being made to keep the sanitary record of each house, the condition of sewers, the cases of infectious diseases that have occurred in it, the disinfection practiced, etc. This may prove practicable for new houses, but even this is dubious, as all infectious diseases are not reported. Lemièrre advocates instead, the general adoption of the plan of disinfecting the house throughout whenever a new tenant takes possession. If this were done as a matter of course and exacted by the tenant as he now demands new wall paper, etc., there would be no reflection on the property nor on the previous tenants. Lemièrre proposes that small houses or apartments renting for less than \$40 a year should be disinfected gratuitously by the municipality, while those renting from \$60 to \$200 a year should be disinfected at the expense of the owner. Every effort should be applied to simplify and cheapen the methods of thorough disinfection. If more generally practised, competition would soon solve the question of expense.

Presse Medicale (Paris), November 10.

Extraction of Foreign Bodies from the Ear. M. LERMOYEZ.—Lermoyez says that hundreds of lives would be saved every year if physicians, parents and nurses realized that a foreign body in the ear does no harm as long as it is not meddled with. The efforts at extraction cause the trouble. Filling the ear with olive-oil will kill insects, and the syringe will remove nearly all foreign bodies if exclusively applied, syringing toward the free space left between the foreign body and the walls of the meatus, or if this can not be discovered, toward the lower front of the foreign body. If the meatus is inflamed from efforts at extraction with a hairpin, etc., the inflammation should be allowed to subside. Lermoyez advocates chloroform for children and timid adults if an instrument has to be used, as any movement of the head is perilous. A retroauricular incision is better than protracted intervention by the natural route.

Revue de Chirurgie (Paris), November.

Technique of Colostomy. H. HARTMANN.—The artificial anus made by the technique described for the relief of inoperable tumors of the rectum, has proved extremely satisfactory in the thirty cases in Hartmann's experience. No complications of any kind have been observed and the anus is continent to a certain extent. The incision is about 10 cm. long and exactly perpendicular to a line from the umbilicus to the antero-superior iliac spine of the ilium. The different tiers of the abdominal wall are separated and the lips of the wound drawn apart by retractors at right angles to the wound and at the top and bottom, making a square opening with one corner pointing to the umbilicus. A small buttonhole is then made in the peritoneum only large enough to admit the thumb and forefinger, in the search for the iliac portion of the omega loop, which is found by following the parietal peritoneum to the point where

it is reflected on the iliac fossa and then the iliac peritoneum, until arrested by the iliac portion of the omega loop or its mesentery. Pulling on the latter always brings the right loop. It is recognized by its knobs, the longitudinal band and the epiploic appendages. This loop of the pelvic colon is drawn well out and supported by a roll of gauze passed through the mesentery beneath. Gauze of another color is then packed lightly around beneath, over the lips of the wound, which it thus tampons. Neither sutures nor ligatures are required. Forty-eight hours later the intestine is opened with the thermocautery without anesthesia, the opening being not more than 2 cm. long, on the afferent end of the exposed loop. A warm, moist compress is applied, and two days later a gentle purgative is given, if there has been no bowel movement, irrigating copiously with tepid water afterward, and covering the wound with moist gauze and oiled silk. The tiny opening in the intestine gradually enlarges, and the mucous membrane becomes everted. On the sixth or seventh day the gauze surrounding the intestine is removed and by the tenth day the roll supporting it is taken out, cutting the latter close to the intestine and pulling each side out separately. The intestine gradually retracts and the mucous membrane everted at the small orifice spontaneously adheres to the lips of the wound in the skin, and by the twentieth day the anus is complete. A certain amount of constipation is desirable and the diet is adapted to this end. An evacuation is induced each morning with an injection into the proximal end. By observing all these apparently trivial points a satisfactory and practically continent anus is obtained, which will squeeze the inserted finger. In only one of the thirty cases was a slight supplementary autoplasmic operation required.

Resection of the Median Nerve in the Forearm. PERRAIRE AND MALLY.—A young woman was operated on for the removal of a diffuse, dissociating lipoma in the median nerve, requiring resection of 8 cm. of the nerve. After removal, all the movements of the fingers were retained and the patient resumed her occupation of seamstress without disturbance of any kind. The sensibility was normal nineteen months after the intervention, except for a patch of anesthesia in the center of the pulp of the forefinger. The flexor brevis pollicis had evidently assumed certain of the functions of the paralyzed antagonist and the abductor brevis.

Entering the Posterior Mediastinum. A. F. LLOBET.—Nassilov first suggested the possibility of this operation for lesions of the esophagus and Rehn has applied it twice on man. Lobet followed Nassilov's directions in an attempt to relieve a young woman with complete constriction of the esophagus due to the action of caustic. She had been fed by means of a gastrostomy done several months before and was in good condition. The fourth to the eighth rib inclusive were resected for 5 cm. and the esophagus reached without injuring any of the thoracic organs. It was incised along the two strictures found, but was not sutured. The wound was sutured in tiers and the operation was successful, the pleura and other organs remaining intact. The patient died eight days later, and the autopsy disclosed a purulent pleurisy, probably attributable to ascending infection from the stomach by way of the lymphatics. The mediastinum should be entered about two finger-widths to the left of the spine for the upper portion of the esophagus and on the right for the lower portion.

Revue Generale d'Ophthalmologie (Paris), September.

The Lashes in Cataract Operations. SCHIÖTZ.—The skin is shaved as a preliminary measure to operations on other portions of the body, and the lashes should also be removed before a cataract operation. Shaving produces an injurious irritation and the stiff new growth disturbs the patient. Epilation is the only rational procedure in these cases. It does not produce any reaction on sound lids and the sprouting lashes are soft and fine. Several days should elapse between the epilation and the operation proper.

Sympathetic Ophthalmia in Spite of Enucleation. ABADIE.—A case is described in which sympathetic ophthalmia recurred fourteen years after enucleation of the eye primarily affected. It resisted all treatment until conquered by injections of three or four drops of a 1 per cent. solution of mercury

cyanid injected into the stump of the enucleated eye. The optic nerve had probably been invaded by the primary infectious process, but the infection had remained latent for years.

Semaine Medicale (Paris), November 7.

Infection of the Uterine Cavity after Delivery. E. WORMSER.—Doederlein reported this year that he found the uterine cavity sterile in 83 per cent. of 250 women examined between the second and fifteenth day after delivery. In nearly every case in which bacteria were found, there had been temperature, subfebrile in most. Wormser instituted a parallel series of investigations at Basle, following Doederlein's technique as closely as possible, but he found that 84 out of 100 patients had bacteria in the lochia and yet there was no morbidity, only 24 having had temperature slightly above normal. His examinations were all made from the eleventh to the fourteenth day after delivery, as he considers it established that sterility is the rule during the first few days. In the immense majority of cases of infection, especially the fatal ones, the infection is of heterogeneous origin, almost always from imperfect sterilization of the hands of the midwife or obstetrician. The best prophylaxis of puerperal fever is, therefore, rigorous disinfection of the hands and the use of rubber gloves if the hands have been infected with virulent germs within twenty-four hours. It is equally important to disinfect the external genitalia. In case of rapid, normal birth it is unnecessary to disinfect the vagina—his statistics for the last three years are equally favorable with and without. But when delivery is delayed, especially after rupture of the waters which neutralize the vaginal secretions, and before any obstetric maneuver, he rinses the vagina copiously with 1 to 1000 sublimate solution. For the same reasons he makes an injection of 1 per cent. lysol in the uterine cavity after intruterine manipulations. The practical results of bacteriologic examination—which is practiced at Basle in every case in which there is temperature for more than twenty-four hours—are the certainty that the fever is due to absorption or to some extra-genital cause if the lochia prove sterile. Bacteriologic examination saves much anxiety by demonstrating the absence of infection or in other cases revealing its presence at the start of the process, before any clinical symptoms have appeared. There is little or no information to be derived from bacteriology in regard to the prognosis. Wormser relates instances in which fatal puerperal infection was evidently derived from a sluggish chronic infectious process elsewhere, a sinusitis in one case, a streptococcus pneumonia in another, and a migration of pneumococci in a third from the lungs through the diaphragm and peritoneum to the endometrium, producing a chain of lesions on its path.

Centralblatt f. Chirurgie (Leipzig), November 10 and 17.

Obliteration of an Intestinal Diverticulum Without Incision. C. BAYER.—A diverticulum was found in the invaginated portion of the intestine near the ileocecal valve during a laparotomy on a boy 2½ years old. The collapsed condition of the patient rendered rapid operating a necessity and the diverticulum was taken up in four folds, a thread passed through each, thus gathering the diverticulum into a small shallow space and obliterating it as a cavity. The child recovered and is now in perfect health.

Radiography of the Neck of the Femur. C. LAUENSTEIN.—Fine skiagrams of the neck of the femur can be obtained by placing the Roentgen light between the knees of the patient, who reclines on his back, the thigh flexed and abducted. The rays should be in the plane of the diaphyses of the femur and radiate toward the lower circumference of the neck. Comparison with similar skiagrams of normal individuals shows clearly any backward bending or other abnormal conditions impossible of detection by other means.

November 17.

Wire as a Permanent Substitute for Bone Defects of the Jaw. C. HOFMANN.—A piece of stout silver wire passed through the stumps of the bone after resection and the ends woven together, forms a remarkably simple and reliable means of substituting defects in the jaws or long bones. It can be bent to adapt it to the exact shape required. A wire is preferred that has a core of a less flexible metal than silver. The

wire prosthesis has proved a perfect support in a case in which it was used to substitute a missing portion of the tibia 6 cm. long, also in a case of extensive necrosis of the lower jaw. The teeth fitted accurately together and the outline was normal.

Buried Wire Netting in Operations for Hernia and Movable Kidney. O. WITZEL.—The silver-wire netting recommended by Witzel as a support to be left permanently in operations, is proving extremely useful in sustaining a movable kidney. It permits the patients thus operated on to be up in ten to twelve days. Witzel never uses a ready-made netting, but always weaves it in the tissues from straight wire as required for each individual case. Less wire is needed and the netting thus made is more elastic.

Muenchener Med. Woch., November 13.

Plaster Treatment of Scoliosis. A. SCHANZ.—The position as corrected and maintained by the plaster dressing is the final result that can be attained in the treatment of scoliosis. In favorable cases this is nearly equivalent to a complete cure. These results can be surpassed only when it is possible to apply the cast in an over-corrected position, and this is now the problem to be solved. Schanz uses the plaster only in those cases in which satisfactory results are not to be anticipated from other treatment, the patients being at an age when the skeleton of the trunk is still sufficiently plastic. The treatment commences with mobilization of the spine, and not until this is attained is the plaster dressing applied. The correction is accomplished by free suspension and extension with occasionally lateral traction. The cast reaches from the trochanters to the neck, where it stops two finger-breadths below the mastoid process. It is renewed a few times and removed after twelve weeks. It is followed by a supporting apparatus and the correcting bed, tonic measures and all the tried and tested means of treating scoliosis and preventing recurrence.

Typical Laryngeal Neuralgia. G. AVELLIS.—The writer has had occasion to treat a number of cases of suddenly-appearing neuralgia of the larynx, in healthy, middle-aged persons, with remissions and exacerbations on swallowing, speaking, moving the head sideways, etc., with a typical painful spot at the emerging point of the superior laryngeal nerve and prompt recovery after administration of an antineuralgic and the local application of dry heat.

Subjective Troubles of Neurasthenia. L. HOEFMAYER.—The principal groups of subjective troubles experienced by neurasthenics can be traced to disturbances in the functions of the intestines and neuroses of the vagus and sympathetic. The treatment is suggested by this etiology. Several cases are described, all of which were cured with gentle laxatives and the systematic use of opium, which has a wonderful effect on the heart disturbances and confirms their nervous character.

Wiener Klinische Rundschau, November 4 and 11.

Therapeutic Application of Catheterization of the Ureters. F. STOCKMANN.—In an experience of 250 cases in which Casper's method of catheterism has been used for practice, diagnosis or therapeutics, Stockman has never observed any harm from its employment. He describes four cases which had resisted all treatment and were cured by systematic catheterization of the ureters. He advocates trying it at least as a last resort before counselling nephrotomy in all cases of chronic pyelitis. In the cases reported he made from five to twenty and thirty-eight pelvo-renal injections of 10 c.c. of a 1 per cent. solution of silver nitrate every second or third day. There was no fever nor reaction. In one case the pain was completely abolished with three injections. In two the affection was consecutive to a gonorrhoeal cystitis; in two others it was caused by the bacterium coli. A fifth case was more of a reflex nature consecutive to an operation for the removal of uterine tumors.

Gazzetta Degli Osp. (Milan), October 14 and 28.

Relation of Neuroses to Anomalies in the Cerebrospinal Axis. A. DE GIOVANNI.—Every functional anomaly in the nervous system is dependent upon some anomaly in its evolution, either from atavistic degeneration, from variations

in ontologic development or from anatomic-pathologic processes. From the slightest to the severest, most classic forms of neurotic manifestations, all are intimately connected with the evolutionary processes of the elements constituting the nerve tissues.

October 28.

Diagnosis of Pericarditis. F. SENNA.—The area of dullness over the heart is not always a reliable means of diagnosing an effusion in the pericardium, as the area may be small with a large effusion or extensive with no fluid. The intensity of the apex-beat and of the sounds of the heart is much more significant. In dubious cases it is well to have the patient lie on the left side to determine whether the lower limit of the dullness coincides with the point of the apex-beat.

Cure of Trophic Lesions by Nerve Stretching. A. MONTINI.—A young woman had suffered for five years with a trophic lesion of the middle finger of the right hand, finally involving the entire hand. Years were wasted in all kinds of treatment until finally Chipault's method of nerve-stretching was applied. The median nerve was stretched several times at one sitting, through an incision 12 cm. long. The symptoms gradually subsided, and after a slight relapse the patient is now completely cured.

Change of Address.

- A. R. Allen, Lincoln, to Bradshaw, Neb.
 H. R. Baumgart, Eldora, Colo., to 260 S. Halsted St., Chicago.
 A. J. Black, Wilton, to Breckenridge, Mo.
 J. F. Coleman, Montrose, to Leadville, Colo.
 F. O. Church, Watertown, to Henry, S. D.
 H. Cushman, 277 Ogden Ave., Chicago, to General Delivery, Washington, D. C.
 Geo. E. Clements, Chicago, to 509 W. North St., Crawfordsville, Ind.
 C. N. B. Camae, 550 Park Ave., to 108 E. 65th St., New York City.
 C. H. Carlson, 406 Sutter, to 140 Geary St., San Francisco, Cal.
 A. M. Dam, 74 Boylston St., to 215 Huntington Ave., Boston, Mass.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 15 to 21, 1900, inclusive:

George E. Bushnell, major and surgeon, U. S. A., member of a board in Washington, D. C., to examine officers of the quartermaster and subsistence departments for promotion.

Herb B. Clayton, lieutenant and asst.-surgeon, U. S. A., as Bushnell, above.

Robert P. Cooke, acting asst.-surgeon, orders directing him to proceed to Boyce, Va., for annulment of contract revoked.

Robert J. Gibson, major and surgeon, U. S. A., member of a board in San Francisco, Cal., to examine officers of the quartermaster and subsistence departments for promotion.

Louis T. Hegg, lieutenant and asst.-surgeon, U. S. A., leave of absence extended.

H. Newton Kierulf, acting asst.-surgeon, now at Seattle, Wash., will proceed to San Francisco, Cal., and report by letter to the surgeon-general for annulment of contract.

William F. Lewis, major and surgeon, Vols., (captain and asst.-surgeon, U. S. A.), member of a board, vice Major Frederick P. Reynolds, surgeon, U. S. V., (captain and asst.-surgeon U. S. A.), in Manila, P. I., to examine candidates for admission into the medical corps of the army.

George W. Mathews, captain and asst.-surgeon 36th U. S. V. Infantry, discharged from the volunteer service in consequence of his having accepted a commission as first lieutenant and asst.-surgeon, U. S. A.

George J. Newgard, captain and asst.-surgeon, U. S. A., sick leave granted.

Benjamin F. Pope, lieutenant-col. and deputy surgeon-general U. S. A., as Major Gibson, above.

Erwin I. Shores, acting asst.-surgeon, previous orders revoked: on being relieved from duty at Fort Caswell, N. C., he will proceed to West Bridgewater, Mass., for annulment of contract.

Henry D. Thomason, major and surgeon, Vols., leave of absence granted: honorably discharged from the service of the United States to take effect Dec. 31, 1900.

Clarence A. Trueholtz, acting asst.-surgeon, from the Department of California, via Seattle, Wash., and Skagway, to Fort Egbert, Alaska, for post duty.

Clarence D. Webb, captain and asst.-surgeon 43d U. S. V., infantry, discharged from the volunteer service of the United States to accept a commission as first lieutenant and asst.-surgeon, U. S. A., to date from Nov. 12, 1900.

William L. Witt, lieutenant, acting asst.-surgeon, from St. Joseph, Mo., to San Francisco, Cal., to accompany troops to Manila, P. I., and to report for assignment in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the navy for the week ended Nov. 24, 1900.

P. A. Surgeon A. W. Dunbar, detached from the *Monongahela*, and ordered to the *Vermont* for temporary duty with the crew of the *Wisconsin*, and then to naval hospital, Mare Island, Cal.

Asst.-Surgeon R. D. Williams, appointed asst.-surgeon, from Nov. 17, 1900.

Asst.-Surgeon J. T. Kennedy, detached from the *Monocacy* and ordered to the Cavite naval station.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Nov. 22, 1900.

P. A. Surgeon J. B. Stoner, relieved from duty at Quebec, Canada, and directed to proceed to Norfolk, Va., and assume temporary command of the service during the absence of the medical officer.

P. A. Surgeon A. R. Thomas, granted leave of absence for one month.

P. A. Surgeon H. W. Wickes, granted leave of absence for seven days from November 28.

Asst.-Surgeon L. E. Cofer, directed to rejoin station at Los Angeles, Cal.

Asst.-Surgeon W. C. Huddy, granted extension of leave of absence for two weeks from November 3.

Asst.-Surgeon L. P. H. Bahrenburg, relieved from duty at Liverpool, England, and directed to proceed to New York City, and report to Surgeon L. L. Williams, at Immigration depot for duty.

Asst.-Surgeon C. H. Lavinder, granted leave of absence for two months from Nov. 20.

A. A. Surgeon L. P. Gibson, granted leave of absence for ten days from Nov. 13.

Hospital Steward F. S. Goodman, granted leave of absence for thirty days from Dec. 19.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 23, 1900:

SMALLPOX—UNITED STATES.

Maryland: Prince George County, Nov. 3-14, 9 cases.
Michigan: Nov. 10-17, Detroit, 1 case; Grand Rapids, 1 case.
Minnesota: Minneapolis, Nov. 10-17, 3 cases.
New Hampshire: Manchester, Nov. 10-17, 10 cases.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper accepted by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION." The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the author and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

NEPHRORRHAPHY.*

CHARLES P. NOBLE, M.D.

Surgeon-in-Chief, Kensington Hospital for Women.
PHILADELPHIA.

The operation of nephrorrhaphy dates back only to 1881, when Hahn,¹ of Berlin, introduced the operation as a substitute for nephrectomy in the treatment of movable kidney. In this country the subject has been ably discussed by Edebohl,² who perfected and published a systematized technique for the operation.

Senn³ presented a method of anchoring the movable kidney, the essential feature of which consists in the substitution of gauze packing for sutures to hold the kidney in place until the formation of granulation tissue shall cause permanent adhesions of the kidney in its new position, the wound being left open to heal by granulation. Deaver⁴ has adopted the principle of Senn's operation, rejecting sutures in favor of gauze packing and a granulating wound. Morris⁵ may be considered the most prominent advocate of the operation in England. He employs silk sutures to fasten the kidney to the cut edges of the transversalis fascia.

Tuffier, of Paris, believes that the proper capsule of the kidney, being smooth, thin, little resisting and but slightly vascular, is not likely to form firm attachments to the muscles of the back, and for this reason recommends the stripping off of the proper capsule from the free border of the kidney, so that the kidney substance proper may come in direct relations with the muscles of the back. Edebohl has adopted this principle in his technique.

The writer adopted at first the technique of Edebohl.⁶ By eliminating some of its features and substituting others, he has developed the technique which will be discussed in this paper.

The two papers of the writer referred to above, discuss the general subject of movable kidney, its causation, symptoms, diagnosis and treatment. Seven years of careful study devoted to the subject have served to confirm most of the views advocated in the previous papers, which are well represented by the following summary:

"Movable kidney is a very common condition among women. I find it in one-fourth of my own patients. Both kidneys are movable in about one-tenth of the cases. The underlying cause of movable kidney is a deficiency of adipose tissue, especially in the perirenal region. Tight lacing, multiple pregnancies, and falls occasionally act as contributing causes.

"The symptoms of movable kidney are both reflex and local. The reflex symptoms of movable kidney

are those at times of neurasthenia, irrespective of its cause. In other cases nervous dyspepsia, palpitation of the heart, distension of the abdomen with gas, and neuralgic areas are the symptoms complained of. Patients are usually unable to lie on the side opposite to the movable kidney. The local symptoms are a sense of weight or bearing down, soreness in the kidney region, attacks of pain similar to renal colic, and in rare instances symptoms of strangulation due to torsion of the vessels of the kidney.

"Movable kidney may be suspected when its rational symptoms are present, but the diagnosis must be made by the physical exploration. This should be made with the patient in a standing position. The diagnosis can be made with the patient lying on her back only in long-standing cases, where the displacement is extreme, as usually in that position the kidney slips up under the margin of the ribs. In many cases movable kidney gives rise to no symptoms and therefore does not require treatment. The rest cure promises to be efficient in cases of slight degree, as the kidney returns to its normal position while the patient is lying on her back, and the increase in fat which the rest cure usually brings about should effect a cure. The rest cure used in cases of long standing, with extreme displacement of the kidney, will improve the general condition of the patient, but will not improve the local trouble. Nephrorrhaphy is a simple and safe operation, which should be done in the cases having well-marked displacement, that is, three inches and upward. The more marked the local symptoms the more necessary is the operation. The reported cases indicate that the results are permanent."

The chief purpose of this contribution is to report the experience of the writer with nephrorrhaphy in full to date, and to consider the final results secured in the older cases, as well as the immediate results of the more recent ones, in relation to the technique which should be selected in performing this operation. This experience embraces forty-three operations done for movable kidney. The first patient operated on had both kidneys movable, and each was operated on at a separate sitting, so that the total number of patients operated on is forty-two. Of these, two died, which on superficial inquiry would indicate that the operation has a definite mortality. The first case, however, was known to have chronic Bright's disease before the operation, but suffered so much pain in the movable kidney that in spite of the existence of chronic interstitial nephritis the operation was undertaken. This patient died suddenly on the fifth day, when apparently in good condition, either from pulmonary embolism or from angina pectoris. No autopsy was permitted. The second patient did perfectly well for about a week, when she bled to death from an ulcer of the stomach, the presence of which was unsuspected. In considering

* Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

the inherent mortality of nephrorrhaphy in patients otherwise sound both of these cases should be excluded.

Of the forty women remaining, so far as is known to the writer, all of them are cured, mechanically speaking. In not a single case has the kidney again become loose. The kidney having the greatest degree of mobility is one in which a double nephrorrhaphy was done in a very anemic and much prostrated woman, in which the operation on the left kidney was followed by suppuration, necessitating the removal of the fixation sutures. This kidney has a range of mobility of perhaps an inch. This fact has a definite bearing on the choice of technique, as to whether sutures are to be employed and primary union obtained, or whether granulation and possible suppuration is to be invited.

Of the forty patients, twenty-nine may be considered cured. They so reported when last heard from, and most of them have been seen or communicated with quite recently. In two the result is unknown. In four, symptomatically speaking, the result was a failure. In five the patients, while benefited, were not cured, and may be considered as improved.

This percentage of cured cases is most gratifying, and demonstrates the value of the operation in properly selected cases. Granted that a proper technique is employed, it is the opinion of the writer that the percentage of cured cases as contrasted with the failures or partial successes will depend on the discrimination with which cases are selected for operation. In by far the majority of cases the symptoms are neurasthenic, or else reflex in character, and unless care is exercised the symptoms will be attributed to a movable kidney, when its presence is merely a coincidence.

The diagnosis of movable kidney is usually so simple and exact that it is within the power of every practitioner to become expert in palpating this organ when displaced. Movable kidney is almost never present in fat women, the only exception being fat women having flabby abdominal walls; hence, the conditions are favorable for making a diagnosis. The following from the writer's original paper contains exact rules for diagnosis:

"For seven years, in my practice, I searched in vain for movable kidneys. During that time I followed the method of examining the patient when she was lying on her back. I understand now why I failed to find the movable kidneys. It was because that in this position they slipped up above the margin of the ribs. In my entire experience I have felt not more than half a dozen kidneys with the patient lying on her back. These were cases of extreme displacement of long standing.

"It occurred to me that by examining the patient standing the diagnosis could more easily be made, and experience has shown that this was the one thing lacking in my previous investigations. The examination should be conducted as follows: The patient's clothing should be loosened, all bands about the waist unfastened, and the skirts supported by a nurse or assistant, so that the patient will not be embarrassed with the fear that her clothing will fall off. She should then stand before a table or desk of convenient height—about 30 inches—with the examiner seated on her right. The patient then bends forward from the hips, and supports some of her weight by resting her hands on the table. She is directed to respire regularly, care being taken to relax herself thoroughly during expiration. The examiner's left hand is placed against the lumbar region posteriorly, and his right hand in a corresponding position in front of the kidney. By a conjoint manip-

ulation the region between the two hands can be carefully palpated, and, if present, the kidney is easily recognized. The points to be looked for are the shape and size of the kidney, and the fact that it can be readily displaced upward beneath the margin of the ribs, and that it will return to its former location as soon as the examiner's hands no longer support it. When the kidney is compressed, as a general rule, the patients complain of tenderness or pain of a peculiar character, and often make the statement that the pain causes them to feel faint or somewhat nauseated."

Seven years' experience has but emphasized the value of the foregoing rules. It has also taught that in a definite percentage of cases the diagnosis can be made with the patient in the recumbent position. Much more skill, however, is necessary to make the diagnosis in this position, as the patient must first cough or strain the kidney down below the margin of the ribs, and it must then be seized by the palpating hand. The disadvantages of examining in the recumbent position are that many cases will be overlooked, that only the more marked cases will be recognized, and that the degree of displacement can not be estimated nearly so well as with the patient in the standing posture.

The technique of nephrorrhaphy as performed by the writer may be described as follows: The patient is placed prone on the table. The Edebohls' air cushion is placed beneath the epigastrium, and should be accurately located; if too low it will tend to displace the kidneys under the ribs, if too high it does no good. The incision is made along the external border of the quadratus lumborum muscle from the twelfth rib toward the ilium. It should be about 3 inches in length. When the muscles are reached they should be separated as far as possible rather than cut, in order to preserve the integrity of the posterior wall of the abdomen. It is usually necessary to ligate cut vessels, as these are much larger than in the anterior abdominal wall. Care should be taken to avoid wounding the iliohypogastric nerve, which runs through the field of operation. If this be cut, it sometimes causes annoying paresthesia in the region of its distribution. When the muscles have been well separated, the subjacent fascia is divided, which exposes the perireal fat. This is drawn outward and downward, and torn through as near the spinal column as convenient, and also at as high a level in the wound as convenient, the object being to deflect this layer of perireal fat outward and downward, so that at the conclusion of the operation it will form a cushion below and to the outside of the sutured kidney. After the fatty capsule is torn through, the kidney, as a rule, comes into view. If it does not, it is either because it is below the field of operation, or else it has slipped up under the ribs. When the kidney is very movable and the Edebohls' pad is used, not uncommonly the movable kidney is displaced downward toward the pelvis. When the kidney is brought into view, it should be gently grasped by the hand and the fatty capsule detached from it by the fingers of the operator. If the kidney is too firmly pressed, it is apt to result in the formation of a hematoma. The kidney is teased out through the incision, and the fatty capsule is stripped off from its external border, upper and lower poles, and lateral surfaces. The region of the hilum is best not disturbed, as the renal vessels might accidentally be wounded. Three silkworm-gut sutures are passed through the lower half of the kidney at intervals of $\frac{3}{4}$ of an inch. The sutures are passed with a straight needle deeply enough to secure a good hold in the

kidney, but not deeply enough to encroach on the urinary canals. Each suture is caught in an artery-forceps. The kidney is now repositioned and the wound is irrigated with salt solution. At this stage it is best to let the air out of the nephrorrhaphy pad, to lessen intra-abdominal pressure. The kidney sutures are now passed with a carrier from within outward through the lumbar muscles, the upper suture being inserted as close to the last rib as feasible. The sutures are so passed that when tied the knots are just external to the deep fascia. Between each fixation suture a chromicized catgut interrupted suture is passed to close the wound in the lumbar muscles, and additional sutures are passed below the level of the lowest fixation suture to close the lower part of the incision in the lumbar muscles. In tying the sutures the corresponding catgut suture is tied first to close the wound, and then the silkworm-gut suture is tied, care being taken to make it snug and not tight, as the function of the silkworm-gut suture is to hold the kidney, but not at all to close the wound of the loin. Should these sutures be employed to close the wound in the loin, it might well defeat the object of the operation by causing the sutures to cut through the friable renal tissue. When all of the interrupted sutures have been tied, the subcutaneous fat is closed by a running catgut suture, and the skin is closed by an intracuticular catgut suture and the usual dressings are applied. It has been stated that the perineal fat is divided on the inner and upper aspect of the kidney, and that it is deflected outward and downward so as to form a cushion and a support upon which the kidney is to rest. This disposition of the fatty capsule is insured by drawing it outward and downward through the wound as the kidney sutures are passed through the external side of the wound. Each silkworm-gut suture is passed through the fatty capsule before it enters the muscle on the external side of the wound, and this is so arranged that the free portion of the fatty capsule is deflected to the outside and below the kidney. When the sutures are tied they not only fasten the kidney to the abdominal wall, but also hold the fatty capsule in its new position.

This technique in essentials has been employed in the last forty of the forty-three nephrorrhaphies. In the first three cases, in which the Edebohls' technique with silkworm-gut drainage was employed, two of the cases suppurated. In the last forty, one suppurated frankly, and in one a silk ligature was accidentally left with a long end hanging out of the wound, which caused a localized infection involving one deep suture. The results of the technique in obtaining primary healing of the wounds is very gratifying. In none of the cases in which primary union was obtained have the buried silkworm-gut sutures given trouble. So long as this experience continues there will be no occasion for substituting other suture material.

The use of a non-absorbable suture for the fixation of the kidney has been objected to on the ground that it might lead to the formation of a stone in the kidney. This objection is purely theoretical, as no such case has been reported; moreover, it is contrary to the teachings of comparative pathology. The suture soon becomes encapsulated in a scar tissue-sheath, which, so far as the functioning structure of the kidney is concerned, makes the suture extrarenal. *A priori* the greatest objection to a non-absorbable suture in nephrorrhaphy is, that if the kidney should again become loose, each suture might cut its way through the cortex of the kidney, in this way making linear scars to correspond

with the original sutures. This objection is so far theoretical, and should it take place, the results will probably be of small moment.

The foregoing results are strong arguments against the allegations of those who oppose this or similar technique in nephrorrhaphy. First, it is alleged that the kidney will not remain in place if sutured; second, that if permanent sutures are employed they will give rise either to suppuration or to the formation of calculi. The results speak for themselves. The technique has the further advantage that primary healing of the wound is obtained, that the patient is not annoyed by dressings, or even by the removal of sutures, and at the end of three weeks she is able to leave her bed.

In this connection a few remarks are in order concerning the various steps in technique which are employed by different surgeons, which it seems to the writer are either unnecessary or undesirable. 1. The incision of the proper capsule of the kidney and its separation over a greater or less area from the external border of the kidney, as practiced by Tuftier, Edebohls and others, would seem to be unnecessary. The only advantage claimed by its advocates is that it favors the permanency of the fixation of the kidney. A distinct objection to the procedure is that it promotes capillary oozing from the renal vessels. By the formation of clots in the depths of the wound suppuration is promoted. On the ground that it was both unnecessary and harmful it was abandoned by the writer after its employment in three cases.

2. The substitution of gauze packing for fixation sutures and the reliance on granulation tissue to fix the kidney in position, as advocated by Beinebott, Senn and Deaver, would seem to be a distinctly retrograde step. The allegations of the supporters of this latter method are in direct contradiction to the results recorded in this paper. If the latter method is to meet with general approval and adoption, it must be because its advocates can show that the results secured by it are better than by other methods heretofore employed. The following objections to the method immediately suggest themselves: The period of convalescence is much prolonged. The change of dressings when the gauze packing is removed and replaced is painful. Local infection and suppuration are invited by the very nature of the open-wound treatment, with the risks always attendant on a suppurating wound, and especially with one in connection with so important an organ as the kidney.

In conclusion, the writer would make the following recommendations:

1. Careful discrimination in diagnosis in order to separate cases in which movable kidney is a coincidence in a case of neurosis from those in which it is the cause of local and reflex symptoms.

2. Resort to the rest cure for cases of slightly movable kidney, especially in young women.

3. The employment of symptomatic treatment in cases in which the relation between the movable kidney and the nervous symptoms present is uncertain. Nephrorrhaphy should be employed in these cases only after non-operative measures have failed to afford relief.

4. The immediate resort to operation in those cases in which local symptoms, such as pain, sense of weight, or symptoms of strangulation, are present, and when the examination of the urine shows indications of congestion of the kidney, such as the presence of hyaline casts or albumin.

NEW POINTS IN THE ANATOMY AND HISTOLOGY OF THE RECTUM AND COLON.

THE TREATMENT OF OBSTINATE CONSTIPATION BASED ON POINTS SET FORTH IN THE FOREGOING.*

J. RAWSON PENNINGTON, M.D.

PROFESSOR OF RECTAL DISEASES CHICAGO POLICLINIC.
CHICAGO.

Doubtless some of the statements herein made may be a radical departure from those generally believed and accepted by the profession; however, I shall try to make no claim that can not be substantiated.

I believe it is universally recognized that the sigmoid flexure begins in the left iliac fossa, at the outer border of the psoas muscle, and that the rectum ends at the anus. The part of intestine included between these two points, therefore, constitutes the rectum and sigmoid. With reference to the point of division between these two organs, there seems to be a difference of opinion. However, we shall not discuss that question in this connection, but recognize that portion having a mesocolon as the sigmoid and the remainder as the rectum. This makes the point of division about opposite the third sacral vertebra. The sigmoid has two fixed points only—the first, its beginning where it is made fast to the ilium; the second its ending where it is anchored to the third sacral vertebra. Any further description of its position is a relative one and depends on its length, the length of its mesentery, its relative degree of distension, the degree of distension of adjacent viscera and the tension of the diaphragm and the abdominal muscles. In a collapsed state, as it is usually found in the cadaver, the sigmoid most frequently occupies the left iliac fossa and dips into the pelvis. Skiagraphs, photographs and specimens, however, show that this is not the position it usually occupies when distended or perhaps when studied clinically. As it becomes distended it rises from this position and extends toward, and often into, the right iliac fossa and frequently above the umbilicus, and in some instances to the diaphragm and under the liver—Figs. 1, 2, 3, and 4. It will also be observed that in the distended or semi-distended state the flexure is held near to and over the sacrum and the bony prominences of the abdominal and pelvic cavities, which suggests the idea that defecation may be aided by intermittingly squeezing the filled sigmoid between these irresistible bony points and the diaphragm and abdominal muscles during the act. It is maintained in this position by means of its mesentery, which surrounds the free border of the intestine in such a manner that its point of union is a little anterior to the posterior surface of the flexure. Near the junction of the rectum and sigmoid the mesenteric fibers are frequently thrown across the anterior aspect of these organs and hitched to the posterior or lateral surface of the rectum and the right side of the pelvic brim in such a manner as to more securely hold the feet of the flexure in a specific relation to each other—A in Fig. 2. When the sigmoid is distended it

appears as a flexed intestine lying on a flat surface. The rectum consists of the remaining portion of this intestine—from the third sacral vertebra to the anus—and is divided into chambers or apartments by partitions extending across it at different points. These partitions or structures are known as the rectal or Houston's valves, and were first described by him in 1830. Other earlier writers evidently referred to these same structures; however, it was his paper more especially that stimulated a discussion of the subject. He described these valves as consisting of mucous membrane, cellular tissue and circular muscular fibers. Since then a few writers, like Kohlrausch, Otis and Martin, have corroborated his discoveries; while Bodenhammer, Kelsey and Mathews have denied their existence, and still others, as Allingham, Cripps and Ball have ignored them. Martin, to whom we are indebted for valuable contributions to this subject, states, after making a histological examination of a rectal valve in an adult, that: "beneath the mucosa is noticeable the heavy layer

Fig. 2.—From a photograph showing the distended sigmoid flexure extending into the right iliac fossa. An incision was made in left inguinal region, sigmoid and rectum ligated, then filled with hot paraffin. After cooling, the abdominal muscles and adjacent viscera were removed when it was photographed. a, Band of mesenteric fibers thrown across sigmoid and rectum at their junction; b, pubes.

of fibrous tissue which gradually diminishes until it is lost at the valve base. Bundles of circular muscular fibers are seen in the middle of the valve. At its base are seen arteries and veins for its special nutrition. This structural arrangement makes this organ the typical anatomic valve. The evidence of the fibrous tissue in the valve is an original contribution to our knowledge of this subject." From this it will be seen that while a few comparatively unknown men in the field of rectal surgery have corroborated Houston's discoveries, our leading authorities on this subject have either entered into lengthy discussions to deny their existence or have ignored them entirely. The position and arguments of this latter class have had much to do with molding the medical mind concerning these valves. Their treatment of them, being practically a unit in point of evidence against their existence, has naturally carried the weight of medical opinion with it. Notwithstanding this preponderance of evidence, which has existed for the last seventy years, original and experi-

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1906.

mental study has convinced me that Houston was right; that the rectal valves are veritable structures. Believing that the most acceptable manner in which to offer conclusive and impartial evidence of this fact would be through a disinterested and recognized authority, I presented to William A. Evans, M.D., professor of pathology and histology in the medical department in the University of Illinois, and the Columbus Medical Laboratory, a number of specimens of valves for histological and pathological examination and submit herewith his verbatim report. I also offer as additional evidence a number of photomicrographs made of the sections from the valves.—Figs. 5, 6, 7, 8 and 9.

EXAMINATION OF HOUSTON'S VALVES.

Specimen 1.—Rectum of a child aged three weeks. The valves project into the lumen of the intestine for a considerable distance. The free border of this projection embraces between one-half and two-thirds of the circumference of the intestine. It is to be understood that a measure of this projection on a microscopic specimen, prepared by the usual

Fig. 3.—Photograph of rectum, *a*, and sigmoid, *b*, of Fig. 1, after removing from the body. Sigmoid extends into right iliac fossa, makes sharp bend anteriorly upon itself, descends and crosses junction of rectum and sigmoid at right angles.

microscopic methods, has only relative value. The maximum projection was in the lowest valve, or the one next the anus. The projection was covered by a mucosa consisting of tubular mucin-secreting glands and interglandular lymph-tissue. In some sections the mucosa was thickened over the valve, in others it was thinned. There was no uniformity except at the angles, where some thickening seemed constant. The muscularis mucosa was more prominent in the valves than elsewhere. At the tip it measured .0125 millimeters. This represented a thickening of about 10 per cent. The submucosa was composed of the usual, loosely-arranged connective tissue, almost devoid of lymph elements and containing a considerable vascular supply. Some of the changes in the submucosa found in diseased cases will be noted below.

Measurement of the submucosa away from the valves showed a thickness of .15 millimeters. The submucosa at the tip measured .475. (Measurements made on three intestines from other subjects showed submucosa away from valve, .225, .36 and .3; submucosa at tip, .75, .35 and .82.) From this it will be seen that the submucosa thickens in the valves to twice its normal dimensions. In this connection it is well to bear in mind that the preparation of the specimen will cause a condensation of the submucosa, with diminution of its dimensions. The circular muscular coat usually dips into the valves. In

this specimen the thickness of the muscular coat away from the valve was .11. In the valve it measured .375. (Measurements of two other specimens showed, circular muscle away from the valve, .075 and .11; circular muscle in the valve, .185 and .25.) The circular muscle is liable to be hypertrophied in the valve. The longitudinal coat is more irregular. In this specimen it measured, away from the valve, .075; at tip of valve, .187.

Outside of the muscular tunic was a loose connective-tissue tunic containing some adipose tissue and moderately supplied with blood-vessels. This structure was composed of white fibrous and yellow elastic tissue. It ran into the valve for about two-thirds of its height and bound together the two longitudinal muscle bundles. Some fibers, and enough to almost constitute a membrane, could be demonstrated stretching across the base of the valve. These fibers can be picked up

Fig. 4.—Same as Fig. 2. Showing the rectum, *a*, and the sigmoid, *b*, with its mesentery, *c*, after being removed from the subject.

with a needle as a bridging membranc-like structure. In this layer were found lymph nodes, nerve ganglia and nerve bundles and the epithelial glands presently to be described.

Specimen 2.—Bowel from baby 2 months old. Rectum filled through the anus with a 2 per cent. watery solution of formalin. Anus closed by stitches made through surrounding skin. Body amputated at twelfth dorsal vertebra and kept in 1 per cent. formalin solution. Inferior mesenteric artery was injected with carmin. Internal iliac with soluble prussian-blue.

Two and a half centimeters from anus is lowest of valves. Circumference of intestine at this point is 6 cm. Valve occupies all of circumference except 1.5 cm. on the right side and rather posteriorly. Greatest width of valve found on left side and rather anteriorly. Greatest depth of valve is about .7 cm.; circumference of howel at level of second valve, about 6 cm.; length of second valve along free edge is 3.5 cm.; depth of second valve at deepest point, .9 cm. This valve is so located that its deepest area is directly over that portion of bowel lumen not obstructed by lowest valve. Distance from second to third valve, 1 cm.; circumference of bowel, 2.5 cm.; above

third valve, 6 cm. Circumference of bowel at third valve is 5.5 cm.; length of free edge of third valve, 2.5 cm.; depth of third valve, 1 cm. at deepest point. Right point of attachment of third valve is exactly over point of attachment of first valve. Left point of attachment comes to posterior middle line.

Bowel was split longitudinally from a point just below the first valve to a point just above the third. Slit was along posterior surface and approximately in the median line. Now the bowel was slit longitudinally into six pieces, beginning at the posterior slit and traveling to the right, so that 1 and 6 represent the posterior surface, 3 and 4 the anterior, and 2 and 5 the lateral surfaces. A suture was made in the upper end and in what would correspond to the left corner.

Sections of these pieces show some valves composed exclusively of mucosa and submucosa; others show the circular muscular tunic running into the valve for about one-half its length. The longitudinal coat passes across without entering at all. Others show a longitudinal muscle running well into the valve. Solitary lymph-glands are found in the valves.

Some of the specimens show a very rich nervous supply

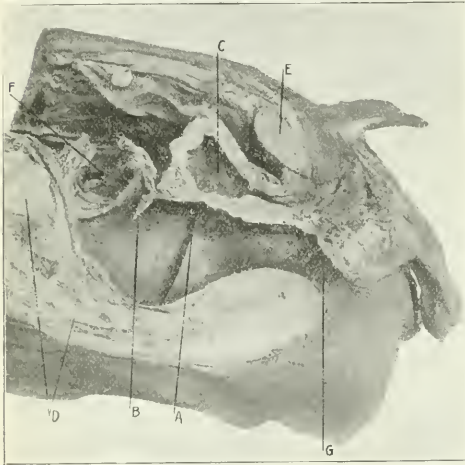

Fig. 12.—Left half of unfilled frozen section; showing the first, *a* and third, *b*, rectal valves and their relation to the bladder, *c*, sacrum, *d*, pubes, *e*, sigmoid, *f*, and anus, *g*.

outside of the muscular layers. Large ganglion cells are demonstrable.

It is peculiar that some of the sections show valves composed of all of the coats, and right near will be another valve composed of a smaller number of coats. Near the clearly outlined valves are smaller invaginations usually composed of a mucosa, submucosa and thick circular muscle coat.

Three other specimens were examined, giving the same results as those already outlined. The mucosa, muscularis mucosa and submucosa were invariably present. The circular muscle was generally present in the valves. The longitudinal muscle was usually present; sometimes it was absent.

Epithelial Glands.—In two of the specimens, in the loose tissue outside of the longitudinal muscle, we found an epithelial structure; one of these comes from the valve next the anus and one from the uppermost or third valve. The one from the third valve shows as nine small parallel tubes arranged in linear fashion; the other as a distinct epithelial structure, showing considerable lumen, and a wall thrown into somewhat papillomatous folds. The folds are covered by epithelium in several layers. Around this is, in some specimens, considerable lymphoid tissue. In other specimens there is considerable rather dense circularly-arranged connective tissue. We do not undertake to say what this structure is,

and still less do we suggest any function for it. It is to be remembered that the anus does not come from the tip of the gut, but from a point anterior thereto. This posterior prolongation, to-wit, the part behind the anus, of the intestine is comparatively slight in certain animals. In others it is very considerable. In birds it communicates with the spinal canal as the neurenteric canal; in man, in the early stages of embryonic development, it sometimes exists as a neurenteric canal. In many of the mammalia, in the early embryonic stage, this canal is present. In many of the reptilian types and other animals bearing tails there is a very considerable posterior or caudal prolongation of the intestine.

Pathologic Specimens.—The pathologic specimens were removed from people suffering from obstinate constipation of long standing. They were clipped out in situ with one exception. In this case a tenaculum was caught behind the valve and the valve was prolapsed until it appeared outside of the anus, when a piece was snipped off. One section was from a woman who, in addition to the constipation, had mucous colitis.

Mucosa.—The mucosa showed epithelial glands containing a very large percentage of goblet cells. No other pathologic process was demonstrated in these structures. They were

Fig. 13.—The right half of Fig. 12, illustrating the second rectal valve, *a*, and its relation to the bladder, *b*, and sacrum, *c*. Note the dilatation, *d*, immediately above and below the valve, *a*; *c*, the anus.

slightly hypertrophied. There was nothing to indicate an atrophic process in the mucosa, at least at this time. Between the glands there was an increase of tissue which was generally round cells, though some spindles and young fibers were apparent. In two of the specimens there was evident local infection with a pus organism, the focus extending into the submucosa. The muscularis mucosa was thickened.

Submucosa.—The submucosa showed a great increase in the connective tissues. This tissue was principally of the white connective-tissue variety and was in bundles. These bundles usually ran across the long axis of the valve. The most marked is illustrated in Fig. 10. There was extensive thickening of the blood-vessel wall. This thickening was the usual type of endarteritis obliterans—*C*, in Fig. 11. The sections removed from the valves in live subjects showed no muscle except a very few circular fibers.

In a section made from a cadaver in which the valves were coarse and resistant (Fig. 9) the following was found: The circular muscular layer was generally hypertrophied. The longitudinal layer showed slight hypertrophy. The adventitia external to the muscle layer showed an increase of white fibrous tissue, together with an extensive endarteritis obliterans.

Fig. 1.—Skiagraph showing the distended sigmoid, *a*, in the right side; *b*, the rectum; *c*, transverse colon; *d*, splenic flexure. The subject was placed in the knee-chest posture, and the bowel filled from below with bismuth emulsion.

Fig. 5.—Photomicrograph of the third rectal valve in a child two months old. It contains mucosa, *a*, and submucosa, *b*, only. Some fibers of the latter spanning its base; *c*, infoldings due to thickening of the circular muscle.

Fig. 6.—Section from the second rectal valve of a child four months old, showing the mucosa, *a*; submucosa, *b*; circular muscular fibers, *c*; longitudinal muscular fibers, *d*, and loose connective tissue, *e*, containing ganglia and nerves, *f*, external to the muscular tunics.

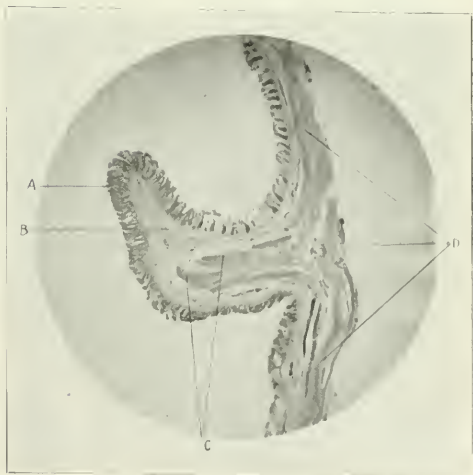

Fig. 7.—Taken from the first rectal valve of a child six weeks old. It contains mucosa, *a*; thick, dense, submucosa, *b*. The circular muscular tunic, *c*, runs into the valve about one-half or two-thirds its length. The longitudinal muscle, *d*, spans its base.

Fig. 8.—Photo-micrograph of rectal valves in child three months old. They contain mucosa, *a*; submucosa, *b*, and lymph nodes, *c*. None of the muscular tunics enter the valves.

Fig. 9.—Photo-micrograph of a section of the free border of the third rectal valve of an adult. This valve was located seven inches above the anus. Its free border spanned two-thirds of the intestine's circumference. It plainly shows: *a*, the mucosa; *b*, muscularis mucosa; *c*, submucosa; *d*, circular muscular layer; *e*, longitudinal muscular layer; *f*, loose connective tissue outside of longitudinal muscle; *g*, blood-vessels with thickened walls.

Fig. 10.—Section of rectal valve in case of chronic interstitial proctitis. *a*, mucosa showing interstitial increase between mucous glands; *b*, round cell infiltration extending to submucosa; *c*, submucosa showing great increase of connective tissue. The fibers running diagonally across the valve. This specimen is from a male 19 years old.

Fig. 11.—Section of first rectal valve in chronic interstitial proctitis in female 27 years old. *a*, Mucosa showing some interstitial increase; *b*, submucosa showing great increase of connective tissue; *c*, blood-vessels with thickened walls.

The number of these valves varies. In fact, they are not only irregular as to number, but as to location, size, position, direction with reference to the axis of the intestine, capacity and structure. As a rule, there are three, sometimes only two; again, there may be four or even more. Usually they are semilunar in shape. Their attachment forms from one-half to two-thirds the circumference of the intestine; their margins are concave and usually directed slightly upward. They are most prominent when the bowel is distended. Their depth in the adult is from one-half to one inch, or even more.

When in regular order the lowermost, or first, one is situated on the left side about opposite the junction of the sacrum and coccyx—Fig. 12. The uppermost one is placed at the upper end of the rectum and on the same side of the intestine; while the second or middle one is situated on the right side at about the junction of the middle and lower third of the distance between the first and the third one—Fig. 13. Frequently they are irregularly situated or coarcted, which might be construed as a deformity—Fig. 14. From studies on the living, by inserting pledgets of cotton into the sigmoid and rectum and having the individual pass them, and from observations made on the cadaver, by repeatedly filling and emptying the sigmoid and rectum with water and other material, and from a study of the direction of the valves with reference to each other and to the axis of the intestine, it would seem that during defecation the fecal mass is rotated from right to left in passing through the cloacal canal. However, this is not always the case. One valve may direct the fecal current to the right and the one immediately below is situated so as to reverse the current or direct it to the left, and the next one to the right, etc. Again, their relations may be such that the upper valve directs the fecal mass immediately into the pocket of the one next below, which is situated at right angles to the bowel's axis. In this case it is necessary for the fecal mass to be literally dumped over the valve's free border. In other instances they seem to be only slightly concave and arranged so as to form a kind of regular plane for directing the fecal current; yet in others they form pockets—Figs. 7 and 8. Again, one valve may be situated almost opposite another, so that when the rectum is distended their free borders almost entirely enclose the canal—Fig. 14. Their histology also is variable. Some are composed of the duplicated mucosa, together with very thick dense fibrous submucosa, noted by Martin, no other coats entering the structure. In some of them, in addition to the coats already mentioned, circular muscular fibers run almost to the tip—Figs. 6 and 9. In others, such as shown in Fig. 7, the circular muscular fibers run half or two-thirds the length of the valve. Sometimes the longitudinal muscle spans the base of the valve without deflection—Figs. 5 and 7. Sometimes it follows the circular muscular fibers—Figs. 6 and 9. Sometimes it splits, some fibers following the circular coat and some spanning the base. Not infrequently the muscular tunics and submucosa at the apex are hypertrophied. Sometimes the submucosa divides, part of the fibers entering the lumen and part spanning its base—Fig. 5. Lymphatic nodules were found in the valves and large sympathetic ganglia located external to the muscular tunics. The structure in these valves, called cellular by Houston, and fibrous by Martin, and usually described simply as submucosa, is probably one and the same structure.

TREATMENT OF OBSTINATE CONSTIPATION BASED ON POINTS SET FORTH IN THE FOREGOING.

I believe that the tortuosity of the sigmoid flexure, together with the hyperplasia, irregularity and deformity of the valves above mentioned, frequently form the principal primitive causes of so-called obstinate constipation. These conditions and obstructions favor germ infection and the development of chronic interstitial tissue. This interstitial tissue surrounds the glands in the mucosa, contracts on them and perverts their secretion, with resulting dry and hardened stools, and finally causes atrophy of the glands.

In the submucosa this interstitial tissue not only surrounds the large vascular trunks, nerves and lymphatics, and contracts and mars their function, but causes

Fig. 14.—Illustrates anatomic coarctation or deformity of the first, *a*, and second, *b*, rectal valves; *c*, third rectal valve.

loss of pliability in the submucosa, which impairs the free movement of the mucosa over the muscular tunic. It also causes loss of flexibility in the muscular tunics and muscular insufficiency, and as a result of these and other pathologic conditions the valves are changed from a physiologic intermittent obstruction to a pathologic and continuous one. The intestinal wall is frequently pouched and thinned immediately above the base of the valve and hypertrophied opposite the valve's free border. These pathologic conditions seem sooner or later to result in obstinate constipation or obstipation and its results. The diagnosis of the obstruction offered by these valves is made by the symptoms of the obstipated patient and by instrumental inspection.

Symptoms.—The patient is the subject of more or less obstinate constipation; he may have a daily evacuation, but it is unsatisfactory; he experiences a sensation after defecation as if feces still remain in the rectum; he may have a desire to defecate, which requires a labored and straining effort to accomplish the act, or he may tell you that he never has a desire to do so and believes his bowel would never move unless he takes some form of physic or an enema. In the former condition it is usually the first or second, or both valves that are involved; while in the latter it may be the uppermost one only that is at fault. In time, he has occasional attacks of diarrhea, or diarrhea alternating with obstinate constipation; also, the symptoms of so-called intestinal auto-intoxication and neurasthenia. The valve being an almost non-sensitive organ, the patient rarely refers his sufferings to this region; yet, in some instances, he may complain of pain and aching in the sacral and lumbar region and a heavy sensation in the pelvis and pains extending down the legs.

Instrumental Inspection.—This requires that the

Fig. 15.—Illustrating the application of the automatic valve clip, *a*, to a rectal valve; *b* is the speculum, *c* the clip applicator, and *d* the rectal valves.

operator be provided with special instruments designed for the purpose and that the patient be maintained in the knee-chest or proctoscopic posture, in order to gain the assistance of atmospheric inflation. For obtaining this position I have had constructed a specially designed table armed with a bracket, light-condenser and reflecting mirror for throwing the light on the field of inspection. The instruments necessary for this examination consist of a set of tubular specula of various lengths and diameters, fitted with glass caps and bulb for inflating the bowel when necessary. With the patient in the proctoscopic posture, the speculum is well anointed with vaselin, grasped with the full hand and gently introduced. The obturator is then removed and the light so adjusted as to illuminate the bowel. By intelligently manipulating the speculum and light, you at once command a view of the various chambers and valves, and observe the degree of rectal distension, the number of valves, their relation to each other, and the relative size of the various chambers.

In the next step, note the character of the mucous membrane, whether edematous, swollen or atrophied, moist or dry, red and inflamed or pale; then compare its relative characteristic in each chamber and over each valve. Should atmospheric pressure not produce sufficient inflation, then effect this artificially, by means of the insufflator. The next step is to test the elasticity of the valves, which is done by means of an angular hook. A healthy valve is readily effaced by means of this instrument. If the valve is hypertrophied or stiffened from other causes it will not be effaced and will interfere with normal defecation. Unfortunately, the condition of these structures is rarely noted until they are in a chronic pathologic state, which changes them from a physiologic intermittent obstruction to a pathologic and continuous one. This is probably due to compensatory hypertrophy of the bowel immediately above the valve, which prevents the early development of noticeable symptoms of obstipation.

When, from interstitial inflammation or other reasons, these valves become pathologic or are the cause of obstinate constipation, noted by Martin, then the question of relief is to be considered. After using the cauter, knife and scissors, and having one case of peritonitis and another of alarming hemorrhage following the cutting operation, notwithstanding I had

Fig. 16.—*A* illustrates the rectal valve, *b*, as it appears when looking through a tubular speculum, with the patient in the proctoscopic posture; *c* represents the lumen of the bowel as seen above the free border of the valve; *B* showing appearance of valve after a section, *d*, has been removed with the clip by pressure necrosis.

been able to give a great deal of relief to sufferers of obstipation, I became very chary about employing the knife on these cases, which led to the development of an instrument with which these structures can be divided with the same clinical result and practically no risk to the patient's life. The little mechanical device which I herewith show you is the product of that effort, and is known as an automatic valve clip. It is made of spring steel, and consists of a permanent and movable plate. To apply the clip the patient is placed in a proctoscopic posture; a tubular speculum is introduced, the clip made fast to the clip introducer, carried through the speculum and applied to the pathologic structure to be divided—Fig. 15. All instruments are then withdrawn. The clip is retained in position by means of its spring and automatic action. The section grasped is destroyed and removed by pressure necrosis, leaving a permanent division of the valve—Fig. 16. The introducer is made with a reversible handle.

The writer is indebted to Mr. Zan D. Klopfer for drawings and charts; Mr. E. Soegaard for photographs; Dr. Carl Theodore Gramm for photo-micrographs, and to the Mica-Plate Static Machine for the skiagraphs.

Columbus Memorial Building.

DISCUSSION ON PAPERS OF DRs. WYETH AND PENNINGTON.*

Dr. J. P. TETTLÉ, New York City.—I am quite sure that the Murphy button does not produce any ill-effects when lost in the intestine, as I have had four or five such cases without any bad results whatever. I think the title of Dr. Wyeth's paper is rather misleading, since we are in the habit of looking on the fistula as a pathologic condition. I think the paper would better have been entitled "permanent artificial anus," because that is what he attempts to produce. We must clearly distinguish between an artificial anus done for temporary purposes and one which is desired to be permanent. Where we do the operation for a temporary purpose so as to aid in the treatment of inflammatory condition Dr. Wyeth's method is not applicable, but where we want to excise the rectum we want as much of the colon as we can get and we must have all of the tissue necessary for making a wide dissection. The long flap renders future closure very difficult. With all due respect to those who say there is no danger in resection of the gut I find there is a death rate of not less than 31 per cent., and any method which requires the entering into the peritoneum for the closure of an artificial anus becomes too dangerous to be used as a simple preliminary. We may, therefore, lay aside this operation so far as a temporary anus is concerned. As to a permanent artificial anus, here we have an entirely different matter to deal with. Dr. Wyeth has struck the key-note when he says he desires to prevent the continual discharge of fecal matter, as this is what is most objected to by the patient. It makes the man unfit for anything, because he knows not the time when that distressing discharge will come out all over his abdomen. Many methods for overcoming this objection have been instituted, and I think the best is by Bailey, of London. Dr. Wyeth's operation is applicable to any of these methods, but the technique should be carried further and we should endeavor to develop a sphincter as well as make an opening that will control the artificial anus. Bailey's operation consists in drawing the muscle out, making the ordinary incision through the skin, dividing the fibers of the external oblique muscle, not by incision but by careful dissection, then dividing the internal oblique fibers by the same method, cut the transversalis, open the canal and drawing out a loop of intestine. The internal oblique is split laterally and a loop is passed through the laterally-split fibers and brought out to the original opening in the external oblique. On a level with Poupart's ligament a second opening is made and loop brought out, a glass rod being used if so desired. I pack and suture the abdominal wall, the intestine being brought out from two to three inches below the point where it comes out from the deeper walls of the abdomen so that it lies flat on the external oblique. In Bailey's method you can apply a firm but soft compress which will absolutely occlude the intestinal canal and prevent any leakage. I can speak from experience that patients can go about their business without any escape of fecal matter and they can not even pass gas without loosening their compress. If we can adopt the method which Dr. Wyeth has demonstrated and can in this way succeed in providing for the accumulation of fecal matter in the intestinal canal we shall have accomplished one of the greatest boons to mankind. The time is coming when artificial ani are going to be much more in vogue than they are at present, and we shall soon recognize that certain malignant conditions which we have attempted to remove can be successfully accomplished with greater safety to the patient than by excision. When such a method is known and it is proved that the patient is made comfortable, operation will no longer be refused. I heartily approve of Dr. Wyeth's method, although I do not know his reasons for never using a glass rod. Out of twenty-four operations for these conditions I have used the rod twenty-one times and in only one of my last seven did I put in a suture. I have never had a prolapse of the small intestine nor any breaking away. I want to say that all of the deaths which Dr. Krips had in his forty-five cases were due to the sutures giving way and the intestine dropping back into the abdominal cavity. It takes eight or ten days before union between the intestine and the skin occurs and sometimes longer for firm enough

union to take place to prevent the patient breaking it loose. I remember in one case my assistant actually saw the break occur on the ninth day in a case of right-sided colostomy.

As to Dr. Pennington's operation, we must acknowledge that he is doing excellent work in this direction, and his work speaks for itself. I have not the time to discuss this question of valves, but the time is coming when we can no longer split hairs as to whether these are valves or mucous folds. There is an anatomical formation that we must recognize, and every man who has used the sigmoidoscope has often seen these valves. It is not a question as to whether or not they exist, but as to their influence in health and in pathologic conditions. Are they the cause of constipation or obstipation? What harm do they do in disease? What do they do in normal health?

Dr. D. W. FINLAYSON, Des Moines, Ia.—I recently had a case in which the sigmoid lay on the right side, and obstinate constipation of long standing was caused thereby. It measured fully 22 inches in length and I am quite sure the valves the author of this paper mentioned existed, and had tended to produce the constipation. I am also inclined to believe these valves seriously interfere with free defecation when they are unusually developed.

Dr. T. C. MARTIN, Cleveland, Ohio.—As is generally known, six years ago I first employed the method which has been presented this morning by Dr. Pennington. With a few minor exceptions, the author has corroborated my findings. He has called your attention to the fact that the distended sigmoid flexure is usually found on the right side, to which fact I called your attention in 1897. In 1862 Dr. Jacobi called your attention to the same thing, and in 1850 Dr. Nelaton referred to the same thing, but this information has been of no practical clinical advantage. I desire to refer to the clinical significance of the position of the sigmoid flexure and to endeavor to impress on you the necessity of making a differential diagnosis between its dilatation and hyperemia and chronic catarrhal appendicitis. After five years of clinical research, I reported to this Section my observations on the surgery of the rectal valve, and I now wish to present certain conclusions based on this experience: 1. What is called stricture of the rectum is hypertrophy of the rectal valves. 2. Two or more of these valves, infiltrated with lymph, constitute what is called benign tubular stricture of the rectum. 3. Valves may be congenitally so situated, or may develop in such close anatomical relation, that they may form an obstruction without there being any disease. It would be of importance in this connection to closely scrutinize the rectal valve in those cases which are often called idiopathic dilatation of the colon. Dr. Pennington had not the time, perhaps, to call your attention to the symptoms of hypertrophy of the rectal valve. Straining at stool during the passage of solid feces is usually present, while the most common complication is dilatation and hyperemia of the sigmoid flexure resulting in auto-intoxication. The obstruction due to hypertrophy of the rectal valve may be relieved by a simple surgical operation which, in skilled hands, may be done with absolute safety, for, by the modern methods now employed, the valve may be seen as readily as is the finger on your hand. There is therefore no danger in the hands of a properly trained surgeon of perforation of the rectal wall, nor of secondary hemorrhage. A man who is not properly qualified, who has never seen the operation and who, after twice trying it, condemns it, does so unjustifiably.

Dr. W. R. EVANS, Chicago.—I know that Dr. Pennington has given Dr. Martin credit for his valuable work. Lack of time in which to read the paper in full prevented this fact from appearing.

Dr. J. R. PENNINGTON, closing the discussion.—We have appreciated Dr. Martin's work and have endeavored to give him full credit for the same. There were two or three points in his remarks, however, which we feel deserve special notice:

1. Houston, in studying the gross and minute anatomy of the rectal valves, filled the bowel *in situ* with spirit in order to harden or fix them. Martin, for the same purpose, filled the bowel *in situ*, using paraffin followed by alcohol. In our histological studies we used formaldehyde to fix the valves *in situ*. In studying the gross anatomy of the valves and the various

* Dr. Wyeth's paper appeared in last week's JOURNAL.

positions of the sigmoid, under different degrees of distention, we used paraffin, bismuth emulsion, formaldehyde solution, alcohol, water, freezing and air. In some of the specimens we used nothing. Such observations, especially those on the sigmoid, could not have been made with paraffin followed by alcohol in the manner which Martin used these agents.

2. Many writers and observers have reported cases and called attention to the sigmoid being found in the right side, but if Martin, Jacobi or Nélaton has ever offered a theory similar to that expressed in my paper, as to why this is true, and the probable advantages gained thereby, I have failed to notice it in literature.

3. Houston, seventy years ago, described the structure of the rectal valve as consisting of mucous membrane, cellular tissue and circular muscular fibers. Martin's observations evidently were the same, except that the tunic which Houston described as cellular tissue, Martin says is fibrous.

We found the valves to be more irregular in structure, some containing mucosa and submucosa only; others had these and the circular fibers in addition, and still others contained mucosa, submucosa, circular muscular fibers, and a part or the whole of the longitudinal coat. We also found the valves to contain lymph-nodes, and in the loose connective tissue external to the muscular tunics we found large ganglia and nerves. In the pathological specimens we found dense fibrous tissue. Hence, we do not see how Martin claims that our findings, other than those stated in our paper, corroborate his, as he claims to have made one discovery only, that of fibrous tissue in the valves. This is probably the same structure referred to by Houston as cellular tissue. On the one hand, cellular tissue is the antecedent of the fibrous variety; on the other, in Houston's day the term cellular was used in a way that would be considered loose to-day.

4. He stated that there was no danger in the operation in skilled hands. To this we must dissent. We understood him to say, in a discussion before the American Proctological Society at Washington, in May last, that there was danger of perforating the bowel in transfixing the valve's free border, and with that we do agree. The intestinal wall is very thin, and the slightest move on the part of the operator or patient is liable to be followed by a fatal puncture of the bowel. After operating a number of times and having one case of peritonitis and another of hemorrhage, we began to look on the operation with fear and this led to the development of the automatic valve-clip. With it these structures can be divided by pressure necrosis, with the same clinical results and with what seems to us little or no danger.

COLITIS, CONSTIPATION AND APPENDICITIS: THEIR ETIOLOGIC RELATIONS.

WITH A CONSIDERATION OF THE VALUE OF INCISION AND DRAINAGE IN CERTAIN FORMS OF APPENDICITIS*

MILES F. PORTER, M.D.
FORT WAYNE, IND.

I desire first to direct attention to the question of etiological relationship between constipation, colitis and appendicitis.

My attention was first attracted in this direction by the following case, seen by me over four years ago: Jessie C., of Ada, Ohio, aged 12, had, when I saw her, the usual signs and symptoms of a periappendicular abscess, which I opened and drained. Her father, who is a physician, told me that from her earliest infancy she had been a frequent sufferer from colitis, with the symptoms and signs usual in such cases. Moreover, the present illness commenced as an attack of colitis, and only after these symptoms had continued for some time did the symptoms of appendicitis arise. She was even at the time of my visit having frequent

mucous stools, tormina and tenesmus, and continued to have these symptoms for some time after the symptoms referable to the appendix had subsided. She is still a sufferer, at times, from the same trouble.

Since that time a number of cases have occurred in my practice, which seem to me to show that appendicitis not infrequently arises as a result of extension of inflammation or infection from the colon. From among these cases I will briefly report the following:

CASE 1.—Mrs. B., of Lima, Ind., was referred to me by Dr. G. W. McCaskey, whom she had consulted on account of bowel trouble. Dr. McCaskey, after examining the case, concluded that the patient had been for months a sufferer from gastrointestinal catarrh, but that she was at present suffering from a mild appendicitis, this being the third attack, the first having occurred three months before. For two years she had been a sufferer from obstinate constipation. On removal, the appendix was found to be the seat of a catarrhal inflammation, with slight signs of periappendicular inflammation. So certain was Dr. McCaskey that in this case the appendicular trouble had its origin from the bowel, that he suggested that it might be advisable to treat the colon for a time in the hope that an operation might thus be avoided.

CASE 2.—Mrs. M., widow, aged 35, was taken sick October 23. I saw her two days later, when I got a history of habitual constipation. She had had a slight passage on the day before she was taken sick, this being the only bowel movement for ten days. She had had several attacks of belly pain prior to this, but without any localized pain or tenderness. When I saw her the abdomen was greatly distended, generally tender, and vomiting was frequent. She also complained of much pain in the back and head. Because of the frequency of peritonitis of appendicular origin, the abdomen was opened in the right semilunar line and a slightly adherent and perforated appendix was removed, and an abundance of foul pus evacuated.

CASE 3.—Mrs. R., aged 56, is at the present writing convalescent from appendicectomy done on the second day of the first attack. Her attending physician, Dr. Drayer, who was my assistant for three years, and has had considerable experience in appendicitis, told me that he had treated her a number of times for attacks of belly pain, which he regarded as acute exacerbations of a chronic colitis, and assured me that this was the only time he had ever found any signs of appendicitis. This patient still has symptoms of enterocolitis.

CASE 4.—Mr. S. was referred to me by his brother, who is a physician of ability. He was taken sick with the usual signs of an acute colitis, including frequent bloody stools, and after five days developed appendicitis, for which he was operated. Many authors consider chronic constipation a causative factor in the production of appendicitis, but I know of only one (Maylard) who speaks of the possibility of extension of inflammation from the cecum to the appendix. He says: "Extension of inflammation from the mucous membrane of the cecum to that of the appendix probably takes place in some cases."

Lange² says: "Appendicitis is due, in America, to two of our natural failings, those of eating too much and chewing too little, the result of which is constipation." I believe this statement would be more nearly correct if the last phrase were made to read, "the results of which are colitis and constipation."

The uric-acid diathesis is acknowledged as a predisposing cause of appendicitis. This condition is usually accompanied, and not improbably caused, by gastrointestinal disturbances. The majority of cases of appendicitis occur in childhood. Enterocolitis and colitis find the majority of their victims during the same period.

Greig Smith³ regards the mechanical causes of appendicitis by far the more important. He says: "It may safely be affirmed, that very few cases of appendicitis would become dangerous if there were a free passage always patent between it and the cecum."

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It is quite reasonable to suppose that either impaction of the feces in the cecum or swelling of its mucous membrane may produce closure of this passage. When we consider that both these conditions frequently, if not usually, obtain in colitis; that colitis is a disease of frequent occurrence; that both colitis and appendicitis occur most frequently in childhood; the conclusion seems forced on us that colitis is frequently the cause of appendicitis.

As for myself, my personal experience has convinced me that colitis and constipation, either or both, frequently cause inflammation of the appendix. If my position is correct, then the physician has in the prophylactic treatment of appendicitis not only a legitimate field, but one from which he may expect to reap a harvest for which both he and his patients may well be thankful.

The second and last question which I wish to discuss is: Is not incision and drainage the best method of treatment in some cases of appendicular abscess? No one of experience in appendicular surgery doubts for a moment that the appendix should be removed in the great majority of cases operated on. Neither can there be any doubt that the number of cases in which incision and drainage is the better operation has grown less as skill and knowledge in this branch of surgery have grown greater. Greater skill will enable some operators to remove the appendix in cases in which its removal at the hands of other operators would be attended with unwarrantable risk.

If the truth of this statement be granted, and I take it that no one will dispute it, then does it not follow that this same "greater skill" would enable those possessed of it to establish drainage with greater celerity and with less shock to the patient than their brothers of lesser skill? Good logic, it seems to me, requires an affirmative answer to this question also. If our reasoning thus far be correct, then either one or the other of the following conclusions must be accepted as true: 1, no case of appendicitis can be saved by incision and drainage that can not be saved by appendicectomy; or 2, incision and drainage without removal of the appendix is the better operation in some cases of appendicular abscess. Other things being equal, appendicectomy is an operation of greater gravity than simple incision and drainage. There are some cases in which the shock of either operation would prove fatal. On the other hand, there are cases that would withstand the simpler operation, but would die if subjected to the graver one. If then incision and drainage is sufficient to bring about recovery, even though it be granted for the sake of argument that it will not be perfect or permanent, then we are forced to the conclusion that some cases may be saved by this method which would die if subjected to removal of the appendix.

The question as to the advisability of removing the appendix, after recovery following incision and drainage, is, of course, not now under discussion.

If one believes that appendicectomy is the graver of the two operations under discussion, and at the same time holds that the appendix should be removed in all cases operated on, at the time of the primary operation, is he not likely to reject as unfit for operation some cases on which he who holds the contrary opinion would operate? If operation will give even the slightest chance of recovery, then the patient is entitled to that chance. I do not think that any one will claim that the immediate death-rate following in-

cision and drainage is greater than that following appendicectomy in case of like gravity. I mean deaths occurring as a result of the attack for which the operation is made.

Deaths due to attacks recurring after incision and drainage may with some show of reason be charged to this method of operating. But it will not do to assume that all such deaths might have been prevented by removal of the appendix, for that would be assuming that the operation of appendicectomy itself had no death-rate, which would be manifestly wrong. On the other hand, I believe it to be true that incision and drainage has per se no death-rate. Some cases, in extremis, treated in this way will die, but not from the operation. I contend that a greater number of this class of cases will die after appendicectomy than will die after incision and drainage.

For a paper published in the *American Jour. Med. Sci.*, 1893, the statistics of which are given in Greig Smith's "Abdominal Surgery," vol. ii, p. 762, I collected 448 cases operated on. Of these, 157 cases of appendicectomy during the attack gave a mortality of 19.7 per cent.; 14 cases operated on during quiescence gave a mortality of 14 per cent. Incision and drainage in 188 cases gave a mortality of 18.18 per cent. This is certainly a remarkably favorable showing for incision when we consider that the cases that were treated by incision and drainage were so treated because their gravity, in the opinion of the operator, precluded the more radical operation.

Through private correspondence with fourteen operators of repute in this country, I collected 177 cases of appendicitis treated by incision and drainage. To these, adding 25 of my own, we have 202 cases thus treated. There was a recurrence in 13 per cent. of those cases. The time elapsing after operation varies from two weeks to twenty-one years.

Dr. Ochsner reports 9 cases, with 5 recurrences; Dr. Joseph Eastman, 20 cases, with 10 recurrences. While I do not wish to be understood as questioning the validity of the reports of Drs. Ochsner and Eastman, I do want to say that their statistics are so at variance with any other statistics with which I am acquainted, that I am forced to the conclusion that they do not teach the truth as regards the frequency with which recurrence of attacks may be expected after incision and drainage.

In my own cases I have had one recurrence. This occurred after four years. Two of my cases were operated on only two months ago. The rest were operated from ten years to six months ago. The average time since operation is about three years. My opinion is then that 13 per cent. of recurrences after drainage is certainly as many, if not more than actually obtain.

Granting that 13 per cent. will suffer with recurrence they will still have the chance of relief which operation affords during the second attack, which chance will be as good as this class of cases have from operation in the primary attack. Or they may have the chance which an interval operation affords. The interval operation is attended by nearly 6 per cent. less risk than is operation during the attack.

Given then 100 cases of appendicular abscess treated by incision, 13 will recur. Operated on during quiescence these cases will give a death-rate of 1.8 per cent. In other words, we will have the death-rate of interval operations in the hands of good operators to-day. I am not unmindful of the fact that many cases treated by incision and drainage will require an operation for

neria later. But this operation will be required in a certain number of pus cases treated by appendicectomy also. Again, an operation for hernia in the absence of infection will give a death-rate much less than the difference in favor of incision and drainage as compared with appendicectomy in cases of the character under discussion. Whether a case suited to incision and drainage could be subjected to appendicectomy with less risk of hernia following than would obtain if treated by the former method remains to be proved. I take it that no competent man would think of treating a case by incision and drainage that could be treated by appendicectomy without drainage, and it is the drainage that causes the hernia.

Of the fourteen operators above referred to all but one, Joseph Price, replied in the affirmative to the question: "Do you from your own experience regard incision and drainage as the best method of treating some cases of appendicitis?"

I wish, in conclusion, to say that it is my firm conviction that no operator can subject all cases of appendicitis to appendicectomy, without a higher death-rate than is necessary.

DISCUSSION ON PAPERS OF DRs. DEAVER AND PORTER.*

DR. NICHOLAS SENNS—I am willing to confess that there are more fistula following the retention of the appendix than its removal. Appendicitis, if not interfered with, leads in a great majority of cases to a number of conditions, but I think there is much to be done in the way of prevention. We all recognize Dr. Deaver as one of the most radical of men. Under ordinary conservative treatment, 80 per cent. of all cases of appendicitis will recover, and perhaps not more than one-half of them will ever suffer a second attack. I am glad that we have in this Section such a representative as Dr. Deaver, as he represents one side of the question and I the other. His statistics are better than mine, as I operate only on desperate cases, where there is no question as to the propriety of performing the operation, while Dr. Deaver operates on every case of pain in the appendicular region. I do not know of any more difficult subject to deal with from a surgical standpoint than appendicular fistula, and it is a dangerous operation to perform when treating it, no matter what the method. I have proposed in a number of instances to operate in the way I have described before, i. e., subperitoneal enucleation, and I prefer this method. Appendicular fistula means a great deal, and when I have reason to believe an attack has terminated in the formation of an abscess which has ruptured into the cecum, I am very cautious, as these cases are extremely dangerous. But if the abscess has formed during a first attack and ruptures into the cecum, I am very loath to recommend operation.

DR. MORDECAI PRICE, Philadelphia—I am exceedingly glad to be able, on one occasion at least, to take Dr. Deaver's side; we are not now in Philadelphia. I can endorse Dr. Deaver very strongly in this connection. I have operated 125 times, twice without pus, and fifteen times the head of the colon was open. In many cases the appendix was separated from the head of the colon by ulceration. I have not yet regretted a single operation. I have devised an operation with a view of avoiding fecal fistula by first opening the abscess and then simply enucleating the appendix. I thoroughly irrigate, draw the colon forward, separate all the adhesions within the peritoneal cavity, repair the head of the colon to the best of my ability and use silk suture for this purpose when it can be borne. I use simple gauze drainage in all cases. I replace the colon as far back as I can so as to have a long drainage tract to close by contraction. Dr. Deaver states that the drainage-tube does harm, and I am sure it is often the cause of fecal

fistula. I have yet to see a case where a cure was not effected within three weeks. The wound will close by the slow contraction of the cicatricial tissue, and I have not seen any case give trouble in this respect. As to Dr. Senn's statement that 80 per cent. of cures take place by medical treatment, I have never heard him make any such statement in any surgical meeting before. I am surprised to hear it and am surprised to hear him advise leaving the appendix in under any circumstances. If I had appendicitis and had my choice of the two men, after Dr. Senn's statements to-day, I should prefer to have Dr. Deaver treat me. This is one of the most serious questions we have to deal with. It is not five weeks since I saw two cases die of so-called medical treatment. I operate on every case that will leave the table alive, and I am more than ever convinced that when a man can not make a diagnosis he should not trust to his medical treatment. The cases that kill are those that have to be operated on before a positive diagnosis can be made. There are three men in this room in whose practice I have operated 22 times with only one death. Gauze drainage and Schuykill water will save everything that you can operate on; the trouble is the men do not use Schuykill water. I had a case of abscess in the kidney region which I simply opened and drained and in which I had made a mistake, as I believe it was a case of appendicitis and the appendix was no doubt gangrenous. I remember a case which a year ago had suffered typhoid for four weeks and pain and misery for a year. At the end of that time the muscles were like boards. His physician, who was a good man, told me he was sure pus was present, but I could not make up my mind what it was. I opened the patient and pus flowed out. I washed him out thoroughly and found a hole in the head of the colon into which I could stick my thumb. There was a large amount of rank pus present and I found five stones in the appendix. I then repaired the head of the colon, broke up every square inch of the bowel, washed out thoroughly, put in gauze and left the wound wide open. I have not used fifty silk-worm-gut sutures in ten years to close these cases. In ten days a fecal fistula occurred, and the temperature was 102. I again opened the wound and put my fingers into a quantity of pus. I used the gauze again and the man is now on the way to health. I consider this the most important part in the treatment of appendicular fistula.

As to the first paper, many young people are affected in this way. Some cases occurring in patients 50 years old have been operated on with good results, and there is no reason why you should hesitate in any case merely because of age. The patient will be more comfortable after operation than before. If you can not make a diagnosis and the case looks like death do an exploratory operation at once. When it is only exploratory a two to three inch opening in the skin would never kill any one.

DR. R. H. M. DAWBARN, New York City—I believe that twenty-five years from now we shall hear the same discussion as at present. He who is radical will be said to be killing his patients, even though he proves the contrary; while the opposite side will still be taken by many of the unconvinced. The most conservative surgeon is the one who conserves the patient's life, however radical his measures. I agree with Dr. Deaver absolutely; and if I had the diagnosis of genuine appendicitis, not merely appendicular irritation, made on my own person I should certainly be operated on at once. While I do not wish to stand up for Croton water, as Dr. Price has done for Schuykill water, we in New York do not expect pus. With so many men anxious to discuss this subject, I do not think any of us should take more than a moment on any one point, and I wish only to allude to one point. One may so frequently prevent fistula, and I have a feeling that in the majority of cases its formation is due to deficient technique. When I find the appendix is gangrenous I have invariably for some years past surrounded the gangrenous part of the cecum with a purse-string suture (a running Lembert) well outside of the gangrenous portion, and then inserted this portion. In a week the slough will separate and this portion would fall off into the feces. It would be a very unusual degree of gangrene that could not thus be surrounded. If the cecum be not left smaller

* Dr. J. B. Deaver's paper on "Appendicular Fistula" appeared July 14.

in caliber than the ileum opening into it no trouble will result. As to the statement that when a gangrenous patch is present fecal fistula will surely follow, I am sure it is not necessarily true. The technique I have named is credited to me in Fowler's work on "Appendicitis."

DR. W. D. HAMILTON, Columbus, Ohio—I have had fair opportunities for studying cases of appendicitis, considering the size of the city in which I live, and much of my experience has been gained within the last eight years. No absolute rules can be given in regard to the disease which will be applicable to all cases. It is not too much to ask the general practitioner to make repeated examinations of the abdomen of the patient from the time at which he is first called, and if the case be suspicious, he should at once call the surgeon and let him take the responsibility of saying when the operation should be done, if at all. Several points have interested me to-day, and one was the question of irrigation. I have no doubt that in some of the desperate cases it should be used, especially when the infection be general and purulent. In other cases it is unwise, lest the infection become general from its use. In my own experience fistulae have ordinarily healed without suture within a few weeks. A few have needed closure by operation. If the patient is kept in bed for a time on a liberal liquid diet and the wound kept clean the fistula, if one of the large bowel, will frequently heal. I remember a case of appendicitis operated on a few weeks ago in which a fecal fistula occurred and three or four weeks afterward it became necessary to establish an opening in the loin in order that drainage might be facilitated.

I wish to emphasize the point Dr. Senn made yesterday, that enucleation of the appendix is useful when the organ is inaccessible and can not be brought outside. It is a useful experiment and is often applicable where it might be impossible to ablate the appendix by any other method.

DR. H. MYSTER, Buffalo—If I had the choice between following Dr. Deaver and Dr. Senn, I should take the former. I agree with him that the question is decided best by early operation. I must acknowledge that I am astonished to hear Dr. Senn state that nine out of ten cases get well by medical treatment. I think we may state that in all cases of appendicitis the first change is congestion, then cicatricial retraction, obstruction and stricture. Pyelitis follows, bacilli get to work, ulceration occurs, gangrene, perforation and peritonitis result. One can not usually make a mistake in such cases. I have wondered if it is opium that Dr. Senn believes in or is it hot and cold applications? As a rule, medicine will have no effect whatever. In regard to the first of the papers, it was stated that certain cases recur after incision and drainage, but in my own practice I have only seen 5 per cent. recur after this treatment. I believe this is the proper thing to do in a great many cases, but if you see the patient early the removal of the appendix should be done as Dr. Deaver says. If we get them late, that is a different matter. The consensus of opinion is that in the late operation, say after six days, the appendix should be left alone. Dr. Deaver says that fistula is the most important sequela, but I do not agree with him, as I have seen only five in my practice. They get well by being left alone, and there was only one exception to this rule. When healing does not take place after resection, end-to-end anastomosis should be performed. Everything considered, I feel that Dr. Deaver takes a very strong position. I entirely agree with him in operating early, but I disagree with him in removing the appendix in every case. I believe in personal equation, and I also believe that Dr. Deaver may be able to do it where others would fail.

DR. W. W. KEEN, Philadelphia—Like the poor, appendicitis is something we always have with us. As a result of the discussion which was held two years ago in Denver, thirteen months ago in Chicago, at the meeting of the American Surgical Association, two questions were proposed: 1, should operation be done in every case the moment the diagnosis of appendicitis is made, and 2, should the appendix be removed in every case? It is sometimes stated that Philadelphia is asleep, but on that occasion the only two surgeons who advocated instant operation and universal removal of the appendix

were Drs. Deaver and Harte, of Philadelphia, every other surgeon who took part in the debate speaking in the negative. I can not but think that in these discussions, we surgeons forget that we are surgeons and that we are called in constantly to see the pronounced cases, but not the mild ones. I am not prepared to go so far as Dr. Senn, who says that 80 per cent. would get well without treatment, yet I can not forget the statistics of Hektoen, who, in 300 consecutive cases seen post-mortem of patients dying from causes other than appendicitis, showed that 100 had evidences of this disease. This shows that a very large proportion of the cases diagnosed as intestinal colic and such like were really cases of slight appendicitis which got well without surgical treatment. I believe there is a very large proportion of cases that surgeons never see and which do get well without surgical treatment. I do not believe in practicing surgery by aphorisms, neither do I believe that it is right that every case should be treated this way or that, as each case is a law unto itself. I have operated on cases of appendicitis just as quickly as I could make the needful preparations, and I have refused to operate. In spite of the theoretical statement Dr. Deaver makes, he does not operate on every case. I believe it might be placed as a rule with exceptions that no case certainly should ever be allowed to pass beyond two attacks, because it shows there is a condition which is sure to recur. Hektoen's statistics show that one may have a single attack and no more. Appendicitis of any gravity should be operated on, and I try to follow this rule, but I do not believe that every case should be subjected to operation. We must remember that we lay down rules here for the whole country. A rule laid down for Dr. Deaver, if made to apply to a man of less experience, one who does an operation once in three or four months, would be giving too great liberty. In many communities there are not enough cases of appendicitis to give experience. We must differentiate not only the case, but the surgeon. What is permissible for a man of large experience and great operative skill is not applicable to every doctor in this country who may be called on to treat a case of appendicitis, and I would urge therefore a consideration of what is best in the case of each individual patient. As a rule, operation will be best, but there are many exceptions. Also, as a rule, removal of the appendix is best, and as we grow larger in experience and more skilful in operating from having had difficult cases to deal with, successfully and unsuccessfully, and learn by our failures we become more and more expert and urge the removal of the appendix in almost every case. I am sure that if we had a very large number of cases of appendicitis it would be unwise for us always to attempt removal.

As to fecal fistula, I agree with Dr. Price. While they are rare, it is still rarer to find one that does not heal spontaneously. A very large proportion of them will get well if left alone. However, I have seen a number of cases that did not get well, and have been so unfortunate as to have one in my own practice. I have seen some very large ones indeed, and my usual rule is to open the abdomen clear into the abdominal cavity to the side of the fistula, cleanse and pack, and then, by making an incision at the side, I insert my finger into the opening. I then invert the margins and by appropriate treatment with a Lembert suture and gauze, complete the operation.

DR. F. W. McRAE, Atlanta—There is one statement in Dr. Porter's paper which it seems to me is misleading, that is the statement as to the frequency of recurrence of appendicitis after simple drainage of the abscess. Recurrence has taken place in more than 75 per cent. of the cases I have seen that have been drained, and removal of the appendix has been subsequently necessary to relieve the condition. Dr. Senn did not mean to say that 80 per cent. of the cases got well without operation, and he did not use the term. He said 80 per cent. would recover from the attack, which does not mean get well. A large proportion will recur and require subsequent operation. An operation for appendicitis done during an acute attack often does not leave a sound belly wall. Those who do this kind of work should consider the possibility of ventral hernia. I saw a case only the other day, of through-and-through closure where drainage was put in, develop a ventral

hemia three years after operation. Dr. Price makes a very dangerous proposition when he says that in every case of appendicitis with infection we should shut off the abdominal cavity with gauze and tear up all adhesions. I do not believe that this practice should be generally adopted, neither do I believe that surgeons generally get as low a mortality as 5 per cent. in this class of cases. I think Dr. Price's suggestion may be carried out in certain cases, but it is dangerous to recommend it as the proper practice for all cases.

Some appendicular abscesses ought simply to be drained. I have seen seven or eight cases of fecal fistula, all of which, with the exception of two, have closed without treatment other than simple cleanliness. In two of them it was necessary to operate. I reported, last December, before the Southern Surgical and Gynecological Association, the method which I adopted in these two cases. The simple point, which is somewhat original, is in the putting in of several tiers of sutures. Four or five tiers of sutures will turn the edges in without turning too much of the gut, and I have seen the method cure where a simple row of sutures would not. As to the gauze packing after operation for fecal fistula, I think Dr. Deaver's statement is somewhat misleading. I consider it had practice to pack the gauze down to the line of suture, and I believe it will often cause a failure of the operation. I use gauze, but do not allow it to go down as far as the line of suture.

Dr. JOHN B. MURPHY, Chicago—I wish to congratulate Dr. Deaver on two points, 1, on the amount of work he has done in repairing fistulae, and 2, the interest with which he has taken up the prevention of the results which he is laboring so hard to devise a means of repairing. Fistulae are not necessarily the results of bad work at the time of the operation, but they should not occur. We are not justified in having cases presented to us that will have fecal fistula. Will we ever get this matter right? Will it ever come to be as bad or worse than it was in the beginning? I will accept the statement and will add to it that more than 80 per cent. of the cases recover without operation, but I believe that 98 per cent., even 99 per cent., will recover with a timely operation. Will we come here and father a procedure which we admit has an expense of 20 lives in every 100? Is there any amount of evidence that will right it, or any proof which will prove it? I have not had Dr. Deaver's unfortunate experience in seeing so many cases of fistula. The men who call me in consultation have been educated to calling me in early. Can we, as physicians, tolerate 15 or 20 per cent. mortality without operation? Do you want your life jeopardized to the extent of 15 or 20 per cent.? We will certainly waste some time by operating on every case, and the questions are: Should every surgeon operate on every case and should every case be operated on? We must assume that good intelligent surgical skill is available in almost every town of two or three hundred citizens, and available within a few hours. Heretofore I have said that I operate on every case of appendicitis, but I wish to apologize for making this statement, as I do not. Cases of moribund appendicitis I leave to the physician, as he is entitled to have them if he keeps them up to this stage. Within the last year one physician has had three cases of this kind on which I refused to operate, and they all died. In some cases I merely empty the stomach and cease to give them food. No case should be allowed to go on to peritonitis, and I feel that any practitioner can make the diagnosis, as it is a very easy matter. The diagnosis can be made in every case within the first twenty-four hours. It is our duty as surgeons to avoid the possibility of fistula by removing the infected appendix at a time when it can be done safely, and there should not be even a loss of 1 per cent. Can any one show us that he has operated on 100 cases without a death, or on 1000 cases and not had a number of deaths? I remember no case operated on within twenty-four hours that died. I am willing to take the responsibility of operation if it has no danger.

Dr. PLATT I have listened with great pleasure to this discussion and consider Dr. Keen made a wise remark when he said that every case must be considered individually, separately and distinctly from all others. I do not think that every case should be operated on. If, within a very short time after the

beginning of the disease, it is believed that suppuration will occur, the operation should immediately take place and may be performed by an experienced surgeon with a mortality which is practically nil. If the patient has been permitted by the attending physician to go on until the disease has passed through a very considerable period, but has recovered, that patient is not well and should be operated on unless it is a very old person, because the operation will be far less dangerous than the risk of recurrence. I do not believe it is wise in all cases to waste time trying to remove the appendix. I have noticed in my own practice that where I have left the appendix in and have drained with gauze the patient has fully recovered and not in one case have I had a recurrence. I have known of serious damage being done by searching far and wide for the appendix, and I believe if we will let it alone nearly all of these cases will recover. But few of them will recur if we drain well with gauze and do not sew up the wound too soon, as this would interfere with drainage.

Dr. F. D. GRAY, Jersey City—Appendicitis is a subject which interests me very much, although I have not had a very large experience with the disease as compared with that of many here, my operation cases not numbering probably more than 175. Not more than seven, however, have proved fatal and the cases have been taken as they came, primary, moderate and desperate, just as we find them. I am a strong believer in early operation, and I think with Dr. Deaver that every case should be operated on as soon as the diagnosis is made. I agree also with what our eminent President has said, that when we talk about advising physicians throughout the country we must not give bad advice; but what shall we aim at? Shall we strive for less than can be done by the best men? I claim that when we talk about operating on all cases of appendicitis we have mainly in mind cases which come to us for advice. I believe that any surgeon with an aseptic hand and instruments and a fair knowledge of technique can open the abdomen and remove a primary inflamed appendix with safety. When we come to statistics, admitting that 80 per cent. will get well without operation, what are the surgeon's results? Do you expect that 20 out of every 100 will die. We would all be ashamed of such results from surgical treatment. I do not claim any especial skill, but, as I have said, I have only had 7 deaths in 175 cases, and 5 of them should not have been touched had I had consideration for my statistics. I would like to plead also for the cases that may not be moribund, but still are suffering from general peritonitis. These are the cases which usually remain under the care of the physician until surgery is called on as a last resort. I have done a laparotomy in about fifteen of these cases and found them suffering from a virulent form of peritonitis. Ten of them are living to-day. After opening the abdomen I eviscerate the intestines completely into hot towels, wash out repeatedly with a saline solution and peroxid of hydrogen, flush the abdominal cavity again, return the intestines and drain with gauze. I do not simply drain in one direction, but in several, and remove the drains in two or three days. This procedure I am convinced will save many lives.

Dr. RUFUS B. HALL, Cincinnati—I do not feel that this discussion should close with the statement that desperate cases should be left to the medical man. We see too many of them in which there is an accumulation of pus six, eight or ten days after the primary attack and these are the patients who deserve a chance to get well. If they are dying I agree with Dr. Murphy, but if not they should be given a chance by letting out the pus. In this class of cases I disagree with the speakers who say that we should remove the appendix in all of these instances. Should the patient get well, a second operation can be done at a time when they would have some show of surviving, but if you do complete the operation at that time you will lose your patient. When you are called to see the case at the bedside you must decide this question for yourself. If you believe that every one of them must be operated on as soon as the diagnosis is made you will lose many.

Dr. H. J. BOLDT, New York City—I agree entirely with Dr. Murphy and operate on every case except those that are moribund. We have heard that about 80 per cent. will get well

without operation and 90 per cent. will survive the primary attack. A second attack may occur, however, and within twenty-four hours a general septic peritonitis may have developed. If the patients get well from the primary attack, by all means advise radical operation during the interval. I fully agree with what has been said by those who take the ground that radical operations should be done in every case of appendicitis.

DR. CHRISTIAN FENGER, Chicago—Operation is not always the first thing to be thought of in appendicitis; if 80 per cent. recover from acute attacks they will be in a state of comparative safety. My own practice and my advice to my students is to first make the diagnosis, but not to operate simply because the diagnosis is made. If the symptoms improve, the patient may recover from the attack, but if they become worse immediate operation is indicated. About 30 per cent. of the patients have a second attack. About one-half of these have the second attack during the first year, while 70 per cent. do not have any recurrence. The question when we should operate is a difficult one, but I wish to emphasize conservatism and do not feel that the 80 per cent. necessarily should be operated on.

DR. WILLIAM EASTERLY ASHTON, Philadelphia—I agree absolutely with Dr. Deaver in the position he has always taken with reference to early operation so soon as the diagnosis is made. If you are called in to see a case and you make the diagnosis you can not say what the condition of the patient may be to-morrow. It is absurd to say: "Call in the surgeon early"; you might as well say: "Call in the cook," as she has as much knowledge of what is going on as the best surgeon in the country. I agree with Dr. Murphy that 20 per cent. mortality in the early operation is horrible. If we can only offer 80 per cent. recoveries, then I for one believe that the patient is running risks which are not justified. The whole question is in our ignorance in diagnosis. If we have a large lump present, it is easy to say that the patient should be operated on, but it is in the early stages where the difficulty arises, as it is impossible for us to know what is going on or what to do. I operated on a case three weeks ago which was first seen by me on Sunday. The patient had been taken sick the previous Thursday, and when I saw him his general condition was good, pulse 80, temperature normal, abdomen flat, and pain on pressure over the right side. I advised operation and transferred him to the hospital, where I found a post-cecal appendix one inches long, thick and gangrenous. In a few hours more perforation and death would have occurred. There was considerable objection to the operation because the man had been getting steadily better so far as his symptoms were concerned, but the appendicitis caused me to urge operation, and it was one too soon.

DR. ERNEST LA PLACE, Philadelphia—There is no doubt that the mortality from appendicitis is too high. We are constantly being shocked by the death of well-known people from his disease, and every effort should certainly be made to diminish this mortality. In every case of appendicitis there is a time when operation will mean recovery. If this is true, and why should it not be true, when we know that a mere opening of the abdominal cavity has no danger, then the medical man is responsible for the death. If we could establish precise rules on which the diagnosis could be made, then the diagnosis would be an indication for operation. Is this possible? Do all of us who have studied pathology, especially recent pathology, know in a given case of appendicitis whether the pain is a symptom which has a microbe element? Is it the staphylococcus? Is it the streptococcus? Is it the bacilli coli? Toxins may develop, the absorption of which may cause death, and yet give very little general recognition. You may have the appendix loaded with the bacilli coli and yet you may have no temperature disturbance. The pulse may have gone up, but if it had been stimulated by the streptococcus there would have been some equilibrium between the pulse and the temperature. How are we going to tell what is going on? I know from experience of a case which occurred some months ago in a gentleman 26 years of age. He had been ill only two days, but it is my rule to take it for granted that it

is a grave case when I am not sure. The man refused to be carried to the ambulance and also to use the elevator, preferring to walk, which he did, to the top floor of the hospital building. His father wanted to be present at the operation, but I refused him permission. When I opened the abdomen his pulse was 90, his temperature normal, and I found three enormous abscesses in the abdominal cavity. Peritonitis developed. You may be sure that the next case I see will be operated on, but should I neglect to do so I shall always have the lasting regret that I had not benefited by experience.

DR. A. J. OCHSNER, Chicago—In order that my statistics which Dr. Porter quoted may not be misleading, I must say a few words in explanation. The nine cases to which he refers and which were treated by means of drainage without removal of the appendix all occurred in my practice during the past two years, 1898-1899. During this time I operated on 248 cases of appendicitis. Consequently this form of treatment was employed in less than 4 per cent. of all cases. In former years I employed it in a much larger proportion of cases. In many of these the pathological conditions were very much less serious in character, and consequently the relative number requiring further operative treatment was much smaller at that time. No surgeon should be guided in this matter by the opinion of another, for with increasing experience and skill each one will find that he can remove the diseased appendix safely at the first operation in a relatively greater number of cases.

The question in any given case is: Will the patient be more likely to recover from the present attack by simply instituting drainage or by adding to this the removal of the appendix? The surgeon in the meantime must not base his treatment alone on the condition he finds, but also on his own skill and experience.

It seems proper in this discussion to speak of a form of treatment which, if employed systematically, will not only make the operation of which Dr. Porter speaks unnecessary, but also prevent the recurrence of the complication which is the subject of Dr. Deaver's paper. In order to show why the treatment I am about to advise is of great value, I must first direct your attention to the anatomical location of the appendix. It is located in the most favorable position possible for its isolation from the general peritoneal cavity, having above it the cecum and the cecal end of the ileum; behind it is the peritoneum covering the iliacus muscle; to the right and in front is the parietal peritoneum, and to the left the small intestines. Were it not for the presence of the very movable small intestines to the left it is plain that an inflammation of the vermiform appendix must necessarily result in a harmless circumscribed abscess in the worst case. This would be the more likely because the omentum folds itself about the appendix at once in case of inflammation. In order to prevent extensive, dangerous and destructive inflammation, then, it will be necessary to secure complete rest for the small intestines. The motion in the small intestines is due to peristalsis, and this is due to the entrance of food from the stomach into the small intestines, even in very small quantities. To secure complete rest it is, consequently, necessary to prohibit the use of food of any kind by mouth, and if the stomach contains food, to remove this by means of gastric lavage. The patient may be nourished by the use of concentrated predigested enemata, not to exceed four ounces at a time, given once every four to six hours. I have employed this method in many cases and it is certainly of great practical value. It relieves the pain by rapidly reducing peristaltic motion and gaseous distention of the intestines; it prevents the small intestines from carrying the septic material from the region of the appendix into the more sensitive portions of the abdomen. In short, it prevents all of the most favorable conditions and complications of appendicitis. I would, consequently, advise the treatment consisting in absolute and complete prohibition of the use of food and cathartics by mouth; of performing gastric lavage, and of employing exclusive rectal alimentation in all cases of appendicitis.

DR. MILES F. PORTER, closing—At our meeting a year ago Dr. Deaver stated that he advised removal of the appendix

in all cases on which he operated and later stated that he did not advise it, but always did it. In his paper to-day he reported a case where he did not remove the appendix, and therefore there is no difference of opinion between us. I am absolutely opposed to the method of operating suggested by Dr. Price. He says that he breaks up the abscess walls, which in my opinion not only harms the patient, but may kill him. It kills patients that do not need to be lost. As to the matter of statistics, I said that 13 per cent. of recurrences after drainage was too large and I still believe it. I must enter a most earnest protest against the statistics given by Dr. McRae, i. e., that 75 per cent. of the cases operated on recur if the appendix is not removed. I am aware of the fact that there is nothing so fallacious as facts, except figures, but making all due allowance, we must not accept this statement. I believe I understood Dr. Murphy, and I believe the impression he leaves is a wrong one, i. e., that when a case is so bad that it scarcely has a chance of recovery he leaves it to the physician. I do not think he means this. I am too sympathetic to let any of these patients die without operation, and 99 per cent. of them will probably die, do what you will; but every now and then you will save one and you will not kill any. Every surgeon should give a patient a chance for his life, and I think that we should be very careful as to the impression we leave regarding statistics. I was very glad to hear Dr. Ochsner's explanation of his method of treatment.

One man reported 175 cases of appendicitis, including severe pus cases, with only 7 deaths; I must say that he is playing in better luck than any operator I know—that is all.

Dr. J. B. DEEVER, closing—While Dr. Senn and I are the best friends, it is evident we do not agree on the subject under discussion. Dr. Senn says that I am a man of extreme ideas; I am glad to go on record as such on the subject of appendicitis. Gentlemen who visit the German Hospital have ample opportunity of seeing many of my cases after operation, and can testify as to the result. I operate as soon as I can make the diagnosis and do not wait until the eleventh hour to do it, which will mean crape on the door. I regret to say that I have not one iota of confidence in the judgment of a man who says that he can wait until pus is present, for such a man knows nothing of the gravity of the disease. I could cite case after case were it necessary, but I would like to ask how many men there are here this afternoon some of whose friends would not have been saved had they had the treatment I advocate. My cases number in the thousands, and I simply say that I know in the majority of instances when a case has appendicitis, and I also know that when such is the case the appendix should come out. This subject has been very thoroughly discussed, but I confess I am much grieved to hear some of the utterances made. It is our mission to promulgate the doctrine which will save and not destroy lives.

Dr. Keen said in Denver that a living man with an appendix is better than a dead man without; I should say that in my opinion a living man without an appendix is better than a dead man with one. Dr. Keen says that I do not operate on every case, and that is true. I may not have the conveniences at hand, friends may object, and the patient may be practically dead when I am called. I do not believe any of us can cure general septic peritonitis. My experience is that in the latter case death is more painful after an operation than before it. I am arguing from the standpoint only which will save the greatest number of lives. Dr. Keen states that early operation will save more lives than late operations, and he also mentions that he sees many cases very late. Why? Because of the teaching that we should wait several days, when the patient is thought to be doing well, before doing anything. I regret seriously that such a stand should be taken. No men have my regrets more than Drs. Senn and Keen, for they are promulgating a theory which will cost many lives.

Hydrogen Peroxid as a Hemostatic.—The *Scm. Méd.* quotes Rifaux to the effect that hydrogen peroxid is extremely effective as a hemostatic. A tampon moistened with it inserted in the nasal fossa in case of hemorrhage will arrest even the most serious and uncontrollable epistaxis.

TREATMENT OF IMMATURE CATARACT.*

JOHN E. WEEKS, M.D.

NEW YORK CITY.

Non-progressive cortical opacities are very rare. The opacity accompanying congenital coloboma of the lens, the partial cortical cataract caused by the adhesion of a retained or acquired pupillary membrane and some forms of traumatic partial cataract do not progress. The anterior punctate cortical cataract, the posterior cortical cataract and the form of zonular cataract, in which the zone is situated well in the cortex of the lens, are extremely slowly progressive. Traumatic partial cataracts, with or without perforation of the capsule, sometimes become stationary and in a few cases the opacification partly disappears. Anterior and posterior polar cataracts are almost always stationary. The small white congenital cataract which occupies the center of the lens and apparently includes only those fibers that are formed during the second stage of development of the lens, the axial congenital cataract and a few cataracts with mixed opacities, are stationary or nearly so. Some forms of monocular stellar cataract, probably of traumatic origin, do not advance. Zonular cataract almost invariably becomes denser as the individual increases in years and in not a few cases general opacification of the entire cortex follows.

The development of cataract is due to a departure from the normal in the nutrition of the lens. The change which takes place in the lens structure may be either hyperplastic and degenerative, or simply degenerative. Cataract which forms during the course of an iritis, cyclitis, choroiditis, or which accompanies intraocular neoplasm, not infrequently presents a swollen appearance, a thickened capsule and a multiplication of epithelial cells. The epithelial cells form in masses on the posterior surface of the anterior capsule, produce cystoid cells at or near the equator of the lens, and sometimes more or less completely cover the anterior surface of the posterior capsule. This form of cataract is sometimes spoken of as inflammatory. To designate these cataracts as inflammatory is plainly a misnomer, since their development is due to perverted nutrition only. In traumatic cataract, with infection of the lens substance, a multiplication of germs takes place in the lens accompanied by an infiltration of small cells and a disintegration of lens fibers. In no other condition will we find a true phakitis.

Cases in which medicinal therapeutics are indicated, due to the condition of the interior of the eye, are those in which intraocular disease, other than cataract, is present, choroiditis, iritis, cyclitis, glaucoma, retinitis, parenchymatous kerato-iritis, atheroma of retinal vessels, etc. The treatment should, of course, be local and constitutional and does not differ because of the presence of opacities in the lens, from that which would otherwise be employed. The influence of such treatment on the lens structure is not to clear up existing opacities, but to prevent further opacification by improving or by preventing further impairment of the nutrition to the lens.

Medicinal therapeutics and other measures to improve health based on the constitutional condition of the patient have a wide range and are of value in preventing the progress of cataract, but are of no importance in causing a disappearance of opacities that have already formed. In atheroma of the vessels,

* Presented in discussion to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

arterio-capillary sclerosis, rheumatic or gouty diathesis, diabetes mellitus, albuminuria, pernicious anemia, extreme prostration and impairment of the health from any cause, proper therapeutic measures should be resorted to. I have had the pleasure of recording the arrest of opacification of the lens in patients whose general condition has been much improved by tonic and other treatment.

The question regarding the value of local therapeutic measures, such as massage, absorbents—so-called—or stimulating remedies introduced into the conjunctival sac, and electricity, in the early stage of senile cataract, to prevent progression in the opacification of the lens or to cause existing opacities to disappear, although very old, is one of much interest. All are apparently agreed that opacification of the crystalline lens is the result of impaired nutrition to the lens. Attempts to improve the nutrition to the lens are perfectly legitimate, and I do not think it beyond the possibilities to so influence the circulation of the eye, in some cases, that the progress of the cataract may be delayed. One who is familiar with the anatomical changes present in incipient or advanced senile cataract, of all kinds, must recognize the futility of attempts to cause opacities that already exist to disappear to any marked extent, and must recognize the fact that he who claims to cause the lens to again become transparent is either a knave or a fool. The prevention of opacification is quite another thing and is well worthy of careful study.

From the knowledge afforded by a study of the reports of methods for ripening cataract, the influence of traumatism on the lens and the results of massage of the eye as applied by others, I am of the opinion that this measure is not of much value in the prevention of opacification of the lens. It has fallen to my lot to operate for the removal of mature cataract on a number of individuals who have been subjected to massage of the eye for many months by those who profess to "absorb" cataract by this means.

Electricity in various ways has been applied by others to patients on whom I have subsequently operated for the removal of cataract. Personally, I have no knowledge that electricity has any effect in improving the nutrition of the eye; however, I am not in a position to bear positive evidence against it. I am of the opinion that the beneficial results to be obtained by its use are disproportional to the time and expense necessary to its proper application.

It is, of course, well known that opacification of the lens in some cases advances to a certain stage, becomes stationary and so remains for a varying length of time. Because of this it is difficult to ascertain what benefit is derived by treatment directed to the arrest of the development of cataract. Only by observing a relatively large number of cases and comparing those treated with similar cases not treated, will we be able to decide the value of any course of medication. For the last twelve years I have been directing some of my patients afflicted with incipient cataract, to employ stimulating collyria and moist heat to the eyes, for the purpose of ascertaining what influence the treatment would have on the development of the cataract. I am not as yet ready to report on this study further than to state that the results are sufficiently encouraging to cause me to feel justified in continuing. It should be added that the general condition of the patient is improved to the greatest possible extent, and so maintained in all of these cases.

It is generally known that changes in the refraction of the lens frequently occur during the development of cataract and that the adjustment of glasses in the earlier stages may improve the vision. In a case recently observed, myopia of 3 D. developed. In all cases where vision can be improved, glasses should be given, not with the expectation of producing any effect on the development of the cataract but for the increase of vision only.

In cases of nuclear, zonular, polar or axial cataract, either in youth or in age, if the tension of the globe is normal and the vision is improved thereby, a weak solution of atropin, sufficiently strong to produce a moderate dilatation of the pupil, may be employed often enough to maintain maximum vision.

Myotics are seldom required, but in certain rare cases where the axis of the lens is comparatively transparent and the apices of the opaque sectors, from the equator of the lens, enter the normal pupillary area and disturb vision, and in those cases where the development of cataract is accompanied by increase in tension as when the lens is swollen, a myotic may be employed. Pilocarpin is usually sufficient, but eserine may be required in some cases.

Regarding the operative procedures advisable in non-progressive cataract, the writer is of the opinion that optical iridectomy is advisable only in those cases where vision can be brought up to 20/40 or better by use of a mydriatic, and a correction of the error of refraction if any exists. This degree of vision should be obtained to permit the individual to pursue the ordinary vocations of life.

In all other cases of cataract where the fundus is normal the removal of the lens is necessary. In operating for the removal of immature cataract a number of procedures are open to us: In young individuals, needling of the lens with or without subsequent extraction of the broken-up lens substance by means of small linear incision in the cornea; preliminary iridectomy, with or without direct or indirect trituration of the lens, for the purpose of hastening the maturity of the cataract, applicable to old or young individuals; extraction either simple or combined. In a paper read before this Section in 1895 entitled, "The Treatment of Some Forms of Zonular and Immature Cataract," in which twenty-five cases were reported, I stated that I had abandoned the ripening operations for the reason that the facility of removal was not sufficiently increased to warrant the extra risk and trouble to the patient. I have not changed the views there expressed. Whenever in the development of cataract, the vision is reduced to such a degree that the individual can not follow the ordinary vocations of life, provided there is any reason for not waiting until the cataract is mature, I do not hesitate to advise operation. The choice of the method to be employed in removing the cataract depends upon the case. How to operate permits of an exercise of judgment, and the surgeon who is best equipped, in the way of experience and in a knowledge of the anatomical and pathological conditions present will succeed best.

DISCUSSION ON "IMMATURE CATARACT AND ITS TREATMENT," P. 1467, BY DR. G. E. DE SCHWEINITZ.

DR. S. D. RISLEY, Philadelphia.—I am personally indebted to Dr. de Schweinitz for bringing this subject once more before the Section. The first paper I had the honor of bringing before this Section, during the presidency of Dr. Connor, in 1889, was on the subject of "Incipient Cataract, Its Etiology and Treatment." That paper was based on a careful analysis

cases of immature and incipient cataract seen in my private practice. I then took the ground to which Dr. de Schweinitz has kindly alluded this afternoon, that the term senile cataract seemed to present the idea of old age as the sole cause of the disease. In contradiction of this view, I stated that the majority of old people do not have opacities of the lens; that though the lens may become straw-yellow in old age, it becomes cataractous only in exceptional cases; that therefore in those who did have cataract we should conclude there was some extraordinary cause producing it. The analysis of 80 cases seemed to show that this cause existed in disease, more or less pronounced, of the uveal tract of the eye. I showed, furthermore, in those cases that in a very large percentage of them not only was there demonstrable disease of the choroid in the eye in which the lens was sufficiently transparent to permit study of the eye-ground, but that floating vitreous opacities were present, and that in the majority, or at least a very large percentage, the individual suffered from headaches, asthenopia, red eyelids, chronic conjunctivitis of the congestive type, etc. In those cases in which the opacity is fixed and non-progressive, it is fair to presume that at some time in the history of that case the conditions I have alluded to were present, but when they reached such a stage that the light was partially excluded and the eye was permitted to rest the disease of the choroid gradually subsided and the opacity did not advance to maturity. This was my conception of the history and cause of opacity of the lens, and I argued that if I could arrest the cause by treatment I could probably arrest the progress of the opacity. I want to say here, and I think it should go distinctly on the records of the Section, that we never see the slightest disappearance of an opacity in the lens. I said then, and I say now, I have never seen such opacities disappear. Where an opacity is formed in the lens you can rest assured it will remain there and I think we should say so in order to prevent imposition on the community by the charlatans who advertise the removal of cataract by absorption.

The lower and inner quadrant is the portion of the lens where most of these opacities begin, and it is just this portion of the choroid that is most exposed to the light. Dr. de Schweinitz, at my suggestion, some years ago studied the condition of the choroids of a large number of stokers, and showed that the portion of the eye exposed to the heat and light was most frequently the site of inflammation and frequently presented opacities of the lens at that portion.

We shall often find that by the prolonged use of mydriatics, the correction of errors of refraction, and by the internal use of potassium iodid and other alteratives, the disease of the choroid is arrested, the acuity of vision very much improved, and the progress of incipient opacity of the lens arrested. There is one other point I wish to emphasize and that is concerning the surgical interference for the ripening of these immature cataracts. I observed carefully a series of 25 cases in which I did this operation. In many of these I did not succeed in making the slightest change, even in the opacity of the anterior cortex. A few seemed to ripen rapidly, but when I tried to extract the lens I found the posterior cortex clear and unaffected by the previous operation. Furthermore, in those instances in which the lens cortex was affected by the rubbing the subsequent extraction became difficult because of the glue-like tenacity with which the cortex adhered to the capsule. I quite agree entirely with the reader of the paper in the statement that he would very much rather take chances of extracting an immature cataract than to extract one which we have endeavored to ripen.

Dr. J. A. LAPPINCOTT, Pittsburg—I wish to express also, as Dr. Risley did, my gratitude to Dr. de Schweinitz for his very able paper. His conclusions are so reasonable that we must certainly all agree with him. I certainly do and my experience has extended over a long time. I just desire to add that I have seen three or four cases of these opacities of the lens that were beautifully symmetrical in the shape of spokes of a wheel, and which lasted in three cases for 16 or 17 years, finally culminating in perfectly opaque cataracts on which I operated.

Dr. W. H. BATES, New York City—I had a patient, 70 years of age, with lenticular opacities. About the time she was under my treatment I became acquainted with a gentleman of New York City, a physician in regular practice, a member of the New York Academy of Medicine, a graduate of Dublin University, and a very bright man, Dr. James E. Kelly. I sent this patient to Dr. Kelly for general treatment. Before she went to see him her vision was 15/200 from the incipient cataract. She came back to me in three months, and I can tell you positively that she then had no opacity of the lens, and her vision was 15/10. That is three years ago, and I saw the lady recently and she still has the same vision and no opacities. I have seen a second case in which there were opacities, and under the treatment of Dr. Kelly and in the course of a few months the lenses became perfectly clear. A third case, a patient 60 years old, with very prominent characteristic opacities of the lens and a vision of 15/50 with correcting glasses, was sent to Dr. Kelly, and in three months' time her vision was improved to 15/10, and a number of the opacities had disappeared.

Now, what did he do for them? I do not know. He told me, or tries to tell me, and the patients say he gives them water, at least three quarts a day, and has them go through exercises. Now, why does he give them water and exercise? The cataractous lens contains a great deal less water than the normal lens. That may be the reason this treatment helps them. I noticed in the patients he treated that the skin became clear where before it had been muddy, which is a condition found in many old persons; after a general hygienic treatment the skin becomes more like that of young people, and it may be that the treatment benefits the eye in the same way it does the skin, since both are formed from the epiblast.

Dr. J. L. THOMPSON, Indianapolis—I wish to speak of one case that I did not send to Dr. Kelly. In 1871 a gentleman came to me with very white-looking cataract in one eye, and when asked if he had ever received any injury, he said he had not. The other eye was perfectly clear. I did not see him for a number of years, when he came in one day for some trifling ailment. I think the removal of a foreign body. About fifteen years ago the second eye became cataractous. He was a drinking man and, in fact, had nearly every vice under the sun. I operated on that eye and did a very beautiful operation, but he had an inflammation, an iridocyclitis, and lost the eye. He was blind then, and wanted to know what I could do for the other eye. I was afraid to touch it, but finally agreed to make a preliminary iridectomy, and lo and behold he could see a little, there being a clear space beyond the periphery of the lens. He complained a year afterward of pain in the eye and had to use eserin, and a month later that lens looked as if it was filled with water. I see that man now occasionally, and you can see the red reflex, but the lens disappeared and the capsule only remains filled with water. Perhaps, if a man could live three or four hundred years, a great many of these cases would cure themselves.

Dr. G. O. KING, Philadelphia—The statement made by Dr. Bates recalls a case in my own experience. A lady in Philadelphia came under my care with well-marked double optic neuritis and vision reduced to almost nothing. There was a well marked incipient opacity in the lens, very much like the one the Doctor described. In the course of a few weeks a consultation was held with Dr. Norris, my teacher at that time, and I remember that one of his first observations was that the patient had beginning cataract. The case was clearly a specific one. Active treatment was begun at once, and at varying intervals the patient was observed by me until now every particle of the opacity of that one lens has certainly disappeared and her vision is 20/20 in one eye and about 20/30 in the other. That is entirely unique in my experience, and I have never observed any opacity absorbed but that.

Dr. I. R. GRADLEY CASE, Collinsville, Conn.—About nine years ago two papers published by Dr. Kalish, in the *Medical Record*, on the absorption of immature cataracts fell into my hands. I had plenty of time at my disposal and tried the method after corresponding with Dr. Kalish, so that I might carry out his plan perfectly on a small list of patients. I

recall now four cases where I patiently rubbed the eye from within outward with the ball of the second finger, as directed, for one-half hour daily for weeks. Of these cases, one of traumatic cataract showed not the slightest change. Another, of congenital cataract, undertaken at his earnest request, showed not the slightest change at the time nor several years later. Two other cases of senile cataract resulted as follows: One became more rapidly progressive than I have noticed in other patients of the same age, and the other remained stationary until the time of the patient's death. I now tell my patients with senile cataract, keep your digestion good, use your eyes reasonably, do not worry.

DR. G. E. DE SCHWEINITZ, closing—Opacities in the nasal quadrant are sometimes nearly non-progressive, that is, their progress is certainly very slow. There is another variety that is associated with a corresponding patch of retino-choroiditis that does progress. My only object in bringing up this subject was that we should discuss the best measures for the relief of these patients, and to state my belief, which has been strengthened by the discussion, that there is some reason to believe that we can help these people with proper treatment.

RHEUMATISM AND THE PREVENTION OF HEART COMPLICATIONS.*

JAMES J. WALSH, M.D., Ph.D.

Instructor in Diseases of the Chest and General Medicine, New York Polyclinic.
NEW YORK CITY.

More than fifteen years ago Eichhorst, of Zurich, in the third edition of his "Handbuch der Speciellen Pathologie und Therapie," transferred rheumatism from the class of constitutional to that of infectious diseases. In doing so he was only expressing a conviction that had been forming among clinicians generally. Because of certain superficial resemblances to gout, rheumatism had been classed among diathetic diseases, but without good reason, as time and closer clinical observation showed. Eichhorst's position was not unique, but it is only after fifteen years that the medical profession is coming to acknowledge its correctness. We have at length come to the point of conceding the infectious nature of rheumatism. The reasons given by Eichhorst before any germs had been described as occurring in the lesions of the disease are to-day the best arguments for its infectiousness. Rheumatism has all of the characteristics of an acute infectious fever—the incubation period, the sudden rise of temperature and the remission, with gradual convalescence. It occurs particularly in damp weather, but so does pneumonia, and the dampness seems to stand only in a secondary causal relation to the disease. Even its contagiousness, under certain circumstances, is well established. It has been known to spread through a hospital ward, and to frequently attack several members of a family at the same time. In schools and barracks single cases of it are rarer than the occurrence of several about the same time. According to Eichhorst, Pöcoek, Schaefer, Jaccoud and von Strümpell, pregnant women have been seen suffering from rheumatism who gave birth to children presenting the symptoms of acute rheumatism.

The infectious nature of the disease is shown by its tendency to produce lesions in the most widely different parts of the body. An acute rheumatic arthritis of the wrist or ankle may be complicated by a rheumatic meningitis, endocarditis, or pleuritis. Autopsies made on patients dead during the acute stage of the disease present striking indications of an infectious disease. Hem-

orrhages into the various organs are noted; there is cloudy swelling of the cells, of the heart, of the kidneys, and of the liver. There is the enlarged spleen of distinctly lessened consistency so characteristic of infectious diseases.

BACTERIOLOGY.

Notwithstanding that rheumatism seems to be an infectious disease, no definite bacterial cause has as yet been established. As long ago as 1883 Babes found bacilli and cocci in the synovial fluid of a patient who died during the course of an acute rheumatism from intercurrent nephritis. Observers have found other micro-organisms in various fluids of rheumatic patients who had succumbed to some complication. All of these were isolated observations until the beginning of the present decade, when Bouchard and Charrin found various forms of staphylococci in six different cases in the synovial fluid of patients suffering from rheumatism. Shortly afterward Achalme found an anaerobic bacillus in the tissues of two cases. A third case of the same kind was noted the next year. Other investigators failed in a number of cases to find the micro-organism described by Achalme, though one or two confirmed his results. Triboulet and Coyon found a series of micro-organisms in rheumatic patients, occasionally staphylococci, sometimes streptococci, in rare cases Achalme's bacillus, and almost constantly a diplococcus. In eleven consecutive cases of acute articular rheumatism that came under their observation in succession, some of them severe, others comparatively mild, this diplococcus was found. Cultures made from the blood always resulted in the growth of this germ, which they consider the cause of rheumatism. Intravenous injection of this diplococcus into animals always causes endocarditis of the left side of the heart, especially of the mitral valve. German observers, as a rule, have not found micro-organisms in the blood or in the secretions. Singer, it is true, found various micro-organisms in the synovial fluid in the blood and in the urine of patients suffering from rheumatism, but only in a small proportion of cases. His results were not substantiated by Chvostek, who is a careful observer. The blood in all of sixteen cases examined by Chvostek was uniformly sterile; only once was the articular fluid removed from rheumatic joints found to contain bacteria. These proved to be bacilli, but scant in number. Some years ago Leyden and the assistants in his clinic found a diplococcus in rheumatism; Senator found a streptococcus. The only micro-organism which may be considered to have sufficient evidence in its favor to justify its being considered as a frequent cause of rheumatism is the diplococcus form. Even this, however, has not been found often enough to justify any definite conclusion as to its specific pathogenicity.

RHEUMATISM NOT A SIMPLE DISEASE ENTITY.

Several important deductions may be made from the multiplicity of the micro-organisms that have been found by different observers. It is clear, even from clinical observation, that acute articular rheumatism as we know it is not a simple nosological entity, but is probably a series of similar diseases more or less closely related to one another. The term "pneumonia" a quarter of a century ago embraced a number of affections that we can now easily differentiate from each other. The ordinary self-limited acute arthritis, which usually terminates of itself in from ten to fourteen days, is perhaps due to the diplococcus found so often. Cases that run a longer course, and prove intractable, are due to other forms of bacterial life, or are complicated by

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

secondary infection. The rapidly fatal cases of rheumatism with high temperature, coma and collapse, of which quite a few have been reported by various observers, are probably due to the anaerobic bacillus described by Achalmé.

THE ACID DIATHESIS IN RHEUMATISM.

If we are to accept rheumatism as an infectious disease with a bacterial cause, the question arises, has the acid diathesis, which meant so much for a preceding generation, in the production of rheumatism, no effect in the etiology of the disease? There are those who, like Haig in England, still insist that the uric-acid diathesis is the constitutional basis of all rheumatic manifestations. This view has long been abandoned by most of the profession. For many of the older practitioners lactic acid is still supposed to play an important rôle in the causation of rheumatism. It is hard to understand on what the conviction of the etiologic importance of lactic acid is based. The feeding of lactic acid to animals does produce joint lesions, but very different from those of acute arthritis. Lactic acid has been used in considerable quantities in recent years as a remedy for diabetes, but it has never been known especially to predispose diabetics to arthritic manifestations.

The idea of an acid diathesis in rheumatism seems to be founded on a series of misconceptions. The urine of rheumatism is said to be acid. Yet there are those who say that it is alkaline when recently exuded, and only acid after standing. There are others who insist that it is originally acid. The only solution of the question seems to be that sometimes the sweat of rheumatism is acid and sometimes it is neutral or alkaline.

It seems interesting to note that if the blood in rheumatism is acid, as it is said to be by many, it would prove a much less favorable culture-medium for microorganisms than when in its normal condition. Most of the ordinary pyogenic cocci either do not grow on an acid culture-medium, or grow much less luxuriantly and with lessened virulence. It is possible, then, that the hyperacidity of the blood is a protective reaction on the part of nature. The reason why pyogenic cocci in the circulation do not produce pyemia is perhaps because their growth is inhibited in numbers and in vitality by the acid medium in which they are. The alkali treatment as ordinarily given in rheumatism would then be a simple undoing of nature's protective process. As there are many who seem to doubt that the alkali treatment does any good, this makes the question of its employment rather serious.

SELF-LIMITATION AND LOW MORTALITY.

Next to its being an infectious disease, the most important thing about rheumatism is that it is self-limited. This feature has been as much overlooked as its infectious origin. To Austin Flint, according to Professor Osler, belongs the credit of having first pointed this out. Notwithstanding the many remedies recommended for its treatment, rheumatism, like the other infectious diseases, remains practically uninfluenced in its course by any remedy. Symptoms, especially the pain and the fever, may be very much alleviated, but the duration is probably very little, if at all, affected by any treatment.

Rheumatism is a disease which is very seldom fatal. Professor Pribram, of Prag, has had under his care in the last sixteen years 627 cases. Of these, but six proved fatal; only one from hyperpyrexia. This was the only

case in which the complication that brought about death could with any assurance be attributed to the rheumatism itself. Of the five other cases, one died from tuberculosis of the lungs, two from nephritis and uremia, one from pneumonia, and one from sepsis including osteomyelitis and metastatic abscesses. The mortality of the disease itself is probably not more than .1 per cent.

HEART COMPLICATIONS.

Professor Osler thinks that the number of heart complications in rheumatism is grossly exaggerated. In 209 cases carefully examined for this purpose he found only 24 endocardial involvements, while French writers give as high as 65 per cent. Vernal, as the result of several hundred observations, gives the percentage in the rheumatism of children as more than 80 per cent.; Church, 67 per cent. in cases between 10 and 20 years of age, and 54 per cent. between the ages of 20 and 30 years. Hirsch found 52 per cent. between the ages of 16 and 20, 65 per cent. between 21 and 25, 50 per cent. between 26 and 30, and 83 per cent. between 31 and 35. Pribram, to whom I owe these figures, and whose monograph on acute rheumatism in Nothnagel's "Spezielle Pathologie und Therapie" shows how thoroughly he has reviewed the literature of the subject, besides having a very practical acquaintance with the affection clinically, gives the average number of heart complications in primary attacks of acute rheumatism as from 38 to 40 per cent. In this he includes about 5 per cent. of pericardial complications.

How often chronic endocarditis is due to rheumatism is quite as interesting a question, and perhaps even more important. The statistics as to the rheumatic origin of chronic endocarditis are quite as indefinite in their way as those of percentage of heart complications that occur from rheumatism. Once more the French authorities give the highest numbers. Seventy per cent. of all cases of endocarditis are said to be due to rheumatism. All infectious fevers may cause endocardial involvement. In taking the history of a patient with a heart lesion, we all realize, especially in recent years, how important it is to consider rheumatism.

TREATMENT.

At the end of the last century, to a student who asked what was the best thing for rheumatism, Corrigan, the distinguished Irish surgeon, said, "Six weeks." During the first half of the century the medical profession, in England particularly, believed very firmly in the efficacy of the alkali treatment. About 1860 the coal-tar colors were found, and among other members of the coal-tar derivative group was salicylic acid, which proved on trial to have a remarkable effect in alleviating the symptoms of rheumatism. Something that is not generally remembered, however, is that an extract of the willow tree had been in use in England for nearly a century as a useful remedy for rheumatism. About the time that salicylic acid became so popular in Germany, salicin acquired a reputation in England.

It is the custom to say that the course of rheumatism has been very much shortened and all of its symptoms alleviated much sooner by treatment with the salicylates than by any treatment employed before the introduction of salicylic acid and its derivatives into therapeutics. There is a very interesting table that presents the facts concerning the influence of salicylic acid and its derivatives on rheumatism as they were observed during eight years at the city hospital in Berlin. For alternate periods varying between half a year and a year and a quarter the salicylate treatment and so-called indif-

ferent treatment were employed in all cases of rheumatism. The alternations from one method of treatment to the other were made deliberately with the idea of counteracting any influence that the season of the year or the special epidemic virulence of rheumatism at any period might have in making cases of the disease more intractable or more persistent. Altogether, 148 cases were treated with the salicylates and 106 with indifferent remedies; that is, iodid of potassium and the alkalies, with whatever other drugs might seem to be indicated by the symptoms.

	Salicylates, Days.	Indifferent Treatment, Days.
Duration of the treatment until the cessation of the fever	4.2	6.5
Duration of the disease until the cessation of the fever	11.6	15.0
Duration of the treatment until the cessation of pain	8.7	9.3
Duration of the disease until the cessation of pain	16.4	18.0

Relapses, under salicylates, 31.3 per cent.; under indifferent treatment, 13.2 per cent.

Heart complications, under salicylates, 17.6 per cent; under indifferent treatment, 16.4 per cent.

Length of stay in the hospital, under salicylates, 36. days; under indifferent treatment, 34.5 days.

As the mortality is practically nil, the important consideration is the avoidance of heart complications. This salicylic acid was said to do very effectually. Experience, however, has not justified this claim. The general evidence of the English collective investigation committee, as quoted by Cheadle, is that cardiac complications are less frequent and less pronounced under full alkaline treatment than by any other method. Pribram says that, while salicylic acid is the best remedy for the relief of the symptoms of rheumatism, it neither shortens the course of the disease nor lessens the number and severity of the heart complications.

Salicylic acid received its reputation in Germany, hence it is interesting to note the present situation there. It was in Senator's clinic that the original work with the drug was done, yet Senator himself said, two years ago, that salicylic acid is not a specific for rheumatism, but that it does relieve the symptoms, lessen the pain and lower the fever. Other coal-tar products, however, accomplish this purpose, and it is only that salicylic acid seems to be less objectionable than other antipyretic analgesics that it is to be preferred.

In Leyden's clinic at the Charité the routine treatment of rheumatism is with antipyrin. Four to six grams are given on the day that the patient enters the hospital and the same amount repeated the next day. This usually does away with fever and pain completely. Then a gram and a half to two grams are given each day for some weeks. Gerhardt occupies a middle position between Leyden and Senator. He thinks that any of the coal-tar antipyretics should be used, but prefers phenacetin. If this fails to relieve the symptoms, antipyrin is given, or one of the salicylates.

This would seem an unsuitable treatment here, where a strong prejudice exists against the use of antipyrin. To administer it in rheumatism where heart complications are feared would seem foolish. Leyden and Gerhardt, both heart specialists, are convinced that antipyrin, far from increasing the liability to heart complications rather diminishes it. It lowers the temperature and the pain, and so brings down the pulse-rate. Anything that reduces the work the heart has to do lessens the tendency to the production of heart lesions. There are undoubtedly cases in which antipyrin acts as

a serious depressant to the heart and the circulation. Notwithstanding very alarming symptoms, deaths from the drug are very few. The occurrence of symptoms seems to be due not to the amount of the drug ingested, but to an idiosyncrasy for it.

I would not, however, be considered as an advocate of the antipyrin treatment of rheumatism. I wish merely to insist that we have not in the salicylates a specific, but only a remedy that relieves pain and fever. Almost any other of the antipyretics will do this quite as effectually.

It is probable that none of the antipyretics have eventually done good in the treatment of rheumatism. The relief of symptoms has allowed patients to get up and be around much sooner than would be the case if the disease ran its course undisturbed by antipyretics or analgesics. In England, particularly, a number of prominent clinicians insist that relapses are more frequent after the salicylic treatment of rheumatism and that the heart complications, instead of being less, are at least as frequent, and probably more severe.

Rest is the most important indication for the heart complications. The heart of a normal person walking is ten beats faster per minute than if he is lying down, which means one-seventh more work. MacLagen says that in England only one-half as many heart complications are noted in rheumatic cases that have been in bed from the beginning of the attack as in those who have been up and around for some time. There is an old prejudice, and a most unfortunate one, that will-power may enable one to throw off disease, or at least to diminish its severity.

The treatment for rheumatism is rest, not alone during the active stage of the disease, but for weeks afterward if there has been any heart complication. The old indifferent treatment is a precious heritage which is uniformly too much neglected. There is no doubt that the deposit on the valves of the heart may in its early and plastic stage be much influenced by the resorbent properties of the iodids. Its careful administration for weeks after an attack of acute rheumatism, while the patient is kept absolutely in bed, would do more to reduce the mortality from heart disease, which is so striking a feature of modern life, than all the vaunted specifics that the manufacturing chemists turn out. Since the public generally have come to realize the value of the antipyretics in the treatment of painful conditions of any kind, many of the milder cases of rheumatism run their course without professional assistance. The result is the development of many an unsuspected heart lesion for which a few years afterward it is extremely difficult to find an adequate reason.

"Prevention of Heart Complications." This is the favorite slogan of the advocates of each new remedy and newest method of treating rheumatism. If it could be accomplished, rheumatism would be much less to be feared than any infectious disease we have. It would be a painful episode in life and nothing more. As a matter of fact, however, no method of treatment so far introduced seems to have any influence in limiting either the number or the severity of heart complications. It is doubtful even if the endocarditis and pericarditis which develop in the course of rheumatism are really a complication. There are undoubtedly cases in which either rheumatic endocarditis or pericarditis occurs and runs its course without accompanying arthritic lesions. When rheumatism appears in one joint, there is no method of treatment which gives any assurance of pre-

venting it affecting other joints. The heart and its serous coverings occupy a corresponding place in rheumatism to that of the joints. It is interesting to note that the rheumatic affection always appears on a particular side of the valves of the heart and is limited to the left heart. The rheumatic process always begins at the point where the valve leaflets touch one another, on the auricular side of the mitral valve, on the ventricular side of the aortic valve. When it appears on the ventricular endocardium it is at points where the valves touch it when they are drawn back. The rheumatic process in the joints occurs in serous surfaces that are also in contact with one another. It is only on the contact points, the joints of the heart, so to say, that the so-called rheumatic complication occurs. Rheumatism in the heart is really not a complication, but is as much of the essence of the disease as is its occurrence at contact points on the serous surfaces of the joints. Until we can get some remedy which will control rheumatism and prevent its spread from joint to joint, or act as a prophylactic against the development of the disease as soon as its preliminary symptoms are manifest, we can scarcely hope to prevent rheumatic heart complications.

THE HEART IN ACUTE RHEUMATISM.*

DELANCEY ROCHESTER, A. B., M. D.

Associate Professor of Principles and Practice of Medicine, University of Buffalo; Consulting Physician, German Deaconess Hospital; Attending Physician, Erie County Hospital;
Attending Physician, Buffalo Hospital of Sisters of Charity; Assistant Attending Physician, Buffalo General Hospital.

BUFFALO, N. Y.

As long ago as 1870, Sir Thomas Watson, in his wonderfully clear lectures, one of the greatest works on medicine published, says: "In truth, acute rheumatism is a blood disease. The circulating blood carries with it a poisonous material, which by virtue of some mutual or elective affinity, falls upon the fibrous tissues in particular, visiting them and quitting them with a variableness that resembles caprice, but is ruled, no doubt, by definite laws, to use, as yet, unknown."

In our actual knowledge of the materies morbi of this particular disease we have made no material advance in the last thirty years. Flint, in 1881, said: "A special predisposition is requisite; in other words, the disease involves a rheumatic diathesis. This predisposition may be congenital and inherited, or it may be acquired. Statistics establish conclusively the hereditary transmission of the disease. When we recall, however, that at that time statistics also "established conclusively the hereditary transmission" of tuberculosis and that in the light of modern science these conclusions have been shown to be erroneous, we are justified in doubting the "conclusive establishment of the hereditary transmission of rheumatism."

Lyman, in Pepper's "System," says: "Hereditary causes exert an important influence upon the occurrence of articular rheumatism—so far as statistics have been collected, it seems probable that from one-quarter to one-third of those afflicted are the descendants of rheumatic ancestors." The same author says: "The question of an infective cause for acute rheumatism has not been decided. Many of the symptoms of the disease and its mode of prevalence seem to be indicative of an infective cause. There is, however, no satisfactory

evidence of the transmissibility of the disease from one person to another, nor has any infective micro-organism been discovered that can excite symptoms of rheumatism."

In Allbutt's system, Dr. Church, in the article on acute rheumatism, says: "Although no satisfactory evidence has as yet been procured of the constant presence of any single specific micro-organism, yet in not a few of its features the whole course of rheumatic fever resembles an infective disease." In the course of his review of the etiology of acute rheumatism, Osler says: "In the character of the fever, the mode of involvement of the joints, the tendency to relapse, the sweats, the anemia, the leucocytosis and, above all, the great liability to endocarditis and involvement of the serous membranes, acute rheumatic fever resembles pyemia very closely and may, indeed, be taken as the very type of an acute infection."

After a careful study of the various hypotheses as to the nature and cause of acute rheumatism, MacLagan, in the "Twentieth Century Practice," says: "It is in connection with the pathogenesis of rheumatic fever that we have been led to consider the nature and mode of action of malaria. We believe the rheumatic poison to be malarial in nature. If it be so, it is a minute parasitic organism whose morbid action, like that of other malarial poisons, is dependent on its growth and reproduction in the system."

Thus we see from this brief review that the trend of opinion is toward the infectious nature of the disease, as Packard says, in his résumé of the subject, in *Progressive Medicine*, for March, 1900: "Rheumatism is a disease produced by external agencies. While in many instances it seems to result from exposure to cold or wet, alone or in combination, there is no way by which we can explain the action of these factors, except by their lowering the vitality and permitting the invasion of the body as is held to be the case with other well-known infections." Of the specific infectious nature of acute rheumatism the writer has no doubt. One of the peculiarities of this infection is that it invades the heart, and particularly the valves of the heart, with much greater frequency than any of the other acute infections, with the possible exception of chorea and pyemia. The possible etiological relation of these three diseases is most interesting, but it is not my function to discuss it.

As to the frequency with which morbid changes occur in the heart in association with acute rheumatism, a review of the literature of the subject, together with my own experience, brings me to the conclusion that endocarditis occurs in fully 60 per cent. of the cases, pericarditis occurs in about 10 per cent. Statistics and observations as to the occurrence of myocarditis are lacking and must always be a subject of doubt, as the data of its occurrence are dependent almost entirely on clinical observations, as so few cases of acute rheumatism come to autopsy during the acute stage and the myocardial changes associated with old endocardial deformities may be dependent on so many other concomitant causes as to be thrown out of consideration. Moreover, the recognition of myocarditis during life is exceedingly difficult. Nevertheless, it is the opinion of the writer that myocarditis occurs in conjunction with all cases of pericarditis and in conjunction with many cases of endocarditis, is present in not a few cases where neither endocarditis or pericarditis is present, and sometimes is wrongly diagnosed as endocarditis.

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

All observers agree that the younger the patient the greater the liability to the cardiac involvement, and if we limit our statistics to the first thirty years of life the percentages of cardiac involvement are much greater and the statement of Sir Thomas Watson, that "with perhaps two exceptions he never knew the disease to occur in an unequivocal form before puberty without its being attended with inflammation of the lining or of the investing membrane of the heart," can be corroborated by most of us.

The interesting fact that the endocardium, the myocardium and the pericardium are attacked so frequently in acute rheumatism can only be satisfactorily accounted for by recognizing the infectious nature of the disease and that these morbid changes are the result either of the direct action of the infecting organism or of that of the toxins produced by it during its metabolism or of both.

The morbid changes in acute rheumatism are found to begin in the fibrous structure of the joints and in the muscles and extend thence to the contiguous structure. In the heart we find the morbid process beginning either in the fibrous structure and extending thence to the muscular and serous, or beginning in the muscular structure, to which it may be limited or from which it may extend to the fibrous and serous structures. Confining our observation to the endocardium we find that the mitral valve is the most common seat of disease and the morbid changes present are thickening of the fibrous layer—between the serous reflections—and the development on the auricular surface of the valve, a short distance from its free edge, of a roughening of the serous membrane and the outgrowth from this region of little verrucose bodies which are firm and fibrous at their bases but are capped with soft fibrin, leucocytes and usually some bacteria—most often those of the pyogenic nature. These substances are undoubtedly deposited from the current of the blood. On the aortic valve the thickening takes place on the ventricular side at that portion—as originally observed by Watson—where the fibrous structure ceases, beyond which there is only the reduplication of the endothelium, and here we have the roughened surface and warty developments as on the mitral valve.

It is seldom that other parts of the endocardium are involved in acute rheumatic endocarditis; but when it does occur, next in frequency to the valvular involvement is that of the chordæ tendinæ. Here, too, is observed thickening and occasionally the verrucose bodies. If other portions of the endocardium are involved it is usually at such parts as are roughened by contact with already diseased valve or chordæ tendinæ.

The right side of the heart is very rarely attacked by the rheumatic poison. When it is, the pulmonary valve is the most common seat of the disease, and next the tricuspid, in relatively the same places as the aortic and mitral.

As to the morbid anatomy of rheumatic pericarditis the disease is usually serofibrinous in nature and occurs in either a circumscribed or diffuse form, but even when occurring in the latter form it usually begins at one part and extends to the whole.

The parts at which the circumscribed pericarditis occurs are the base of the heart near the origin of the great vessels, the parts of the pericardium lying beneath the 4th and 5th ribs and the interspace between and the cardiac layer opposite and that portion of the pericardium upon and opposite the apex of the heart.

From any of these points the inflammation may

become diffused and in most cases does so. The anatomical changes are hyperemia and serous exudation into the subserous layer of the pericardium, that is, the subjacent myocardial cells of the heart in the visceral pericardium, followed by dimming of luster of serous surfaces, denudation of the epithelium, exudation of plastic lymph and production of the so-called "battered" appearance and the adhesion of the visceral to the parietal layers, or the separation of the layers by the exudation of serum and its final absorption and the adherence of the two surfaces either in part or in whole by firm fibrous union. As to rheumatic myocarditis, the morbid change is one of parenchymatous degeneration, granular or fatty. It is usually associated with pericarditis or endocarditis as has been said, but does undoubtedly occur independently of either. Dr. S. West has reported instances of acute dilatation in association with rheumatism, one of which came to autopsy revealing marked fatty changes in the muscle-fibers.

Dr. Poynton has shown that the myocarditis which accompanies pericarditis is not an extension of the inflammation from the pericardium to the myocardium, but that there is granular and fatty degeneration of the cardiac muscle due to the toxic effects of the rheumatic poison, as well as actual destruction of muscle-fibers by inflammatory exudation.

Broadbent says that it occurs with all classes of endocarditis, and Flint believes that it occurs with all cases of pericarditis. Senator says that a certain degree of myocarditis is associated with all cases of rheumatic endocarditis and pericarditis. The late Dr. Sturges said that carditis is the proper term to apply to the cardiac inflammation accompanying rheumatism, for always two, and generally all three of the structures are involved. Excepting in cases associated with pericarditis—and even in some of these—the part of the myocardium to be first involved is, in the opinion of the writer, the musculi papillares to which the chordæ tendinæ are attached. The grounds on which this opinion is based are clinical and inferential, as I have never, unfortunately, had a case of acute articular rheumatism come to autopsy.

Myocarditis.—In proceeding to the consideration of the clinical phenomena of the cardiac manifestations of acute rheumatism I shall call your attention first to that which I believe to be the most common, viz., myocarditis. A careful observer who examines the pericardium every day while in attendance on a case of acute rheumatism, will discover any cardiac involvement from the physical signs before any symptoms show themselves. I shall therefore first call attention to the physical signs indicative of acute myocarditis.

From inspection and palpation, we generally learn nothing until the disease is far enough advanced to interfere with the muscular activity. Then the signs are, decided weakening, advancing to disappearance of cardiac impulse. On careful daily percussion of the precordium, even before the preceding signs show themselves, there can generally be marked out a slight increase of cardiac dulness to the left, at about the level of the nipple or a little below it, even before the apex is materially displaced.

But the chief reliance is to be placed on auscultation, and I firmly believe that the soft systolic murmur heard at the apex and over the body of the ventricle, generally not transmitted very far toward the axilla, is due to the myocardial change in the musculi papillares to which the chordæ tendinæ are attached.

Permit me here to relate the following case:

M. L. entered the Buffalo General Hospital Jan. 25, 1891, suffering from acute articular rheumatism, involving the joints of both hands, both wrists and one elbow. His temperature ranged between 103 and 105 F. Examination of his chest revealed a blowing systolic murmur heard at the apex and transmitted to the axilla. His treatment was rest in bed, milk diet, salicin and alkalies. His fever had subsided in a week, and his joint pains persisted for a while longer. The murmur disappeared February 22. He was kept in bed for ten days longer, however. March 4, examination of the precordium showed normal heart-sounds of good strength and proper rhythm.

I have five other cases of mitral insufficiency occurring in acute rheumatism in which, under rest, sodium salicylate and, eventually, iron and strychnin, the murmur has entirely disappeared and remained absent.

My grounds for the belief that this murmur is myocardial and not endocardial in origin, are as follows: In order that a systolic murmur may be produced by endocarditis involving the mitral valve there must be enough deformity of valve to allow of regurgitation. This deformity must come either through the interference with the closure of the valve by the verrucose bodies on the leaflets or through deformity of the leaflets from irregular swellings or contraction of the fibrous tissue entering into their structure or that of the chordæ tendinæ. These last are late developments in the structural changes that go on in the valves, and may, I think, be dismissed without further consideration.

The development of the verrucose bodies presupposes an inflamed surface of valve on which the fibrous deposit takes place from the blood. Moreover, these verrucose bodies must attain sufficient size to interfere with the proper closure of the valve. Now, if we remember that these bodies are developed, not on the free edge, but a little back of it on the auricular side of the valve, it is readily understood that they must attain considerable size before they interfere with the closure of the valve and in all probability must have developed the fibrous structure of their bases or, in other words, have become organized. Now, it seems to the writer that it is more rational to suppose that the systolic mitral murmur which appears so early in rheumatism is really dependent on a yielding of the valve because of lack of power to hold the valves in place through the weakening of the fibers of the musculi papillares to which the chordæ tendinæ are attached.

We have abundant evidence that a mitral systolic murmur can arise in this way if we will turn our attention for a few minutes to the mechanism of this cardiac murmur occurring in anemia and in some of the other acute infections besides rheumatism. The study of the heart in pernicious anemia and in the graver secondary anemias show, as a rule, no morbid change in the endocardium, but marked degenerative changes in the myocardium. These changes, according to Balfour, are always decidedly more advanced in the musculi papillares to which the chordæ tendinæ are attached. That we may have a mitral regurgitant murmur due to acute fatty degeneration, the result of infectious toxemia, is illustrated by a case of typhoid fever which came under my observation several years ago, in which a mitral regurgitant murmur developed in the third week, and continued to be heard until the patient's death, a week later. The autopsy showed

no valvular or endocardial disease whatever, and no dilatation of the ventricular cavities, but did show a markedly fatty condition of the heart muscle. In this case there was no way of accounting for the murmur except that just indicated. If we may have a mitral regurgitant murmur resulting from myocardial change the result of anemia or of acute infectious toxemia we can rationally believe it to be present in rheumatism in which there are present the toxemia of the disease and the anemia that is invariably associated with it.

The further evidences of progressive myocarditis are weakening of the first sound, which loses its muscular quality and becomes short and high in pitch. At the same time occurs accentuation of the pulmonary; then disappearance of the aortic and usually at such time disappearance of the murmur also, and finally disappearance of the pulmonary, so that no heart sounds are heard at all, or only occasionally, and when they are heard the first sound is not to be distinguished from the second in length, pitch or quality. The distinction can sometimes be made from the points of greatest intensity of sound.

The following case illustrates the fact that aortic murmurs may arise even when not due to the actual valvular deformity:

On Feb. 3, 1891, E. McD. entered the Buffalo General Hospital, suffering from an attack of acute articular rheumatism. The joints involved were one hip and the joint of one arm. He gave a history of previous attacks. Examination of the precordium revealed an enlarged and dilated heart, an aortic obstructive and mitral regurgitant murmur and occasionally an aortic regurgitant and a mitral obstructive murmur.

On March 2, four weeks later, the examination revealed the heart somewhat enlarged, the mitral regurgitant murmur still present, and, on rapid movement of the arms or rapid respiration, the mitral direct murmur also, but both of the aortic murmurs had disappeared.

Evidently aortic murmurs that could disappear in four weeks could not be due to any actual deformity. The mechanism in this case too can be rationally attributed to the weakened heart muscle. Normally at the systole, the blood is driven with such force through the aortic orifice that the semilunar valves are flattened back against the aortic wall and offer no obstruction to the outflowing blood. When, however, as in this case, we have a weakened ventricular contraction and a mitral regurgitation too, the force with which the blood is driven through the orifice is diminished, the aortic valves hang out into the lumen of the vessel and form obstruction sufficient to produce the murmur. Regurgitation through the aortic orifice is prevented in the normal condition, by the fact that the semilunar valves fit exactly together when they clap back during the ventricular diastole, provided that the musculofibrous ring to which they are attached at the aortic orifice gives them the necessary support. If, however, as I have no doubt was the condition in this case, the musculofibrous ring is weakened by albuminoid or fatty change, it does not give the necessary support and when the back pressure is produced by the rebound of the column of blood in the aorta, it allows the valves to give way and permit regurgitation into the ventricle.

Endocarditis.—As regards symptoms, the statement made in regard to myocarditis is likewise true in regard to endocarditis. Symptoms of this condition usually

develop only after the condition has already been discovered by physical signs.

A systolic murmur heard at the apex, as I have said, I believe usually to be due to myocarditis, but undoubtedly many times we have endocarditis associated. Under these circumstances the murmur is apt to be harsher in quality and to be transmitted farther into the axilla and heard behind in the left interscapular region and about the lower angle of the scapula. Moreover, the murmur persists and maintains its intensity, while the myocardial murmur varies in its intensity and with improvement in the case usually disappears. Occasionally we have a diastolic murmur at the apex or a little above it, indicating mitral obstruction. It is usually associated with a systolic murmur and, so far as I know, has not been observed as a primary lesion in any case of acute rheumatism. When this lesion is present a faint thrill can usually be felt in a limited area above the apex and a little to the right of it.

A systolic murmur heard in the aortic area in acute rheumatism I believe is almost always due to obstruction at that orifice either from thickening of the valve or from the presence of the verrucose bodies on its ventricular surface, though, that it may occasionally occur without an organic change is illustrated by the case just related.

Aortic insufficiency may also occur, but it is rare in the acute stage and is usually associated with obstruction. There is always some cardiac enlargement associated with this lesion and usually dilatation of the left ventricle. The signs are diastolic thrill felt over the sternum at the junction of the manubrium and gladiolus and over the third and fourth left interspaces near the left edge of the sternum. A diastolic murmur is heard in these same regions; it can also usually be heard in the second right interspace and sometimes at the apex of the heart. It is usually decidedly harsh in quality, though occasionally is soft. The capillary pulse and the peculiar water-hammer characteristic of the pulse in the arteries should, of course, always be mentioned as associated with this lesion.

Lesions of the right side of the heart are so rare that mention of them could very well be omitted. Proof is lacking, to my mind, that the right-sided endocarditis occurring in intrauterine life is rheumatic in origin. The diagnosis of endocarditis of the right heart is made by the recognition of the murmurs originating at the tricuspid and the pulmonary valves respectively. I mention them here only to call attention to the fact that sometimes the murmur resulting from aortic obstruction is heard with greater intensity on the left than on the right side of the sternum, but that it is always transmitted to the carotid arteries, whereas, the murmur arising from obstruction at the pulmonary orifice is never so transmitted, and the murmur of mitral insufficiency is sometimes heard at the pulmonary orifice or a little to the left of it.

Aside from physical signs the only symptom of acute endocarditis worthy of mention as diagnostic of this condition is embolism, which sometimes results from the sweeping off of the film deposit from the verrucose bodies on the valves. These emboli are usually carried to the head, but may go to any part of the body. To even refer to the symptoms of embolism would carry me beyond the scope of my part of the discussion.

Pericarditis.—This, simply from the relative infrequency of its occurrence, I think should be classed among the complications of acute rheumatism. Its

diagnosis is often exceedingly difficult, while more often it is very easy. As the symptoms are so varied in different cases and in some cases are very severe, while in others they are entirely absent, I shall call attention first to the physical signs, especially as on them we ultimately depend for diagnosis in all cases. The first of these to appear is usually a soft to-and-fro friction-sound usually heard best at the base. Often it is difficult to say whether an abnormal sound is endocardial or pericardial in origin, but I have learned to be very suspicious of sounds arising at the base of the heart during the acute stage of rheumatism. Almost invariably—even when heard with only one sound—they are pericardial in origin. This is particularly true of that heard with the second sound and of that heard in the pulmonary area systolic in time and not transmitted to the carotids.

The next most common place for the friction-sound to be heard, is over the left third and fourth interspaces near the edge of the sternum, where it may be mistaken for tricuspid murmur or for that of aortic regurgitation.

Occasionally it can be heard at the apex itself or along the left edge of the heart above the apex. In this region it may be mistaken for mitral murmurs. The evidences of effusion by physical signs are first a weakening of the first sound of the heart, next the occurrence of dulness in the semilunar space. This dulness is sometimes present with the patient in the upright position, disappearing two or three minutes after the patient lies down on the back. Sometimes before, more often shortly after, the occurrence of dulness in the semilunar space, dulness appears at the base of the heart, sometimes most pronounced on the left side in the second and third intercostal spaces, more often on the right of the sternum in the second and sometimes up into the first intercostal space. While this dulness is pronounced in the recumbent position, it sometimes disappears shortly after the upright position has been assumed. This movement of the fluid in pericarditis is always slow and takes two or more minutes for its accomplishment. Finally, when there is considerable fluid present, the area of dulness assumes the oft-described pyriform shape with the base at the diaphragm. Sometimes the amount of fluid is enormous; more often it is only 100 or 200 c.c. I have never observed the separation of the left clavicle from the first rib, as described by some observers.

With the increase in the amount of fluid the physical signs obtained by inspection, palpation and auscultation change materially, as well as those obtained by percussion.

We notice the apparent elevation of the apex-beat and its gradual complete disappearance from view and touch. We notice the disappearance of the friction sound, generally leaving the base of the heart last, and sometimes persisting there throughout the entire stage of effusion. The heart sounds become fainter and gradually disappear, the second sound being usually the last to go. In addition to these distinctly cardiac signs we sometimes get broncho-vesicular or distinctly bronchial breathing in the left interscapular and scapular regions. While the vocal resonance is also somewhat increased in these regions, it is usually not so pronounced as we would be led to expect from the character of the breathing sounds. There is sometimes a hyper-resonance, tympanitic in quality, to be elicited on percussion in the left infrascapular and lower axillary region. Sometimes there is a decided dulness in these regions. The signs of the so-called third stage are

simply those of the gradual absorption of the fluid and the return of friction sound, coarser in quality than in the first degree. Symptoms of acute pericarditis are partly local and partly constitutional. Pain and tenderness in the precordial region are sometimes quite marked. The pain is sometimes decidedly acute and stabbing in character; more often it is a vague and distressing sense of oppression, especially during the stage of effusion. The breathing may be decidedly interfered with; orthopnea and cyanosis may occur. Dysphagia may occur in the first stage, if there is marked posterior inflammation, from the pain induced by the passage of food through the esophagus, and in the second stage from the actual pressure of the fluid on the esophagus. Aphonia may occur from pressure on the recurrent laryngeal as it winds around the aorta. The nervous symptoms may be limited to restlessness; more often they are quite pronounced, especially in children: restlessness, sleeplessness, crying out and wandering in the sleep, delirium sometimes noticeable only on first waking, sometimes becoming very marked, occasionally developing maniacal or suicidal tendencies. Indeed, so marked are the nervous symptoms at times that cases of rheumatic pericarditis have been mistaken for meningitis. Involuntary passage of urine and feces sometimes occurs, and the patient passes into a state closely resembling collapse. "Whenever in acute rheumatism," says Watson, "you find your patient flighty or wandering or more distinctly delirious or afflicted with any form or degree of convulsions, examine carefully the conditions of his heart." Vomiting may occur, and is always a most serious symptom at whatever stage it comes on, and not infrequently it means that the end is not far off.

There is usually increased frequency of pulse, its volume is small and tension low. It sometimes becomes irregular, especially toward the end, and occasionally the pulsus paradoxus develops. The patient's face may be pale, flushed or cyanotic, and often bears a distressed and anxious expression. The temperature is usually slightly elevated, though it rarely goes above 103, and sometimes does not rise at all.

But as said at the beginning, sometimes all of the symptoms are lacking, and we must depend on our physical signs for diagnosis, and while in some cases, seen late in the course of disease, it is exceedingly difficult to differentiate between pericarditis with effusion and dilated heart, if daily examinations of the precordium are made this difficulty will not be encountered.

The prognosis in acute rheumatic endocarditis is usually good so far as immediate results are concerned, except that there may occur central embolism. The serious element is the ultimate resulting valvular deformity and its effect on the musculature of the heart and on the general or the pulmonary circulation and on the general nutrition. In pericarditis there is a distinct element of danger in the effusion. This may become so great that the heart is unable to continue in action, thus causing death, or, even if the effusion is not great enough for such a result, it may still so embarrass the heart's action as to interfere with proper circulation in brain or lungs or kidneys, and thus indirectly lead to serious results. The chief immediate danger in the cardiac manifestations of acute rheumatism is dependent on the extent and character of the myocardial disease. While in the majority of cases of cardiac involvement the myocardial changes are slight, and may be confined to the columnæ carneæ to which the chordæ tendinæ are attached, "in the severe cases of endocarditis, as said by

Dreschfeld, "the myocardium shows indurative changes, which may be looked on as due to an extension of the inflammatory process, the fibrous septa and the lymphatic spaces being chiefly involved; even the muscular fibers may show changes partly due to compression and partly to myocarditis." In those cases where pericarditis and endocarditis are both present, there is always, as shown by Sturgis, myocardial involvement. As well said by Broadbent: "It is to the accompanying myocarditis that we must attribute the cardiac dilatation, which is so marked a feature in pericarditis. Probably the chief danger in rheumatic inflammation of the heart, of which pericarditis is a part, lies in the damage to the cardiac muscle." Recognizing the fact that the myocardial involvement is so important an element in the prognosis, it behooves us to do our utmost to diagnose the condition when present. It is not necessary to go over again the points in this condition.

As to the treatment of the cardiac manifestations of acute rheumatism, it does not differ materially from the treatment of the disease on which these manifestations depend. If the salicyl treatment is good for the joint manifestations of the toxemia called rheumatism, it certainly should be just as useful in the cardiac manifestations of the disease. In practice we find that it is, and that to the use of these drugs the cardiac manifestations usually yield as rapidly as do those of the joints. In those cases in which there has been apparent failure I believe it has occurred because the dose was not large enough and the interval between doses was not short enough. Even in cases where there is old valvular disease and marked cardiac hypertrophy with dilatation, the salicyl compounds are most useful and do no harm. This is well illustrated by the following cases.

CASE 1.—In December 1899, there entered the Buffalo General Hospital an Italian carpenter, 24 years of age, who gave a history of acute rheumatism when 7 years of age, and every winter and nearly every June since then; of gonorrhœa two years before entrance and of pain in the precordium radiating to left shoulder, arm and hand for the preceding two months. Examination of the precordium showed an area of cardiac dulness from the third left intercostal space, half an inch left of nipple line, upper border of seventh rib, ensiform cartilage, right parasternal line, third right costal cartilage; palpation and auscultation revealed a markedly dilated hypertrophy with double lesions of the mitral valve and double lesion of the aortic valve.

During his stay in the hospital, he developed on January 25, an attack of acute rheumatism, involving the joints of both arms and hands and the right knee and ankle. He was given sodium salicylate in 0.25 gm. without any benefit. He was then placed on methyl salicylate (oil of wintergreen) in 0.6 gm. doses t.i.d. His pulse increased so much in frequency that the medicine was stopped in forty-eight hours. On February 2, he was placed on sodium salicylate in 0.6 gm. doses every four hours and steadily improved. On February 10, his temperature was normal and by the 14th the joint pain and swelling had disappeared. On the 18th he had a slight return of the joint pain and swelling, which disappeared in twenty-four hours. The sodium salicylate was kept up in the 0.6 gm. dose t. i. d. until March 1, when it was changed to 1 gm. daily. His general condition was looked after by the use of baths, carefully selected diet and the administration of iron pyrophosphates and sulphate of strychnin, with the occasional administration of digitalis. On March 26, he was discharged from the hospital; the condition of his heart was better than when he entered, in spite of the fact that he had had an attack of acute rheumatism and had been kept on one or another of the salicyl compounds for six weeks.

The case just related occurred in the service of Dr. Stockton. The next case occurred in my own service at the Sisters of Charity Hospital.

CASE 2.—Walter W., laborer, age 20, American by birth, was admitted to hospital Feb. 15, 1900. Family history was good. Patient had one previous attack of rheumatism four years ago and gonorrhoea two years ago. One week before entrance the present attack began. At time of entrance both knees and ankles and right shoulder were involved and patient complained of pain in chest, especially on deep inspiration. Temperature at time of entering was 102.2, pulse 104, respiration 26.

Examination of the chest revealed a heart reaching the left anterior axillary line, the apex in the sixth intercostal space; on the right side dullness extends to a point a half-inch beyond the right border of the sternum. Cardiac impulse is weak and apex-beat is diffused in sixth interspace from anterior axillary line to nipple line.

There is a decided mitral insufficiency; the pulmonary closure is markedly accentuated and the aortic closure is scarcely audible. Heart was a decidedly dilated heart with mitral insufficiency. Patient kept absolutely still in bed; after a preliminary dose of calomel followed by Rochelle salts, sodium salicylate was administered in 1 gm. dose every two hours and a salicylic-acid ointment 10 per cent. was applied to the inflamed joints.

February 18 the patient complained of severe pain in the precordium; no pericardial friction was noticeable. Treatment was continued and salicylic ointment rubbed into precordium.

February 18, as the pain, swelling and fever persisted the salicylate was increased to 1.25 gm. every two hours through the day, and four hours through the night. This was continued until February 22, when temperature reached 99 and pulse had fallen to 92, when the same dose was given *t. i. d.* On the 24th, it was made 0.75 gm., and on the 26th 0.50. At the same time he was given an alkaline mixture *ante cibum*, and tinct. ferri chloridi *i. e. c.* *post cibum*. On March 3 the salicylate was discontinued and tinct. nucis vomicee was given in 1 *e. c.* dose *ante cibum*.

Examination of the chest March 5 showed the area of cardiac dullness decidedly less, the apex being in the fifth interspace, half an inch to the left of the nipple line; the impulse was more powerful and the aortic closure was distinctly audible though still not as loud as the pulmonary.

When I went off duty, April 1, he was sitting up and in very good shape, the pulmonary and aortic sounds balancing each other very well. In this case, although there was greatly dilated heart and possibly the superposition of a pericarditis, the salicylate was given in large doses and was kept up for seventeen days with the very best of results.

Of course, all such cases are to be kept absolutely still in bed, and are kept on liquid—preferably milk diet—150 to 250 *c. c.* being given at intervals of two to four hours. The bowels are kept open with salines and the sodium salicylate is given in doses of from 1 to 3 gm. every two hours until improvement takes place, and the interval is then gradually extended to three and four hours and then the dose gradually reduced.

In some cases where there are old endocardial lesions not compensated, strychnin should be administered, preferably hypodermically. No case of pericarditis should be allowed to die on account of the amount of effusion present. In a given case of acute rheumatic pericarditis the effusion has generally reached its acme by the sixth day and should then begin to subside. If it does not, or if before the time pronounced symptoms of cardiac disturbance show themselves, paracentesis pericardii should be performed. With physical signs of effusion of some size present, the symptoms which call for the performance of this operation are: marked change in the volume, frequency or rhythm of the pulse, particularly the occurrence of the *pulsus paradoxus*; marked increase in the frequency of respiration, dyspnea, orthopnea, cyanosis; cough, hicough or vomiting; difficult or painful swallowing; and the supervention of

pronounced nervous symptoms. The operation itself is not difficult to perform. There are one or two things to be said, however, in regard to this operation. First, and most important, it should never be done with a needle, as there is always thus danger of wounding the heart itself, but should be done with a trocar and canula. If the exudate is purulent, aspiration is a mere waste of time, an incision should be made and the pericardium drained and very carefully washed with sterile water. The point of election for the operation should depend somewhat on the preceding signs. If there has not been marked friction-sound at that point, the fourth intercostal space about one inch to the left of the sternum, is the point of election; but if there has been marked friction sound there, there is danger of adhesions having occurred at that place, and this point should not be selected, for fear of wounding the heart. Under these circumstances the fifth or, if the dullness warrants it, the sixth or seventh space should be chosen.

In all cases of acute rheumatism in which has occurred cardiac involvement, whether endocarditis, pericarditis or myocarditis, it is of the utmost importance that rest in bed should be persisted in until the heart sounds have returned to their normal condition and have persisted so for at least a week. During this period of convalescence the restoration to the normal is often greatly hastened by carefully regulated massage, Swedish movements, and sometimes the use of the Schott baths.

By this persistence in rest the murmurs which have appeared often disappear under the improvement in muscle tone, thus maintaining the position taken that many of them are myocardial rather than endocardial in origin, as illustrated by the cases reported.

In concluding the part of this subject allotted to me, I desire to call particular attention to the following points as of the utmost importance and worthy of thorough discussion:

1. Acute rheumatism is an infectious disease.
2. Endocarditis is an integral part of the disease and not a complication.
3. Pericarditis is a complication, just as much as inflammation of any of the other serofibrous membranes, meningitis, pleuritis or peritonitis is, although it occurs more frequently than any of them.
4. Myocarditis is an integral part of the disease, not a complication; occurs much more frequently than is usually supposed; is frequently unrecognized, and is the most serious feature of the disease.
5. The occurrence of endocarditis, pericarditis or myocarditis, or the previous existence of a valvular disease, whether compensated or uncompensated, is no contraindication to the use of the salicyl compounds, but rather an index to push their administration to overcome the toxemia of the disease. Whatever one is chosen, it should be given in sufficiently large doses at sufficiently short intervals.
6. Rest in bed for a sufficiently long time is the most important part of the treatment of the cardiac manifestations of the disease.

CRISTIANI, of Geneva, announces that he has succeeded in transplanting entire lobes of the thyroid body in young rats. The grafts not only retained their vitality in the new conditions, but increased in size by epithelial sprouts from the thyroid alveoles.

EAR DISEASES IN INFANCY AND CHILDHOOD.*

J. HOMER COULTER, M.D., PH.D.

Professor of Ear, Nose and Throat Diseases in Chicago Clinical School, and in Harvey Medical College.
CHICAGO.

The statistics which show an infant mortality of from 20 to 25 per cent, before the end of the first year of life are a woeful and terrible comment on the ignorance or carelessness of some one, be it parent, family physician, modern circumstances or environment. Wherever the blame belongs it must soon be known, and a remedy applied which will stop such a sacrifice of human life. Such a record does not comport with modern achievement and advancement, and can not long be tolerated as one of the failures of medicine. In this percentage there is a large, too large, ratio of ear conditions presented as a causal or complicating element in the cause of death.

The ear conditions which are most frequently met with in infancy and childhood are acute middle-ear suppuration with or without its more or less severe and serious complications, impacted cerumen, foreign bodies, furunculosis, granulations, eczema, necrosis, polypi, meningitis, extradural abscess, cerebral abscess and traumatism.

Of these, it is well known, acute and chronic middle-ear suppuration are by far the most frequent and most important. It occurs much more frequently than all the others combined, if we exclude those conditions which arise as a direct result of the middle-ear difficulty. The differential diagnosis of each of these conditions is largely a matter of general knowledge; I will hence refer to the symptomatology only as may be necessary to elucidate the discussion.

In many localities a discharge from the baby's ear is looked on as about of the same importance as the eruption of the teeth. It is not unusual to see cases of ear discharge which have been so long neglected by parents that their very odor drives them to seek relief. Too many deaf victims are thus deformed because of this neglect for the aching or "running" ear of childhood; nor is the fault always with the parent. Too often indeed the attention of the family physician has been called to the condition only to be told by him that "it is not a serious matter;" "the use of a little warm water will soon cure it."

Fortunately, however, it is fast becoming a matter of general recognition that these little patients with suppurating ears live constantly under the perils possibilities of Damoclean swords. We have come to know and realize that when a child complains bitterly of earache it should be put to bed and given a good cathartic, with a hot foot-bath; we know that middle-ear trouble is usually more severe in children than in adults, both because of the weaker resisting powers of the tissues and because of the axiomatic fact that in children the reflexes are more prominent and frequent than in adult life, and with this knowledge we may be able to realize why our diagnoses in these cases are inversely important as they are difficult to make.

As of great importance, and separate from the detail for treatment, I wish to emphasize the value and desirability of establishing in each case, as far as possible, a satisfactory etiological basis for that case. In cases

of exanthemata or adenoids this is, of course, a simple matter, but there are cases which are so clouded as to appear quite idiopathic in character, and we are sometimes almost forced to shield ourselves under that gauzy justification "taking cold." In no case in our efforts at cure of any condition of the ear, should we by carelessness allow our treatment to become an etiological factor in any complication of the condition. Traumatism of the ear, both slight and serious, must always be a class unto themselves, and are amenable to such treatment as the circumstances of the case and the ingenuity of the attending surgeon may suggest.

The classifications of the causes producing prominent ear troubles in children are numerous, but necessarily bear a close resemblance. To Logan's two classes I would add a third, in the following manner:

1. General, as exposure, climatic influences, etc.
2. Exanthemata, typhoid, diphtheria, postnasal pathologies, etc.
3. Traumatism and foreign bodies in the tympanic cavity.

Hinkel, in concluding a valuable paper on this subject says, 1. earache, however slight, may signify disease of a serious nature; 2, recurring earache in children indicates lymphoid involvement; 3. acute inflammations may be aborted with proper treatment early applied.

Ear pathologies following or resulting from nasal conditions or the acute infectious diseases being the most frequently met with, will be considered briefly.

Phillips, in a study of 350 ear cases, claims that 83 per cent. were complicated by some form of nasal disease. In 72 cases occurring in children, 6 were caused by measles, 25 by adenoids and 4 by scarlet fever. A number of complications, some of them much larger than this, practically corroborate this estimate.

The matter of percentages, however, is not so vital as is the recognition of the fact that the conditions, as adenoids and nasal pathologies generally, as well as the exanthemata, are likely to lead to serious conditions in the ear. This being admitted, and the further axiomatic statement granted, that these cases can be in a large measure controlled or cured, the natural corollary follows that early, proper treatment, surgical or medical, of these conditions will practically prevent complications.

The careful and extensive researches of competent and careful pathologists, as Rohrer, Zaufal, Bezold, Kyle, Randall, Randolph and others, all seem to agree that in the fetid variety of middle-ear suppuration the bacilli are abundant, and also that there is much greater danger of mastoid involvement and severe symptoms in those cases in which the streptococci are found. It is but reasonable, consequently, to urge that the physician having demonstrated the existence of such conditions in the ear, or even in the absence of microscopic proof, having tangible evidence of the probable existence of the streptococci, he should be as solicitous and careful of the case as he would were the same infection existent in some other more accessible or more vital organ of the body.

Streptococcus pyogenes must be acknowledged as one of the most important bacteriological elements in the etiology of acute middle-ear disease. "It has been well established that we often get a mixed infection with this germ in scarlet fever, diphtheria, typhoid, tuberculosis and pneumonia, and hence I think it is an important agent in the production of acute middle-ear troubles."—Allen.

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J. June 5-8, 1900.

Invasion of the Eustachian tube is so frequently the result of infection pneumatically produced as to be beyond question a matter of prophylactic control. Purulency in any part of the nasal passage or upper pharynx should direct the physician at once to prophylactic measures.

A careful compilation of almost 1000 cases of middle-ear disease in children, apparently demonstrates that not less than 70 or 75 per cent. will give a history of nasopharyngeal disease. Frankenburg, in an examination of 158 deaf-mutes, found 51 who had a marked adenoid condition. As a rule with the exanthematous and nasopharyngeal diseases of infancy and childhood, the more serious the affection and the younger the child, the more certain is there to be ear disease present.

Hereditary and other diatheses must not be overlooked in the ear diseases of childhood; and while syphilis and tuberculosis are, fortunately, seldom seen as primary ear infections, in childhood, as hereditary factors they may become important in almost any case.

It is well to remember that extensive middle-ear involvement may be present with but little or no evidence in the drum membrane.

Foreign bodies in the ear need not be a source of much trouble if properly treated. Always remember if it be an inanimate object, that it should be removed as easily as it was introduced. A simple syringe will in almost every case remove the trouble. If there be present an insect, a drop or two of ether or chloroform will make it an inanimate object and easily washed out. Cholesteatoma of the ear is not an unknown condition in children. For a most complete histological and pathological discussion I would refer to a paper by Dr. Panse, published in Vienna, in 1897, and translated by Dr. Alderton.

When there is present a correlative inflammatory condition in other contiguous tissues or cavities, then treatment of that condition becomes imperative, lest additional etiological force be added to the primary pathology. In 358 post-mortems of internal ear diseases in children, only 62 were found to be unaffected (Rumbold).

A well-known member of this Association in commenting on these statistics, predicts that practically every one of them came from an infected Eustachian tube, the infection being forced there by a nasal or pharyngeal stenosis.

It would seem quite unnecessary in this connection to intensify the importance of adenoids as a cause of ear trouble, and the absolute necessity for their complete removal when present. More than a double score of recent contributions to medical literature unanimously endorse the statement just made. It would seem that we have quite enough conclusive demonstration of the effect of adenoids and that every physician would now make the presence or absence of adenoids one of the first points in his diagnosis.

It will be generally admitted that few conditions of disease require a more careful, tactful, scrutinizing and intuitive capacity for diagnosis, than do the complicated ear diseases of childhood. This very fact consequently opens for us a field in the way of a more perfect technique in operating, and a more exact detail in diagnosis, which is most inviting. But we must not once overlook the importance of the constitutional, dietetic and hygienic conditions of these patients. Measures for the relief of irregularities in these particulars are most important in many cases. The very

fact that frequent cases of purulent ear disease in children do of themselves recover without much treatment is perhaps responsible for some of the neglect which is countenanced by physicians. I am, however, forced to the conclusion that a large part of this absence of exact, positive and reliable knowledge, or this misinformation as is more frequently the case, is due to a lack of correct and detailed anatomical and physiological knowledge on the part of physicians generally. True enough we can not all be expert anatomists, but the practice of to-day demands that each one shall have a more exact idea of the ear and its anatomical relations than merely that it is "a hole in the head through which we hear." This knowledge is all the more important in the case of children, for with them a satisfactory and thorough examination is often quite impossible.

Our prognosis in the ear diseases of children should never be hasty or unwarranted. It will depend on the following conditions:

1. The age and physical condition of the child.
2. The severity of the attack, and if it be a purulent condition, on the seriousness of the concomitant disease which gives rise to the purulency.
3. Whether or not there be brain or sinus involvement pending or threatened.
4. The extent of bone necrosis present when first seen.
5. Nursing.

Treatment.—In the ear troubles of children, and nowhere else so markedly, the rule holds good that the earlier the treatment is begun the better. Surgery will not cure all conditions, nor will it always prove a prophylactic blessing; so also will local applications or constitutional treatment prove an ignis fatuus if always depended on.

If the case be an acute middle-ear involvement, as it is in far the largest percentage of cases, what shall be our method and means of treatment? Much will depend on the circumstances and conditions surrounding that particular case, modified indeed by all of those circumstances which were named as governing our prognosis, and principally in addition will it depend on the causative factors acting in the condition.

Earache in children is always a condition of sufficiently serious import to demand the close attention of both parent and physician. The use of opium in these cases is rarely or never to be advised. It certainly serves to mask the symptoms so that it is often impossible to recognize the approach of a serious condition. The application of heat or cold will usually give quite as much relief from the pain. In the use of the douche care must be taken not to use too much pressure in the stream entering the ear lest the infection be forced into parts previously uninfected; for the same reason the greatest care should be exercised if any remedy of the H_2O_2 series be used for cleansing after the formation of pus.

Ordinarily if the pain is not much relieved within twenty-four hours by the application of heat or cold, then heroic measures must be adopted. Usually there will by such time be present sufficient indications to warrant a paracentesis. That such operation should be done as soon as there is any bulging noted in the tympanum, is now the unanimous verdict of otologists. It would seem that the relief which is almost always afforded by this operation would be a most convincing demonstration of its value even to the most conservative practitioner. Yet we frequently see these cases

only when they have finally burst through and largely destroyed the tympanic membrane, and perhaps also, on account of late or insufficient drainage, impacted the mastoid cavity.

Randall's indications for paracentesis are:

1. Great pain, with bulging of the membrane from contained pus.
2. When the tension of the membrane is high and the bulging even slight.
3. Insufficient drainage through a membrane already ruptured, and danger of extension to the antrum.
4. Excessive and continued pain which is not relieved by hot applications, especially if the tension be very high.

I fail to find any reliable record in recent medical literature of any unfortunate results attributable directly to the operation of paracentesis. I do not maintain that it is as simple and as easy of satisfactory accomplishment as is the opening of a whitlow, nor that it should ever be attempted by one who can not through a speculum get a view of the drum membrane, yet rare, indeed, must be the circumstances in this day when a competent man who has the necessary instruments could not quickly be obtained.

"The good that we are able to accomplish by this operation is simply immeasurable, when we contrast the little patient operated on and restored to its parents with little or no impairment of hearing with the one who has received improper treatment and is suffering from a purulent discharge that seems to bid defiance to every form of treatment: we can not refrain from being enthusiastic over a procedure which marks another advancement in this, the grandest surgical era the world has ever known." (Allen.)

As if in contradistinction to the rules of Randall just referred to, Pierce has given us the negative indications for paracentesis as follows:

1. Presence of fluid in the middle ear without pain or fever.
2. Pain for twenty-four hours with congestion, but without fever or demonstrable presence of fluid.

Either of these conditions I can not but think are met with very rarely, and even when seen, as in the second indication, it is open to question whether or not a paracentesis would not be advisable, if only as a means of depletion for the congestion.

Many of our best authorities urge in this class of cases, and particularly those which tend toward an idiopathic etiology, the use of leeches in order to deplete the congestion so frequently present. I believe, however, that their repeated application will be more frequently necessary than will be the performance of a secondary paracentesis. On the other hand, the leeches will be much more appropriate in a certain number of cases where it may be for any reason difficult or impossible to secure a satisfactory examination of the drum membrane, as it sometimes is in young or intractable children, or where the services of a competent aurist can not be easily obtained.

It would seem that nature herself had given us a valuable endorsement of paracentesis; since by the almost ever-present bulging of the membrane, the presence of a fluid or suppurative process is quite unerringly indicated. In corroboration of this the post-mortem reports of Ponfick and others, made on a large number of children in whom there was middle-ear infection, shows that in a large proportion the drum membrane had not been ruptured, and that in many

cases the tympanum was more resistant than was the tympanomastoid partition, thus again arguing the necessity of an early paracentesis.

The paracentesis operation is one so well known to the members of this Section that I will not describe the technique in detail, only to express my approval of the direction and extent of incision as was suggested, I believe by Dr. Myles, that is, the cut being made from the lower edge of the posterior-inferior segment of the tympanum should be extended for some distance upward and outward into the cartilaginous canal, where very frequently there is some bulging of the tissues.

Attempt at politizerization in any of the ear diseases of childhood is mentioned only to be condemned as impractical in almost every conceivable case. So, also, though not so universally, is to be avoided the application of poultices, as tending to produce a soft and spongy condition, or even furunculosis of the soft tissues.

Very much of our success in the treatment of ear diseases in children will depend on the thoroughness with which we examine and treat the nasopharyngeal or pharyngeal pathologies so frequently present as distinct etiological factors in the ear condition. Whether it be some one of the exanthemata, typhoid, purulent rhinitis of childhood, adenoids or tonsillitis, it demands our care and attention as imperatively as the ear condition itself. The appropriate prophylaxis so opportune at this time has already been referred to as most important.

I do not wish to discuss in this connection the comparative merits and objections to the so-called "wet" and "dry" treatment of ear diseases, only to admit that neither is applicable to every case. This much, however, will be unanimously admitted—that pus having formed within or about the tympanic cavity, from whatever cause it may, must find a sufficient means of escape or there will be trouble for the child. As a matter of fact it requires but little inflammatory action to close the Eustachian tubes in a child and when such closure does occur in a condition of middle-ear purulency, then the pus will go either through the membrane or into the mastoid cells.

It is not because of the proportion of fatalities that occur in suppuration of the middle ear that I would urge its particular importance at this time, but rather because of the number of suppurative ears with which we meet in any practice, any one of which is apt to go on to mastoid involvement with sinus or brain complications and death; in addition also should not be forgotten its tendency to recurrence. Furthermore, the disease process may continue for a long time and work irreparable injury before any well-marked symptoms of the seriousness of the condition are made manifest to the degree of forcing the patient to seek the advice of his physician.

Parents should be impressed with the fact that any considerable impairment of the hearing is a most unfortunate condition for a child, and that it is a handicap which can usually, though not always, be prevented. It is a most judicious provision that in many schools the teachers are expected to look after the hearing as well as the eye-sight of the children, and to report to the proper authority any case which gives evidence of ear affection or infirmity.

It is only by a combination of the forces just referred to that we can secure any very marked results in the way of preventing ear infections in children from becoming serious and oftentimes fatal conditions. If it

were possible in each of these cases to have skilled nursing, I am convinced that the proportion of mastoids and brain involvements would be vastly reduced. And while I would not underrate a mother's interest and care, as we ordinarily see it exhibited, yet we know that a severe case will often not get that thoroughness at the mother's hands which is so essential to recover without the major operation.

The diet should at all times be a limited and mild regimen; while the bowels and eliminative functions generally should be exercised to their fullest capacity short of producing weakness.

When we have succeeded in impressing on physicians and parents the relative importance of a discharge from the baby's ear; or of the portentous nature of a continuous earache, and that early and thorough cleansing and antiseptics are always and ever a necessity, then will many of the serious conditions and the unfortunate results of the ear diseases of children be aborted.

A delicate touch and a deft hand and the ability to control and properly and thoroughly examine children are more the gift of nature than possible acquirement; yet much in the way of skill can be acquired which will aid us wonderfully in our efforts at the relief of these little sufferers.

DISCUSSION.

DR. EDWIN PYNCHON, Chicago—I have been very much interested by the Doctor's paper. I might call attention to one little point in regard to the removal of foreign bodies. Injections of warm water are more often recommended than anything else. I will say that I have been infinitely more successful by the discharge of compressed air in the external auditory canal in the removal of foreign bodies than by any other method. I use a very fine-tipped Eustachian catheter which I enter into and press against the roof of the auditory canal so as to allow the air to enter. Any hard body, like a button or little stone or piece of coal can be almost instantly removed in this way. Next as to the dry treatment. Of course it is theoretically all right, and if we can get the bacteria in an absolutely dry place they will die. But I do not believe we can get the ear sufficiently dry to cause them to die, so I use the wet treatment. I furnish a printed sheet of directions, so the patients meet with no difficulty in the use of the wet method. In the treatment of suppurative diseases of the ear, after the drumhead is broken and the discharge is free, my usual direction is that with a fountain syringe, a pint of fluid be used in the treatment of each ear, and it must be as hot as can be comfortably borne. In case there is an odor to the discharge I use a one per cent. carbolyzed solution. In case there is no odor my custom is to use bicarbonate of soda in strength of one teaspoonful to the pint. Using the douche once or twice a day will not do as much good as when it is repeated six or eight times a day. It is my habit to impress a few things on the patient: 1, that the fall of the fluid must not exceed 4 feet; 2, that a small tip must be used and gently introduced into the opening of the ear, but must not be pressed in with any force, or so as to close the opening or prevent a free escape of the fluid. By this method I have had very fine results. Prior to the rupture of the drum-head I want to call attention to a treatment that I have found to be of value, namely, the filling of the external canal with glycerin whereby the fluid in the tympanum is withdrawn by osmosis, as suggested by Dr. A. H. Andrews, of Chicago. It is usually better to use a 12.5 per cent. solution of phenol in glycerin. I have also used a one per cent. solution of the alkaloid atropia in castor-oil with very good results.

DR. F. J. QUINLAN, New York City—In acute cases where adenoids are present where you can not get an opportunity to remove them by surgical procedures, I know of no better method than to take a Eustachian catheter, wrap the end with cotton saturated with sterile suprarenal extract, and rub the fossa of Rosenmüller and that part of the vault. This acts much like applying leeches to the external structures. Subse-

quently the zinc chlorid and the silver nitrate is rubbed into the parts and the process subsides. Going on to paracentesis, a few years ago we made the dot, and then we made the puncture and then the incision, and in later years we have found the incision is insufficient since it fills up with the exudate so that within possibly twenty-four hours we have to repeat the procedure. The old incision was made at the point of greatest resistance, regardless of the segment.

DR. L. J. LAUTENBACH, Philadelphia—I wish to speak of this matter of adenoids. You may recall the elaborate measures which have been so commonly adopted. The chief thing to do is first to relieve the adenoids as well as the general symptoms in these cases, and the simpler the method of operating the better. You may do it without telling the patient what you are going to do. The method I stated on this floor last year is the one I have been using since. The reason I began the use of that method is that I believe many of these cases are killed by the anesthetic. Many of us would hesitate to report our most remarkable and unsuccessful cases. Last year I reported my method of removing the adenoids with an artificial finger nail. I clean the parts thoroughly and then do the operation, asking the consent of the parents if I think it wise, and doing the operation without asking their consent if I think it better.

DR. J. H. COULTER, Chicago—Dr. Quinlan and Dr. Pynchon have very kindly completed my paper, and more eloquently than I could have done. I have only used this operation for about two months. Dr. Quinlan informs me that he has used it for over a year. The operation as just described by Dr. Quinlan has given me excellent results, such as I never obtained from the old method making the incision. The incision should, I think, depend somewhat on the prominence of the mucous membrane. A good, free, ample, incision, making a distinct flap is demanded. In that way you will get results that will be surprising to you. With open drainage at the point indicated everything is usually ideal and the results are much more permanent.

I hesitate to say a word at this time concerning adenoids, since I expressed myself perhaps too plainly last year and the year before, on the use of the finger nail in the pharynx. I will only say that no surgeon could use his finger nail in the pharynx of my child with my consent. The man who does the operation in that way must have cultivated a more acute tactile sensibility through his finger nail than I have been able to acquire, or his finger must be of double-jointed construction to accomplish the operation satisfactorily. In find that the introduction of the finger into the nasal pharynx of the child always gives pain. The operation, if such term may be so applied, is, to me at least, unsurgical, and is unsatisfactory. Now, whether it be due to plain awkwardness or want of a cultured and skilful tactile sensation I do not know, but I do know that I can not differentiate, with my finger-end in the pharynx of a small, struggling, gagging child or infant, between the impression given by adenoids and that produced by the folds and soft convolutions of the infantile mucous membrane; nor do I believe the ordinarily skilful operator can do so.

TREATMENT OF SKIN CANCERS WITHOUT OPERATION.*

HENRY W. STELWAGON, M.D.
PHILADELPHIA.

It is my purpose to consider plans which have given me satisfactory results in treating the more superficial epitheliomata of the skin. I have no new remedies to offer, but desire to add my endorsement to that of Robinson, Gotthel and others, to the advantages of caustics, properly employed, and to give somewhat in detail the manner of carrying out the treatment. In doing this I do not wish to be understood as disparaging excision as the

*Presented to the Section on Cutaneous Medicine and Surgery, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

best method in many cases, but having seen both plans often employed, I am convinced that for the more superficial skin cancers the treatment by the caustic method is equal and in many cases superior to that of operation.

It has been clearly shown by microscopical investigations that the outlying pathological epithelial cells may often be found considerably beyond the apparent border of the disease, and are, therefore, often missed by the surgeon's knife. In the caustic method such cells are usually destroyed or weakened by the products of cauterization or by the marked inflammatory action resulting, and a reappearance of the growth is thereby rendered less probable. Further, if the parasitic view of the cause of these growths be accepted, and I doubt not that this will finally be demonstrated, it can readily be understood why the caustics usually employed may have a very positive influence on the parasitic agent. Moreover, the resulting inflammatory action on the surrounding tissues, and the ensuing suppuration have an influence antagonistic to outlying morbid cells.

Another important consideration which is often overlooked in the management of these cases is that the secret of the successful and permanent removal of an epithelioma is to get the case in its earliest stage, before there has been chance for an invasion into the surrounding tissue. It is often just at such times that these patients first apply for advice, but the suggestion of the knife, or even of the curette, is followed in many instances by a postponement of treatment, and in consequence a greater growth of the lesion and less probability finally of permanent removal. A cauterization at this time, against which there is rarely opposition, would result in permanent cure. The antipathy of the average person, and even of the surgeon himself when he is the patient, to the knife, must be recognized. If an operative method is only held out to such patients, it means either a postponement, which is detrimental, or not infrequently a transference to some cancer quack, who may do damage to the patient, or who may perchance be quite successful in removing the growth.

Irrespective, however, of the natural objections of many of these patients to operative measures, I believe that the caustic method properly followed out lessens the chances of recurrence. There is no damage done with caustics if they are judiciously and boldly used; it is the temporizing treatment with mild caustics or the hesitating treatment with active caustics, which may often do harm. The mild caustics, in fact, of which silver nitrate is an exponent, should have no place in the treatment of these growths. The pain of the caustic application is often spoken of as reason for its non-employment, but patients themselves do not find this an objection, and often commend the method to friends or acquaintances likewise afflicted. Moreover the pain may be considerably lessened by the incorporation of cocaine, and if necessary by the administration of a moderate dose of an opiate.

There are many caustics which have a very positive action, but I desire to speak only of those which have been most useful in my hands, and with which I have successfully treated many cases of skin cancer of the superficial type. These are four in number: arsenious acid, caustic potash, zinc chlorid, and pyrogallol. The first three are those which are most commonly employed by those who have had the largest experience in treating cutaneous epitheliomata by the caustic method. Many other caustics have, it is well known, been used, some of which still have an occasional advocate, but a large experience usually narrows the choice to the three

active ones here named. I have not the slightest hesitation in stating that of these four the most valuable by far, and the one most frequently to be employed, is arsenious acid, in this respect, as well in others, thoroughly agreeing with Dr. A. R. Robinson, who has probably done more than any other physician to bring this method before the medical profession of this country.¹ The other three named have, however, a field of usefulness. As an adjuvant of no mean value to these several caustics—with the exception of the caustic potash—I have been in the habit of employing salicylic acid, in the proportion of 5 to 10 per cent. This addition, as a rule, does away with the necessity of any preliminary preparation of the surface in those cases in which the skin is as yet but slightly broken or ulcerated. As a rule, however, in all those cases of epitheliomata over which the epiderm is, in places at least, still comparatively intact, and in which arsenious acid, zinc chlorid or pyrogallol is to be used, it is best to apply momentarily a weak solution of caustic potash of about 5 to 10 per cent. strength; this removes the outer epidermic surface and makes the action of the applied caustic much more rapid and thorough. This potash solution should not be allowed to have a caustic action, but merely a superficial effect, and then washed off. In those cases in which the central part is ulcerated, but the outlying portions still covered with skin, this application should only be made to the latter. In most cases, of course, the surface is already an open one, and the selected caustic may be applied without the preliminary application of the potash solution. If crusts are adherent they should be gently removed with the curette or with oil soaking or soap and water washing before the caustic is applied.

In the selection of one of the four caustics named, one fact is to be remembered, and that is that pyrogallol and arsenious acid have practically an elective action, destroying the pathologic tissues and having, when properly employed and not too long applied, but little influence on healthy structures. This so-called elective action is doubtless due, in part at least, to the feebler resisting power of morbid tissue. Moreover, pyrogallol is, as a rule, a painless caustic. Now as the caustic to be employed in a given case it may, I think, be said, that in small lesions, it is a matter of indifference whether either arsenious acid, zinc chlorid, or caustic potash be used. In large-sized lesions, if the epitheliomatous area is curetted first, a measure to which some have recourse, then the pyrogallol ointment is best for destroying what pathologic tissue and cells may have been left after the curetting. A momentary application of a 50 per cent. or stronger caustic potash solution may also be used for this purpose. It is in very superficial types, in which the tendency is to run along the surface rather than deeply, that pyrogallol ointment may be employed to advantage. It has its special field, however, in cases similar to the last named, when the patient is advanced in years, or in a depressed condition of health. Its painlessness, or comparative painlessness, especially commends it for such cases, in which stronger caustics or operative measures could not well be employed. In extremely sensitive women this remedy can also be used.

Pyrogallol is, however, it should be stated, the weakest and probably the least certain of the several named. It is also slow in its action. I have never been able to get sufficient destruction in five or six days as some

¹ Internat. Jour. Surg., 1892, p. 179; 1893, p. 161.

writers suggest; it requires from ten days to three weeks for satisfactory results, and may later need a repetition for a shorter period. The formula employed should be one of 25 to 33 1/3 per cent. strength, made up with three parts vaselin to one part simple cerate; or with three parts resin cerate to one part resin plaster. The proportion of the simple cerate or the resin plaster is to be varied according to the season, whether warm or cold. The ointment may be made more effective by the addition of 10 per cent. of salicylic acid; if this should give rise to pain, a small quantity of cocain, 5 to 10 grains to the ounce, can be added. The method of applying it is as follows: It is spread thickly on the woven side of patent lint or on a piece of kid, to the thickness of 1/8 to 1/4 inch. It is applied to the diseased area, extending beyond the edges 1/4 to 1/2 inch. Depending on the region involved, it may be advisable to bandage it on or to fasten with adhesive strips; as a rule this is only necessary during the night. The dressing is renewed every twenty-four hours, the surface being gently wiped off at each renewal. At the end of three or four days a certain amount of slough is produced; this is, so far as possible, gently rubbed or picked off, or the part may be poulticed for several hours to a day. The ointment is immediately reapplied as before for three or four days more, and in this manner it must be continued for ten days to three weeks, according to circumstances; finally, after removing the slough, a mild indifferent ointment may be used, and healing permitted to take place. For this purpose an ointment of resin cerate, or zinc oxid, with a few grains of carbolic acid to the ounce, will answer well; it is changed two or three times daily, according to the amount of discharge, and the parts washed at least once daily. If complete healing should not ensue, or should a recurrence subsequently show itself, the same plan is to be repeated.

Zinc chlorid has been employed for the removal of morbid growths for some years, and had in former days, probably, a greater number of advocates than at present. It destroys healthy and morbid tissue alike, the former possibly somewhat less rapidly than the latter. Its action is a peculiar one, in that it seems to mummify the tissue. The same preliminary preparation should be made for its use as with the application of pyrogallol; the overlying skin, if intact, being softened with the potash solution. While this is not so necessary with this caustic, it hastens its destructive action. It is rarely used pure, but is most commonly employed as a paste with flour. It is a painful caustic, and as its painfulness is evidently lessened by the addition of cocain, this may be incorporated to the extent of 5 to 20 per cent. Probably the best paste is that known as Bougard's, the composition of which, as usually given, is as follows: wheat flour and starch powder, each 4 drams; arsenious acid, 4 grains; cinnabar and ammonium muriate, each 20 grains; corrosive sublimate, 2 grains; zinc chlorid crystals, 4 drams; boiling water, 6 drams. The first six ingredients are thoroughly mixed and the zinc chlorid dissolved in the water, and then the two mixtures rubbed up together secundum artem. It is difficult to have this paste made with the amount of water as given; it is advisable, however, to use as little water as possible, so that the paste may be of stiff-dough consistency, and then to add at the time of application a sufficient quantity of a saturated solution of cocain hydrochlorate to bring it to working consistency. The paste is spread on any suitable ma-

terial and applied to the growth, extending slightly beyond the border. The depth destroyed is usually equal to two or three times the thickness of the layer of paste. There is a variable amount of inflammatory swelling in the course of twenty-four hours; but this is rarely so marked as from the arsenical application to be spoken of later. At the end of twenty-four to forty-eight hours, according to the intensity of the inflammation, the plaster is removed. If the destruction is deemed insufficient, the mummified tissue is to be gently pared away, which can be done without pain, and a fresh application made. In lesions of superficial character rarely more than one application is necessary. The dead tissue is removed by paring it away and by poulticing; or instead of poulticing an ointment may be kept constantly applied and the slough permitted to come away gradually. The separation of the slough requires usually from five to twenty days. The subsequent treatment is the same as with the use of the other caustics. This paste is a good one, and it has given good results. It will hold its power several weeks or longer if kept in an air-tight receptacle. I have employed it two months after it was made and it was still active. It is, of course, necessary, as it becomes dryer, to add a greater proportion of the saturated solution of the cocain.

A paste made extemporaneously, consisting of one part zinc chlorid and three parts flour, using the saturated solution of cocain hydrochlorate to make it up into a paste, will also act satisfactorily. Zinc chlorid is of special service when the growth is seated over a vessel, as, for instance, over the temporal artery, as its mummifying action prevents any hemorrhage from destructive action. On a few occasions I was tempted to try a larger proportion of arsenious acid in the Bongard paste, but the resulting action was much more destructive than desired, and the mummifying property of the zinc chlorid was considerably lessened. Salicylic acid may, however, be added to advantage, in the proportion of 5 to 10 per cent.

As before stated, however, arsenic is undoubtedly the best caustic to employ in many of these cases. It certainly has, relatively speaking at least, an elective action. Marsden, Robinson, Gottheil and others, including myself, who have employed it frequently, have never seen toxic absorption from its cautious use. It may be employed in several strengths, according to the case and the effect required. Marsden, who was the first to emphasize the value of this caustic in these cases, advised a paste made of two parts of arsenious acid and one of mucilage acacia. Robinson recommends two strengths, one of equal parts of arsenious acid and powdered acacia, and one of two parts of the arsenic and one of the acacia, using sufficient water at the time of application to make into a paste of the consistency of stiff butter. I have employed it, in most cases, in about equal proportions; in small and somewhat deep-seated lesions, using two to three parts of arsenious acid and one part of acacia, and in slight and very superficial cases, using it as weak as one part of the arsenic to two of acacia. I have always used a saturated solution of cocain hydrochlorate to make it into a paste, as this has to some extent lessened the pain of the application. Marsden advised against applying the remedy to a larger surface than one square inch at one time. If the area is somewhat larger than this, and it is desired to treat it all at one time, satisfactory results can be obtained by using zinc chlorid paste centrally and the arsenical paste peripherally. I have usually

observed this precaution. Robinson and Gottheil state that they have employed it over much larger areas than a square inch, and have never observed dangerous action from absorption, the cases of course being kept under surveillance at the time. The paste is spread over the diseased area, well overlapping the edges, spreading to about the thickness of $\frac{1}{4}$ inch; over this is placed a piece of patent lint; in five to ten minutes the paste has hardened somewhat and the edges of the lint, if necessary, may be trimmed. This may usually be left on for twenty-four to forty-eight hours; poultices are then to be applied and the slough is gradually removed. If for any reason poultices can not be continuously applied, they may be applied during the daytime and a simple ointment dressing at night. In some instances, in which the constant application of poultices is not feasible, an ointment dressing is applied until the slough comes away, and in fact until complete healing takes place. The slough clings for some time; with poultices it usually comes away in five to ten days; with ointment it takes considerably longer. Robinson advises that the application be left on not longer than twenty-four hours, there being a possibility that too much action will have taken place if kept on longer, and that dangerous absorption might ensue. In cases of any extent, when the action seems sufficient, I am of the same opinion; if, however, the growth is small, its removal in this time has not seemed necessary. The effect of the application is that in ten to twelve hours a good deal of inflammatory swelling and edema have taken place; if at the end of twenty-four hours there is no evidence of such action, the plaster should be removed and a fresh one applied. Ordinarily one to two days' application will suffice to show sufficient destruction and inflammatory action.

In weaker proportions, arsenious acid may be used with great advantage in the superficial spreading epitheliomata, such as mentioned when speaking of the use of pyrogallol. For this use the application much employed by the late Professor Hebra in the treatment of lupus vulgaris can be used. It consists of arsenious acid, one part; artificial cinnabar, three parts; rose-water ointment, twenty-four parts. This may be used over palm-sized areas and without risk of bad results from absorption. It is spread on patent lint, to the thickness of $\frac{1}{8}$ inch or more, and applied to the whole diseased patch; this is covered with some impermeable material and fastened on with adhesive strips or with a bandage. It is changed every twenty-four hours. At the end of the first day slight swelling and some pain are noticed, which increase during the next twenty-four hours. This application is to be continued for three days, sometimes four; at the end of this time if the action is insufficient a further application is to be made. The subsequent treatment is the same as with other plans. If there are still evidences of disease after the slough comes away the treatment can again be repeated. The incorporation of cocain in this ointment will render its action less painful.

Caustic potash is a powerful caustic and must always be used with care. It is rapid in its action, one thorough application usually sufficing to destroy the entire growth. It has its special field in small and beginning cutaneous skin cancers, and in those in which time is important and in which the patient can only remain under observation a short period. The stick should be employed; or the strongest possible solution. The former is preferable. If the surface of the growth is crusted this should be removed, and the parts outside of the diseased area

protected with a layer of vaselin, after which the caustic is applied. If the lesion is small and superficial, the desired effect is usually sufficiently attained in a minute or two, and then further action is to be prevented by the application of dilute acetic acid or vinegar. The free use of caustic potash without restraint with this acid application means unnecessary pain and often unnecessary destruction and disfigurement. This caustic is painful, but only at the time of application. If the growth is somewhat large, injections of a weak solution of cocain may be made at first, or moderate obtunding may be secured by the cataphoretic introduction of cocain. Subsequently the parts may be poulticed until the slough comes away, which may require several days; or when this can not be followed out, an ointment similar to that prescribed after the use of the pyrogallol ointment may be continuously employed. In the latter event the slough is slow in coming away.

The proper use of this caustic constitutes an extremely valuable method of treating these growths, and has, as already remarked, the great advantage of rapidity. It might even be satisfactorily used in larger epitheliomata, if applied under anesthesia. The reactive inflammation which always follows the application of this caustic is in itself an element of some value.

The several methods here briefly described are, I think, worthy of much more extensive use. Their employment should no longer be left to charlatans. With a proper appreciation of their value, I believe the number of advanced skin cancer cases would be materially diminished.

DISCUSSION.

DR. SHERWELL.—I would like to endorse this paper of Dr. Stelwagon. But he has not mentioned another caustic which deserves more commendation than arsenious acid. While I have used all the other caustics named, still the acid nitrate of mercury is used ordinarily in conjunction with cauterizing. Of course, the curettage is painless, for the diseased tissue of the ordinary cancer is scraped out like old cheese; then an application of a 30 per cent. solution of acid nitrate of mercury is made in about from five minutes to sometimes thirty minutes. In the first moment the pain is intense, but easily borne. Arsenic is claimed to have an elective force, and I believe it does, by its inflammatory action in killing these specifically diseased cells. I claim that the acid nitrate of mercury has precisely the same influence.

I believe the knife is quite as well used where the tissues are free, as in the lobe of the ear, the penis, the lips, etc., where a full and free excision can be made; but ordinarily, in skin cancers, I believe the three caustics which the Doctor names, and my own as well, are best employed.

DR. W. T. CORLETT, Cleveland—I wish to add my testimony for treatment of cancer without operation with the knife. For eight or ten years my habit has been to treat cancers without resorting to cutting. I have not had the extensive experience with local applications which Dr. Stelwagon has, but I have used electrolysis in all cases of cancer presented to me. I do not wish to boast about results, but during eight or ten years, I have never had a case of epithelioma return. The advantage of electrolysis is that it can be done at a single time and can be done thoroughly. You know just where you are, how far to go and so on, and the resulting cicatrix is very satisfactory.

DR. CHARLES W. ALLEN, N. Y. City.—One might suppose by the papers and discussion which have recently appeared that the members of the profession were just beginning to appreciate the great advantage of treating skin cancer without the use of the knife. I think that in point of fact most of the men in this country who have practiced dermatology for a number of years have been treating cancer in that way for a long time; and it is only because we have had a number of excellent papers—one of which appeared some time ago at the hands of Dr.

Gotthel, a very finely illustrated article, afterward published in book form—that we have become more active possibly in reporting cases and speaking about it.

I have employed for the past fifteen years various known surgical measures, and beginning with pyrogallol have continued to arsenic, going through them all, including electrolysis, which has been mentioned. I believe all are good in some cases. I have used electrolysis about the eye on small epitheliomata with excellent results, with very little scarring, and as far as I know now without return. I can say with Dr. Corlett, that those which I operated on to a finish with electrolysis have not up to the present time returned to my office. Whether they remained cured or not I can not say absolutely. Where the disease has gone deeply, arsenic is the best remedy, for the reason of its elective influence.

DR. W. S. GOTTHEL, New York City.—I am glad to hear Dr. Stelwagon take the position that he does with reference to the treatment of cutaneous cancers, and so admirably defend a position which I believe to be absolutely correct. Entirely too much deference has been paid to the opinion of surgeons on these points. We have no excuses or apologies to make at all. We believe that we can prove that better results, both as regards permanent cure and cosmetic effect are gotten from the caustic treatment of the very great majority of cutaneous carcinomata than obtained with the knife. I can recall cases treated as long as fifteen years ago, and still under occasional observation, in which the results have been absolutely satisfactory, and in which the scarring is so superficial that a close inspection is required to see it. Some of these were quite extensive; and while I have never hesitated to use the various caustic agents over the necessary area, however large, I have never seen a case of arsenical or other poisoning result.

Arsenic is the most appropriate agent in the great majority of cases. Near the natural openings, or on the mucous membranes, nitric acid or the acid nitrate of mercury, or the potash, etc., is preferable. Only in a very few cases, where for any reason the chemical agents are inapplicable, should the knife be employed. The notoriously large number of returns after its employment should lead us to restrict its field as much as possible. I am a firm advocate of the principles of treatment that Dr. Stelwagon has laid down.

DR. R. A. McDONNELL, New Haven, Conn.—The use of caustics on the skin is generally prefaced by an apology for not using the knife. If we have once made up our minds to use a caustic, then it seems to me that the caustic selected should be one that will act deeply, promptly, and without too long-continued pain. Caustic potash has those qualities. After the use of caustic potash in a very considerable number of cases of skin cancer, I wish to add my testimony to its excellence for this purpose.

TENIA FLAVOPUNCTATA.

WITH DESCRIPTION OF A NEW SPECIMEN.*

FREDERICK A. PACKARD, M.D.

PHILADELPHIA, PA.

The patient from whom the specimen that forms the basis of this report was obtained was a woman aged 40, born in Syria, and admitted to the ward of Dr. A. V. Meigs, at the Pennsylvania Hospital, on Jan. 11, 1899. Owing to her inability to speak any but the smallest amount of English, her past history could only be obtained with great difficulty. The complaint for which she was admitted was a pain in the right side of the abdomen, dating back about three years. This pain was found later to be due to a suppurating hydatid cyst of the liver, from which she finally died. There is nothing in the history in connection with the parasite that I show except that shortly after admission she passed a segment of a tapeworm measuring 16.5 cm.

in length. This was given me for identification by Dr. Meigs, and it is through his kindness that I report the case.

The specimen was handed to me in 70 per cent. alcohol, and presented the characteristics which will be described later. The patient died from septic poisoning on February 4, and I had the opportunity of performing the autopsy. The only point of interest in connection with the specimen was that on opening the intestines there was found a second specimen of parasite 2.5 cm. above the ileocecal valve. The parasite was living when found, actively moving, and with a small knot quite tightly tied 15 cm. from its lower extremity. The head was plainly seen. On examining both specimens it was evident that we had to deal with a cestode differing from those ordinarily seen in this country.

The total length of the section of worm passed during life was 16.5 cm. The smaller segments, at what appeared to be a point near the neck, measured 3 mm. transversely by 2 mm. in length; at the larger end the breadth of the segments is 7 mm. and the length 1 mm. In most of the segments there is seen at one edge a little elevation extending in from the edge about 1 mm., corresponding, apparently, to what has been spoken of in some specimens as the yellow spot. These little elevations do not form a complete series, as occasionally there is found a segment where the elevation is on the opposite side of the segment. There is no appearance about the worm of a true yellow spot. On dehydrating segments in absolute alcohol and clearing in oil of cloves there is seen in each of a series of 7 segments a dark line less than 1/10 of a millimeter in thickness extending inward toward the center of the segment to a length of 3 mm. These dark lines have a rather brownish color in contrast to the yellow color of the rest of the segment. Even with a low power it can be seen that there are no branching uteri, but that running up to near the periphery of each segment there is a dark area, which on magnification proves to be an egg sac. The dark brownish line spoken of does not always run inward from the corresponding side of neighboring segments; thus in the 7 segments spoken of it extended inward from one side in 5, from the opposite side in 2. Thus, beginning at one end in the first segment the line ran from the left-hand edge as the specimen was held; in the second from the right-hand edge; in the third from the left-hand edge; in the fourth from the right-hand edge; in the fifth, sixth and seventh from the left-hand edge. With a higher power this brownish streak is found to be evidently a canal. In some specimens this is more clearly defined than in others, and in some the inner extremity seems to terminate in a bulbous enlargement. The main portion of the body of the segment is seen to be made up of a thin-walled sac filled with eggs. In many of the segments the brownish streak mentioned above can not be seen, either with the naked eye or under the microscope.

The specimen obtained after death was 27 cm. long and different in its appearance from that passed during life in no way except for the presence of the head and of a short neck, and for the difference in color. The specimen passed during life was of a brownish-yellow color, while that found at autopsy was almost pure white with a faint-yellow tinge. A closer examination shows that this specimen consists of a head and of a short neck separated from the former by a slight constriction, and of a segmented body. The head is distinctly black at the tip, the color being shown to have

*Presented to the Section on Pathology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

a distinctly purplish tinge on a magnification of 10 diameters. It is flattened from side to side and measures 1 mm. by 0.5 mm. The disposition of the pigment in the head is rather peculiar, it being arranged somewhat as are the leaves of a four-leaf clover, as though each division represented the sucking discs seen in other tenia. No distinct cupping can, however, be seen. Just below the head there is a distinct constriction. The neck is short and broad, measuring about 1 cm. in length by 1.5 mm. in breadth. At a distance of 1.5 cm. from the head distinct transverse striations can be seen with the naked eye, the markings evidently indicating division into proglottides. The segments differ in no wise from those described above that were taken from the specimen passed during life, except for the fact that the brown transverse streak is visible in very few of the segments. On clearing with oil of cloves after dehydrating in absolute alcohol, there is seen to be the same arrangement of the egg sac that is present in the other specimen. In none of the segments of either specimen is there present any branched arrangement of the egg sacs, nor is there any central clumping, such as is seen in the bothriocephalus latus. It is evident, therefore, that this is not a variety of tenia ordinarily seen in this portion of the world, nor is it an example of bothriocephalus. In trying to identify this specimen I have come to the conclusion that it must be an example of the rare parasite, tenia flavopunctata. This has been described but six times as occurring in the human subject.

Weinland¹ describes a specimen which was supposed to be bothriocephalus, which was voided by an 18-months-old child, and came into the possession of Ezra Palmer, Jr. He describes a yellowish spot clearly visible to the naked eye situated about the middle of each joint. Six different specimens were comprised among the segments examined by him. No specimen showed the presence of either head or neck. The whole worm measured between 200 and 300 mm. in length. The segments full of eggs were oblong in shape with the transverse diameter longer than the longitudinal. The yellowish spot was found to lie near the middle line in the anterior part of each joint. It was found to be the testicle, which appeared under the microscope as a globular gland with a long, slender canal reaching out to the side of the joint. He states that the genital openings were situated all on one and the same side of the worm, a condition that is not present in the specimens that I report. The description of the uterus is as follows: "There is no main stem in the midst with lateral branches, but on the contrary the eggs are crowded over the whole joint. It sometimes appears as if they were arranged in straight lines along the joint, but this is certainly owing only to the regular lines of muscular contractions." "From a careful dissection of the young joints we should judge that it—the uterus—consists of globular blind sacs, located here and there in the joint, connected by fine tubes terminating finally in the vagina." The eggs are said to be very large and under a low power to appear as transparent balls with a yellow dot in them, while with a higher power three distinct egg shells were to be made out. He suggests the possibility that the cystic form of the tapeworm dwelt in an insect which had been swallowed by the child.

Loucart examined segments of Palmer's specimen, which were sent him by Weinland, and figures of the segments accompany the article on this parasite in his work on the parasites of man. In the segments

which he examined he could distinguish nothing but a large number of eggs with their clear enveloping wall, and a club-shaped organ occupying a transverse position near the anterior border of the joints.

The second specimen was that described by Leidy.² In this case the worm was obtained from a 3-year-old child after the administration of santonin. The child was a native-born citizen of Philadelphia. The specimen is described as consisting of a dozen fragments which reached the length of about a foot or fifteen inches, or more, and were supposed to belong to three separate parasites. No head was present. The widest portion of the body of the specimen was 2.5 mm. in diameter. The joints or proglottides were described as being proportionally short, and the breadth was said to exceed the length several times. The pair of longitudinal vessels was said to be extremely well marked. The ripe joints were of a pale-brown color from the presence of contained eggs. Other joints smaller than those of the ripe ones were seen mingled with the others. The egg-cavity is described as being a simple sac bounded by thin walls of the joints. In the segments containing eggs nothing could be made out in regard to the structure of the generative apparatus, but in those without eggs he describes a narrow, clavate organ which he suspected to be the seminal receptacle. This organ is described as lying near the fore part of one side of the joints, commencing with its thick end near the median line and proceeding outwardly, somewhat tortuous and tapering, along the anterior border of the joints. The joints without eggs also showed scattered here and there from two to five rounded or oval bodies which were supposed by Leidy to be testicular. The longest fragment among the specimens examined by Leidy was 13 inches in length. This was supposed to represent a nearly complete worm, as the joints were very much smaller than the main portion. Leidy made a careful study in regard to the proportions and relations of the segments. All the segments were without eggs. The description of the eggs in his specimen was that they were raw-sienna colored, mostly spherical, and usually measuring .072 mm. in diameter. Embryos were described as oval and measuring .04 by .032 mm., and were provided with six hooks, arranged in three pairs. He states that previous to the specimen described by him the only example of tenia flavopunctata was that of Weinland. Leidy's specimen did not exhibit the yellow spot. In his specimen, as in that described by Weinland, the parasite was found in this country, and in both cases voided by children. In the latter respects my specimen differs from these two, inasmuch as it was found in an adult and in one who was a Syrian and had been but a short time in this country.

In the same year Parona³ described an instance of the occurrence of this same parasite in the fecal matter of a child aged 2 years. He found a few eggs of the ascaris lumbricoides and some resembling those of *T. solium*. After the administration of a dose of oil, two specimens of cestodes were obtained and a like number after the administration of flix mas. The four specimens were identical in character and measured from 12 to 20 cm. each. They looked like a small tenia with head, neck and body. The head was very small, the neck short and terminating after 3 or 4 mm. in the body, in which appeared distinctly the lines between the proglottides. The cuboidal head measured .5 mm. in diameter, with four oval cups of a diameter of 112 by 88 microns, and were placed above and obliquely. There was no rostellum and no ring of hooklets. The head passed

into the neck with a slight constriction. The length of the neck was 2 to 3 mm. The strobiles were short, trapezoid and with rounded angles. The proglottides are described as always broader than long and measured at least .5 mm., while the largest were 3mm. in length. The width of the proglottides varied from .5 mm. near the neck to 4 mm. at the lower extremity. The mature proglottides were rich in eggs accumulating in the end of the segment and partly hiding the course of the ovarian duct. This duct was described as being somewhat club-shaped with its most slender part toward the margin of the proglottis. Parona states that it was always on the same side of the worm and appeared to be of a yellowish color. He notes the absence of a branching uterus. He describes the eggs as being found freely in the feces of the child, and as of oval shape and intense yellow color, and measuring 58 by 68 microns. The proscelics were of a distinctly oval shape, possessing hooklets and showing active movement. The eggs were described as being like those of the *T. solium*, the shell of double contour and one-third thicker than that of the last-named parasite. The description of Parona's specimen would apply almost precisely to the specimens that I present. These specimens described by Parona were made the subject of an article by Grassi⁴ in which he notes the resemblance between the specimens of Parona and the *T. leptocephala* of the mouse and rat. He explains the variation of Parona's specimens from those mentioned as being due to the changes occurring after the death of the parasite. He states that the arrangement of the genital organs, length of the tenia and the size of the proglottis are similar in the two worms. Grassi has advanced the view that a parasite so rare in the human species might be looked on as not having the human body as its regular host and its identity with ordinary parasites of other hosts should be in each case carefully investigated.

Adolf Lutz⁵ mentions the fact that Blanchard had collected only four cases, those of Palmer, Leidy, Parona and Grassi, the first mentioned being that described by Weinland. Lutz had brought to him in 1893 a specimen of tenia voided by a child after the administration of santonin. The specimen included the head. Four somewhat large sucking discs and a poorly developed rostellum without hooklets were present. The segments numbered 960, among which some were sterile. There was most resemblance between this and Weinland's specimen. Owing to the statement made by Grassi that a similar parasite infests the rodents he investigated the intestinal contents of the rats and mice in San Paulo, and found that frequently there was present a cestode which corresponded on the one hand to the *T. leptocephala* and on the other hand to the specimen obtained in the human subject. He therefore agrees with Grassi that the rat is the usual host of the *T. flavopunctata*. While making his investigations he found in the examination of the feces of a child aged 2½ years, born of foreign parentage but growing up in San Paulo, the eggs of a cestode resembling those of *T. nana*. In order to still further study the question as to the identity of the *T. flavopunctata* and the parasites found in the rat, he made a more complete study of the parasitic contents of the rats found in St. Paulo, examining the excrement from time to time for eggs, and found in one animal kept a long time after the discovery of eggs in the excrement two examples of the *hymenolopis diminuta* (*T. flavopunctata*), and a larger number of small tenia corresponding to the *hymenolopis nana* (*T. nana*). In a 4-year-old girl born in San Paulo examina-

tion of the stools discovered the presence of somewhat numerous eggs resembling those of *hymenolopis nana*. After the administration of an anthelmintic he found a very large number of small tapeworms, about 10 per cent. of which showed a head. These evidently were examples of *hymenolopis murina*.

It would seem from Lutz's article that there is little if any connection between the various parasites found by him in the rat and the supposed *T. flavopunctata* derived from his first patient. His description of the parasites found is quite brief, but in that of the parasites found in the rat there is not sufficient description to identify his specimens with the *T. flavopunctata*. The specimen that I present herewith is of such a size that it is inconceivable that the mouse or the rat could share with man the privilege of being the host of this parasite, unless in these animals the worm attains a far less size than is the case in the human being. It may be that the supposition of Grassi is correct and that the rare examples of the *T. flavopunctata* in man are in reality instances of infection by one of the parasites having as its usual host one of the lower animals, and showing different developmental characters when dwelling in the human intestine. Proof of this is not definitely furnished in Lutz's article.

Zschokke⁷ has described a specimen which he found preserved in a museum of the veterinary school at Alfort. It consisted of two pieces measuring 18 and 20 cm. in length, and of numerous shorter fragments and separate joints. The preparation had been for a long time in the Alfort museum and was supposed to have been obtained in the latter part of the last century. The parasites were very opaque, hard and fragile, and it was difficult to investigate their internal structure.

Choledkowsky⁸ has described a tenia (*T. Brandti*) found by him in the intestines of hogs and cattle which bears some superficial resemblance to the *T. flavopunctata* as regards the relative length and breadth of the segments and the arrangement of the genital outlet. There is, however, a totally different arrangement of the egg-sacs, which in the specimen described by him form a branching organ resembling that of the beef and pork worm, whereas all authors agree in stating that the eggs of the *T. flavopunctata* are contained in a large thin-walled sac.

It seems to me that the specimens presented herewith must be looked on as examples of the *tenia flavopunctata*. The rarity of this parasite in the human being makes it, I believe, worthy of report, especially in order that others may be on the watch for other instances. Whether it is merely an accidental parasite of the human being and has its ordinary habitat in the intestine of some other animal during its sexually mature period can not be definitely stated.

Pathogenesis of Sympathetic Ophthalmia.—I. W. Selenkowsky has established that toxins generated by bacteria in one eye may be carried to the other eye and induce a sympathetic inflammation. He injected filtered toxins of the staphylococcus aureus into one eye of numerous animals with positive results of inflammation in the other eye in every case. —*St. Petersburg Med. Woeh.*, October 6.

A COMPACT OPERATING-CASE FOR MILITARY SERVICE.

WITH A DESCRIPTION OF SEVERAL NEW INSTRUMENTS FOR THE SAME.

NICHOLAS SENN, M.D.
CHICAGO.

The surgical work of the military surgeon in the field is limited almost exclusively to the treatment of accidental wounds. He seldom is called upon to perform major operations for any other indications. His success as a surgeon depends largely on his proficiency in guarding against wound infection, and his mechanical skill in the treatment of compound fractures. During an active campaign he will often find himself thrown on his own resources with a limited supply of instruments and dressing material, and often without skilled assistance, and under these trying circumstances has often to perform difficult operations which can not be postponed. Military surgery is in every sense of the word, emergency surgery. A quick perception of the nature of the case, and prompt, intelligent action are necessary to perform the many life-saving operations during and after all engagements, when often without warning and with limited preparations hundreds of wounded plead at the same time for surgical assistance. The military surgeon must possess the necessary knowledge and manual dexterity to perform at a moment's notice, and with the simplest instruments and limited assistance, all life-saving operations, in all cases demanding timely intervention to meet the urgent indications. Aseptic surgery has necessitated a great change in the manufacture of surgical instruments. All attempts at ornamentation have been abandoned. The beautifully carved handles and blades that adorn the pages of ancient works on surgery have become objects of curiosity, and are to be found only in the shops of dealers in antiquities. The modern surgical instruments are made as plain and smooth as possible. Knives and retractors are made of one piece of metal, and niches and crevices are avoided whenever this can be done, and scissors and forceps are constructed so that the two parts can be readily separated and joined together again, to facilitate thorough cleansing and sterilization. Another great improvement noticeable in the instruments in use at the present time is their smaller size and more delicate construction. The old-fashioned, sword-like amputating knife is seldom seen now, as any amputation can be done with a medium-sized scalpel, since surgeons have abandoned transfexion methods. The best surgeons need the fewest instruments. Very few instruments are required to perform any operation, provided the selection is made with the requisite care, and the surgeon is familiar with their use.

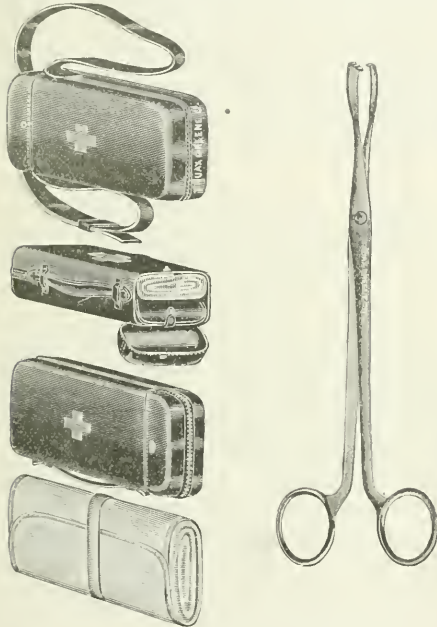

The military surgeon should from the very beginning of his professional career endeavor to do his surgical work with as few instruments as possible. For field service the instrument case as well as the instruments should be well adapted for emergency work. Aseptic surgery has made it necessary to make a radical change in the construction of instrument cases. Within the memory of nearly all the older military surgeons the method of packing, storing and transporting of surgical instruments has undergone a somewhat rapid succession of notable changes, and while each has marked an advance in the mechanics employed, it is evident that the inventive skill of the instrument-maker has not kept pace with the rigid demands of aseptic

surgery. The old-fashioned velvet-lined instrument box and pocket-case very fortunately disappeared some time ago, and were replaced by wooden boxes with carved spaces for each instrument, devoid of any lining, and the so-called aseptic pocket-case. In due course of time, the wooden boxes had to give way to another improvement—the metallic cases, which for some time appeared to answer the modern requirements. In the metallic cases the instruments were held in their places by hooks, loops and cross-bars, and it was not always easy after their use to return them to their proper places, to say nothing of the damage inflicted upon the instruments in the transportation of the cases and the disagreeable rattling caused by the instruments not held firmly in position. An instrument case for field use must contain all the instruments necessary

for emergency operations; it must be compact, and so arranged that the case and its contents can be sterilized by the simplest and quickest method, and the instruments, after use, can be replaced without any difficulty and unnecessary loss of time. Cases made of wood or metal are entirely out of place in the field. They are apt to get out of order by hard usage, and add unnecessary weight and bulk. For a number of years the writer has made an extended study of the contents and case for surgical work in military and emergency surgery. He has found by observation and ample experience that the instruments used in emergency work can be safely carried in roll-up, washable, canvas rolls, in which each article is held securely in place by non-elastic loops. If the name of each instrument is stamped with indelible ink in the place it should occupy, there will be no difficulty experienced in replacing properly and quickly the entire set after use. This plan constitutes an ideal method, for it makes pro-

vision for changes that might appear desirable in the set, and discarding such as might be regarded as unnecessary, and additional patterns may be included from time to time. A second and similarly stamped roll, properly sterilized, should be in readiness in a separate compartment of the outer leather case, so that the instrument may be transferred to it after each exposure to infection. The form and character of the outer wrapping of the canvas roll holding the instruments is of the greatest importance. It should be light, soft and flexible, without any sharp corners, and, if possible, small enough to be carried in a hand-bag or overcoat pocket. The outer cover of the author's field-case is made of soft leather, with rounded ends and corners, with a double compartment, one for the roll of instruments, the other for the empty canvas roll. A slip-handle, also of leather, is provided,

so that the case can be carried like a hand-bag. For military service a leather strap is attached, so that the case can be carried over the shoulder.

The instruments selected for this case are the following:

One combined metallic male and female catheter; 11 Kocher's hemostatic forceps; 1 Abbe's hemostatic forceps and needle-holder combined; 1 small scalpel; 1 large scalpel; 1 straight bistoury; curved, sharp-pointed bistoury; 1 small tenotome; 1 tenaculum; 1 straight scissors; 1 scissors curved on the flat; 1 MacLean's folding amputating knife; 1 bone-cutting forceps; double-end retractors, with guards; 1 author's saw, with guard for blade; 1 plain dressing-forceps; 1 ligature-carrier and retractor; 2 author's tissue forceps, with 3 and 5 teeth and catch slide; 1 bone chisel; 1 bone gouge; 1 sharp spoon and periosteal elevator; 1 author's bullet forceps; 1 author's bullet probe; 2 ordinary probes; 1 exploring trocar; 12 silk-worm-gut sutures; 12 surgical needles (assorted); 2 skeins of braided silk; 1 coil of silver wire; 6 needles for intestinal suturing.

The six knives are included in two protecting metallic plates that rest side by side, forming one fold of the canvas roll.

The knives are made of one piece of steel and the handles are corrugated, ensuring a firm grasping surface. The most important feature of the list of instruments is the large number of hemostatic forceps. Besides the eleven Kocher's forceps, the Abbe's and tissue forceps are available for hemostatic purposes. The Kocher pattern is given preference because it combines the artery crushing power of the serrated designs with the delicate adaptation of the mouse-toothed variety. With this double hold on the tissues there is very little risk of losing its grasp. If a deep vessel requires to be tied and the ligature does not readily slip into place, two instruments are applied close together, and by separating the locked handles a cone is made by the grasping ends of the forceps over which the ligature readily glides away from the instruments into its proper place. Although the author never uses anything but an ordinary scalpel in performing any amputation, he has included in the set MacLean's folding knife, which may prove a convenience to many surgeons who are in the habit of using larger knives. The retractors, two in number, are each provided with blunt and sharp retracting blades. The latter are three-pronged, and are furnished with guards that permit of safe use of the sharp end as a handle when using the blunt end. The bone-cutting instruments comprise a cutting forceps, the author's saw, a sharp spoon and periosteal elevator, a chisel and a gouge. A mallet is not included, as a substitute for this instrument can be found almost anywhere. The bone-cutting forceps will answer an excellent purpose if only a limited amount of chiseling is to be done.

The smaller instruments are of the author's patterns, and will be described below, while the small instruments are of the usual forms.

The canvas cover is eight inches in width and, including flap, 31 inches in length. The whole is encased in a flexible leather cover, 9 inches in length, 5 inches in breadth, and 5 inches in thickness, and weighs, complete, 4½ pounds. One of the principal advantages of the instrument case is that after removing the canvas cover from the leather case, the cover, with all its contents, including needles and suturing material, can be sterilized at a moment's notice by boiling for a few minutes in a soda solution.

After the operation the instruments are to be thoroughly cleansed, dried and transferred to the second aseptic canvas cover. The author made use of one of these cases during the Spanish-American war, and his experience with it during that time has convinced him that it possesses merits which should entitle it to the careful consideration of military authorities. To make this case useful for military service, the author found it necessary to devise a number of new instruments, which it contains, in order to meet the demands made necessary by the small-caliber, jacketed bullet, and others to adapt them for emergency work. These instruments require a brief explanation.

BULLET PROBE.

The metal encased bullet has made the famous Nélaton bullet probe almost obsolete, as the test for lead which it yielded by rubbing the porcelain tip of the probe against the leaden bullet will no longer be of any diagnostic value in searching for modern bullets. The tip of this probe is likewise too small in following the tubular wounds made by bullets. The author's bullet probe consists of a soft metal, flexible rod, pointed in the center and tipped at both ends with porcelain bulbs, as at this time the old-fashioned leaden bullet has not

been entirely abandoned in warfare, and remains in common use in civil life. The porcelain tips are made to correspond in size to the caliber of the bullets commonly used; that is, one corresponds to the 22 and the other to 38, French scale. Probing for bullets in recent gunshot injuries is seldom justifiable as a diagnostic resource, but in cases in which it is deemed advisable by the nature of the wound and the probable location of the bullet the bulbous end of the probe should correspond as nearly as possible to the caliber of the bullet, as false passages are more likely to be made with a small instrument than one which corresponds approximately to the size of the bullet. In the old porcelain-tipped probe some risk always attended exploration by the porcelain bulb becoming detached and remaining as an additional foreign body in the wound. Heretofore, in the construction of probes with this class

of tips, the porcelain bulb has been attached to the rod by boring or moulding a perforation in the bulb, which the wire rod would fit, and fastening the two parts together with cement. This procedure was a well recognized defect, and resulted not infrequently in losing the bulb in the wound, an accident which occurred in the writer's own practice. After much experimenting, a probe has been made with a perforation through the whole thickness of the bulb, the rod passing through the whole length of the perforation, its distal end being riveted in a small depression on the surface of the bulb.

This modification in the manufacture of the probe renders the instrument perfectly safe, and without detracting the least from its value as a diagnostic instrument. The diagnostic value of the probe has been greatly enhanced by furnishing the ends with porcelain tips which in size more nearly correspond to the caliber of bullets in most common use. The full length of the pointed probe described is nine inches.

BULLET FORCEPS.

Since leaden bullets have largely given way to a core of lead surrounded by a hard metal mantle, it has become necessary to change the construction of forceps intended for their extraction. At the time when the leaden bullet was used exclusively, it was possible to remove them with the aid of forceps with short, tenaculum-shaped jaws, because with even a light force it was easy with such an instrument to penetrate the lead, thus securing a grasp sufficiently firm for its extraction. Such instruments are, however, practically worthless in attempting to extract a steel or nickel-cased bullet. The American bullet forceps, which retained its well-earned fame as long as its use was limited to the extraction of leaden bullets, must now give way to instruments with a better grasping power. It is evident that forceps with concave serrated jaws would answer in such cases, provided the grasping surface would correspond in size with the metal jacket. To use efficiently a forceps of such construction would necessitate several forceps with different grasping capacities and a previous knowledge of the exact size of the bullet to be extracted. An in-

strument to be of use in all cases must be one that is so constructed that it will grasp securely bullets of any size. This object is gained by forceps with concave jaws, the terminal margins of which are provided with two short, strong teeth, sharpened to a fine point. A third shorter and stouter tooth, interposed between the two lateral teeth, would form in each jaw a third point of contact in case of smaller bullets. The forceps terminates in a blunt cone, which makes the instrument available when closed as a bullet probe in the absence of instruments specially adapted for this purpose.

MINOR OPERATING SAW.

This instrument consists of a slender blade provided with a lifting back and attached to a small, solid handle of such shape as to admit of a firm grasp of the instrument. The fenestrum in the handle reduces the weight of the instrument and increases the grasping surface.

RAT-TOOTHED TISSUE FORCEPS, WITH CATCH SLIDE.

This forceps is of the spring-blade type, with slide catch. These forceps can be used for dissection and hemostasis, and can be made useful as retractors. The jaws are of the rat-tooth variety, the smaller size with three and the larger with five teeth.

SARCOMA OF VERMIFORM APPENDIX.— SARCOMA OF THE EXTERNAL URETHRAL ORIFICE.

THEO. G. DAVIS, M.D.

BRIDGETON, N. J.

I. H., male, aged 51 years, blacksmith, had for more than a year recurrent attacks of pain in the right iliac fossa, becoming more severe, so that five weeks before entering Bridgeton Hospital, for operation, he had been confined to the house for three weeks by an attack. The question of malignancy was considered, because his father had died of "cancer," and on tracing history of father's case, I find that the cecum was much thickened and softened, but no microscopic examination was made. I mention this because Hollender has recently stated that "cancer of intestine is apt to recur in families." Having opened the abdomen, by the usual incision, we found the appendix lying posterior of cecum, pointing upward and slightly outward, firmly adherent and bound down by results of previous inflammation. It was severed near the cecum, and peritoneum closed over stump by mattress sutures; the cecum did not appear to be invaded. The abdomen was closed in layers. The appendix was about 1½ inches in length, firm, thickened, lumen almost obliterated. Sections examined microscopically proved it to be a small rounded sarcoma. Five months have passed and patient seems perfectly well, has gained fourteen pounds, and is at work.

This is the third case of sarcoma of the vermiform appendix to be reported; the others have been reported by Glazebrook,¹ and by J. Collins Warren.²

R. A., female, age 47, was annoyed by pain, irritation and bleeding. On examination, a dark-red, somewhat eroded mass was found, with base at urethral orifice. Free dissection of vestibular space and removal of anterior half of urethra was made. The mucous membrane of urethra was attached to the skin by silkworm-gut sutures. A catheter was placed in the bladder, and the vagina packed with gauze.

Recovery was uneventful, and now, five months afterward, she appears well. Microscopic examination proved it to be a small round-celled sarcoma.

This is the fifth case to be reported in surgical literature—one each by H. Beigel, E. Ehrendorfer, Galabin and C. A. L. Reed.³

THE USE OF ALCOHOL IN TREATMENT OF CARBOLIC ACID BURNS AND POISONING.

HERMAN A. KLEIN, M.D.
CHICAGO.

Having used alcohol in the treatment of carbolic acid poisoning and burns with most gratifying results, I venture to give my observations for the benefit of those who have had no experience with this antidote. It not only enables us to save many lives that are threatened by the accidental or intentional misuse of carbolic acid, but it widens the field of use of one of the most powerful germicides, for it enables us to use the full germicidal properties of the acid without any dangerous caustic effect. I believe that the following cases justify my statements:

CASE 1.—Some one threw about two ounces of carbolic acid on the face and hands of a woman, and when I arrived, about fifteen minutes after the occurrence, I bathed the injured parts freely with alcohol for half an hour. Marked improvement took place at once; pain was diminished, and the skin assumed a healthier color. I also applied carron-oil. In about a week the patient had fully recovered without any mark on the face.

CASE 2.—A woman, aged 29, drank 2 ounces of carbolic acid. I saw the patient ten minutes afterward, and gave alcohol internally, 4 ounces every half-hour until three doses had been taken, then 1 ounce every hour for four doses. I administered $\frac{1}{4}$ gr. morphin hypodermically, followed in two hours by another injection of morphin. After this there was little medicine given. The patient was discharged in six days.

CASE 3.—A man, aged 45, received a serious injury in the arm; subsequently infection took place. I applied 95 per cent. carbolic acid to the infected wound for a minute, followed by alcohol. After four applications infection disappeared and the patient made an uneventful recovery.

DISCUSSION ON DR. EVANS' PAPER.*

DR. FREDERICK HOLME WIGGIN, New York City.—My experience coincides with the statements made by Dr. Evans, that following end-to-end anastomosis there is little danger of cicatricial contraction. I prefer this method of joining the bowel in all cases where it can be accomplished. I have been fortunate enough to have been able to watch several of my patients on whom this operation had been performed and to follow them up for a number of years, and in no instance has there been any reason to believe that any stricture of the bowel had resulted.

Years ago, when we were beginning to perform operations for intestinal anastomosis, I performed many operations of this character on animals, using both the Maunsell method of suture and the Murphy button. Some of these animals I kept for a number of months, one or two for nine months, and had great difficulty after death in finding the point or points of union. During the last few years I have given up the method of invagination preliminary to suturing, advised by

Maunsell, as I have found it to be unnecessary. The suture which he advised was one beginning on the inside of the bowel, passing through all the coats of the gut, then passing through all the coats from the outside into the interior of the other segment of the bowel in order that it may be tied on the inside, thus drawing in the edges of the divided gut and joining the peritoneal surfaces together.

The suture material which I have found to be the most satisfactory in this work is horse hair because it is fine enough to thread in a milliner's needle No. 6 or 7; because it can be easily tied, and also because it is elastic and there is little or no danger of the sutured part becoming strangulated.

While I occasionally use the Murphy button, especially in cases where time is an important factor, yet, as a rule, I prefer the suture method. The objections which I have to the button are the following: 1. Because it places in the intestine a foreign body which is occasionally therein retained, and which also serves as an anchor to hold the anastomosed portion of the bowel in a fixed position allowing the uninjured portion to kink about it, which has resulted in intestinal obstruction. 2. Because it makes the patient dependent on the craft of the cutter rather than on the skill of the surgeon, the spring of the button being made at times too strong, and at other times too weak. 3. Because there is the trouble of being obliged to keep buttons of various sizes constantly on hand. 4. Because there is some danger of the lumen of the button becoming plugged with fecal mater, causing thereby obstruction, which has resulted in death. 5. Because there is danger of the holes, placed at the ends of the button for the purpose of drainage, causing perforation of the mucous and muscular coats. They have been, and may be, cut through, unless great care is used, by the intestine being pressed into the holes and against their edges when the segments of the invaginated button are pushed together.

DR. W. A. EVANS, closing.—I did not go into a consideration of the different devices for operation. In looking up the objections to intestinal anastomosis I found that some stress had been laid on the danger of secondary stricture after nearly every kind of operation. In some articles this objection has been brought very prominently forward. Jacobson's "Surgery" gave secondary contraction a prominent place among the objections to the Murphy button. I believe that in all cases where we do either suture anastomosis or a button anastomosis the element of danger from the development of secondary connective tissue in the intestinal wall is slight.

Therapeutic Application of Methyl Salicylate.—When the sound skin is painted with methyl salicylate and an airtight bandage applied, the salicylate is absorbed and eliminated in the urine as rapidly as in case of sodium salicylate taken internally. It relieves the pain in all affections accompanied by local pain, neuralgia, gonorrhéal arthritis, colic from gallstones, etc., as well as in articular rheumatism. These assertions by S. Barski (*St. Petersb. Med. Week.*) are based on an experience of 122 cases of various affections in which methyl salicylate was applied in this way, with most gratifying results.

Injury of Ureter During Laparotomy.—N. Fenomenoff relates in a Russian journal quoted by the *Sen. Méd.* of November 14, that he had the misfortune to excise a small portion of one ureter during a tedious operation for removal of cystic tumors in the broad ligament. Instead of suturing the ureter to the abdominal wound and abating the kidney later, he resolved to exclude the kidney at once, as *restitutio ad integrum* was impossible. He, therefore, drew the proximal stump of the ureter down as far as possible to prevent a diverticulum, and threw two ligatures around it, then replaced it in its normal position and sutured the abdominal wound, draining through the vagina. The patient made an uninterrupted recovery, complaining merely of a few dull pains at times in the lumbar region at first. She left the hospital in a month, and during the year since the operation has been in good health, with no indication of abnormal function even on analysis of the urine.

* This discussion was accidentally omitted last week, when the paper appeared.

INTRA-ABDOMINAL TORSION OF THE OMENTUM.

The diagnosis of intra-abdominal disease is at times surrounded by so many difficulties that the clinician can not too securely fortify himself against error; but even the most careful and well-informed observer may occasionally be forced to exploratory operation in order to determine the exact nature of the conditions present and to afford the relief that seems urgently necessary. It is well-known that the bowel may become not alone incarcerated in natural or adventitious openings or loops, but also twisted on itself. The omentum, likewise, alone or together with the intestine, may be herniated and, like other organs with a pedicle or analogous attachment, it may undergo torsion, which, if not relieved, must terminate in gangrene and fatal peritonitis. The literature of such twisting of the omentum seems to be scanty, and the difficulty of recognizing the condition apart from operation is almost insurmountable, by reason of its apparently constant association with some form of hernia.

Not alone may the omentum be twisted on itself, but it may also be doubled up on itself once or oftener in a hernial opening. To this latter condition the designation retrograde incarceration has been applied. Both phenomena may be associated, or each may exist independently.

To the small number of cases in the literature Dr. Joseph Wiener, Jr.,¹ adds the report of another, which illustrates the essential features of the disorder. A man, 79 years old, with a right-sided reducible inguinal hernia of thirty years' standing, was suddenly seized with pain in the right iliac region, which subsided in the course of twenty-four hours. Three weeks later a similar attack occurred, the pain being cramp-like in character but unattended with vomiting or fever. The bowels had moved regularly. The abdomen was soft and tympanitic. A round tumor as large as an orange, tender to touch, of doughy consistency and dull on percussion, was found midway between the right anterior superior iliac spine and the free border of the ribs, between the axillary and the mammillary line. The sac of a right inguinal hernia was found empty. The temperature rose to 101.1 F., the pulse to 100, and the respiration to 31. A diagnosis of intra-abdominal abscess was made. On opening the abdomen by an incision over the tumor,

a piece of omentum as large as the palm of a hand, infiltrated and dark-blue in color, was found, with its distal portion adherent to an epiploic appendix of the ascending colon and the proximal portion continuous with the remainder of the omentum by a narrow pedicle, which was twisted on itself five or six times.

The condition under consideration has hitherto occurred only in patients suffering from hernia, though it was not always found in relation thereto. It has not been recognized prior to operation. Manipulation in attempts at reduction of hernia is thought to be a predisposing etiologic factor in some cases; circumscribed peritonitis with adhesions may act in a similar way. Violent abdominal movement may be the exciting cause in bringing about the twisting. The possibility of the existence of this condition should be borne in mind in operations for hernia attended with symptoms of strangulation, in which only a strand of omentum is found in the inguinal canal, and investigation should be made to determine that there is no torsion of the intra-abdominal portion of the omentum.

REQUIREMENTS FOR ADMISSION TO MEDICAL SCHOOLS.

Laxity in the requirements for admission to medical schools is one of the most serious shortcomings of American medical education. In the classes of too many of our medical colleges will be found those who are not fit for the medical profession because of lack of training and education, but who yet go away with medical degrees. The proportion of unworthy men, it is feared, is much larger in some schools than it is in others. Such men should not be admitted to the study of medicine. Once admitted they are dragged along with the classes and eventually a diploma is thrust on them. We read in the catalogues of the medical schools that students are admitted by diploma, certificate and examination; but in the majority we fail to find that any control is exercised as to the source and authority of the diploma or certificate. If the certificate is from a high school there is nothing to show that the high school is controlled and approved by some authoritative body capable of doing it, as, for instance, a state or other university. There is also good reason to believe that in many instances the entrance examinations to which the applicant is subjected in lieu of certificate or diploma are of the most perfunctory character. The general scope of the preliminary education by schools that do not demand college degrees for admission is stated often in the most general and indefinite terms.

The new requirements for admission to the medical department of the University of Michigan, copies of which have just been received, are a refreshing exception to the vagueness generally characteristic of such statements. The branches that must have been pursued successfully, and other conditions for admission, are stated clearly and explicitly. A schedule is submitted showing as exactly as such a thing can be shown what

¹ Annals of Surgery, Nov. 1900, p. 648; THE JOURNAL, Nov. 24, p. 1376, abstract 58.

the applicant shall have done in English language, history, mathematics, natural sciences, modern languages and Latin, and certain possible substitutions, before he is admitted to the medical courses. This is a good step in the right direction. Instead of relying implicitly on certificates and diplomas the student must show that he can fulfil certain fundamental requirements that experience and reason proclaim as absolutely essential. In this way the work of the preparatory schools is controlled and brought into better harmony with the work of the medical schools.

The medical department of a great state university can well afford to take a decided lead in all matters appertaining to raising the standard of medical education. It ought to be wholly independent of the number of students admitted. The larger the number of applicants the greater reason to stiffen the requirements. Numbers may flatter the board of regents, but they do not make of necessity great universities.

ENDOCARDITIS IN ITS RELATIONS TO OTHER DISEASES.

In an exhaustive report on endocarditis before the German Congress for Internal Medicine,¹ Litten reaches certain conclusions, which seem to represent fully our present knowledge of this interesting affection. Litten's report appears to have met the approval of the Congress, as many of its members expressed their satisfaction with it.

With the exception of the atheromatous or arteriosclerotic form, endocarditis is almost always a complication in the course of an infectious disease and is caused by micro-parasites. The current designations "verrucous" and "ulcerative" do not carry with them any precise significance as to the origin and cause of endocarditis, which from the clinical and prognostic standpoint may be divided into benign and malignant. Benign endocarditis causes only slight changes without much if any clinical disturbances, but it may lead to chronic valvular disease. It always—or nearly so—involves the left side of the heart and may give rise to aseptic infarcts in the systemic circulation. Pulmonary infarcts in such cases usually result from venous thrombi or thrombi in the right heart.

Malignant endocarditis is always dangerous, develops in either side of the heart, and assumes at one time the verrucous, at another the ulcerous form anatomically. The emboli given off may act mechanically or in an infectious manner, depending on the nature of the underlying condition. Hence malignant endocarditis may be divided into two groups, one without, the other with, suppuration.

Trauma may cause inflammatory disease of the valvular endocardium, terminating either in healing or in chronic valvular disease. Secondary infection may transform this benign endocarditis into a malignant and septic-pyemic.

According to its secondary nature, endocarditis is classified by Litten as follows, on the basis of etiology: I. Endocarditis benigna, which includes the following variations: rheumatica, peliötica, choreatica, gonorrhoeica, scarlatinosa, morbillosa, variolosa, diphtheritica, typhosa, pneumonica, tuberculosa, e. influenzae, and traumatica. II. Endocarditis maligna; this is divided into, 1. e. non-suppurativa, which includes e. rheumatica, e. choreatica, and e. gonorrhoeica; and 2. e. suppurativa, septic-pyæmia—primary or secondary in any of the above forms. Benign and malignant gonorrhoeal endocarditis are caused by the same agent, the gonococcus, the difference being merely one of degree dependent on the virulence of the bacterium. The nature of the cause of rheumatic endocarditis is not known any more than the cause of typical articular rheumatism is known: rheumatic endocarditis may be assumed to be caused by similar agents of varying virulence.

This summary may be regarded as the most comprehensive and most successful of all the efforts at classifying endocarditis in its various forms. The more it is studied the better does it satisfy the demands on a scheme of this character. Its basis is essentially etiological. The old anatomic subdivision into ulcerative and verrucous long proved insufficient and confusing. The clinical subdivision into benign and malignant is helpful provided the line of distinction between the two be drawn not too sharply, as the difference is but one of degree. It is needless to say that benign here refers to the type of the disease.

ECLECTICS, HOMEOPATHS AND REGULARS IN CHICAGO AND THEIR OFFICIAL RECOGNITION.

An interesting document has been prepared by the regular attending staff of the Cook County Hospital, of Chicago, for the purpose of inducing the Board of Cook County Commissioners to readjust the ratio now in vogue at the hospital of distribution of the patients among the regular, homeopathic and eclectic services.¹ It appears that 16.66 per cent. of all patients now entering the hospital are assigned to the eclectic service; 20 per cent. to the homeopathic; and 63.33 per cent. to the regular. This apportionment, originally based on the number of students in the different "schools," does not now fairly represent the attendance of the various colleges. In 1899-1900 there were 101 eclectic students in Chicago, or 3 per cent., 659 homeopathic, or 19.3 per cent., and 2648 regular, or 77.7 per cent. During the past six years there has been a diminution in the number of eclectic students, a slight growth in the homeopathic, and a steady and enormous increase of students in the regular schools. Similar results are obtained by comparison of students graduating each year from the different schools. The "Chicago Medical Blue Book" for 1900 gives the following as the number of physicians in Cook County and Chicago: eclectic 191, or 5.64 per cent.,

¹ See editorial Cook County Hospital and Politics. THE JOURNAL, Dec. 1.

homeopathic 558, or 16.53 per cent., regulars 2633, or 77.87 per cent.

The present system of distribution of patients in the Cook County Hospital is consequently not a just one—a more liberal share should be accorded the regular service. Placing the basis of distribution on the number of students in the colleges professing the different "systems" of medicine here recognized would give, on a scale of 33: eclectic, 1 patient; homeopaths, 5 patients; regulars, 26 patients. A similar disproportion exists in the number of the three distinct attending staffs. Last year 27.7 per cent. of the eclectic graduates became internes, 3.8 per cent. of the homeopathic, and 2.6 per cent. of the regular—the eclectic "school" having over ten times as many internes as the regular in proportion to the graduating classes from which the internes are chosen by the respective staffs.

It is asked that such a reapportionment of patients be made as would be in accordance with the representation of the various "schools" of practice in the county; or that the annual competitive examination for internes be thrown open to any graduate of any medical school in Cook County, a committee of four, one eclectic, one homeopath and two regular attending men, chosen by the respective staffs, to examine on every subject usually examined in; in materia medica and therapeutics a separate examination is suggested by committees from attending staffs of the three schools, the markings being added to the other averages in order to determine the relative positions of the successful competitors from each "school"; the number of successful candidates from each "school" shall determine the ratio of patients to be assigned to each "school" for that year. i. e., the scale shall represent the total number of internes and the allotment of patients to each staff shall bear the same ratio as the number of internes from each "school" to the total number of internes admitted. The last proposition ought to appeal to those interested in higher medical education; a healthy competitive spirit would arise among the various schools; and the men best qualified would be chosen for internes, irrespective of the "school" in which they happen to have taken their medical degree. It is hoped that the governing body will canvass thoroughly the situation and that a full discussion of this matter may be had by representatives from the institutions that are interested in the outcome.

Incidentally this document, evidently prepared with much care, brings to light valuable information concerning the relative status of different "schools" in this medical center in which there were, during 1899-1900, no less than 3108 medical students. From 1894-95 to 1899-00 the number of regular students gradually increased from 1681 to 2618. Surely a city that draws so many students has placed upon it a responsibility of the most important nature; demanding the serious attention of its citizens. If it shall continue as one of the great medical centers such questions as the one

touched on in the foregoing must receive a solution which is strictly a fair one to those directly concerned. Aside from the scientific aspects of the question, on which much might be said, the economic interests involved are of themselves alone of no mean importance to the city. Will the members of the medical profession join in an effort to secure their rights?

THE ENGLISH LANGUAGE AND MEDICINE.

The recent order of the Emperor of Germany to have instruction in the English language, instead of the French, made compulsory in the higher public schools of that country is significant in several directions. It may be taken for granted that the order was inspired by policy and that sentiment had no agency in its issuance. The world is becoming more and more Anglicized in a linguistic point of view, and the prescience of the Japanese statesman, Mori, who some thirty years ago advised the adoption of English by his countrymen is yearly becoming more manifest. Wherever commerce goes the English speech follows; it is the language of business throughout the world. This pre-eminence has been gained not altogether through the expansion, commercial and otherwise, of the English-speaking people, but also from its own advantages of conciseness, copiousness and general adaptability to all the needs of human intercourse. A German merchant is quoted by a Washington diplomat as saying that he uses it for his correspondence because he can say in a page of English what would take three pages of German, and say it more clearly and exactly.

Another evidence of the fact is the way that English supersedes other languages among immigrants in this country; not only do these languages disappear in the second generation, but the immigrants themselves often begin soon to use English either wholly or in part, by preference in their intercourse with each other. It is only in isolated communities and where particular effort is made to that end that the foreign language holds its own. The medical bearings of these facts are, if not at once obvious, easily pointed out. Until a very recent period the international language of diplomacy, science and culture has been French, and even yet it holds its position to a certain extent. In medical literature, international congresses, etc., French is still the official favored language, as it is in diplomacy, though English is coming more and more to the front. The recognition by Germany that it is the coming international tongue is an important step, in which, however, it has been anticipated in some degree by one or two Hollandish societies that have for some time printed their transactions in English. In 1890 27 per cent. of the civilized world used English as their common speech, a larger proportion than that of any other tongue. At the present time it would undoubtedly be found that this percentage has materially increased, if the statistics were available. It is the present language of the future and there is no reason why it should not be the

international language of medicine and science wherever and whenever such a language is required.

It would seem, therefore, to be the duty of English-speaking physicians to insist on the recognition of these facts, not necessarily to the prejudice of other languages, but simply to do all in their power to make their tongue the universal language of medical science. In time this will be brought about by its own merits; its advantages will be appreciated in scientific as it has been in business communications between man and man. The extension of the English language is, from present signs, likely to be more rapid in the future than in the past, especially on this continent and in those parts of the world coming under the influence of European and American civilization. English is already the mother tongue of the great majority of the white race in the two Americas; it is spoken throughout the Orient more than any other European language; its medical literature is proportionately greater in volume than any other, and the fact that it is largely overlooked by continental writers should inspire us to more firmly demand its recognition. Medical knowledge should use the language which is destined to be foremost of all.

ALCOHOL IN CRIMINALITY.

Alcohol is generally assumed to accomplish its work in the production of crime, and to lead to acts of violence, especially in this country; in the well-policed regions of continental Europe we do not look for such effects, at least not to so great an extent. It is commonly said moreover that in Germany the universal custom of beer-drinking is not attended with the social dangers experienced here from the common excesses in the stronger alcoholic beverages and that if we could imitate them it would be better for us. A little medical testimony on this point may therefore not be out of place. In a recent article published in the *American Journal of Insanity* for October, Dr. Emil Kraepelin, the corypheus of German psychiatry at the present time, gives incidentally the results of a study of the newspaper reports of criminal acts committed during 1898 by persons under the influence of alcohol in the district from which his clinic drew its patients. The population of the district in 1898 was 640,673, and of these 237,770 lived in towns, the majority of which were small. From the newspaper clippings he gathered the following: 11 murders were committed by alcoholics and 47 severely injured, 9 of whom subsequently died of their wounds; there were 25 brawls in which a number of persons received minor injuries, and 2 riots in which the police were overpowered, injured and even besieged while bands of young ruffians terrorized the town. Besides these, arson, robbery, and theft were committed by alcoholics; 13 persons were injured, 6 fatally; 2 persons died of acute alcoholism, and 2 committed suicide. These data he considers are only the more startling facts reported in the papers consulted by him and do not in his opinion at all completely represent the actual effects in this particular line of alcoholism in the district. If, as he says, the sum of the homicides

and woundings due to alcohol is as great as that attributable to all the other forms of insanity in a non-metropolitan German district, "one can hardly dispute the truth of the assertion that alcoholism is the form of mental disease which above all threatens the community." His article is not devoted to the subject of alcoholism; it is a general consideration of the relation of the state to insanity. These incidentally mentioned statistics of alcoholic criminality are, however, of interest in comparison with similar data from like regions in this country. We are here apt to consider ourselves as especially afflicted in this regard, but the fact is that conditions are not so very different where alcoholic habits are common, not even in Europe, as we have perhaps been inclined to think.

THE METRIC SYSTEM.

A bill is passing through the various stages in Congress which, if it becomes a law in its present form, will encourage the adoption in the United States of the metric system of weights and measures on Jan. 1, 1903. The bill has been reported favorably by the committee on weights and measures, and therefore there is a probability of its becoming a law. The friends of the measure, however, are not over sanguine, knowing that much opposition is still to be met. It is not to be denied that changing from the present cumbersome and complicated system, with its variety of units, to the simple one used by all except English-speaking people, will upset business and cause confusion in the commercial world. Substituting the meter for the yard alone would play havoc in our dry goods stores. But all this confusion would soon subside and a little preparatory education would remove much of the difficulty when the time came to meet it. It is a change that will not be made all at once, but will be done by degrees. The sentiment for this change may be a growth. In medicine, the system has already been more or less in use, as the AMERICAN MEDICAL ASSOCIATION, in 1879, passed a resolution looking to its adoption. Other scientific bodies have also taken similar action and in various ways have encouraged its use. It has not been as readily accepted as it was hoped, but each year the number using it is increasing. All first-class pharmacists are familiar with the metric system and can fill a prescription written in it as well as one written in the old apothecaries' measure. Hence, if Congress should authorize the adoption of the system on Jan. 1, 1903—and we certainly hope it will—the medical profession will be ready and more than willing to adopt it.

UNDESIRED NEWSPAPER NOTORIETY.

Newspaper notoriety is very acceptable to some, of unconcern to a few, and extremely objectionable to the great majority of the members of the medical profession. When a physician's name is printed in the newspaper every time he leaves his home to be absent a few hours, or when he performs some operation out of the ordinary, or whenever he reads a paper before his local society, there is generally good reason to believe that he comes under the first of the classes mentioned. As a rule, the

name of a physician does not get into a newspaper unless the owner of it is at least willing that it should get there. On the other hand the names of those who come under the third head get in the newspaper occasionally and, of course, without sanction or permission. Newspapers are always searching for the sensational and the mysterious, and if a reporter can find the slightest foundation for an article that will bear flaming headlines he will not hesitate to write up an operation, a supposed new discovery or anything else of a sensational or mysterious nature in medicine, and use in connection with it the name of a member of the medical profession without regard to the wishes of the one whose name is so used. This is illustrated in the case of Dr. W.W. Keen, of Philadelphia, whose name and photograph were used in connection with a most sensationally worked-up article on an operation under cocain anesthesia. Those who know Dr. Keen appreciate the fact that he would under no consideration allow his name to be used as was done on that occasion, and he took such action that it will probably not be repeated. Recently, in Chicago, a sensational report of a discussion in the local medical society was printed in an afternoon paper, and a more elaborate and probably more sensational report was to have appeared in various morning papers, had not certain prominent physicians acted quickly and suppressed its publication through personal interviews with the editors. Another instance of undesired publicity is referred to in our correspondence column in this issue. No one who knows Dr. Babcock would for a moment suspect him of wishing for newspaper notoriety, particularly such as that of the syndicate article to which he refers. It is to be regretted that there are some connected directly or otherwise with the medical profession who, perhaps for pecuniary reasons, are willing to aid newspaper reporters in thus outraging professional courtesy, for it is evident that at least occasionally some one possessed of a little medical knowledge must have had a hand in the performance. It impresses upon one the conviction that ethical principles ought to be among the first conveyed in medical instruction, and that no student should be graduated who is not thoroughly grounded in them. If more attention was given to the higher morals of our profession in our medical colleges there would be fewer of these violations in this particular way.

CANCER INVESTIGATION.

We now have in the United States at least two centers for the systematic investigation into the origin of cancer, namely, the New York State Pathological Laboratory, at Buffalo, under the direction of Roswell Park, and supported by public funds, and in Boston, where a committee from the Harvard Medical School through the generosity of the late Caroline Brewer Craft has been enabled to plan systematic work. This is a very satisfactory beginning. The first annual report¹ of the cancer investigation committee of Harvard Medical School shows in a general way the scope of the work which is in charge of the department of surgery, of which J. Collins Warren is the head. Analysis of the statistics for Massachusetts, by W. F. Whitney, is stated to show

a marked increase in the death-rate from cancer, the curves being remarkably similar to those of the British registrar-general. This goes to confirm the impression that there is a general increase in the frequency of this disease. Edward H. Nichols reviews the general reasons for and against the theory that cancer is due to the action of a parasite. Nothing new is presented. He found the so-called cancer bodies in certain types of cancer, especially of the breast, but not in epidermoid cancer. Animal inoculations and culture experiments with human cancers were all followed by negative results. Inoculations of animals with the blastomycetes of Sanfelice and Plimmer resulted in nodules of granulation tissue, but no tumor like cancer was produced. R. B. Greenough studied the presence of the so-called "Plimmer's bodies" in cancer; they were found in twenty-three cancers of the breast, being most numerous near the periphery of the tumors and in the metastases. Three epidermoid cancers did not contain any such bodies. E. E. Tyzzer writes about tumors and sporozoa in fishes, but the facts given relate wholly to sporozoa, which do not seem to cause tumors in fishes. Edwin A. Locke describes the reconstruction in wax of a nodule of cancer, a very interesting task. The model shows the relations of the tissues and the manner of growth. Each column is an outgrowth, all parts of the nodule being united with other portions of the tumor. Such models will form a valuable means of instruction. Oscar Richardson reports on a number of faultless culture experiments with carcinomatous tissue, the general result being that no organism that could be regarded as in any way specific was found. This résumé shows, as stated in the report, that the work is in its preliminary stage; no definite conclusions of any sort can be drawn in regard to the main problems at issue. It is a matter for congratulation that well-trained and well-organized groups of investigators may find such favorable opportunities for original research in such an inviting field as the origin of cancer.

THE PRESENT STATUS OF HYDROPHOBIA.

Modern scientific medicine is under heavy obligation to Louis Pasteur, not only for many original and illuminating observations, but also for the healthful impetus he gave to careful, painstaking investigation; and in this material age not the least tribute that can be paid his work is the acknowledgement of its intensely practical value. His studies in fermentation and in parasitology opened new avenues of thought and activity, and have led to results far exceeding the most sanguine expectations of his time. His method of treating hydrophobia was long regarded with doubt and suspicion, but the lapse of time has only tended to place it on a firmer basis and secure for it the recognition it deserves. It was, in some respects, next to vaccination for smallpox, the first of the biologic methods of treatment. The evolution of our knowledge concerning hydrophobia is traced in a most interesting manner by Babes² in a recent communication. As he points out, it is really only within the last twenty-five years that correct notions on this subject have prevailed, and it

1. Journ. Boston Soc. of Med. Sc., 1900, v. 31:80.

2. Berliner Klin. Wochenschrift, 1900, Nos. 42 and 43.

is now generally agreed that hydrophobia, or rabies, is a specific infectious disease transmitted between animals and man, although the hypothetical micro-organism has not yet been isolated. The medium of communication is usually the saliva of a rabid animal, either through a bite-wound or other solution in continuity of structure, and the central nervous system is the principal seat of the morbid process. Inasmuch as dogs are the most common agents for the transmission of the disease, the use of muzzles and the impounding of these animals serve to diminish greatly its prevalence. In the nervous system nuclear hyperplasia of the adventitia and miliary accumulations in the vicinity of the vessels have been found, and more recently attention has been called to the presence of marked inflammation of the gray matter, especially of the oblongata and the spinal cord, the infiltration assuming a peculiar nodular form. The period of incubation of hydrophobia is long, and considerable time elapses before the effect of protective inoculations becomes manifest, but it has been found that cauterization of the wound of infection prolongs the period of incubation and thus may prove a useful adjunct in treatment. However introduced, the virus of rabies reaches the central nervous system. A stage of premonitory fever has been observed preceding the outbreak of the actual symptoms, and these also may be attended with fever. It is suggested that the anti-rabic inoculation results in a neutralization of the virus before this reaches the nervous system, while when once the nervous system is actually involved the outlook is much less favorable. It seems almost certain that rabies is dependent on the action of a micro-organism, with the identification of which it can be hoped that an anti-toxin will be secured capable not alone of conferring protection against the disease, but also of effecting a cure after symptoms have developed.

Medical News.

CALIFORNIA.

DR. ALFRED E. REGENSBURGER, San Francisco, has resigned from the faculty of the College of Physicians and Surgeons.

THE HEALTH OFFICER of Oakland discovered four cases of smallpox in that city November 24 and 30; all the patients are colored and are employes of the Pullman Company as cooks on dining cars or porters.

IN LOS ANGELES writants were issued, November 28, for the arrest of three women and one man charged with practicing medicine without having obtained certificates from the State Board of Medical Examiners.

THE DIRECTORS of the Institute for the Deaf, Dumb and Blind at Berkeley are about to appeal to the state legislature for an appropriation of \$12,000 with which to erect and equip a hospital building for the institution.

THE TRUSTEE of the Garcelon estate transferred to the Meritt Hospital trustees, Oakland, November 28, stocks and bonds aggregating \$75,000. This is the first payment on the \$400,000 bequest of the late Mrs. Catherine Garcelon for the establishment of a general hospital at Oakland.

THE PRESENCE of smallpox in Grass Valley has been confirmed after investigation by Dr. H. H. Look, of the State Board of Health. The disease is of a relatively mild type, resembling that which has been and is prevalent in Jackson, Rio Vista, Marysville and other towns in the state.

SANTA ROSA, Cal., has passed a quarantine ordinance which provides that whenever the board of health shall ascertain that any person is sick with smallpox, scarlet fever, diphtheria or any other disease dangerous to the public health, the board shall at its discretion have full control of said person or

premises, and shall if it deem proper order the premises vacated.

A SANATORIUM FOR CONSUMPTION.

A number of gentlemen of Southern California have formed an organization which is building a sanatorium in Strawberry Valley, to be known as the Idylwild Sanatorium, for the care of invalids, particularly of the tuberculous class. The company owns more than a thousand acres of land extending to the mountains on either side of the valley, the altitude of which is slightly over 5000 feet above sea level. The scenery is grand and picturesque, resembling that of the White Mountains. The air is dry and clear and never unpleasantly hot in summer, while in winter the temperature occasionally falls below freezing point, and has been known to touch 18 F. There will be a few cottages and tents to rent near the sanatorium, the company furnishing light, water and sewerage connections for those who desire to keep house. Pure water has been piped to the sanatorium from a mountain stream.

ILLINOIS.

THE FAIR for the benefit of St. Joseph's Hospital, Joliet, will result in a net gain to the beneficiary of nearly \$5000.

DR. LESLIE M. HOYT, Sycamore, who sued the city for \$20,000 for injury to an eye from the overhanging limb of a tree, has settled for \$1800.

AN EXAMINATION for physicians, midwives and other practitioners will be held in Chicago by the State Board of Health, January 9, 10 and 11.

Chicago.

DR. GEORGE F. FISKE has returned from his European trip.

DR. NICHOLAS SENX leaves Tuesday, December 18, for Central America, to be gone about four weeks.

INFANT MORTALITY increased for the week ended December 8 in a marked degree, the deaths of children under 1 year being 91, while during the previous week only 56 were reported.

THE NOVEMBER mortality was 1746, equivalent to an annual death-rate of 12.49 per 1000, which compares favorably with the average mortality per mille for the previous ten years, which was 14.87.

IT IS NOW announced that the coroner-elect has appointed Dr. George Leiminger, as coroner's chief physician at a salary of \$2500. The new appointee is recorded in Polk's Directory as the "Inventor and Proprietor of Formaldehyde Generator."

SINCE the close of November the increase of mortality among the aged has been unprecedented. Last week, out of a total of 447 deaths, 104, or more than 23 per cent., occurred in those over 60 years of age.

THE FIRST CASE of smallpox since June was imported from Ashland, Wis., and detected November 30. The federal health reports show an increase of 350 per cent. in the prevalence of smallpox throughout the United States and the Health Department urgently recommends a general and individual resort to vaccination.

KANSAS.

THE EXHIBIT made by the State Board of Health at the Paris Exposition has been awarded a silver medal.

SMALLPOX is prevalent in the state. There have been reported to the State Board of Health 37 cases in 11 different localities. Wichita leads with ten cases.

THE PHYSICIANS of Topeka must register in a book provided for the purpose in the office of the city physician, giving their names, addresses, schools from which they graduated and other information, and this must be done before December 20.

THE NEW MEDICAL BILL prepared by the legislative committee of the State Board of Health is liberal. It does not interfere with "Christian Science," osteopathy or any other "cures" so long as each system of practice is confined to its "school" methods.

LOUISIANA.

THE GRADUATION exercises of the Charity Hospital Training School for Nurses, New Orleans, were held December 12.

THE NEW ORLEANS Board of Health has again been disappointed by the city council. Instead of \$51,000, the sum asked for, the board is budgeted for the small and manifestly insufficient sum of \$3000.

THE BOARD OF ADMINISTRATORS of the New Orleans Charity Hospital decided at its last meeting to add 100 nurses to the present corps, and thus to provide trained nurses for the male medical and surgical wards. It was also decided to erect a special building for the accommodation of the nurses, to cost \$25,000. Plans for this building, which will be 40x120 feet, with dormitories, lecture room, library and sitting room, etc., will be submitted at the next meeting.

SHIPS COMING from plague-infected ports will now be detained only five days at New Orleans provided the new rules of the board of health are observed. "The vessels are to be disinfected in midstream, will anchor 100 feet from shore at night and forty-five feet from shore in the day time. Metal funnels will be used on the hawsers attached to the shore to prevent rats from leaving the ships, and men armed with shot-guns will be stationed on shore and in skiffs to shoot any rodent that may attempt to get away. All dead rats are to be handled with rubber gloves and cremated. Long gangplanks closely guarded will be used to get the cargo ashore."

MARYLAND.

THE BOARD OF MEDICAL EXAMINERS of Maryland has granted license to practice medicine and surgery to 20 of the applicants who were recently examined by it.

Baltimore.

THE HEBREW CHARITY fund now amounts to \$10,415.

THE LAENNEC SOCIETY has been organized at the Johns Hopkins Hospital. It is the fourth society to be organized there and is devoted to the study of tuberculosis.

HEALTH COMMISSIONER BOSLEY has made the following appointments, to take effect December 15: Dr. Alan W. Smith, inspector of throats; Dr. Samuel A. Keene, medical examiner, vice Drs. Charles B. Canby and Albertus Cotton respectively.

A SUIT for \$5000 damages has been brought against the Johns Hopkins Hospital by two individuals who claim to have received personal injuries through a live electric wire while walking along the street in front of the hospital.

THE TOTAL DEATHS for the week ended December 1 were 157, 38 less than the previous week, a death-rate of 14.26 per 1000 for whites and 20 per 1000 for colored per annum. There were 3 deaths from typhoid fever, 6 from diphtheria, 24 from tuberculosis, 5 from cancer, 19 from pneumonia and 16 from Bright's disease.

A METHOD by which infectious diseases may be often distributed through a community, has been brought to the attention of the health department. The law requires funerals in case of death from diphtheria to be held within 24 hours. It has been found that the mother of the deceased, either from being too poor to procure mourning clothes, or because of the short interval, borrows them from a friend. After the funeral they are returned without any attempt at disinfection. Mourning goods are especially adapted for conveying germs, as they can not be boiled like linen, etc. Cases have occurred in this city in which there is every reason to believe that diphtheria was communicated in this way.

MASSACHUSETTS.

DR. ARCHIBALD J. RAMSEY, superintendent of the Massachusetts Almshouse Hospital, Tewkesbury, assumed charge of the Long Island Almshouse and Hospital, December 1.

DR. J. HOBART EGBERT, Holyoke, sailed for Honduras, November 28. He is to be chief surgeon for the New York-Honduras Mining Company, and will have his headquarters at San Juanito.

THE AUTOMOBILE AMBULANCE, which has now been in commission for four weeks at the Massachusetts General Hospital, gives entire satisfaction. It is especially useful in transporting patients from the hospital to the Convalescent's Home at Waverley, a distance of eight miles.

DAMAGES amounting to \$600 have been awarded Louise de Lisle, a dramatic aspirant, who sued Dr. Frank T. Brough, Boston, for \$2000, because, as she alleged, he so removed a crease in her left cheek as to distort the position of her ear, and thereby prejudiced her chances of dramatic success.

THE COMMITTEE appointed to consider the division of the Somerville schools into medical districts under constant supervision, has reported favorably on the project. The board of health has been notified that the school authorities will cooperate with them, and the board of aldermen have been requested to provide the board of health with the funds necessary for the expenses of medical inspection.

MICHIGAN.

MASON COUNTY has an epidemic of smallpox. It is reported that there are a hundred cases in Custer and Scottville. Custer township is under strict quarantine.

AT MUSKOGON, Dr. Augustus G. Reitz was found guilty of practicing medicine without a certificate. A stay of twenty days was granted, and the case may be taken to the higher court.

CEREBROSPINAL meningitis was reported present during November at 4 places, whooping cough at 20, measles at 20, smallpox at 37, diphtheria at 75, scarlet fever at 168, consumption at 174, and typhoid fever at 254.

MEMORINEE is alive to the fact that smallpox prevails in the upper peninsula, and has issued orders that after December 10 no child shall be admitted to the public schools without a certificate of successful vaccination within seven years, signed by a practicing physician.

MISSOURI.

THE SUIT of Dr. James W. Crewdson, Louisiana, for medical services to the late Fielden Estes, amounting to \$6900, was concluded November 24, when the jury returned a verdict of \$2375 for the plaintiff.

A RECEPTION was held in the new addition to the University Medical College, Kansas City, December 7. On December 5 the new demonstrating and clinical room of the college was dedicated by Dr. Jabez N. Jackson.

A MEETING was recently held by a number of the prominent physicians of St. Louis to organize a post-graduate clinical school and hospital. The intention was to associate those, as far as possible, who had no allegiance in other directions, and who would be ready to give their entire attention to post-graduate duties. It is hoped that the organization can take place in time to begin work in the spring, so that in 1903, with the increase of medical men in St. Louis co-incident with the World's Fair to be held here, the college may be well under way and in good working shape.

THE NEW BETHESDA HOSPITAL for Incurables at St. Louis, was opened December 1. It has facilities for the accommodation of 80 patients. There is an excellently fitted up operating room, and an isolated ward for the treatment of contagious diseases. The entire three-story brick structure, without furnishings, electric lighting and newest sanitary appliances was given free from debt at a cost of something over \$70,000 by Mr. R. M. Seruggs, of St. Louis.

THE CONSOLIDATION of two important medical colleges in St. Louis, under the name of the Marion Sims-Beaumont College of Medicine, which was effected November 22, is said to be preliminary to affiliation with the St. Louis University as its medical department. The Marion-Sims building at Grand avenue and Caroline street, with new additions already projected, will be used by the new college. The new institution will have abundant clinical advantages, the following institutions being under the control of members of the new faculty: Alexian Brothers' Hospital, Rebekah Hospital, St. Mary's Infirmary, Josephine Hospital and Grand Avenue Dispensary. In addition, the following hospitals will afford clinical material: City Hospital, St. Louis Insane Asylum, Protestant Hospital and Baptist Sanitarium. The governing faculty will include the following: Dr. Young H. Bond, gynecology and pelvic surgery; Dr. Leonidas H. Laidley, gynecology, pelvic surgery and clinical gynecology; Drs. Frank J. Lutz, Jacob Geiger, of St. Joseph, William A. McCandless and J. R. Dale, surgery; Dr. John T. Larew, surgical anatomy and clinical surgery; Dr. Thomas C. Witherspoon, operative surgery on the cadaver and clinical surgery; Dr. Clarence M. Nicholson, anatomy and clinical surgery; Drs. Carl Berek and Adolph Alt, ophthalmology; Drs. William G. Moore, Hugo Summa and George C. Crandall, medicine; Dr. Jacob Friedman, clinical medicine and chemistry; Dr. Joseph R. Lomen, chest diseases; Dr. Benjamin M. Hypes, obstetrics; Dr. Walter B. Dorsett, obstetrics and gynecology; Dr. Robert C. Atkinson, diseases of children; Drs. Charles G. Chaddock and Sidney I. Schwab, nervous diseases; Dr. Max A. Goldstein, otology; Dr. Hermann H. Born, anatomy; Dr. Remy J. Stoffel, therapeutics; C. D. Lukeus, dentistry, and Bransford Lewis, genito-urinary diseases.

MONTANA.

COMPULSORY VACCINATION has been ordered in Butte and Silver Bow county.

SMALLPOX was reported during November in Butte, Anaconda, Carbonado, Bridger, Missoula, Dillon and Walkerville.

A NEW pest-house has been rendered necessary by the number of smallpox cases in and around Butte, and a building 100x20 feet will be erected at once, near the present isolation hospital.

THE TEMPORARY or ad interim board of health project has been abandoned, as it has been discovered that the governor has no legal authority to make such appointments. The matter, therefore, must wait until the legislature meets, when a bill will be introduced to create a state board of health, defining its duties and powers.

NEBRASKA.

DR. J. CAMERON ANDERSON, Omaha, on the inauguration of Governor-elect Deitrich, will be made surgeon-general of the state.

KEARNEY AND NORTH PLATTE are afflicted with smallpox. At the latter place, the public schools have been closed, public meetings discontinued and many men in the railroad shops laid off in the attempt to conquer the disease. Nebraska has no state system of local health boards. The organization is dependent entirely on the will of individual communities, and there is necessarily great difficulty in enforcing quarantine regulations, except in the great cities, on account of this fact. Dr. Victor H. Coffman, health commissioner of Omaha, makes an earnest plea for the prompt report of infectious diseases to him, and says that if the physicians of the state refuse to co-operate with the health authorities by reporting and quarantining smallpox, a serious epidemic is certain to occur.

NEW JERSEY.

DR. HENRY J. F. WALLHAUSER, Newark, is suffering from an attack of appendicitis, and is seriously ill.

CLAYTON physicians have organized and determined to make no calls within town limits for less than \$1. or in the outlying districts for less than \$1.25. They have also instituted a "black-list."

DAILY MEDICAL INSPECTION of schools has been inaugurated at Paterson, and a force of four physicians is at work examining all children isolated by their teachers. The inspectors are, however, not allowed to prescribe for the children either at their homes or at the schools.

THE CAMDEN Board of Health has decided on plans for the new municipal hospital, which contemplate a main building to contain detention, inquiry and operating rooms, and two ward buildings, each having a capacity of 15 or 16 beds, together with annexes, etc. The buildings will cost about \$18,000.

THE BOARD OF EDUCATION of Orange has before it the proposition to appoint a competent physician who shall examine the pupils at all the schools at stated intervals, and also give instructions to the teachers in the detection of the first signs of disease. This system they aver, can be established at an expense not to exceed \$200 a year.

NEW YORK.

NEW YORK STATE HOSPITAL for the care of crippled and deformed children of Tarrytown, established under the laws of 1900, is now open for the reception of patients.

THE NEW PAVILION of the House of the Good Shepherd, Syracuse, which contains chiefly private rooms, operating, anesthetizing and sterilizing rooms, is now ready for use.

THE BOARD OF HEALTH of Batavia has been instructed to secure some method of fumigation which will cost the town less than \$5 a house, the amount at present charged by the physician who has this matter in hand.

THE SUPERVISORS of Erie county favor the erection of a consumptive pavilion to cost \$42,000 this year, and a building for the care of cancer patients next year, to cost \$32,000; the county architect has already submitted plans for the buildings.

THE TRUSTEES of the State Hospital for the Treatment of Incurable Pulmonary Tuberculosis report that after examining 26 sites they have selected one at the west end of Lake Clear, Franklin county, subject to the approval of the State Board of Health and the Forest Preserve Board.

THE OPENING of the new hospital at the Onondaga County House has suggested to Dr. Ely Van de Warker, Syracuse, a plan for utilizing the clinical material for the benefit of the students at the College of Medicine. To this end, he suggests the organization of a medical corps composed of the leading physicians of the city, who shall in turn give their services to the inmates free of expense to the county.

THE SEMI-CENTENARY of the founding of the Troy Hospital was celebrated November 28, at the Troy Club. Dr. David W. Houston presided; Dr. Solom E. Nichols, president of the hospital, gave a historical sketch of the hospital; Dr. William Osler, Baltimore, delivered an address on "The Influence of a Hospital on the Medical Profession of a Community," and Dr. William P. Mason, Troy, spoke on "Some Mediterranean Water-Supplies."

Buffalo.

A PUBLIC HEARING by the supervisors committee on charitable institutions was given to representatives of all charitable societies which desire appropriations from the county for the coming year. Among the institutions which receive annual appropriations varying from \$1000 to \$1500 are the Buffalo Eye and Ear Hospital; the Charity Hospital for Eye, Ear Nose and Throat; the dispensary of the German Hospital; the University Dispensary, and the Fitch dispensary.

THE EXECUTIVE COMMITTEE of the Alumni Association of the University of Buffalo, has in preparation a novel program for

the early part of the next year. An evening is to be devoted to the consideration of various features of medical education as it was, and now is in Europe. It is anticipated to illustrate these features by lantern slide views. The pictures to be shown will show the interior and exterior views of medical schools and hospitals ancient and modern, reproductions of paintings representing medical, pathological, hygienic and anatomic subjects, such as the school of anatomy by Rembrandt, etc.

New York City.

THERE ARE NOW 17 cases of typhoid fever in the state prison at Sing Sing. The supply of water is taken from the Croton reservoir, and this water is boiled before being used in the prison.

THE APPROPRIATION made for the Department of Public Charities for 1901, makes it necessary to reduce the payroll nearly \$15,000, and it is thought this will involve the discharge of about 300 employes from the city hospitals.

AN ANNEX to ward 23 in Bellevue Hospital was formally opened, November 24. It has 12 beds and an especially well-equipped operating room, and is for women only. The donor positively refuses to allow her name to be published.

AN AMENDMENT to the charter of Bellevue Hospital, which has been proposed, provides that on Feb. 1, 1902, the control of Bellevue Hospital and its subsidiary institutions shall be taken from the Department of Public Charities and be vested in a board of seven trustees to be appointed by the mayor, to serve seven years.

SO FAR there have been 47 cases of smallpox reported to the board of health since the outbreak of ten days ago. While there seems to be no reason for expecting an epidemic, the occurrence of a few cases in sections of the city far from the locality in which most of the cases have developed, points to the probability of occasional cases appearing here and there for some time to come.

DR. JOHN BYRNE, the venerable and widely-known surgeon of Brooklyn, has been driven by the ravages of consumption in his family, to leave the homestead in Clinton street, where he has spent forty years of his life. Although he is hale and hearty at 75, and his wife appears equally vigorous, he has lost four children by the "white plague." In order to save his remaining children he will leave the old home at once, and travel in France for a time.

THE NEW private patients' building of the New York Hospital was thrown open for inspection December 5. The building is ten stories in height, and is equipped in a most lavish manner. The first floor is for executive purposes, the second for the hospital staff, and the upper floors contain rooms for the patients and operating rooms. At the rear is a separate isolated department, with an independent heating and ventilating system. This new addition to the New York Hospital has been made without stint of money, and the splendor of its appointments suggests the thought that it represents a doctors' trust.

OHIO.

THE STAFF of the Lawrence Hospital for Women, Columbus, has been increased by the election of the following as associate physicians: Denman R. Kinsell, Jr., Henry W. Whitaker, Elmore E. Adel, James C. Lawrence, Clarence C. Ross, Will W. Homer, Andrew B. Nelles, Edwin A. Hamilton and Thomas A. Evans.

A physician of Cleveland, has caused the arrest of Dr. George F. Whitney, of the same city, and a graduate of the Medical Department of Western Reserve University, on the charge of practicing medicine without a license. He further alleges that Dr. Whitney is a spiritualist and gives prescriptions actuated by slate-writings.

DR. WILLIAM U. COLE, Columbus, Director of Public Safety, has already initiated experiments with germicides with a view to ascertain exactly what agent will suffice to disinfect a house effectually. He probably will order that all cases of tuberculosis be reported to the health department, that arrangements may be made for systematic disinfection at regular intervals.

PENNSYLVANIA.

BY A BEQUEST of Mrs. Pauline Auberle, a hospital for children will be erected in McKeesport. A total of \$250,000 was devised to Catholic charities.

JOHN MAGUIRE, mining inspector of the eighth anthracite district, has reported that within the past eleven months 30 fatalities and 98 accidents have occurred among the miners of that district.

THE BERKES COUNTY DAIRYMEN'S ASSOCIATION, at its recent annual meeting held in Reading, called the attention of Deputy

Inspector R. M. Simmers to the fact that adulterated milk was being sold in that county. About 100 dealers will be placed under surveillance.

THE COMMITTEE of the Pittsburg common council, appointed six months ago to look for a site for a municipal isolation hospital for infectious diseases, now consider the Point the best available location, as it is chiefly occupied by warehouses, and as there are few residences in the locality.

RECENTLY a conference was held at Harrisburg in the interest of the public health, game, fish, and forestry protection, of this State. A bill increasing the appropriation of the State Board of Health from \$6000 to \$12,000 was endorsed, and a further appropriation of \$50,000 was asked for to be devoted to the investigation of the pollution of streams supplying cities with water.

AT A RECENT meeting of the trustees of the State Hospital for the Insane located at Norristown, the position of resident physician occupied by Dr. Susan J. Tabor was declared vacant, and an advertisement for another resident ordered. The action of the board has stirred up a good deal of feeling, especially in Philadelphia, which is the home of Dr. Tabor, and since the complaint against her was "extravagance and wanton destruction of property" Dr. Tabor has demanded a complete investigation of the charges.

Philadelphia.

THE GERMAN HOSPITAL received \$8074 in cash and about \$1000 in other gifts, on its donation day, November 29. C. F. Rumm and Sons sent a check for \$5000 to endow a free bed for the use of employees of the firm.

A FRIEND of the University of Pennsylvania, whose name has not been made public, has recently given the sum of \$4000 for the equipment of a physical laboratory in that institution, and has presented a fund of \$550 to be devoted to prizes.

THE fourtenth annual dinner of the ex-residents of the Philadelphia Hospital was held last week, more than 50 members being present. The officers elected were: Dr. Edward L. Dwyer, president; Drs. H. C. Wood and J. K. Lineaweaver, vice-presidents, and Dr. E. R. Stone, secretary.

THE faith-healers, Sollenberger and Ezra Sheets, whose names have been mentioned several times in THE JOURNAL in connection with a "baby farm," were sentenced by Judge Audenried in the criminal court each to jail for a term of 3 months. They were charged with having caused the death of a child 7 months of age, by not calling needed medical attention.

THE HEALTH of the city during the past week has been unusually good, the total number of deaths being only 376. For the corresponding period of last year there were 412 deaths. The principal causes of death were: nephritis, 29; cancer, 14; tuberculosis, 57; heart disease, 38; la grippe, 2; pneumonia, 2; suicide, 2; diphtheria, 21; typhoid fever, 7, and scarlet fever, 1.

DR. RUSH SHIPPEN HUIDEKOPER has been commissioned as chief of a corps of veterinary surgeons provided by a recent act of Congress. The bill creating this department was introduced by Senator Penrose of Pennsylvania.

ON THE recommendations of Col. J. Lewis Good of the Health Department, Councils Committee on Fire and Health during the past week agreed to recommend the appropriation of \$15,000 to provide quarters at the municipal hospital for the treatment of pay patients. It is suggested that a pavilion to cost \$5000 be erected for patients suffering with diphtheria, and one to cost \$10,000 for scarlet fever patients. Each department should accommodate 15 to 25 persons and the charge for a private room should not exceed \$25 a week.

THE MEDICAL INSPECTORS of the public schools have effected an organization among themselves to be known as the "Society of Visiting Physicians of the Public Schools." A committee of this society has collected statistics showing that during the first eight months of the medical inspection 5876 cases of disease were found in the public schools, of which 3446 were contagious. Among the latter were 12 cases of diphtheria, 4 of scarlet fever, 112 of measles, 118 of mumps and 212 of poliomyelitis; contagious skin diseases, 116; ringworm, 753; conjunctivitis, 397; scabies, 8; whooping cough, 20; typhoid fever, 3; tuberculosis, 2; and scalp diseases, 8. More than 1000 cases of defective vision were found. A committee was appointed to present these facts before the sub-committee on Appropriations of Councils and to ask for an appropriation which has been unanimously endorsed by both the College of Physicians and the County Medical Society.

ANOTHER PHYSICIAN has been threatened with a lawsuit, which may in a measure have been due to the vigilance of a medical inspector of schools. It appears that a child attending

one of the schools became ill and remained away from school about one month. On his return he was asked as to his ailment and his reply was that he had suffered from "diphtheria." This was referred to the visiting physician of the school, who ordered the books of the patient to be disinfected, and the boy was further ordered by the school medical inspector to get a certificate from his family physician to the effect that there was no further danger from contagion. It is said that the boy returned with a certificate from the doctor reading somewhat as follows: "This is to certify that — has entirely recovered from diphtheria, and that there is now no danger of contagion." It is said this case had never been reported to the board of health and now the doctor has been prosecuted. The penalty is imprisonment, or fine of \$50, or both.

SOUTH CAROLINA.

THE MEDICAL COLLEGE of the State of South Carolina, Charleston, held its opening exercises, October 1. The dean, Dr. Francis L. Parker, delivered the address of welcome.

THE GREENVILLE SANATORIUM was opened recently by its inaugurators, Drs. Thomas T. Earle, Curran E. Earle, and Joseph B. Earle. The building is located on high ground, two stories in height and thoroughly equipped. It is now ready to receive patients.

UTAH.

THE SMALLPOX situation in the state is alarming. In Salt Lake City, there are more than 50 cases; in Provo, 14; in Payson, "several hundred"; in Lehi, 18, and in Ogden, 20.

DR. EVERETT O. JONES, Murray, has resigned as district health officer, because the county commissioners declined to allow his bill for services to smallpox patients.

CHAIRMAN WILSON of the Salt Lake City Board of Education is strongly in favor of the medical inspection of schools and school children, suggested by Dr. J. C. Elliott King, health-commissioner, and will support the measure when it is brought up at the next meeting of the board.

IN SALT LAKE CITY, 31 new cases of smallpox were reported for the last week in November, making the total up to that time, 58. Of these 15 were in the isolation hospital, and the remainder under quarantine, presumably at their homes. Only four of the patients had ever been vaccinated.

WASHINGTON.

THE SEATTLE General Hospital has moved into its new building, which was opened for public inspection November 30.

A SEATTLE DAIRYMAN was fined the maximum, \$99.99 for selling milk containing borax and other adulterants in the city. The case will be appealed.

THE PATIENTS at the Stellacoom and Medical Lake insane hospitals are increasing in number so rapidly that it will be necessary to enlarge the accommodations at both these institutions. At Stellacoom two new wings are to be built, one for male, the other for female patients, and at the Medical Lake institution a new wing for female patients is needed.

WISCONSIN.

AT THE COMING session of the legislature, the State Board of Health will endeavor to secure the passage of a law giving the established sanitary authorities more power to enforce vaccination.

THE PHU RHO SIGMA organized a Milwaukee branch on November 28. Dr. William F. C. Witte was elected president; Dr. Edward A. Gansel, vice-president and Dr. Edward W. Timm, secretary.

SMALLPOX is said to have broken out at Olanah among the Bad River Indians. The commissioner has authorized Indian Agent Campbell to institute quarantine and take such other measures as he may deem necessary.

THE MARRIAGE LAW, to be presented by W. L. Woodward before the next legislature, provides that a board of medical examiners be organized and maintained by the state, whose certificate that the applicants are free from "true insanity, in herited insanity resulting from vice; primary, secondary and tertiary affections of congenital organs; hereditary tuberculosis or consumption" must precede the granting of a license to marry.

GENERAL.

THE COMBINATION DIPLOMA MILL.

The long struggle between the regular profession as represented by the State Board of Health and the "diploma mill" which has been notorious for several years past under various names, such as the "Illinois Health University," "Independent Medical College," "Metropolitan Medical College," etc., has been apparently brought to a satisfactory conclusion. Hereafter when legal proceedings have been taken against the in

stitution it has promptly changed its name and continued the sale of diplomas without interruption under the same management. This time, however, the post-office authorities caused the arraignment of Dr. James Armstrong, who is set down in Polk's Directory as a graduate of the Curtis Physio-Medical Institute, Marion, Ind., in 1892. Thomas Armstrong, secretary, and Dr. John H. Randall, vice-president of the institution and a graduate of the Chicago College of Medicine and Surgery, a physio-medical institution, in 1894, on the charge of using the mails to carry on a scheme to defraud. They were put on trial December 4, before Judge C. C. Kohlsaat in the United States District Court. "Dr." C. K. Drumhiller, formerly "professor of anatomy" in the institution, said that he had found the methods of the defendants dishonest, and had left them. "Dr." Joseph De Barthé, Baker City, Ore., testified that he had purchased a diploma but had found it valueless in some states where he had attempted to practice. He was afterward engaged as "professor of medical jurisprudence." In his official capacity he made numerous trips to sell diplomas and quiet complaints of the "graduates" in various parts of the country. He acknowledged that he had sold a hotel proprietor a diploma for \$125, and he received \$20 from Dr. Armstrong for his services. They preferred to deal with out-of-town people, as they asked fewer questions. In case of annulment of its present charter, the institution had nine other charters in reserve which would allow it to operate for eighteen years at least. During his connection with the college, few of the "faculty" had appeared and fewer lectured. Occasionally a student would want to know something about medicine before being graduated, and such persons would be accommodated. Mrs. Eliza Fales, stated that she had obtained a diploma in dentistry for a young man, "in absentia" after four hours' effort and the expenditure of \$75. Former employees testified that they had signed the names of the faculty to diplomas which they also engrossed and mailed at the rate of about fifty a week. The prosecution then introduced a circular in which the "faculty" of the college attacked the old-school physicians and the "murderous surgical procedures of allopathy, homopathy and eclecticism," and plaintively exclaimed: "What criminal in justice is this which refuses these brilliant, successful, skillful men (graduates of the Metropolitan) the right to relieve pain, ameliorate suffering and cure disease?" Dr. James A. Egan, Springfield, secretary of the State Board of Health, testified that the institution with which the defendants are connected has been opposed by the state authorities from the start, and that the state had been instrumental in revoking the various charters under which the school operated. Having settled these points, United States District Attorney Bethea called witness after witness to testify as to what qualifications for the practice of medicine they had when awarded diplomas by the Armstrong brothers. Various diplomates of the institution also testified. One who is announced as "professor of surgery" was a veterinary surgeon and as a "side-line" peddled diplomas to barbers, laborers and others. Another had assisted at one dissection—of the heart of a hog—and was instructed to practice in Kansas. A third, who had paid \$128 for a diploma, was arrested when he attempted to practice in Chicago. The Armstrongs bailed him out and gave him 15 cents to pay his fare out of the state. He thereupon made complaint to Post-Office Inspector Gould. Evidence was then introduced that the requirements for graduation in the Armstrong school did not come up to those of any recognized medical college. For the defense, "Dr." Mary D. Barney testified that she had studied several months at the college, but was unable to recall the names or authors of text-books employed. She acknowledged that she was a lecturer in the institution. "Dr." Jarvis G. Haley, who secured a diploma in 1898, but had been "taking care of the sick for twenty years," testified that many lectures and clinics had been given. He said that the officials of the college considered the State Board of Health an illegally-constituted body. After arguments from counsel, the case was given to the jury, who found the defendants guilty under a statute which permits an extreme penalty of 18 months' imprisonment and a fine of \$1,500. The passing of sentence was deferred until to-day, December 15. James Armstrong was held in default of \$5000 bail and the other defendants were released on bail.

HAWAII is aroused because it is proposed to send certain California lepers, now confined in San Francisco, to Molokai. The Hawaiians assert that they are able to take care of their own lepers, but they object to their country being set apart as a perpetual leper lazaretto.

THE INTERIOR of Alaska is threatened with an epidemic of smallpox. Cases are reported along the Yukon from Dawson

to the lakes, the town of White Horse being among the last reported. It is stated that the Indians are alarmed over the disease and fear extermination. Strict quarantine has been established at Skagway, and White Horse is under control of officers.

SMALLPOX in 37 infected states and territories in 1900 shows 4834 cases as against 1076 in the corresponding period of five months in 1899. In 9 states where no smallpox was reported last year, 500 cases have been reported thus far. Ohio had in 1900, 1523 cases; in 1899, 57; Texas, 583 and 189; North Carolina, 516 and 105; Minnesota, 492 and 71; Colorado, 372 and 7, and Wisconsin 297 in 1900 and none in 1899. Illinois has had 121 cases this year—117 from Cairo and 4 from Chicago, as against 7 in 1899.

THE MARINE-HOSPITAL SERVICE has just sent to Cuba two floating disinfecting plants equipped with all modern disinfecting machinery, for service at the ports of Matanzas and Cienfuegos. In constructing these barges, the hulks of sailing vessels were purchased, the necessary alterations made to fit them for the reception of machinery, and they were then provided with steam chambers, formaldehyde apparatus, sulphur furnaces, biclilorid pumps, etc. A large iron steamer took the two vessels in tow at the port of Philadelphia, and they arrived at their destinations during the last week without any mishap, and are now anchored in convenient positions in the harbors, ready for immediate service. The barge for Matanzas is named the *Guardian*, that for Cienfuegos the *Scout*.

THE SAMUEL D. GROSS PRIZE.

This prize of \$1000 will be awarded on Oct. 1, 1901, no essay that was deemed worthy of the prize having been received on Jan. 1, 1900. The conditions annexed by the testator are that the prize "shall be awarded every five years to the writer of the best original essay, not exceeding 150 printed pages, octavo, in length, illustrative of some subject in Surgical Pathology or Surgical Practice, founded upon original investigations, the candidates for the prize to be American citizens." It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery, and that on the title page, it shall be stated that to the essay was awarded the Samuel D. Gross Prize of the Philadelphia Academy of Surgery. The essays, which must be written by a single author in the English language, should be sent to the "Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 219 S. 13th st., Philadelphia," on or before Oct. 1, 1901. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay. The committee will return the unsuccessful essays, if reclaimed by their respective writers, or their agents, within one year. The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize. The trustees are: W. W. Keen, M.D., J. Ewing Mears, M.D., J. Chalmers Da Costa, M.D.

ANOTHER DECISION AGAINST MAGNETIC HEALERS AND MANIPULATORS.

A decision of the Appellate Court of the Third District of Illinois, filed December 7, on an appeal from the county court of McLean County, interprets section 7 of the medical-practice act of Illinois as including under the head of medical practitioners those who employ rubbing or manipulation of the parts affected as a healing agency. The only exception to the law, the court holds, is in when the remedy is exclusively mental or spiritual. A person giving massage treatment to cure diseases is therefore a medical practitioner under the law. This decision affects magnetic healers and a large number of operators who claim to cure ailments by manipulations of various kinds. The combination of "mental and spiritual" treatment with operative treatment is not exempted; the person must be an exclusive faith healer to escape the conditions of the statute. The appeal was made by the State Board of Health, and the decision of the county court is in the Board's favor, the case being remanded.

THE SPREAD OF BUBONIC PLAGUE.

Statistics on file in the Bureau of the U. S. Marine-Hospital Service show that during the year 1900 plague was transported into 22 ports and places by vessels arriving with the disease on board or with a history of its occurrence on the voyage. In the following named places it effected no lodgment and made no spread: Naples, Plymouth, Trieste, London, Cardiff, Bremen, Calais, Sio Thiago in Cape Verde; Beirut in Syria; New York

Port Townsend in Washington; Hamburg and Constantinople. In the remainder of the places the outbreaks were comparatively small, and did not assume the proportions of a great epidemic. This shows that a scientific knowledge of the disease renders it far less to be dreaded than formerly, and shows also a gratifying vigilance and alertness on the part of quarantine and health officers. The principal ravages of the disease have been confined to India, where from the last reports there have been 66,294 deaths during the year, and where it is notorious that the preventive measures undertaken by the British Indian Government have been seriously hampered by the religious fanaticism of the native population, and the difficulty of undertaking any epidemic suppressive measures without interfering with the laws of religious and racial caste.

CANADA.

CAUSE OF ARSENIC IN BEERS.

The recent report from Manchester, England, in connection with the deaths and illnesses which have occurred through beer-drinking, has directed some attention to the Canadian product and the vice. About twenty years ago legislation was introduced by Mr. Gladstone into the British Parliament authorizing the substitution of invert sugar for malt in the manufacture of beer, and the duty was removed from the malt and placed on the beer brewed. This change was known as the "Free-Mash-Tun" system. These invert sugars, as saccharin, glucose and maltose have to be treated with sulphuric acid, and it is when this is used impure, as it frequently contains arsenic, and the latter being soluble, is not separated, that the beer will contain arsenic. The two great countries which have adopted the "Free-Mash-Tun" referred to are England and the United States, whilst the two countries which have not adopted this system are Germany and Canada. In the latter the law provides that no substitute for malt whatever shall be used, the duty being imposed exclusively thereon, and no duties resting on the beer produced. In Canada no substitute is allowed under heavy penalties.

TUBERCULOSIS SANITARIUM.

The National Sanitarium Association has come forward with a more distinct and definite offer to build and erect near their Muskoka Cottage Sanitarium accommodation for the consumptives of Toronto. They will proceed with the work immediately and fully expect to have it completed in a year. No aid whatever will be asked from the city on account of capital account; and the institution will be available for the city's poor patients with free transportation to and from Gravenhurst on payment by the corporation of the City of Toronto of only the usual per diem allowance. The plans of the National Association also contemplate the erection of a suitable institution about five or six miles from the city for those advanced cases which have no hope of recovery. The National Sanitarium Association has already spent \$77,000 on capital account for the treatment of consumption.

MONTREAL MUNICIPAL HOSPITAL.

The proposed new Civic Hospital for Montreal is getting well under way. Four pavilions for hospital purposes will be erected with a central administration building. Each building will consist of two floors and will accommodate fifty patients, with twelve beds for private cases. The estimated cost will be \$100,000, which will be raised by means of a loan, repayable, principal and interest, within twenty years. The control of the institution will be in a joint board of nine members, made up as follows:—Five members, including the chairman to be appointed by the city council; two members to be named by the executive boards of the English general hospitals, and two members from those of the French hospitals. All matters of expenditure and finance will be subject to ratification by the city council.

FOREIGN.

FOURTEEN medical men have recently been elected, according to the *Lancet*, to the mayoral chair in England and Wales.

THE FRENCH minister of public instruction has notified the high schools—colleges et lycées—that anti-alcohol instruction should be given an official place on the program on a par with arithmetic or grammar.

THE FAMINE in India is nearly at an end. According to the correspondent of the London *Lancet*, those seeking relief are now only 1,250,000, and the Indian harvest promises to be a large one. The plague remains about the same, with a weekly mortality of about 2000.

THE ITALIAN physicians are endeavoring to have their parliament pass a bill restricting the issuance of licenses to foreign holders holding diplomas from countries granting a like priv-

ilege to Italy. A clause, however, is attached thereto which practically will shut out all foreign practitioners. The envious native practitioner desires the wealthy American and English patients who winter in his land.

DR. R. FIELDING-OWLS, Dr. C. Balfour Stewart and Dr. A. S. Grünbaum have recently been appointed lecturers in the Liverpool School of Tropical Medicine.

THE PARIS Faculty of Medicine have decided to establish a chair of tropical medicine for the purpose of teaching the parasitology and bacteriology of tropical diseases.

THE FRENCH chamber of deputies has unanimously adopted a resolution asking the government to prohibit the manufacture and sale of all alcoholic liquors pronounced "dangerous" by the Academy of Medicine. The resolution was aimed at absinthe. "The increase of the consumption of absinthe," said the mover, "marches arm in arm with the increase of cases of driving insanity, which will end in becoming a national disaster."

IN THE name of twenty university professors of Germany, Austria and Switzerland, Prof. Max Gruber, of Vienna, has written a brief, forcible appeal to university students pointing out the terrible increase in venereal diseases in general and also among students, and portraying in plain terms the dangers to self and the future family. The urgent warning is given to seek medical aid at once in case of infection. Every newly-enscribed student receives a copy of this pamphlet.

THE BRITISH CONGRESS OF TUBERCULOSIS, notice of which has already appeared in these columns, will be opened in London on July 22, 1901, a week previous to the meeting of the British Medical Association. The congress will last four days. Delegates are to be invited from foreign countries, and it will be international to a certain extent. It will transact business in four sections, viz., Human Medicine, Veterinary Medicine, State Medicine and Pathology. One hundred pounds has been appropriated by the British Medical Association toward the expenses of the concern.

THE *Deutsche Med. Woch.* of November 15 publishes the brief, final report of the malaria expedition in charge of Prof. Koel. The party returned by way of the Carolina and Ladrone islands, where numbers of children were examined for malaria, but no traces of it could be found. Many persons were brought to him suffering from supposed syphilis, lupus or leprosy, but investigation disclosed that the disease was frambesia—yaws—in every case; in some of the islands every child examined was found to have it. Several genuine foci of malaria were located in the neighborhood of Cairo. None could be discovered in Northern Germany suitable for the purposes of the expedition, not even in the formerly notoriously malarial marsh lands along the coast of the North Sea. Malaria seems to be rapidly diminishing in Northern Germany. The expedition, therefore, considers its task provisionally accomplished.

Correspondence.

Newspaper Notoriety—A Protest.

CHICAGO, Dec. 5, 1900.

To the Editor:—Have medical men no protection against "write ups" in the columns of the daily press? In the *Chicago Daily News* of to-day appears an offensive and grossly incorrect sketch of myself which was not only unwarranted and without my knowledge or consent, but which deals with my blindness in a way that is most degrading to my self-respect. My only consolation lies in the consideration that those colleagues whose respect I value can not read that article without appreciating the fact that it could not have emanated in any wise from me. I have many times been solicited by reporters to allow them to publish sketches of my professional career. In most instances I have flatly refused such permission. In a few instances, when told that the knowledge of my endeavors would stimulate other unfortunates to rise above their affliction and would thus prove a help to them, I have consented to the publication of a sketch of my life. I have always, however, scrupulously avoided any allusion to the nature of my special line of work lest I should be accused of unprofessional advertising. And now comes an article which violates every sense of decency in my nature and brings my name before the public in a manner that is brutal in its disregard of my feelings. I am humiliated and chagrined.

ROBERT H. BARCOCK, M.D.

The Physician-Druggist.

SPRINGFIELD, OHIO, Dec. 10, 1900.

To the Editor:—In issue of December 8, of THE JOURNAL, p. 1485, in the editorial entitled "The Physician-Druggist" you state that there seems to be no adequate reason why regular medical societies should refuse membership to a physician-pharmacist. Please allow me to disagree with you very decidedly on this point. I know of no pharmacist that is not a dealer in all forms of nostrums and patent medicines; they display advertisements in their windows and shelves, and use many means to increase their sale. Is not this sufficient reason that they should be rigorously excluded from all regular medical societies? Or should we affiliate with them and pretend to endorse such methods as they pursue? Very respectfully,
N. MYERS, M.D.

[Our correspondent evidently did not read the editorial right. Physicians can, and do have, drug stores in small villages all over the country, and yet are ethical and honorable. It is not necessary that they should "deal in all forms of nostrums," or that they should "display advertisements" and use other means to increase the sale of nostrums. If they did they probably would not make acceptable members of a medical society.—Ed.]

A Warning Against a Possible Swindler.

PHILADELPHIA, Dec. 10, 1900.

To the Editor:—I learn by inquiries addressed to me, and by a letter returned from the Washington (D. C.) postoffice, that some swindler has gotten hold of some of my notepaper, cards and envelopes. Probably while pretending to wait for me in my absence he has slipped into my office and gotten them from my desk. He has been writing himself letters of recommendation upon my notepaper, and using my cards as introductions. He calls himself by various names. Dr. Von Liebig, Max Weil, and Dr. M. Lobo, are three that I have heard of. Will you kindly let me say through THE JOURNAL that I have given no letter of recommendation to anybody, except special letters addressed to special persons, and recommending medical men for special positions for which they have been candidates. I never give a letter of general introduction or recommendation, and especially not a letter asking for charity. Anybody presenting any such letter purporting to be signed by me, should be arrested for forgery, or whatever may be the technical offense. Yours very truly,
SOLOMON SOLIS-COHEN, M.D.

Marriages.

G. MANNING ELLIS, M.D., to Miss Mary Loop, both of Chatanooga, Tenn., December 4.

OSCAR R. TOMLINSON, M.D., Tate Spring, Tenn., to Miss Blaud Wilson, of Sewanee, Tenn., December 8.

LOUIS H. ALLEN, M.D., San Francisco, Cal., to Miss Maud Allen, of East Oakland, Cal., December 5.

EARL V. ADAMS, M.D., D.D.S., Birmingham, Kas., to Miss Lena May Sharp, of Topeka, November 28.

P. H. MAYGINNES, M.D., Cushing, Okla., to Miss Anna Caterlin, of Sedalia, Mo., November 27.

MAX ROTHSCHILD, M.D., to Miss Lucie May Jackson, both of San Francisco, Cal., November 27.

GUY WATTS WAGNER, M.D., to Miss Mabel Letitia Standidge, both of Chicago, December 5.

BARTON J. POWELL, M.D., Stockton, Cal., to Miss Mabel Lyon, of Sacramento, Cal., November 21.

J. LYMAN BELKLEY, M.D., Sandy Creek, N. Y., to Miss Lena Weston Cox, of Ballston Springs, November 17.

HERMAN J. HUYETT, M.D., Milan, Ill., to Miss Jessie Perrine, of Livingston County, N. Y., at Davenport, Iowa, November 22.

WILLIAM COOPER EIDENMULLER, M.D., San Francisco, to Miss Goldie Jane Rounds, of Vallejo, Cal., at San Francisco, November 28.

Deaths and Obituaries.

LUDDER M. FINNEY, M.D., Tulane University, New Orleans, 1890, formerly assistant quarantine physician at the Mississippi quarantine station, and later sanitary inspector of the State Board of Health, serving in that capacity in several Central American ports, at his home in New Orleans, November 28, aged 38.

WALTER R. STEPHEN, M.D., University of Pennsylvania, 1872, an honor man in his class, who had practiced nearly 30 years in Reading, at his home in that city, from pleurisy, after a short illness, November 27, aged 49.

CLARENCE E. FOSTER, M.D., College of Physicians and Surgeons, New York, 1881, ex-coroner of Wayne County, at his home in Honesdale, Pa., November 26, aged 43.

WILLIAM W. DICKSON, M.D., McGill University, Montreal, 1858, at one time president of the Ontario Medical Association, and twice mayor of Pembroke, at his home, from typhoid fever, November 25.

WILLIAM N. BUSH, M.D., University of Georgia, 1857, a surgeon in the Confederate army, after declining health for several months, at his home in Lancaster, Ky., November 29.

WILLIAM G. HAY, M.D., University of California, 1895; assistant to the chair of dermatology in that institution, suddenly, at his office in San Francisco, November 26, aged 32.

FRANK A. CLARK, M.D., Jefferson Medical College, 1880, at his home in Shamokin, Pa., after an illness of two years, from paralysis, November 30, aged 59.

J. EDWIN MOSELEY, M.D., Vanderbilt University, Nashville, Tenn., 1898, after an illness of three weeks, at his father's home in Clarksville, Tenn., aged 25.

FREDERICK KEBLER, M.D., Ohio Medical College, 1875, at a sanatorium in Somerville, Mass., of which he had been an inmate two years, November 22.

ALEXANDER S. JORDAN, M.D., University of Pennsylvania, 1863, after an illness of four years at his home in Riegelsville, November 23, aged 61.

FRANK TUNSTON, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1864, at his home in Wapello, Iowa, November 25, aged 63.

THOMAS H. HOOD, M.D., Louisville Medical College, 1874, from apoplexy, at his home in Cynthiana, Ky., November 29, aged 58.

W. V. MARQUIS, M.D., New York University, a surgeon in the Civil War, at his home in Glenshaw, Pa., November 27, aged 67.

JAMES A. LORD, M.D., Rush Medical College, 1879, from Bright's disease, at his home in Edgerton, Wis., December 1, aged 42.

O. P. MCKAY, Jefferson Medical College, from pneumonia, at his home, Fayette, Pa., November 24, aged 56.

WILLIAM I. PAINTER, M.D., Jefferson Medical College, 1894, from typhoid fever, at his home near Double Springs, Ala.

WALTER C. PEASE, M.D., Jefferson Medical College, 1873, suddenly from heart disease at Cumberland, Wis., December 6.

CALEB W. PHARR, M.D., Missouri Medical College, 1851, recently, at his home, Clarksville, Mo.

GEORGE BURR BANKS, M.D., College of Physicians and Surgeons, New York, 1860, at Huntington, Long Island, N. Y., December 4, aged 67.

S. C. ANDREWS, M.D., at Newton, Ill., aged 62.

Miscellany.

Bogus American Diplomas.—From the report of a recent meeting of the General Council of Medical Education and Registration, as published in the English medical weeklies of December 1, we make the following excerpt, which is self-explanatory. Considering the action taken by the courts regarding the Armstrongs, as reported in this issue, it is also timely.

The following communication, remitted to the General Medical Council by the Executive Committee from the For-

engine Office in regard to the sale of false American diplomas, was received and entered on the Minutes:

FOREIGN OFFICE, SEPT. 24, 1900.

Sir:—I am directed by the Secretary of State for Foreign Affairs to transmit to you, for the information of the General Council of Medical Education, the accompanying copy of despatches from Her Majesty's Consul at Chicago, respecting the sale of false American diplomas.—I am, Sir, your most obedient humble servant.

F. H. Villiers.

The Registrar of the General Medical Council.

BRITISH CONSULATE, CHICAGO, July 3, 1900.

My Lord—I beg to report for your lordship's information that the Postal Inspector of Chicago has at last been able to arrest and to have held in heavy bail for trial Dr. Armstrong and his associates of the People's Institute, Van Buren Street, Chicago.

Armstrong and his partners, under various names, have been doing a very lucrative business in selling diplomas to persons in England, and their agent, Z. Wightman Van Appin, disposed of large numbers of useless diplomas in British India. I hope to obtain a list of the persons who purchased these diplomas in India from Mr. Van Appin, and will at once forward it to your lordship. From a postcard that has been held by the postal authorities, who have been so good as to communicate it to me, I see that Mr. Allan Fisher, who styles himself M.D. and Ph.D., writing on the 15th ultimo from "Mere," "Wiltshire," to Dr. Armstrong, "People's Institute, Van Buren Street, Chicago," states that he has delivered a Diploma of D.D. to a Mr. Johnson (no address given), who is very much pleased with it; and that he had hopes of selling two M.D. diplomas for the sale of which he was in treaty with persons whose names are not mentioned.

The postal authorities also hold return postcards showing that Dr. Armstrong and company are in treaty with the following parties, either to sell diplomas or have already sold them: diplomas: T. Rai Tharoda Kano Lahiri, M.D., 6012 Simla Street, Calcutta; and is corresponding with Z. Dr. Hassall, 70 and 80 Paul Street, Manchester, Eng.; J. M. Lethera, M.D., Honse No. 3, Zier Thost Bang (?), Girgaum, Bombay, India; (This address is very indistinctly written.) Z. Wightman Van Appin, care of Dr. J. Murdoch, 714 Shelby Street, Louisville, Kentucky.

I think the police will probably be able to find out some useful details of the business of bogus diploma selling by Dr. Armstrong in Great Britain from Mr. Allan Fisher, who is now acting as selling agent for the diplomas of the Independent Medical College and the Metropolitan Medical College of Chicago, Illinois. These so-called colleges have charters issued by the State of Illinois, the laws of the State being very lax in the matter of granting such charters, but their diplomas are being sold all over Great Britain and British India, and probably in the Colonies, to anyone who may be willing to buy them.

It is possible that Mr. Allan Fisher has been duped by Armstrong and company, but he is now evidently acting as their agent, and sells D.D. diplomas as well as M.D., signed by the same people, or rather by the same person, as it has been found out that all the signatures are made by a girl in different handwritings.

Armstrong and his associates have been held in heavy bail for trial for making a false statement, defraud, and for the moment the diploma mill is said to be closed.

Her Majesty's government of India may also be able to find out through the addresses I have given above if there has been anyone appointed in India to sell the diplomas.

Mr. Z. Wightman Van Appin himself bought a Ph.D. and M.D. diploma for one hundred and forty-four dollars, and then was sent to India with a quantity of blank diplomas of all kinds to fill in, and will inform your lordship later on of the result of the trial of Armstrong and company. (Signed) Wm. Wyndham.

It is quite evident that the "Z. Wightman Van Appin" referred to is the same gentleman whose case attracted attention through an article in THE JOURNAL (July 7, p. 45) some months ago. At that time he was attempting to get a degree in one of the Louisville colleges, his name being A. Zwrightman Van Noppen.

Societies.

Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.

THE MINNESOTA VALLEY MEDICAL ASSOCIATION, at its annual meeting held in Mankato, December 5, elected Dr. Oliver H. McMichael, Vernon Center, president, and Dr. Edwin D. Steel, Mankato, secretary.

THE UNIVERSITY OF MARYLAND MEDICAL SOCIETY, on November 27, elected the following officers: Dr. Summerfield B. Bond, president; Dr. William I. Messick, vice-president, and Dr. Jose I. Hirsch, secretary.

THE SUPERIOR-DULUTH DOCTORS' ASSOCIATION, at its annual meeting held at West Superior, Wis., November 23, elected the following officers: Dr. Charles A. Stewart, Duluth, president; Dr. William F. Ground, West Superior, vice president, and Dr. John B. Weston, Duluth, secretary-treasurer.

THE NORTHERN CENTRAL ILLINOIS MEDICAL ASSOCIATION held its twenty-seventh annual meeting, December 5, and elected Dr. Fernando C. Robinson, Wyanet, president; Drs. John Ross, Pontiac, and Jane Reid Keeler, Sterling, vice-presidents and Dr. George A. Dieus, Streator, secretary and treasurer.

THE LOUISVILLE CLINICAL SOCIETY, at its annual meeting held November 27, elected Dr. Fwing Marshall, president; Dr.

John R. Wathen, vice-president, and Dr. Philip F. Barbour, secretary, and appointed a committee consisting of Drs. William H. Wathen, Joseph W. Irwin and Martin F. Coomes to co-operate with the health officer in arousing interest in the matter of the health of the city and in securing facilities for the examination of milk, foods and water, and for the care and protection of children from the contagious diseases.

THE ST. LOUIS MEDICAL SOCIETY, at its meeting held December 1, listened to a paper by Dr. Hugo Summa on "The Diagnostic Value of a Floating Tenth Rib." He maintained that its floating condition might properly lead one to suspect maldevelopment in various other ways. He gave many instances where the condition existed, that showed post-mortem bilobed, lobulated or otherwise malformed kidney; a peculiar spleen, an anomalous liver or other anatomical peculiarities due to arrested development. The discussion was participated in by Drs. Bartlett, Meyer and E. W. Lee, the last of whom cited corroborative instances.

Chicago Neurological Society.

Clinical Meeting, November 1, 1900.

Vice-President Hugh T. Patrick, in the chair.

INTERMITTENT CLAUDICATION AND ATYPICAL SCIATICA.

DR. HUGH T. PATRICK presented a patient with what he considered to be atypical sciatica dependent principally on arterial disease and hence closely related to the "claudication intermittente" of Charcot.

In this connection he briefly related the principal features of a case which he had hoped to also have present in person. The patient was a woman, 66 years old, who had been in fairly good health until about six months before, when she began to have trouble with the lower extremities. The legs below the knees became slightly swollen and somewhat painful, especially at night, and she was greatly annoyed by paresthesia and muscular cramps. Within the last few weeks tingling and numbness had appeared in the last two fingers of the right hand, and she said that in cold weather the fingers turned greenish-white and seemed to be dead. In addition to the sensory symptoms, she complained of great weakness of the legs, particularly after walking a short distance, and on examination it was found that although she started off fairly well, after walking about twenty yards the steps became small and somewhat uncertain and thereafter progression rapidly became more difficult until she was compelled to come to a full stop. The pulse was 95 and small and was not to be felt in the dorsal artery of the foot on either side. There was slight anesthesia of the foot and the Achilles jerks were absent.

The patient presented was a man 69 years old who, twenty-eight years before, had had severe sciatica beginning on the left side, afterward extending to the right and lasting more than four years. Twelve years ago he had a similar attack, but active treatment in the beginning limited its duration to a few weeks. The present trouble began nine years ago much as the previous attacks had done, but was less acute and almost immediately involved both sides. From the first the pain was not severe, indeed, could scarcely be described as a pain at all, but was rather a sensation of drawing or pressure with intensely disagreeable paresthesia and intense restlessness of the legs. Although the discomfort was greater in the region just below the sciatic notch on either side, none of the ordinary signs of sciatica were present. The patient complained particularly of the fidgety feeling and paresthesia which prevented him from getting to sleep and of the weakness and increase of the sensory symptoms caused by walking. Examination showed a senile heart with a systolic murmur, and a distinct, although not advanced, arteriosclerosis. It should be added that for some time the patient had been troubled with attacks of transient dizziness. The pulse in the dorsal artery of the foot was good and the urine normal.

SYRINGOMYELIA IN A NEGRO.

The next patient presented was a pure negro, 26 years of age, who had noticed at the age of 15 or 16 that the right hand was not so strong as formerly. From that time the progress of the disease had been steadily forward until at the present time he gave the symptoms of a syringomyelia extending from the lumbar enlargement to the nucleus of the sixth nerve. The

distribution of the sensory disturbance was of particular interest. There was practically no disturbance of the tactile sense; analgesia was limited to the right arm and right half of the body, in front from the chin to the groin and behind from the vertex to the buttock, while thermo-anesthesia was present in this area and also involved the left arm, the left lower extremity from the crest of the ilium down and the right lower extremity from the knee down, leaving uninvolved only the left half of the body from the clavicle to the crest of the ilium and the right thigh.

SODIUM BROMID FOR MORPHIN HABIT.

DR. ELBERT WING reported a case of morphin habit treated by the administration of sodium bromid in very large dosage. The patient was the wife of a physician and was formerly a trained nurse. She was 28 years old, in excellent health and was taking from ten to fifteen grains of morphin hypodermically daily. Her heart, lungs and kidneys were normal. There was constipation. The treatment was commenced with two drams of sodium bromid given in a half glass of water every two hours through the day until five doses or 600 grains per diem had been given. Through a misunderstanding the dose was exceeded twice. Direction was given that the patient was to have morphin when she asked for it. The diet was restricted and mainly of milk.

The treatment was carried on for a few days and a large quantity of bromid given, which apparently had the effect of producing restlessness, delirium, and other unpleasant symptoms, in spite of tonics simultaneously administered. It was discontinued, but pneumonia developed and carried the patient off on the seventh day.

Dr. Wing gave a résumé of Dr. Neil Macleod's nine cases, and two of Dr. Church's, treated by sodium bromid, the treatment being instituted for the cure of drug habits, either morphia, chloral or alcohol. Dr. Macleod thinks the method without or with little danger, even at home. Dr. Church thinks it may be undertaken with full hospital facilities. The cases so far reported seem to point to the following conclusions. The method is not without danger and should not be undertaken with heart, lungs or kidneys not normal, and never in septic conditions. Macleod's original dosage, namely, 1 ounce the first day, 1 ounce the second day, $\frac{1}{2}$ ounce the third day, if necessary, should not be exceeded without first waiting twenty-four hours. If then resumed, it should be with great caution. In any case, very perfect care should be taken to guard against taking cold.

DR. ARCHIBALD CHURCH said that while the bromid treatment did cure the opium habit, it nevertheless remained a fact that 33 per cent. of reported cases had proved fatal, and emphasis was laid on the fact that large doses of bromid might be dangerous.

DR. MOYER said that Dr. Bannister and himself had presented, in 1881, a joint paper, read before the American Neurological Society, on "Bromid Mania." It was clearly shown that small doses of bromid would cause mania in certain cases of otherwise perfectly normal individuals. Certain German observers have noted the same thing. Bromid is certainly capable of making most profound body disturbance. Mention was made of a patient losing 50 pounds in weight in three months while taking moderate doses of bromid. At another time the same patient lost 30 pounds in a similar way, but regained weight after discontinuing the salt. Dr. Moyer considers the bromid treatment of the opium habit and of alcoholism as unsatisfactory and that we have better and safer means.

DR. C. H. LUDOR called attention to the fact that the dose, as given, of bromid, did not represent the amount in circuit when the bromid was being given continuously. If 400 grains be given at a dose in twenty-four hours, but one-half of said dose will have been excreted and Drs. Bill, Quinke, and Ware have severely proved that in forty-eight hours after a given dosage a sixth of the dose still remains in the circulation and traces may be found in the urine weeks after cessation in the use of the bromid. It would then be very essential to use extreme care in continuing massive dosage of bromid.

DR. J. B. HERRICK quoted Dr. W. Mitchell as authority for untoward symptoms in the administration of the bromid,

which symptoms may or may not disappear on withdrawal of the drug.

DR. S. KUH maintained that the relatively smaller doses suggested by Dr. Wing and even withdrawal of the drug for twenty-four hours, did not constitute a safeguard. A case is mentioned where even 20 grains of the bromid, four times a day, had caused alarming symptoms.

DR. HUGH T. PATRICK related a case of alcoholism when 1 dram of the bromid was given every hour until 16 drams had been given. The symptoms then became alarming; the pulse and respiration were slow, with cyanosis and incoherency. After thirty-six hours there was a gradual improvement and the treatment was successful.

DR. DANIEL R. BROWER mentioned a case where 15 grains of bromid caused, on several occasions, maniacal symptoms.

New York County Medical Association.

Stated Meeting, Nov. 19, 1900.

President Dr. Parker Syms, in the chair.

UTERINE MYOMA.

DR. GEORGE T. HARRISON presented a large myoma, which had been removed by enucleation after it had been converted into a subcutaneous tumor, apparently by a course of thyroid extract.

GENERAL SEPTIC PERITONITIS.

DR. IRVING S. HAYNES read a paper with this title. Under the head of general septic peritonitis he included all cases of inflammation of the peritoneum, septic in origin, and unlimited in extent by adhesions. Of the 15 cases forming the basis of the paper, 8 had been caused by rupture of the appendix. The early vomiting in cases of general septic peritonitis he said was the result of shock, and was not of importance unless its character and persistency indicated obstruction. In his adult cases the pulse, in the early stages, had ranged between 90 and 120, the unfavorable cases showing a tendency quite early to a rapidity of pulse beyond the average. At first the temperature would be only between 101 and 102 F. One of the earliest signs of improvement was a disappearance of the characteristic anxious expression of countenance. These persons invariably die if not operated upon, and although even with operation the mortality was very high, operative intervention held out the only hope. Having opened the abdomen, the cavity should be most thoroughly irrigated with normal salt solution, the process being kept up until the fluid returns clear. He did not favor sponging or unnecessary handling or exposure of the bowel. Full strength solution of hydrogen peroxid might be used in small areas provided it was followed by washing with saline solution, but he would not advise its more extensive use, because it undoubtedly injures the epithelium. If the distention of the bowel were excessive, it might be necessary to reduce this by making a small linear incision into the bowel, closing it afterward by suture. The "wick drain" was probably the best. In conclusion, the speaker warned against overstimulation of the heart by the too free use of cardiac stimulants, though he did not think one was likely to use too large a quantity of whiskey by the hypodermic method of administration.

DR. CHARLES N. DOWD said that reports indicate an encouraging percentage of recoveries in these cases which, only a few years ago, had been looked on as uniformly fatal. The good results are not dependent on the particular technique employed. In general, the successes had been among the mild cases of general septic peritonitis—those border-line cases in which the effused serum is cloudy, and thick pus, if present at all, was limited to the site of infection. Recovery almost never occurred in cases showing thick pus and flakes of fibrin scattered through the coils of intestine, or numerous localized abscesses.

DR. BENJAMIN T. TILTON did not look for any great improvement in the present surgical technique, but rather for better statistics as a result of the medical profession as a whole bringing these cases earlier to the surgeon. He objected to the method of wiping off the intestine, for this did not fully meet the indications, though inflicting trauma on the peritoneum.

DR. A. BROTHERS said that he had tried Dr. George R. Fowler's method of elevating the head of the bed to favor the escape of pus, and he was convinced that this simple plan would sensibly diminish sepsis. He had formerly advocated free flushing of the peritoneal cavity, but at the present time he only resorted to it in cases in which a large quantity of pus had been already distributed throughout the cavity. Ordinarily such flushing did more harm than good by disseminating the septic matter.

DR. JOHN F. ERDMANN endorsed the technique recommended by the last speaker. Where there were pus foci, he used peroxid of hydrogen locally, followed by salt solution.

DR. HYNES, in closing, said that his experience had been that most cases operated on within six or eight hours after the occurrence of infection would recover. He was not in sympathy with those who spoke against flushing the peritoneal cavity, and was disposed to believe that such irrigation would not tap the lesser peritoneal cavity.

THE USE OF HOT WATER VAGINAL INJECTIONS.

DR. J. H. BURKENSCHAW read a paper on this subject. He said that the use of such a douche for only five minutes had the opposite effect of that intended, i. e., it increases the pelvic congestion. At least three gallons of water should be used for each douche, and its temperature should be between 107 and 120 F. The hips should be raised, and the patient should be directed to remain in the recumbent position for half an hour after the douche.

DR. GEORGE T. HARRISON wished full credit to be given to Dr. Thomas Addis Emmet for having given to the profession this exceedingly valuable therapeutic measure. In his experience it had proved invaluable in cases of parametritis following childbirth.

DR. J. RIDDLE GOFFE said that he had found it convenient to have the patient lie on a wooden top fitted on the bath tub and take the hot water from a combination faucet. He prized these douches highly, yet he was convinced that their employment after many perineal and vaginal operations was responsible for anemia of the parts and consequent interference with healing. The insertion of a light vaginal tampon was preferable.

DR. FREDERICK P. HAMMOND said that the all-important point was not the quantity of water, but the duration of the douche. By diminishing the caliber of the outlet as much good could be done with one gallon of water as from three gallons. An effective douche would cause a determination of one-third to one-half of the blood to the pelvis, hence it would produce headache in anemic persons—indeed hot vaginal douches should be forbidden until the anemia had been controlled. The douche was also contraindicated in acute perimetritis or salpingitis. In cases of uterine or cervical dysmenorrhea without much ovarian implication, a prolonged hot vaginal douche would give great relief.

DR. W. EVELYN PORTER said that he was able to secure for his patients all the benefits of the prolonged vaginal douche by using a moderate quantity of water and regulating the outflow by pinching the tube from time to time. By the use of a Kemp's tube, a T-bandage and a vulvar pad the douche could be given very satisfactorily.

DR. A. B. TUCKER remarked that he had been surprised at the great benefit experienced in many cases of retrodisplacement from the proper use of the hot douche.

DR. F. H. WIGGIN thought this advocacy of the hot vaginal douche was a long step backward, and did not accord with modern surgical notions.

DR. A. PALMER DUDLEY took a similar view. He said that even the young men going out from the Woman's Hospital today were not so deeply impressed with the value of the douche, particularly as it had been demonstrated that its action did not extend beyond the cellular tissue.

Chicago Medical Society.

Weekly Meeting, November 28, 1900.

President Dr. J. H. Stowell in the chair.

DR. A. H. FRANCUSON exhibited a patient on whom he had performed a Schede operation for chronic empyema. Dr.

Joseph Zeisler showed a case of acromegaly. Dr. H. H. Ritzenhouse reported a case of ankylosis of both elbows following acute arthritis.

DR. A. F. LEMKE presented six cases of pulmonary tuberculosis that had been under the compression treatment in various stages of the disease at periods varying from two years to a few months. These were selected to show the effect of the treatment on the various manifestations of tuberculosis of the lung. In some the diseases was unilateral; in others bilateral. The good effects of compression locally are brought about by the limitation of areas of disease already existing by favoring fibrosis in and about these areas; by occluding the avenues of dissemination of the virus, and by compressing cavities to enable them mechanically to heal. Other effects of compression are due to rest of the organ as a whole; emptying of secretions; prevention or diminution of absorption of toxic bodies; prevention of secondary infections, and the diminished tendency to hemorrhage. There is anatomical evidence that compression will further the natural tendency on the part of the tissues to cicatrize. That it will palliate is shown by diminution of cough, of expectoration, of fever and sweats, and by the almost constant tendency to gain in weight. There is no evidence that fresh tubercles can develop in a compressed lung. Average quantity of nitrogen, which may be introduced into the pleural cavity without untoward effects is 120 cubic inches. Healthy lung tissue may be compressed for a year or more and retain its capacity for expansion upon the removal of pressure. Experiments were made on dogs, in which the left pleural cavity was injected with nitrogen or normal salt solution every two weeks during a period of eight months.

The following are the uses of intrapleural injections of nitrogen: 1. Curative in pulmonary tuberculosis. 2. Palliative—to prolong life for weeks or months, although the disease may be too extensive to make recovery probable; to diminish fever and expectoration; to check pulmonary hemorrhage; to compress cavities, tuberculous and otherwise, and establish mechanical conditions that will permit their healing. 3. To compress the lung just prior to surgical operations in which the pleural cavity is to be freely opened and to determine the presence or absence of pleural adhesions before opening the pleural cavity to drain, to drain abscess or bronchiectatic cavities, cysts, etc.

DR. WILLIAM A. EVANS said that compression tends: 1. toward the development of those processes by which repair in tuberculosis is accomplished; 2. toward limiting the tubercular process, which is necessary for repair, and in order that the tubercle bacilli shall not spread to other parts of the same lung or to the other lung. Two points should be remembered: cure of the nodules already established, and the possibility of preventing the spread of those nodules to other areas of the lung. Compression exercises a remedial effect on hemorrhage. It tends to prevent it, and in cases in which hemorrhage is a feature compression prevents the continuance of the hemorrhage. At no period in the development of tuberculosis is the spread of the disease so rapid, the generalization of the tubercular process so frequent, as subsequent to hemorrhage. It is said that tubercle bacilli are found in the wall of the bronchial tubes and are carried there by the blood stream, and in consequence there is a dissemination of the tubercular process in the lung. If this method of healing has no other field, it would be indicated in those cases in which life is threatened by hemorrhage. The speaker referred to another group of cases in which it was thought, at first, that the use of the method would have but a small field, namely, those in which there is considerable elevation of temperature; but actual experience with the method proves that the fever almost universally subsides after the affected lung is compressed.

DR. R. B. PIERCE said that he had been much interested in the work of Dr. Lemke upon this subject, and knowing his enthusiasm he submitted his first report to analysis, and, he hopes, impartial criticism. (See THE JOURNAL of October 14, 1899, p. 959.) The first thing to impress him was

that many of the cases had been under observation for very short periods of time, and on tabulating them he found that seventeen of his 53 cases had been under observation for periods varying from one day to one month. He rather arbitrarily selected one month as the limit below which he could expect no consideration for his method except as a treatment for the symptom hemorrhage. In placing the limit as low as one month as a period of observation of so chronic a disease as pulmonary tuberculosis, he had been at least generous. Deducing these cases there are 36 cases under observation for periods varying from one to nine months. From this list he had deducted the cases in which Dr. Lemke admits that there is no, or only questionable improvement, the cases distinctly worse, one which died of peritonitis, seven who were sent to a more favorable climate, and one, Case 14, in which there seemed to have been a mixed infection of tubercle bacilli and leptothrix. Together these amount to 20 cases, leaving 16 in which Dr. Lemke claims, and apparently justly, to have obtained improvement.

Submitting these cases to further analysis, Dr. Preble made two sub-groups, one of four, and the other of twelve, cases. In the smaller group, there has been a gain in weight of 22, 12, 17, and 25 pounds. In two cases the physical signs disappeared; in one the signs were lessened, the temperature reduced to normal. In one case there is the marked gain of 25 pounds, but the patient still coughs and expectorates freely, and the temperature continues. Two of these cases might be regarded as cured, and in both the others there has been a marked improvement. Of the 12 cases in which improvement may be regarded as slight, to moderate, there was a varying gain in weight up to ten pounds, and averaging 4.33 pounds, and in no one of these did the cough or expectoration disappear. In 4 of this 12 there is no statement of the condition of the lungs at the end of treatment; in the other 8 the signs are lessened and improved. These results do not seem to the speaker to be very encouraging, especially when it is considered that many of the best established aids to the recovery of tuberculosis have been added to the injections of nitrogen. This is not stated by Dr. Lemke in his article, but has been stated to him—Dr. Preble—personally by Lemke. This is as it should be, but it seriously interferes with the interpretation of results, particularly as Dr. Lemke's results are not markedly better than have been obtained by established lines of treatment. There are two cases in the series to which he desired to draw particular attention—Cases 20 and 17. During the second injection given Case 20 a pneumothorax did not develop, although the gas passed freely through the needle. It was inferred that the tip of the needle was within the lumen of a bronchus, thus allowing the gas to escape into the air-passage. There is nothing of importance about this except that the needle might equally well have stopped within the lumen of a blood-vessel, which would have been a very serious affair. A number of the cases suffered from syncope and dyspnea, which might easily be referred to emboli of gas perhaps of the pulmonary artery. One case, during the second injection, went into collapse, and, when restored, showed a complete right-sided hemiplegia from which he has never recovered. Here one is justified in the thought that the needle stopped in the lumen at some branch of the pulmonary vein and led to gas embolism of the vessels of the left internal capsule. About two years ago Jane way reported two cases of transient hemiplegia following the injection of hydrogen peroxid into an empyema cavity. These cases were thought to be probably due to gas embolism, and resulted from the development of a small amount of gas in an opened pleural cavity. The same accident has been observed during irrigation of an empyema cavity. These cases would suggest that possibly the same thing might happen from injection of the gas into the pleural cavity. No one can know where the inner end of his needle is, and in this is the great danger.

To sum up, are physicians justified in taking up a method which has inherent in it serious sources of danger, such as are illustrated by Case 17, when a review of the cases reported shows only a questionable improvement over the usual methods of treatment?

Dr. JOHN B. MURPHY discussed the danger of the compression treatment. In the early use of the method the first thing he feared was a separation of the pleura itself from the apex, producing paralysis of the vocal cords, and finally death. Two such cases had been reported from the mechanical separation of the pleura from the apex. As to accidents, something like 1400 injections have been made, with only two accidents, one a fatal hemorrhage on the table, when the needle was inserted into the pleural cavity, before the gas was connected. The patient had had repeated hemorrhages before, and he believes that this hemorrhage was due to the excitement of the patient. The second accident was one in which paralysis followed the injection of the nitrogen gas, the gas, he believes, having entered a vein. In his earlier work by the compression method he feared this accident might occur, but now he believes there is no danger from that source whatever, because he had learned to know that the gas is admitted without pressure instead of with it; the nitrogen is aspirated into the pleural cavity, and not forced into it. If the needle should enter a vein, the current will not be in, but out. All things considered, he believes now the treatment can be administered without danger to the patient, in fact, with much less danger than any operation of magnitude of which he knows. Practically, what are the results? 1, there is cessation of cough; 2, after a few days diminution of expectoration; 3, reduction in temperature, and often the temperature is reduced to normal; 4, the patient gains in weight. Is there any other method of treating tuberculosis in which this occurs with the uniformity that is noted by the compression treatment? He was glad that Dr. Lemke did not speak of the cases as being cured. He felt that at the end of three or four, or possibly five or six, years, the cases could be referred to as having been cured. If he had a cough, elevation of temperature, expectoration, and repeated hemorrhages, and all these disappeared, he would not care a fig whether his case was called a cure or simply a subsidence of the symptoms, because the result is the same to a patient.

Dr. WILLIAM E. CASSELBERY referred to the Koch, the Bergeon, and other methods of treating tuberculosis, which have failed, and said the method that had been outlined was suitable for a certain class of cases, particularly cases of apical tuberculosis limited to one side. It is suitable for cases of hemorrhage in which the tubercular process is not widely disseminated through both lungs. It is seemingly suitable also, to a limited extent, in cases in which there are adhesions and high fever. Personally, if he had an apical tuberculosis, he would not hesitate, if he were one of the patients selected as best adapted to the method, to avail himself of its advantages.

Dr. LEMKE, in closing the discussion, referred to emboli resulting from the introduction of the gas into the pleural cavity. This accident occurred in but one of the series of cases, and this patient was one of the first who was subjected to the treatment. Hemiplegia in one case was evidently due to gas embolism, although he was not positive about this. This was the only case in which hemiplegia had occurred out of 1400 injections. Aspiration, in cases of hydrothorax, is said to have caused hemiplegia, the result of an embolus that has been separated from a thrombosis of the pulmonary vein or some of its branches. Again, there are cases on record where simple operative procedures, such as involve the irritation of the pleura, have given rise to transient hemiplegia. So the hemiplegia might not have been due to gas embolism in the case mentioned. He was particularly careful not to speak of any of the cases as cured, because many physicians believe that a period of four to six years should elapse before using this word in its literal sense. The dangers of making the injections are practically *nil*. He had never seen any case in which the pleura has been infected as the result of injection, consequently this should not be considered as a danger. Some of the patients, when injected for the first time, have experienced considerable dyspnea; others have fainted and had to be stimulated. But this was largely psychical, and possibly in some cases it was due to the fact that the lung was compressed rather suddenly. In other instances he has observed a tendency to syncope. During the second and third injections these symptoms, were not ob-

served. Symptomatically the patients he had exhibited were cured, in that the temperature was normal, cough and expectoration had disappeared, and they had gained considerably in weight.

College of Physicians of Philadelphia.

SECTION OF OPHTHALMOLOGY.

Meeting October 16, 1900.

President Dr. George C. Harlan, in the chair.

DR. WILLIAM THOMSON exhibited two men operated on at the Wills Eye Hospital for removal of metallic foreign bodies by the small magnet from posterior portion of the eyeball. In one case a piece of iron 8 by 1.5 mm. penetrated the inner side of cornea near horizontal meridian and was located by the X-rays imbedded at a point 5 mm. below and 3 mm. to the temporal side of the macula. Body was removed through a scleral incision, and very little reaction followed. In the second case a chip of steel entered the cornea 2 mm. above and to the outer side of the center, wounding the iris and the lens and imbedding itself, as shown by radiographs, 2 mm. above and 6 mm. to nasal side of macula. The lens was extracted, after which the foreign body was removed.

DR. GEORGE C. HARLAN showed an Italian girl 14 years of age, presenting the history and the ophthalmoscopic appearances of embolism of the central artery except that the arteries contain blood and pulsate freely on pressure. The patient appeared to be in perfect health. Sight was suddenly lost in the right eye on October 7, and she appeared at the Pennsylvania Hospital two days later. The fundus presented a grayish appearance; the red spot of macula was darker than normal; the vessels were slightly obscured, and there was retinal opacity; arteries were normal in caliber and pulsated freely on pressure. There were no hemorrhages. Urine and blood were normal. No marked change in the disc exists. The diagnosis at first seemed to indicate venous thrombosis.

DR. GEORGE E. DE SCHWEINITZ suggested that hemorrhage into the nerve sheath might be responsible for the condition.

DR. S. D. RISLEY exhibited a man from the Wills Eye Hospital, 59 years of age, on whom he had performed simple extraction of cataract in each eye. Vision was 6/5 in each eye and the man enjoyed perfect binocular vision both for distance and in reading; the pupils were central and round, and reacted normally to light. There were no adhesions.

DR. WILLIAM M. SWEET reported a case of a piece of glass in the ciliary body located by the Roentgen rays and its removal with forceps. The injury occurred to an engineer from an explosion of a locomotive oil glass on March 1. A fragment penetrated the cornea in the lower outer quadrant near the sclera and passed through iris and periphery of lens. Three months after the accident the lens had been absorbed, but haziness of the vitreous prevented a view of the interior globe. The position of the foreign body has been revealed by the radiograph. It was situated close to the ciliary body at its lower temporal portion. An iridectomy was performed at the Jefferson Medical College Hospital, through an incision at the lower outer corneoscleral junction, and a pair of forceps passed up to the spot indicated by the radiograph. The glass was subsequently removed. Warm saline solution was injected to replace the amount of vitreous lost. The man was discharged cured on the eighth day.

DR. GEORGE E. DE SCHWEINITZ reported some cases of traumatic palsies of the ocular muscles, with causes: paralysis of the inferior rectus from a knife thrust; division of the pulley of the superior oblique during an operation for abscess; injuries to the superior oblique; paresis of the right inferior rectus following a fall on the left side of the head and forehead, spontaneous disappearance of the ptosis; traumatic paresis of right superior oblique following a fall on the right supraorbital region, later paresis of accommodation, complete recovery; paresis of left inferior rectus following a fall on the head succeeded by concussion of the brain, recovery; paralysis of left superior oblique following a fall on the head succeeded by a severe concussion of the brain, recovery.

DR. S. D. RISLEY recalled the history of a case presented to the section last year in which a man had been thrown from a buggy, remaining unconscious for two days. Three months later there was almost complete paralysis of all ocular muscles on the right side supplied by the third nerve except the levator. He presented the history of two cases which properly belong to the first group.

DR. B. ALEXANDER RANDALL referred to a case of paralysis of inferior rectus, decreasing when he first saw the man, in which complete recovery followed absorptive treatment.

Chicago Academy of Medicine.

October 12, 1900.

IS THE AMERICAN TO BECOME A DEGENERATE INDIAN?

DR. JAMES G. KIERNAN read this paper.

Under the influence of the notion of zoologic districts the opinion that the English-speaking American of Caucasian lineage was to become an Indian, was advanced by Pruner-Bey and Quatre-fages four decades ago. After two generations of residence in North America the glandular system of the English-speaking race of Caucasian type was reduced to the minimum of its normal development. The skin became like leather; the color of the cheeks was replaced by sallowness. The head became smaller, rounder, and covered with stiff dark hair, the neck became longer, and greater development of the cheek-bones and the masseters occurred. The temporal fossae grew deeper, the jaw bones more massive, and the eyes lay in deep approximated sockets. The iris became dark, the glance piercing and wild. The long bones, especially in the superior extremities, were lengthened, so that the gloves manufactured in England and France for the American market were of a particular make with very long fingers. The male pelvis approached that of the female. America, in the opinion of De Quatre-fages, has thus from the English race produced a new white race which might be called the Yankee race. One of the data on which Pruner-Bey based his opinion was successfully overturned by the American anthropologist, Morton, who showed that there had been no diminution in the size of the head. This question can be answered logically only by the application of the principle that in science a theory to be exploited must not only explain all the facts, but must exclude every other explanation. The first point involved is that of the influence of American continental environment on the races constituting the Indians. According to Keane, American aborigines are not indigenous. The racial elements of the American aborigines appear to be proto-Europeans of the first stone age—a somewhat generalized primitive Caucasian type—and proto-Asiatics—a somewhat generalized primitive Mongolo-American type—both European and Asiatic still preserving many common features of the common pleistocene precursors. The study of American aborigines points to two streams of immigrants from the Old World. The Eskimo Botoeudo section has been traced to the long-headed paleolithic man of Europe, which continental geology has shown to have been connected with North America through the Faroe Islands, Iceland and Greenland, down to post-glacial times. The other section, which probably greatly outnumbered the first, came apparently later, during the new stone age, from Eastern Asia by the Behring waters, and is now represented by the still prevalent round-headed element.

The author then discusses the basis for the Indian transformation hypothesis, saying that the influence of the transformation factor, although the term "degenerate" be applied to it, is not intended to imply a morbid element tending to race extinction. A change from one species into another, whether in animals, plants, or in individuals, or their tissues, can not take place without anomaly. When the balance of the struggle for existence becomes disturbed, the degenerative organs gain at the expense of the organism. Sometimes this goes so far that new organs are formed. Any variation to be transmitted must pass through periods of embryonic, as well as periods of post uterine, stress. In passing through these periods it has to resist the influence not merely of atavism, but of the maternal

environment. The individual cell is by no means a slave to heredity. It is capable of certain modifications under the influence of certain external conditions. If the environment of the mother be favorable to the variation, it is apt to pass through the periods of intra- and extra-uterine stress unmodified. If, on the other hand, the environment be unfavorable, the reverse is likely to obtain. It is not the variation per se that may prove malign, but the influence which surrounds it. Race characters may be evolved which, considered apart from the general organism, are an expression of advance. Considered as a race for physical and not esthetic purposes, the Caucasian face is a degeneration. The negro and the Mongolian types approximate more neatly the vertebrie type, and least the embryonic type. The progress of development of the face in the vertebrates is checked in man, because the upright position renders it unnecessary to bend the head as in quadrupeds, and because the enormous cerebral development has rendered an enlargement of the brain cavity necessary.

There are factors tending to produce and maintain American race types of features. Races coming from the Old World have Mongolian elements which could be awakened by the Mongolian environment if present in the Americans. The early generations of Europeans in North America, whether these be the English Puritans, the Dutch New Yorkers, the Irish Marylanders, the English Virginians, the Pennsylvania Germans, and the mixed races of Scotch-Irish, French and German descent of the Carolinas, Georgia and Alabama, admittedly exhibit facial resemblances to the so-called Indian type. However, when the conditions of stress to which these people have been exposed began to disappear, this element vanishes. This is excellently illustrated in the family of the discoverer of the electric telegraph.

The question arises, Does the alleged transformation of the European into an Indian comply with the scientific requirements of a working hypothesis? It certainly fails in the requirement of explaining facts. The Indians still sometimes retain characteristics assimilating them to the Europeans. This proves that European characters can resist the influence of American environment even when such characters occur in a generalized, and hence plastic type. The theory does not exclude the influence of Mongolian admixture present to a large extent in all Europeans, even the English-speaking peoples. This would explain the seeming assumption of Indian race characters, since under similar conditions in Europe race characters occur simulating those of the American Indian. The theory, therefore, does not comply with the scientific rule and can not be accepted.

PROF. FREDERICK W. STARR, of the University of Chicago, objected to the general use of the term American. When Dr. Kiernan said American he probably meant only the people of this country and the Americans of Canada, and not the Mexicans, the people of Central and South America, nor the Eskimo. The American Indian, if the result of his environment, is certainly not a degenerate because he has lived in America. He is better adapted to his environment than we are.

A parasite is not a degenerate, because it is better adapted for its peculiar mode of life, but the speaker would not think of comparing the American Indian with the parasite. Indians have better sense than to keep degenerates alive. They have no institutions in which to preserve their degenerates. The type is pure throughout, and well represented in the different individuals of a tribe. The two elements mentioned by Keane are doubtless present in the Indian population. There is undoubtedly Chinese and Japanese blood in the American Indian. The American Indians come from more than two sources. They have sprung from many different original types, and at many different times when the connection with Asia was easier than at the present day, when islands were existing in the Pacific that have now disappeared, when men of different color and types found their way into America, and here they have been converging. There are 58 different language stocks represented in North America. Customs, habits and religions differ as much as language, and when these different customs are compared they coincide with different areas as mapped out on the basis of languages.

Throw a population into America, and only those whose physical type best fits them to live here will survive. In the course of time there will result a type adapted to their surroundings, a state of affairs which was found here by the white men from Europe, and one which will be found thousands of years hence when the Chinese investigators go over the world to study what is to be found in different continents.

Three cartoons are used extensively in the papers and especially during times of war. One is called Uncle Sam, or Brother Jonathan, the Yankee. He is portrayed as being slender, angular; has broad prominent cheek-bones, straight hair and a tapering face. A perfectly well-defined type. Everybody knows Uncle Sam. The second type is the F. F. V., "first families of Virginia." He is depicted as being slender, not as angular as the Yankee; he is lithe, sallow, olive complexioned, with straight black hair and dark eyes. The third type is John Bull, round, juicy, oily, with a red countenance and with curly grayish hair. A perfectly well-defined type, and yet, all three are pure English. What is the difference between them? John Bull stayed at home, whereas the other two came to America and have been living here for several hundred years. Consequently they have undergone a change; they are not the same. There is a difference between the two immigrants just as there is a difference between the Indian from Virginia and the Indian from the North. The expected was the result of natural selection, which always tends to produce a type adapted to its surroundings. We never get rid of the old types entirely. Many years hence there will be physical differences between the man from England and Russia, although they will converge and there will be a homogenous population such as the white man found when he came to this country. There will be local differences, which are partly due to surroundings and partly to the original type, but there will be a convergence, a blending of all into one type. The Indians are all Indians, although there are sub-types in the shape of different tribes.

DR. EUGENE S. TALBOT agreed with Professor Starr that environment has much to do with the type, but conditions must be taken into consideration. There are two extremes, the brachycephalic and the dolichocephalic in this country among the Indians and all races of people. There is a tendency, however, not only in Europe but in this country, to the mesocephalic type and with that change appear the degenerate faces, the jaws becoming smaller. Dr. Talbot does not believe that the white races of America are becoming of the Indian type. The Indian type has large jaws, prominent cheek bones, and perfect teeth, while the mixture of races and the soil and climate are changing Europeans in this country to a race with small jaws, with small teeth and small cheek bones. That the change is taking place, Dr. Talbot showed by a series of photographs of four generations. The first picture showed a dolichocephalic head, which gradually changed until in the fourth picture it became the brachycephalic. The change in the jaws is also plainly seen until there occurs arrest of development of the jaws, the sunken face, with cheek bones not so prominent. The bones of the nose are also reduced. The changes taking place in this country are not conducive to a return to the Indian type so far as the jaws, face and teeth are concerned. The North American Indians do not have decayed teeth to any great extent, where in the American there is a degenerated tooth structure. This degenerate condition will continue in the evolution of the face of the white people.

DR. STARR did not see the connection between these pictures and the argument in question. According to Dr. Talbot, there is a degeneration going on from one generation to another. This degeneration is found only in degenerating families, in people of high respectability and genius, in people who have portraits of the family running through generations. Those pictures teach the lesson that the families they represent are going to die out because they are not adapted to the climate. They are not the people who are going to be the future population of the country; it is the people without portraits; people who are not making inventions; people who are not attracting attention, who are going to survive.

Therapeutics.

TONSILLITIS.

The harmful influence of micro-organisms which constantly inhabit the throat may be successfully combated by a perfectly healthy condition of the body, the resisting power of which may be temporarily lowered by undue exposure to cold and thus permit these germs to carry on their work and multiply. A derangement of the gastrointestinal canal is a frequent forerunner of disease of the throat.

Rheumatism seems to figure as an etiological factor in tonsillitis.

Three principal forms of tonsillitis have been described by the authorities:

1. The catarrhal form, in which the mucous membrane only is involved and which may extend to the pharynx, producing there also a general catarrhal condition.

2. The follicular form or lacunar tonsillitis, when the follicles are involved and are filled with a cheesy substance.

3. A suppurative or phlegmonous tonsillitis—quinsy.

The acute catarrhal form, although occurring as a primary disease, seldom occurs alone, but is usually associated with acute pharyngitis. Below are given some suggestions as to treatment of the different forms:

Acute Tonsillitis.

R. Sodii salicylatis		
Potassii citratis, āā	gr. xl	2 66
Syr. pruni virginianæ	ʒiiss	10
Aquæ q. s. ad	ʒii	64

M. Sig. One dessertspoonful every three or four hours, for a child of 5 or 6 years. —Ashby.

FOR LOCAL APPLICATION.

As a local application the following may be found of service in such cases:

R. Iodi	gr. iiii	2
Potassii iodidi	ʒi	4
Glycerini q. s. ad	ʒi	32

M. Sig. Apply locally to the tonsils three times a day by means of a brush or cotton swab.

AT COMMENCEMENT OF ATTACK.

R. Tinct. ferri perchloridi	ʒi	4
Glycerini	ʒi	64

M. Sig. One teaspoonful every two hours.

Iron given as in the above form without the addition of water is by some authors regarded as a specific in treatment of tonsillitis; believing that it relieves the pain, shortens the duration and lessens the congestion, as it has a local as well as a systemic effect.

GARGLE IN ACUTE TONSILLITIS.

R. Tinct. belladonnæ	ʒss	2
Glycerini	ʒiiss	10
Decoct. althææ q. s. ad	ʒvi	192

M. Sig. Use as a gargle two or three times daily. —Schnitzler.

R. Tinct. aconiti	m. viii	15
Syrupi aurantii	ʒiii	12
Aquæ destil., q. s. ad	ʒiii	64

M. Sig. One teaspoonful every two hours for a child of 4.

TONSILLITIS WITH RHEUMATIC HISTORY.

R. Sodii salicylatis	ʒii	8
Tinct. cinnamomi	m. v	33
Aq. destil. q. s. ad	ʒiii	96

M. Sig. One teaspoonful in water every two or three hours for a child of 10 years or older.

R. Pulv. opii deodor.	gr. ii	12
Tinct. veratri viridis	m. viii	5
Hydrarg. chloridi mitis.	gr. ii	12
Ol. anisi	m. i	06
Sacch. lactis, q. s.		

M. Ft. capsule No. xx. Sig. One every hour for adults. —Newcomb; *Med. Record*.

Acute Follicular Tonsillitis.

This is the most frequent form, and especially involves the crypts, and, by extension, the whole tonsil.

R. Sodii boratis	ʒiii	8
Sodii bromidi	ʒi	4
Acidi carbonici	m. xx	1 33
Glycerini	ʒiv	16
Aquæ destil., q. s. ad	ʒiv	128

M. Sig. Use as a gargle four or five times a day.

Dr. E. Fletcher Ingals applies the following to cut short the attack:

R. Guaiacol		
Ol. amygdalæ exp. āā	ʒii	8

M. Sig. Apply to the inflamed tonsil with a cotton swab once or twice daily.

This should always be applied with a swab and applied quickly, as it is very penetrating, and causes some pain when it first touches the tonsil, which in a short time ceases, as the guaiacol is a local anesthetic. This application also reduces the temperature.

R. Sodii bromidi	gr. lxxx	5 33
Sodii salicylatis		
Tinct. opii deodor., āā	ʒi	4
Cascareæ cordial q. s. ad	ʒi	32

M. Sig. One teaspoonful every four hours in water.

—E. F. Ingals.

SALOL.

Salol is a favorite remedy with a great many practitioners, and is usually given in rather large doses to children, watching, carefully the condition of the urine during its administration, istration.

R. Salol	ʒi	4
----------	----	---

M. Ft. chartule No. xv. Sig. One powder every four hours for a child of 6 years or older.

R. Sodii salicylatis	ʒi	4
Sodii phosphatis,		
Sodii bicarb. āā	ʒiiss	6
Aq. menth. pip.	ʒiii	96

M. Sig. One tablespoonful every four hours.

R. Sodii salicylatis	ʒiiss	6
Sodii iodidi	ʒss	2
Tinct. aconiti	gtt. x	66
Syrupi aurantii q. s. ad	ʒiii	96

M. Sig. Shake. One teaspoonful every four hours for a child.

R. Argenti nitratis	gr. lx	4
Aquæ destil., q. s. ad	ʒi	32

M. Sig. Brush the tonsils quickly by means of a cotton swab.

OF USE IN CUTTING SHORT THE ATTACK.

Formalin is a remedy that will probably be used more with better acquaintance with its physiological action.

R. Formalin	m. xvi	1
Tinct. ferri chloridi	ʒi	4
Aquæ menthæ pip.	ʒiv	128

M. Sig. Use as a spray every two hours in the beginning of acute form

R. Aluminis,		
Acidi tannici, āā	gr. xxv	1 5
Aquæ q. s. ad	ʒiv	128

M. Sig. Use as a gargle.

R. Tinct. ferri chloridi,		
Potassii chloratis āā	gr. lx	4
Glycerini	ʒi	32
Aquæ destil.	ʒi	32

M. Sig. Use as a gargle every hour.

The following prescriptions are taken from Keating's work on "Diseases of Children." He states that it is always advisable to keep the bowel slightly relaxed at least for a day or two, and prescribes the following, adding magnesium sulphate to meet that indication:

R. Magnesii sulphatis	3iij	12
Quinina sulphatis	gr. vi	36
Acidi sulph. dil.	gtt. xx	1 33
Syr. zingiberis	5ss	16
Aque q. s. ad.	3iij	96

M. Sig. One dessertspoonful every three hours for a child 3 or 4 years of age.

FOR LOCAL APPLICATION.

R. Tinct. ferri chloridi	3ii	8
Glycerini	3ii	64

M. Sig. Apply locally with a swab every two or three hours.

AS A SPRAY, OR GARGLE.

R. Thymol	gtt. ii	12
Acidi carbol.	m. xxx	2
Sodii boratis	5iiss	6
Glycerini	5vi	24
Aque destil., q. s. ad.	3vi	192

M. Sig. Use as a spray or gargle two or three times daily.

AS A TONIC DURING CONVALESCENCE.

R. Quinina bisulphatis	gr. xx	1 33
Tinct. ferri chloridi	5i	4
Syrupi zingiberis	3i	32
Aque destil., q. s. ad.	3iij	96

M. Sig. One dessertspoonful before each meal three times a day, to be taken through a glass tube. —Keating.

FOLLICULAR AMYGDALITIS.

R. Creosoti—beechwood	m. viii	5
Tinct. myrrhae.		
Glycerini, aa	3ii	64
Aque destil.	3iv	128

M. Sig. Use as a gargle every hour.

CARBOLIC INJECTIONS IN SCARLATINAL AMYGDALITIS.

H. Judson Liper reports the successful employment of Heuber's treatment. By means of a long bent needle, from two to four drops of a 1 in 40 solution of carbolic acid are injected into two or three different spots in the tonsil. Liper has used this method even in suckling infants.

R. Acidi carbolici—crystals.		
Aque destil., q. s. ad	3i	32

M. Sig. Inject from two to four drops into the tonsil. —N. Y. Med. Jour.

LOCAL ANTISEPTIC.

The infectious nature of tonsillitis and other forms of throat troubles should lead to trying antiseptic methods instead of astringents. The following combination is recommended as a local antiseptic:

R. Acidi carbol—crystals.		
Camphorae, aa	gr. xv	I
Glycerini.		
Aque destil, aa	3ii	64

M. Sig. Paint this on the inflamed parts three times a day. It will be found to have a mechanical action as well as an antiseptic one. —Archives of Pediatrics.

Phlegmonous Tonsillitis—Quinsy.

If quinsy can be diagnosed sufficiently early the attack may sometimes be aborted and, in the opinion of Dr. Holt, when it occurs in children, salol is the best remedy. It should be given in doses of two grains every two hours to a child of 5 years, and be assisted by the local effect of very hot or cold applications, according to the sensation to the patient.

AN OLD, BUT RESPECTED REMEDY.

R. Tinct. guaiaci ammoniati	3i	32
-----------------------------	-------	----	----

Sig. One teaspoonful in milk taken into the mouth as a

gargle and then swallowed. Repeat every two hours until it begins to purge—for adults.

R. Acidi salicylici	3ii	8
Sodii bicarb.	5iiss	6
Glycerini	3i	32
Aque menthar piperitae q. s. ad.	3iv	128

M. Sig. One tablespoonful every two or three hours.

TO ALLEVIATE PAIN.

To allay the pain cocain can be applied under the direction of the physician.

R. Cocaina hydrochloratis	gr. xx	1 33
Aque destil., q. s. ad	3i	32

M. Sig. Apply locally by means of a swab or spray to relieve the pain.

R. Potassii chloratis	3ii	8
Zinci sulphatis	gr. x	66
Tinct. myrrhae	3i	4
Syrupi simplicis	3i	32
Aque destil.	3iv	128

M. Sig. Use as a gargle three times daily.

R. Tinct. veratri viridis	m. xxx	2
Morphina sulphatis	gr. i	66
Aque	3ii	64

M. Sig. One teaspoonful repeated in one hour, then every three hours for an adult. —New Eng. Med. Month.

AS A GARGLE.

R. Acidi carbolici	3i	4
Glycerini	3iij	96
Tinct. iodi	3iv	128
Aque, q. s. ad	Oi	512

M. Sig. Use as a gargle in phlegmonous tonsillitis. —Buchanan.

R. Potassii chloratis	3ii	8
Potassii nitratis	3iv	16

M. Sig. One teaspoonful dissolved in a half glass of hot water as a gargle every two hours.

As soon as fluctuation is detected, an incision should be made with a guarded bistoury. After the incision the following gargle may be used:

R. Sodii salicylatis.		
Sodii boratis, aa	gr. xl	2 66
Syrupi simplicis	3i	32
Aque destil., q. s. ad	3viij	256

M. Sig. Use as a gargle.

In tonsillitis, where the temperature ranges high the child should be kept in bed and cold compresses applied to the throat and sponge baths given to quiet the patient and reduce the temperature. The diet should be guarded, consisting in the main of liquid—milk, soft-boiled or raw eggs, gruels, soups, custards, etc. The patient may hold small pieces of cracked ice in the mouth, which relieves both the thirst and the pain.

Medicolegal.

Local Health Officers Represent the State.—It is apparently the established rule, the Supreme Court of Michigan says in the case of Murray vs. the Village of Grass Lake, that local health officers acting under a general statute of the state conferring their powers are not performing corporate functions, but are represented in the state, and that the municipality is not liable for the acts of such boards, either of misfeasance or nonfeasance.

Future Medical Attendance Subject for Experts.—In the case of Martin vs. the Southern Pacific Company, an action brought by a husband to recover damages for injuries to his wife, one of the physicians who had attended upon the wife, while testifying, was asked as to the character of the medical attendance which she would require in the future. This question was objected to on the ground that it was seeking to

substitute the opinion of the witness for the conclusion which should be made by the jury. But the testimony, the Supreme Court of California holds, was properly admitted. The character of the injuries sustained by the wife, as well as their probable duration, and the professional care required for their alleviation, it holds, were proper subjects for the opinion of experts. The husband was entitled to recover for whatever damage could be shown as certain to result in the future, and the testimony of the physicians who had attended upon his wife, the court declares, was a proper mode of establishing this fact.

Barring Membership in Any Other Sick Benefit Society.

—In the case of *Bretzlaff vs. the Evangelical Lutheran St. John Sick Benefit Society*, the Supreme Court of Michigan holds that it cannot be said that the limitation in the constitution of this society that members "must not belong to any secret society or any other sick benefit society" was unreasonable or against public policy. The society, it says, was organized among the members of a particular church. Its members might be called upon to visit and care for the sick, and to use part of the income of the society in their care. If a member might join one other sick benefit association, he might join so many of them that he might not be able to perform the duties he owed to this association. Hence, the court does not think it unreasonable or against public policy to make such a provision as this in the constitution of such an association. Moreover, a person who helped to organize this society and signed an application blank containing a declaration that he had read the constitution and by-laws and was willing to submit himself to the same, the court holds, must be deemed to have known this provision, and was bound by it, and his contract with the society was rendered void by his being a member of another mutual benefit association at the time of the organization of this one and remaining such until his death, without the knowledge of that fact by the officers of this society.

Enforces Contract Not to Practice Medicine in Town.

—The Supreme Court of Michigan affirms, in the case of *Lemon vs. Randall*, a decree restraining a physician from continuing his practice of medicine in a town after he signed an agreement for a valuable consideration, not to practice his profession there. The agreement referred to was dated at that place, and stated that, for value received, he thereby sold and turned over, on and after the first of the following month, to the physician whom he named, his good will in the practice of medicine in that town and vicinity, and agreed to use his influence to introduce him to his patrons, and secure for him their patronage and influence, and that he would not re-enter into or engage in the practice of medicine there after such date, without a written agreement with said other physician. The defense relied upon was that this agreement did not embody the whole agreement between the parties, and that contemporaneously with the making of this agreement the other physician entered into certain engagements relative to purchasing a house, which, it was alleged, he failed to keep. However, the court calls attention to the fact that the other physician refused to sign a written memorandum binding him to make such purchase, and it says that it thinks it doubtful whether the physician who signed the agreement first mentioned understood the promise of the other as creating any obligation other than a moral one. But, assuming that he understood that there was a binding agreement to purchase the house, the supreme court holds that it was void under the statute of frauds, requiring some memorandum of an agreement to purchase real estate to be made in writing and signed, and, hence, that it could not be used as a defense here.

Osteopaths Practice Medicine.—The judgment of the District Court of Lancaster County, appealed from in the case of *Little vs. State*, wherein a practitioner of osteopathy was convicted of practicing medicine without a license, was affirmed, November 21, by the Supreme Court of Nebraska. The practice of osteopathy was described as consisting principally in rubbing, pulling and kneading with the hands and fingers certain portions of the bodies and flexing and manipulating

the limbs of those afflicted with disease, the object of such treatment being to remove the cause, or causes of trouble. This, it was urged did not make the practitioner a practitioner of medicine within the meaning of the statute defining the latter as any person "who shall operate or profess to heal or prescribe for or otherwise treat any physical or mental ailment of another." The supreme court, however, is of the opinion that those who practice osteopathy for compensation come within the purview of the statute as clearly as those who practice what is known as "Christian science," and that, therefore, this case falls within the principle of *State vs. Buswell*, which it decided in 1894; 40 Neb. 158. It then held that the act to establish a state board of health; to regulate the practice of medicine in Nebraska, etc., is as much directed against any unauthorized person who shall operate on, profess to heal, or prescribe for, or otherwise treat any physical or mental ailment of another, as against one who practices "medicine, surgery, and obstetrics," as those terms are usually and generally understood. And it now declares that with the rule announced in that case it is fully satisfied, although it is possible that the decisions of some other courts are in conflict with it. The doctrine declared in that case, it goes on to say, will carry out the legislative intent and effect the object of the statute, which is "to protect the afflicted from the pretensions of the ignorant and avaricious," no matter whether the person pretending to heal bodily or mental ailments does or does not profess to "follow beaten paths and established usages." In construing statutes effect should be given to the intention of the legislature. But, it was argued that osteopaths do not profess to treat any physical or mental ailment, that they merely seek to remove the cause of such ailment or disease, and, therefore, do not come within the definition mentioned. The answer to that is that it is apprehended that all physicians have the same object in view, namely the restoring of the patient to sound bodily or mental condition, and whether they profess to attack the malady or its cause, they are treating the ailment as the word is popularly understood. Wherefore, the court says that it can see no good reason why the practice of osteopathy does not fall within the provisions of the statutes under which this prosecution was instituted, as clearly so as do ordinary practitioners, or those who profess to heal by what is known as Christian science. Nor does it consider that the offense is without a penalty under the Nebraska statutes. It holds that one who practices what is known as osteopathy, without obtaining a certificate from the State Board of Health, is a practitioner of medicine as defined by article 1, chapter 55, Compiled Statutes, and is liable to the penalty prescribed specifically for practicing medicine without a license. It further holds that "surgery and obstetrics," as those terms are popularly understood, are embraced in the title of an act to regulate the practice of medicine, and hence that the act in question is not invalid on the ground that the definition of a practitioner of medicine contained therein and quoted above, is broader than the title of the act, which is "to regulate the practice of medicine." Then, it holds that the act is not void as being prohibitive in its effect, its attempt being to regulate the practice of the art of healing and it being prohibitive only as to those who have not been duly licensed by the State Board of Health to practice the art of healing. Last of all, it holds that several misdemeanors of the same kind, as for example charging violations of such a statute, may be set forth in as many counts of an information, and the prosecutor is not required to elect upon which count he will proceed.

New Instrument.

Apparatus, With Non-Perishable Valves, for Administration of Nitrous Oxid and Ether, Separately or in Combination, Without Change of Inhalers.

S. ORMOND GOLDAN, M.D.

NEW YORK CITY.

The essential part of the gas apparatus is a stop-cock containing two valves. The inspiratory valve is set in an inner

cylindrical tube, which works by a handle through a right-angled slit in an external cylinder supporting the expiratory valve superiorly, and inferiorly gives attachment to the gas bag. The valves themselves are made of thin sheet hard rubber, and are therefore non-shrinkable and stand all climates. When the handle is turned down to point indicated by "air," Fig. 1, the gas bag is closed by means of the obturating function of the inner tube; when the handle is turned upward, to place indicated by "gas," Fig. 2, air is excluded and gas is inhaled by means of the inspiratory valve. Expirations of the patient pass out through the expiratory valve; at the same time the inspiratory valve is closed. During inspiration the inspiratory valve is opened at the same time the expiratory valve is closed, preventing inhalation of air, and conversely during expiration the inspiratory valve is closed, avoiding waste of gas.

When the handle is pushed backward, to place indicated by "no valves," Fig. 3, the valves are thrown out of action; the patient then breathes back and forth into the gas bag. This three-way action of the stop-cock is a feature not represented in any of the dental gas-inhalers of American manufacture, and is one of the important factors conducing to very

is permitted to breathe air first; the handle is then pushed upward, inhalation of gas begins, and is complete in time varying from thirty seconds to one minute. Is evidenced by stertor, cyanosis, dilatation of pupils, and hard full pulse! The handle should now be depressed and air admitted, when cyanosis, stertor, etc., cease, and consciousness quickly returns, but before it is complete the gas should again be admitted. In this way gas anesthesia may be maintained indefinitely.

The gas and ether apparatus consists of, in addition to the above, an ether chamber, which is interposed between the face piece and the stop cock, Fig. 2. This is made after Clo-

FIGURE 1.

FIGURE 2.

er's principle. Instead of revolving around the central axis, technically called the whistle, the chamber itself is stationary and the handle revolves the central part. The chamber itself is about one-third the regular size, and holds 1½ ounces of fluid ether, which is poured in through the hollow glass-topped stopper; by this means it can be ascertained when more ether is required, by permitting the ether to run into the stopper by elevating the chamber. Another feature about this chamber is, it can be separated at the middle and the interior cleaned, and if preferred, a strand of gauze inserted as a receptacle for holding the ether. A varying quantity of ether is supplied, by turning the handle from 0 to 4, and it can be turned on at any time during gas anesthesia.

When gas and ether are to be administered, the parts should be adjusted as in Fig. 2, the handle turned to "air" on stop-cock and to 0 on ether chamber. The gas bag need be only moderately filled with gas. After the patient is partially anesthetized by gas, the ether should not be at once turned on, but the valves of stop-cock thrown back out of action, that the patient may breathe back and forth into the gas bag three or four times, then ether is turned on gradually. A very little air may be admitted; in this way deep etherization

1 N. Y. Med. Jour., July 29 and Aug. 5, 1899; April 28 and May 5, 1900.

rapid anesthesia by ether, when preceded by gas, to be present fully described.

One hand only is necessary in manipulating this stop-cock. By raising or lowering the handle by means of the thumb, gas or air may be admitted at will. The gas bag is made of black sheet-rubber, of about 2½ gallons capacity. The face piece is made of small, medium and large sizes, suited to either children's or adults' faces, and of different patterns to suit the individual taste of the administrator. Fig. 1 shows the metal pattern; in Fig. 2 the body is made of celluloid; Fig. 3 is made of leather entirely covered by rubber; all have the inflatable pneumatic rim. The second and third variety fit the face more closely than the metal pattern; all of them can be thoroughly sterilized.

When gas alone is employed, the apparatus should always be tested before using, and the gas bag thoroughly collapsed before being filled with gas. The inhaler is closely applied all air excluded about the edges of face piece, and the patient

very quickly (two to four minutes) follows that of gas anesthesia, with no cyanosis or stertor. After etherization is complete, the right-angled arm and ether bag may be adjusted.

For the administration of ether alone, the parts should be adjusted as in Fig. 3. Note that the right-angled arm giving attachment to the thin rubber bag, has an air-shutter. By this means air may be admitted without detaching the arm. The ether bag is of fullest respiratory capacity. Turning the handle to 0 the patient should be encouraged to breathe fully and deeply; all air passages should be fully opened; the patient now breathes only air. Ether is then very gradually turned on; at the same time the air passages are gradually closed, so that by the time all air is excluded, the patient is breathing full ether, and very quickly becomes surgically anesthetized. Air must, of course, be admitted from time to time, whenever required, and the ether chamber replenished when necessary.

The apparatus is not only the lightest and most portable of any valued device for gas-ether anesthetization at present obtainable; it is also the most inexpensive, at the same time combining the two great features of any instrument; efficacy and simplicity.

FIGURE 3.

Explanation of the Diagrams.—Dotted lines indicate external part of stop-cock, heavy lines and shaded parts, internal tube. Arrows indicate direction of inspiration and expiration. The valves are indicated by shaded lines. A. Inspiratory valve. B. Expiratory valve. C. Index handle. D. Right-angled slit. P. Proximal end of stop-cock, attaching face-piece. X. Handle turned down; air breathed. X 2. Handle turned up; gas breathed. X 3. Handle turned up and back; gas breathed back and forth into gas bag.

The apparatus may be obtained from the manufacturers, Claudius Ash & Sons, London, England, or 30 East Fourteenth Street, New York City.

AMERICAN.

1. **Pernicious Anemia.**—Dana gives the history of a case of pernicious anemia with decidedly morbid family history. He calls attention to this point and discusses the general pathology of the condition. There was a striking lack of vitality on the part of the generation to which the patient belonged. Out of fourteen children, twelve died in infancy and the other two before the age of forty. There was no evidence of leues, though he says it might have been present.

2. **Gastroptosis.**—Lockwood concludes his article as follows: 1. in the great majority of cases an adequate cause for the gastroptosis is not discoverable; 2, gastroptosis does not of itself, in an uncomplicated form, produce symptoms; 3, the displacement of the stomach, however, is a predisposing cause of a variety of gastric neuroses, of sensation, motion, and secretion; 4. these neuroses are usually induced by some definite mental or physical strain; 5, the displacement of the stomach is a strong exciting cause for muscular atony; that atony is the most common cause for the symptoms presented; 6, a complicating atony is associated with a more or less profound neurasthenia, and that a direct relation exists between these two conditions; 7, gastric acidity is increased in direct proportion to the atony, unless counteracted by gastritis; 8, mild degrees of gastritis are apt to occur in stomachs that are displaced, but the symptoms are neither severe nor persistent; 9, gastritis occurring in atonic and displaced stomachs reduces the excessive acidity of these cases and seems to modify the severity of symptoms; 10, atonic dilatation without mechanical hindrance is exceedingly rare; 11, dilatation, or better, muscular insufficiency, may occur in gastroptosis from duodenal kinking, from arterio-mesenteric constriction, or from pyloric spasm; 12, pyloric spasm is common in displaced atonic stomachs with hyperacidity, and may lead to a temporary dilatation; 13, in a large number of cases, inattention to the conditions of atony, of neuroses, and of gastric secretions has led to an unsuitable, insufficient diet which reacts both on general nutrition and on local conditions within the stomach; and 14, surgical intervention is applicable only to the cases in which dilatation exists.

3.—See abstract in THE JOURNAL of October 27, p. 1104.

4. **Typhoid Fever.**—The treatment of typhoid fever at the New York Hospital, according to Keays, consists in baths to regulate the temperature, sodium bromid, phenacetin, acetanilid and applications of cold to the head if necessary for headache. If sleeplessness is not relieved by baths, trional in 10 to 20 gr. doses, or sodium bromid is used. Delirium, if severe and not otherwise relieved, receives the same treatment. Sodium bicarbonate and myrrh are used for a mouth wash. When nausea is complained of, the food is modified, prepared milk made by adding cerium oxalate, 5 gr. and sodium bicarbonate, 10 gr. to the half pint, or peptonized milk is given. If this is insufficient, gastric sedatives are employed, such as minimum doses

of dilute hydrocyanic acid or small quantities of wine of ipecacuanha. Counter-irritation over the epigastrium sometimes is valuable. Constipation is treated by calomel in small doses followed by saline purgatives. About the second or third week no cathartics are given, but glycerin suppositories or soap-suds enemata are used. In diarrhea, if due to constipation, indicated by small movements, large enemata wash out the lower bowel and relieve it. If it is not due to fecal impaction, mild astringents, such as bismuth subnitrate or tannalin are employed. Distention is generally treated by enemata containing from half a dram to a dram of turpentine. Turpentine stupes are also used. With the baths some cases require no other stimulation, but in others a moderate dose of whiskey should be given, except in alcoholic cases. Brandy may be used if whiskey does not agree. The mild forms of bronchitis which occur are disregarded. If it becomes extensive or troublesome the ordinary remedies are used. The urine is measured during the active stage and a record kept. A specimen of urine is examined every three days unless more frequent examination is required. When the quantity of urine passed is small, the patient should be encouraged to drink more fluids. The ordinary, mild forms of nephritis are disregarded. Intestinal hemorrhage is relieved by quiet, discontinuance of tub baths, alcohol spongings for the temperature and antipyretics. If severe, the foot of the bed is raised, and hot saline enemata of about eight ounces each, are given every three or four hours and stimulation increased. If these are insufficient, hot saline solution is infused. Hot-water bottles are used to keep the temperature up if it falls below normal. If pneumonia supervenes, the treatment is modified only as new symptoms referable to pneumonia arise. In heart failure appropriate treatment is added, the baths are stopped and the temperature reduced if necessary by antipyretics. Phlebitis is treated by keeping the limb as quiet as possible and by the use of 25 per cent. ichthyl ointment along the course of the vein involved. Other measures sometimes used are carbolic dressings, tincture of iodin and lead-and-opium wash. For bed-sores, preventive treatment is employed. Each patient's back, shoulders and hips are rubbed daily with a paste made of zinc oxid, with 50 per cent. alcohol. Reddened areas are protected by dressings and rubber rings, and if necessary the patient is put on a water bed. If bed sores form, the dead tissue is cut away and stimulating dressings of 25 per cent. ichthyl ointment are employed. The routine diet is milk, but if the patient complains of hunger, broth or beef juice is given, and when the temperature has reached normal, more active feeding is begun. Proper mastication of the solid food is urged and the patient's diet is regulated for several weeks. In convalescence the stimulants are cut down as fast as the pulse permits and tonics given if needed, but good feeding and sleep are chiefly relied on. The bowels are kept well open by means of mild cathartics and after about ten days of normal temperature, the patient is allowed to sit up, but if there is any sense of weakness the time is cut short. The time is increased until the patient can sit up eight or ten hours, when he is given his clothes. Exercise is gradually tried, and after about three weeks with normal temperature, the patient is discharged. All utensils used for typhoid patients are marked and used for no one else; the bedding, dejecta and everything are disinfected.

5. **Diet in Typhoid.** Brown's general conclusions are as follows: 1. The bacillus typhosus while the initial is not the preponderating factor in the toxemia. 2. In ordinary cases, the functions of digestion are attended by heat production, which is varied in amount by the kind of food ingested, proteids and carbohydrates giving the least number of heat units while promoting the most effective digestive fluids. 3. The process of digestive secretion is accompanied by a transudation of certain portions of the cell substance in the various glands, which require considerable time for restoration before they are capable of efficient work. Hence we should not feed too often. 4. An inefficient digestion leaves a large residue of food which undergoes fermentation, causes distention, increases the danger of hemorrhage and perforation; also forms a favorable culture-medium for the various bacteria, so increasing the toxemia,

which in turn hastens the disintegration. 5. Milk unprepared is not a liquid food and will take as long to digest as many solid foods.

6.—See abstract in THE JOURNAL of December 1, p. 1426.

8. **Tuberculous Out Patients.**—Dutcher discusses the conditions found in certain sections of Baltimore with especial reference to tuberculosis and its spread. They point, she says, to the rapidity with which the Baltimore houses are becoming centers of infection. During the past year 190 patients were under her observation, who occupied 234 houses. Old tenants moved out and new occupants moved in without any attempt at disinfection. The importance of the education of the public by house-to-house visitation is emphasized.

9. **Early Diagnosis of Tuberculosis.**—After reporting several cases to illustrate the points he makes, Rochester states the symptoms and signs on which he places positive reliance as the diagnostic indications of pulmonary tuberculosis. They are the history of cough or present cough, with or without expectoration, the difference of a degree or more between the highest and lowest temperature of the twenty-four hours, loss of strength, or weight, or both, more or less pronounced anemia, night-sweats though even only occasional, history of present existence or change of cervical lymph-glands and the persistence or development of cough after any of the acute infections. He describes his method of examining the chest when cough or any one of these symptoms, together with dullness, is present; in most cases the right apex is first affected. A slightly lessened movement, diminished expansion and a slight diminution in percussion-resonance are the earliest signs. One of the early signs is a slightly diminished intensity of breathing, particularly during inspiration with prolonged expiratory sound. Increase of vocal resonance and occurrence of expiratory whistling souffle or whispering pectoriloquy, associated with prolonged expiration, if heard in the supraclavicular region, are, he thinks, proof positive of infiltration, and if associated with any two or more previously enumerated symptoms, of tubercular infiltration. Other signs mentioned by him are the transmission of heart sounds to the intracavicular region of the right side, the cardio-respiratory murmur just below the clavicle, and if, in addition to this, there are moist râles, the diagnosis is more sure. He advocates the tuberculin tests in cases requiring still further evidence and does not discourage the value of sputum examinations.

11. **Sanatorium Treatment.**—The results of a recent trip to Europe have been utilized by Solly, who gives some of his experiences. He sums conclusions as follows: Sanatorium treatment is a good thing, particularly when patients are kept in the full air, but that is not quite such a good thing, or as widely applicable, as its advocates believe. It is not the quantity of the air, or the negative virtue of purity, that is alone desirable, but the quality of the air that is also of supreme importance; in other words, climate is of the greatest value, and if equally good hygienic conditions are given to the patient, he who is placed in the climate best suited to his needs is going to improve the quickest, and his disease is more likely to be permanently arrested. The oft-asserted belief of the advocates of home sanatoriums that a tuberculous patient is best cured in his own climate is a fallacy, in the author's opinion. He is cured as much on the mountain top, the wide plain, or the seashore as those erred at home, and no more and no less. There are certain evident economic reasons why home sanatoriums should be encouraged, up to a certain point. Where circumstances permit, however, it is safer to change the air and locality of the consumptive for a time, and by doing so results are brought about much more rapidly and surely than if he remains at home; but, climate without hygiene is but as "sounding brass and a tinkling cymbal."

14. **Sodium Cinnamate in Tuberculosis.**—Mann reports his experience with injections of sodium cinnamate beginning with 1 100 to 1 50 gr. and increasing it up to 1 3 or 1 4 gr rarely exceeding this. The injection should be repeated ever other day and perfect aseptics is essential. The duration of the treatment varies considerably, and he excludes from his report

all cases where the treatment has extended over less than two months. His experience with the drug has been favorable on the whole. He thinks he has had evidence that it quickens to a marked extent the healing processes when they are sluggish or altogether inactive in some, though not in all the cases. On the whole he believes the results have been better than they would have been without the treatment.

15. Stomach Conditions in Early Tuberculosis.—Reed concludes his paper as follows: 1. In early tuberculosis the secretion of HCl in the stomach is very frequently excessive, the peptic glands being in a condition of irritability which causes stimulant remedies of the creosote class to disagree and act injuriously. 2. Oils tend to depress the secretory function of the stomach and in consequence cod-liver oil is likely to help the cases which the creosote class of drugs hurt; but, on the other hand, hurts the cases in which the gastric secretion is inactive, the very ones in which creosote and the like often do good. 3. It ought to be the rule to ascertain the condition of the secretory function of the stomach before pushing either class of remedies. 4. When analysis of the gastric contents cannot be made, it is safer to combine creosote with cod-liver oil, so as to let one neutralize the other in their influence on the stomach. 5. The motor function is very generally depressed in tuberculosis and must be restored before a cure can be brought about. Drugs avail little in this direction, but diet, exercise, especially in the open air, faradism and abdominal massage—except when hyperchlorhydria complicates—are all valuable means of effecting the result.

19.—See abstract in THE JOURNAL of September 1, p. 579.

22. Bacteriology and Medicine.—While not disparaging the value of modern research in medicine, Robinson insists on greater attention to practical clinical studies and points out what he considers the errors that have been committed by too much attention to laboratory methods and bacterial research. He thinks the time has come when we should cry out against the too exclusive theory of disease. The germ theory is mighty and has prevailed up to the present time, but he does not wish to confess that it is universally applicable and that there are not other side-lights bearing upon the point. The etiology and prophylaxis of the disease demand our careful examination. We should always recognize and consider the patient himself as far more important than the disease. The clinician should rank foremost, not the bacteriologist.

31. Pancreatitis.—Lund gives the general results of six cases of pancreatitis in patients between 30 and 50 years of age, 5 of which were in women, 4 having also gall-stones. In no case was a definite diagnosis made, and operation was performed in 5, with one recovery. Of the deaths, one occurred two months after the operation from inadequate drainage, two from shock, and operation was declined by the surgeon in one non-operated case on account of the poor condition of the patient. Two of the cases would be properly classed as periancreatitis, and one as necrosis of the entire pancreas following undoubtedly upon hemorrhagic pancreatitis. Case 5 was a localized necrosis of the pancreas resulting in abscess. As regards diagnosis, he thinks the pain is not quite so sharp as a perforated gastric ulcer and the moderate tenderness on deep pressure is as characteristic in pancreatitis, as is acute pain in light pressure in gastric ulcer. In all cases there was a sense of fullness of the stomach as of tumor. Muscular spasm was not so marked as in perforating gastric ulcer or acute appendicitis. An absolute diagnosis is generally impossible. Mild cases will recover both with and without operation. Severe cases require early operation for the following reasons: 1, because the primary hemorrhage in itself leads to necrosis and disintegration of gland tissue, and hemorrhages may be topped, and necrosis prevented by gauze packing and drainage, and 2, because the patient is in a better condition to withstand operation early than later, when the disease is more advanced. In a certain class of cases, the primary shock may be so severe as to render operation out of the question. He thinks the mortality should be considerably diminished with early operation and adequate provision for lumbar drainage. The first exploratory incision should be made in the median line above

the umbilicus and where the mass of blood clot or the abscess cavity extends into the left lumbar region, an incision must be made upon the finger passed into the cavity to afford drainage. In symptoms pointing to pocketing of pus above the spleen, the subphrenic space should be drained by resecting the tenth or eleventh rib in the posterior axillary line. The pleural cavity will be opened, but probably will be walled-off by adhesions. At any rate drainage of this pocket is essential in order to avoid perforation of the diaphragm by the abscess as happened in one of these cases. Care in diagnosis, rapid operative procedure, and careful nursing are necessary, as the proximity of the inflammatory process to the solar plexus and other important organs makes inflammation of the pancreas dangerous and difficult to treat.

32. Gastric Hyperacidity.—The treatment adopted by Illeves for hyperacidity of the stomach is described by him as follows: The patient is given a diet of a caloric worth sufficient for the weight and conditions containing as high proportion of proteid foods as comfortable for the patient. (In his experience the average patient with stomach trouble is eating less than half of a sufficient diet.) This diet is separated into six daily meals, the constituents of each meal, with some alternative choice, being prescribed. The treatment tends to use up the acid secreted and facilitates the motor function. Starches should be limited, and of carbohydrate foods sugars or predigested starches, dextrinized flours, as *Avena* flour or Horlick's food, used as much as possible, since starch digestion in the stomach is impeded in these cases. For all symptoms of disorder, as distress or eructations, some proteid, as a raw egg, is to be taken. An alkali, bicarbonate of soda in half-teaspoonful doses, or 15 grains of magnesium hydrate, may be taken in addition to food or in place of it for the relief of symptoms. In some cases large amounts of alkali, 3 drams bicarbonate of soda, must be used in the twenty-four hours. Three pints of water are prescribed to be taken in small amounts at a time throughout the day. In addition, general rules in regard to bath, exercise, the bowels, the work, and general manner of living are laid down in writing. Debility must be treated by tonics. *Nux vomica* is a most useful agent here to improve the tone of the system and thus also perhaps the motor capacity of the stomach. Where anemia is present by blood tests, iron should be given. Chlorosis is not infrequently associated with hyperacidity. After an administration of iron with the regular régime for a few weeks, these cases as a rule lose all symptoms of hyperacidity even with cessation of treatment. There is little doubt that it is a similar improvement in nutrition which accompanies the increased diet, and good régime and freedom from nerve disturbances which ensure the cure in a majority of all the cases. The exact details of course differ with the cases, some are intermittent with no need of local treatment except during the period of attack while the general régime should be employed constantly to prevent recurrence. He finds the treatment gives excellent results in most cases. Less than 10 per cent. returned without relief and in these obstinate cases lavage often was found a useful adjunct.

33. Subperiosteal Fractures.—Cotton reports a number of cases in which he finds subperiosteal fractures differing from the ordinary green-stick type, the fracture being directly across the bone which was held in position by the intact periosteum. He says in conclusion: It seems that fractures in children showing no deformity and no appreciable mobility are not uncommon; that they might be readily overlooked; that they often need no reduction, having no deformity; that they repair with callus and quickly.

34. Irritable Breasts.—Cabot calls attention to the form of tumor occasionally seen in breasts, which correspond to the description of irritable breasts given in the old text-books of surgery. He thinks the condition lies rather on the borderline of medicine and surgery. The nature of the tumor is not definitely proved and he asks whether there is not any possibility that, in some of these cases, the accumulation might not be a galactocele, also whether it is possible or likely that these lumps are physiological. As to the prognosis, the question is

to be settled whether or not they become cancerous as some writers seem to think, and whether they should be operated on is also a matter of disagreement. The majority recommend potassium iodid internally with acetate of lead ointment externally and attention to the general condition. His paper seems to be mainly questions in regard to the different features and theories of this condition.

36. Appendicitis.—Bunts favors early operation in cases recognized as appendicitis and with moderate severity of symptoms. He thinks that this is better than waiting to operate between the attacks, for no one can tell what the result of the attack will be. In cases of great urgency and intensity of symptoms, the operation should be at the earliest possible moment. In cases not recognized as appendicitis for several days, he also thinks operation is indicated, though it may not be so urgently demanded. The white-blood count may be a guide in these cases as to the progress or diminution of the inflammation. If the former, operate; if the latter, delay is permissible. In cases recognized as appendicitis, but which have begun to abate before the physician sees them, he would advise against operation and would operate after the subsidence of the attack, when a few weeks of convalescence and recuperation have put the patient in a better condition to withstand the slight shock. He does not advise operating in all cases that have reached the interval. If the preceding attack has been a severe one, he urges it or if the patient has to go where it would be impossible to get operative relief in case of another recurrence, or is not sufficiently intelligent to be trusted as regards his case; but if he is intelligent, can obtain medical aid at any time and will agree to submit to an operation when needed, he does not insist because there may never be another attack. In cases in which delay has resulted in general peritonitis and septicemia, he has been tempted to say that operation is hopeless, as the chances are that the surgeon will get the credit of killing his patient, yet he does not say positively that he would follow that course.

39. Hemorrhoids.—Eliot described his operation as follows: Opposite the base of the hemorrhoid, parallel with and corresponding to the muco-cutaneous junction, a curved incision is made and carried upward in the same plane as in a Whitehead operation beneath the pile-bearing area until the base of the hemorrhoid is reached. A second curved incision is then made in and through the mucous membrane, forming an ellipse with the first-mentioned incision, and including within this ellipse any area of ulceration at the base of the hemorrhoid that may have developed as a result of the irritation to which the exposed surface of the mucous membrane overlying the hemorrhoid is subjected. From the junction of the two curved incisions, that is, from each pole of the ellipse, an incision is carried vertically upward through the mucous membrane only and the resulting quadrangular flap of mucous membrane is reflected from the surface of the underlying hemorrhoidal area, having its base of blood-supply superiorly. After the dissection of this flap of mucous membrane, the same vertical incision is deepened through the hemorrhoidal tissue proper, the resulting hemorrhage being slight, owing to the direction of the incision, thus forming a rectangular mass of hemorrhoidal tissue which is transected at its base with stout catgut—if necessary with chromized gut; the ligatures are then tied tightly and the hemorrhoidal mass removed. The rectangular flap of mucous membrane is then stitched to the skin, and the retention of any discharge prevented by cutting the catgut ligature long and allowing the ends to protrude below between the sutures, thus acting as a drain. This same procedure is repeated in not more than two other places where the development of the hemorrhoids is most pronounced. At the conclusion of the operation, a dressing of sterile gauze is placed over the suture line, a large tube, surrounded by iodoform gauze having been previously introduced upward into the lumen of the gut to facilitate the exit of any gas or of accumulated fecal material. The advantages of the operation are that it produces prompt union and permits the complete excision of all areas of ulceration at the base of the hemorrhoids and lessens the possibility of future infection.

40. Squint in Children.—Veasey operates in all cases where proper glasses and orthopedic exercise fail to cure up to the age of about 6 years. The operation used consists of a tenotomy of one muscle or advancement of its opponent or both. If the defect is convergent a small amount of residual squint should be allowed to remain and in divergent squint it is better to produce a very slight convergence.

51. Carbonic Acid Gas Per Rectum in Pertussis.—Kerr reports a number of cases in which this method of treatment of whooping-cough was employed and describes the technique. He used a rubber tube with a hard-rubber nozzle, similar to those employed for rectal injections, connected with a bottle in which carbonic acid gas was generated for from about five to ten minutes, two or three treatments daily being sufficient, preferably between meals. The administration of the gas appeared to check the number and severity of the paroxysms very decidedly. The only effect noticed was a tendency to diarrhea which he attributed to mechanical irritation. In all but one there was a certain amount of eutaneous flushing after each séance. The duration of the disease itself was uninfluenced.

58. Autoinfection.—This article by Johnson calls attention to the possibilities of derangement of the nervous centers and other organs through autoinfection from the intestines, especially in infants.

59. Membranous Anginas.—After mentioning several cases Bissell concludes his article as follows: 1. The streptococcus pyogenes and the micrococcus of sputum septicemia can produce membranous anginas, accompanied by physical disturbances sufficient to result in death. 2. The *oidium albicans* produces pseudo-membranous exudates easily mistaken for a Klebs-Loeffer inflammation. 3. The only positive means of determining a Klebs-Loeffer infection is by microscopic means. 4. From the sanitary standpoint as regards quarantine, anginas due to the streptococcus pyogenes, micrococcus of sputum septicemia and the *oidium albicans*, require little consideration.

60. The Longevity of the Gonococcus.—The case reported here by Ruggles is of interest on account of the persistence of the gonococcus for more than ten years in the absence of all suspicious coitus. The man had been married nine years and had no trouble from his former complaint, but a dissipation with alcoholics and beer brought on an attack which microscopically revealed the microbe. The author holds that in view of these facts the gravity of the condition should be recognized and great scientific care should be taken in every case to prevent the suffering of the innocent.

61. Blood Examinations.—The methods of blood examination and their deficiencies are noticed by Matzinger, who points out that with the present methods the mere count of reds, the estimation of hemoglobin at arbitrary times without careful consideration of the many factors which may influence them, is little better if not worse than useless. We must notice the effect of the different hourly and daily physical conditions in estimating the relation between corpuscles and plasma, chromocytes and leucocytes, and perhaps chromocytes and hemoglobin. The ordinary limits of variation must be first established before disease limits of any practical value can be laid down. The mechanical difficulties are also noticed. The necessity of greater accuracy and of giving ample time to the blood-count is shown. He prefers the Oliver hemocytometer for ordinary use and calls attention to the personal error in the use of any of these instruments. He believes, however, that any careful, unbiased physician, no matter how busy, who possesses a little knack in handling instruments and the ordinary amount of patience, can get very useful information in at least all chronic diseases and disorders associated with fever. A specific gravity outfit for hemoglobin, the Oliver tintometer or hemocytometer and a box of cover-slips with a microscope are all that is required for good work, if he will remember that digestion, vasomotor disturbances, exercise, position and last but not least, individual peculiarities, etc., have to be considered when interpreting the findings.

63. **Lay Medical Education.**—Bonning holds that the laity should be instructed in medical matters, that the principles of biology should be taught in schools, also the general facts in regard to contagion and infection and that special lectures on reproduction, etc., should be given to advanced classes. There should also be medical lectures in the community to educate the public as to the curable and incurable diseases and the proper means within their power of meeting these. He holds we ought to educate the public not to be guided by gossiping friends, but to consider every worthy and educated physician as a confidential adviser.

65. **Significance of Reflexes.**—The general subject of reflexes in diagnosis and prognosis is reviewed by Neff, who goes over all the facts and sums up as follows: 1. The examination of the more important reflexes is a matter of practical value to the physician. 2. In order to appreciate the diagnostic and prognostic value of the reflexes, a knowledge of their behavior in health is essential. 3. A certain technique is always indicated, otherwise wrong inferences may result. 4. When examining reflexes for diseases undue importance should never be attached to an alteration in a single reflex. 5. Certain definite changes in reflexes are suggestive and at times pathognomonic. Such modifications should be considered with the syndrome of the suspected disease.

66. **Purulent Pleurisy.**—Miner reviews the methods of treatment of empyema and describes the operations, especially thoracotomy by simple incision and thoracotomy with rib-resection, which is the operation in favor in adults in this country; thoracoplasty as a sort of last resort is also mentioned.

67. **Metabolism and Nutrition.**—The article by Breischer is long and can not be abstracted in detail. He gives the results of experiments on himself with special diet and reiterates the views expressed by himself in earlier papers regarding the advisability of adopting a minimum quantity of albumin to nourish the human individual.

71. **Mitral Insufficiency.**—Robison describes the symptoms in mitral insufficiency and suggests the following as therapeutic needs in the condition: 1. Proper heart nutrition, by diet, rest, massage, Schott baths, and mental rest; 2, proper innervation, by strychnia, oxygen, fresh air and sunshine; 3. regular muscular action, by digitalis—the remedy par excellence—and other cardiac tonics, and 4, the relief of suffering in the latter stages, by securing diuresis by calomel, digitalis and diuretics and removal of fluid of ascites, hydrothorax, etc.

78. **Hepatic Cirrhosis.**—From a study of the tissue formation in cases of cirrhosis of the liver, Flexner comes to the following conclusions: 1. In all forms of cirrhosis the white fibrous tissue is increased. 2. Along with the increase of white fibrous tissue there is a new formation of elastic tissue, which is derived from pre-existing tissue in the adventitia of blood-vessels and the hepatic capsules. 3. Both white fibrous tissue and elastic tissue, in all forms of cirrhosis, may penetrate into the lobules. This penetration takes place along the line of capillary walls or follows the architecture of the reticulum. The chief distinctions between the histology of atrophic and hypertrophic cirrhosis depend upon the degree of extralobular growth and the freedom with which the lobules are invaded. In hypertrophic cirrhosis there would appear to be less interlobular growth and an earlier and finer intralobular growth. 4. The alterations in the reticulum, per se, consist, as far as can be made out at present, of hypertrophy rather than hyperplasia of the fibers. It is still uncertain whether any of the differential methods now in use suffice to distinguish between the reticulum and certain fibers derived from the white fibrous tissue of the periphery of the lobules.

80. **The Justus Test in Syphilis.**—This blood reaction is based upon the following proposition: Mercury destroys the hemoglobin of the blood. In non-syphilitic the organism promptly replaces the lost pigment, while in syphilitic patients it can not at once restore the still further reduction caused by mercury, hence the first examination after inoculation or injection

of mercury will show a distinct fall of from 10 to 20 per cent., which, as treatment is continued, is followed by a steady rise to the normal. Christian and Foerster conclude that to properly estimate the value of this test we should find out whether it occurs in syphilis only and not in any other disease and they give the results of experiments and examinations which cover some 29 cases; in 16 a reduction of the hemoglobin occurred, no change in 6 cases, increase of hemoglobin in 7 cases. In 6 cases where a decrease is noted the fall being 5 per cent. or under, the results were practically negative. In the remaining 10 cases where a positive reduction was noted they found it occurred in 3 cases of active secondary syphilis where no test was needed to make the diagnosis complete. In 2 cases there was a fall in the hemoglobin prior to the appearance of the rash. This might have led them to infer that the test had some real value in the differentiation between chancre and chancreoid were it not for the results obtained in two other cases both undoubtedly cases of chancreoid where the fall also occurred and in one of which it was the most marked in the whole series. In 6 cases no change whatever in the hemoglobin took place, and in 3 of these the disease was very active, the eruption profuse, and in one of a pernicious and malignant type. In tertiary syphilis with tubercular lesions, or latent ones, with no lesion to be seen, the results were entirely negative or showed some slight increase. No appreciable change was noticed in any of the control-cases save in one instance, a case of sexual neurasthenia, where there was a fall of 18 per cent. As regards the value of the test the investigation leads the authors to the following conclusions: 1. that in the diagnosis of doubtful ulcers it is of no value; 2. that it seems to occur in a certain proportion of cases of acute secondary syphilis, where it appears to be a symptom of the disease and can in no sense be considered a true test, as the diagnosis in such cases is already complete, and 3. that as a test it is unreliable.

81. **Tuberculosis.**—Ravenel has investigated the possibility of the conveyance of contagion of tuberculosis by cattle in the act of coughing. He used the ordinary nose-bag, near the bottom of which was placed a shelf of soft pine wood sterilized by steam heat each time before using. In this way he was able to collect whatever was ejected in coughing by the cow, the more solid particles being easily removed and examined under the microscope. He was thus able to detect tubercle bacillus in every tuberculous cow in which it was tried. What might be theoretically expected was practically demonstrated, viz., that the cow, as well as man, atomizes its sputum and projects it into the air in minute quantities which may float for a considerable period of time. Specimens collected in this way were used in inoculating experiments in guinea-pigs and a considerable proportion of positive results obtained, even when the bacilli could not be demonstrated. In 34 examinations carried out in 5 different tuberculous animals, the bacilli were detected 20 times. By the means of a special nose-bag, guinea-pigs were also exposed to the breath of cows in whose sputum tubercle bacilli had been found, for periods of two hours or more at different intervals. The animals were killed after several weeks, but no evidence of tuberculosis was found in them.

82. **Plague in Manila.**—Robinson gives the results of personal observation on bubonic plague in Manila. He remarks that it is not dreaded in the Orient as it is in the West, and that Europeans seem little liable to it. Plague has been known to exist in Hongkong for the past five years and in this time but two cases have occurred in Europeans, and both of these could be directly traced to cohabitation with Chinese. The first cases of plague were discovered in Manila on December 29, 1899, and prompt and efficient measures were instituted, notwithstanding the opposition of the natives. The results of these were soon apparent, as the epidemic was well in hand in two weeks.

83. **Renaut's Bodies.**—Spiller reports the finding, in a peculiar case of vesiculobullous dermatitis and gangrene described more fully elsewhere, of the structures in the nerve bundles of the brachial plexus which were doubtless the formations de-

scribed by Renault in 1881 and later by other writers, and which have since been known under the name of Renault's bodies. These are not so well known as desirable, and there is some danger that they may be regarded as new and unrecognized forms of degeneration of the nerve. He is not able to make definite statements in regard to their function, but thinks there is little evidence that they are intended for the protection of nerve fibers, as has been held by some observers. These bodies are formed of delicate wavy bands of connective tissue arranged concentrically in a transverse section of a nerve, and, in the main, longitudinally, though in some places transversely, in a longitudinal section. They contain a few oval nuclei also arranged concentrically in transverse sections. A nucleus is usually within one of the bands of the wavy connective tissue. A central homogeneous mass is not very distinct in his preparations. In longitudinal sections of a nerve, Renault's bodies are much longer than broad, and sometimes spindle-shaped. He has not been able to observe anything resembling a nerve or vessel in the center of any of them. They are usually at the periphery of the nerve body, but may be in the center, and, while generally round in transverse sections, are not always so. They are always sharply separated from surrounding nerve fibers, and this is one indication that probably they are not degenerated tissue. He has also found the peculiar cells discovered by Langhans and named by him "one and more chambered bladder-cells" which are of various forms and contain many dividing septa, one to three nuclei near together. These are very irregular in shape and the cell body is unstained in his specimens excepting in the dividing septa.

85. **Forceps Delivery.**—Bentley favors the use of forceps. In his last 100 cases he has used them in 35 and would have used them in more but for the prejudice of the patients. If the forceps are applied well over the head and traction is made in the right direction they will not slip. He does not think that the axis-traction forceps are indispensable. All that is necessary is instruction as to the correct axis in which to direct traction, which can be done with the ordinary forceps, while the tendency of the fetal head to rotate can not be so well favored by axis-traction forceps. As regards occipito-posterior positions he has seldom made the diagnosis before rupture of the membranes, and after that it is useless to attempt to alter the position excepting by the slight means we have of imitating the natural course of rotation of the occiput forward, and this, in his opinion, can be done better with the ordinary forceps than with anything else. In five years he has delivered ten cases with face to the pubis, two of these primipara and was successful in every case but one, which he attributed to the incompetency of the would-be nurse, from whom he had no help whatever. He has had but a few superficial tears, which as a rule required only one stitch, and never more than two. He attributes his success to: 1, treating each case on its own merits; 2, relaxing the central portion of the perineum at the expense of the outer sides, and 3, keeping perfectly cool and being in no hurry. The infants have usually required artificial respiration and other usual means of resuscitation.

91. **Opium in India.**—Dawbarn gives the substance of a conversation in regard to opium in India with Rudyard Kipling, who believes that it is not damaging to the natives of India, that it is useful to some of them in protecting them from malaria on account of the narcotino contained, and is also a tonic as used there. He also criticizes the missionaries and clergymen who condemn the opium business in India, overlooking home evils. Dawbarn is careful to say these statements are Kipling's, not his own. In conclusion he notices a description of the preparation of opium, one phase of which is the moistening of the material with saliva, which he thinks ought to go far to prevent if not to cure the opium habit.

92. **Lavage.**—Musser calls attention to the abuse of lavage when left in the patient's hands and says that not 5 per cent. of the cases of gastric disease under his care have required it. If he employs it, he prefers to do it himself or have a medical man to do it. To allow patients to do it soon develops in them a habit.

100. **Ichthoform.**—This substance, a compound of ichthylol and formaldehyde is here reported on by Aufrecht, who tested its powers on serum and gelatin cultures and on fresh meat and found it exceedingly disinfectant. He thinks, therefore, that it will be a very valuable local application to wounds. A number of experiments were made on animals to determine its toxic properties, giving an initial dose of 1.5 gr. increasing it until the guinea-pigs received as much as 12 gr. Two of the six guinea-pigs experimented on died, but showed no special signs of any poisoning by ichthoform. The heart, spleen, liver and intestines were perfectly normal. The control experiments made with iodoform showed that death was caused by 3 gr. doses with marked engorgement of the heart. In rabbits as much as 25 or 30 gr. were given apparently without affecting the health of the animals; 46 gr. produced temporary toxic symptoms. In one patient as much as 4 gr. of ichthoform were given daily in a case of chronic intestinal catarrh without apparent bad effects and with a decided decrease in the indican and the sulphate excretions. He thinks that its use is indicated in cases where there is an increase of elimination of ethyl-sulphuric acid, in acute intestinal fermentation, stasis of intestinal contents, intussusception, diffuse peritonitis with atony of the intestines and in tubercular enteritis. He believes it to be a relatively non-toxic substance, surpassing iodoform and analogous antiseptics and that it is an intestinal disinfectant of the first order and yet wholly or practically odorless and tasteless.

101. **Myrtol.**—Solis-Cohen has employed this drug, which is obtained from myrtle oil by fractional distillation and is probably a combined substance containing special constituents not yet separated, some sedative, some stimulative. It is an oily liquid of slightly yellow tint, pungent taste and characteristic odor. Like all substances of this class it is eliminated by the mucous membranes and by those of the bronchial and genito-urinary tracts particularly, hence it has been employed in disorders of the bronchial mucous membranes and those of the bladder and urethra. Linarix records a number of cases of gleet and gonorrhoea and cystitis in which treatment with myrtol was very successful after the other remedies had failed. He sometimes combines it with other drugs such as salol and methylene blue with sandalwood oil, etc. Cohen's own experience with myrtol has been favorable. The best results have been in obstinate cases of bronchorrhea, dilated bronchi, fibroid tuberculosis, with bronchietatic cavities and in bronchitic asthma. In all these cases there have been failures as well as successes, but myrtol seems to have the power in most cases of promoting healthful, and diminishing unhealthy secretions. In most cases of asthma in which paroxysms seem to be brought about by the effort to dislodge secretions not sufficiently moist to be easily expectorated, myrtol seemed to increase the ease of expectoration while later it diminishes its frequency and quantity. He gives several illustrations of his results and remarks that he has called attention to it not as a miracle-working substance, but as one of a number of drugs belonging to a useful group to which we can resort from time to time with the hope of accomplishing much good. Its influence in suppressing cough is decidedly marked and it should be given always in those cases of chronic or subacute inflammations of the respiratory or urinary tract in which eucalyptol, sandalwood oil, terebene, and turpentin for one reason or another have failed or seem undesirable. He has not found it produce stranguity in any case. The dose is about the same as that of turpentin, terebene, or sandalwood oil, which is 5 to 15 min. given from two to five times in the course of twenty-four hours. When combined it may be given in emulsion, dropped on sugar or given in sealed capsules—in other words, it is handled just the same as turpentin. Other disorders mentioned by other authorities are leucorrhoea, uterine ulcers, wounds, skin affections, dysentery, hemorrhoids, sore throat, conjunctivitis and diabetes. Cohen's experience, however has been purely with its use in affections of the respiratory tract in which he has employed it more and more satisfactorily.

102. **Euquinin.**—Bernheim has employed euquinin, the carbonic ether of quinin, which is not a mixture but a definite chemical compound with a melting-point at 95 C. and soluble in alcohol, ether, chloroform, solutions of hydrochloric acid, ferric chlorid, and vinegar. The bitter taste is less marked than in quinin and may be covered easily by syrup or flavoring oil. He has used it in malarial fever, neuralgia, angina, cold in the head, influenza, rheumatic pain, whooping-cough, anemias, and gastrointestinal disorders in thirty-five cases altogether. He finds its effects similar to quinin in malaria, though a little more prompt perhaps and a smaller dose is required. In whooping-cough the attacks appear less frequent and severe. In other disorders the effect was similar to other antipyretics and anti-neuralgics, though smaller doses were required. The ringing in the ears and gastric disorders were less than with quinin. In no case did he see any unpleasant by-effects and thinks it may well replace other quiniins.

104.—This article has appeared elsewhere. See *THE JOURNAL* of October 27, '98, p. 1115.

116. **Curability of the Insane.**—Everts remarks on the opinion extant about thirty years ago, that 80 or 90 per cent. of these cases of insanity were curable if intelligently treated. His experience has led him to conclude that this was a grand mistake. The mid-century specialists in psychiatry erred because they were ignorant of the biologic sciences and they concluded that as nearly all diseases were amenable to treatment, therefore insanity should be. About one case in three of insanity is liable to recover, because not all diseases of the brain are degenerative. The value of asylum treatment or any treatment of insanity is practically to prevent such curable diseases from becoming chronic and incurable.

British Medical Journal, November 24.

Some of the Sequelae of Cranial Injuries. ERNEST TREDNICK.—The author has collected a number of cases of cranial injury including 6 chiefly of the frontal bone in which there were moral perversions produced and 8 of skull injury causing traumatic dementia, 1 of diabetes following brain trauma, and 1 of epilepsy relieved by trephining. He also has collected from various sources 45 other cases of traumatic epilepsy in which the injury ranged from laceration of the brain substance and hernia cerebri to simple concussion. In 33 cases the injury was parietal; in 8, frontal; 2, mastoid; 1, vertex, and 1, occipital. The unconsciousness after injury ranged from a few minutes to several days. Epilepsy appeared at periods from immediately after the accident to eleven years. Twenty-four of the cases in which the injury was parietal were operated on; in 1 with no results; in 1, fits recurred; in 1, one fit occurred a year; in one, comparative recovery; three died and the remainder completely recovered. Of the 9 cases which were not operated on 5 died, 1 was cured, and in 3 the epilepsy continued. In 7 cases of frontal injury operated on, 4 recovered, 1 improved but died, and another treated with potassium bromid died, and 1 not operated on also died. He thinks these results show the value of trephining when the injury to the cranium has occurred, and would advise careful examination in old cases of epilepsy to see if any old scar exists. His paper is defective in that it does not give the time that had elapsed since the patients have been under observation in the so-called recoveries.

An Epidemic of Peripheral Neuritis Among Beer Drinkers in Manchester and District. ERNEST SEPTIMUS REYNOLDS.—Reynolds has investigated the beer-drinkers' disease recently occurring in Manchester, England. The symptoms seem to show an epidemic of peripheral neuritis involving the sensory, vasomotor and motor nerves associated with running of the eyes and nose in many cases and marked lesions of the skin, such as erythema and erythromelalgia, blisters, keratitis, etc.; there were also symptoms of paralysis. Such an epidemic has never occurred in the district for the last twenty-two years to his personal knowledge and at present is met with only in the beer and porter drinkers. It is something like the ordinary alcoholic paralysis at first sight, but differs from it in the great amount of sensory and vasomotor disturbances,

and especially in the peculiar skin lesions which are not present in the ordinary alcoholic paralysis. So far as known, there are only three causes of peripheral neuritis of the type mentioned and associated with marked tenderness on pressure of the muscles; they are beri-beri, alcohol and arsenic. The former will not explain the lesions of the skin and against alcohol is the fact that the features of this epidemic are something new and beer-drinking is not a new thing in the district. He found on November 18, a considerable amount of arsenic in certain beer used in the district and confirmed the observation next day and has Prof. Dixon Mann's authority for stating that he has also found arsenic in a different sample. He believes that the source of the arsenic will be found in the sulphuric acid used in the hop industry.

The Lancet, November 24.

Mouth-Breathing and Its Relations to Diseases of the Throat, Ear, Nose and Accessory Cavities. MAYO COLLIER.—The writer here describes the effects of mouth-breathing. He first speaks of the anatomy of the respiratory passages and the physiology of the act of breathing, and then says that the pathologic effect of mouth-breathing is catarrh of the larynx and pharynx, with cough. He asks whether there are not other effects, and maintains that there are. The dilator muscles of the nose are put functionally out of use and in mouth-breathers there is a marked pinched depression in the alae of the nose which is diagnostic of the condition, and gives a sharp and pinched expression to the features. The air in normal breathing through the nose abstracts part of the contents of the nasal pharynx and nasal chambers, which is rapidly repaid and tension equilibrated. In mouth-breathing this fails, and the result is a general redness of the mucosa of the nose from unsupported intravascular pressure. The abstraction of small quantities of air from its nasal chambers and the nasal space by the stream of air on its way to the lungs via the mouth, if not instantly compensated by a corresponding inflow of outside air via the anterior nares will cause a lessening of the tension of the air in the nose and accessory cavities. This lessening tension will be responded to by the lining membrane of the nose and accessory cavities as a general redness or flushing of the parts, and this will occur in direct proportion to the degree of rarefaction. On the recognition of this fundamental fact rests, in his opinion, the whole science and treatment of the throat, ear, nose and accessory cavities. If mouth-breathing is persisted in, even in the hypothetical conditions of a healthy and patent nose it would ultimately induce anterior nasal obstruction from atrophy following disuse of the nose-valve. This will be followed by swelling of the lining membrane of the nose and accessory cavities from vascular dilatation. This again would lessen the cavities of the nasal respiratory tract and tend to set up nasal obstruction. A vicious cycle is set up. Mouth-breathing tends to obstruct the nose, and this very obstruction maintains and continues the mouth-breathing. The turbinal body is the most functionally-active organ in the whole system. It is calculated that two quarts of water a day are given up to inspired air by this body and the lining of the nasal tract and that all the air that enters the larynx, no matter what the outside temperature may be, is warmed to near the body temperature. This important function, therefore, is put out of use. He explains how a mouth-breather may breathe normally during the day, but soon after he places his head upon a pillow, the nose is blocked, and explains this by the loss of tone of the turbinal bodies with or without hyperplasia. The effect of changing from the upright to the prone position obstructs the nostril and dilatation of the turbinal body in the lowered nostril. He finds that the effects of atrophy and dilatation of the turbinate bodies are not limited to the respiratory tract, but involve also the cavities and chambers which connect with the nose and nasopharynx. Affections of the ethmoidal, sphenoidal, and maxillary sinuses may be originated or kept up by obstructive conditions of the nose, and sometimes total obstruction is produced. Deafness will be produced by blocking of the nose, and treatment directed to restore the patency of the nose will restore the patency of the Eustachian tube. He maintains that the key to the prevention and treatment of diseases of the ac-

cessory cavities of the nose including the tympanic cavity is to maintain the natural physiologic condition and see that its respiratory capacity is sufficient readily to equilibrate the air in the respiratory tract during respiration. He maintains, moreover that this condition of chronic turbinal distension and hypertrophy has a tendency to produce unsymmetrical upper jaw, high-arched palates, prominent nose, open mouth and a thin, flattened face. He has seen many children with beautifully-formed faces, symmetrical dental arches, and perfect nasal respiration, become in after-life quite altered. He also mentions the effect on the general health which is noticed in children affected with post-nasal growths or enlarged tonsils. He thinks that in these cases want of proper oxygenation at night is the probable cause of the altered and damaged complexion. Whatever be the explanation, it is our common experience that if the nasal respiration be restored, and nose and throat trouble cured, the patient speedily returns to health.

Ichthylol and its Uses in Some Skin Diseases. ALEXANDER BROWNLEE.—The writer's experience with ichthylol leads him to say that from 2 per cent. to 5 per cent. ichthylol applications are best in acute forms of inflamed skins, and from 5 per cent. to 10 per cent. in more chronic drier conditions. In acne vulgaris anything between 10 per cent. and 25 per cent. is useful. In all cases the internal administration of the drug is an assistance. He believes that ichthylol taken internally has a direct influence on the skin and is most probably excreted by it. Moreover, the taking of ichthylol increases weight, and this applies more particularly to weakly, strumous children. The one disappointment which he records is that itching is not relieved as quickly as one might expect, certainly not as quickly as the pain is relieved. Patients express gratitude for the feeling of comfort experienced, but itching soon returns. The pruritus does indeed disappear after a time, but it is always the last symptom to go. In prurigo and pruritus vulvæ or ani he has not found much benefit to result from the use of ichthylol, particularly in those cases where there is no organic cause, such as diabetes, ulcus cervicis or anal fissure. He has tried ichthylol in eleven such cases, and in only one has he had satisfactory results, in a case of pregnancy with pruritus vulvæ. When prescribing ointments, he always advises patients to use their oldest under-linen, as ichthylol has a staining effect, although it is stated that if quickly washed in warm water any clothing thus stained is made quite clean again. Ichthylol, of course, is not applicable to every case of eczema or acne, neither does he claim for it a specific action, but it is undoubtedly a useful drug in these diseases.

Fourteen and One Half Hours' Artificial Respiration in a Child One Week Old: Recovery. GEORGE E. KEITH.—The case of a child one week old is reported, which was operated on for phimosus under chloroform, passed into a cyanosed condition and required fourteen hours of steady application of artificial respiration together with very active stimulation with brandy and came through all successfully without apparent damage.

Bulletin de l'Académie de Médecine (Paris), November 13.

Intravascular Pressure.—An important monograph received by the Academy in competition for the Pourat prize suggests an improvement for volumetric apparatus such as Mosso's plethysmograph. Instead of the mercury U-tube, a registering sphygmoscope records the differences in amplitude and variations in pressure. To obtain the numerical value of the pressure it is only necessary to attach a compensating manometer to the sphygmoscope. The anonymous writer also describes an apparatus for determination of the intravascular pressure by means of the fingers. It consists of two cylindrical metal U tubes, connected by a rubber tube, and also attached to a T-tube. The free branch of the latter communicates with a lever which records the tracings on a revolving cylinder. A very elastic rubber cot, like the finger of a glove, is fastened in each end of the two cylindrical tubes and in them the index and middle fingers of each hand are inserted. By this combination of four fingers a distinct, strong pulse-beat can be registered on the drum. The small apparatus is fastened by

a standard to the table and accurately records the vasomotor variations or oscillations in the peripheral capillary system.

Bull. de la Soc. Med. des Hop. de Paris, November 15.

Pulmonary Embolism and Tardy Phlebitic Symptoms. P. MERKLEN.—Phlebitis originating in an embolism is usually less serious than ordinary phlebitis, but Merklen reports two fatal cases. He distinguishes between resolving and obliterating phlebitis. Pulmonary embolism of phlebitic origin is apt to occur by the third and fourth week. Barth classifies phlebitis according to the reaction of the vein. When there is no reaction the phlebitis may terminate suddenly by the sweeping away of the obstruction with danger of embolism. On the other hand, the phlebitis may linger and terminate incompletely, but the formation of intravenous adhesions in this case rapidly obviates the danger of embolism. Hagopoff prevents phlegmasia alba in parturients by raising the lower limbs at an angle of 20 degrees. If there is fever he increases the angle to 50 degrees for fifteen days, and if there are evidences of varices he supplements this measure by alcohol frictions morning and night. Massage in phlebitis is dangerous until three or four weeks have passed after the slightest temperature and then the veins themselves should be avoided.

Journal de Med. de Paris, November 11.

Veratrin in Climacteric Pruritus. LUTAUD.—When the pruritus is localized, with or without eruption, Lutaud orders a salve applied morning and night of 15 cgm. veratrin in 30 gm. lard. If the pruritus is general, he prescribes the veratrin internally: 2 cgm. in licorice powder, for 1x pil., commencing with one pill and increasing by one to a maximum of six a day, taken half an hour before or three hours after meals. The analgesic properties of the veratrin are very successful in the rebellious pruritus of the menopause.

Presse Medicale (Paris), November 14.

Musset's Sign in Pleurisy. H. FRENKEL.—The rhythmic movements of the head isochronous with the radial pulse, observed in persons with an affection of the aorta, have been considered a pathognomonic sign of an affection of the circulatory system. But Frenkel relates an instance in which it was a pronounced symptom in a serous pleurisy of the left side with a large effusion, and no evidences of any disturbance in the circulation.

Revue de Médecine (Paris), November.

Wound of Left Vertebral Artery. BOUCHARD.—A stab wound in the neck resulted in an intraspinal hemorrhage causing absolute paralysis of the trunk and all the members. In the course of two years, however, the patient recovered almost completely and was able to walk. The pressure of the hematorrhachis must have been less intense in the upper portion of the spinal cord, which explains the non-interference with circulation and respiration.

Berliner Klinische Woch., November 5 and 12.

Diagnosis of Pyelonephritis Calculosa. L. THUMM.—In the case described the phloridzin test and the determination of the freezing-point of the blood demonstrated the existence of serious alterations in the parenchyma, accompanying an abscess in the pelvis of one kidney, while it also demonstrated the soundness of the sister organ, justifying nephrectomy. The course of events confirmed the diagnosis in every point.

November 12.

Anatomic Lesions in Acromegaly. E. MENDEL.—A rounded sarcoma was found in the hypophysis at the autopsy of a young woman who had suffered from acromegaly for two years. Besides the typical symptoms, there had been hemianopsia, cessation of menses, absent knee-jerk, hypertrophied thyroid and spleen, and intense frontal and occipital headache. Mendel thinks the lesion in the hypophysis is insufficient to explain the symptoms observed, and attributes the disease to a general affection of the blood-glands, due to the action of some unknown poison with a special affinity for the hypophysis.

Centralblatt f. Bakteriologie (Jena), November 5.

Third Preliminary Communication in Regard to Malaria. A. CELLI.—The parasites of the gravest forms of

malarial infection were found as widely distributed throughout Northern Italy as in the southern portion, and even in some of the valleys on the Italian side of the Alps. Wherever malaria was found the anophelis was discovered, but the latter was found in many places free from malaria present or past. Celli made a special study of relapses and states that the presence of certain forms of the parasite in the blood in severe tertian and quartan fever and also the ability to be up and about differentiate relapses from fresh infection. He has observed a relapse nine months after the last manifestations of estivo-autumnal fever and eight months after mild tertian. These relapses can be postponed by prolonged and lavish use of quinin with iron and arsenic, but it is impossible to prevent them altogether in some patients. It is impossible therefore to rely on quinin as an adequate means to exterminate malaria until some means has been found to destroy the germs in the blood which keep up the relapses and resist quinin. He noticed that a temperature of at least 25 C. was an indispensable preliminary to an epidemic.

The Paestum Malaria Prophylaxis Experiments. B. GRASSI.—The results of this season's tests of the prophylaxis of malaria by protection against mosquitoes, enable Grassi to affirm with certainty that it is possible to free Italy from malaria in a comparatively short space of time. The houses had wire screens at doors, windows, chimney openings, etc., and each house had a netting pavilion in the yard for those who wished to sleep during the day. Persons obliged to be in the open air after dusk wore veils gathered on a rubber band around the hat and thick, very closely-woven, cotton gloves. The number of persons thus protected was 104 and only three showed symptoms of malarial infection. Grassi himself slept three nights a week and other physicians or students four nights or every night. No quinin was taken, the entire party used only 16 grams of quinin during the months of the test, and this was given mostly to persons who suffered from lack of their accustomed medication. These results are more surprising when compared with the detailed statements of the health of the neighboring farms and stations all around the protected zone. Out of a population of 307 souls, all but five contracted malarial infection, and these five were sons of the soil who had probably acquired some degree of immunity. Three kilograms of quinin were taken by these 307 persons during the period of the Paestum experiment. Grassi adds that he had much to contend with from the carelessness and neglect of some of the protected parties. Prizes were found the best incentive to ensure compliance with the prophylactic measures ordered, as some had no faith in them.

Centralblatt f. Chir. (Leipzig), November 24.

Pyelocystostomosis. O. WITZEL.—The bladder can be pushed up in the cadaver as far as the iliac crest and in the living subject to the kidney, without injury. In case of hydro-nephrotic distension of the latter organ it is possible to establish a direct communication between the kidney and the bladder in this way. The bladder is filled and a catheter 60 to 80 cm. long inserted in necrosis, the pelvis elevated. After a lateral incision, as for ligature of the iliac communis, the bladder is brought up and fastened. The lowest portion of the kidney is drawn down and an opening of 1 cm. in diameter made between the two stretched narrow organs. The catheter is pushed into the pelvis of the kidney and held by a stitch, its outer end connecting with a rubber tube terminating in a vessel full of an antiseptic fluid. Witzel has perfected this technique on the cadaver, but has not yet had an opportunity to apply it on man.

Deutsche Med. Woch. (Leipzig), November 1 and 8.

Functional Heart Affections. H. HOCHHAUS.—In almost every case of cardiac neurosis Hochhaus found the blood-pressure increased even when the pulse was soft and high. In organic heart disease the blood-pressure averages 120 to 140 mm. mercury. Permanent elevation of the blood-pressure justifies the assumption of a functional disturbance in doubtful cases, and hence affords a less favorable prognosis. Radiography has shown that the heart action is excessive in a functional nervous heart affection; the difference between the

shadow in diastole and systole is much greater than normal or in organic affections. Consequently the increase in the blood-pressure is evidently due to the increased heart action. The usual heart remedies are contraindicated in functional neuroses, but Hochhaus has been successful with small doses of digitalis associated with quinin.

Genetic Connection Between General Nervous Affections and Appendicitis. O. SCHAUMAN.—The possibility of a genetic connection between appendicitis and certain affections of the adnexa is admitted by Schauman. He does not go so far as to assume a direct relation of cause and effect, but merely that they all develop on a similar or common foundation, a peculiar, usually congenital, anomaly in the organs.

Pericardotomy. LINDNER.—Resection of the ribs is indispensable, Lindner considers, in pericardotomy for a purulent effusion. He reports two cases in which this operation was done as a last resort, with the most favorable results. In one case three-fourths of a liter of fetid pus was evacuated. The effusion was sero-sanguine in the other and had developed consecutive to an articular rheumatism complicated with influenza.

Monatss. f. Geb. u. Gyn. (Berlin), September.

Operative Treatment of Carcinomata Uteri in Russia. D. VON OTT.—A thousand cases of total extirpation of the uterus by way of the vagina are reviewed. The mortality was 10.3 per cent. In 250 cases operated on over five years ago, 30 have had no recurrence to date, including 4 dating from ten years ago. The adnexa are never removed unless for special reasons. Pregnancy is no contraindication to the vaginal route. In von Ott's own clinic the mortality in 189 cases was 1.6 per cent. In 18 out of 62 operated on before 1894 there has been no recurrence and nearly all of the 62 are still alive.

Monatsh. f. Prakt. Derm. (Hamburg), November 1.

Masks in Therapeutics. P. G. UNNA.—After seven years of experience with air-tight masks, Unna limits their use to lupus, ulerythema centrifugum and nevus flammeus, but considers them of great value in these affections. He applies them over a weak solution of sublimate or potassium in the first, after a course of green salve and as a preliminary to "Spiek" treatment. He makes the mask by fitting pieces of "zinc plaster" over the face and smearing with "zinc glue." A piece of dressing mull is then fitted over the mask and smeared again with the glue. The strips for fastening are then put in place and glue again applied. The mask is kept on for a few hours or over night, then smeared inside with the glue and dried in a warm place. The whole is then painted inside and out with a solution of celluloid. It is ready for use in forty-eight hours and keeps several weeks. If painted again with celluloid every fortnight the mask will keep in good order for months. In case of ulerythema the mask is made to fit over the region affected and the compress beneath is moistened with a 1 to 1000 solution of potassium. For nevus the mask is worn only at night, over cotton moistened with his "ichthyol varnish."

Wiener Klinische Wochenschrift, November 8, 15 and 22.

Reflex Spasm in Abdominal Muscles in Pleuritis and Perihepatitis. R. SCHMIDT.—In cases of pleurisy or perihapatitis in which the reflexes are vigorous and the recti muscles well developed, a reflex spasm is liable to occur in connection with the act of respiration. In three cases the writer observed that toward the end of a deep inspiration a sudden spasmodic contraction occurred in the upper portion of the right rectus, extending upward to the fifth intercostal space. The same spasm could be artificially produced by pressure on the painful intercostal space.

November 15.

Fulminating Gangrene a Primary Necrosis. F. HITSCHMANN AND O. T. LINDENTHAL.—The elbow of a healthy man was resected on account of old traumatic ankylosis and a plate of celluloid inserted. The forearm became anemic and insensible the next day, and gas bubbles were noted in the tissues, with extensive necrosis of the muscles around the wound, but complete absence of any indications of inflamma-

tion. The gas-formation and necrosis progressed the same as in dead tissue. The essence of fulminating gangrene therefore seems to be a putrefaction of living tissue. Everything is to be gained by early amputation, but in case it is refused extensive incisions and injections of hydrogen peroxid are the most appropriate treatment. In the case described staphylococci were found in the lesion with the anaerobic bacillus previously described by the writers, who have now recorded seven cases of fulminating gangrene, in only one of which was this bacillus absent.

Hetero Bone-Plastic Operation on the Skull. K. BÜEDINGER.—Defects from three abscesses in the skull of a 5-year-old boy were closed with plates of bone from the calcaneum of a limb amputated from a woman of 70. The patient died from general tuberculosis four years later. The skull was found healthy and nearly intact. The results impel Buedinger to proclaim the advantages of the cancellous portion of the bone for this transplantation. The spaces fill up with new-formed tissue, and if the calcaneum is used, the plate of bone can be cut with the scissors to exactly fit the defect. The advantage of heteroplasty is that no second operation is necessary, and the transplanted piece heals in place as a foreign body.

Centripetal Ataxia in Man and Monkeys. E. HERING.—Comparing the disturbances in frogs, dogs and monkeys after division of the posterior roots, with the results of clinical observation in tabes, in each are noted the loss of centripetal stimulation, disturbances in position, atony even to disturbances of the finer co-ordination of the fingers in monkeys—the atony increasing with exclusion of light—increased passive mobility, relaxation of the muscles, so-called trophic disturbances and muscular atrophy and movements in the extremities of the resting animal, comparable with certain involuntary movements of the extremities in the tabetic at rest. This atony consecutive to paralysis of the centripetal fibers is evidently a centripetal atony and the close analogy between experimental and clinical data justifies the assumption that the atony in tabes is also centripetal, but whether sensory or not is still undetermined. It is probably due to the exclusion of the centripetal tracts, which are the means of involuntary regulation of the movements, not through the spinal cord, but by means of the higher located portions of the brain. Hering calls especial attention to the difference between the atony in tabes and the atony consecutive to a lesion of the centripetal tracts in higher located segments of the central nervous system. The atony in the latter case is not so intense as in tabes and affects chiefly the more delicate movements. There is no direct proportion between the atony and the absence of the sense of movement, which is another argument against the sensory theory. In tabes whole movements are lost which the normal subject makes unwittingly, involuntarily, and which the tabetic subject also makes when his attention is called to them. This work obtained the prize awarded by the Vienna Medical Society.

November 22.

Substitute for Iodoform. A. FRAENKEL.—Iodoform stimulates granulation by its fibroplastic influence, and Fraenkel believes that this is probably an attribute of any finely distributed, inert foreign substance. He has been extensively testing carbo ossium from this point of view, selecting this substance on account of its traditional value as a dressing for wounds. He reports twenty-two cases of local tuberculosis in detail, with microscopic views of sections of tissue. They show that the results of the carbo ossium are, to say the least, fully equal to those of iodoform, while there is no possibility of intoxication. The fibroplastic influence is marked, but as a deodorant, iodoform is superior. In all other respects carbo ossium is at least its peer.

Zeitschrift f. Orthop. Chir. (Stuttgart), vii, 2.

Effect of Supporting Corsets in Scoliosis. A. HUSSY.—Tables showing series of cases of scoliosis treated with and without corsets prove conclusively that corset treatment should yield precedence to other and more effective methods of treatment, unless there is much pain, or when, without the support of the corset, respiration is impeded. But even in these cases

supplementary gymnastic treatment is indispensable. In all other cases the corset is contraindicated, as it seems to have a decidedly injurious influence on the torsion and hump, unless it can be applied in an over-corrected attitude. This is only possible for a few hours at a time, and hence the corset should be worn only part of the day, and never unless it can be constantly supervised by the physician, as otherwise much harm may result.

Curvature of the Neck of the Femur. M. WAGNER.—This comprehensive review of the present status of the question of coxa vara concludes that the prognosis—with appropriate treatment—can be considered favorable. Many apparently severe cases recover without an operation. The chances of spontaneous recovery are greater the more the subjective symptoms predominate. The painful stage may last for months or years. The degree of subjective disturbances and interference with function during this acute stage are no criteria for the necessity of an operation. This can be determined only by examination in narcosis. If there is freer mobility in narcosis it is too early for osteotomy, although a tenotomy may be needed to correct the contraction of the adductors. Cases resisting prolonged massage and exercise are treated by Hoffa with subtrochanteric, oblique osteotomy, which has proved extremely successful and harmless in his experience. The oblique incision allows considerable stretching and separation of the two ends of the bone. It diminishes the actual contraction, renders ample abduction possible and banishes Trendelenburg's symptom almost entirely. By the lowering of the trochanter the abducter elements of the pulling force of the muscles passing from the pelvis to the trochanter are materially increased. Resection is necessary only in extreme cases. Suitable after-treatment is indispensable.

Tabetic Arthropathy. A. E. AHRENS.—Three severe cases are described of deformity of the knee occurring in the course of tabes on a syphilitic foundation. They proclaim the benefits of conservative treatment and that the splints applied not only allow the patients the use of their limbs, but also arrest the progress of the joint affection.

Nordiskt Med. Arkiv (Stockholm), November.

Treatment of Psoriasis With Injections of Arsenic. ALMKVIST AND WELANDER.—Intravenous injections undoubtedly exert a powerful therapeutic action on the efflorescence of psoriasis, but this effect is transient and does not prevent its reappearance. They also produced disagreeable by-effects, pigmentation, eruptions, stinging, itching, numbness or other nervous symptoms in the twenty-seven cases in which the method was given a thorough trial by the writers. They consider it a failure and have abandoned it.

Chronic Non-Tuberculous Peritonitis With Effusion. K. G. LENNANDER.—Besides the four cases described at length, others on record are reviewed. The conclusions are that simple, chronic peritonitis is a frequent complication of the various affections accompanied by ascites, and that it is the cause of the latter. Chronic peritonitis may be cured by laparotomy, even when it is complicated by other affections. Four laparotomies were necessary to complete the cure in one of Lennander's cases, and the patient has been in good health since, more than a year. Operative treatment proved ineffectual in another case with renal and cardiac complications.

Change of Address.

- F. E. Adams, Plain, Ohio, to Alliance St., Pittsburg, Pa.
 J. E. Ashury, 187, to 102 W. Alhance St., Atlanta, Ga.
 C. M. Blair, Roseberg, to Lufkin, Tex.
 H. C. Bliss, 413, to 455 Woodland Ave., Cleveland, Ohio.
 L. P. H. Bahrgren, Liverpool, Eng., to Asst.-Surgeon U. S. Marine-Hospital Service, Barge Office, New York City.
 J. W. Bounds, Weston, to Maple, Tex.
 S. E. Crose, 117 1/2, to 219 W. Washington St., Indianapolis, Ind.
 J. B. Chadwick, 4627 E. 10th, to 3921 Dixon St., Kansas City, Mo.
 M. F. Clausius, Barrington, Ill., to A. A. Surgeon U. S. A., Manila, P. I.
 A. V. Cole, Chicago, to Lexington, Mo.

New Patents.

- Patents of Nov. 20 and 27, of interest to physicians, etc. :
 661,340. Vaginal syringe. John A. Bell, Naperville, Ill.
 662,223. Medicinal boot or shoe. Harvey F. Crawford, Brocton, Mass.
 662,278. Anral battery. Christopher W. Levalley, Milwaukee, Wis.
 662,150. Throat shield. Wm. W. McCormick, Santa Rosa, Cal.
 662,053. Exercising and massage device. Bernard A. McFadden, New York City.
 662,585. Manufacturing diethyl-ether. George H. Benjamin, New York City.
 662,588. Device for measuring and administering medicines. Wm. O. Bloom, Worcester, Mass.
 662,487. Invalid-bed. Wm. H. Donaldson, Chicago.
 662,716. Intrauterine battery. John G. L. Gaedeke, New York City.
 662,627. Sanitary dispenser for plastic substances. Joseph F. Lohan, New York City.
 662,830. Speculum. John Sklar, New York City.
 662,658. Instrument for injecting gas into the human body. Emile Sterne, Paris, France.
 662,659. Suspensory bandage. Lynn C. Thompson, Darlington, Ind.
 662,477. Lifting device for invalids. Charles B. Ulrich, Duluth, Minn.

Queries and Minor Notes.

TIME-LENGTH OF DEAD FETUS IN UTERUS.

MINGO, IOWA, NOV. 5, 1900.

To the Editor:—Please give me references as to where I can find something on the length of time a fetal body may remain in the uterus after its death, with or without dangerous results to the mother; and oblige. W. W. G.

ANS.—We are unable to give the reference desired, and do not know of any statement of the absolute limit of time applicable for all cases. A lithopodion may possibly be carried indefinitely in a functionally inactive uterus.

SECRETARY'S ADDRESS WANTED.

CHICAGO, Dec. 3, 1900.

To the Editor:—Please give name and address of the secretary of the Medical Examining Board of North Carolina. Yours, respectfully, W. T. H.

ANS.—J. Howell Way, M.D., Waynesville.

COMMISSIONS AGAIN.

WALLA WALLA, WASH., Nov. 29, 1900.

To the Editor:—Is it a violation of the code of medical ethics for a physician living in the country or small town, having no hospital advantages to send patients to hospitals or sanitariums, where they can have the advantage of surgical skill and experience, likewise hospital care and treatment, and receive as a compensation for his trouble and expense a portion of the fees received by the hospital, sanitarium, or surgeon who takes charge of his patients?

Will physicians sending or receiving patients and dividing the fees violate the code of medical ethics? Respectfully,

N. S. B.

ANS.—Questions like the above are propounded all too frequently. The code of ethics does not especially forbid many things that are against good morals, for the reason that the raising of such questions was not expected from those that had imbibed its spirit. Diversion of fees implying, as it necessarily does, a greater charge to the patient than otherwise would have been made, is certainly contrary to the spirit of the code, which is supposed to govern a profession that cultivates the highest moral principles in its dealings with its clients and in the professional interest of its members with each other. A physician is not expected to obtain compensation for trouble or expenses incurred for a patient who is able to pay, from a third party surreptitiously overcharging him, nor is a sanitarium or specialist supposed to take more than its or his special services are worth, to divide with anyone bringing to them business. If Dr. A. collect for it trouble or expense in sending B. to Dr. C., let Dr. A. collect for it directly from B.; it is as unethical for him to expect Dr. C. to collect such compensation for him without B.'s knowledge as it is for the latter to attempt to avoid its payment. The honor of the profession is compromised by even the suspicion of such practice.

QUACK DOCTORS IN AUSTRALIA.

Under the above title the *British Medical Journal* publishes some remarks on quack doctors from the *Bulletin*, of Sydney, Australia, which are so good and so unique in some of the suggestions made that they will bear another reproduction. The idea of the state assisting in the support of a physician where the population is not large enough to support one is not as absurd as it might at first appear.

It is not suggested that the quack should be merely prohibited from calling himself a doctor, but that he should be prohibited from existing at all and utterly blotted out. There is much to be said for the proposition. The qualified practitioner is sometimes an incapable fool but the very worst of him must know a good deal of his trade, or he could not have passed his examination. The unqualified man may sometimes know a good deal, but as a rule the best of him remains unqualified because he does not know enough to be the worst kind of a qualified man. All the same the unqualified man is sometimes better than the qualified man, very often he is worse than nobody, and kills his patients faster than they would have died if left alone; but on the strength of the press denounce the medical bill in the alleged interest of very far back residents, and asks if it is humane in places where there is no doctor to prevent the bush quack doing his best, or to prohibit the quack, who probably knows a little medicine, from prescribing. This looks plausible on the surface, but there is not much underneath it. A place that can support a chemist generally has a doctor; also there is no reason why a combined order of doctor and chemist should not exist. As for the quack, who is not a chemist, he sits and dopes, and wears as many hoots as the qualified man, so a place which cannot support a doctor cannot support a quack. Where there is a quack and no qualified doctor, the reason generally is that the place cannot support both of them, and would take his place first; if he were shifted, a qualified man would take his place. As for the very poor and unpopulous places, where there is neither doctor, nor quack, nor chemist, and a little precarious botching at the human frame is done by the storekeeper, or the blacksmith, they are merely a proof that the state has failed in its duty. Even in the poorest and emptiest regions the state sees that appliances for arresting, and imprisoning, and hanging the public are not wanting. It is equally essential that appliances for healing them are not wanting. In every settled district the state should see that a doctor is supplied, and where the population is below a certain figure—the figure which would support a physician is below a minimum that can support a medical man—a sober, capable medico should be supplied, and subsidized in proportion to the deficiency in population. It is as essential to have a doctor to so many square miles, in order that no single inhabitant shall be absolutely out of reach of medical aid, as to have a policeman so that no inhabitant shall be denied the privilege of imprisonment. It is quite as cheap to preserve the existing population in this way as to import new population under a system of migration policy cheaper, perhaps, when the saving in tombstones and grave-digging is considered.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 22 to 28 inclusive: George E. Bushell, major and surgeon, 1st S. A., relieved from duty in the office of the surgeon-general, Washington, D. C.; leave of absence granted on account of disability. Timothy F. Goulding, acting asst.-surgeon, from Washington, D. C. to post at Mass.; on leave of absence. James H. Hepburn, acting asst.-surgeon, previous orders revoked; he is relieved from duty at the General Hospital, Fort Bayard, N. M., and will proceed to Fort Apache, Ariz., for post duty. John Van Hout, major and surgeon, 1st S. A., relieved from further duty in the Department of the Lakes, and expiration of his present leave of absence he will report at Washington, D. C., for duty in the office of the surgeon-general. H. Newton Kierulff, acting asst.-surgeon, former orders revoked; he is relieved from duty in the Department of Alaska and will proceed to Seattle, Wash., for duty as transport surgeon on the *Kintuck*. Samuel O. L. Potter, major and surgeon, Vols., honorably discharged from the service of the United States, on tender of his resignation, to take effect Dec. 1, 1900. Erwin I. Shores, acting asst.-surgeon, former orders relieving him from duty at Fort Caswell, N. C., revoked.

Dudley W. Welch, captain and asst.-surgeon Vols. (recently appointed from first lieutenant and asst.-surgeon, 43d U. S. V. Inf.), with rank from Nov. 12, 1900, is assigned to the 43d U. S. V. Inf.

Navy Changes.

Changes in the Medical Corps of the navy for the week ended Dec. 1, 1900:
Asst.-Surgeon C. R. Burr, ordered to the *Monongahela*, Dec. 1.
Asst.-Surgeon R. K. McClanahan, detached from the navy yard, Washington, and ordered to the *Indiana*, Dec. 1.
P. A. Surgeon R. Spear, detached from the naval hospital, New York City and ordered to the *Bufalo*, Dec. 5.
Asst.-Surgeon R. B. Williams, ordered to duty at the naval hospital, New York City, Dec. 5.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ended Nov. 29, 1900:
P. A. Surgeon J. B. Stoner, bureau letter of Nov. 20, directing P. A. Surgeon Stoner to assume temporary command of the service at Norfolk, Va., amended, and directed to assume command of the service at Norfolk, relieving P. A. Surgeon J. M. Eager.
P. A. Surgeon J. M. Eager, relieved from duty at the port of Norfolk, Va., to take effect Nov. 30, 1900.
Asst.-Surgeon W. C. Holdy, granted leave of absence for seven days from Nov. 25.
Asst.-Surgeon W. C. Billings, to proceed to Clarksville, W. Va., for special temporary duty.
Asst.-Surgeon F. J. Thornbury, granted leave of absence for four days.
Asst.-Surgeon Dunlop Moore, to proceed to Port Townsend quarantine, and report to medical officer in command for duty.
Asst.-Surgeon R. H. Earle, to proceed to Columbia River quarantine, and report to medical officer for duty.
Asst.-Surgeon J. D. Long, to proceed to Baltimore, Md., for temporary duty during absence of Asst.-Surgeon Billings.
Asst.-Surgeon B. J. Lloyd, to proceed to San Francisco quarantine and report to medical officer in command for duty and assignment to quarters.
Asst.-Surgeon C. C. Pierce, relieved from duty at the Tortugas quarantine station, and directed to proceed to Key West, Fla., and report to medical officer in command for temporary duty.
A. A. Surgeon W. C. Bailey, granted leave of absence for three weeks from Nov. 14.
Hospital Steward F. L. Brown, relieved from duty at Cape Charles quarantine, and directed to proceed to Boston, Mass., and report to the medical officer in command for duty and assignment to quarters.
PROMOTION.
Asst.-Surgeon L. E. Cofer commissioned as passed assistant surgeon.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General U. S. Marine-Hospital Service, during the week ended Nov. 30, 1900:

SMALLPOX—UNITED STATES.

Alaska: Nov. 24, Skaguay, 1 case; Whitehorse, 1 case.
Kentucky: Lexington, Nov. 27, 1 case.
Louisiana: New Orleans, Nov. 17-24, 1 case.
Michigan: Detroit, Nov. 17-24, 1 case.
Minnesota: Minneapolis, Nov. 17-24, 3 cases.
Missouri: St. Joseph, Oct. 1-31, 1 case.
Nebraska: Omaha, Nov. 17-24, 3 cases.
New Hampshire: Manchester, Nov. 17-24, 3 cases.
New York: New York, Nov. 17-24, 1 case, 1 death.
Ohio: Cleveland, Nov. 17-24, 23 cases.
Pennsylvania: Nov. 17-24, Pittsburg, 3 cases; Steelton, 2 cases.
Texas: Houston, Nov. 17-24, 17 cases.
Utah: Salt Lake City, Nov. 17-24, 31 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Nov. 3, 1 death.
Bohemia: Prague, Oct. 27-Nov. 3, 10 cases.
British Columbia: Nanaimo, Nov. 23, 12 cases.
Ecuador: Guayaquil, Sept. 8-30, 33 deaths.
Egypt: Alexandria, Nov. 5, 1 case.
England: Southampton, Nov. 2-10, 3 cases.
France: Paris, Nov. 3-10, 11 deaths.
Greece: Athens, Oct. 27-Nov. 3, 3 cases.
Gibraltar: Nov. 11, 1 case.
India: Oct. 20-27, Calcutta, 1 death; Madras, 3 deaths.
Italy: Naples, Nov. 14, 15 cases, 1 death.
Mexico: Mexico, Nov. 4-11, 1 death.
Russia: Moscow, Oct. 27-Nov. 3, 7 cases, 2 deaths; Odessa, Nov. 3-10, 16 cases, 7 deaths; St. Petersburg, Oct. 27-Nov. 3, 7 cases, 1 death; Saratov, Oct. 27-Nov. 3, 30 deaths.
San Domingo: Puerto Plata, Nov. 10-17, 3 deaths.
Scotland: Glasgow, Nov. 9-16, 22 cases.
Spain: Corunna, Nov. 3-10, 1 death.

YELLOW FEVER.

Cuba: Matanzas, Nov. 19, 3 cases.
Mexico: Vera Cruz, Nov. 10-17, 9 cases, 1 death.

CHOLERA.

India: Bombay, Oct. 23-30, 10 deaths; Calcutta, Oct. 20-27, 8 deaths; Madras, Oct. 20-27, 13 deaths.
Straits Settlements: Singapore, Sept. 22, 1 case, 1 death.
PLAGUE.
China: Hongkong, Oct. 15-22, 3 cases, 3 deaths.
Egypt: Alexandria, Oct. 22-29, 1 case.
India: Bombay, Oct. 30, 85 deaths; Calcutta, Oct. 20-27, 7 deaths; Madras, Oct. 20-27, 1 death.
Japan: Nov. 2, Kobe, 2 cases; Osaka, 11 cases.
Madagascar: Tananave, Oct. 8-15, 4 cases, 4 deaths.
Straits Settlements: Penang, Oct. 16, 2 deaths.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street ; ; Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION. . . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

No. 25.

Original Articles.

TREATMENT OF HERNIA IN CHILDREN.*

A. J. OCHSNER, M.D.

CHICAGO.

During the past few years the interest in this subject has increased very greatly. In this country the first real impulse was given to the surgical treatment of hernia in children by the excellent paper of William B. Coley, which was based on an extensive personal observation. This has since acquired remarkable dimensions, as is shown by the paper of Bull and Coley, which appeared during the past year. In England the subject has been discussed at length, especially in the British Medical Association, by Langton, Eccles, Campbell, Harrison, Heaton, Owen, Parker, and many others; and on the continent Broca, Mugnai, Fraenkel, Felizet, Lucas-Champonnière, Tillmann, and others urge the operative treatment as applicable to a large proportion of all cases of hernia in children.

That operative treatment is indicated in strangulated hernia in children was recognized many years ago, although the prognosis was much less favorable in the pre-antiseptic time. During the early part of the last century Lawrence reported a successful operation for this condition in a child 14 months old. Robert Adams operated on a child of 18 months, Pantin on one in the second month, Hunt on one only twenty-nine and Dupuytren on another twenty days old; Goyrand successfully operated on a hernia in a child of 4 months, which had been strangulated for three days; Caesar Hawkins operated in the seventh week, Roux on a child 2 years of age, Lawrence on three very young children, successfully, and Erichsen reports one unsuccessful attempt.

For several years I have had an opportunity of observing an unusually large number of these patients in my clinical work at the Augustana and St. Mary's hospitals of this city. One of these institutions belongs to the Swedish, the other to the Polish people, and both of these nationalities are very numerous in the territory tributary to these hospitals, and in case an operation is advised on a child belonging to either nationality, it is usually brought to one or the other of these institutions, thus coming under my observation. Unfortunately, it has not been possible up to the present time to follow all, or even a large proportion, of these cases for a number of years, because of the frequency with which they change their places of residence; hence, my experience can have no value from the standpoint of reliable statistics, but I believe that as a matter of clinical observation this experience is undoubtedly of some value.

I have chosen the foregoing subject for this paper be-

cause it has seemed to me that a discussion of it by the Surgical Section of the AMERICAN MEDICAL ASSOCIATION must necessarily be of great profit at the present time. Everywhere herniæ in children are being treated surgically, the results being more satisfactory even than in adults, both as regards permanency of cure and safety of the operation. If a careful consideration of the subject shows that the same indications exist in children as in adults, then this form of treatment should be encouraged; if, on the other hand, it seems clear from past experience that most of these patients will get well without an operation, then it will be necessary to determine the conditions on which a selection of cases for operative treatment must be based.

It has seemed to me proper to refer here to the extensive statistics collected by Malgaigne fifty years ago, with which every surgeon is familiar, which show that there is one hernia for every twenty-one children during the first year of life, that this proportion remains true up to the age of 6 years, that then there is a rapid decrease until there is but one hernia in seventy-seven children at the age of 13. During the following years there is constant and rapid increase in the male, so that at the time of recruiting the armies, which occurs at the ages of 20 to 21, there is one hernia in thirty-two males. In the female there is no further increase until the beginning of the childbearing period, when there is at once quite a sudden one in the number. At the age of 28 there is one hernia for 21 persons; at the age of 30 to 35, one hernia for 17; at 35 to 40, one for 9; at 50, one for 6; at 60 to 70, one for 4, and at 75, one for 3. From this age on the patients suffering from hernia seem to die more rapidly than the remaining proportion, so that from the age of 80 to 85 there is but one hernia in fourteen persons, from 85 to 86, but one in twenty-three, and of those whose age exceeds 86, but one in fifty-six. It is plain, however, that the only time at which we can be absolutely certain that the statistics are correct is at the age between 20 and 21 in the male, because at this time all the males are actually examined by competent surgeons.

Many other interesting statistics exist, of which those of Werhner and Macready seem especially valuable, but the foregoing are sufficient for the purpose of this paper, as the different statistics do not vary to any great extent in the important facts bearing on the treatment of hernia in children, namely, that without surgical treatment over 75 per cent. of all herniæ heal spontaneously before the child has reached the age of 12 or 13 years; also that at this age and during the following six or eight years there are almost no herniæ in girls, while in boys there is a very rapid increase during this period, a condition which has been attributed to the fact that during these years girls are generally well cared for among all classes, while boys learn their trades, indulge in rough sports and are likely to exert themselves beyond their strength.

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

If the relative number of herniæ changes from one in twenty-one children up to the sixth year of age to one in seventy-seven at the age of 13, 73 per cent. of all children suffering from hernia at the age of 6 must have healed spontaneously by the age of 13, even if there were no herniæ formed at all during this period. This, however, is not the case, as more than one-half the life of these children has in the meantime been spent, and everyone who treats such cases knows from personal experience that many of the children coming under observation between the ages of 6 and 13 are suffering from herniæ of recent date. Consequently, it is certain that much more than 73 per cent. of all herniæ at the age of 6 heal spontaneously before the child is 13.

Berger's statistics are interesting in that they show the relative number of herniæ which have continued from childhood. Of 9967 adults with hernia, only 479 gave a history of having suffered from this condition since childhood. Bull and Coley's statistics show almost identical proportions: out of fifteen thousand adults with hernia, only 700, or less than 5 per cent., had been ruptured since childhood. This proportion is borne out in a remarkable manner by the fact that the four hundred cases which the latter authors had selected for operation were chosen from eight thousand children suffering from hernia.

It is worthy of note that Malgaigne's statistics were collected fifty years ago, at a time when, with the few exceptions noted above, no herniæ in children were treated surgically and, in fact, very few of these received any form of treatment. Judging from these and other statistics, it seems reasonable to conclude that probably 95 per cent. of all herniæ in children will heal spontaneously, or at least without surgical treatment, if proper conditions are secured. This has also been borne out by my own experience. In explanation of this fact, a description of the changes which take place as the child outgrows its hernia, in an interesting paper by Thomas Charles Martin, has seemed of especial interest to me. He shows that in the broadening of the pelvis the parietal peritoneum enlarges at the expense of the mesentery; the latter being thus shortened prevents the entrance of the intestines into the inguinal canal. At the same time there is a displacement of the internal ring, which still further aids in curing the hernia.

Primarily, the natural defect which results from the descent of the testicle through the inguinal canal must be considered a most important predisposing cause, which accounts for the much greater frequency of inguinal hernia in the male than in the female. Next to this comes a further increase of a tendency to the formation of hernia due to an inherited weakness in the structures of the abdominal wall. Macready places this hereditary defect at 25 per cent. of all cases, while Kingdon agrees with Malgaigne in placing heredity as an important factor in 33 per cent. of all cases.

It is doubtful whether the long mesentery is primarily a predisposing cause, or whether it occurs secondarily from the stretching which results from gaseous distension due to digestive disturbances.

Bertillon and others have proved that the number of herniæ in the offspring of the poorer classes is much greater than in the well-to-do; hence it is clear that there are conditions of very great importance aside from the anatomic causes.

ABNORMAL INTRA-ABDOMINAL PRESSURE.

There can be no doubt that the most important direct cause of herniæ in children is an abnormal intra-abdominal pressure, as pointed out by Eccles, Langton,

and others. This may be due: 1, to gaseous distension of the stomach and bowels, caused by faulty feeding and consequent indigestion; 2, to great pressure exerted during the act of defecation, on account of constipation; 3, to the same condition due to obstruction on account of phimosi; 4, to severe vomiting; 5, to long-continued coughing. In connection with all of these conditions, it is to be remembered that children suffering from digestive disturbances necessarily suffer much from pain, and the exertion incident to crying will greatly increase the existing abnormal intra-abdominal pressure. In order to quiet the child the mother will nurse it at irregular intervals and this will again increase the digestive disturbances, and this, in turn, the intra-abdominal pressure and pain.

INCREASED INTRA-ABDOMINAL PRESSURE DUE TO COUGHING.

I have observed cases in which the herniæ healed regularly during the summer months, but reappeared in the autumn as soon as the children acquired coughs which lasted almost all winter. By the time spring arrived the herniæ had attained considerable size, only to heal again during the summer, while the patients were free from coughs. By placing these children in bed and elevating the lower end sufficiently to make an angle of 20 degrees, giving them remedies to relieve the cough, the herniæ disappeared within six weeks. Then advising the mothers to give the children cold baths every day, and to bring them for inspection often enough to keep the condition under control, and giving them cod-liver oil and malt extract as soon as the cold weather appeared, they went through the next winter without coughs and consequently without a recurrence of the herniæ. In the same manner children who are suffering from obstruction to the upper air-passages, on account of enlarged tonsils, nasal adenoids or polypi and consequent conditions, will rapidly recover from their herniæ if these conditions are relieved by proper treatment.

INCREASED PRESSURE DUE TO GASEOUS DISTENSION.

It is very usual for the children who are brought into the hospitals for the treatment of hernia to have greatly distended abdomens, due to digestive disturbances resulting in gaseous distension of the stomach and intestines. If this occurs in nursing infants, the mother should be instructed to nurse the child at regular times. Her own habits and diet should be regulated. If the child is constipated, this condition should be relieved. Aside from this, the mother must be instructed never to carry the child, because she will not follow the advice of keeping it in the inverted position and, consequently, will increase the intra-abdominal pressure whenever she picks up the child. It should sleep in a separate bed with the lower end elevated sufficiently to make an angle with the floor of about 20 or 30 degrees. This will keep the hernial sac empty of intestines and omentum and will very greatly assist in the obliteration of the hernia. If the mother's milk continues to give rise to indigestion, notwithstanding every precaution available for making it wholesome, it is often best to place the child partly or wholly on artificial food, at least for a time. Above all things, however, it is important to impress the mother with the necessity of being regular in feeding the child, and to again place it in its bed as soon as it has been nourished, or, better still, to lean over the child's bed and nurse it without disturbing its inverted position.

I have repeatedly placed these children in the hospital and sent the mother, who was exhausted from over-work and care of the sick child, home to rest, permitting

her to come to the hospital morning, noon and night to nurse the child. After the first day or two the mother becomes rested, her journeys to and from the hospital compel her to be out-of-doors, and the fact that she is relieved of the care of the child gives her the necessary rest and sleep. In the meantime her milk improves, the child becomes accustomed to lie quietly in bed and to take its nourishment regularly, its digestion is improved, the gaseous distention disappears and with it the abnormal intra-abdominal pressure, which is still further relieved because the child sleeps most of the time and seldom cries. After the child has been in the inverted position for a few days the hernial sac remains empty so long as it remains in this position, even if the child strains and cries.

INCREASED INTRA-ABDOMINAL PRESSURE DURING DEFECACTION, DUE TO CONSTIPATION.

Children suffering from hernia should not be allowed to become constipated, because the increased intra-abdominal pressure necessary to accomplish the evacuation of the bowels in constipation in itself is sufficient to prevent a hernial opening from closing. This is one of the most common causes of hernia in children, and one of the easiest ones to be eliminated.

INCREASED INTRA-ABDOMINAL PRESSURE DUE TO OBSTRUCTION TO THE PASSAGE OF URINE AS A RESULT OF PHIMOSIS.

That phimosis is a frequent cause of hernia in children is plain from the fact of the greater frequency of umbilical hernia in male than in female children. The greater frequency of inguinal hernia in children can readily be accounted for by the difference in the anatomic structures, but this is not the case in umbilical herniæ, which are shown statistically also to be more common in male than in female children.

It has lately been suggested that phimosis can not be an important cause of hernia in children, because if this were the case the Jewish nation must necessarily be much freer from hernia than others. This is, however, not the case. In fact, it has been shown by statistics, especially in Russia, that at the age of 20 to 21 proportionately more Jews than Christians are afflicted with hernia. Eccles, in an article on this subject, has laid stress on the uselessness of circumcision for the cure of hernia, his argument being based on the fact that Jews are no less likely to have hernia than Christians. Krasnow found, on examining recruits from two departments for the Russian army, that there were, relatively, five times as many herniæ in the Jews who presented themselves for examination as in the Christians. A number of the former confessed that they had produced their herniæ artificially in order to secure rejection from military duty. Granting this to be the cause of the great increase, it could have no bearing on the number in Jewish patients in America and England, where there is no compulsory military service. This, however, can be explained by the fact that the Jews are more subject to hereditary diseases of all kinds, on account of the system of intermarriage in families.

If the phimosis is relieved, either by circumcision or by dilatation of the prepuce, and the child kept in bed for four to six weeks with the foot of the bed elevated, the hernia will almost invariably be cured. During the same time the diet and the bowels must be carefully regulated, and it is doubtful which of these three means has been of the greatest importance in obtaining a cure. It is surprising how rapidly the opening will contract under these conditions. Moreover, during this time the

patient acquires regular habits which can afterward be easily maintained if their importance is explained to the mother, and especially if it is impressed on her that by following the directions, which will naturally appeal to her on account of their simplicity and reasonableness, she will be able to make operative treatment unnecessary.

That all of these conditions are of the greatest importance can be demonstrated practically, with the greatest ease, by comparing the relative frequency of hernia in children of the very ignorant poor, of the intelligent poor, and of the well-to-do. In the former class, after the child is weaned but little attention is given to its diet, to the condition of its bowels, and to the condition of the prepuce in boys, and consequently herniæ are very common, while they are much less common in the second, and still less so in the third class, as has been shown by Bertillon, from carefully compiled statistics, and is a matter of experience with every surgeon who treats these various classes.

STRANGULATED HERNIA IN CHILDREN.

If a strangulated hernia in a child can not be easily reduced, under complete anesthesia, by taxis, the child being held in the inverted position during the manipulations, it is undoubtedly wiser to relieve the conditions by an operation, because the intestinal wall in children is very delicate and easily injured by taxis. In my experience the hernial opening has always been very narrow; still, I have always succeeded in replacing the hernial contents without enlarging the opening by first drawing out more intestine and then gradually replacing it, the child being placed in the inverted position.

If the hernia is an acquired one, which is not common in children, the sac is carefully dissected free to a point within the abdominal cavity. It is then ligated and removed and the ligated stump is permitted to retract into the peritoneal cavity.

If the hernia is congenital it is best to dissect up the neck of the sac for about an inch, and I leave the portion surrounding the testicle to form tunica vaginalis, while the upper portion is carefully dissected up to a point within the peritoneal cavity; it is then ligated, the superfluous portion is cut away and the stump is permitted to retract into the peritoneal cavity, as in case of the acquired hernia. It is thus only necessary to close the skin and the opening will close completely in from four to six weeks if the child is kept in bed with the foot of the bed elevated. R. H. Russell gives in support of this simple operation the fact that inguinal hernia in children occurs because of the presence of the hernial sac, which has remained after the testicle descended into the scrotum. Consequently, all that is required for the purpose of curing this hernia permanently is to completely remove this sac. His experience as to results seems to justify this view. H. O. Marcy has for many years repeatedly directed attention to this condition. That equally satisfactory results can be obtained by following Bassini's or Halsted's method can easily be seen, especially from the statistics of Coley, and those of Halsted. However, Funke and others have noticed severe atrophy of the testicle following herniotomies in children, in which an attempt was made to close the inguinal canal.

If it is possible to reduce a strangulated hernia in children by taxis, the irritation caused, primarily by the strangulation and secondarily by the manipulation, seems to favor closure of the hernial opening. I have repeatedly seen this occur within six weeks if the child was kept in bed in the inverted position.

The most unfavorable cases are those in which the abdominal walls are congenitally weak, a condition which seems to be hereditary in many patients. Again, of these cases, those in which there are three distinct areas of weakness—the abdomen of three hills described by Malgaigne—seem to be least favorable of all. In this class surgical treatment may become necessary, and here it is well to perform the typical Bassini or Halsted operation, or that described by Ferguson at the meeting of the AMERICAN MEDICAL ASSOCIATION in June, 1899, the important point in the operation being to secure an accurate closure of the inguinal canal to make up for the natural deficiency in the tissues. Two precautions should be borne in mind: 1. The stitches should be tied very loosely, in order not to cause pressure necrosis of the already weakened tissues. 2. The tissues of the cord in the male should be manipulated very carefully for fear of causing an atrophy of or preventing the full development of the testicle. This is especially important in these cases, because herniæ in this class of patients are very likely to be double, and if both testicles should atrophy the patient would be permanently injured. In this class very frequently no truss will retain the hernia.

REDUCIBLE HYDROCELE.

It is not uncommon to find a hernial sac closed opposite the internal inguinal ring and the portion beyond distended with fluid in the inguinal canal, preventing the closure of the latter opening. It is, of course, impossible for the patient to wear a truss, and unless the fluid is removed this can not heal. Simply making a small incision over the inguinal canal, ligating the upper end of the sac opposite the internal ring, cutting it away beyond this ligature and closing the wound in the skin has, in my experience, invariably and permanently cured these cases. In a number of these I have obtained the same result by tapping the sac and injecting five drops of .95 per cent. carbolic acid, but the other operation seems preferable.

There is but one other condition which justifies the operative treatment of hernia in children, and that is when, on account of adhesions, the hernia, although not strangulated, is still irreducible. In this class of hernia a truss can not be worn with benefit, because it presses on the hernial contents, usually omentum, instead of the empty canal; moreover, the opening not being empty its closure is necessarily impossible unless the adhesions are absorbed, which, if occurring at all, necessarily require a long space of time. In this variety of hernia, unless it be complicated with the form just described, it is not necessary to do anything further than in case of strangulated hernia. The hernial sac being removed, the opening will again close spontaneously.

In operation for relief of femoral hernia in children it is never necessary to do anything beyond dissecting out, ligating and cutting away the sac, permitting the stump to retract into the peritoneal cavity, and closing the skin. These cases are exceedingly rare. I have never seen a strangulated femoral hernia in a child, and only once an irreducible one due to an adherent omentum, which necessitated an operation.

USE OF TRUSSES.

Too much stress has been laid on the importance of trusses in the treatment, and too little on removing the causes, of hernia in children.

It is far easier to retain a hernia and thus encourage the closure of the hernial opening, by first relieving the abnormal intra-abdominal pressure and then applying the truss simply as an aid, than it would be to accomplish the same object by the use of the truss alone.

If it is at all possible it is always best to place the child in bed in the inverted position and to reduce the intra-abdominal pressure by the methods which have been described above, before making use of a truss at all. Then, if it is not possible to maintain this position sufficiently long to obtain a cure it is well to apply a perfectly-fitting truss.

The fact of using a truss does not make the other precautions unnecessary. The child should still be cared for so as to remove abnormal intra-abdominal pressure from every cause, and the foot of its bed should still be elevated in order to make use of gravity in keeping the hernia empty and to facilitate the shortening of the mesentery.

My observations and a study of the available literature on this subject have led me to accept the following conclusions:

1. The development of herniæ in children is favored by: *a*, faulty development of the abdominal wall; *b*, insufficient strength in the tissues involved in closing the umbilical, inguinal or femoral openings; *c*, abnormal intra-abdominal pressure; *d*, unclosed condition of the tunica vaginalis.

2. The causes *a* and *b* are likely to be inherited.

3. The abnormal intra-abdominal pressure is due: *a*, to gaseous distension resulting from improper feeding; *b*, to the exertion necessary to accomplish defecation in case of chronic constipation; *c*, to the same exertion necessary to evacuate the bladder on account of obstruction due to phimosis; *d*, to severe, long-continued coughs.

4. A large majority of all cases of hernia in children will heal spontaneously if the increased intra-abdominal pressure is relieved, the hernial sac being kept empty.

5. This can be accomplished by means of trusses or, much more rapidly, in inguinal and femoral hernia, by placing the child in bed with the foot of the bed elevated, the time required usually not exceeding six weeks.

6. Children with a tendency to the formation of hernia should be guarded against developing coughs.

7. Their diet should be given at regular times and chosen with a view to avoiding gaseous distension.

8. Constipation should be entirely prevented.

9. In case of boys, phimosis should be relieved if present.

10. Badly nourished and badly cared for children of the poor should be treated in hospitals, being placed in bed in the inverted position, the cause of increased intra-abdominal pressure being removed at the same time by proper treatment.

11. Operation is indicated *a*, in strangulated hernia; *b*, in irreducible hernia due to adhesions; *c*, in case the opening is unusually large in a free hernia, especially if the condition is hereditary and the hernia can not be retained by means of a truss; *d*, in reducible hydrocele.

12. Except in Class *c*, the operation should consist simply in carefully dissecting out the sac, ligating it within the abdominal cavity, cutting away the sac and permitting the stump to retract within the abdominal cavity, and simply closing the wound in the skin.

13. The recumbent position, with the foot of the bed elevated, is of very great importance in the operative as well as in the non-operative treatment of herniæ in children.

14. If the child can not be kept in this position sufficiently long, a well-fitting truss should be worn night and day until there has been no protrusion for at least six months, at the same time the necessary precautions

being constantly taken to guard against intra-abdominal pressure from any cause.

divided. There is no anastomosis with the nerves of the other side, and in all probability none with neighboring nerves. Consequently, that part of the muscle distal to the nerve loses its innervation and undergoes paralysis and atrophy. In the further development of a hernia, the atrophic and hence unresisting portion of the abdominal walls is protruded in response to intra-abdominal pressure.

Dr. Andrew F. Currier mentions a lowered vitality from tuberculosis, syphilis, chronic alcoholism and fatty degeneration at the menopause, or prolonged drainage, as a predisposing cause.

FREQUENCY.

Dr. John Homan says that he is surprised to find that thirty women out of over three hundred, undergoing abdominal operations, have ventral hernia—nearly 10 per cent.

Dr. H. O. Marcy finds that it is variously estimated by different authors that ventral hernia follows the closure of the abdominal wound, after laparotomy, in from 5 to 10 per cent. of the sum total of cases.

PREVENTION.

Since Dr. H. O. Marcy has adopted the method of closing the abdominal wall in layers, with buried sutures, in over one hundred cases of laparotomy, he has had but one case of ventral hernia.

FIG. 1.

Dr. Charles P. Noble finds that closing the abdominal wall in three layers, and suturing the aponeurosis of one side on that of the opposite, making a flat seam, by an alternate up and down stitch, has been valuable in preventing hernia.

Dr. William J. Mayo states the surgical principle involved in closing the abdominal wall in the following: "The ingenuity wasted in dealing with the peritoneum has been enormous, the formation of buttresses, or peculiar method of handling a membrane, which is notoriously impotent to aid in holding back the protrusion is a waste of time."

The only object in view is to prevent this membrane from insinuating itself between the muscular and aponeurotic structures, and preventing the union of the real retention agents.

A careful study of the anatomic structure of the parts involved, and the technique of different operators, has led me to adopt the method of operating which I now present to you.

TECHNIQUE.

Ventral hernie may be considered as median and extra-median, the former following median abdominal in-

IMPROVED TECHNIQUE FOR THE CURE OF VENTRAL HERNIA.*

M. M. JOHNSON, M.D.

HARTFORD, CONN.

According to Gross, "ventral hernia is a hernia involving the parietes of the belly, which are rendered defective in consequence of a wound, or accidental separation of some of the muscular and tendinous fibers."

CAUSATION.

The essential factor in the production of these hernie is a deficiency in the fibrous aponeuroses which give strength to the abdominal walls. (Kelley.) Dr. Henry O. Marcy says that as a result of the surgical division of the abdominal wall, it may occur from defective union in consequence of improper closure of the parts, and Spencer Wells points out the fact that operators have often failed to include the peritoneum in the line of sutures. Another and not infrequent cause is found in the imperfect or non-union of a portion of the abdominal wall from the use of the drainage-tube and from stitch abscess and long incisions.

A review of 340 cases of ventral hernia following abdominal incisions showed that, in the great majority, the wound healed by granulation (Bull and Coley), while Dr. P. Assmy wisely assigns division of the motor nerves as the cause of ventral hernia following extra-median abdominal sections. In these incisions, parallel or nearly parallel to the linea alba, the terminal branches of the intercostal nerves supplying the rectus muscle are

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

cisions, the latter resulting mostly from operations for appendicitis.

An elliptical incision is made a little within the border of the opening in the abdominal wall. This must be done carefully, as there is frequently a loop of intestine adherent to the inner surface of the hernial sac. The skin and superficial fasciæ—if it can be distinguished—is then dissected back, exposing the sheath of the rectus muscle. On the outer side a similar dis-

FIG. 2.

section is made an inch or more over the external oblique. The edges of the opening are trimmed and a No. 25 silver wire suture is inserted at the upper angle of the opening by lifting the abdominal wall and passing the needle through the peritoneum, rectus muscle and skin about one inch from the free border of the opening. The needle on the other end of the wire is similarly passed through the abdominal wall on the opposite side. Silver wire sutures are inserted, at intervals of one inch, the entire length of the incision. All the subcutaneous tissues are then united by a continuous kangaroo-tendon suture, and the skin is closed by a continuous suture of the same material.

FIG. 3.

The deep wire sutures are now taken up one by one, moving them back and forward, to make sure that a loop of gut is not included between the wire and the abdominal wall. The ends of the wire are wound around a pencil or ivory on either side and drawn sufficiently tight to relieve the tension on the kangaroo-tendon stitches. This is the old and nearly obsolete "quill

suture" used for a new purpose. Half the wires are removed in ten and the remainder in fifteen days. When the hernia is in the median line the principle is the same. The object is to relieve the tension on the stitches which hold the muscular tissues together until firm union has taken place.

CASE 1.—This case illustrates the extramedian operation. The patient, a boy 6 years old, came under my care at the St. Francis Hospital, on Oct. 3, 1897, to be

FIG. 4.

treated for ventral hernia. He gave the following history: July 17, 1895, he was operated on for sunnurvative appendicitis at the Hartford Hospital. A few days later perforation occurred. He remained in the hospital thirteen months, and during this time four more operations were performed to close the perforation, the last, by Dr. Wiggin, of New York, was successful. During his treatment at the hospital a rubber drainage-tube was lost in the abdominal cavity. Later an abscess formed in the lumbar region, just above the brim of the pelvis: when the abscess broke the drainage-tube came out.

Here we have a long history of operations, suppuration and drainage. The opening into the abdominal

FIG. 5.

wall was $3\frac{1}{2}$ inches long by 3 inches wide. At a consultation, the staff voted against an operation, as there was little hope of success, but the patient was removed to the Woodland Sanatorium, where the operation was performed Nov. 27, 1897. An elliptical incision was made a little within the border of the opening in the abdominal wall, adhesions broken up and the skin dis-

sected back so as to expose the sheath of the rectus muscle. A similar dissection was made on the outer side over the external oblique.

Beginning at the upper angle, four silver-wire sutures were inserted from the peritoneum through the abdominal wall, one inch from the border of the incision on either side. The muscular tissues were closed by a continuous kangaroo-tendon suture, passing through all the subcutaneous tissues, as they could not be separated owing to the long-continued inflammatory and suppurative process. The skin was closed by a continuous suture of the same material. The deep sutures were drawn sufficiently tight to relieve the tension on the stitches through the muscles, and were retained by winding them around an ivory pencil. The patient was placed on a liquid, animal diet to prevent the distension of the viscera. The end wires were removed in ten and the remaining ones in fifteen days, and the patient was kept in bed three weeks, making an excellent recovery. The details of this case have been given somewhat fully to show that it was an exceptionally bad case for a good result. At the end of 2½ years he was photographed and there was no return of the hernia evident.

FIG. 6.

CASE 2.—A woman was operated on for the removal of a fibroid tumor of the uterus, Nov. 22, 1894. She was admitted to the St. Francis Hospital, where the operation for the radical cure of her ventral hernia was performed by the writer, Dec. 30, 1898. Fig. 5 illustrates the size of the rupture.

The usual elliptical incision was made, the tissues were dissected back on both sides so as to expose the sheath of the recti muscles, and silver-wire sutures were placed as previously described. The subcutaneous tissues were closed by the usual continuous suture passing through the sheath of the recti muscles. The skin was closed as usual and the deep silver wires were made sufficiently tight to relieve the tension. At the end of ten days the dressings were removed and primary union had taken place perfectly; two of the silver-wire sutures were removed and the rest of the wires five days later. At the end of three weeks she was discharged, fully recovered. Fig. 6 illustrates the condition one year four and a half months after the operation.

The reason for the unsatisfactory results, so frequently following the operations for the radical cure of ventral hernia, in the class of cases where a very long incision is made, thus depriving the rectus muscle of its nerve-supply, followed by a protracted period of suppuration and drainage, attended by a considerable loss

of tissue, and a slow closure by granulation, is the strong tension necessary to bring the abdominal walls together, causing a giving way of the tissues before a proper union of the parts has been secured. The technique here described fully meets these requirements and has proved highly satisfactory in a series of these extreme cases.

THE ESSENTIAL FACTORS FOR THE CURE OF HERNIA IN THE MALE.*

HENRY O. MARCY, M.D.

BOSTON, MASS.

That hernia may be safely cured by surgical intervention is now recognized as one of the special triumphs of modern aseptic surgery. It is scarcely more than a decade since the profession in general discountenanced operation except under very restricted limitations, and the records of all our general hospitals are replete with long series of cases followed by dire disaster, owing to delay in operation for the relief of strangulated intestines in which now a speedy cure would ensue by prompt surgical intervention.

It is not the purpose of this paper to discuss the history of modern operations or the various methods of prominent surgeons, but rather that we may eliminate the non-essentials and emphasize the really important factors which must pertain in order to effect a cure. All forms of hernia except that of the inguinal in the male may be dismissed with the simple statement that they consist of openings through the strong retentive wall of the abdominal viscera, more or less direct, and that the proper closure of these openings is usually a simple procedure which should be followed by primary union and permanent cure.

The inguinal variety in the male is by no means so simple, since here the abdominal opening usually follows the canal through which the spermatic cord and vessels pass. If this opening is normal, is it necessarily a source of weakness? If so, why are not all men subject to hernia? Statistics show that this variety is much more common than that of all others, so common, indeed, that by estimate one in every ten to fifteen male adults is the subject of hernia; over three millions of the inhabitants of the United States are thus, in a greater or less degree, sufferers and incapacitated for hard active service.

If this form of hernia is so universal, to ascertain its cause and the reason of its development is obviously of the first importance. It may be easier of solution to reverse the proposition and inquire why all men are not subject to hernia, or, in other words, what the normal anatomic and physiologic conditions which prevent the escape of portions of the abdominal contents through the inguinal canal are. Since I have reason to believe that this phase of the subject is comparatively little understood and has been rarely emphasized in its proper surgical importance in its relation to the restoration of the structures in order to effect a cure, I must be pardoned in dwelling a little in detail on certain of these factors.

In a way, it seems strange that the testicle should develop within the abdominal cavity, and that by a seeming change of plan, as if an afterthought, it should be extruded therefrom at a period when all the other organs are not alone permanently closed, but in a high degree have completed their development. Why not much better to have permitted their retention within the abdomen, as

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

are the ovaries in woman? Far safer from seeming injury, and also in this way short circuit the deposition of their secretion within the vasa deferentia? Again, what a fruitful source of profit to the modern junior surgeon, who would very probably daily seek, by a laparotomy, to ascertain the exact condition of these important organs—of a value second only to their counterparts in women!

Having developed within the abdominal cavity, it becomes necessary in their change of abode that they carry before them a process, or pocket of the peritoneum, which, in the mature normal condition, becomes the tunica vaginalis testis. This necessarily lines the inguinal canal with a delicate intrafolded membrane, which becomes more or less fused with the vessels of the cord and also permits a certain amount of mobility as well as a normal variation of vascularity.

The peritoneal surface opposite to the internal ring, as it covers over the separated component parts of the cord, is described in normal anatomy as the infundibulum processus peritonei, in simple English, funnel-shaped. But, from repeated investigations, I am assured that this is a mistake, that normally there is no funnel-shaped depression, although it may be easily made to appear thus by traction on the cord. As far as I have been able to ascertain, this is traceable to the otherwise very valuable contribution on the subject of hernia, published by Cloquet in 1835.

This author reached his conclusions after dissecting more than five hundred subjects who had suffered from hernia, and it is not to be wondered at that, for this reason, he mistook a pathologic for a normal condition. I am myself assured that the real cause of hernia, in most instances at least, is a lack of the developmental process by the imperfect closure of the internal ring, although it may not show itself as a hernia until the later period of life. This is the more in evidence, since it is only possible by the closure of the internal ring to prevent a more or less constant hydrostatic pressure in the line of the already partially opened canal, the entering wedge ever forcing apart the readily yielding structures.

On the contrary, when the internal ring is closed firmly around the vessels, compressing them upon each other so that the entire abdominal parietes act upon a single plane, the intra-abdominal pressure acts laterally upon the walls of the canal. Note, for example, the extraordinary feats of strength of athletes when these muscles are called into special play. The only other instance in the body where nature avails herself of this mechanical principle is the passage of the ureter through the walls of the bladder, permitting the easy escape of the urine through the ureter, although the fuller the bladder the less the liability of reflux into the kidney. In pathologic conditions where this takes place, it is interesting to note the foreshortening of the ureter in its passage through the bladder wall.

Given a small infundibular process as the first factor in the problem, it is interesting to note that the internal ring, as a rule, enlarges by a depression of its lower border, since the internal abdominal pressure is first brought to bear upon these buttressing structures. These having yielded, little by little the force called into play is now exercised upon the structures of the anterior wall of the canal, but not until these give way is it usual for the patient to complain of inconvenience sufficient to have the attention of the surgeon called thereto. It is very easy for one to demonstrate by a careful examination a foreshortened, slightly dilated inguinal canal

brought about by these conditions, of which the subject has never made complaint. Here are conditions ready to become emphasized by some special strain which, instead of producing a valve-like closure of the canal, suddenly gives way because of its loss of obliquity, and the man finds himself "ruptured." In other words, there has been an escape through the dilated canal of a certain portion of the abdominal contents. Given these conditions, the forecast of the man's future is quite clearly in evidence—a retention apparatus, the ordinary truss-bearing individual; conditions becoming more pathologic, brought about by intra-abdominal pressure exercised in the line of its opening instead of at right angles to it, rendering instrumental supports of no avail; usually more or less complete invalidism, or an operation to effect its cure.

The effect of mechanical supports is obvious. By pressure exerted from without inward force is brought to bear almost wholly on the structures external to the inguinal canal. The internal ring is acted on only through this pressure and the deeper structures can not be supported in a way to effect their restoration. Indeed, the more common result of truss pressure is that which pertains to undue pressure in any other part of the body, a weakening of the parts involved, owing to impaired nutrition. It is on this account that it is often unwise to advise a patient to have recourse to a truss, and prompt remedial operative intervention may effect an easy cure and save many of the complications which oftentimes render operation on old hernia really difficult and formidable, even to surgeons of large experience.

Although to some this may seem elementary, student-teaching, its importance is generally overlooked and scarcely referred to by many authors. So important is it that I regard it as the very key to the possible surgical intervention for effecting cure. Further in our investigation, when an infundibulum pertains, we are to ascertain the structures that are defective. Here again we have recourse to anatomic study. The inguinal canal is rendered oblique in its passage through the abdominal wall by the firm retentive structures which enter into the formation of the lower border of the internal ring and the posterior wall of the canal. This may be described as a direct, slightly elliptical opening through the firm sheath of the transversalis. Its muscular fibers, as they descend toward their pubic attachment, are replaced by a double tendinous interweaving of exceptional strength. Oftentimes the opening through the transversalis is through the lower border of the muscle rather than its tendinous expansion, to-wit, a careful anatomic examination will demonstrate muscular fibers about and below the lower border of the internal ring, and then it may be described as a direct opening through the transversalis muscle. This is not, however, the more common condition, and when found I do not consider that it possesses any material advantage. As far as I am able to learn, the first of the great anatomists who pointed out this extraordinary development of the transversalis fascia and emphasized its physiologic importance was Sir Astley Cooper. So valuable was it considered by his contemporaries that, for a considerable period, it was called the transversalis fascia Cooperi.

It will readily appear that the proper development of these parts is the great bulwark for maintaining the obliquity of the canal and, as a consequence, its defect is the almost universal cause of inguinal hernia in the male. Singularly enough, this has not been pointed out as of special importance in relation to the operation for

the cure of hernia, but on careful reflection, it must be recognized as the first important stable factor in the reconstruction of the inguinal canal to its normal obliquity, by which only is it possible to effect a rational means for permanent cure.

The history of operative measures for the cure of hernia has also an important bearing on this phase of the question. From the time of the Roman surgeons, through the centuries, attempts, by a great variety of operative procedures, were made for the cure of hernia. The open dissection methods finally resolved themselves into two distinct classes. The first was to leave the wound open, packed with charpie or lint smeared with some kind of ointment, and for the most part, that which gave the better result, soaked in spirits of wine, which alcohol we should now class as an antiseptic. This permitted slow granulation and produced a more or less firm cicatrix, a result deliberately aimed at in this later period by Dr. McBurney, of New York.

The other method, and by far the most successful one, was the removal of the testicle and cord, which gave a wound subject to a possible primary closure with far less loss of the firm supporting structures, even if a suppurating wound. Notwithstanding the suffering from large wounds thus made without anesthetics, and the mortality due to infection, this method became so very common that it was at last checked by royal edict, lest the country suffer from the lack of population.

Both these methods, as we readily see, dealt with the deeper supporting tissues of the transversalis.

The earlier procedures of a considerable number of operators, more or less masters in the antiseptic technic, consisted in making an open wound and closing the re-freshened structures down to the anterior wall of the inguinal canal. A very important paper by Dr. Bull, of New York, reviewing the history of a large number of cases which came under his observation, following this method of operation, pointed out very correctly that a large majority became recurrent, without making an analytical showing of the cause. The influence of this contribution was so great that it for a time produced a decided reaction against all methods of surgical intervention. At the present time, however, no man is a more earnest advocate of the surgical cure of hernia, and there is none whose experience exhibits a better showing of results than Dr. Bull.

The essentials of operative procedures for the cure of inguinal hernia in the male, regardless of its degree of pathologic deviation, may be classed as follows: First, a wound sufficiently large to bring into easy observation all the factors pertaining to it. This necessitates the removal of the cord from the canal, usually best carried upward and inward, and the free separation of the hernial sac—the opening of the same in order to deal intelligently with its contents. These properly disposed of, the separation of the peritoneum is carried quite within the internal ring, and the sac is closed off at its base and resected. This is best effected by means of a suture, rather than a ligature, since it can not then slip from the enclosing suture. If closed with three or four continuous sutures, the enclosed structures are safely held at rest with only sufficient force to produce approximation, and these should be taken obliquely upward in the line of the reformed canal. If by ligature, the constriction must be much greater in order to prevent slipping, which necessarily lessens the vitality of the parts. I have myself known of one fatal case in which a surgeon of repute closed the sac in this way by a ligature which included an arterial branch not usually found

in this locality. The autopsy showed that death was caused by the slipping of the ligature and hemorrhage within the peritoneum.

Next follows in sequence, but already pointed out as fundamental in importance, the reconstruction of the posterior wall of the canal. The structures which should enter into it are best studied by introducing the finger into the abdominal cavity before the closing of the peritoneal sac. In many cases it may be sufficient to suture, from below upward, the transversalis fascia and reform the internal ring by closing the structures closely beneath the uplifted vessels. In large, old, deformed herniæ this will usually be insufficient, and many expedients are resorted to for the reinforcement of these structures. It has been urged by some operators to place all the strong structures of the abdominal wall posterior to the cord, covering it only for external protection by the subcutaneous, non-resistant structures. Theoretically this is at fault, since it substitutes in place of the hernia a direct, although small, opening through the entire resisting parts of the abdominal wall, which opening is in the line of the intra-abdominal pressure, and the cord thus disposed lacks its normal protection, impairing the nutrition and normal function of the testicle. Experience has shown the correctness of this criticism. I have operated a number of times for the cure of recurrent herniæ in which failure had followed this method of operation. The hernial opening was directly through the new internal ring above the cord, and the inguinal canal in its true anatomic sense was wanting.

A very considerable number of ingenious devices have been instituted for the reinforcement of the posterior wall of the canal where atrophy of the parts, incident to old pathologic changes, has supervened, e. g., the transplantation of the pyramidalis, the imbrication of the lateral walls of the canal, the interweaving of the peritoneal folds of the sac with the strong, tendinous fibers of the conjoined tendon with Poupart's ligament, etc. These may all, in certain rare conditions, have a proper place and usefulness in the reinforcement of the parts.

In recent hernia, in which the tendon of the transversalis is of normal development, the intrafolding of the yielding part and suturing quite upon the cord from below upward, in order to reform the internal ring, is sufficient. This may be effected by any method of suturing or variety of suture material, but it is of obvious advantage that an absorbable suture material be used, as the suture must be buried. The intrafolded reinforcement is much more neatly effected and the parts held at rest in easy, unconstricted approximation with much less amount of suture material by the use of a double line of continuous suture where only one knot is requisite.

When, owing to long-continued truss-pressure or other causes, there is great relaxation and defect of structures, I have found it by far the simpler and better way to evert the edges of the conjoined tendon and Poupart's ligament, and with a double continuous suture coaptate their posterior borders and close the parts quite upon the cord from below upward to aid in the reconstruction of the internal ring. This not alone re-enforces the parts with firm resisting structures, but the edges of the tendinous structures thus coapted are everted and aid in forming the lateral walls of the reconstructed canal. Thus the parts are firmly buttressed posteriorly and upon either side, while the canal is restored to its full length, thus insuring its normal obliquity.

It now remains only to replace the cord in the sulcus

thus formed, and close over it to its former relationship, the tendinous expansion of the internal and external oblique muscles. In doing this we again form a firm buttress over against the internal ring, which not alone supports it, but restores the valve-like function of the canal when undue pressure is exerted, which, as we have before stated, is the anatomic and physiologic reason why all men may not become easily ruptured. Here again, and for similar reason, we consider it of first importance to use the absorbable suture. A fine, subcuticular, continuous, buried animal suture closes the wound, which is sealed with iodoform-collodion, reinforced by a few fibers of absorbent cotton. This constitutes the only dressing, and the only restraint enjoined upon the young or old is that the movements of the body shall not bring special strain upon the parts involved.

During the process of repair suffering is so minimized that it may be called discomfort rather than pain. Sleep follows without opium; reading and writing are harmless. The enforced period of retention in bed often serves as a sort of rest cure to the overworked sufferer, who returns to his work at the end of his month of comparative restraint refreshed and invigorated rather than weakened by his sojourn in the hospital.

Primary restoration of the parts, when aseptic, well-vitalized structures are alone involved, without infection, is so assured that it is now accepted, if suppuration occurs, that there has been some fault in the technic. This may never be absolute, but in my own experience, extending over a number of years, 2 per cent. covers this defect.

By a general consensus of opinion, danger is hypothetical rather than real. My entire experience covers thirty years of active surgical practice, and includes about 500 operations on all forms of hernial cases. All have made seemingly easy recovery when the intestine was not involved, and as far as traceable quite 90 per cent. have remained cured. This may be an overestimate, since the relapsing cases are, for obvious reasons, the more difficult to trace.

All varieties of suture material have their advocates and, as a consequence, should be considered among the less essential factors. Some of us are greatly troubled in removing silk and wire buried by surgeons who advocate their use. Only the last week I operated on a patient, from a western state, in whom the defect was traceable to painful sinuses discharging for months, from which I removed large loops of thick silk. Not until the patient was on the operating-table did I learn that suit for \$15,000 had been entered against the surgeon who had buried them. This can never be charged as a result of a properly placed aseptic animal suture.

I think my introduction to the profession of the buried animal suture my best contribution to surgery. This was first published in 1871 and was first employed for the cure of hernia in 1870. I used catgut almost exclusively until 1880. For what I considered a good and sufficient reason, about 1875 I discarded silk as a buried suture. After a long search for a substitute for catgut, using the tendons from various animals, in 1882 I found the marvelously beautiful tendons from the tail of the smaller species of the kangaroo. These I have used continuously until the present, and am more than satisfied with their great superiority over other suture material. The collodion seal is a corollary to the buried suture. Not the least value of the suture is that it absolutely obviates the necessity for drainage, permitting the primary closure of the entire wound. The vitalized

serous effusions and leucocytic proliferation should be retained as Nature's "first aid to the wounded."

If our science, our theory and practice go for anything, the making and maintaining of an aseptic wound in aseptic and well-vitalized structures is the practical issue sought and to be attained. This effected, with coaptated like structures held at rest by buried aseptic, absorbable sutures, the only factor remaining to complete our ideal technique is a dressing for the purpose of preventing subsequent infection. This is secured so simply and easily by iodoform-collodion, strengthened by a few fibers of cotton, that this dressing reaches an ideal completion. It is fluid-proof in that no exudate can escape from beneath it, and as a consequence it is germ-proof in that it is by no means possible for any foreign material to enter the wound. Beyond this, it holds the approximated structures in even coaptation, at rest, with a certain fixity of support. Water does not loosen it, and it is detached from the vivified cutaneous cells beneath only by the slow separation of the exfoliated epithelium. If for any reason it is needful to remove it, this is easily effected by soaking in alcohol or ether. The late Dr. John P. Maynard, of Dedham, first made the discovery that the cellulose of cotton fiber was soluble in ether and alcohol, and more than forty years ago gave to the profession this very valuable substance called collodion. Early it was applied for the sealing of wounds, those of a slight character oftentimes healing by primary union, under its protection. It was popularly called "artificial cuticle," but naturally fell into disuse because, when it covered septic wounds it was in the highest degree harmful.

Iodoform is soluble in it and is not injurious to it, and ordinarily it is of little additional value. Under certain conditions I believe it to be inhibitory to the development of the micrococcus albus in the proliferating epithelium, and quite as valuable in this direction as the silver salts, which are much more difficult of application. To one who may doubt the efficacy of a potent agent seemingly locked up in a collodion film, we need only cite the powerful vesiculating effect of the cantharidal collodion. A wound made and maintained aseptic in well-vitalized structures, held at rest in easy coaptation by buried tendon sutures, will be followed by non-inflammatory primary union.

The fear, the anxiety, the constant supervision and watchfulness of nurse and attendant are entirely obviated. Wound supervision is finished before the patient leaves the surgery. Subsequent dressing is of no avail except to keep the parts from extraneous injury. The work of the surgeon for good or ill has its finality at the single period of manipulative intervention.

The surgeon freely profits by the vast contributions of those who have preceded him. It should be his inspiration to contribute as he may be able to this storehouse of knowledge. The individual counts for little, but fundamental principles are enduring. For more than a quarter of a century I have endeavored to emphasize with greater or less clearness the anatomic and physiologic foundations upon which it is alone possible to reconstruct the parts involved in inguinal hernia in the male. These may be epitomized essentially as follows: 1. Free dissection of the parts under aseptic conditions. 2. The proper disposition of the hernial contents. 3. Suture and resection of the sac. 4. The reconstruction of the inguinal canal to its normal obliquity. 5. The buried animal suture, preferably tendon, is absolutely essential in order to effect this. 6.

The closure of the wound without drainage. 7. Protecting the wound with iodoform-collodion seal, and the application of no other dressing.

DISCUSSION ON PAPERS OF DRs. OCHSNER, JOHNSON AND MARCY.

DR. W. B. DEGARMO, New York City.—I consider the first paper a very important one. Children are certainly entitled to a cure, but the question still remains under discussion as to how. I think the author has gone over the subject thoroughly. An important predisposing cause of hernia in children is the persistence of communication between the cavity and the cavity of the abdomen, which Dr. Marcy so clearly pointed out years ago. I think it is a predisposing cause not only in infancy, but rather late in life, and I have seen what we call congenital hernia occurring as late as 21 years. Many of us carry the defect through life. As to the immediate causes, I have developed views which are at variance with the text-books, for in my opinion the most important immediate cause at all ages is constipation. This may not be borne out by the experience of others, but it is certainly true so far as my observation goes. I endorse the list of operative cases as formulated by Dr. Coley, but I hesitate to operate on children under 5 years of age, as I think 95 per cent. of them may be cured by a truss. There is no reason why we should not operate on them, except our natural feeling against operative measures on infants. I can not endorse the treatment of hernia in children by confinement to bed, as they depreciate in health so soon as they are placed there. There are very few cases that can not be treated with the truss and the child be allowed to play around.

As to operative treatment, the method I prefer is Bassini's. The subject of ventral hernia, it seems to me, has been very thoroughly covered. We should stitch up the normal layers of the muscular walls separately in all cases if possible. I think all of us find the relaxation suture necessary, at least in large abdomens, and I usually prefer silkworm gut to any other suture, removed in ten or twelve days.

Dr. Marcy's paper may be disposed of promptly, as I do not wish to criticize it. He was the first man to point out the importance of restoring the obliquity of the inguinal canal, and he was then many years ahead of the times. No man living has pointed out the true anatomical relations as graphically as Dr. Marcy, and we are also indebted to him for kangaroo tendon as a valuable buried suture.

DR. A. H. FERGUSON, Chicago.—The subject of inguinal hernia is a very interesting one, and it is the only portion of this discussion to which I will devote a few minutes. Whatever honor belongs to the radical cure of oblique inguinal hernia by the Bassini and Halsted methods is due primarily to Dr. Marcy, but I must say, however, that I am compelled to take variance with all these operative procedures in the vast majority of cases; in fact I characterize all these operations as shot-gun prescriptions because they do not take into consideration all of the etiological factors. It is true that the rotundity of the peritoneum is restored by tying off the sac, and that the inguinal canal is also restored, but what about the other structures. These are only passive structures and the next in front of the internal ring and canal is the internal oblique muscle, which is the only active muscular protection that the internal ring has. Physiologically it is beautifully protected by this muscle as it runs across to the conjoint tendon from its origin at Poupart's ligament. The normal origin of the internal oblique at Poupart's ligament in the male is a little more than one-half of this ligament, while in the female it arises from two-thirds. This is no doubt one reason why oblique inguinal hernia is more frequent in the male than in the female. When there is a deficient origin of the internal oblique muscle at Poupart's ligament, the active protection of the internal ring is gone and there is an angle. Sometimes this deficiency extends to the anterior superior spine. In 95 per cent. of inguinal oblique hernia there is a deficient origin of the internal oblique muscle at Poupart's ligament. When the intra-abdominal pressure exerts itself and distends the peritoneum and the internal ring, which is composed of the transversalis fascia, then the protecting muscle being absent the hernia protrusion meets with nothing more until it reaches the

aponeurosis of the external oblique muscle in front of the inguinal canal. The point I wish to impress on you is that there is a new etiological factor at work in hernia which has not been recognized, namely, the deficient origin of the internal oblique at Poupart's ligament. I divide the radical cure into two classes: 1. the typical operation, which restores all the structures from within outward and leaves them the same as they are in the normal inguinal region, and 2, plastic operations which are necessary to strengthen specially weak points in the hernial region, caused by congenital defects or by pressure of hernial contents or a truss. No young man should be allowed to go on wearing a truss until his abdominal wall has thinned out.

DR. W. J. MAYO, Rochester, Minn.—I think the author of the first paper called your attention to an important point when he said that by putting these children in bed, carefully correcting their diet, and relieving them of their constipation and any urinary disturbance, a large percentage would be quickly cured. The paper by Dr. Johnson is also an important one. It is not necessary to add anything to what has been said by Dr. Marcy, but there are one or two practical points I would like to mention connected with the cure of hernia. I have no idea of discussing the Bassini operation, but the most important point about it is that he divides the scar. Instead of being brought together in a single line it is divided into two lines. In the Johnson operation the first line of scar tissue is protected by Poupart's ligament, and the outside line by the oblique layers of muscular tissue. This method can be carried to other parts of the body and you can divide the scar in a ventral hernia in the same manner. Umbilical hernia is one of the most difficult that we have to deal with and usually occurs in fleshy people. If you put them on their back and ask them to rise up, you can easily determine where the recti muscles are, which may be separated several inches. If you make the incision down to one side of the sac you can examine the inside and the contents, and cut off the omentum at the base. The operation can be done either laterally or transversely.

DR. A. J. OCHSNER, closing.—Theoretically it is always bad to put children in bed when they can be treated without. If treatment by means of a truss is as effective as treatment in bed then the latter is wrong. If you put the child in bed in the inverted position, you give the mesentery an opportunity to shorten, and at the same time take care of the intra-abdominal pressure, which is due, as Dr. DeGarmo has said, to constipation. It is also, however, due to the pressure necessary to overcome the gaseous distention. As a matter of fact, by overcoming these difficulties, the children improve so enormously that in my experience weak, emaciated children, whom you would consider in good condition to contract almost any disease, will build up wonderfully. I have not seen one single child which did not improve enormously while in bed, and consequently the objections which would suggest themselves to any one are eliminated. I would like to ask the members to try this form of treatment, as I have been greatly pleased with it. It consists simply in keeping the hernia sac empty, and in keeping away the abnormal intra-abdominal pressure.

DR. H. O. MARCY, closing.—We will all agree with Dr. Ochsner that children are benefited by rest in bed, and I think that they are benefited also by early operation. Why should we have institutions for the young intended to prevent these children entering life handicapped by hernia if it is not safely a preventable condition? As to ventral hernia, it seems to me that this is a simple thing to avoid. In the last 1500 laparotomies I have had but one hernia; of course I speak of aseptic laparotomies. If you prevent ventral hernia you will save much subsequent suffering. If the cases are restored cured, the way to do it is to build it back to its normal anatomy, and reconstruction of the abdominal wall in layers will do this. I think the problem of hernia is practically settled. There were a few fundamental principles mentioned in the paper which I did not read, owing to lack of time. A man should be a thorough master of the technic of hernia and the operation should not be confined to a few men. We must remember that 3,000,000 people in this country wear trusses. The large ma-

majority of this great truss-bearing army are entitled to be cured.

Dr. M. M. JOHNSON, closing—As regards restoring the normal layers if possible, I would say that in a large number of ventral hernie following appendectomies there has been a long process of suppurating and drainage, often followed by a loss of tissue and atrophy, to the extent that all the lines of the normal layers are obliterated. It is in this class of cases that you must unite the parts en masse, as stated in my paper.

HYDRENCEPHALOCELE.*

CARL BECK, M.D.

NEW YORK CITY.

The prognosis of hydrencephalocele, formerly so extremely unfavorable, has become more promising under the auspices of asepsis, as well as under those of the Roentgen rays, which have but recently added a further element of better knowledge. As an illustration the following cases may serve:

CASE 1.—A boy of 5 weeks of age well nourished and otherwise normal, shows a spherical, non-pulsating tumor of the size of an orange, projecting from the nasofrontal region and sinking downward to the *ala nasi*. (Fig. 1.) At birth the tumor was a trifle smaller. The family history shows nothing abnormal. The father is a German laborer, the mother was born in New York City. Both parents are anemic. The mother was a multipara—four previous children—and the confinement was normal. In connection with the question of injuries being etiological factors in the defects of development of early intrauterine life, it is interesting to note, that the mother fell from the fourth story of her residence eight months before confinement, escaping with a fracture of three ribs and of the olecranon and a contusion of the knee. Pleuritis followed the thoracic injury, but recovery took place three weeks afterward.

The walls of the tumor were thin and the integument appeared normal. Contractions of the tumor were observed, especially while the child was crying. During sleep the tumor appeared somewhat smaller. There was exquisite fluctuation and the contents could almost entirely be pressed within the skull, which procedure did not cause any reaction. Neither pulsation of the brain could be detected, nor could the border of the cranial opening be distinctly felt.

In view of these facts, especially of my inability to palpate so solid a mass with certainty, I diagnosed meningocoele, and thought of aspiration followed by the injection of a small quantity of iodoform-glycerin.

The Roentgen rays, however, modified my views. A skiagraph (Fig. 2) showed behind the light shade, representing the fluid, a dark one, which had to be interpreted as a solid mass confined to the area of the large triangular bony opening. That this was cerebral substance could be verified by the subsequent operation.

The skiagraph also showed that the nasal bones were shifted downward so that an interspace of the width of a man's thumb was left between it and the frontal bone. Now I dropped the idea of the treatment by injection and proceeded to excision, which was done without anesthesia. After constriction at the base of the tumor for the purpose of ascertaining whether cutting off the circulation and pressing upon the contents would produce any reaction, a prophylactic silk-suture was conducted around the whole circumference

of the tumor at its base, in order to be able to control any excessive hemorrhage by quickly pulling the suture-ends together. Now, an elliptic flap was dissected from the center of the tumor and the cavity opened laterally. After about one tablespoonful of normal cerebral fluid had escaped, further exposure of the sac revealed its lining, consisting of *dura mater*, partially protecting degenerated cerebral substance. Near the base, according to the darker shadow of the skiagraph, cerebral substance, covered by dark-red, velvety, succulent and easily-bleeding tissue, was protruded. After severing the protruding portion from its lateral connections, which were thinly spread over the walls, it was possible to reduce it into the cranial cavity. Two-thirds of the sac was removed and the remaining stump was freed from the frontal bone, including periosteum, until apposition without tension could be obtained. The edges were then united with thin formalin-catgut and supported by another row, consisting of the overlapping

Fig. 1.—Nasofrontal hydrencephalocele in a boy of five weeks of age.

soft tissues. Finally the skin edges were united with stout silk. Although the loss of blood was scant, the infant appeared very anemic after the operation and refused nursing until two hours afterward. No stimulants were administered. There was no reaction, and to-day, ten days after the operation, the wound is perfectly healed and child appears normal in every respect.

A skiagraph taken one week after the operation shows that the bony canal became somewhat smaller.

Another skiagraph (Fig. 3) taken six months later showed considerable narrowing of the bony canal, the nasal bones also having approached the *os frontis* in the meanwhile. The child has developed well and is normal in every respect. (December, 1900.)

CASE 2.—A boy, 7 weeks of age, whose family history reveals nothing abnormal. The parents immigrated from Polish-Russia several years ago. The mother is a multipara and is, like her husband, fairly well nourished.

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

This child, otherwise well developed, shows an ovoid tumor, the size of which exceeds that of his head, and projects from the foramen magnum. The walls of the tumor, which, if not held, sink down alongside the spinal column, are moderately thick at the center and very thick and hairy at the base, while at the translucent tip they are very thin. The translucent area, which contained cerebral fluid, fluctuates, while the remaining portion is solid. The fluid can not be pressed within the skull. The skull appears microcephalic, the sutures thick and the fontanelles small.

The tumor has slowly enlarged since birth. The child has nursed well. It can not cry, but moans once in a while in a voice which has an animal timbre. It never cried like normal children. During moaning slight pulsation of the tumor could be observed. There was always considerable restlessness.

Ophthalmoscopic examination was thus very difficult, but it could be ascertained that the child was blind.

Four different efforts to get a skiagraph were made, but the restlessness of the child also prevented a fair reproduction. Still the fact that there was a pedicle, of moderate size, apparently not in entire connection with the brain, could be registered.

Fig. 2.—Hydrencephalocele—skiagraph of Fig. 1—showing hiatum between nasal and frontal bone and fluid and solid portions.

Aspiration and injection of iodoform-glycerin were advised as a first therapeutic step, but in the meanwhile kind neighbors suggested to the parents that they could earn a fortune by exhibiting the "freak" at a dime museum. So the child was freely handled until two weeks later alarming symptoms set in, the child refusing nursing and going into convulsions several times a day. I now saw the child again. The translucent portion of the tumor appeared congested. The temperature was 102.4 per rectum, and pulse and respiration were also higher than normal. The typical danger of all hydrencephalocèles, spontaneous rupture of the sac—which meant death—appeared to be imminent. Considering the absolutely fatal prognosis of hydrencephalocele in the case of non-interference, I advised immediate excision. After ascertaining, by a rubber tie, that constriction of the base of the tumor had no dangerous effect, I proceeded to the ablation of the tumor. When the sac was first opened at the tip about two ounces of a slightly yellowish, opaque fluid escaped. After further dividing the integument, subcutaneous tissue, fat, interspersed muscular tissue

and dura, the solid contents, which appeared like normal brain-substance, presented themselves. They contained the distended posterior cornua of the lateral ventricles and the thalamus opticus covered by normal pia. The basis of the tumor was in connection with the brain by a pedicle of moderate circumference.

After ablation the basal edges of the wound were inverted and united by formalin-catgut. The skin-flaps were secured by stout silk and protected with iodoform-gauze-collodion dressing.

Although there was no loss of blood, constriction being upheld until apposition, the child presented the symptoms of shock until an hour after operation, the body remaining motionless, the respiration slow and irregular and the face appearing very pale. Nursing was refused until five hours later. On the following day the child's condition was good, the temperature and respiration being normal and the pulse only slightly accelerated.

On the third day the temperature was 104.2, respiration irregular and the feeble pulse could not be counted. Stimulants had no effect. Exitus occurred on the fourth day, apparently from purulent meningitis. The autopsy was declined by the orthodox parents.

Fig. 3.—Skiagraph of Case 1, taken six months after removal of hydrencephalocele, showing considerable narrowing of the bony canal—the nasal bonea having approached the os frontis.

In view of the pedunculated form of the tumor an operation at an earlier stage would probably have saved the child's life. Still, considering the microcephalic condition of the head, the desirability of such a result could be questioned.

In connection with these histories, I may also refer to a case of encephalocele concerning a poorly-nourished boy of 3 months of age, suffering from complicated hare-lip and cleft palate at the same time; he gives a good family history. The father is a German laborer. The mother, a multipara, was born in New York City. At birth, a globular, pulsating tumor was detected, which had moderately increased in size since. With a broad base it springs from the contracted skull laterally from the superior angle of the occiput. The child had slight attacks of spasms once in a while.

The treatment was very simple. It consisted in exerting pressure by a large iodoform-gauze-collodion dressing, which had the slight disadvantage only, that after long employment dermatitis set in. Under this pressure treatment, the tumor diminished gradually in

size and disappeared entirely in the course of a year. In the meanwhile the hare-lip, as well as the cleft palate, were also successfully operated on. Now the child is 2 years old and enjoys perfect health.

SYMMETRICAL DEVELOPMENT,

OR DOES OUR PRESENT SCHOOL SYSTEM DEVELOP THE HIGHEST POWERS OF THE PUPIL?*

E. STUVER, M.S., M.D., Ph.D.

Member Colorado and Wyoming State Medical Societies, The American Medical Association, International Medical Congress, Fellow of the American Academy of Medicine; Active Member of the National Educational Association, Etc.

FORT COLLINS, COLO.

"Man is the noblest work of God," the acme of creative energy in the world, and the grandest product of cycles of evolutionary progress. While all this is true, still, owing to his exceedingly complex organization and unstable equilibrium, he is very liable to derangements which, unless promptly corrected, rapidly lead to deterioration and decay. This tendency has made the subject of evolving, or developing man's highest powers and noblest characteristics a theme which has received the earnest attention of the greatest philosophers, educators and philanthropists the world has produced since the earliest dawn of civilization.

The kind of education that will best equip the individual for the most complete living and enable him to do the most good in the world has always been a momentous question, but as mind gains a greater ascendancy over matter, and the forces of nature are called into requisition to do the work of the world, properly developed bodies, well-trained minds, and fully-rounded moral natures are becoming of increasingly greater importance to secure a true civilization.

The spirit of greed and rapacity which "would wade through slaughter to a throne, and shut the gates of mercy on mankind"; which would erect an oligarchy for the benefit of the few, and reduce the great body of the people to veritable slaves, can only be checked and higher ideals substituted, by a better and more effective education for the masses of the people.

In order to obtain a clear conception of man's organization and the possibilities of his powers, it is necessary to take a comprehensive view of his nature, and know something of the physical, mental and moral potentialities impressed on him through ages of evolutionary progress. Unless we enter on the study of the best methods of developing man's highest and noblest powers with a broad and comprehensive view, we are almost certain to become ardent advocates of some partial and restricted system which trains and cultivates certain of his powers to the neglect of others. If our minds are carried away with the importance of physical training we are liable to overlook or neglect the mental and moral attributes of his nature, in which case we would probably produce excellent specimens of ancient gladiators, modern prize-fighters, or conscienceless bullies; if we are imbued with the transcendent importance of the mental powers, and devote our whole attention to their cultivation, we may produce prodigies of youthful precocity, which, owing to undue development or shattered physical powers, or perverted moral natures, land in premature graves, drag through life miserable, suffering wrecks or become harpies and fatten on society, or, if not so successful, criminals and fill our jails and peni-

entiaries; or, lastly, if our whole attention is devoted to moral training, we will probably have as a result a lot of physical nonentities and mental incompetents, in short, useless or worse than useless fanatics.

With the dangers of partial or one-sided development clearly before our minds, I desire in this paper to emphasize the importance of the simultaneous, symmetrical development of all the powers, physical, intellectual and moral.

In order to obtain a secure foundation for so important a work, it is necessary that parents, and especially teachers, should have at least a clear outline knowledge of man's phylogenetic development. Every one should know that "a child is born with organs, aptitudes, powers, possibilities, desires, impulses, and with instincts, but is without knowledge, habits or moral character;" also that the child instead of being a "little man" with the same thoughts, feelings, inclinations, capacities and powers only on a smaller scale than a man, is in truth an altogether different being, and may be aptly characterized in his various stages of development as an epitome of the development of the race. He passes through the successive stages of savagery, barbarism and semi-civilization before attaining to the full civilization in which we live. During this progress the spectral forms of his dead ancestors surround him on all sides, and the mighty mental accumulations and beliefs of a long-forgotten past impress on him the various stages of credulity, inquiry, faith and full-blown reason through which these ancestors have passed.

They should know that in both organization and function there are great differences between the adult and the child, and their nurture and training should be different, and made to conform to their organic and functional capacities.

The glands, heart, lungs and muscular and osseous systems of the child possess a high degree of organic and functional perfection, and this would logically seem to indicate that the proper exercise and development of these various organs and systems is the rational and proper occupation of the child during childhood and early youth. In support of this inference it may be said that in the savage and barbarous stages of race development, to which the child corresponds, these organs and functions are developed to a high degree of perfection.

Such things as weak, flabby muscles, flat chests, failing hearts and impaired digestive organs were unknown, because their existence would have meant extinction to their possessors. The muscular, osseous and respiratory systems were developed to a high degree of perfection, which was not attained by disuse and confinement in illy-ventilated rooms for a considerable part of the day, and the whole of the night, but by a careful and systematic exercise of the parts undergoing development.

But while the physical organization was systematically developed and had attained a high degree of perfection, and the special senses, especially the sight and hearing, were carefully trained from the earliest childhood until they became phenomenally acute among savage races, the intellectual faculties in many particulars remained in a rudimentary state. The powers of continuous mental application, abstract reasoning and broad generalization were unknown in the savage, and were only acquired by the race through the slow gradual process of evolution.

While, as above indicated, the organic development and functional capacity of the heart, lungs and glandular organs, and the muscular and osseous systems of the child at birth have reached a high degree of perfection,

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

on the other hand, his nervous system is in a very immature and undeveloped state, and does not reach full maturity until about the age of 33 years. The brain of the young child as compared with that of the adult, contains a larger percentage of water, is softer, more easily irritated, and is much sooner fatigued on mental exertion; but on the contrary, the perceptive faculties, whose development depends on the training of the special senses, are keen and alert, and attain a high degree of perfection if given an opportunity in childhood to develop in accordance with the laws impressed by nature upon the race throughout the ages. With these fundamental principles clearly in mind, let us now see whether our courses of study and methods of instruction are based on a correct foundation and are in harmony with the evolving powers of the child. Right here I desire to say that any criticisms I may make on existing conditions or methods are not made in a spirit of fault-finding, or for the purpose of casting reflections on our great army of teachers, who are, as a rule, faithful, conscientious and sincere workers, often laboring under great difficulties and struggling against unnecessary obstacles, but solely for the purpose of calling attention to some evils which the best interests of our seventeen millions of pupils demand should be corrected. Parenthetically, too, I want to say that hereditary defects, improper home-training, dietetic errors, late hours, parties and all that kind of dissipation are not laid at the door of the schools, but are matters which should be corrected by the parents.

With the way thus cleared, and surrounded by a group of earnest, trusting 5-year-old faces, let us follow them to the kindergarten and see what should be, and what is being done for them. Here, if they are so fortunate as to have a teacher imbued with the true spirit of Froebel's teachings, they pass a happy time, and receive much benefit. Their books are plants, flowers, trees, fruits, birds, insects and the various objects, animate and inanimate, of the external world by which they are surrounded. The everlasting hills, rising in majesty and grandeur around them; the sighing of the wind among the trees, the murmur of the brooks, the glorious sunsets, the autumn forest with all its gorgeous hues and kaleidoscopic changes, in short, the almost infinite variety of objects and the innumerable beauties of nature can be made most impressive sermons by the true kindergarten teacher, sermons that will sink deep down into the soul of the child, and leave an impression on its body, its mind and its character which the storms and the vicissitudes of life will never obliterate. But, alas! Such teachers as we have in mind are like angel's visits, rare, indeed, and come like a ray of hope from the great beyond.

In the great majority of instances, even the life of the kindergarten is smothered by the blighting curse of formalism and routine, and instead of being a blessing it becomes a curse, and through ignorance or disregard of the most rudimentary physiological laws, lays the foundation of physical defect or disease. But, you may ask: On what grounds do you make such statements? In the first place, as Maudsley has very beautifully shown, it requires frequent repetition and long-continuation of a sensory impression to make a well-established pathway to and from the brain, over which such impressions may be conveyed with the greatest ease and accuracy. Every one knows how exceedingly difficult it is to become a skilled pianist, or to attain proficiency in any work requiring delicate, rapid and finely co-ordinated muscular movements. Long and careful prac-

tice is devoted to securing facility of the coarser muscular movements, and when this has been accomplished, the finer and more delicate movements are gradually acquired. In kindergarten work this fundamental physiological law is often ignored or transgressed. The children, instead of first having been carefully trained in the coarser muscular movements, which are brought into play in walking, running, playing, skating, horse-back riding, molding in clay, building objects of various kinds with large blocks, gathering flowers or geological specimens, or the many other ways that naturally suggest themselves, are put to sewing and various occupations that not only require delicate and accurate co-ordination of the muscles brought into play, but also throw a great strain upon the eyes and are responsible for much of the myopia and other defects of vision which are becoming so prevalent in our schools.

The second fundamental physiologic principle to which I desire to direct attention—and I want to insist upon this, because it applies not only to the kindergarten and primary grades, but to all grades of our school system—is, that in the child and youth the association fibers which connect or unite the various brain-centers are in an undeveloped state. Owing to this condition the various brain-centers are largely isolated, and must depend on their own nervous energy in the performance of their special functions. This explains why young children are unable to concentrate their attention on one subject for any great length of time; why they tire so easily; why they become restless, and why they should have frequent changes of work as well as periods of rest and intermission, to permit the tired brain-centers to regain their strength and tone. As the child grows older, these association fibers gradually develop, and distant brain-centers are connected and can work together harmoniously and assist and strengthen each other.

In order, however, that this cerebral development may be the most symmetrical and perfect, it is necessary that the motor brain-centers be developed simultaneously with the higher intellectual centers.

To secure this result requires pure, rich, vitalized blood, and a proper exercise of the functions on which the development of the centers depends, or in other words, to have well-developed motor-centers the pupil must have plenty of plain, nourishing food, pure air and outdoor exercise. When these conditions are complied with the intellectual centers rapidly store up power and at the proper time produce most wonderful results, as has been so often illustrated in the history of our country and that of other nations, and explains why Franklin, Webster, Lincoln and hosts of others, with meagre educational facilities, became intellectual giants and shed glory and luster over our nation. It also explains why our old-fashioned country schools, with all their drawbacks, crudities and imperfections, but free from the high-pressure cramming, artificial and, I might say, diluting methods of our graded schools, brought their pupils closer to the great mother nature, and permitting their brains to develop slowly and acquire power, have accomplished so much good.

The old motto *mens sana in corpore sano* is just as true as when written, and should appeal to us with even greater force than to those for whom the words were penned centuries ago. While this truth is beginning to be appreciated by educators, and much attention is given to athletics and physical training in some of the higher institutions of learning, in the great majority of our town and city graded schools proper physical cul-

ture and bodily development are either inadequately cared for or entirely ignored.

I desire to call attention to the following errors which I believe are common in a great majority of our schools:

1. During the early, plastic years of childhood young children are given too many studies.

2. The daily sessions are too long.

3. Recitations are generally too long.

4. Intermissions or periods of relaxation are not frequent enough, and the children do not have enough exercise in the open air, with free spontaneous, unrestrained play.

5. Pupils are frequently deprived of the privilege of attending to the calls of nature.

6. The system of examinations generally followed is attended by many evil results.

7. Many teachers resort to cruel, dangerous and harsh punishments, instead of whipping when corporal punishment is necessary.

I desire to say that these conclusions do not represent my own unsupported opinion, but are entertained by many of the most prominent educators and physicians in our own country, and, indeed, I might say, the world.

First, let us briefly consider the school buildings, their surroundings and the teachers. While many of our school buildings are models of beauty, comfort, convenience, and fulfill hygienic requirements admirably, on the other hand, in many places, especially in the large cities, accommodations are entirely inadequate, and thousands of children can not be admitted to them for lack of room; many of the rooms are poorly ventilated and dark, it being necessary to keep the gas burning in some the whole day, which renders them unfit for school purposes. There is much over-crowding, many teachers having from 75 to 150 pupils.¹ In this connection I desire to call attention to the timely and exceedingly valuable suggestion of Dr. J. C. Culbertson, a member of the Cincinnati school board. Dr. Culbertson has made a careful study of the health conditions in the schools of his own city, and strongly recommends that when it is necessary for cities which have facilities for rapid transit to build new school houses, they should be built out in the country, where large play-grounds, pure air, sunlight and ideal health conditions can be secured. I consider this a most excellent suggestion, and if carried into effect I believe it would rapidly improve the health of city pupils.

We are justly proud of many of our teachers, but while this is true, the fact must be admitted that there is a decided lack of professional *esprit du corps*, and a large percentage have never been properly trained for their work; only about 15 per cent. have taken a course of professional training in normal schools,¹ and many lack that thoroughness of education necessary to make them first-class teachers. A large number do not expect to make teaching their life-work, but merely a stepping-stone to some other profession or calling. Thus it will be seen that while occupying a position of the utmost importance and most far-reaching consequences, the majority of our teachers lack one or all of the requisites for successful teaching, namely, enthusiasm and natural ability for the work, thorough education and careful professional training. The result of this is that in many schools the work, instead of being inspired and vitalized by a love for truth and a desire to penetrate and understand the secrets and laws of nature, is dull and mechanical and consists principally in routine and cramming for examinations, which, as you all know, has little real educative value.

Children Are Given Too Many Studies.—The great increase in recent years of the number of subjects included in our common and high school courses compels pupils to take too many studies at the same time, thereby creating a tendency to superficial and imperfect work, and the pernicious habit of leaving a subject before it is thoroughly understood. It is very seriously doubted by many of our best educators whether the breadth of culture thus gained is not more than counterbalanced by the lack of thoroughness and mental power which were acquired by students of fifty years ago. No one who has seen the pale, delicate children groaning under a load of books almost too great for their strength can doubt that the pushing, crowding and high-pressure to which they are subjected from the time they enter until they leave school have a very deleterious influence on healthy physical development, and are responsible for a large part of the dyspepsia, nervous irritation and mental irritability which, unfortunately, have become such prominent characteristics of our people. Young children are not only given too many formal studies, but some studies for which in mental development they are entirely unprepared and can not comprehend. As a notable example of this I desire to call attention to the everlasting number-work and arithmetic drill which appear to have become a mania with the majority of teachers in our schools to-day. From the time the unfortunate children enter the first primary grade through the eight long years, until they emerge from the grammar course they are subjected to a continual grind in number-work, problems and examinations. Morning, noon and night these are a veritable "old man of the sea" to them, hanging like a pall over their hours of leisure, and even invading their dreams; they become not only a menace to the health and happiness of the children, making them cross, nervous and irritable, but also a nuisance to their parents, who can not enjoy a quiet half-hour because a puzzled child can not solve a long list of problems far beyond its comprehension, and appeals for help. But, after all, what results are attained by this work, worry and grind? I believe I am justified in saying that they are nearly always inadequate and often a dismal failure, and that any 11 or 12-year-old pupil who had never looked into a written arithmetic, but who had been carefully drilled in mental arithmetic, can do better work and obtain a clearer comprehension and more thorough grasp of the subject in three or four years than the struggling child obtains by its eight years of arduous and detested toil.

If it is true, as claimed by the eminent psychologist, Prof. G. T. W. Patrick, of the University of Iowa, that the child does not reach the "arithmetic age" until about the age of 10 or 11 years, we have good grounds for recommending that this useless arithmetic grind, this brain-irritating and mind-paralyzing exercise be banished from the schools, and that the time now worse than wasted be devoted to acquiring a knowledge of the fundamental facts of botany, geology, zoology and other subjects that the children can understand and enjoy. If such a course were adopted the children could be brought into closer contact with the beauties and wonders of nature, and in an informal way, receive a clear insight into her mysteries. By putting much of the primary work on the basis of pleasant diversion, the pupils would not only learn more about the various subjects thus taught than if presented in a formal way, but they would, in addition, acquire a physical strength and moral uplift which would enable them to overcome easily the otherwise serious obstacles of their formal

work. The barren rules of grammar would crystallize into the charming beauties of applied language, and hitherto dry and barren subjects would reveal unappreciated beauties.

The Daily Sessions for Young Children Are Too Long.—It was a revelation to many people, and especially to the educators, that when manual training was introduced into some of our city schools those pupils who devoted a considerable part of each day to this kind of work not only made as good progress in their regular studies, but even excelled the pupils who devoted the whole daily session to study, while at the same time they enjoyed better health, were more contented and happier.

The same thing is shown in the schools where, owing to over-crowding, some of the pupils can only attend school half of the daily session. In these cases it has been found that the half-day pupils accomplished as much or more than those who were in school all day. Indeed, as Dr. J. C. Culbertson² well says: "Manual training, and so-called Sloyd work, should be made part of the regular course of study in all schools." "All boys and girls should be educated in the use of their hands, so that these members of the body can and will co-ordinate with brain functions." "This means everything through life, including self-sustentation, self-reliance and individual independence."

Time will not permit me to enlarge on the many advantages arising from manual training; to point out how the training of the muscles develops the controlling motor-centers of the brain and produces a broader and richer sensory content, a larger and more accurate knowledge of the world and a deeper insight into the forces and laws of nature. This training and co-ordination of the muscles develops the motor-centers of the brain, develops the association fibers which bind together and strengthen the three billion nerve-cells which go to make up the nervous system, and at the same time, by removing irritation and giving nature a chance, favors the storing and up-building of power in the higher brain centers which in later years, dominating and supported by a magnificent physical organization, assume a commanding position both in the world of thought and of action, and produce most wonderful results, while the poor, hollow-eyed little pedant, the youthful prodigy, with his stimulated, irritated and weakened brain and mind is relegated to a life of mediocrity or is consigned to the grave or an asylum.

Recitations Are Generally Too Long.—The power of concentrating the mind is very limited in the young child. In a very few minutes his interest and attention begin to flag, and if the attempt is made to compel him to continue the work after this point is reached he becomes fatigued, nervous and restless, and such attempts are not only barren of good results, but are positively injurious because in the first place, impressions made on a tired brain do not last, and the attempt to fight against nature is without any permanent good result, and secondly, because such work irritates and weakens the unstable brain. With young children during the first five or so minutes, when their faces glow with enthusiasm and they give close attention to the work in hand, good is being accomplished, but as soon as it requires an effort of the will to follow the work, and they become tired, they are being injured, and the recitation should stop at once, even if not more than one-half the routine time has been occupied. Change their work or turn them out to play and you will accomplish much better results than if you attempt to im-

pose undue burdens on the protesting brain and convert a soul-inspiring work into a detested drudgery.

Intermissions or Periods of Relaxation Are Not Frequent Enough, and They Do Not Have Enough Exercise in the Open Air, With Free, Spontaneous, Unrestrained Play.—Play is a God-given impulse implanted in the child for its protection and development, and the more thoroughly this subject is studied the more strongly does the truth impress itself on rational thinkers that nature's ways are far superior to man's ways and should be as closely followed as possible.

Who does not sympathize with the little boys and girls who prefer to go to the fields, woods and hills to gather flowers, watch the birds and squirrels, collect insects, chase butterflies and moths or examine the rocks on a bright, warm spring day, rather than sit in a musty school-room? I tell you, my friends, the children are right. The voice of Nature is crying within them for physical, mental and moral pabulum, and we are giving them the stones of a barren routine, or an indigestible man-made dietary.

There is a disposition on the part of some teachers to do away with the old-fashioned, open-air recess. They advocate in its place calisthenics, or some kind of formal exercise. In the whole range of educational subjects there is no question fraught with more important consequences to the children than that of proper sanitary surroundings, and ample provision for healthful outdoor exercise. As previously indicated, the brain of the child is unstable and easily irritated. Nerve force rapidly accumulates in the motor centers, and unless frequent opportunities be given for its discharge in muscular movements, the attempts to inhibit these movements by will power will not only set up irritation of the brain, make the child peevish and unamiable, injure its health and interfere with its proper physical development, but will at the same time weaken the mind and defeat the very object for which long sessions are intended, namely, the accomplishment of the largest amount of work in a given time.

Oxygen is necessary to produce nerve force,³ to stimulate the respiration and circulation of the blood, to develop the muscular system and to destroy the poisons continually accumulating in the system, and since no room with from 40 to 60 pupils can be occupied much over an hour and the air be fit to breathe without dangerous drafts being created, pupils should have a 15-minute, open-air, out-door recess in the middle of each long session. During the recess the windows should be thrown open and the rooms thoroughly ventilated, the foul exhalations eliminated and the air vitalized. This out-door exercise is best for the child because it removes him from the monotony, formalism and routine of the schoolroom and enables him, yes, compels him, to inhale full draughts of nature's life-giving element, pure air, to free his system from accumulated poisons and spontaneously to develop his powers and adjust himself to his environment.

A properly conducted recess not only increases the sympathy and fraternal feeling between pupils, increases their physical strength and enlarges their intellectual and moral horizons, but it also draws them closer to mother nature, the source from which to derive true power and inspiration.

While I do not want to be understood as opposing calisthenics and gymnastic exercises, because properly conducted they are very useful adjuncts and give gracefulness, vigor, bodily symmetry and pleasure, I do want to protest against the custom of supplanting the out-

door recess by these exercises, which in recent years has crept into some of our schools.

Notwithstanding the fact that the great majority of our educators and nearly all our most eminent physicians strongly endorse out-door recesses with free, unrestrained, spontaneous play, still enough teachers supplant them by calisthenics to do a great deal of harm.

During spontaneous play the motor nerve centers discharge their stored-up nerve force involuntarily, spontaneously and without effort on the part of the higher brain centers, while on the other hand, calisthenics and gymnastic exercises require considerable effort of the will in directing their various movements, so that at their close the higher brain centers, instead of being rested and strengthened, are more fatigued than at their beginning. Such exercises soon become distasteful and a drudgery, and as the distinguished author and educator, Joseph E. Baldwin, very tersely says: "Drudgery hurts, and does not help. Work and then play is the Divine plan. We may easily quadruple the value of our schools by studying to keep our pupils fresh. Strong men find recreation a necessity; how much more must immature pupils play as well as work, and thus grow. He who helps to lead the school-world to play wisely deserves to be crowned as a benefactor." As to the frequency of recesses, he speaks as follows: "The hygienic and educative benefits of the hourly recess are incalculable; young children soon become fatigued, and so we make their periods of work very brief. The periods of work are lengthened as the pupil advances. The fatigue limit is a great practical study. Much may be done to keep pupils fresh by having easy work follow difficult work. Change rests, but periods of absolute freedom are indispensable. In schools of the future it is believed a recess of ten minutes will be given at the end of each hour." In contrasting romping and calisthenics, the eminent surgeon, Frank H. Hamilton, says: "Calisthenics may be very genteel, and romping very ungentle, but one is the shadow, the other the substance of healthy exercise. Girls need health as much, nay, more than boys. They can obtain it as boys do, by running, tumbling, by all sorts of innocent vagrancy. At least once a day girls should have their halters taken off, the bars let down and be turned loose like young colts."⁴

In the middle of the day the pupils should have a full hour or more in which to eat a warm lunch, and give the digestive process a chance to be properly begun. Giving pupils a short intermission at noon in which to eat a cold lunch, composed principally of pickles, rich cake or pie, which are the only things their perverted appetites crave, is the fertile source of many digestive, assimilative and developmental troubles which curse their subsequent lives.

Children Should Be Given Free and Ample Opportunity to Attend to the Calls of Nature.—To most persons it may seem that this admonition is entirely superfluous, and that the dictates of humanity and common sense would make this privilege universal. From my own personal experience as a member of a school board, as a practicing physician and from quite an extensive correspondence with teachers, educators and physicians, I am sorry to say that the practice of denying pupils this privilege is more prevalent than I would have believed it to be without a thorough investigation. Indeed, I am satisfied that even superintendents and principals of schools do not fully appreciate how frequently teachers err in this matter. This can probably be explained in part at least by the fact that it is a delicate subject about which parents do not like to make com-

plaint and which does not receive the attention and discussion in teachers' meetings that its importance deserves.

Whatever may be the causes of the practice, it exists to a greater or less extent, and exerts a most baneful influence both morally and physically on the pupils subjected to it.

As every one should know, the disregard of, or failure to attend to, the calls of nature promptly is the source of many physical ills, and may be the cause of life-long disease and misery. In the first place, it may produce chronic constipation, which, as every physician knows, is a regular Pandora's box of evils, and may lead to the gravest consequences. The toxins produced by the retained fecal matters are absorbed into the circulation; they penetrate to the most remote cells of the body; they poison the blood and the brain, lower the vitality of the body and weaken the mind. This poisoning causes headache, neuralgias, lassitude and malaise, which make work a drudgery and life a burden. It is even asserted by Dana "that organic changes in the central nervous system are doubtless due to the absorption of toxic substances produced by microbic processes in the alimentary canal." By clogging the system with effete matters digestion is impaired, nutrition rendered imperfect and growth and development retarded.

The strain on the bladder caused by efforts at retention may lead to paresis, incontinence of urine and chronic inflammatory conditions of the bladder, and the irritation and congestion thus produced may cause irritation of the sexual organs and lead to secret vices, thereby wrecking the child, not only physically, but morally as well.

Too Much Home Study Outside of School Hours Is Required, Especially of Young Children and Girls at Puberty.—This question as to the amount of home study that pupils should do outside of school hours is a very important one, and one about which there is a wide divergence of opinion. There can be no doubt that if children could have plenty of out-door exercise in pure air, surrounded by proper moral safeguards, and the time now devoted to entertainments, parties and other social dissipation were largely spent in sleep or devoted to healthful recreations, or a judiciously selected course of general reading, they would enjoy much better health and be better off in every way without any formal home study. Such conditions, however, are difficult to secure, and when it comes to a choice between allowing children to run the streets and be brought in contact with the demoralizing influences which they must meet with there, I think they had better have at least enough home work to keep them away from evil associations.

Whether home study will be beneficial or hurtful to a child depends much on the surrounding conditions, and the motives or incentives that prompt it. If done through enthusiasm, or a love of truth for the truth's sake, the results will likely be beneficial; if, on the other hand, the child is compelled to study by the slave-driver's lash or threats of failure and disgrace, the effects will in all probability be injurious.

Unfortunately, under our cramming, high-pressure method of education, with its frequent examinations and grand-stand plays for public show and approval, truth is lost sight of and the children are spurred on and incited to cram, memorize and fill themselves up for examinations and public exhibitions, regardless of the permanent effects of such a course. This sort of work keeps the child in a constant state of worry, anxiety and excitement; the brain is irritated, the vitality lowered,

the mind weakened and the importance of truth and honesty lost sight of. Under such a system even the brightest and best pupils will lie awake nights and worry over their grades, their examinations and their promotions, when never a thought or care on such matters should disturb them. Nor is this evil confined to the higher grades of the schools, but applies to many pupils in the primary grades.

The period of puberty is one of rapid development and growth, and makes great demands on the strength and vitality of the child, who, as a consequence, should be very carefully protected against mental worry, overstimulation, undue excitement or anything that will divert the vital forces from the great work which they have to perform.

Dr. Miller² very clearly depicts the condition of the child as follows: "The child fatigues much more readily, that is, his organism is much more quickly depleted and poisoned during the period of most rapid growth. The average boy has the most rapid growth between the ages of 14 and 16." In these two years he increases in weight by as much as he did during the entire six years preceding the age of 14. At this period of most rapid growth, the period of pubescence, the brain loses considerable weight, because of the fact that the usual blood-supply is lessened by a portion being withdrawn to nourish the viscera and other organs undergoing revolutionary changes during this period. While the weight of the brain is only one forty-fifth of the weight of the body, it requires one-eighth of all the blood to nourish it. At no time in his whole school career is the boy so deserving of sympathy as at the time of most rapid growth. In all learning, two features are involved: proper presentation of material by the teacher, and proper attitude of the mind on the part of the pupil. Seldom, if ever, can the latter condition be supplied by the boy or girl in the midst of the physical and mental revolutions and evolutions of pubescence. The great curse of the age is the demand for rapid education. Parents and teachers crowd the children through a long year's work. Health is sacrificed for promotion. What is learned while the child is fatigued is soon lost, the mind's force being equally dissipated. Vital force is required faster than it is generated. The work of today is done on to-morrow's credit, and the system of a child is wholly at a loss to protect itself against disease and accident."

While the above is true of the boy, it applies with still greater force to the girl, on whose system the physiologic processes of puberty make greater demands than they do of the boy, and in addition to performing the same work as her brother in school, her parents are not only ambitious that she shall take high rank in the regular studies, but also that she shall acquire the accomplishments, such as music and painting, at an early age. Is it any wonder then that under this high pressure and stimulation the girl, robbed of rest, sleep and exercise, fails to develop into perfect womanhood. The nervous force so necessary at puberty for the establishment of the menstrual function is wasted on what may be considered trifles compared with perfect health, and the poor sufferer adds another to the great army of neurasthenics and sexual incompetents which furnishes material for the neurologists and gynecologists. Every physician who has given any thought or attention to the subject can doubtless recall many cases of broken health, unhappy homes and wrecked lives due to over-work and lack of exercise while in school.

Examinations.—The question whether the present

methods of conducting examinations do more harm than good is very important and deserves careful consideration. There can be no doubt that where pupils are subjected to an everlasting grind of monthly examinations, term-examinations and annual examinations, and are continually being reminded that if they do not do this or accomplish that they will fail to pass and not receive their coveted promotions, great injury is done. I believe that when pupils are subjected to such a system, and in addition have the misfortune to be under teachers who, failing to realize or appreciate their true needs, give them puzzling problems or work that will mystify them, or is too difficult for them to perform, the examination becomes a menace rather than a help to the pupils. They are worried, annoyed and kept in a constant state of mental excitement from the time they enter the primary department of the public schools until the doors of the university close upon them.

Insufficient or no time is given for original observation and investigations, for that calm deliberation, serious reflection and earnest thought so necessary to make thorough students, ripe scholars, good citizens and the best type of ladies and gentlemen. These things are sacrificed in order to give place to facts and details which will make a brilliant show before the public, that will convert the pupils into smoothly working machines which turn out elaborate and highly ornate work to dazzle the dear people and impress them with the wonderful things the educators are doing.

This system of substituting names and shadows for things and realities, especially when conjoined with the pernicious practice of awarding prizes, not only impairs or ruins the health of the pupils, but has a very degrading effect upon them from a moral standpoint; because, instead of imbuing them with a love of truth for the truth's sake and impressing them with the fact that truth, honesty and justice are the grandest possessions in the world, a high grade or class standing is made the *summum bonum*, often regardless of the manner in which it is obtained.

Any teacher, by a careful system of grading recitations and a systematic preservation and inspection of the work done by the pupils, together with a general review of the subject-matter gone over, say three times during the school year, can arrive at a much fairer and better knowledge of the capability and progress of the pupils than can be obtained by continual examinations.

Moral Training.—During the plastic years of childhood and youth more attention should be given to implanting correct moral and ethical principles; because it is better to inspire the heart with a noble sentiment than to teach a fact of science, and because truth, honesty, nobility of character, good manners and a proper regard for the rights and feelings of others are of much greater value to the child than all the mere book-knowledge in the world. It ought not to be necessary for me to suggest that the personal actions and behavior of the teacher are of supreme importance in moral training. Teachers who are not perfectly truthful infect their pupils with falsehood and deceit; those who can not control themselves and disregard reasonable rules and regulations destroy the regard for law and order in their pupils, and help to increase the army of anarchists. The child should be taught to rely on his own powers, and be made to feel that he is an important element in the social organism; that it is his duty to work, not only for his own individual advancement, but to do everything in his power to promote the health, happiness and welfare of his fellow men.

Punishments.—The pendulum of public and professional opinion has swung far in the opposite direction from the harshness and undue severity of our forefathers. While in the great majority of cases this benign rule is salutary and highly commendable, still in many instances it is so obscured by namby-pambyism and hypercritical pretensions on the part of a certain class of judges and teachers, who strive to gain popularity by condemning corporal punishment in any form, that it not only demoralizes the pupils and furnishes a constantly increasing supply of material for our jails and penitentiaries, but it is also supplanted by much more brutal and inhuman forms of punishment. How many teachers and superintendents who would not give a boy a richly deserved whipping on a switch or soft strap, for fear of leaving discolorations on the skin, will pull his ears, strike him over the head with a heavy book or the hand, grasp him by the shoulders and jam him down into his seat. If it is necessary to resort to corporal punishment in a school, let it be administered only after careful investigation and due deliberation, calmly and without passion. Superficial discolorations, caused by a light switch or soft strap will not injure any boy who really deserves corporal punishment, but may do him a great deal of good.

Conclusions.—In conclusion, then, I desire to emphasize the following points:

1. The physical, intellectual and moral powers of the pupils should be developed at the same time.

2. Parents and teachers should thoroughly appreciate the fact that in its development the child is an epitome of the development of the race, and possesses many of the impulses and passions incident to the savage, barbarous and semi-civilized phases through which the race has passed, and that, in order to attain the best results, the instruction must be carefully adapted to the ever-changing, ever-varying needs and to the comprehension of the child.

3. As "teaching is the art of promoting human growth," the successful teacher must understand his own powers and limitations; he must understand the growing pupil and be able to put himself in the latter's place, and he must have a thorough knowledge and grasp of the subject taught. Teachers should have a more thorough and comprehensive knowledge of the laws of mental development; a better understanding of educational methods and the best means of imparting instruction. To insure such knowledge and teaching power, the rank and file of teachers should have a more thorough education, a more careful professional training and preparation for their work, and, last, but by no means least, they should be better paid, and thus encouraged to make teaching their life-work.

4. We need more enthusiasm and less routine; more original investigation and search after truth for the truth's sake, and less cramming for examinations; less talking and lecturing on the part of the teacher, and more time devoted to training pupils in systematic and logical analysis, and in clearness and accuracy of expression.

5. Then, too, not so many studies should be pursued at the same time, but the work should be more thoroughly done and a stronger grasp of the fundamental principles on which all true education depends should be secured. To get time for such training, the number-drill and arithmetic, together with other formal and abstruse work should be greatly curtailed or entirely omitted from the primary grades and the children should be given greater opportunities to study natural

objects in their natural surroundings. The study of flowers, trees, rocks, birds, animals, insects, etc., in their natural conditions and environments is of infinitely greater value to the pupils than the fragmentary conception of such things that can be given to them in the schoolroom in the midst of artificial surroundings. In addition to imparting more exact information, the outdoor excursions furnish healthful exercise, inspire enthusiasm, rest and strengthen the brain and mind and elevate the pupils morally, while the indoor study of such objects soon becomes a drudgery and is of comparatively little benefit.

6. More time and attention should be given to manual training. This training of the muscles develops the motor centers in the brain, discharges the accumulating nerve force in the motor centers, develops and strengthens the association fibers between the various brain centers and permits the higher brain centers to develop normally and store up power. This gives the student a richer sensory content, a more harmonious physical and mental organization and a better-balanced moral nature.

7. Greater care should be exercised in promoting the health and proper physical development of the pupils.

8. All harsh and dangerous punishments should be banished from the schools.

THE CONTROL AND PREVENTION OF EAR DISEASES AMONG SCHOOL CHILDREN.*

Surgeon-in-Charge of the Philadelphia Eye, Ear, Nose and Throat Institute; Nose and Throat Physician to the Odd Fellows' Home; Late Chief of the Eye Clinic of the German Hospital etc.

LOUIS J. LAUTENBACH, A.M., M.D., Ph.D.

PHILADELPHIA.

History shows that it is difficult to develop equitably the mental and physical nature of human beings, and that periods noted for great bodily vigor are often deficient in corresponding mental growth. Even now, with added wisdom as to their co-relation, and the best intentions, undue stress is too often laid on one or the other. So in the recent past the mental condition of the child has received the bulk of the attention of educators and it has remained for the past decade to bring into prominence the fact that mental health and activity is not an independent entity, but is inextricably connected with the physical condition. To-day physical examinations are instituted in nearly all our colleges, in most of our preparatory schools and in many advanced private as well as public schools.

Perhaps no physical function lends itself more to mental activity than acute hearing. Whether in the human race hearing is present at birth or some months thereafter, it is easily observed that this faculty dominates the earliest sense impressions. As a human being is first of all a social creature, dependent on human intercourse for mental stimulation and for food-thought, the faculty by which we obtain this must affect tremendously for good or evil the mental and, indirectly, the physical condition. The truth of this can be most readily seen by noting the effect of its absence. Then the

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

important part that sense plays in developing the mental condition and character becomes apparent, and we find that the word "deaf" is almost instinctively followed by "dumb," and that together they have an implied meaning beyond the statement of the physical condition, being synonymous with stupidity, moroseness, laggardness, and want of ambition. There are wonderful and noted exceptions to this, but we speak of the average.

Many a supposedly stupid child has really a bright mind, but suffering from undetected or neglected defect of the hearing, is not fitted to grasp instruction and information imparted for the benefit of large classes of normal children, and the hurried teacher or parent, unable to give the particular attention demanded, the child falls farther and farther away from the ordinary standard. Now, deafness or partial impairment of hearing is no rarity in school children. According to statistics, a degree of impairment in both sexes of one-third or more from the normal standard exists in both ears in about 7 per cent., and from 13 to 25 per cent. in one ear.¹ Of course, the deaf mutes and idiots are not included in this percentage. It is less frequent than deficient eyesight, which, according to Allport² is present in from 25 to 50 per cent. of school children. Investigations looking to the obtaining of statistics may seem to flavor a little of paternalism, but without doubt it is of direct benefit to the child, the parent and the teacher, as well as to the human race, and can readily be justified on these grounds.

It is becoming increasingly difficult for the head of a family to make a living, and his labors leave at best but an hour or two for his family, and the recognition of this overtaxed home life tends more and more to throw part of the responsibility, formerly borne by the parents alone, for the children's physical well-being on the school authorities and teachers. That part of the children's physical being which more especially concerns the teaching authorities is that concerned with the acquisition of knowledge, and, therefore, any deficiency in sight or in hearing interferes with the work they are expected to accomplish, and often explains why some children are so backward, even at times almost stupid, with their work. The advantage of testing the sight and hearing and the observation of any deficiency with a further step looking to its correction must at once appeal to all who have the welfare of the school child at heart. Recognizing these facts, several Western cities, particularly Minneapolis, Milwaukee and Chicago, have tentatively applied methods and suggestions looking to this end with advantage for a varying period of years, until now Dr. Allport's methods, or modifications thereof, have been adopted in them all. As defects of vision are more obtrusively apparent than those of hearing, eye examinations alone were originally advocated. Now the ear being included the observations are much more valuable.

Omitting all reference to the eye examinations, and coming around to the question of the hearing, we will find that the tests can be easily made with a fair degree of accuracy.

If the pupils are examined by the teacher, the work should be done in a fairly large room, preferably before school hours, and each case examined should be asked, whether he has pain in either ear, whether he ever has discharge or odor from either ear, whether he breathes freely through either nostril—he can determine this by holding the finger over either nostril, breathing through the other—whether he usually breathes through his mouth, whether when he awakes

mornings his throat is dry. Now, closing one ear with a piece of rubber placed over the end of the child's finger, ask him whether he can hear you distinctly while you are talking to him at a distance of twenty feet; ask him questions requiring direct answers while at this distance. Then take a watch and hold it about five feet from his ear and ask him to tell you when he hears it, gradually approaching it nearer and nearer to the ear. It should be heard at least three feet or more from the ear. Now test the other ear in the same way.

If, in any of these respects the pupil seems to be defective, the fact should be noted on a printed sheet and the parents notified of such deficiency and advised to consult any reputable specialist.

Of course, this work would probably be more accurate if placed directly in the hands of a school physician salaried by the city—the statistics gathered by him might prove of great value, as he undoubtedly would keep accurate records of all the cases examined, and would be able to classify cases and conditions and produce reports which would be of service to the medical profession, as well as the teaching staff, whereas the teacher, having neither time nor knowledge to do this work, can be expected only to keep a list of the children examined and to record the cases of impairment of these senses, losing all the other valuable information obtained from testing the healthy children.

Dr. Allport's original suggestion for conducting these tests of the special senses was to have an oculist and aurist appointed by the board of education, who should superintend the tests, collect data, make reports, etc. The examinations were to be made by principals and teachers; those pupils found defective, with their names, condition, etc., were to be enrolled on statistical blanks, on which in due time the result of treatment on special organs and general health and conduct should be noted. These blanks were to be handed to the superintendent and to the board oculist and aurist, who were to file them and report on their findings to the board of education.

As, however, boards of education are not always kindly disposed toward this method, objecting in some cases, to the appointment of physicians, in other cases objecting to compelling superintendents keeping statistical reports, other expedients were adopted. Such objections existed in the Chicago schools,⁴ where now the examinations are made by the teachers and principals in accordance with the instructions of Allport's combination card, and which has careful instructions for the guidance of teachers appended. The Milwaukee public schools use a sheet and warning card, by Dr. Würdemann, which is similar to the Chicago card, and contains in addition instructions for ear examinations.⁵

By means of systematically pursuing this work the teacher can become a force for good in overcoming deafness and deficient mental development of the before-mentioned 13 to 25 per cent. of school children, or detect incipient trouble when discovery and prompt treatment is worth so much to all concerned.

By such means as these are the parents aroused to take a more thorough oversight, and the common causes of ear disease⁷ in children will be the better known and avoided or overcome by their care. To-day, enlargements in the throat and nose, perhaps the most frequent of the causes of such disease among children, are usually neglected and as for catarrhal conditions, they are but rarely treated in children, unless they become sufficiently grave to affect the general health. Among the frequent underlying causes of deafness⁸ among children is the

throat and nose complication of the acute fevers—unfortunately, there is often no effort to prevent the development of ear involvement, because the disease itself demands all our attention, but even then much can be done by the prompt application of common sense to prevent it assuming often a serious form.

The enlargement of the nasopharyngeal gland, or third tonsil, results often in violent ear-pains followed by inflammation of the middle ear, with suppurative discharge, or it may cause deafness without perforation and suppuration, and even without pain.

Patients will soon learn that the thorough scrubbing of the ear, instead of being a health measure is rather a cause of disease; they will also learn that the nose douches so prevalently used are generally misapplied. When used, the solution should invariably be warm and the pressure employed be barely enough to force the fluid through the nose into the throat.

They probably will soon have called to their attention that vomiting in children is a source of ear disease, especially, I hope, will they learn that the regurgitation of food in infants may cause serious mischief in the ears. By the application of common sense with experience, they will be taught that the period of dentition is a critical period, so far as the integrity of the throat, nose and ears is concerned; that this is a period of increased activity of this region and any irritant applied here at this time is apt to be followed by ill effects.

All these thoughts will, I hope, be stimulated into existence in the average parent through such systematic examinations of these special senses and prove of great value to all concerned.

It follows, necessarily, that the examination of nose and throat is imperative whenever the hearing is deficient, and that inflammations or lesions of nose and throat liable to involve the ear, but not yet affecting them, can not be taken too seriously. Pharyngeal adenoids, so common in children, as well as enlarged tonsils and polypi, should be removed as soon as possible⁹, and catarrhal affections treated and hypertrophies reduced before the ear structures become affected. Unless this be done the needless sacrifice of life, hundreds of children dying yearly from middle-ear disease discovered only after death—as well as the sacrifice of health and usefulness—will simply continue indefinitely. Such desirable results will be greatly facilitated by the systematic examinations of the hearing of all school children and a statement of the necessities of any defective case, to the parent by the school physician or teacher. Pupils, parents and teachers would alike be benefited by such a course. The physician also would gain much, in that he would receive his cases earlier in their history, and would usually have a remedial condition to deal with in place of the thankless, tedious, up-hill fight attended with little satisfaction, either in profit or in gratitude and appreciation of his patients, and sometimes even of his brother physicians.

THE ANTECEDENTS OF ORGANIC HEART DISEASE IN CHILDREN.*

FREDERICK A. PACKARD, M.D.

PHILADELPHIA.

In every dispensary or hospital for the treatment of diseases of children, and also to almost the same extent in private practice, there are seen many cases of organic heart disease in later childhood where only few facts bearing directly on the etiology can be found. In adults the case is different, because in them many of the organic valvular defects and many of the murmurs produced by degenerative changes in the myocardium are due to wear and tear necessitated by the conditions of life. In adults also disease of the heart secondary to lesions in other organs—notably the kidneys—and to errors in metabolism is encountered more frequently than in the case of children. In childhood these factors do not enter except in occasional instances, and the occurrence of endocarditis or of myocardial changes giving rise to cardiac signs and symptoms must in them be attributed to the occurrence of infection.

Under the heading of infection should be considered not only such diseases as are accompanied by a classical symptomatology, and therefore designated by a specific name, but also the minor affections which are so frequent in childhood. This frequency is due undoubtedly partly to the "tenderness" of the skin and mucous membranes at this period of life, partly also to the fact that many of the major infections especially attacking children are apt to leave the mucous membranes in a condition very liable to infection. I have elsewhere shown that angina can readily be followed by endocarditis, and while this was no new discovery and had been recognized by others, I feel that the very occurrence of such an association should cause us to feel that other minor and frequent local lesions may be followed by inflammatory disease of the valvular apparatus of the heart. Ordinarily in obtaining the past history of cases of cardiac damage positive facts can be obtained only in regard to such diseases as the eruptive fevers, while ordinary colds, angina, gastrointestinal infections and similar apparently minor conditions are either forgotten or are considered too trivial to mention. Nevertheless any of these, it is fair to presume, may possibly give rise to visceral complications if the infecting agent is sufficiently virulent or the vital resistance of the child's tissues sufficiently lowered.

For the purpose of obtaining some idea as to the relative frequency of various diseases occurring in the past history of children with chronic heart lesions, I endeavored to study the notes of a number of cases of the latter trouble. The study was necessarily incomplete owing to the impossibility of obtaining accurate past histories of cases, especially in hospital work. Many of the histories that were available to me I did not use because of the absence of internal evidence that a sufficiently careful inquiry had been instituted by the

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

interne. For instance, in a very large number of cases there is no evidence to show whether the interne had questioned the child's parents in any but a most general way, while many stated that the child had "passed through the ordinary diseases of childhood." The number of cases, therefore, for study had been disappointingly small, but I hope that the figures given may at some time be combined with others and make a number sufficient to permit us to arrive at some conclusion. Excluding all those which do not come up to the standard which I had fixed in regard to accuracy, I found that there were only 75 histories remaining which I was able to study in the time at my disposal. I have purposely omitted from these cases previously reported by me as having followed minor infections, inasmuch as the addition of these cases would give an undue proportion of examples of cardiac damage following one particular source of infection. I have therefore taken without selection, save in regard to completeness and accuracy of the history, consecutive cases of cardiac disease admitted to the hospital because of heart lesion. Of these 75 cases 3 were said to have never had any prior illness before the onset of cardiac symptoms. The most frequent preceding illness was rheumatism; this, of course, would have been expected; yet among the 75 cases a history of preceding rheumatism was obtained in only 34, considerably less than 50 per cent. That this low percentage represents fairly accurately the frequency of rheumatism on these cases is rendered certain from the fact that owing to the well-recognized association of articular rheumatism and cardiac lesion, its prior existence would certainly have been determined in any case where the past history was investigated at all. Rheumatism was the only preceding disease mentioned in 16 of the cases; in the other 18 cases it was variously combined with a history of measles, whooping-cough, chorea and other ordinary infections. In a control series of 75 cases admitted for troubles other than cardiac disease, rheumatism occurred in only one case.

The history of measles was that given most frequently after the disease last mentioned. The occurrence of this disease was noted in 24 of the 75 cases, while in one case it was the only disease mentioned in the past history. It would, of course, be unfair on account of this frequency to consider measles the next most frequent causative factor after rheumatism, inasmuch as measles is undoubtedly the most frequent infection in childhood; in the 75 control cases without cardiac disease measles was noted 43 times. Whooping-cough preceded cardiac lesions in 19 cases, and was the only infection noted in one case. Among the 75 control cases, whooping-cough had occurred in 37. This relative proportion in the two sets of cases must be considered as accidental, as it is impossible to conceive of any preventive rôle that could be played by whooping-cough in relation to cardiac disease. The disproportion of chorea in the past history of cardiac and non-cardiac cases is very marked. Among the 75 cardiac cases it had been present 16 times, while it had only occurred in 2 of those without cardiac lesion. Scarlet fever had been present in 11 of the cardiac cases, in 3 of which it was the only preceding illness. Among the 75 cases without cardiac disease scarlet fever had been present in 7. The frequency of diphtheria in the past history of the cardiac and non-cardiac cases is so nearly equal—8 in the former and 9 in the latter—that it can be thought to have practically no influence. Pneumonia preceded the development of cardiac symptoms in 6 cases, while its relative frequency in children may be somewhat determined by the fact that it had been

present in 4 of the 75 cases without heart lesion. Curiously enough, variella resembled whooping-cough in the relatively greater frequency with which it had been present in the cases of children with healthy hearts as compared with those with cardiac disease. In only 5 of the cases had chicken-pox been present, while it occurred in the past history of 14 cases of diseases other than those of the heart. Mumps occurred in the past history of 4 of the cardiac cases, in only one of those without heart disease. Typhoid fever was mentioned in the past history of 4 in each class of cases. In 2 of the 75 cases of heart disease repeated attacks of tonsillitis had occurred, in one no other disease having been experienced, in the other the patient having suffered from measles and whooping-cough. The fact that among the 75 cases without cardiac disease there were none giving a history of repeated attacks of tonsillitis has but little value as positive evidence, because such attacks are not made the subject of ordinary inquiry and are not readily remembered by the parent, while I strongly suspect that in the 2 cases where such a history had been elicited the obtaining of the information was due to direct questioning by internes who knew of my interest in this subject. Among the 75 cases, the other diseases mentioned as having occurred in the history of the patient were cerebrospinal meningitis, 2 cases, one of which had had no other illness but pneumonia, and the following illnesses had each occurred in one case: meningitis, rubola, gastro-enteritis, "indefinite illness," pleurisy, chronic bronchitis, acute nephritis, cholera infantum and osteoarthritis.

Without further analyzing the results of the examination of these 75 histories, I would merely mention the main facts in regard to the diseases ordinarily supposed to be frequently followed by endocarditis. Rheumatism, as I have said, had occurred in only 34 of the cases, chorea in 16, scarlet fever in 11, diphtheria in 8, while in 14 of the cases none of these diseases last mentioned had been experienced by the child. If the small control series of cases can be taken as any guide, it would seem that measles, variella, whooping-cough and typhoid fever have little or no influence in the production of endocarditis. We must therefore attribute many of our instances of inflammatory lesions of the endocardium to the slighter infections, such as coryza, various skin lesions, affections of the mucous membranes of the throat and nose, and the infections of the gastro-intestinal tract. The number of cases analyzed by me is very small, yet I believe that as far as they go they point to the necessity, which theoretically every one realizes, of a careful examination of the heart, both during and after slight infections, and that this organ should be a matter of careful inquiry as much in those last mentioned as is the case with the more severe infections like rheumatism and scarlet fever.

DISCUSSION ON PAPERS OF DRs. BECK, STUVER, BARTLETT, LAUTENBACH, AND PACKARD.

DR. C. F. WAHNER, Fort Madison, Iowa.—I sometimes think it would be a good thing if at some time in life every physician had been a teacher. It may be I have been prejudiced by my own experience. For a number of years I was a teacher, and had quite a varied experience in this respect in academies, high schools and colleges. This is a great problem before us, because we lack the co-operation of the municipal authorities in the larger portion of the United States. We have no systematized laws existing between health authorities and schools, and when physicians wish either as private citizens or professionally to initiate reforms they meet with opposition from their professional brethren, who say that they are only doing

this to advertise themselves. You see we have trouble in our own ranks. It is true that in large cities like Chicago, Philadelphia, St. Louis and New York there is an effort made to exercise some medical supervision over the school children, but that is not yet as it should be. In the rural districts, and the smaller cities this is all left to what influence we can exert through our patients.

I want to say regarding overwork, that I have very little if any sympathy for the kindergarten system, for, already overcrowding and overramming have taken hold in these schools, and the little ones have been taken away too soon from their parents. I think we send our children to school too early, demand too much of them, and the school curricula are too extensive. In some schools there are children of 8 or 10 years of age who should be spending most of their time on fundamental principles of education, yet these children are already studying Latin, algebra and abstract thinking. The result is an abnormal product—a prodigy—of which I am sorry to say parents and the public generally are often strangely proud. Many children we know are handicapped by disease; they are choreic or have other nervous troubles; they are affected with tuberculosis or scrofula, whatever that may mean. These children should not be in schools, but should be out-doors playing and breathing fresh air instead of being confined in schools and compelled to study from 9 till 12, and from 1 to 4 o'clock, and then take home a satchel full of books and study until bed-time. This is overwork, and it produces neither a healthy physical system nor mental system. Many children are handicapped by chorea. It may be of the kind produced by an affection of the nervous system; it may be of the hysterical kind. Not very long ago, what might be called an epidemic of chorea broke out in the schools of my town. A child had been promised a bicycle, but did not receive it, and the result was an attack of chorea. Very soon afterward there were about a dozen children in that school affected with chorea. I tried to interfere, but was told it was none of my business.

I believe if there is any one thing on which we can use our influence, and which needs our help, it is the improvement of our public school system. In the large cities teachers are overworked because of the constant additions made by superintendents, often merely to gratify personal vanity. Instead of adding more work to the already overburdened pupils and teachers we should endeavor to lighten this work. I am neither pessimistic nor retrogressive in my ideas, yet I wish to ask, in spite of all the popularization of education, how many Miltons, Homers and Platos have we had in the last four centuries? We can not make scholars of all persons any more than we can make gymnasts and sprinters out of all. The examination system is the most abominable one ever devised. What is the use of a competitive examination between a pupil who learns a lesson at a glance and another who plods and studies for hours over the same lesson? You might with equal propriety institute a comparison between a thoroughbred trotter and an ox for speed and their respective merits as coaches. Could you not decide the matter without an exhibition of speed between the two? So can a teacher who has had children under her care for months, nay, years, decide which one should be promoted and which one kept back without the nerve-exhausting and unfair test of an examination every month or two. Mere knowledge, the acquisition of so many facts, is not what counts in the equation of life, but the use any one can make of what knowledge he possesses, is the real value. At present, the only thing we can do is to create healthy sentiments among our patients, until laws are passed on these lines.

DR. E. E. GRAHAM, Philadelphia.—The mere fact that these processes are developmental shows that they are normal. It is just as normal for the child at the age of 6 or 8 years to be going through certain developmental processes as it is for an infant of seven or eight months to get the first tooth, or the child of 4½ years to complete dentition. There can be no question that during the development of the function of an organ, that organ can be easily overworked; but it is a great mistake, I think, to place the blame on the former development of a function and not on the strain or overwork of that function. If we are willing to admit that during the period

of early school life—from 6 to 9 or 10 years—there are certain normal processes going on in the body, and, of course, we are willing to admit that the developmental process is very active at that time, why should we put down such normal process as a cause of disease, or of a "break-down?" Instead of making that contributing cause we should put the blame on the strain of such things as weekly competitions. In the public schools, the children are graded almost invariably every week or two. In later life, as in medical schools the grading is done at the end of the first, second, third and fourth year, and it is well known that the strain on the ordinary medical students at that time is very quickly recognized; the students are very much prostrated after examinations. Now, if the child of 6 or 8 years is put through this test every week or two; if twice a year the child is graded and made to understand that a certain examination must be gone through successfully or else the work of the previous six months is lost, there is little doubt that the nervous powers of these children will be overstrained. Again, the school hours are too long, and the terms are too long; for, while at this season of the year the medical schools are closed up, the little children in the public schools are still attending school. This is a question which we should face and consider, as we meet with it almost every day in our work. We should consider also if improper diet and insufficient sleep are not often contributing causes.

DR. J. L. SUTHERLAND, Grand Island, Neb.—We have had it impressed on us year after year, that our public school system is very faulty. The more one studies the question in all its bearings, the more he is apt to think it a stupendous undertaking to remedy the evil. To my mind, outside of the larger cities perhaps, this evil should be overcome to a great extent by simply instituting two measures. 1. Making the qualifications of the teacher greater, and 2, allowing him a little more latitude in the exercise of his functions. I mean by the first that the teacher should be required to know a little more of human nature. Teachers should be able to gauge the individual capacities of the pupils under their charge, and should grade the requirements accordingly. No teacher should be employed at the present day who has not the ability to tell, after a few months, whether any pupil under his charge is or is not fit to pass to the next grade. A little more latitude in this respect would enable us to do away with the examinations for promotion, and by this alone, a large part of the present existing evil would be thus eliminated.

Another thing, politics has too much to do in our school boards. A man who puts himself forward in the interests of our suffering school-children, is looked on as a crank, and no matter how superior his education, if he does not belong to the political combination he can not get on the school board; and even then, a comparatively ignorant majority on the board will prevent his doing much good. Whenever a physician in his own humble way undertakes individually to correct some of these evils, his motives are often impugned by some of his fellows, who claim that he does it for his personal aggrandizement. I wish to say that there is too much in our school curriculum, and much of it is absolutely unnecessary. It would be far better to let the younger element out to study birds, flowers, rocks, etc., part of the time. In a paper which I presented to our state society three years ago, I touched on this subject, taking the liberty to criticise our public school system and to offer a few suggestions. And I repeat now, that if these evils are ever to be eradicated, the medical profession will have to do the larger share. We will have to keep on in the rôle of educators, and we will have the consciousness of having tried to do our duty, and perhaps will succeed in causing both parents and teachers to see that the physical well-being of the child is entitled to some consideration, and that education means something more than the "cramming" a young head with a certain number of facts, many of which it does not understand.

DR. FRANK ALLPORT, Chicago—I am particularly interested in the examination of school children's eyes and ears, and what I say will bear on this. Some years ago, investigations along these lines were made in Germany. Ophthal-

mologists were appointed by municipal authorities, to go from school to school and personally examine scholars. Valuable deductions were obtained. The same plan was operated in Philadelphia by Risley and his associates, but while the method of examination answered very well in monarchial Germany, where people are more accustomed to obey authority, it proved too oppressive in America, and so much ill feeling and jealousy was engendered among the laity, and in professional circles, that the plan was abandoned, and never revived.

Some years ago, when living in Minneapolis, I conceived the idea of a systematic examination of school-children's eyes and ears by teachers, which I placed in operation in that city at the request of the Board of Education. The plan consists simply of the annual examination of children—under the instruction of an eye and ear surgeon, appointed by the board—by teachers, by means of simple and pointed questions, easy to ask and easy to answer. Teachers say they feel unqualified to act in this capacity. This is an untounded objection. Teachers are not expected to become physicians or diagnosticians. They are simply requested to ascertain a few easily accessible facts, and to separate those children having good eyes and ears from those having bad eyes and ears. It is surely simple enough to ascertain whether a child habitually suffers from red eyes, headaches, cross-eyes, discharging ears, mouth-breathing, and whether they can read certain print at given distances, or hear a whisper at a certain number of feet. These are fair samples of what is to be done, and I am sure you will agree that it does not require a medical education, or a great intellect.

There are ten questions to be asked and answered, and the result will disclose the existence of most serious eye or ear defects. The teacher will not know what the defect is, but she will know that *something* is wrong, and that is sufficient. If a defect is discovered, a card of warning is sent to the parent notifying him of the result, and advising that some eye and ear surgeon of repute, or the family physician be consulted, either privately or at some dispensary. Bear in mind, however, that the parent is not *ordered* to do this; he is simply *advised*. This advice he may totally disregard if he wishes, the responsibility now rests on him. Many parents pay no attention to the cards of warning at first, but do so later, after discovering beneficial results in their neighbors' children. Many never do anything, in spite of repeated warnings. This is regrettable, but it should not discourage us, as a fair proportion of cards produce responses, and good results, and this should reward us for our efforts.

School authorities sometimes complain that the extra labor by teachers is a serious objection. This was a considerable element of obstruction, when the plan was first inaugurated, and a principal examined perhaps 2000 pupils. I have, however, lately recommended that the tests be made by the room teachers, who never have more than 50 pupils under their supervision. By thus subdividing the work, and keeping a few pupils after school each day, a room can be easily examined in a week, and therefore every room in a city can be examined in the same length of time. Besides this the room teachers are better able to make the tests, as they are better acquainted with the defects of their pupils than the principals. Under such a system the 250,000 pupils of the city of Chicago have been easily examined during the last two or three weeks, without inflicting hardship on anybody. I believe that these tests will *lighten* a teacher's labor, for many children are a burden to teachers, and exact much extra work from them on account of defective eyes and ears which, when relieved, proportionately lessen the teacher's work.

An important point in favor of these tests is their cheapness. No salary is involved, and the only expense is for the printed matter, which is merely nominal. For instance, the cost to the city of Chicago will not exceed \$200 per annum. In answer to the question of a gentleman, I will say that these charts, with test letters, and teachers' instructions may be obtained from Almer Coe, optician, 65 State street, Chicago. In answer to another gentleman, I will say that the tests should be made annually, as new children come into the school each year, or pass from grade to grade, and eye and ear defects are

liable to occur in children who last year were healthy. These tests are being received with great favor, over most sections of this country, and I am recently in receipt of a letter from Mr. Bha-Bha, inspector-general of education in Southern India, requesting me to send him charts, literature, etc., as he is about to place the matter in operation in India. I find as a result of my own investigations and the investigations of others, that about 33 per cent. of school-children have defective eyes, and perhaps 20 per cent. defective ears, noses and throats, and I leave it to you to imagine the enormous benefit that must follow the general and systematic examinations of school-children's eyes, throughout the civilized world.

DR. EDWIN ROSENTHAL, Philadelphia—We very frequently notice in Philadelphia cases of hysteria among school-children, especially in precocious children. I have had such children under my care, and have sent some of them to the ophthalmologist simply to learn what effect the fitting of glasses would have on these children. I think you will find almost as many eyeglasses on the children of Philadelphia as among the children of Boston. I believe too little stress is laid on the influence of the family physician on the school life of our children. We have such inspectors in Philadelphia, but they only take into consideration the diseases that are infectious—not only diphtheria, scarlet fever and measles, but cutaneous affections of this class. The system has only been in operation in Philadelphia, about one year, so we can not say how much good will come from it. The family physician has more influence with the school-children than any one else. He has frequently criticized the attitude of the medical inspectors in Philadelphia. This is a mistake, for while these inspectors may not be prominent physicians, they endeavor to do their duty conscientiously and well. If Dr. Allport would bring up this matter of making tests before the school teachers' convention I am sure it would have a great influence for good.

DR. L. J. LAUTERBACH, closing the discussion—The *Ladies' Home Journal* stated in an article that 16,000 children had been removed from the schools of five American cities because of school break-down. This is not such a large number. If you take 250,000 children—the number in Chicago's schools—I am sure you will find a large proportion of those children who will be compelled at some time in the school year to stop their studies. Even this large number might stop work in Chicago alone without being looked on as a very large disproportion, when you consider the frequency of sickness among children. There is nothing more misleading than indefinite and inaccurate statistics. In order to make the above accurate the cities should have been named. Another interesting fact brought out to-day is the one as to the mental development of different periods of school, particularly the fact that school children of 10 years can not fix their attention on a subject steadily for more than forty-five minutes at a time. I look upon this regular annual examination as really a means of preventive medicine. As before indicated, this is not a method for ordering glasses, but when you take into account the numberless cases of chorea, and the frequent development of epilepsy or other nervous disorders arising from a peripheral irritation in hundreds of cases, and remember how busy is the average American parent and how little time he gives to the physical health of his children, the importance of having the teachers make these examinations of the hearing and sight of the pupils must be obvious. There is nothing so wonderful as the supervision, both personal and systematic, in the German schools. By persistence in definite lines of work and a limitation to a few necessary studies these children while still young exhibit a proficiency in languages, sciences and other subjects without any difficulty. One of the speakers seemed to indicate that physical examinations should perhaps be put in the hands of medical inspectors. I am afraid that this is a mistake, and that it would lead to a great deal of opposition. Our object should be to have all the school authorities—whether they be saloon-keepers, merchants or professional men, on our side. It is an unfortunate fact that the moment a doctor wants anything, no matter what it is, or what his object, he will be misunderstood both by his professional

brethren and by the general public. Therefore, everything which we do in this important matter must be so conducted that all the forces needed to help must be secured, and all opposition avoided, if such is possible.

ARTHRITIS DEFORMANS.

ITS CLINICAL FEATURES, DIFFERENTIAL DIAGNOSIS AND PATHOGENESIS.*

ALOYSIUS O. J. KELLY, A.M., M.D.

Instructor in Clinical Medicine, University of Pennsylvania;
Assistant Physician to the University Hospital, etc.
PHILADELPHIA.

If one may judge from the multiplicity of names that have been applied to arthritis deformans its nature is not so well understood, and I am confident that it often goes unrecognized and is frequently mistaken for some other disorder. In proof of this the disease is variously described as rheumatoid arthritis, chronic rheumatic arthritis, rheumatic gout, rheumatisme noueux, osteo-arthritis, pernicious arthritis, chronic villous polyarthritis, arthritis deformans, deforming arthritis, etc. The designation arthritis deformans, which is generally employed in this country and in Germany, seems to me the preferable; it is sufficiently indicative of the distinguishing features of the disorder; it suggests no relationship to any other disease, such as rheumatism, and it is non-committal as regards its etiology.

I have thought to summarize briefly the distinguishing clinical features of the disease, to speak of the differential diagnosis, and to detail the results of some recent scientific investigations which I believe materially assist in the elucidation of the nature and pathogenesis of the disease. The study of these collectively will then enable us to appreciate fully the therapeutic indications.

CLINICAL FEATURES.

As we meet it clinically, arthritis deformans may develop either acutely or chronically. If the former be the case, the affection is always polyarthritic; if the latter, it is generally polyarthritic, but it may be monoarthritic. The acute polyarthritic form, although it may manifest itself as a primary disorder, usually develops secondarily to some acute infectious process, such as influenza, tonsillitis, gonorrhoea, etc. It usually affects young women, though it is also met in later life. In many respects it resembles acute rheumatism. In fact though the occurrence of acute arthritis deformans is generally conceded, Spender states that while it would be rash to assert that there is no such thing as acute arthritis deformans, the condition so described is usually a pyrexial rheumatic forerunner. This, he believes, in predisposed persons leads on to arthritis deformans proper. In the great majority of persons, however, there is no such predisposition.

The disease generally commences acutely in the smaller joints of the hands and feet. Sooner or later the larger joints share in the process and the disease may sometimes rapidly progress until there is scarcely an unaffected joint in the body. The joints involved present an almost pathognomonic spindle-shaped appearance—the fusiform variety of Garrod as contrasted with the crippling. In some cases there is considerable accumulation of synovial fluid and the ligaments and periarticular tissues seem stretched and tense; in other cases the interarticular fluid is less in amount, but the ligaments are more infiltrated, thickened and softened,

and the joint is correspondingly soft and doughy to the touch. Pain is usually a fairly prominent symptom. At times, where contrasted with the manifest alterations of the joints, it seems rather insignificant. It may, however, be marked, and is always increased on manipulation and motion of the affected joints. Fever usually accompanies the attack, but it is only moderate and of short duration. Muscular atrophy is almost always present from the inception of the attack. It is especially characterized by its selective action on certain muscles or groups of muscles. The lymph-glands in the neighborhood of the affected joints are often swollen and may be tender to pressure. In addition there may be slightly increased perspiration of the extremities, which are often cold; mottling and freckling of the skin; and other vasomotor and trophic disturbances. While, after the lapse of a certain time, the general health of the patient may improve somewhat, the condition of the affected joints gradually becomes worse. Deformities increase; motion becomes more restricted; adhesions between the articulating surfaces of the bones develop; the ligaments become thickened and indurated; osteophytic out-growths in and about the ligaments, bursas, tendons and their sheaths make their appearance; muscular atrophy becomes more marked; dislocations may occur, until the clinical picture resembles that presented by the disorder when chronic from its commencement. In the later stages of the affection, the nature of the case under consideration can be recognized only by a knowledge of its clinical course.

Chronic polyarthritis deformans may be a primary or a secondary affection and it may develop in a variety of ways. It usually comes on insidiously—without premonition. In some cases, however, there are premonitory symptoms, such as paresthesias, neuralgiform pains, irregular mottlings or frecklings, local perspirations, muscular pains, increased myotatic irritability, accelerated action of the heart, etc., but if present they generally pass unnoticed, or are attributed to some fleeting affection. And indeed in many cases such symptoms are correctly ascribed to some other disorder, even if arthritis deformans does subsequently develop. Generally, as intimated, there arises more or less suddenly a painful swelling of one of the small joints of the hand. Soon after, the corresponding joint of the opposite hand may become similarly affected. The pain and swelling may then entirely subside, only to recur, however, in a short time and to progress until the disease is fully developed. Inquiry in these cases will usually elicit the information that the patient is a woman in the fifth decade of life. Garrod found that of 500 cases but 89 occurred in males. Some evidence of hereditary predisposition may be ascertained. The woman's family relations or more immediate ancestors may have suffered with arthritis deformans, gout, rheumatism, tuberculosis, or some one of the long list of nervous disorders. It has been asserted that the daughters of gouty fathers are somewhat prone to develop arthritis deformans. Heredity, however, is of much less significance in arthritis deformans than it is in any of the other diseases mentioned. In addition, the patient will probably have suffered with some derangement of the menstrual functions or she will have had positive disease of the genital organs; she will probably have been unusually exposed to the inclemencies of the weather, or she will have been subject to want, privation, worry, fright, undue fatigue, mental anxiety, or depressing emotions. In younger women the first manifestations of arthritis deformans may follow re-

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

peated pregnancies in rapid succession, prolonged lactation, or a puerperium imperfectly recovered from. In other cases, those in which for instance, the foot or ankle is first involved, the patient may be under the impression that the joint must have been sprained but he or she is unable to definitely fix a date for the occurrence of such accident. Under other circumstances, after some undue exertion a sense of weakness, tiredness, or stiffness develops in the back or in the posterior region of the neck. In a few days the corresponding vertebrae become more or less fixed and the disease is localized to this region. In still other cases a distinct injury seems to have preceded the definite localization of the disease in a certain joint; whereas in other instances, an attack of acute rheumatism or gonorrhoeal rheumatism appears to bear an etiologic relationship to the development of the arthritis deformans. There are various other ways in which the disease commences, but the foregoing will serve as types.

In whichever manner the disorder develops, in their subsequent course, all cases present many features in common. Perhaps one of the interphalangeal joints or a metacarpal-phalangeal joint is the first attacked. Not uncommonly, the joints of the first and second fingers are the first involved. Soon, however, the corresponding joints of the opposite hand may become implicated. Or a wrist may be the first diseased and a short time afterward the other wrist may present signs of similar involvement. Curiously the thumb often escapes implication, in some cases entirely, in others for a long time only, while in still others only its metacarpal-phalangeal articulation may become affected. In some unusual instances the last named joint is the one first involved. Usually the disease soon spreads to the foot and the metatarsal and phalangeal articulations exhibit alterations similar to those observed in the hands. Then the knee may become diseased, and this may be followed in more or less rapid succession by disorder of the elbow, shoulder, the temporo-maxillary articulation, and the joints of the trunk. Finally, such may be the ravages of the disease that not a joint in the body will be spared. The patient is then rendered absolutely helpless, but despite this, the poor unfortunate's life may be prolonged twenty or thirty years, until death ensues as a result of some intercurrent affection.

The two distinguishing clinical features of arthritis deformans are the deformities of the joints and the atrophy of the muscles. The former is such an obvious manifestation of the disease as to amply justify its incorporation into the designation given the disease. These deformities are especially characterized by their symmetric distribution and by the marked tendency they exhibit to involve the small joints of the hands and feet and the knees. The appearance of the enlarged joints varies somewhat in different cases and also at different stages of the same case. The enlargement may be slight or excessive and the joints themselves may assume almost any shape. The skin covering exhibits many and varied trophic alterations. It is usually thinned, glossy, and reddened. At other times it presents a bluish tint that is considered quite characteristic. As the conformation of the joint depends in part on accumulation of synovial fluid within the joint cavity and adjoining bursas, in part on thickening and infiltration and the structures about the joint, and in part on osteophytic new-formations and lipping of the articular surfaces of the cartilages and bones, the ap-

pearances vary in different cases. The joints are usually more or less spindle-shaped and this is especially the case in acute cases in which the accumulation of synovial fluid is likely to be marked, as also in acute exacerbations of chronic cases. In some chronic cases also the spindle-shaped appearance of the joints is well marked. In other cases, however, there is more or less of a depression between the heads of the articulating bones. This is evidently produced by softening and disintegration of the ligaments, whereby separation and misplacement of the bones readily result. In the eminently chronic cases, however, the swelling, as a rule, is extremely irregular. In these cases not only is there more or less accumulation of synovial fluid and infiltration and thickening of the ligaments, but there occur in addition, osteophytic out-growths and bony deposits in the ligaments, joint tissues, tendons, sheaths, bursas, etc., as well as lipping of the articulating surfaces, and the utmost distortion results. In some cases the bursal enlargement is markedly disproportionate to the bony outgrowth and leads to great irregularity in the conformation of the joint. This is sometimes well seen on the posterior aspect of the wrist; in many cases, however, it is well observed about the small joints of the hands. In certain cases such is the disproportionate enlargement of the bursas that their contour can be well made out. In some cases the synovial fluid is relatively inconspicuous and the joint is correspondingly dry.

Bannatyne, writing of the clinical aspects of these joint lesions, describes them so well that I am constrained to reproduce his words. He writes: "As to the eye, so to the touch, we find three conditions: *a.* A tense, elastic and resistant swelling with distinct fluctuation, often with secondary sac-like protrusions of synovial membrane—best seen in the joints of the fingers, and evidently caused by the presence of a considerable quantity of fluid under some tension. *b.* A soft, flabby, doughy feeling, as if joints, ligaments and all the surrounding tissue had undergone maceration. Over the joint-cavity there is a sort of depression in the middle of the otherwise generalized swelling and everything feels doughy or pulpy. There is seldom much fluid present in such cases, but they are most acutely progressive. It is usually a secondary stage of the acute form, and shows that much disorganization of the joint has taken place. *c.* The third condition is that described by the French under the name 'arthrite sèche.' In these cases the joints are enlarged and nodular and one feels that the heads of the bones have undergone enlargement; there is much crepitation on movement; joints can with difficulty be moved, and this even, if passive, causes much pain; and there may be ankylosis. It is usually a sequel of the more acute stages."

In every case of arthritis deformans there exists more or less deformity, but the degree of this varies somewhat in different cases. It is usually most evident in the hands and about the knees. In well-marked cases the deformities of the hands consist in deflection, extension and flexion of the fingers. Usually all three are evident in the same case, but in varying degree. The fingers are generally deflected to the ulnar side, rarely to the radial side. The ulnar deflection occurs from the metacarpal-phalangeal articulation, but in addition to this there is often a radial deflection of the terminal phalanx. The latter is generally attributed to osteophytic outgrowths occurring upon the ulnar side; the deflection of the entire finger, however, is

dependent especially on relaxation and softening of the ligaments, in part also on bony outgrowths and the action of certain muscles—the extensors. The fingers, in addition, are usually flexed and extended on the hand, and sometimes they overlap each other. In the early stages of the disease, these deflections may be more or less readily overcome; but as time passes they become permanent and irreducible. This results in consequence of the abundant growth of periarticular osteophytes. Deformities similar to these sometimes arise in the feet, but they are less common.

The knees are usually markedly deformed; they are flexed and fixed. Charcot long ago described the chief deformities, about the knees, as follows: 1. The lower end of the femur projects in front of the head of the tibia. 2. The internal condyle becomes less prominent. 3. The patella, thrown outward, rests on the outer condyle. 4. The head of the fibula projects externally. The ankle-joint is usually firmly ankylosed and the foot and great toe abducted.

Sooner or later the joints become ankylosed. This ankylosis is usually of the fibrous variety, which fact may be recognized by the slight motion possible on careful manipulation. At times, however, even very careful manipulation is provocative of much pain, and, in an effort to prevent it, the passive movement of the joint is resisted either voluntarily or involuntarily by the patient, and thus the character of the ankylosis is again disclosed. Under rather rare circumstances true bony ankylosis results, particularly in the vertebrae. In other cases, the ankylosis is more or less bony in that it is due to the interlocking of osteophytic outgrowths. Crackling on motion is usually well marked in all the joints. Except in the later stages, however, it is not essentially different from that elicited in other forms of arthritis. When complete denudation of the articular surfaces of the bone has occurred a peculiar, quite characteristic and almost pathognomonic grating sensation is produced.

Dislocations, though they do not arise in every case, are very common. They usually become more marked as the disease advances, but they are likely to be less evident in cases with extensive osteophytic outgrowth than in those in which marked destruction of the joints has taken place rapidly. They seem also to be less marked in joints that have been moved more or less, in the hand, for instance, that has been compelled to perform some labor, than in joints kept for a long time at rest. The dislocations may be complete or incomplete. They may result from extensive destruction of the structures that enter into the formation of the joints and from the increased tonicity of one set of muscles augmented by a relatively greater atrophy of the opposing set of muscles. They are especially liable to affect the fingers, wrists, knees and hip. In the fingers the dislocation is usually forward, the distal phalanx being displaced beneath the proximal ones; the wrist may be displaced either forward or backward; at the knees the tibia is generally displaced backward; at the hip the femur may be displaced in any direction, though it is usually backward.

Next to the joint deformities, atrophy of the muscles is the most conspicuous clinical feature of arthritis deformans. It is a very early and persistent symptom and is especially characterized by its marked selective tendency. It varies much in different cases; at times it is relatively slight, again it is extremely aggravated. It affects the interossei and the extensors principally, though dystrophic alterations will be found in all the

muscles of the limb. At times but a single muscle of a group will be implicated; again all the muscles of that group. There sometimes occur muscular spasms that are of variable intensity and duration. At times they are extremely severe and produce great pain and the most grotesque distortions. Increased myotatic irritability is usually to be observed, and the tendon reflexes are generally slightly exaggerated. Sometimes there are fibrillary twitchings, and rarely slight reactions of degeneration—the latter, however, only in the presence of distinct peripheral neuritis.

Brief reference may be made to a number of other clinical features of arthritis deformans that are of only relatively less importance than the joint lesions and the muscular atrophy. There is rarely, if ever, any fever, except in the acute cases, as already intimated. At times, however, careful measurements of the temperature will show some fever in the chronic cases. Pain is a constant symptom, though it is variable in intensity. It may be due to a variety of causes, such as the alterations in the joints, neuritis, and rarely to involvement of the spinal roots in disease of the vertebrae. There is usually marked acceleration of the pulse-rate. This is considered by Spender and others to be a quite characteristic symptom. The pulse-rate usually increases with the progress of the disease and in the later stages it may reach a frequency of 120 and more per minute—and this without any discoverable lesion of the heart or blood-vessels. The pulse sometimes returns to its normal frequency, and this may be interpreted as a sign that the progress of the disease has been arrested. Commonly, however, the pulse remains rapid despite the evident arrest of the affection. In contrast to the pulse of gout and rheumatism, the pulse of arthritis deformans is usually fairly soft and compressible, unless, of course, there be arteriosclerosis, which is uncommon. Cutaneous pigmentation and various dystrophic alterations of the skin are quite generally met. Spender is especially impressed with the diagnostic importance of disseminated freckles, which he thinks occur in at least two-thirds of the cases. He believes their occurrence especially significant of early arthritis deformans. In addition, the skin is thin, glossy and of a pinkish hue, rarely of a bluish tint. There may also occur local sweatings of the forehead and extremities, which are usually cold; disturbances of nutrition, especially longitudinal striation of the nails; subcutaneous fibrous nodules and fibrinous exudates, especially in the neighborhood of the affected joints; enlargement of the lymphatic glands, especially those of the groin and axilla, as well as those in the neighborhood of the affected joints; edema of the legs; neuritis; anemia; purpuric hemorrhages; scleroderma; and rarely various disturbances of the abdominal and thoracic viscera. Affections of the endocardium and pericardium, though uncommon, do occur. This occurrence, long ago commented upon by Charcot, is especially insisted upon by Bannatyne and others. The Garrods, however, state that valvular lesions are not more common among those affected with arthritis deformans than among those not thus afflicted, and believe that when found in a patient affected with arthritis deformans they are to be attributed to a previous rheumatic infection. During the past winter, I had occasion to observe in the medical wards of the Hospital of the University of Pennsylvania, under the charge of Dr. Musser, a woman with well-marked arthritis deformans, who had a mitral stenosis.

The partial or monarthritic form of arthritic deformans affects chiefly old men, and its origin in many

cases seems to date from an injury. It is characterized by the slight tendency it manifests to spread, though the other joints do not enjoy complete immunity. At times there may be slight involvement of the opposite hip, or disease also of the spine or of a shoulder. The condition is often described as *morbus coxae senilis*. Heberden's nodes is the name given to small nodosities that develop slowly on the lateral aspects of the distal phalanges. These are the result of osteophytic out-growths at the articular surfaces of the bones, which present in addition the other alterations characteristic of arthritis deformans. They are sometimes found in persons otherwise unaffected with arthritis deformans, though they are also found in persons with the localized form of the disease in the hip, or the vertebrae. They are rarely if ever encountered in persons presenting the usual lesions of the disease in the hands and feet. Arthritis deformans as it occurs in children is much like the arthritis deformans of older people, but it presents in addition some peculiar and interesting features, the discussion of which is not pertinent at present.

DIFFERENTIAL DIAGNOSIS.

The recognition of arthritis deformans and its differentiation from other disorders that more or less closely resemble it, are matters of extreme importance. The diseases with which it is most likely to be confounded are, of course, rheumatism and gout. There can hardly be much question that many cases of arthritis deformans are incorrectly diagnosed either rheumatism or gout and that the true nature of the arthritis is not recognized until it has given rise to extreme and irremediable deformities. These three diseases—gout, rheumatism, and arthritis deformans—formerly held to be more or less related to each other, are now recognized as being totally distinct affections. The relation consists in a more or less superficial resemblance clinically, and in the fact that one disease may follow the other in the same patient.

As already stated, acute arthritis deformans most closely resembles acute rheumatism, and in many cases, in the early stages at least, differentiation is most difficult. The acute forms of arthritis deformans may be distinguished from acute rheumatism by the fact that the former is much the more intractable affection of the two; fever, when it develops in arthritis deformans, is less high and of shorter duration than that which attends rheumatism; arthritis deformans does not exhibit any especial tendency to flit from joint to joint—a joint once affected generally remains so, and other joints become involved; the affected joints are less red, and less painful than in rheumatism; in arthritis deformans the small joints are especially prone to be affected, the profuse sweats that accompany acute rheumatism are not present, though slight perspiration is common enough, the erythemas that accompany rheumatism are absent, there is less likelihood for the development of endocardial and pericardial complications—by some it is even denied that such are ever due to arthritis deformans or its cause—the abundant deposit of urates in the urine, so common in rheumatism, is usually absent and finally the disease does not respond well to treatment with salicylic acid and the salicylates. The same facts hold good with reference to the differential diagnosis in the more chronic cases and their acute exacerbations. In acute rheumatism the articular alterations subside without impairment of the functions of the joints, whereas if the disease be arthritis deformans, sooner or later, deformities make their appearance. There occur ankylosis, absorption of the articulating

cartilages, eburnation and abrasion of the bones, lipping of the cartilages at their edges or the growth of new cartilage in the synovial sheaths, osteophyte formation, relaxation and softening of the ligaments, muscular contractures and dislocations. Chronic rheumatism, of course, does often localize itself in the joints, and even in the small joints of the hands, less frequently in those of the feet, but it never results in the deformities, lipping of the cartilages, osteophytic new-growths, etc., so characteristic of arthritis deformans. In rheumatism the enlargement of the joints is fusiform and regular, and the joints affected usually manifest some evidence of local inflammation. The deformities that occur are the result of disuse and alteration of the capsules and ligaments. The joint involvement is markedly asymmetric in its distribution and the temporo-maxillary joints and the vertebrae are rarely if ever implicated. The acute exacerbations, which are quite common, show rapid migration from one joint to another and they usually quickly subside under the influence of the salicylates. In arthritis deformans the muscular atrophy is also more early in its development and more rapid in its course than in rheumatism. In chronic rheumatism also we may elicit a history of previous attacks of articular involvement with intervals of complete intermission, or a history of previous chorea or erythema nodosum. Again, examination of the heart may reveal a valvular lesion. We must remember, however, that in young children arthritis deformans may manifest deviations from the typical course observed in older persons. It affects many joints in rapid succession and causes their great enlargement and well-marked muscular atrophy. The swelling is sometimes excessive and unaccompanied by the characteristic deformities—for a time at least. In children the disease is much more rapid in its course and more quickly destructive than in adults and elderly persons, in whom it is usually slower, but accompanied by well-marked deformities.

Spender considers that what he speaks of as the collateral symptoms of arthritis deformans are of considerable significance in the diagnosis. Thus he states that, examining a case of arthritis of doubtful nature, if we count the pulse, we may find a steady tachycardia of between 90 and 120 per minute; or there may be a growing melasma on the face, or perhaps numerous spots or little stains on the arms; or the hands may be cold and sweating; or there may be neuralgic twinges in the upper and lower limbs. He believes that if any one of these symptoms be present beyond question, and if it can be proved to have been synchronous with the arthritis in beginning and progress, the nature of the arthritis is demonstrated thereby. He states that he does not pretend to yet explain the connection of the facts, but only to record them.

There can be no question that many cases of arthritis deformans have been and still are mistaken for gout. This is a most unfortunate occurrence when we consider the indications for treatment, which are almost diametrically opposite in the two affections. Care and patience, however, will usually enable us to make a differential diagnosis. Arthritis deformans is pre-eminently a disease that affects women of the poorer classes, who have been exposed, as already intimated, to want and privation, prolonged fatigue, worry and anxiety, and to the inclemencies of the weather, or who have had disease of the genitalia. On the contrary, gout is a disease that especially affects men who are well-to-do, well nourished, who have not been exposed to depressing influences, but

who have enjoyed the good things of this life and are popularly known as good livers. The etiologic factors in arthritis deformans therefore are chiefly nervous; those of gout are chiefly dietetic. In gout there is usually a distinct hereditary tendency which is much less apparent in arthritis deformans. The nervous factors that play such an important rôle in the etiology of arthritis deformans, when they occur during the course of the disease, cause an aggravation of the symptoms; the same factors are without such influence in gout. In arthritis deformans the onset is usually slow and insidious, there is often but little pain or swelling at first, and the patient frequently does not feel impelled to seek the advice of the physician until the disease is more or less advanced. In gout, on the contrary the onset is usually sudden, there is considerable pain, swelling, heat, tenderness and infiltration of the soft tissues about the joint or joints affected. Arthritis deformans generally affects one of the small joints of one hand, then other joints of the hands, and finally it may spread to almost all the joints of the body, including the temporo-maxillary joint and the vertebrae, but it exhibits no especial predilection for the great toe; gout, on the other hand, generally commences in the great toe; as it spreads it tends to implicate the larger joints; it involves the fingers in the later stages only of the affection, if it does not leave them entirely unaffected; it practically never involves the temporo-maxillary joints, and but most exceptionally the vertebrae. The symmetric distribution of the lesions so commonly observed in arthritis deformans is, as a rule, entirely absent in gout. The characteristic deformities of the hands, such as the ulnar deflection, never develop in gout. The deformities that do occur in gout are due to tophaceous deposits—to the presence of sodium bicurate—in the joints and the periarticular tissues. In arthritis deformans these deposits are never encountered unless gout has preceded or possibly followed the arthritis deformans; the deformities are due to destruction of the articulating surfaces of the bones, to lipping of the cartilages, and to osteophytic outgrowths. In gout chalky deposits are also found in the external ear and in other portions of the body; these are never observed in arthritis deformans. In gout, uric acid is usually found in excess in the blood and in the urine; this is not the case in arthritis deformans. Arthritis deformans is improved or the progress of the disease is at least stayed by a good, full, plentiful diet. Such is usually poison to a gouty patient; his condition is improved by a very abstemious and restricted diet. In fact, indulgence in certain articles of diet, such as the sugars and certain acids, and the drinking of certain alcoholic beverages, more particularly the malted beverages, are almost certain to provoke an acute paroxysm of gout. These attacks, which are quite characteristic of gout, are often of extreme violence, but there are often intervals of comparative or absolute freedom from suffering. Arthritis deformans is of long duration, progressive from the commencement, but there occur more or less acute exacerbations which, however, are never of the violence of those that characterize gout. Finally, complications, such as the arteriosclerosis and chronic nephritis which are so common in gout, are extremely uncommon in arthritis deformans.

Tuberculosis of the joints resembles in a superficial way arthritis deformans, but in tuberculosis there are rarely if ever so many joints implicated as in arthritis deformans, the course and origin of the affection is different, the characteristic deformities, the extreme muscular

atrophy and the symmetric distribution of the lesions are not observed, and the diseased joints break down and permit of the recognition of the nature of the affection by an examination of the extruded material or of the joints themselves. Sciatica may be differentiated from the monarthritic variety of arthritis deformans localized to the hip by the presence of pain along the distribution of the sciatic nerve, and by the absence of rigidity and restriction of movement at the hip-joint. The joint lesions that accompany locomotor ataxia, syringomyelia, hemophilia and gonorrhœa are distinguished primarily by the recognition of the underlying disease, as well as by other features, the narration of which at present would carry us beyond the justifiable limits of this communication. We must remember, though, that certain isolated cases of arthritis deformans run their course unattended by manifestations other than the joint lesions and the muscular atrophy.

PATHOGENESIS.

When we consider the pathogenesis of arthritis deformans we are immediately confronted by the fact that the disease not only presents characteristic joint lesions, but that it also exhibits lesions of the muscles and various trophic, vasomotor and constitutional symptoms that are no less a part of the disorder. It is because of the difficulty of adequately accounting for the varied manifestations of the disease that most of the theories heretofore propounded to explain its development have been found wanting. That theory that does not explain the disease in its entirety must be abandoned—at least modified or added to.

That the disease is allied to either rheumatism or gout is now no longer held by competent authorities. That rheumatism, and in some cases gout also, may precede the development of the arthritis deformans does not permit of much doubt. That arthritis deformans itself is a hybrid, the consequence of a mixture of gout and rheumatism, can no more be maintained than the fancy that it results from one or the other of these two affections. That it is the consequence of anemia, as has been held by Forsbrooke, or of wear and tear, as has been suggested by Lane, or of reflex action induced by some disease of the uterus or the viscera, as maintained by Ord, does not agree with the facts at hand. That anemia is present in most cases is true; that the result of wear and tear is particularly evident on the articulating surfaces of the bones after the disease has existed for some time is also true; but that the disease is the consequence of either one or the other of these conditions does not admit of proof and is negated by many well-known facts. There remain but two theories that are at present at all worthy of our consideration in an attempt to fathom the nature of the disease. These are the neural or nervous theory and the infectious or bacterial theory. The former was propounded a number of years ago by the late J. K. Mitchell, of Philadelphia, and has been maintained by a number of distinguished clinicians ever since; the latter, or bacterial theory, is of much more recent date, and still lacks the endorsement of the great body of clinicians and investigators. It seems to me that in the present state of our knowledge neither theory is entirely without justifiable objection. I believe, though, that a germ of truth is to be found in each.

The principal reasons that have been adduced to support the neural theory are: 1. The nature of certain of the etiologic factors of the disease. These have already been referred to, and mention has been made of the etiologic relationship of worry, anxiety, emotional dis-

turbances, fright, undue fatigue, etc. 2. The occurrence of the disease at a time when, in many instances, nervous disturbances manifest themselves; that is, about the time of the menopause, or during the exhaustion following repeated pregnancies, prolonged lactation, etc. 3. The symmetry of the joint lesions. 4. The tendency of the disease to spread centripetally. 5. The association of various vasomotor and trophic disturbances. 6. The fact that similar joint disorders occur in the course of certain evident diseases of the nervous system. Those who from time to time have upheld the neural theory have not been in unison with regard to the nature of the nervous factors that originate the joint lesions and other manifestations of the affection. By some they have been ascribed to reflex action, and the reflex disturbances incidental to disease of the female genitalia and to the menopause have been pointed to in support of this supposition; by others, the disease has been held to be a trophoneurosis and in support thereof the various trophic and vasomotor disturbances have been instanced; by others the affection has been attributed to a peripheral neuritis, and it has been pointed out by such that there can be no question that peripheral neuritis has been found in some cases; by still others, the disorder has been held to be a spinal disease.

Including, however, for the time being, all the preceding under the generic heading of the neural theory, when we come to examine this critically, there are many points that it leaves obscure. For instance, in locomotor ataxia, syringomyelia, ataxia paraplegia and other nervous disorders associated with arthropathies, the latter are found in connection with some definite disease of the nervous system—with a disorder the lesions of which are readily recognized. In arthritis deformans no lesions of the nervous system have been found, with the exception of the isolated cases in which some peripheral neuritis has been detected, and the other rare cases reported by Folli, Klippel and Bannatyne. Folli had an opportunity to examine at necropsy four cases. Two of these were typical cases, and they revealed alterations in the anterior horns of the gray matter of the cord. In one case the lesions were merely atrophic, in the other they were both atrophic and degenerative. Bannatyne found degeneration and vacuolation of the ganglion cells of the anterior horns of the spinal cord in one case. These, however, are isolated observations; the nerve lesions are relatively inconspicuous; they have not been found with any regularity—with that regularity we should expect after so many years of observation, and they can not possibly be held answerable for the widespread destruction of the joints, the muscular atrophy and the other clinical features of the disease. When we assign the development of the disease to reflex action we must be immediately conscious of the exceptional status we accord the affection. There is in the entire domain of pathology no counterpart of such a destructive disease resulting from reflex action, and the viscera when examined reveal but most inconspicuous, if any, alterations. Usually attributed to morbid impulses originating in the female genitalia, it must be remembered that a certain percentage of the cases occur in males, and still another percentage in young girls, at an age when reflex impulses from the genitalia are generally supposed to be wanting. And again it must be borne in mind that the uterus is very largely under the domination of the sympathetic nervous system as contrasted with the cerebrospinal axis. With regard to the idea of its being a trophoneurosis, it may be stated that evidences of trophic and vasomotor disturb-

ances are most conspicuous. In respect to the neural theory also we must remember that the disease sometimes arises in the absence of the depressing etiologic influences of nervous character; that it often, in fact usually, does not arise symmetrically, but first one joint is affected, then the corresponding joint of the opposite member, and ultimately the disorder becomes symmetric, and that in many instances the disease does not manifest any tendency whatever to spread centripetally. All these we should expect were the affection of purely nervous origin.

Let us now for a moment examine the infectious or bacterial theory. We find that Schüller first suggested the infectious nature of this disease. Since his original communication this phase of the subject has been investigated by a number of observers, of whom may be mentioned Schüller himself, Chauffard and Ramond, Bannatyne, Wohlmann and Blaxall and von Dungere and Schneider. Schüller found in the diseased joints a bacillus with polar staining, with cultures of which he was able to produce in the joints of animals lesions similar to those observed in man. Bannatyne, Wohlmann and Blaxall, examining the synovial fluid obtained by aspiration in twenty-five cases of arthritis deformans, obtained in twenty-four of the cases a minute bacillus which exhibited polar staining. They also detected the same bacillus in several pieces of synovial membrane obtained during aspiration, and in the cartilages, synovial membrane and periarticular tissues in a few sections. By microscopic examination, they found it also in the blood in several acute cases, but never so characteristically as to warrant them in diagnosing the disease from this alone. Inoculation experiments were unsatisfactory. Some joint lesions were produced in rabbits, but they were not of a definite character. This bacillus is probably identical with that discovered by Chauffard and Ramond. These authors were able to isolate what they termed a slender diplobacillus from the synovial fluid and from scrapings from enlarged glands in the neighborhood of the diseased joints in cases of arthritis deformans. The bacillus described by Schüller is probably a different organism from the two preceding, and Schüller himself in his latest communication, states that his bacillus is the cause of chronic villous polyarthritis—a disease that he sharply differentiates from arthritis deformans. The last-named disease he attributes to disturbances of metabolism. Von Dungere and Schneider examined the fluid taken from the knee and wrist joints during life and that taken from various joints and the gall-bladder after death, of a patient suffering with arthritis deformans. Microscopic examination of the fluid from the gall-bladder revealed a micro-organism, and cultures from the fluid from all the joints as well as that from the gall-bladder revealed the same bacterium. This was a small diplococcus that could not be identified with any of the known organisms, though it resembled the lancolate bacillus. When injected into rabbits' knees it produced lesions identical with those found in the joints of the patient. The authors believe that an attack of acute rheumatism from which the patient suffered seventeen years prior to his death and eight years prior to the commencement of the manifestations of the arthritis deformans, predisposed his joints to the arthritis. The development of the chronic polyarthritic deformans is attributed to infection from a chronically inflamed gall-bladder.

Bannatyne, who is an ardent supporter of the infectious nature of arthritis deformans, urges the following in support of his contentions: 1. the frequency of the

occurrence of arthritis deformans as a sequel of other forms of known infective diseases; 2, its numerous nerve symptoms for which no adequate nerve lesions have been found; 3, the occurrence during its course of such complications as pneumonia, pleurisy, pericarditis, endocarditis, etc.; 4, its polyarthritic character; 5, its course and progress, and 6, the presence of enlarged glands proximal to an affected joint.

Personally, I am inclined to accord considerable importance to the results of the above cited bacteriologic investigations, and to the views enunciated by Bannatyne and concurred in by Luff and others. I believe, though, that Bannatyne and others, possibly in the enthusiasm of their discoveries, take a too restricted view of the subject, and forget, or at least overlook, the demonstrated significance of the neural element in the etiology of the disease. Were I to express my own opinion, based on my own limited observation and study, I would state that I believe arthritis deformans to be an infectious trophoneurosis, and I further believe that the facts at our command bear out this opinion.

I have already alluded to some of the shortcomings of the purely nervous theory, but I trust I have at the same time pointed out sufficiently clearly the importance of the neural element in the etiology of this disease. I have also indicated that the present state of our knowledge does not warrant us in assuming that the disease is of spinal origin—in fact, the information that we possess indicates that the disease is certainly not of spinal origin. I have also shown that it can not be considered the result of a peripheral neuritis—indeed, it is to be wondered that such a supposition could have been seriously entertained; nor are we warranted in supposing that it results in consequence of reflex action, the impulses being emitted from some viscera, particularly the female genitalia, the seat of real or fancied disease. Of the various phases, therefore, in which the neural theory has appeared from time to time, there remains the trophoneurotic, and it is of this nature I believe the neural element in the etiology of arthritis deformans to be.

If we endeavor to supply the defects in the purely neural theory by assuming that the disease is an infectious trophoneurosis, we have firm foundation from which to proceed in the fact that bacteria have been found in the diseased joints in a considerable number of cases by competent investigators and clinicians of wide experience. We know that arthritis occurs in the course of or following certain infectious diseases, such as tuberculosis, pyemia, gonorrhea, scarlet fever, typhoid fever and acute rheumatism. We know that in some of these infections there exists more of a predilection to joint involvement than in others, and we know also that any one of them may exist without joint implication. This is as true of rheumatism as it is of any of the other infections mentioned. There may occur rheumatic infection without involvement of the joints similarly as there may occur typhoid infection without intestinal lesions. Arthritis deformans sometimes occurs after certain infectious diseases, such as rheumatism, influenza, suppurative tonsillitis, diseases of the gastrointestinal tract, etc.—under conditions, therefore, that permit of the ready entrance into the body of bacteria. In certain of these infections the joints, though they may not become diseased, are yet subject to the irritative influences of the toxins circulating in the blood. It is not unnatural to suppose that in the condition of diminished resistance thus brought about the joints readily become the prey of the bacteria provocative of arthritis

deformans. In many cases under the influence of the trophoneurotic etiologic element the joints become especially prone to disease; in other cases, such as the physical wear and tear to which certain joints have been subjected, that they readily succumb to the morbid agencies provocative of arthritis deformans. This is seen especially well exemplified in the involvement of certain joints that have been accustomed to perform an undue amount of work. Other joints in the same patient may remain entirely unaffected. Then again we are justified in assuming that the special bacteria concerned in the causation of arthritis deformans possess a selective tendency to involve the joints—just as other bacteria find a congenial soil in certain special tissues of the body and there proliferating give rise to their deleterious consequences.

The events subsequent to the invasion of a single joint by the bacteria are such as we should expect from our knowledge of infectious diseases in general. A single joint is at first involved; then, possibly under the influence of the nervous system, the corresponding joint of the opposite member becomes diseased. But sufficiently often several joints of one limb are implicated before the affection spreads to the opposite side of the body. Corresponding joints of the two sides of the body do not become simultaneously involved as we should expect were the disease of purely nervous origin. Indeed, in some cases, the affection is not at all symmetric; it is very irregular in the distribution of its joint lesions. It may rarely be distinctly one-sided. The supposition that the disease is of purely nervous genesis because the joint lesions spread centripetally is contradicted by the fact that sufficiently often the disease does not spread centripetally, but in a most irregular fashion.

The bacteria having lodged in the joint not only engender the local lesions, which have already been referred to in sufficient detail, but they also produce a toxin. This being absorbed into the circulation gives rise to the other symptoms of the disease. It is to the operations of the toxin that the fever, the anemia, the slight sweatings, the local asphyxias or erythemas, the mottling of the skin, the pigmentations, the alterations of the nails, the atrophic glossy skin, the scleroderma, the tachycardia, the purpuric hemorrhages, the muscular atrophy, etc., are to be attributed. It will be observed that practically all of what may be termed the secondary symptoms of the disease are due to derangement of the nervous system. As no definite lesions have been detected in the nervous system, though they have been diligently searched for, these derangements may, with good reason and from analogy, be ascribed to the action of a toxin. From what we have learned of the action of bacterial toxins, we are aware that they are capable of setting up not only structural alterations, but also disturbances of nutrition, the latter of which escape detection by the microscope, but may sometimes be studied by the physiologic or pathologic chemist. The nutritional alterations precede the structural, and reasoning from this point of view, it is not surprising that histologic alterations should have been absent from the spinal cords examined. Nor is it to be wondered at that a few observers, as has been mentioned, should have found slight changes in several cords. We are well aware that the action of a toxin, if prolonged, may lead to such alterations as have been detected. And the same may also ensue in case the toxin be of increased virulence. The neuritis found in some cases may also be ascribed to the same cause.

That the tachycardia is the result of the action of a toxin is attested by the fact that in some instances when the disease has been arrested—therefore, when the bacteria have ceased their activity—the pulse-rate returns to the normal. In most cases, however, the disease is steadily progressive, more and more toxin is constantly elaborated, and the tachycardia gradually becomes worse.

The muscular atrophy, so characteristic of the disease, has been the subject of much study on the part of clinicians and investigators, and various theories have been adduced to explain its occurrence. It has been said that this atrophy results from disuse of the joint or joints—it being well known that when joints are no longer used the muscular apparatus concerned in their previous functioning tend to progressive atrophy. This view is negated by the fact that the muscular atrophy the result of disuse is much slower in its development and less well marked than is that characteristic of arthritis deformans; by the fact that it affects all the muscles of the limb; by the fact that the atrophy of arthritis deformans is out of all proportion to the atrophy observed in cases of disuse from causes other than arthritis deformans; by the fact that it exhibits marked selective tendencies, and by the fact that in the majority of cases the tendon reflexes are slightly increased. The idea that the muscular atrophy is due to central spinal causes can not be entertained in the absence of demonstrable spinal-cord lesions, nor can it be maintained that it is due to peripheral neuritis, as has been claimed by Pietres and Vaillard, in view of the exceptional occurrences of peripheral neuritis in this disease. All the facts at our command indicate that the atrophy is of a mixed nature. It resembles that found in association with other joint disorders in that it tends to affect the extensor muscles more than the flexors; it is therefore spoken of as *relax*. But that it results largely from the action of a toxin is attested by many facts. In its marked selective tendency, Bannatyne sees a significant indication of its toxic origin. In support of this view he compares the atrophy of arthritis deformans with that the result of the operation of alcohol, in which the extensors, especially of the leg, are affected; with that of lead, which affects chiefly the extensors of the wrist and fingers, and with that of the diphtheria toxin, which exhibits a marked affinity for the muscles—and their nervous supply—of the pharynx and the internal muscles of the eye. He draws attention also to the fact that in some cases only the motor filaments of a nerve are affected, and he states that there is good reason for the supposition that even trophic and vasomotor filaments may be especially picked out. In the aforementioned instances there occurs a peripheral neuritis to account for the atrophy of the muscles: in arthritis deformans it is much more likely that the atrophy is the result of some central disturbance, some alteration of the nutrition of the cells in the anterior horns of the spinal cord. This view is supported by the fact that there is usually increased myotatic irritability and slightly increased reflexes—indications of an irritative lesion somewhere. In a few cases the reflexes are diminished and there may supervene also the reactions of degeneration. These cases usually reveal a peripheral neuritis, or there may be degeneration of the peripheral motor neuron.

In some cases doubtless the bacteria circulate in the blood. Evidence of this we find in the discovery by Bannatyne and Wohlmann of micro-organisms in the blood of patients affected with arthritis deformans, and

in the detection by Chaffard and Ramond of bacteria in the lymph-glands to the proximal side of the affected joints. To this may also be attributed the enlargement of the lymph-glands, the enlargement of the spleen said to have been found by several clinicians, certain subcutaneous fibroid nodules which have sometimes been known to undergo central necrosis, and lesions of the endocardium and pericardium, the occurrence of which is admitted by a number of observers, though denied by others.

In arthritis deformans certain disturbances of metabolism have been found. These have consisted, on the one hand, in the detection by Schüller, of diminution in the lime-salts and the earthy phosphates in the urine, and on the other hand, in the detection by Bain of a diminution in the excretion of uric acid and phosphoric anhydride, without disturbance of the normal relationship between the uric acid and the alloxur bases. Schüller, who, as has already been mentioned, differentiates sharply between chronic villous polyarthritis and arthritis deformans, attributes the latter disease to disturbances of metabolism. These are characterized by the diminished excretion of lime-salts in the urine and the deposition of such salts in the articulating extremities of the bones, and in the periarticular tissues about diseased joints. I prefer, for the present, however, to consider these conditions not the cause of arthritis deformans, but the consequence of the factors that induce the arthritis itself—a part of the disease, therefore.

Finally, that arthritis deformans is in great part an infectious disease, is indicated by the markedly infectious character of all the acute cases. In these cases probably the bacteria are of excessive virulence, and are capable of producing their deleterious effects unaided, or but slightly aided, by a neural etiological fact. In the chronic cases, however, we have to deal with an infectious trophoneurosis. The trophoneurotic factors predispose the tissues to bacterial invasion. This accomplished, the subsequent manifestations are in part controlled by, and produced through, the operations of the nervous system.

This view with regard to the infectious trophoneurotic nature of arthritis deformans, of course, permits of much further elaboration, but enough has been said on this occasion. I trust, though my remarks may not have seemed conclusive and convincing, that they have at least been suggestive.

Chronic Acid for Buccal Lesions.—Jarre announces that local applications of chronic acid promptly cure all inflammatory and ulcerative lesions of the buccal mucous membrane. It should be applied in a concentrated solution and rinsed out at once to restrict its action to the superficial tissues.—*Int. Med. Congress.*

SEPARATION OF THE RECTI ABDOMINIS
MUSCLES AND STRETCHING OF
THE LINEA ALBA.

UNNOTICED FACTORS IN THE PRODUCTION OF ABDOMINAL
AND PELVIC DISTURBANCES IN WOMEN.

J. CLARENCE WEBSTER, M.D.

Professor of Gynecology and Obstetrics in Rush Medical College,
affiliated with the University of Chicago.
CHICAGO.

Since the publication of Glénard's work on enterop-
tosis in 1885, in which attention was directed to dis-
placement of the abdominal viscera as a cause of suffer-
ing, especially in the female sex, numerous observations
have been made corroborative of many of the statements
of the French writer. At the present time there is a
consensus of opinion among prominent clinicians as to
the importance of the subject, but the profession at large
have given it very scant consideration. Investigations
made by me during the last two years have con-
vinced me that alterations in intra-abdominal pressure,
associated with visceral displacements, are the chief
source of trouble in many cases in which abnormal
symptoms are considered as neuroses or as reflex dis-
turbances due to some pelvic lesion. Much just criti-
cism has been heaped on the gynecologist because of the
marked prominence given by him to various minor pel-
vic conditions, such as endometritis, laceration of the
cervix, catarrhal patches on the cervix, etc., as causes
of suffering in women. Such criticism has greatly
helped to do away with much of the meddlesome gyn-
ecologic practice of former years, but careful observa-
tions made by scientific workers in the department of
women's diseases have led to the same end.

The nature of the normal relationships of the abdo-
minal and pelvic contents and the methods by which they
are altered is a somewhat complicated problem, involv-
ing a consideration of anatomic, physiologic and phys-
ical factors which are not yet thoroughly understood.

It is not my purpose to refer to these in detail, but
rather to direct attention particularly to one factor, viz.,
the abdominal wall. This structure, composed of a var-
iety of tissues, the most important of which are the
fascial and muscular layers, normally exhibits a certain
degree of tonicity helping to maintain the position of
the trunk and to exert pressure on the abdominal con-
tents. The latter function it shares with the diaphragm
and pelvic floor.

The average specific gravity of the viscera and contents
is very little more than that of water—the liver, for ex-
ample, is about 1.05 sp. gr.—and it is customary to re-
gard the visceral mass as a body of water, so far as the
physics of the abdomen is concerned. This being the
case, it is evident that the pressure at the surface is dis-
tributed at right angles to the latter in all directions.

In addition, the influence of the weight of the mass
has to be considered. This varies according to the po-
sition of the individual. In the erect posture it causes
a slight bulging of the lower part of the abdominal wall
and the pelvic floor is slightly lowered. If the position
be altered so that the pelvis is higher than the thorax,
the bulging of the lower abdominal region and pelvic
floor is lessened, while near the thorax the abdominal
wall is pushed slightly forward.

Schwerdt has endeavored to calculate the intra-abdo-
minal pressure experimentally. He measured it within
the stomach in the erect posture by means of a water
manometer and found it to be 11 cm. In the rectum
it measured 39 cm. The difference of 28 cm. represents

the weight of the viscera supported by the pelvic floor.
The vertical distance between the diaphragm and the
pelvic floor was 36 cm. and it was therefore evident
that the pelvic floor did not sustain the whole weight
of the viscera. At first sight it might appear that the
difference of 8 cm. represented the support given to
various viscera by their ligamentous attachments, and
this might seem to be all the more probable when it
is remembered that the specific gravity of the viscera
is very little more than that of water. Were the com-
parison to free fluid absolutely correct, the water man-
ometer placed in the rectum would register the weight
of the whole column of 36 cm. of water.

Are we then to conclude that the difference of 8 cm.
is due to ligamentous support of the viscera? Cer-
tainly not, because the stomach and intestines contain
air and gases, and the specific gravity of the whole
column extending from diaphragm to pelvic floor must,
therefore, be less than that of water. Schwerdt cal-
culates that the proportion of the weight of the viscera
supported by the ligaments is one-eighth, but it is likely
that this is too high an estimate and several workers
think it doubtful if, under ordinary circumstances, the
ligaments act as supports at all. Symington has shown
that normally the suspensory ligament of the liver
is not tense, and Buist points out that this organ,
whose greatest vertical diameter is 8 cm., must easily
be supported by the subjacent viscera, since Schwerdt's
experiment shows that the manometer registers in the
stomach a pressure of 11 cm. So it is with the intestines.
There is no proof that, under normal conditions,
their mesenteric attachments act as constant supports
or are ever meant to be such. Their structure is not
of the consistence to make them efficacious for this
purpose. Indeed, whenever pathological conditions are
introduced which put continued strain on the ligaments
they always prove to be unfit for the work thrown
upon them and undergo gradual elongation. This
being the case, it is evident that the important factor
in sustaining the viscera in their normal relationships
is the strength of the abdominal wall and pelvic floor.

Normally, there are variations in the intra-abdo-
minal pressure, depending on different conditions, mainly
on the state of fascial and muscular structures in the
parietes. The stronger these tissues the more the
resistance offered to the pressure of the viscera and
the better the latter are supported.

The importance of the pelvic floor has long been
recognized. The various hernial developments associ-
ated with weakness or laceration of different parts
of its structure have been well investigated and many
measures have been devised by gynecologists for the
relief of the symptoms accompanying these conditions.

The other factor, the abdominal wall, has received
very little attention. Several writers, Prochnowik,
Landau, Tuffier, Fritz and others have referred to it,
but their writings have received little notice. Recently,
Wolkow and Delitzin have drawn attention to the im-
portance of the abdominal wall, anatomically and
physiologically, in giving support to the abdominal
viscera. They have experimented on the cadaver, weak-
ening the wall, by removal of one or the other of its
component parts, and thus bringing about descent of
various viscera.

There is a difference of opinion as to the relative
values of the fascial and muscular structures. Stan-
more Bishop, for instance, urges the prime importance
of the fasciae, and speaking of the anterior part of the
wall, he states that the recti muscles are of compar-

atively little value as a source of strength. From the experiments of Wolkow and Delitzin, however, it would appear that these muscles are of considerable importance, their removal being followed by a stretching of the linea alba and a bulging due to descent of the viscera.

When one considers the effect of certain physical exercises in strengthening and thickening the abdominal wall it is easy to understand the importance of the musculature.

Weakness of the abdominal wall following muscular atrophy from dress-pressure and disuse is an additional corroboration.

The effects of local weakness in the abdominal wall have been fully described in surgical works under the various forms of hernia. General weakness of the wall has been known as "lax abdominal wall" and "pendulous belly," but there has been no detailed study of the latter conditions.

From my investigations I am convinced that in

sible to dissect any extensive portion of it as a distinct layer. The fact that the stretching in its earliest stages is generally found at the umbilicus is evidence that this point is the weakest in the middle line of the abdominal wall.

As a result of stretching of the linea alba separation of the recti muscles takes place. In extreme degrees of the affection, the recti may be separated in the middle region of the belly as much as five or six inches, the intervening portion of the wall being bulged by the enteroposited viscera.

In the past two years, I have not examined a single case of pendulous belly in which these conditions were not present. In no instance was there any general stretching of the abdominal wall, unaccompanied by marked separation of the recti muscles.

Etiology.—In almost all cases the diastasis is found in women who have born children. The most marked examples occur in those who have gone through several labors, though they may be found in those who have

women general laxity or weakness is a very rare condition and that what is described as such is, in the main, a local disturbance consisting in separation of the recti muscles and stretching of the linea alba. My observations prove that these alterations, in moderate degree, are very frequent, are important causes of ill-health in women and are to a considerable extent amenable to treatment. So far as I am aware, their significance is, in the practice of medicine, generally overlooked. Many variations are found in the extent to which they are developed. In the least marked cases they are recognizable usually only in the region of the umbilicus. In more marked stages the area affected may extend an inch or more above the navel and a similar distance below, though rarely the part above or that below may be affected. In the most advanced conditions the diastasis extends from the pubes to near the ensiform cartilage.

The more marked the case the more thinned is the linea alba; sometimes, it is so stretched that it is impos-

Fig. 2.—Dissection of anterior abdominal wall in a multipara, with diastasis of the recti muscles. a. Inner edge of right rectus; b. Inner edge of left rectus; c. Linea alba stretched and thinned.

had only one or two children. Indeed, the examination of the abdomen of primigravida in a large number of maternity cases has convinced me that in the great majority of women there is some degree of separation of the recti in the region of the navel as a result of the distension of pregnancy. After labor, in many instances, however, owing to retractility of the abdominal wall, all evidence of stretching may disappear, though in a considerable proportion of cases, permanent widening remains, which is likely to become increased in succeeding pregnancies.

All conditions increasing intra-abdominal pressure in pregnancy tend to favor the development of the diastasis. Thus, women who work hard in the second half of pregnancy, especially those who lift or carry heavy weights, are more apt to become affected. Sometimes a sudden strain or fall is the starting-point of the condition. Among all classes, the wearing of corsets in pregnancy is not infrequently an important associated cause. It is very easy to understand how this should

act detrimentally. The intra-abdominal space being artificially constricted above and being gradually encroached on by the growing uterus from below, the various viscera are more and more compressed into the intermediate area, where the weakest and least resistant portion of the abdominal wall is at the umbilicus. In all women, flatulence and constipation, abundant adipose tissue in the mesentery and omentum must be regarded as favoring causes. So also is any condition which induces excessive coughing in pregnancy. General weakness or emaciation also predisposes, by lowering the tone of the tissues of the abdominal wall.

Of equal and perhaps greater importance is the effect of these conditions after delivery. In this period perhaps the two most important factors concerned are tight-lacing in one class of women and too-early hard work in another. A certain degree of diastasis having been established as a result of pregnancy, it

women who have not been accustomed to wear corsets, tie the skirts tightly around the waist or engage in heavy or vigorous exercise. In those women with slight or moderate diastasis, whose mode of dress or work leads to increased intra-abdominal pressure, the visceral displacement most frequently found is prolapse of the right kidney. In such cases it is very difficult to estimate the frequency of descent of other viscera, especially the hollow ones, by physical examination of the abdomen.

In a number of cases in which I have performed abdominal section for pelvic troubles I have found the transverse colon and, sometimes, the stomach, lower than normal, whereas by external examination I had been previously able only to distinguish prolapse of the right kidney.

Where marked stretching of the linea alba takes place, descent of the viscera and elongation of their attachments occur. In the most extreme degrees the

Fig. 3.—Operation for repair of weakened abdominal wall. The drawing represents the inner edges of the separated recti muscles exposed. a. Stretched and thinned linea alba. b. Anterior layer of sheath of rectus. c. Edge of rectus muscle exposed by opening sheath. d. Skin and subcutaneous tissue.

is easy to understand how increased intra-abdominal pressure resumed after labor may lead to a continuance or intensification of the pre-parturient weakness.

In nulliparous women slight degrees of stretching of the linea alba are occasionally found, marked degrees rarely. I have never met with an extreme case.

It is thus evident that of all the factors which may be associated with the development of this condition in women, pregnancy is the most important. Occasionally, cases are found in which the chief cause is distension due to tumors or ascites.

Results.—The inevitable result of marked or continued stretching of the linea alba is enteroptosis. This is met with in different forms and degrees, considerable variations existing as regards the order and range of descent of the viscera.

In cases in which the diastasis is only slightly or moderately developed, the variations are most marked. These, I believe, depend largely on the mode of life and dress. Thus, in some cases, no descent of any of the viscera can be made out. These are almost always

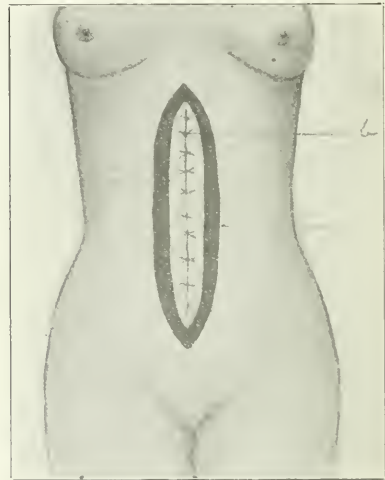

Fig. 4.—Operation for repair of weakened abdominal wall. The drawing represents the recti muscles with the fascia covering them drawn together and sutured by strong linen. a. belly is very protuberant and pendulous, the projecting portion being filled with small intestines, omentum, transverse colon and, sometimes, the stomach. Great variations are found as regards the extent to which the viscera are prolapsed. Alterations in the shape and position of the liver are probably, as Hertz has shown, chiefly related to the influence of corset-constriction.

Downward displacement of the right kidney is frequently found, the left organ being much less often affected, and to a less degree. The spleen is occasionally displaced.

The abdominal wall between the recti usually becomes thinned. The recti themselves are pushed laterally as the linea alba is stretched and extend in a curved line from sternum to pubes, the convexity reaching well out into the lumbar region.

Prolapse of one or other part of the pelvic floor is frequently met with. This is mostly found where the floor has been injured in labor. It is very easy to understand why this complication should be brought about as a result of enteroptosis. Retroversion of the

uterus, with or without prolapse of the floor is also often found.

Symptoms.—The symptoms vary greatly. They are those which have been described in recent literature in connection with enteroptosis. In severe cases the patient may complain of weakness and dragging in the back and abdomen, aggravated on long standing, walking or working. The bowels are usually sluggish. Pains may be felt in the iliac, lumbar or other regions. Various dyspeptic symptoms may be present. Pulsation of the aorta may disturb the patient. Nausea and vomiting may be distressing. The patient often loses weight and a neurasthmatic state is frequently induced. Not even in the most marked cases are these symptoms always present. Often some are absent and, in many instances, one complaint is prominent above all others.

When the linea alba is not much stretched, there may or may not be symptoms. In this class they are very rarely absent, in some degree, in those who constrict the abdomen by their dress, stand long or engage in heavy work. Frequently in such cases the chief cause of distress is marked downward displacement of the kidney. Patients of a nervous temperament are most easily affected. Of all the symptoms those which I have found most constant are weakness and dragging

tracts the abdominal muscles this part of the wall bulges forward. Frequently, palpation between the recti causes a feeling of soreness which the patient states to be similar to that which she feels while walking or working.

In the most extreme cases in which the recti muscles are pushed far out, palpation of the lumbar regions may lead the physician to think that he is feeling a prolapsed kidney or some other swelling. In my clinic this error is frequently made by students. The mass which is felt is mainly made up of an abnormally-placed rectus muscle.

In extreme cases associated with great descent of the intestines the lower portion of the abdomen bulges markedly when the patient sits or stands.

Treatment.—In every case the patient should be advised to give up the corset and suspend the skirts from a loose waist or from the shoulders. This procedure is sufficient to relieve all symptoms in many cases in which the trouble is not very marked, even though there be considerable displacement of the right kidney. When there has been atrophy of muscles constricted by the corset and tight skirt bands, a course of massage to improve the affected parts should be recommended. This may be profitably combined with mod-

Fig. 5.—Patient (Mrs. D.) with marked separation of the recti. The photograph represents the marked bulging between the recti as the head and chest are raised from the table, the abdominal muscles being thus made to contract.

in the abdomen and back, aggravated by long standing or exertion.

Diagnosis.—The diagnosis of diastasis of the recti is easy. The patient should be made to lie flat on her back and the abdomen palpated in the following manner: The physician places the finger tips of his right hand on the middle line of the abdomen near the navel. His left hand grasps the patient's hands and she is asked to raise her head and chest somewhat from the table, in order to contract the recti muscles. As the muscles shorten they tend to approach the middle line. In this way the physician gauges the extent of their separation, thus determining the degree to which the linea alba is stretched.

In many cases in which the condition is marked this procedure is not necessary. As the patient lies relaxed, the edge of the separated muscles may be easily palpated. The vertebrae may be felt with great ease, especially in thin women, and pulsation of the aorta is often visible.

Often a distinct groove may be noticed along the middle line of the abdomen, and when the patient con-

Fig. 6.—Patient (Mrs. D.) with marked separation of the recti. The photograph is taken as the upper part of the body is being raised from the table. The physician's fist is buried in the gap between the muscles, which are contracting. In this case there was pronounced pendulous belly. As the patient lay relaxed on her back, the distance between the muscles at the level of the umbilicus measured $5\frac{1}{2}$ inches.

erate gymnastic exercises calculated to bring these muscles into action.

In marked cases the above treatment may often give some degree of relief as long as the woman avoids every form of exertion tending to increase the intra-abdominal pressure. But as it is impossible to be assured of this avoidance in the majority of women, it is best to have recourse to other measures.

First, the patient may, in addition to the adjustment of her clothing as above described, wear continually a broad silk-elastic abdominal binder. Such a mechanical substitute for the normal abdominal wall, by supporting the viscera, often gives great relief.

This method of treatment is open to the following objections: The binder must be worn continually, resulting inevitably in atrophy and weakening of many of the trunk muscles. It is often unpleasant to the wearer, especially in hot weather. It has to be renewed at intervals of a few months, a serious consideration for a poor woman. It is least effective and most

quickly gets worn when the patient engages in daily work.

For these reasons I have introduced the following surgical procedure as a means of restoring the abdominal wall to a more satisfactory condition.

An incision is made in the middle line of the abdomen, dividing the skin and subcutaneous fat until the linea alba is reached. Its length varies according to the extent of the separation of the recti. In very bad cases it may extend from the symphysis nearly to the ensiform cartilage. The umbilicus should be entirely removed if it be deep and difficult to clean thoroughly. Otherwise the mesial incision may be carried on one side of it. When the linea alba is exposed the skin and fat should be dissected off the fascia on both sides of the middle line, until the edge of each rectus is reached. The sheath of each muscle should then be entered at its inner border, near the lower angle of the wound, and this incision should be carried along the edge of the muscle as far as is necessary, the anterior layer of the sheath being divided where it becomes the stretched linea alba. The muscles are then loosened from their internal attachments to the sheath. A series of sutures are then passed from side to side through each muscle and its corresponding anterior sheath-layer. When these are tied the muscles lie in

Fig. 7.—Abdomen of patient (Mrs. D.) after operative repair. The wall is considerably reduced in size and the bulging much less prominent.

apposition close to the middle line covered by the fascia. As suture material, I have always used strong linen prepared by a modification of Gubaroff's method. It is left permanently buried. Careful apposition of the fascial edges may be made by catgut. The edges of the incision through the skin and superficial fascia and fat are then closed.

This is often followed by a bulging of the skin along the line of the incision in cases in which separation of the recti has been very marked, and is an evidence of the reduction in size of the abdominal wall due to approximation of the muscles. Owing to retraction in the tissues the bulging of the skin afterward disappears. In marked cases I have removed a strip of skin and fat from each edge of the wound before closure, in order to diminish the bulging.

This operation was first performed by me in November, 1898, in the Royal Victoria Hospital, Montreal. Since that date I have performed it in 51 cases. The results have been most satisfactory. In only two instances was there any trouble with the stitches from infection. These were slight, only a small extent of the healed area being affected.

In nearly every case there was more or less downward displacement of the kidney. In less than 8 per cent. of these, where the organ descended very low I performed nephrorrhaphy. In 55 per cent. of the cases retroversion or prolapse of the uterus was present and was treated by operative measures.

The operation has always been followed by improvement; in most cases by complete cure. Some patients who had been much run down and neurasthenic generally recovered health very slowly.

In several women in whom the right kidney was considerably dislocated, nephrorrhaphy was not carried out, in order that the repair of the abdominal wall might be tested as to its value in supporting the viscera. I asked all of these to write to me if symptoms developed which might possibly be connected with the kidney. Only one has communicated with me, complaining of some dragging in the back, and she has desired to have the right kidney fixed by operation.

I urge all who undergo this operation to abandon corsets and support their skirts from shoulders. Particularly are they enjoined to avoid all severe or sudden exertion for at least six months. During the early weeks of convalescence daily massage of the abdominal parietes is advisable. Afterward, light gymnastic exercises, calculated to improve the abdominal muscles, may be carried out.

In cases where the enteroptosis has been marked, the patient should wear a broad silk-elastic binder for six or eight months after operation.

Cocainization of the Nerve Trunk as a Means of Surgical Anesthesia.—Instead of anesthetizing the entire lower part of the body as in medullary narcosis, Jaboulay proposes to cocainize merely the nerve trunk innervating the region to be operated on. The *Semaine Méd.* of November 14 states that he has successfully applied this method in a scapulo-humeral disarticulation in which septicoemia prevented the employment of general anesthesia. After local anesthesia of the soft parts an incision was made for the ligature of the subclavian artery. The nerve plexus and the artery were denuded at the same time and after the ligature had been applied, a few drops of a 2.5 per cent. solution of cocain were injected into the two principal branches of the brachial plexus. As soon as the upper portion of the arm had become insensible, the disarticulation of the shoulder was accomplished without pain. The patient merely experienced a shock when the inner portion of the flap was cut in the domain of the intercostal nerves. Anesthesia of the upper members is particularly favorable by this method, but Jaboulay thinks it is equally applicable to the lower members and to other regions, such as the territory of the trigeminaus for example.

Physical Signs of Pleuritic Effusions.—The *Semaine Méd.* of October 10, mentions among the other signs of effusion described by A. Pitres in his recent works, the increased frequency of the respiratory movements, which is, however, by no means proportional to the amount of the effusion. The type of the breathing was superior costal in 42 per cent. of his cases and mixed in 51 per cent. The normal type was only observed when the effusion was less than a liter in amount. Dulness over Traube's space is occasionally observed in healthy persons who have never had pleurisy, and consequently is not a sign of the affection. The wooden sound produced by percussion of a sound lung is very faint if there are nodules. The sound is brassy in case of a gaseous effusion, but clear and silvery directly over a fluid effusion in the pleural cavity, unless it is masked by a tumor or old adhesions. He always attaches a manometer to his aspirating apparatus and stops when the negative pressure reaches 20 m. of the mercury column. The amount of fluid withdrawn is of less importance than the difference in the intrapleural pressure from removal of the fluid.

SHALL THE CONCEPTION OF INFLAMMATION BE
ABANDONED?

Andrew H. Smith discusses the question whether it is advantageous to recognize the existence of inflammation as an intermediate process. Would it not be gainful, he asks, if a more direct interaction between the morbid agent and the reparatory effort was admitted. He points out that the conception of inflammation as an intermediate process is incorrect and in reality confusing. "If we inject sterilized oil of turpentin into the cellular tissues the place becomes red, hot, swollen and painful, not because it is the seat of "inflammation," but because it is the seat of so and so many drops of oleum terebinthinae." It is claimed that in the textbooks inflammation may be defined correctly enough, but it is treated as systematically and exhaustively as many real pathologic and nosologic entities, the etiology, symptoms, progress and treatment being duly set forth. It is contended that as long as inflammation is conceived as the disease or "as the dominant process in disease" it may tend to obscure the exact relationship between the cause and the effect. An exhaustive, unprejudiced study of the various forms of noxæ on the one hand and the reactive and the reparative changes in all the various tissues on the other hand, would leave no room for "inflammation," because the phenomena currently designated as inflammatory would have received proper consideration in connection with each morbid agent. Smith consequently proposes that the entire doctrine of "inflammation," as well as the designation "itis" should be abandoned.

We are confronted at once with the question of nomenclature. With *tuberculosis* as a precedent, the action of other organisms, according to Smith, may be expressed by such terms as *streptocosis*, *staphylocosis*, *gonocosis*, etc. An undetermined infection would be *microbosis* or *bacteriosis*. In the same way *pericardiosis* would signify infection of the pericardium, *pericardial pneumocosis*, pneumococcus infection, etc. For other inflammations not necessarily infective the words *traumosis* and *toxosis* are suggested; *fibrosis* and *cirrrosis* are terms already in use for the designation of chronic tissue changes often classed as of inflammatory nature. Should this new nomenclature gain general acceptance, we would have good reason to expect some interesting developments in the coinage of new terms by the dermatologists, who so far seem to be the most fertile nomenclators. All

efforts toward greater exactness in medical science are deserving of encouragement. Whether the substitution of certain names for terms now in use, as *pericardial pneumocosis* for *pneumococcus pericarditis*, would materially advance matters may be questioned, however. But that great advantage is derived from an exact nomenclature, in which the etiologic factors are given as prominent a place as possible, can not be disputed. This is quite feasible with the help of the old terminology. The fact remains that the reactions to injuries of various kinds and the process of repair have so many and such essential characteristics in common that in the present state of our knowledge it is of great importance to be able to study these phenomena from a general standpoint, as is now done under the heading of inflammation.

That the use of the word "inflammation" and of the ending "itis" should be allowed to obscure the etiologic relationship and to lead to the establishment of faulty therapeutic principles, depends on an imperfect and erroneous conception of the true nature of the inflammatory changes. To ignore the causes underlying such important manifestations as the various inflammatory processes and diseases would be a step backward indeed. At the same time, as successful treatment must be directed against the various bacterial and other causes of inflammations, it is to be borne in mind that at certain times and places inflammatory changes are so poorly controlled as to require immediate intervention by the physician, regardless of the cause at work, as, for instance, in occlusion of the entrance to the larynx from exudation into the surrounding tissues, in the excessive accumulations of fluids in the pleural and other cavities, etc. Inflammation is not always our friend, as suggested by Smith, but may become directly dangerous. Hence the necessity for occasionally "treating inflammation" as such, so as to gain time for attacking the fundamental cause at work.

BACTERICIDAL ACTION AND OSMOTIC DISTURBANCES.

Alfred Fischer,¹ professor of botany in Leipzig, has studied the action of different kinds of serums and other fluids on the bacterial cell, in order to throw more light on the nature of the bactericidal effects of serums. Heretofore the theory of the bactericidal action of serums almost universally adopted is Buchner's alexin theory, which explains the bacterial destruction as caused by digestive ferments. In fact, alexin—or protective body—is held to be a proteolytic enzyme.

Baumgarten and his pupils, however, have rather persistently opposed Buchner's theory, claiming that much of the bactericidal action is due simply to disturbances of nutrition, and of osmosis in the bacterial cells placed in serums of varying composition outside of the body. Alfred Fischer also shows that the sensitiveness of bacterial cells to osmotic disturbances induced by sudden changes in the concentration of the

1. Zeltschr. f. Hyg. u. Infektionskr., 1900, xxxv, 1-55.

fluids has not been taken into proper account in the studies of bactericidal agents. He shows that the well-known Pfeiffer phenomenon—disintegration and transformation into balls of comma bacilli when introduced into the peritoneal cavity of immune animals—is the result of osmotic disturbances, the increased pressure within the bacterial cell forcing the protoplasm out in the form of small balls. This phenomenon Fischer calls *plasmoptysis*, in contradistinction to *plasmolysis*, in which the protoplasm is separated from the cell membrane and broken up into small masses. Plasmoptysis occurs in the case of many bacteria when placed in various serums; it also occurs on transferring bacteria to salt solutions of greater concentration than the ordinary media, and from salt solutions to water, bouillon and other fluids of less concentration. The presence of nutritive substances in some of the solutions used was found to delay the deleterious effect of osmotic disturbances. In plasmoptysis the wall of the bacterial cell bursts and the contents are forced out; in flagellated bacteria this occurs at the points of departure of the flagella, because of the weakness of the wall at those places. Death undoubtedly occurs after plasmoptysis, especially if the fluids are poor in nutritive substances. Most serums are of poor nutritive quality and of greater concentration than the ordinary bouillon, hence osmotic disturbances have not been excluded in the earlier studies of so-called bactericidal serums. Without entering into further details, suffice it to say that new evidence is necessary to establish the truth of the alexin theory, and in the experiments undertaken for that purpose osmotic disturbances of all kinds must be excluded rigidly. If bacteria are destroyed by digestive ferments in serums, evidences of digestive transformation ought to be demonstrable chemically; so far this has not been done.

While Baumgarten and his students would explain the bactericidal action of serums outside of the body as the result of osmotic and nutritive disturbances, Meltzer² suggests that similar disturbances may take place in bacteria that have gained entrance into the body, which is thus protected from the dangers of the infection. Perhaps some of the diplococoid and other forms of the colon bacilli described by Adami and his pupils are explainable on the score of osmotic changes.

THE INDISCRIMINATE USE OF ALCOHOL

There has been much warm discussion and comparatively little demonstration bearing on the question whether alcohol is a food or a poison, and we are inclined to the intermediate view taken by Dr. H. S. Anders in THE JOURNAL a short time ago, that it may be either or neither in accordance with the purposes for which it is used, the dosage and the frequency with which it is administered and the susceptibility of the particular individual. In these respects alcohol agrees with numer-

ous other substances of the materia medica, which are equally capable of good and of evil according to varying circumstances.

It must be admitted that the question of custom is not without influence in this connection. Thus the use of opium in India, of arsenic in Styria, of alcohol, tobacco, tea and coffee throughout the civilized world, has apparently stamped these with a certain food-value, however limited, but it surely will not be contended that any of them is necessary to life or health, except of course, as they may be needed for therapeutic purposes. Now, in so far as these substances are incapable of harm the physician and the hygienist may be somewhat indifferent to their indiscriminate employment, except that here again moderation must be counseled, as in all other things, for extremes in practices, of themselves healthful, are likely to be injurious. Therefore, with regard to the use of alcohol the evidence should be weighed judiciously and a decision reached in accordance with the conclusion whether the greatest good is to be secured by sanctioning and indulging in its unrestrained, or even its limited, use, or by forbidding altogether its employment except for therapeutic purposes.

A most interesting contribution to this subject is made by the distinguished alienist, Professor Forel,¹ who relates that, having been brought up in the midst of a country of vineyards, he became accustomed from childhood to the daily use of wine. In adolescence he suffered from disorders of digestion, especially cardialgia and headache; but it was not until he became director of the Burghölzli Hospital for the Insane, and professor of psychiatry at Zurich, that he realized the necessity for total abstinence personally and the application of the same principle to the patients under his care, so many of whom owed their illness and their tendency to relapse to alcoholic intoxication. The results that followed this departure amply confirmed the wisdom of its institution, permanent cure being effected in a considerable proportion of cases in which previously relapse had been the rule.

Forel goes on to point out that in all countries where the alcohol-habit prevails it accounts for from one-half to three-quarters of the crimes, a large proportion of the suicides, of cases of mental disorder, of deaths, of diseases generally, of poverty, of vulgar depravity, of sexual excesses and venereal diseases, and of dissolution of families. One of the worst features however is the hereditary one, a larger proportion of the children of alcoholics being idiotic, epileptic, neurotic, alcoholic, degenerate and deformed than the children of healthy parentage. These results, it may be contended, are due to the excessive or long-continued indulgence in alcohol, but this is a question of individual tolerance and susceptibility, and it is scarcely possible to fix on any definite demarcation between moderation and excess.

2. Trans. Cong. Am. Phys. and Surg., 1900, v. 12 25.

1. American Journal of Insanity, lvi. No. 2, p. 297.

The only safeguard, therefore, would appear to reside in total abstinence, and Forel contends that the physician who is not a total abstainer can not enforce such abstinence on the part of his patients.

IRRITABLE BREAST.

The breast is a compound tubular gland whose function is only periodically called into activity. A few drops of milk, however, may occasionally be found present at birth and at puberty, and it is said that the application of a child to the breast quite independently of pregnancy may excite the secretion of milk. Accumulation of milk in an acinus whose secretory duct has become occluded or otherwise obstructed, gives rise to a cyst, or galactoecele. The breast is further peculiarly susceptible to disease as a result of infection during the period of nursing, and is frequently the seat of hyperplasias or new-growths, benign and malignant. Hypertrophy of the mammary glands is a physiologic manifestation of pregnancy, continuing throughout the period of lactation. Adenoma, fibroma and carcinoma are common forms of new-growths in the breast.

In a communication presented at a recent meeting of the Boston Society for Medical Improvement, Dr. R. C. Cabot¹ reported a condition in two spare, pale, neurotic, unmarried young women, attended with the presence of a tender and painful lump in the upper outer quadrant of one breast. In one case the lump was about the size of a large horse-chestnut, and in the other a little larger. In both it was flattened from before backward, and it was felt with greater difficulty when the breast was pressed against the thorax than when it was grasped in the fingers from side to side. In one case the axillary glands were not affected, while in the other they were slightly enlarged and somewhat tender. There was no retraction of the nipple and the tumor was freely movable beneath the skin, and not accurately circumscribed. In each case the tumor diminished in size, while another appeared in the opposite breast. Marked improvement followed general treatment.

The condition agrees with the descriptions of irritable breast, but its nature and pathology are obscure. It has been thought to be of inflammatory origin, but Cabot suggests the possibility of its being a galactoecele. The question of prognosis is rendered somewhat uncertain by the fact that some observers believe that carcinomatous transformation may take place. If this belief is well founded surgical removal would be justified; but, on the other hand, the tumors have often been reported to disappear in the sequence of local applications and improvement in the general condition. In the discussion it was pointed out that the disorder is observed especially at two periods of life, namely, that of adolescence and that of the menopause. It appears, likewise, to be related in some way with disease of the

uterus and its appendages, or with menstrual irregularities; and relief can sometimes be afforded by abstraction from the uterus of two or three ounces of blood, repeated several times at intervals of a month. Good results have been attributed in some instances to the application of galvanism—from 15 to 20 milliamperes for ten or fifteen minutes twice a week. In some cases that have been operated on a diffuse fibroid condition of a portion of the breast has been found, with secondary retention-cysts. When the breasts are large and pendulous, support and slight pressure have yielded beneficial results. Massage also may prove serviceable.

"A COMPLICATION OF DOCTORS."

"Death from bowel trouble and a complication of doctors," was the verdict of a coroner's jury in a recent case in Aurora, Ill. It appears that six physicians were called in at different times, and several more were sent for, but failed to come, most of them without any knowledge of the services of the others. The patient's condition was apparently not considered dangerous until toward the last, and it is quite possible that it suddenly took a serious turn. There was probably no glaring error in diagnosis on the part of any one of those who were called and who, it may be reasonably presumed, did only what might safely be done for such a case as apparently existed. The verdict therefore is a rather gratuitous insult to the medical profession, and was probably intended as such. It, however, points a moral, which is generally applicable, namely, the necessity of full inquiry into the most trivial case, and the possibility that such a case may, however slight its apparent importance, take a more serious aspect. Another moral illustrated by this case is the danger of calling one physician after another in the way here practiced. It does not appear, however, that this point was appreciated by the jury or intended to be noticed by them in their peculiar verdict.

PARASITIC HEMOPTYSIS.

In the latest Public Health Report of the Marine-Hospital Service, based on the report of Stiles and Hassall,¹ attention is called to an Asiatic parasite that appears to have found a lodgment in this country, the *Paragonimus Westermanii*, a lung fluke that produces the disease known as parasitic hemoptysis in Korea and Japan. It was first found in a cat and dog in 1894 and 1895, but recently the government inspectors have met with it repeatedly in hogs at the Cincinnati packing-houses. It is thought probable that with the increasing intercourse with the Orient, sporadic cases in man will sooner or later be encountered. The human infection is described by Manson in his recent work on "Tropical Diseases," where the parasite is called *Distomum Ringeri*. The symptoms are cough and hemorrhage from the lungs, and in cases where the parasite attacks the brain, localized or Jacksonian epilepsy. The sources of infection to man are not very well known, but are probably through some invertebrate, and are conveyed

1. Boston Medical and Surgical Journal, Nov. 29, 1900, p. 555. See Abstract Dec. 15, p. 1583.

1. See also abstract of paper read by Dr. C. W. Stiles before the Philadelphia Pathological Society, Nov. 22, p. 1647.

through drinking water, hence the importance of attention to this point. Infected animals and human sputa or hemorrhages are dangerous because of their disseminating the ova, and with them the range of disease, but the meat of infected animals is not dangerous *per se*. It is well that the medical profession should receive this timely warning and cases of hemoptysis or localized convulsions in ex-residents of the Orient, whether native or foreign, will bear inspection. As to the need of abattoir inspection there should be no need of amplification.

TEMPERANCE IN FRANCE.

The reported passage of a resolution by the French house of Deputies against the manufacture and sale of alcoholic liquors pronounced hurtful by the Academy of Medicine, and especially of absinthe, in France, is an evidence of the interest aroused in the alleged causes of national degeneracy in that country. According to all reports, France is suffering in several ways, and her experience should serve as a warning to other countries where the same evils exist to a greater or less extent. Absinthe is an extreme evil, but there seems to be a general awakening in several continental states in regard to the evils of drinking, not only of absinthe, but also of other forms of alcoholic beverages. The temperance workers should derive some encouragement from even a partial prohibition measure in France, which has only recently come to realize its dangers from this and other causes.

PROFESSIONAL SECRECY AND CRIMINALS.

According to a newspaper report, a Chicago physician is supposed to know the whereabouts of the principal in a recent murder case and refuses to give any information on the ground that he is bound to protect his patient by the ethics of his profession. In commenting on this supposed fact, the newspaper assumes that the medical profession has set up such a rule as would require physicians to conceal criminals, and says: "Too often fugitives from justice are aided in their attempts to escape by doctors who are over-zealous in their observation of so-called professional ethics. It is time for the medical profession to define clearly where it stands on this important matter." There is a serious misapprehension of facts in the above quotation. Medical secrecy does not demand anything of the physician that would make him an accessory after the fact in a criminal case. Physicians are not justified in doing anything to balk justice or to mislead authorities. They are not, however, detectives or policemen, and it is not to be expected that they should desire to usurp their functions. The physician in question has no excuse in medical ethics if he did anything actively to mislead the authorities, such as concealing the times of his visits, or acting in any way differently from what he would in an ordinary case, one in which there was no suspicion. Criminals have no special privilege as regards medical secrecy, and there is no reason why a physician should plead medical ethics as an excuse for concealing their location, certainly not if it required him to dissemble or mask his own actions. For alleged reasons of public policy, laws have been passed in some states making

professional communications to physicians privileged, but there has been no such legislation in Illinois, and a physician secretly treating known criminals who are wanted by the police might easily be subjected to serious inconvenience and possibly to penalties. The situation is not a satisfactory one and the wisest plan might perhaps be to treat all suspicious patients as emergency cases; apply first aid needed and then refer to a hospital.

A HOSPITAL STRIKE.

A recently reported occurrence in a Chicago hospital is of interest as possibly pointing a moral. According to the newspaper account, a nurse in a private hospital was detailed to attend a certain patient. It developed, however, that the case was one of scarlet fever, and she refused to obey and was consequently promptly discharged. As contagious diseases were not usually received in the hospital the other nurses held that their associate had been wronged, and they went on a strike. What the final outcome to the affair was, has not, to our knowledge, been published, but assuming the facts to be as stated, the occurrence illustrates certain possibilities that are not altogether satisfactory to contemplate. A strike of nurses in a hospital is a disagreeable matter and might easily be a very serious one, involving possibly the comfort, the welfare and, it might be, even the lives of helpless patients entrusted to their care. A sympathetic strike, however altruistic the course may seem to its partakers, is even more an evidence of an inconsiderate and one-sided view of their duties and their relations. When so much is said, as is at present, about the high professional ideals that exist among hospital trained nurses and their efforts to realize them, the report of such a performance as the one here noticed is an unpleasant disappointment, indicating as it does that the alleged ideals and professional feelings are not always effective on conduct, if existent. If nurses wish to be considered as anything more than ordinary mercenaries in the battle against disease and for human welfare, such occurrences will have to be extremely infrequent, and that a single instance has occurred is a disaster to their prestige as a class.

THE CROTTE CURE AGAIN.

At the Columbus meeting of the AMERICAN MEDICAL ASSOCIATION desperate efforts were made by a representative of a Frenchman, named Crottié, to have the ASSOCIATION endorse his electrical method of treating consumption, for which he claimed great virtues. In spite of the fact that he failed to get recognition in any of the devious ways attempted, he caused to be sent out through the press dispatches the announcement that the ASSOCIATION had not only endorsed his treatment, but that the members had tendered him a banquet in token of the great work he had done for suffering humanity. Through efforts made by THE JOURNAL, the same publicity was given to a general denial that had been given to the false announcements. Later, we find these people working in another way to get medical endorsement of the method. Asserting that medical men would not give the method a fair trial, and claiming that by it the results were "100 per cent. of cures in the incipi-

ient stages, 75 per cent. in the secondary stages, and 50 per cent. in the cases that would under regular treatment be considered hopeless." The St. Luke's Hospital, of New York, consented to experiment with the method. From the *Medical News*, of December 15, we learn with what result. In spite of the careful tests detailed, which we copy from the *Medical News*, the unbiased scientific opinion of all who observed them was that there is nothing in the treatment, and this opinion is most positively conveyed in a circular sent out by the hospital in answer to all inquiries.

The treatment was given regularly and systematically. Not only were the bacteriological examinations and blood-counts made at the Hospital, but the sputum was sent to the New York City Board of Health, where experiments were made upon guinea-pigs with the supposedly attenuated virus to see whether there was any actual lessening of virulence of the tubercle bacillus. These experiments were carried on carefully, exactly and hopefully for three months with *absolutely negative results*. None of the changes that were claimed would take place eventuated, from the bacteriological standpoint. The effect of placing the patient in front of the static machine was as ineffectual as placing him before a mirror. None of the patients of the experiment improved any more than did others of like degree of infection on the same good food, regular hours and rest.

In spite of the unfavorable verdict, the experiments at St. Luke's are, it is said, being quoted by the promoters of the scheme as evidence that the treatment has been adopted and endorsed by the authorities of this reputable institution. Reference has been made to them in medical meetings and medical literature, and always with the assumption that the test experiments were successful. It is a case of touching pitch and being defiled; denials are useless, the quack's point has been gained. It may be necessary or useful sometimes to test these exploited "cures" in hospitals; we do not say it was not so in the present case, but it has its disadvantages. Hereafter the Cotté treatment can be safely let alone, unless it should become necessary by legal proceedings to stop the misrepresentations of its promoters.

THE MEDICINAL TREATMENT OF PULMONARY TUBERCULOSIS.

As we mentioned in our editorial columns,¹ the newspapers recently discovered a new specific for pulmonary tuberculosis, but, unfortunately, reportorial judgment in this instance was in error, while if the published doses had been administered the mortality would have been not inconsiderably increased. The fact is that the recommendation made in a medical journal of a line of treatment that had proved successful in the hands of competent observers was jumped at by the enterprising, but not equally discriminating, reporter as the exploitation of a specific. Dr. Adolf Hoff,² one of the assistants at the clinic of Professor Stoffella, of Vienna, described the plan of treatment pursued with outpatients suffering from pulmonary tuberculosis. The fundamental formula is as follows:

R. Arsenous acid	1
Purified potassium carbonate	2
Cinnamic acid	3
Distilled water	5

Boil and make a perfect solution. Then add:

Cognac	2 5
Aqueous extract of opium	3
Distilled water	2 5

Make a solution and filter. Dose: 6 drops after the midday and the evening meal, gradually increased to 22 drops.

In addition hydrotherapeutic measures are employed. These consist in applications to the chest and the back of cold water, with friction at night before retiring, followed after the skin has been well dried by the donning of an armless jacket well wrung out in cold water, and covered by a shirt. The jacket is worn throughout the night, being removed, however, in the morning before the patient gets out of bed. The chest and the back are then thoroughly dried and the cold wet rubbing is repeated, after which the patient gets up and dresses. In a small number of instances the persistence of the fever requires the employment further of the following formula:

R. Cinnamon-water	70
Tincture of chinoidin	2 5
Quinin sulphate	155
Aromatic sulphuric acid	165
Simp of cinnamon	20

Mix. Dose: 1 tablespoonful thrice daily.

When the cough is especially troublesome and unyielding, iodonin may be prescribed in the following combination:

R. Iodonin	2-35
Purified ammonium chlorid	3-5
Sodium chlorid	10

Mix and divide into 10 equal parts. Dose: as many as four a day.

Medical News.

CALIFORNIA.

DR FRANK T. FITZGIBBON was appointed city vaccinator of San Francisco, November 30, to succeed Dr. W. G. Hay, deceased.

YAB CHOW, the San Diego Chinaman, arrested for practicing medicine without a license, has forfeited his bail and left for the North.

DR. HENRY A. L. RYKFOGEL has resigned as city bacteriologist of Oakland and Dr. Charles W. Rowe has been chosen as his successor.

THE ASSOCIATED PHYSICIANS' HOSPITAL SOCIETY has been incorporated at Bakersfield by Drs. J. L. Catson, Thaddeus W. Hehn, Thomas E. Taggart, and others, with a capital stock of \$10,000.

THE SAN FRANCISCO Board of Health has petitioned the board of supervisors to appropriate funds for the purchase of an X-ray apparatus for the City and County Hospital, and for the installation of electric lights in the operating rooms in that institution and in the Central Receiving Hospital.

COLORADO.

ST. LUKE'S HOSPITAL, Denver, by decree of its board of directors, will allow no member on its medical staff who is connected with any other hospital.

ON ACCOUNT of the typhoid fever epidemic at Fort Collins, where more than 200 cases are now reported, the local board of health has employed Dr. William C. Mitchell, Denver, bacteriologist of the State Board of Health, to investigate into and report on the cause of the outbreak.

THE NEW HOSPITAL of the Denver and Rio Grande Railway at Salida is nearly completed, at a total cost of about \$45,000. The employees of the road who support the hospital are making strenuous efforts to have its management left with them rather than with the railway company, as heretofore.

DR. THOMAS J. CARLIN, Health Commissioner of Denver, has applied to the city council for an appropriation for the proper medical inspection of schools. He has also drawn up a set of rules regarding the use of disinfected cuspidors, which will be given to proprietors of stores, and compliance with which will be enforced.

2. Wiener Med. Wochenschrift, Nos. 47 and 48, 1900.

CONNECTICUT.

DR. EDWARD P. WOODWARD, the oldest practicing physician in Bristol, Conn., had a paralytic attack, November 27, but is improving.

DR. EDWARD T. BRADSTREET, Meriden, has been appointed medical examiner to the coroner of New Haven county, succeeding Dr. G. H. Wilson, who resigned after 18 years' tenure of office.

DR. THOMAS D. CROTHERS, Hartford, has been appointed professor of diseases of the brain and nervous system, with especial reference to the effects of alcoholic and drug poisons, at the New York School of Clinical Medicine.

ILLINOIS.

DR. S. M. WYLLIE, Paxton, left for a trip to Costa Rica, December 18.

DR. WILBUR P. ARMSTRONG, Springfield, who has been critically ill for several days, is now said to be improving.

THE NEW INFIRMARY at the Illinois Northern Hospital for the Insane, Elgin, constructed at a cost of about \$38,000, was opened December 4. The building will accommodate 110 patients.

THE MARIETTA PHELPS HOSPITAL at Macomb is now completed. It contains 14 rooms, besides the necessary operating-room, bath-rooms, etc., and is thoroughly fitted and equipped for its work.

THE COMMITTEE of the city council of Moline appointed to investigate the City Hospital scandal, has reported that the physician and director of the hospital charged with using violent and profane language in the operating-room, and with adding croton oil to a bottle of port wine to detect theft of the latter, should be severely criticized for his conduct and should resign.

DR. MORRIS MEYEROVITZ, chairman of the committee on lodging-houses and sanitation of the State Board of Health, will recommend the following regulations for lodging-houses: 1. Mattresses must be made of washable rubber. 2. Houses must be fumigated at least once a week. 3. Better toilet arrangements must be provided. 4. Each lodging-house shall have a temporary isolation room, for use in case of an outbreak of communicable disease, and before the local health board is able to act.

Chicago.

DR. ALBERT B. HALE has recovered from his recent illness, returned to Chicago, and resumed practice.

DR. BAYARD HOLMES, who has been seriously ill with wound-infection and erysipelas, has recovered and is regaining strength rapidly.

DR. CHARLES M. CLARK, surgeon of the Thirty-ninth Illinois Volunteer Infantry during the Civil War, is lying seriously ill at his home, 1030 W. Twelfth St.

NO INFLUENZA deaths have been reported since December 7, although the influenza bacillus is found frequently in the laboratory examinations. Diphtheria is also much less severe than usual.

SUIT HAS BEEN BROUGHT against the Commissioner of Health and others by a woman, who claims \$50,000 damages for being confined in the isolation hospital, where she contracted smallpox, and thereby destroyed her beauty.

DURING the thirty days from November 7 to December 7, 129 calls were made from various schools, for medical inspectors. In 86 instances children were excluded; 54 exclusions being on account of diphtheria, and 8 school-rooms were disinfected.

A TOTAL of 444 deaths was reported for the week ended December 15, being an annual death-rate of 13.59 per 1000. Of these 238 were males; 205, females; 90 under 1 year and 84 over 60 years. Consumption caused 43 deaths, pneumonia 75 and violence 24.

THE PRESIDENT of the "diploma-mill," whose latest name was Metropolitan Medical College, was sentenced on December 15 to serve one year in the Du Page county jail and to pay a fine of \$500. Sentence on the other two defendants was deferred until the next term of court.

SMALLPOX is causing great concern. At present the few cases are imported. This fortunate condition of affairs can not be expected to continue, as the disease is epidemic in other parts of the country. The warning given by the Health Department is: "Do not neglect vaccination."

INDIANA.

A DOCTORS' BUILDING seven stories in height, is under construction opposite the Denison House, Indianapolis.

AN ITINERANT osteopath, clairvoyant and magnetic healer, was fined \$25 and costs at Delphi, December 1, for practicing medicine without a license.

DR. LYMAN E. OTT, Franklin, has resigned as a member of the board of pension-examining surgeons, and has been succeeded by Dr. John W. Dixon.

THE MEDICAL COLLEGE OF INDIANA is about to erect a large addition to its present college building. The addition will be four stories high, and will be used for laboratory work.

DR. RALPH DRAYER, city bacteriologist of Fort Wayne, has resigned because the president of the city board of health had failed to report or to enforce quarantine regulations in a case diagnosed by Dr. Drayer as diphtheria.

IOWA.

SIoux CITY has enacted an ordinance that all members of any family in which diphtheria develops, shall be inoculated with antitoxin.

THE CENSUS of the insane of the state shows that 2901 are under restraint in the three state asylums, 987 in the 52 county institutions, and 453 in the 4 private hospitals, making a total of 4341.

DR. WILLIAM D. MIDDLETON, Davenport, dean of the medical department of the Iowa State University, has been honored by the medical students of the university, who have named their new scientific society the "Middletonian."

THE BOARD OF HEALTH of Sioux City has two unpleasant facts to face: 1, that the appropriation for the year is exhausted four months before its close, and 2, that smallpox is prevalent in the town and country around Sioux City.

DR. WILLIAM T. WRIGHT, Denison, had a runaway accident, November 20, while making a night call. His team became frightened, and he jumped out, but his foot caught in the lines and he was dragged for nearly half a mile. He was badly bruised, and nearly frozen, but it is thought that he will recover.

MARYLAND.

DR. CORNELIUS DEWESE, for four years pathologist at the Maryland Hospital for the Insane, Spring Grove, has resigned to accept a similar position at the Government Hospital for the Insane, Washington, D. C.

DR. ABRAM CLAUDE celebrated his eighty-second birthday in Annapolis, December 4. Dr. Claude has been mayor of Annapolis a number of times and held the professorship of natural science in St. John's College from 1871 till 1883. He is a graduate of St. John's College and of the University of Maryland.

MARYLAND is the only state which does not have a pharmacy law. At a meeting of the Maryland Pharmaceutical Association, held December 12, in Baltimore, Dr. Alfred R. L. Dobne reported that he had canvassed the entire drug trade of the state in the interest of a bill to restrict the practice of pharmacy to competent persons.

Baltimore.

DR. WILLIAM OSLER has been elected president of the Laecme Society at Johns Hopkins Hospital.

THE PROCEEDS of the "Zoo" on December 20 and 21 will be given to the Maryland General Hospital. The lady visitors of the hospital will have charge of the entertainments on those days.

WITHIN SIX DAYS two physicians of the city, Drs. Marshall Smith, health warden of the Twentieth ward, and S. Griffith Davis, were attacked by diphtheria, but both are reported as doing well.

BIDS for the proposed National Temperance Hospital have been submitted and are under consideration. The building is to be erected on Baltimore street, near Carrollton avenue, and will cost about \$30,000.

PROF. JOHN J. ABELL, of Johns Hopkins Medical School, was seriously injured by an explosion of chemicals December 11, while experimenting in his laboratory with epi-nephrin, the active principle of the suprarenal capsule.

THERE have been performed at the Johns Hopkins Hospital 15 operations for perforation of the bowel in typhoid fever, the operators being Drs. Finney, Cushing and Mitchell. Of these, 6, or 40 per cent., recovered, an unusually large proportion.

THE DEAN of the University of Maryland, School of Medicine, reports 332 students in that school. Of this year's matriculants, all but three were able to furnish the evidences of scholarship required by the American Medical College Association. The total number of matriculants in the law, medical and dental departments is 790. There is also a flourishing nurses' training school.

DR. WILLIAM OSLER has had executed and placed in the hall of the Medical and Chirurgical Faculty a life-size bust crayon portrait of Dr. Charles Frederick Wiesenthal, the physician of Frederick the Great, who settled here in 1755, and who is re-

garded as the father of the medical profession of Baltimore. He established a medical school shortly after his arrival, and during the Revolutionary War was a surgeon in the Maryland line.

MICHIGAN.

DR. COLLINS H. JOHNSTON, Grand Rapids, who went to Custer to investigate the smallpox outbreak there, reports that in that town of not more than 300 inhabitants, there were about 100 cases of the disease, and that until a short time before, no steps had been taken to prevent or limit its spread.

THE SUPREME COURT has decided that members of state boards shall not receive more than the usual compensation for their services, whatever those services may have been. This decision will probably affect in a material degree the amounts to be paid to the members of the State Board of Health who have been investigating the smallpox epidemics, and who have heretofore been allowed \$25 a day for such services.

MINNESOTA.

ASBURY HOSPITAL, Minneapolis, which was under quarantine on account of smallpox for nearly a month, was re-opened December 6. The disease was confined to the original patient affected.

THE NEW city hospital at Owatonna was opened December 15.

THE WALKER SANATORIUM, which was re-opened only a short time ago, was burned December 8, fortunately without loss of life. The loss was \$7000, with an insurance of \$2000.

DR. HENRY M. BRACKEN, Minneapolis, has prepared an exhaustive review of all the cases of leprosy in the northwest. The number is 75, 61 of which are Minnesota cases, although only 17 patients are now living in Minnesota. He thinks that the establishment of a leprosarium in the state should be seriously considered.

NEBRASKA.

DR. ANDREW JOHNSON, Omaha, has been appointed superintendent of the Institution for Feeble-Minded at Beatrice.

DR. GEORGE H. BRASH, Beatrice, has been appointed a member of the State Board of Health in place of Dr. Benjamin F. Crummer, of Omaha, who has done most effective work as a member of the board.

NEW JERSEY.

DR. WINTHROP D. MITCHELL, who has been city physician of East Orange for six years, has resigned.

BECAUSE of the outbreak of diphtheria in the Elizabeth General Hospital the institution has been quarantined. The Blake Memorial Hospital for Women, which adjoins the General Hospital, has been ordered closed by the board of health. There have been 8 cases of diphtheria at the General Hospital, with 1 death.

THE FRIENDS of Dr. Samuel A. Helfer, Hoboken, who, at the time of the steamship fire in June last, was incessant in his labors in caring for the injured and recovering the bodies of the dead, have petitioned the German minister at Washington to bring the matter before the Emperor and to recommend that a medal of honor be awarded Dr. Helfer.

THE STATE BOARD OF HEALTH has instituted suit against the Trenton Abattoir Company, charging it with bringing diseased cattle into the state. It is further charged that cows found to have been suffering from tuberculosis were bought by this company and subsequently sent to Trenton, where the milk from the animals was sold. Health Inspector Bell demanded that the animals be killed at once. Two witnesses were present when the diseased animals were destroyed. A penalty of \$25 for each head of cattle may be imposed.

THE STATE BOARD OF HEALTH is considering the advisability of disinfecting the books used in circulating libraries of the state, and have decided that they must be fumigated at regular intervals. Experiments are being carried out which, it is hoped, will determine the best method of disinfecting books. It is said that this action was due to the fact that books have been sent out to a town in the country where scarlet fever was prevailing and were then transferred back to the library. At present there are forty-four distributing libraries over the state. The books are to be disinfected as they are returned.

NEW YORK.

DR. FREDERICK W. MANLEY has resigned as house-surgeon of St. Joseph's Hospital, Syracuse, and will practice at Rensselaer. He will be succeeded by Dr. Aloney I. Rust, whose place as house-physician will be taken by Dr. Thomas F. Foreman.

Buffalo.

DR. HAL B. BROWNELL has been appointed examiner in lunacy by Judge Emery.

THE COMMITTEE OF JUDGES appointed by the council of the Academy of Medicine to act on the Marcel Hartwig prize essay, announce that all papers presented by fellows of the Academy during the year will be eligible for the prize of \$50. Three copies of each paper, either printed or typewritten, must be sent to the committee, of which Dr. Grosvenor is chairman. All papers must be handed in before the next annual meeting to be held in June.

THE SPENCER LENS COMPANY, of which Dr. Roswell Park is president, is making an attempt to establish under American conditions a scientific institution similar in methods to that of Carl Zeiss, in Jena. To this end it has secured the services of Dr. (Phil) Hermann Kellner, for many years assistant to Professor Abbe, as scientific director, and of Carl F. Dieckmann, formerly of Göttingen, and more recently of Jena, as general superintendent.

ACCORDING to figures compiled in the department of health, scarlet fever has increased nearly 25 per cent. in the present month, and there is every indication that an epidemic may prevail here before the winter is over. All school principals are being notified of cases within their jurisdiction. The number of cases of diphtheria is also increasing and probably 90 cases will be reported before the end of this month. Typhoid fever is abating. In October there were 52 cases, in November 57, and in the first 11 days of December only 8 cases were reported.

New York City.

THE NEW government hospital, which has been erected at a cost of \$200,000, was accepted by the sinking fund commission December 11.

THE REPORT of the health department shows that there are now twice as many cases of typhoid fever in the city as there were at this time last year. This is explained by the long mild autumn.

THE COMMISSIONER OF CHARITIES has applied to the board of estimate and apportionment to condemn property on Lenox avenue, between 136th and 137th streets, that a new hospital may be built thereon to take the place of the old Harlem Hospital, which is unfit for habitation.

SMALLPOX continues to spread slowly, several new centers of infection having arisen as a result of a street-car conductor continuing at work after the eruption had appeared. So far there have been 54 cases taken to North Brother Island, of whom 8 have been discharged and 3 have died. Vaccination, both public and private, is proceeding rapidly.

ACCORDING to the annual report of the State Charities Aid Association, the most urgently needed additions to the department of public charities are: a new Harlem hospital, a separate hospital for cases of consumption, a convalescent hospital, a small municipal lodging house for women and children, and nurses' homes in conjunction with the hospitals on Randall's and Blackwell's Islands.

OHIO.

DR. ROBIN W. C. FRANCIS, Cincinnati, has been appointed demonstrator of physiology in the Medical College of Ohio.

THE 48 women in the state penitentiary at Columbus ask for nearly as much medicine as the 1800 men there confined, according to the prison physician, Dr. Thomas.

LAKEVIEW HOSPITAL, Cleveland, has received a gift from H. Melville Hanna of 1000 shares of Northern Pacific preferred stock, the present value of which is about \$82,000.

DR. LOUIS MALONEY, who has been serving as acting-assistant surgeon in Cuba and the Philippines for the past two years, has been invalidated on account of fever contracted in the tropics.

THE ANNUAL REPORT of the Cleveland State Hospital for the Insane shows that 1466 patients were treated during the year and that, on November 15, 1055 patients were under treatment. The percentage of recoveries was 31.75. The per capita cost of maintenance was \$142.54.

"DR." HULETT, Columbus, state secretary of the osteopaths, has advised those of his faith in the state, not to take the state examination, on the ground that the State Board of Medical Registration and Examination has no right to grant certificates, even if the examination is passed.

ON ACCOUNT of the prevalence of smallpox in that district of the state, the board of health of Jackson has ordained that all school children be vaccinated; that those unable to pay will be vaccinated free of charge; that all public balls and dances are prohibited until further orders, and that all cases of chicken-pox or other contagious diseases be reported at once to the board.

PENNSYLVANIA.

DR. JAMES B. MONAGHAN, Shenandoah, has been appointed physician to the Schuylkill County almshouse at Pottsville.

THE LAW authorizing school directors to assume certain functions of boards of health has been accepted by only 56 out of 2700 directors.

THERE have been 275 cases of smallpox with 8 deaths reported in the state during 1900, in 50 localities. Diphtheria has been partly suppressed in 38 places, and scarlet fever in 19.

DR. FRANCIS X. WEIL, health officer of York, reported 46 cases of diphtheria during November, three-fourths of which occurred in one ward of the city. The board of health has distributed antitoxin freely to the physicians of the city, has ordered a formalin lamp and has raised the salary of the health officer from \$30 to \$40 a month.

THE STATE BOARD OF MEDICAL EXAMINERS has published the statistics of candidates recently examined. The result is as follows: Of graduates of the University of Pennsylvania, 121 were examined and 2 failed; of Jefferson Medical College, 38 were examined and 4 failed; of the Medico-Chirurgical College, 20 were examined and 4 failed; of Western Pennsylvania Medical College, 67 were examined and 9 failed; of Woman's Medical College (Philadelphia), 16 were examined and none failed; of Baltimore Medical College, 12 were examined and 5 failed; of Maryland Medical College, 4 were examined and 3 failed; of the College of Physicians and Surgeons, Baltimore, 3 were examined and 2 failed; of graduates of other institutions and miscellaneous, 38 were examined and 8 failed. The total number examined was 327, of whom 41 failed.

Philadelphia.

A PROVISIONAL bequest of \$5000 has been made to the Presbyterian Hospital by Mrs. Helfenstein of this city.

DR. J. HENDRIE LLOYD, who has been for many years on the staff of the Philadelphia Hospital as neurologist has resigned.

AN INCREASE in the number of assistant medical inspectors and other employees of the board of health has been asked for, namely, two medical inspectors, at a salary of \$1200 a year; one assistant disinfecter, at \$900; one milk inspector, at \$1020; two collectors of milk specimens, at \$720, and three assistant inspectors of house drainage, at \$1200.

IN THE CASE of Dr. Gerald D. O'Farrell, Jr., who was prosecuted for not reporting a case of what was called diphtheria, the defendant stated that it was a mistake, and when he stated on the card returned to the school that it was "diphtheria" he was thinking of another case of this disease which he was treating at the time. The magistrate dismissed him with a warning.

IN ORDER to satisfy itself of the needs of the insane department of the Philadelphia Hospital (Blockley), members of finance committee of council paid a visit to that institution on December 10. Dr. John V. Shoemaker, president of the Board of Charities and Corrections, and Superintendent Geary escorted the visitors through the institution. An appropriation of \$50,000 has been asked for.

THE HEALTH of the city continues to be much better than for the corresponding periods of previous years. The total number of deaths for the week ended December 15 was 369, which is 76 less than for the corresponding period of last year and 112 less than for the same period of 1898. The principal causes of death were: Nephritis, 18; cancer, 15; tuberculosis, 47; heart disease, 27; pneumonia, 53; diphtheria, 16.

THE MEDICAL INSPECTORS of public schools have made their report from January 1 till October 31. It shows that 5876 cases were reported. Of these 3446 were contagious, chief among which were sore throat, 1520; ringworm, 753; conjunctivitis, 397; pediculosis, 212; measles, 152; mumps, 118; impetigo, 112; chicken-pox, 73; influenza, 31; whooping-cough, 20; ivy poisoning, 13; diphtheria, 12; scabies, 8; scarlet fever and syphilis, each 4, and consumption, 2. More than 1000 cases of markedly defective vision were also found.

SOUTH DAKOTA.

DR. LYMAN F. BARCOCK, city physician of Deadwood, has resigned because his suggestions were not acted on, and because he had not been given any authority with which to enforce these suggestions as to the public health.

A PRESBYTERIAN minister of Wilmot has applied to the circuit court to compel the State Board of Health to issue him a license to practice medicine. He has been arrested several times for practicing medicine without a license, but has escaped on the ground that his prescriptions were given only in emergencies and that he made no charge for his services.

THE SUPERINTENDENT of the state asylum at Yankton, in his report, details the need of increased accommodation for patients, as the institution is overcrowded and as insane patients are now being held in county jails because there is no room for them at the state asylum. He also advocates that the name of the institution be changed to the "State Hospital," and asks for an appropriation of \$204,672 for the next two years.

THE SMALLPOX cases having increased to 30 at Deadwood, owing to refusal by the city officials to exercise proper quarantine, and so aid the physicians in preventing the spread of the disease, as noted in last week's JOURNAL, neighboring towns threatened to quarantine against Deadwood unless there was an immediate change in policy. The city now admits the presence of the disease and is taking every precaution to prevent its further spread.

TENNESSEE.

DR. JAMES A. ALBRIGHT, secretary of the State Board of Health, reports that between March 5 and November 16, 1389 cases of smallpox were reported in the state, three-fourths of which occurred in negroes.

DR. JOSEPH W. JOHNSON, Chattanooga, who has been studying in Paris and Vienna for several months, has been recalled to America by the death of his father, and as soon as the estate matters are settled will practice in Chattanooga.

THE CONTROVERSY between the State Board of Health and certain local physicians regarding the diagnosis of cases known as chicken-pox, measles, "Cuban itch," etc., has been followed by an outbreak of smallpox, just as it has been in many other localities. In Campbell county, 20 cases of smallpox were found diagnosed as chicken-pox; in McMinn, 17 cases were reported, and also a number of cases in Hamilton County. Eighteen deaths have been reported.

TEXAS.

DR. J. M. NIXON, Bell County, and president of the county medical society, has been accepted as a medical missionary to the Methodist Episcopal church, and ordered to China.

DR. JONN M. MCCITCHEON, Temple, has been re-appointed health officer of Bell County. The commissioners intend to act upon his suggestion and establish an isolation hospital on the county farm.

UTAH.

THE STATE BOARD OF HEALTH has issued an order that no child who has not been vaccinated shall be admitted to a public school in the state.

DR. EUGENE W. WHITNEY, Salt Lake City, has been appointed inspector of contagious diseases among school children. He is to receive a salary of \$150 per month and is to give his entire time to the duties of the office.

A RIFLE QUARANTINE has been established at Scofield, where there are 17 cases of smallpox. This has been done without sanction of the State Board of Health, which has been endeavoring to learn particulars of the epidemic and to adopt measures for the limitation of the disease.

AN ORDINANCE was passed by the Salt Lake City council December 4 making it a misdemeanor for persons knowing of the existence of measles, chicken-pox and all eruptive diseases not to report the same to the health authorities. The penalty attached to a violation of the ordinance is a fine of from \$5 to \$100 and ninety days in jail.

VERMONT.

A BILL looking to the incorporation of a public hospital at Brattleboro has been passed by the House of Representatives of the state.

THE STATE BOARD OF HEALTH held its biennial meeting for organization at Burlington, December 4. Dr. Charles S. Caverly, Rutland, was elected president; Dr. Henry D. Halton, Brattleboro, secretary, and Dr. Truman R. Stiles, St. Johnsbury, treasurer. Dr. J. H. Hamilton, Richford, who has been secretary of the board for ten years, resigned, and resolutions of regret were passed by the board.

AT THE ANNUAL MEETING of the directors of the Mary Fletcher Hospital, Burlington, held December 5, the following staff was elected for the ensuing year: Drs. Patrick E. McSweeney, Samuel E. Maynard, William R. Prime and Harris R. Watkins, attending physicians; Drs. Leroy M. Bingham, John B. Wheeler, Donly C. Hawley and Henry C. Tinkham, attending surgeons, and Dr. Marshall C. Twitchell, ophthalmologist.

AN AMENDMENT to the law regulating the practice of medicine in Vermont has been presented to the House of Representatives which provides that the board of censors shall issue certificates permitting practice by any persons who present diplo-

mas from medical colleges and also pass examination before the board. Applicants shall pay a fee of \$5 to the board for examination. Only state medical societies shall elect boards of censors.

WEST VIRGINIA.

THE HARRISON COUNTY HOSPITAL COMPANY, of Clarksburg, has been incorporated with a capital stock of \$50,000.

THE STATE BOARD OF HEALTH examined 34 applicants for license to practice medicine, at Wheeling, November 15. Of the applicants, five were colored.

A PLAN has been formulated by a resident of Morganstown whereby a hospital shall be established in that place for the benefit of students at the university.

DR. W. C. BILLINGS, U. S. M.-H. S., has been sent to Clarksburg to take charge of the smallpox situation. There are now 10 cases in Clarksburg and more than 100 in Harrison and Wetzel counties.

WYOMING.

THE CITY COUNCIL of Cheyenne has adopted regulations providing for the appointment of a sanitary inspector to look after the dairies furnishing milk to the city.

PROPOSALS for construction of a post hospital and hospital steward quarters at Fort Mackenzie have been advertised for by Major J. W. Pope, chief quartermaster, Denver.

GENERAL.

DR. IRA C. BROWN, formerly of Buffalo, has returned to Manila on the *Thomas*, having been appointed chief surgeon for the district of Panay, P. I.

DR. FRANCIS M. NESMITH, superintendent of Garfield Hospital, Washington, D. C., has severed his connection with that institution to accept a like position at the Presbyterian Hospital, Chicago.

GOODWIN BROWN recently contended before the industrial commission that vigorous legislation was necessary to protect the country from the influx of insane immigrants. He declared that quite 50 per cent. of the patients in the New York State insane hospitals were foreign born. The foreign-born insane are said to cost that state over \$1,000,000 annually.

DR. CLARENCE TREHOLTZ, asst.-surgeon, U. S. A., with his wife, will attempt to make a winter trip to Fort Egbert, Alaska, traveling part of the way by steamer, part by railroad, and over 500 miles by dog sleds. Under orders from Gen. Shafter, Dr. Treholtz purposed to start this week on his long journey. The distance from White Horse to Egbert is 560 miles.

UNIQUE OBSTETRIC FEES.

The first medical convention of the physicians of the Lake St. John, Chicoutimi and Saguenay district in Canada assembled in a general convention November 11 at Chicoutimi, Quebec, according to the *Bull. Méd. de Québec*. Among the questions discussed was that of fees, and all agreed not to accept less than \$3 for an ordinary accouchement, with 25 cents additional for every hour over six, \$4 for a twin accouchement, and 50 cents for adhesion of the placenta or hemorrhage.

ASSOCIATION OF MEDICAL LIBRARIANS.

The "exchange" of this association has been moved from Philadelphia to Baltimore, and is now located at the Hall of the Medical and Chirurgial Faculty, under charge of Miss Noyes, the faculty's librarian. The object of this association, which was founded in Philadelphia in May, 1898, is "to foster medical libraries and to maintain an exchange of medical literature among its members." The exchange was founded last October, and a large number of books and periodicals have been procured by exchange, gift or purchase, and distributed to the membership libraries. Already there are over 150 medical libraries in existence, over 100 of these being separate medical libraries and the rest branches of general libraries. In many large towns the members of the profession have begun to make collections and they will receive important aid from this exchange.

THE ARMY EFFICIENCY BILL.

DR. H. L. E. JOHNSON, Washington, D. C., chairman of the committee on national legislation of the AMERICAN MEDICAL ASSOCIATION, under date of December 18, telegraphs as follows: "The committee on national legislation has been in conference with the military committee of the Senate and House of Representatives considering the Army Efficiency Bill, 4300, and has recommended a substitute for Medical Section 18, according to the wishes of the civilian physicians of the United States and of the surgeon-general. The committee on national legislation appeals to every member of the AMERICAN MEDICAL ASSOCIATION requesting him to write or telegraph at

once to both the chairman, Senator Hawley and Representative Hull, urging them to vote for and favor the passage of the substitute presented by the committee. The original bill is highly objectionable.

NATIONAL QUARANTINE STATIONS IN PORTO RICO.

The Marine-Hospital Service expects to have its quarantine stations in Porto Rico well equipped for the coming quarantine season. The floating disinfecting plant for San Juan is finished. It was found impracticable to locate a floating plant in the harbor of Ponce, on account of the unprotected character of same. Authority has, therefore, been obtained for stationing such a plant in the harbor of Guanica, about twenty miles west of Ponce, on the southern coast of Porto Rico. An excellent hulk has just been purchased by the Service for this purpose, and, as the machinery is already completed, all that remains is to remodel the hulk and install the machinery. It is, therefore, only a question of a few months until this barge will also be ready to be towed to its destination. Porto Rico will then be able to handle with efficiency and dispatch any infected vessels which may reach the island.

QUARANTINE ON DELAWARE RIVER.

In order to facilitate the conduct of the national quarantine service on the Delaware River and Bay, and to afford the shipping interests of Philadelphia greater facility in receiving information regarding vessels detained in quarantine and other matters pertaining to the quarantine service, the surgeon-general of the Marine-Hospital Service has detailed Surgeon H. W. Austin, in command of the Service in Philadelphia, to be quarantine officer for the Delaware Bay and River. The routine of the stations at Reedy Island and Delaware Breakwater will be conducted by the medical officers in immediate charge thereof, but they will be under the general supervision of Surgeon Austin, who is authorized to make periodical inspections of the stations and to visit them at any time when requested by the medical officer in immediate command.

THE HEALTH OF HAVANA, CUBA.

The report of Major W. C. Gorgas, surgeon U. S. Army, chief sanitary officer of the city of Havana, Cuba, for November, 1900, shows such a rapid decline in the prevalence of yellow fever that the disease is expected to disappear by the middle of December. During the month 206 cases were under treatment, of which number 54 were fatal. Immigrants from Spain furnished 240 of the cases and 44 of the deaths. It is stated that nearly 20,000 immigrants have arrived during the period January 1 till November 30, 1900. Notwithstanding the prominence of yellow fever in the mortality lists of the month, the number of deaths from all causes was only 444, which, on an estimated population of 250,000, is equivalent to an annual death-rate of 21.31 per 1000 living. The absolute number of deaths is smaller than that reported not only in any month of the year but in any month of the past ten years. Major Gorgas calls attention to the small number of houses in which yellow fever has occurred in 1900, compared with the total number of houses in the city, and to the relatively large number in which disinfection has apparently been successful. During the year 847 houses were infected. As no second case occurred in 668 of this number the measures taken to eradicate the disease appear to have been effective. In 122 of the infected houses a second case occurred after disinfection. These were again carefully disinfected and in 790 no third case occurred. He is of the opinion that the results of isolation and disinfection are well worth the labor, money and time spent on them.

CANADA.

THE VICTORIA HOSPITAL FOR SICK CHILDREN, Toronto, is now only \$19,000 in debt. Six years ago there was a debt of over \$100,000. The different lodges of the fraternal societies have been especially generous in the respect of financial assistance.

DR. W. H. ANDERSON, a graduate of Toronto University, has been appointed bacteriologist at the Williams Head Quarantine station in British Columbia in succession to Dr. Higgins, who returns to the government experimental station at Outremont, Montreal. Dr. Higgins was appointed to the Williams Head station when bubonic plague was at San Francisco, at Honolulu and in the Orient.

EXAMINATION OF SANITARY INSPECTORS.

DR. WYATT JOHNSTON, Montreal, recently conducted an examination of the sanitary inspectors in the employ of the health department of that city. As a result many of these will be dismissed, as they are not considered to have the requisite knowledge for one employed in such a capacity. Hereafter

Montreal will employ men of more marked intelligence and ability in the conduct of this work.

TORONTO WOMAN'S MEDICAL COLLEGE.

The friends of this college are agitating for a special hospital. A meeting was held last week and the movement placed in the hands of Dr. Wishart, the secretary of the college. The women doctors of Toronto claim that they are accorded no privileges in any of the hospitals, with the single exception of the Western Hospital, and even in that, they are not allowed to treat any of the charity cases. The women of Canada will be asked to contribute twenty-five cents each toward founding such hospital.

SMALLPOX IN THE YUKON.

DR. MONTZAMBERT has at last succeeded in tracing the origin of the smallpox outbreak in Yukon. He states the disease found its way into that country through a man from Seattle, who had gone direct to the creeks, and in that way spread the disease. From the Yukon, the epidemic spread to Skagway, and was thence carried to Victoria, B. C., by the steamer *City of Seattle*. There were 350 passengers on board this steamer and these were kept in quarantine off Williams Head the requisite length of time.

ONTARIO HEALTH REPORT.

The November monthly report of the Ontario Provincial Board of Health shows that the total deaths registered during that month numbered 1906, as against 1501 for the corresponding month of last year. From typhoid fever alone 130 deaths occurred, this being the highest number on record. Of scarlet fever there were 10 deaths; diphtheria, 49; measles, 3; whooping-cough, 20; tuberculosis, 156. Typhoid fever has been very prevalent throughout Ontario all fall, which is set down to the dryness prevalent during the greater part of the season.

THE DOMINION CATTLE BREEDER'S ASSOCIATION AND TUBERCULOSIS.

This association met at the Winter Fair held at the Ontario Agricultural College at Guelph last week, and adopted a very strong resolution in regard to the tuberculin test in cattle. It reads as follows: "Resolved, That in the opinion of the cattle breeders of Canada, here assembled, the regulations relating to the importation of pure-bred animals, which requires the injection of tuberculin as a sure indication of the presence of tuberculosis, are unsatisfactory and likely to bring serious injury to the cattle-breeding industry of Canada; that while the test may be used as an aid in the detection of the disease, it is not sufficiently exact to be relied upon; that the disease may exist in such parts of the animal which makes it impossible to be transmitted by contagion or otherwise, and that no real service to the country is being rendered by its use in that connection. Therefore we earnestly request that the Minister of Agriculture take such steps as may seem desirable in order to discontinue its use in that connection."

"MEDICAL ALLIANCE OF AMERICA" SCHEME.

The Medical Alliance of America (Limited), of which notice appeared in *THE JOURNAL* over a year ago, has now invaded the city of Toronto, and apparently the physicians of that city are unmindful of the warning of the *Montreal Medical Journal*, as published in its September issue of 1899. The physician is first approached with an ordinary member's contract or application; \$1 for admission and 15 cents per week, a whole year's assessment being required to be paid by the physician at once in advance. For this he receives the assurance that when sick himself his doctor's bill and medicines shall be paid for him just as for any ordinary member. The physician who joins this alliance is assured that he will be paid \$1 for an office visit and not more than \$1.50 for an outside visit. The contract, however, reveals the peculiar reading of the scheme. The prospectus of this alliance sets forth that their objects are to do away with the lodge-practice system, bad debts, and the taking of nostrums as well as the counter-prescribing of druggists, all no doubt commendable features, but other features are open to objection. It is to be sincerely hoped that the profession will look well into the propositions of the alliance before subscribing their names to any of these contracts. Their agents are claiming that over 200 doctors in Montreal, the Canadian home of this institution, have become members of the alliance.

FOREIGN.

THE FAMOUS English surgeon, Sir William MacCormac, has been authorized by the queen to accept the decoration of the French Legion of Honor conferred on him by the French government in appreciation of his care of French wounded soldiers in 1870, besides his scientific achievements.

LIETARD calls attention, in *Janus*, to the *Gazette Hebdom. de Méd. et de Chir.* for the last week in 1871. It contains a letter from Dr. Dechambre, resigning his post as editor rather than countenance the appearance of any advertisements on the cover of his journal. Lietard regards it as a historical relic worthy of recognition.

Daneffe has reported in *Janus* six metal trusses found on skeletons dating from the fifth and seventh centuries. The leather and cloth covering the pad were quite well preserved in tombs made of stone. None of the similar trusses in the principal museums of Europe, he states is older than the thirteenth century.

Ambassador Andrew D. White, acting on instructions from Washington, has written to the German Secretary of Foreign Affairs, begging him to express to Dr. Velde, of the German legation at Peking, America's sincere gratitude for the services rendered by him to American soldiers and sailors during the siege of Peking.

THE WATER-SUPPLY of Paris has been studied by an official committee which recommends that the springs, the source of the drinking water, should have a zone of protection drawn around them to prevent contamination, and in some cases more than a hundred square kilometers will be necessary. In this zone all measures must be taken to prevent infection of the water, with extraordinary precautions in case of typhoid fever.

The Austrian Lower House appointed on December 12 a committee of medical experts to investigate the prevalence of tuberculosis. In lower Austria 25 per cent. more deaths result from this disease than any other. Even smallpox, prior to the general vaccination caused a lower death-rate. The commission is to report as to the advisability of founding isolated sanatoriums for the tuberculous instead of admitting them into the general hospitals.

PROF. W. H. ERB's sixtieth birthday was celebrated at Heidelberg, November 30. The *Muench. Med. Woch.* reviews his achievements in science as a discoverer, educator and practical physician, and holds him up to posterity as the ideal physician, with the keen individualizing glance of the investigator as he approaches the bedside, the tranquility of wide experience, comprehensive knowledge and remarkable memory. Besides his achievements in neuropathology, his work on electrotherapeutics was the pioneer in this line.

LODGE PRACTICE IN PARIS.

A NEW SOCIETY has been formed in Paris, the "Co-opération des Familles," which has notified physicians that their names are on the list of the society's physicians, but that each will be expected to make a reduction of 12 per cent. in treating members of the society. The account will be presented and paid in full, as usual. An agent of the company will call later and collect the 12 per cent., 10 for the member and 2 for the administrative expenses. The *Gaz. Méd. de Paris* remarks that the medical profession can not contend effectually against this rising flood of reductions and commissions, this modern style of doing business, in Paris at least, for the societies are very powerful.

DEATHS.

Among the deaths abroad of prominent practitioners we notice that of Dr. Richard Neale, November 22, aged 73. His "Medical Digest" has been one of the best-known British medical publications. If it is discontinued by his death it will be a serious loss to the profession in Great Britain. The death of Dr. J. Mortimer Granville, who is best known for his criticisms on the treatment of insanity in England, and for various semipopular publications, occurred November 23, at the age of 67. He was for a considerable time on the editorial staff of the *Lancet*, as well as on lay journals. He was a popular rather than a scientific writer, and was, in some of his views, eccentric to say the least; he was nevertheless to be counted as among the better known medical writers of his day. Deputy-Surgeon-General George MacKay, of the Indian Army, died November 20, aged 80. He received his earlier education in Ontario, Canada, where his father was stationed as major in a British regiment. Professor Ollier, the eminent French surgeon, died at Lyons, November 26. Dr. Durand, of Gros, has recently died, one of the earliest writers on hypnotism, his first work dating from 1855. His chief works were written over the pseudonym of "Dr. Philips." He published this year "New Researches on Ethics and Morals." At one time he was a naturalized citizen of the United States, but returned to France in 1860. Dr. G. Hartlaub, of Bremen has died, in his 87th year. He had won world-wide fame as an authority on ornithology.

PRECAUTIONS AGAINST TUBERCULOSIS IN GERMANY.

The Department of the Interior of that empire has just given out the following instructions, according to report of Consul J. F. Monaghan: 1. Professional women who lay out the dead must report at once in writing to the police authorities if said person died of tuberculosis of the lungs or tuberculosis of the larynx. Should the deceased have been treated shortly before his death by a physician, the physician has to state the cause of death on the death notice at the request of the laying-out woman. This notice, with all the facts, must be handed in to the police before the person is buried. 2. Doctors must under all circumstances where they have patients with lung or larynx tuberculosis give a written notice to the police. Should they consider that the sick person endangers other persons, they must give written notice to the police. 3. All cases of lung or larynx tuberculosis in private institutions for the sick, orphan asylums, poorhouses, workhouses, hotels, and lodging-houses of all kinds must be reported by the attending physician to the police. Should there be no physician in attendance, the owner, keeper, or person in charge of the above-named institutions must report the same to the police within three days after the same has come to his notice. 4. The police are forced, as soon as they are notified of the death of a person suffering from lung or larynx tuberculosis, to have the room and articles belonging to said person disinfected as soon as the body is transferred to the house in the cemetery, where it must lie twenty-four hours before being buried. In case of persons suffering from lung or larynx tuberculosis, the room and effects of said person must be disinfected as soon as he is transferred to another place. In carrying out the disinfection, any recommendations of the physicians should be observed. It is recommended that the police in disinfecting proceed under the direction of the district physician. The cost of disinfection is to be paid out of the town or city treasury in case the person who has died or is suffering from lung or larynx tuberculosis is too poor to pay the same. The notices of such cases or copies of the same must be sent as soon as possible by the police to the district physician; also all facts or remarks relating to the same. Any person disobeying the regulations cited in paragraphs 1, 2, and 3 shall be subject to a fine of 150 marks (\$35.70) or imprisonment up to six weeks.

LONDON LETTER.

A REMARKABLE CASE OF TRANCE.

A case of trance is under observation at the Royal Infirmary, Newcastle, which is declared to be unprecedented in English medicine. Dr. Drummond gave a demonstration on the patient to a large number of physicians. He is a clerk, aged 26, who through life has been of a reserved and depressed nature and regarded as eccentric. In March he became unconscious. For seven months he has lain in a state of profound stupor, without any movement. He swallows unconsciously. But his unconsciousness was not as complete as was supposed, for now while on the road to recovery he remembered certain events which had occurred. The strongest electric current failed to elicit any response. At first he lost flesh and became a "living skeleton." He was then fed by injections, later the stomach-pump was used, and finally he was fed in the ordinary way.

DEATH FROM THE USE OF ROENTGEN RAYS.

A remarkable case has just occurred in which death is alleged to have been due to the use of Roentgen rays. A woman aged 68, while riding a bicycle, met with an accident resulting in an intracapsular fracture of the neck of the femur. In order to diagnose the exact nature of the injury the Roentgen-rays were employed, and two exposures of 35 and 45 minutes were given on April 7 and 27, respectively, with a 10-inch coil and $5\frac{1}{2}$ -inch spark. After the second exposure an eruption appeared on May 5. A gangrenous slough 6 inches in length and 3 inches in width, with a surrounding zone of inflammation, formed on the abdomen. Death took place November 5. According to the medical evidence at the coroner's inquest, the cause was exhaustion from shock, the result of fracture of the thigh and the action of Roentgen rays. No other cause of death could be found at the post-mortem examination. At the time of death the slough had been cast off, leaving a healthier surface, which, however, showed little sign of repair. The fracture did not unite. The heart was flabby and thin. The jury returned a verdict, "that the deceased met her death from shock and exhaustion following the acci-

dent and the effects of the Roentgen rays on a weakened system; no blame is attached to either the doctor or the photographer."

LATE SYPHILITIC PYREXIA—INTERMITTENT ESSENTIAL FEVER OF SYPHILIS.

At the Clinical Society, Mr. Campbell Williams reported a case of this comparatively unrecognized condition. A man aged 43 contracted syphilis in December, 1896. After the secondary stage he suffered from little except a sore tongue. He was treated mainly with mercury alternated with iodids for a period of two years, and was free from all symptoms for eighteen months before ceasing attendance. In April, 1900, he had periostitis of the right clavicle, and pyrexia. His temperature rose every afternoon, and the crisis took place in the small hours of the morning. Syphilitic fever was diagnosed and he was put on mercury. On April 25 his temperature became normal and had remained so ever since. In the discussion which followed, Dr. Sidney Phillips remarked that such cases were by no means uncommon and referred to one which he had recorded in the Transactions of the Medical Society of London. In another case under his care, a woman who had contracted syphilis ten years previously, developed pyrexia such that might be mistaken for malarial fever. Some years ago a case was reported by the late Dr. J. S. Bristowe of a man who had intermittent pyrexia of obscure origin, until syphilitic choroiditis was discovered in the eyes. Mercury was then given and the patient recovered. Dr. T. D. Savill also agreed that such cases were not uncommon and was surprised that the fact was not recorded in text-books.

DIAGNOSIS AND TREATMENT OF THORACIC ANEURYSM.

At the Medical Society of London, Dr. De Havilland Hall read a paper on this subject. He commented on the difficulty of diagnosis at the onset when physical signs were very obscure. He pointed out that a harsh, clanging cough in a middle-aged man with atheromatous vessels and a syphilitic history were very suggestive of aneurysm. He laid stress on the frequency of recurrent laryngeal paralysis, especially on the left side, and emphasized the importance of systematic laryngoscopic examination in obscure cases of intrathoracic mischief. This examination was necessary as a routine since unilateral abductor paralysis was compatible with a practically unaltered voice. Of 41 cases of aneurysm which he had seen, 22 presented hoarseness and 19 paralysis of one or other vocal cord, usually the left. He alluded to the paroxysmal nature of the dyspnea. Tracheotomy was generally useless, as the main cause was pressure on the trachea. He regarded the diastolic "thud" as the most reliable auscultatory sign of aneurysm, the presence or absence of a murmur being of comparatively small importance. The combination of loud tracheal breathing and dysphagia pointing to pressure on the trachea and esophagus was very suggestive of aneurysm. The Roentgen ray promises to be of great service in diagnosis.

As to treatment, the cases subjected to the Tufnell method required to be carefully selected. He was not in favor of restricting the diet to the quantity advised by Tufnell. He found that restriction to 10 to 12 ounces of solids and from 12 to 16 ounces of liquids was sufficient. Under this plan drugs should be avoided. He had tried subcutaneous injection of gelatin in one case, which was not benefited.

ARSENICAL POISONING IN MANCHESTER FROM BEER-DRINKING.

The extraordinary and unprecedented outbreak of arsenical poisoning in Manchester and the surrounding district, owing to contamination of beer with arsenic, has produced a profound sensation throughout the country. For some time the doctors in Manchester and the neighboring town of Salford have noticed that the number of cases of "peripheral neuritis" has been rapidly increasing. Recently they reached alarming proportions. Increased drinking in connection with the elections and rejoicings over the British successes in South Africa was thought to be the cause. But soon it was noticed that the cases presented unusual features. Large numbers were observed in the various infirmaries and they swarmed in the out-patient departments of the hospitals. The patients were beer-drinkers who sought advice on account of weakness and sensations of "pins and needles," numbness, pricking, scalding, etc.,

in the limbs. In advanced cases they were paralyzed and unable to get about. Others were seen for various rashes; erythematous, papular desquamation and keratosis of the palms and soles. Sweating was marked in some cases. In others the patients complained of colds in the head or nose, or influenza, or they became hoarse. Only a few gave a history of nausea and vomiting. The superficial reflexes were often found increased, even in chronic cases. The knee-jerks were usually diminished or abolished, but in some severe cases they were increased. Diarrhea was exceptional. For a time these patients were supposed to be suffering from alcoholic multiple neuritis, until Dr. E. S. Reynolds, assistant physician to the Manchester Royal Infirmary, discovered that arsenic was present in the beer which they drank. He announced this at the meeting of the Medical Society of Manchester on November 21. This outbreak of arsenical poisoning has been widespread in the district for two months and there is strong evidence to show that cases began as long ago as six months. In the beer, arsenic has been found in quantities varying from trace up to 0.28 grams per gallon. In the sugars used as malt substitute for brewing, 3 and 4 parts of arsenic per 10,000 were found. The source of the arsenic is the sulphuric acid used to prepare these sugars from cane sugar and starch. Sulphuric acid is made from arsenical pyrites, and therefore contains arsenic as an impurity. The greatest precautions are now being taken. Beer is being subjected to analysis all over England, and the government has ordered an inquiry into the matter. Immense quantities of beer have been thrown away. The Manchester coroner has warned all publicans that they are responsible for the purity of their beer and that if a death should occur they will be held responsible.

THIRD PAN-AMERICAN MEDICAL CONGRESS.

The following circular has been issued: The organization committee has postponed the meeting of the Third Pan-American Medical Congress until February 4. It will be held from that date until the 7th, inclusive. All literature pertaining to the Congress is in Spanish, but occasional news items will be sent to the weekly journals. Delegates can go either by the land routes, which are all via Florida, or by the water route from New York. Full particulars concerning these routes, excepting that of the Ward Line steamer from New York, will be found in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of November 3. Those coming from south of Washington and west of Pittsburg will probably select the Florida route, while those from the northeast will find the Ward Line more convenient. The steamer *Seguranza* of the Ward Line leaves New York January 30, arriving in Cuba on February 3, the day before the beginning of the Congress. The new Ward Line steamer *Morro Castle*, holding 135 cabin passengers, leaves Havana on February 9, reaching New York February 11. The round trip, everything included, is \$60. Those going via this route will be absent from New York twelve days.

Any of the delegates going by the Ward Line, who desire it, may, by a supplementary payment of \$25, return via Santiago. This trip will take from ten to twelve days, during which time the passengers live on the ship, and have their meals there if they desire. The party goes from Havana by rail to Cienfuegos in one afternoon, there taking the steamer to Santiago, and from Santiago to Nassau in the Bahamas, and from Nassau to New York. The stay in these different ports will be for a day or more.

English-speaking members of the Cuban reception committee will meet all steamers on their arrival in Havana and escort the delegates to the hotels assigned to them. The best hotels in Havana are, Telegrafo, Mascotte, Inglaterra and Pasajoa. Rates, \$3 and \$5 a day.

The entertainment committee, appointed by the city council of Havana, for the purpose of making it pleasant for the delegates during their stay, have arranged a program which, although as yet not fully determined on in every detail, is nevertheless one which adds an attractive feature to the meeting.

There will be a large ball given at the Tacón theater. This will be under the management of a sub-committee and an auxiliary ladies' committee. The committee is sparing no pains to make the ball the great social feature of the week, and one that will be most enjoyable, not only to the delegates, but also to any ladies in their parties. (There will be a banquet given at the same place.) On another day an excursion will be made to the sugar plantation of Mr. La Costo, near Havana, on three government transports. On arriving there the delegates will be shown the manner of growing sugar cane, gathering it, grinding, cooking and refining the sugar derived therefrom, as well as all other points of interest connected with the method of making sugar, and life on a sugar estate. Refreshments will then be served either on the estate or on the transports returning. These transports will be so arranged for the guests as to give the greatest amount of comfort and pleasure during the trip. On another day there will be a parade of the police and an exhibition of the fire companies, in which they will show the promptness and skill with which they combat any fires taking place in the city. Receptions will also be given by various officials, and private dinners by numerous Cuban physicians to the delegates with whom they are acquainted.

The three general sessions of the Congress at which papers of general interest will be presented and addresses delivered by official representatives from the different countries, will be held at the Tacón theater in Havana. The section meetings will be held in the university on the first floor, and on the first and second floors of the Institute. The delegates from Mexico are at present in the lead, and a large number of abstracts have been received from them.

Mention will here be made of the names of the presidents of the different sections, all Cubans, as the presidents are representatives of the country in which the Congress takes place, and the secretaries for the United States. All communications and titles of papers should be sent to the United States secretary of the section covering the subject, or to the associate secretary for the United States of the Congress, Dr. Ramon Guitóras, 75 West 55th street, New York City. A preliminary program will be published shortly.

SECTION OFFICERS.

The officers of the different sections are the following:

General Surgery, Dr. Tomas Plascencia, president; Dr. W. P. Nicholson, Atlanta, Ga., secretary.

Medical Jurisprudence, Dr. Jose M. Cespedes, president; Dr. H. A. West, Galveston, Tex., secretary.

Anatomy, Dr. Federico Horsman, president; Dr. A. D. Bayan, 100 State street, Chicago, secretary.

Orthopedic Surgery, Dr. Tomas Plascencia, president; Dr. John Ridlon, 103 State street, Chicago, secretary.

Obstetrics, Dr. Eusebio Hernandez, president; Dr. Gustav Zinke, 13 Garfield place, Cincinnati, Ohio, secretary.

Pediatrics, Dr. Joaquin L. Ducnas, president; Dr. I. N. Love, 49 West 44th street, New York City, secretary.

Ophthalmology, Dr. Enrique Lopez, president; Dr. John E. Weeks, 40 East 57th street, New York City, secretary.

Otology, Dr. Carlos Desvermeine, president; Dr. J. F. McKernon, 62 West 52d street, New York City, secretary.

General Medicine, Dr. Carlos Finlay, president; Dr. Judson Daland, 317 South 18th street, Philadelphia, secretary.

Physiology, Dr. M. Sanchez Toledo, president; Dr. A. P. Brubaker, 105 West 34th street, Philadelphia, secretary.

Pathology, Dr. Raimundo Castro, president; Dr. A. E. Thayer, 352 West 117th street New York City, secretary.

Railway Surgery, Dr. Tomas Plascencia, president; Dr. Duane Eve, 700 Church street, Nashville, Tenn., secretary.

Medical Pedagogy, Dr. Manuel Delin, president; Dr. Otis K. Nowell, 13 Central Park, west, New York City, secretary.

Therapeutics, Dr. Raimundo Castro, president; Dr. Hobart A. Hare, 222 South Fifteenth street, Philadelphia, secretary.

Gynecology and Abdominal Surgery, Dr. Gabriel Casasa, president; Dr. H. P. Newman, 103 State street, Chicago, secretary.

Mental and Nervous Diseases, Dr. Gustav Lopez, president; Dr. Charles P. Hughes, 3857 Olive street, St. Louis, Mo., secretary.

Dermatology and Syphilography, Dr. Henry Robelin, president; Dr. A. Ravogli, 5 Garfield place, Cincinnati, Ohio, secretary.

Dental and Buccal Surgery, Dr. Erastus Wilson, president; Dr. Eugene Talbot, Columbus Memorial building, Chicago, secretary.

Laryngology and Rhinology, Dr. Carlos Desvervigne, president; Dr. G. H. Makuen, 1419 Walnut street, Philadelphia, secretary.

Military Medicine and Surgery, Dr. Eugene Sancho Agramonta, president; Maj. Jefferson Kean, U. S. A., Quemados, Cuba, secretary.

Marine Hygiene and Quarantine, Dr. Luis Cowley, president; Dr. H. M. Woodward, surgeon, M. H. S., Washington, D. C., secretary.

General Hygiene and Demography, Dr. Vicente de la Guardia, president; Dr. Alvah H. Doty, Quarantine Station, Staten Island, N. Y., secretary.

TRANSPORTATION.

Dr. H. L. E. Johnson, Washington, D. C., chairman of the transportation committee, makes the following announcement: The Southeastern Passenger Association has granted stop-over privileges in Florida to return passengers from the Third Pan American Congress of Havana, within the time limit of tickets. The customary stop-over methods pursued in the case of winter tourists' tickets must be followed. Stop-over papers and receipts for tickets must be obtained by all passengers desiring to take advantage of the privilege. Delegates and other passengers for the occasion should consult their local ticket agents for further information on this point.

In regard to railroad rates from Chicago the following may be announced: The rate from Chicago to Havana and return is \$74.95, including meals and berth on steamer from Tampa or from Miami, Fla., to Havana and return to these places. Passengers may go from Chicago by various routes. It will probably be arranged to have a party from Chicago go over one route and back another. Correspondence with those living in, and west of, Chicago is desired by the editor of THE JOURNAL, so that definite arrangements may be made in time.

REQUEST OF SECRETARIES.

Dr. William Perrin Nicholson, Atlanta, Ga., secretary of the Section on General Surgery, requests those desiring to read papers before his Section to send the titles of their papers to him at the earliest possible moment.

Dr. G. Hudson Makuen, 1419 Walnut street, Philadelphia, secretary of the Section on Laryngology, urges the laryngologists and rhinologists of the United States to attend the congress. He requests the titles of the communications which they desire to present.

Major J. R. Kenn, Columbia Barracks, Cuba, secretary of the Section on Military Medicine and Surgery, hopes that medical men with military experience will contribute papers illustrating all the many phases of this important and interesting branch of professional work. Contributions should be mailed to him as promptly as may be practicable.

Dr. Henry Parker Newman, 103 State street, Chicago, Ill., secretary of the Section on Gynecology and Abdominal Surgery, announces that he would again urge those who have papers in preparation for his Section to send abstracts, not to exceed 200 words, at once to the local secretary, Dr. Tomas V. Coronado, 105 Prado, Havana, Cuba, so that they may have a place on the preliminary program.

Dr. R. M. Woodward, surgeon, Marine-Hospital Service, Washington, D. C., secretary of the Section on Marine Hygiene and Quarantine, announces that it is desired that his Section be well represented. He has already received notices from several men prominent in sanitary affairs, signifying their intention to attend the meeting. He will be glad to furnish all necessary information to anyone interested in the subject and will see that abstracts of papers are sent to the committee in Havana if sent to him before January 20.

Correspondence.

Foreign Bodies in the Ear.

PHILADELPHIA, Dec. 11, 1900.

To the Editor:—In an abstract, from *Le Presse Médicale*, Paris, of an article by M. Lermoyez, the author says "that hundreds of lives would be saved every year if physicians, parents and nurses realized that a foreign body in the ear does no harm as long as it is not meddled with, etc." To any physician having a considerable experience with foreign bodies in the ear, such a statement will appear quite as ridiculous as it is untrue. In fact, the whole paragraph would indicate the writer to be a timid neophyte, whose first attempt in this line had resulted in nothing less than the tragic demise of his suffering patient at the hands of the trembling operator, whose death-dealing instrument had pierced some vital spot.

In no cavity of the body, scarcely excepting the orbit, is a foreign body, if allowed to remain, capable of producing more harm and greater distress than that of the ear, especially if lying close to the tympanic membrane; even inspissated cerumen, if mingled with dust and other extraneous matter, as it generally is, will produce in a short time very unpleasant subjective symptoms, and inspection will show more or less dermatitis with inflammation and swelling of the drumhead, not to mention deeper involvement if any considerable time has elapsed.

What physician has not seen the most violent and even grave symptoms following the retention of insects and other foreign bodies in the ear? And he, including M. Lermoyez, who would advise non-interference in such cases, is either criminally negligent of plain duty or too timid to practice medicine.

With a strong light and in gentle, but steady fingers nothing is so good for the extraction of any foreign body as a silver probe, flattened into a little spatula at one end, which is bent to an angle of about 45 degrees with the shaft. This can be carefully insinuated behind the object and generally withdrawn at the first effort. After this, gentle syringing with warm boric acid solution and carefully drying, leaves the meatus in the best condition for prompt recovery from any damage already sustained.

G. A. HILL, M.D.

Natural Asepsis.

SOCORRO, N. M., Dec. 15, 1900.

To the Editor:—One day last summer I was called to see a country maiden lady, 40 years of age, who had six weeks before, while walking in the barn-lot, stepped on a thorn, which ran through her shoe and into her foot, entering between the metatarsophalangeal joints of two of the toes. It was poulticed with home-made mixtures for a few days and healed without the slightest suppuration. Four weeks after this a small, hard tumor appeared on top of the foot, pain was also noticed when patient put the foot to the floor. I made a small incision over the tumor and, on slight pressure, the thorn came out. Not the slightest indication of pus. Wound of knife healed primarily. The patient then stated, and her reputation for truth is beyond question, that there had never been a drop of pus from in her body; that wounds always healed by primary union or, if very much lacerated, the un-nourished part mummified and dropped off. Thorns in her flesh became encased in a bone-like deposit and remained so until removed. She is a small, poorly-nourished woman, but fairly healthy. Did any one ever hear of a similar case?

J. F. STONG, M.D.

Marriages.

FRANCES PEELE, M.D., to George P. Beebe, both of Brooklyn, N. Y., December 8.

SAMUEL C. MUIR, M.D., to Miss Nancy Sharpe, both of Bardonia, Ky., December 6.

WILLIAM L. MCCLAIN, M.D., to Miss Kate Cravens, both of Scottsburg, Ind., December 5.

BASIL D. SPAULDING, M.D., to Miss Margaret A. Cannon, both of Richmond, Va., December 4.

PAULUS A. IRVING, M.D., Richmond, Va., to Miss Lucy Taylor, of Orange County, Va., December 12.

LAFAYETTE BENNETT, M.D., Auburn, Logan County, Ky., to Miss Annie Means Braden, of Hopkinsville, Ky., December 19.

WILL M. GARTON, M.D., U.S.N., to Miss Beatrice S. Farquhar, daughter of Rear-Admiral Farquhar, U.S.N., at Washington, D.C., December 12.

Deaths and Obituaries.

Ephraim Ingals.

When Ephraim Ingals died higher medical education lost one of its most steadfast advocates; the West a pioneer, and Chicago one of its best-known and best-beloved physicians. He was born at Abington, Conn., May 26, 1823, son of Captain Ephraim and Amasia Goodell Ingals. His ancestor, Edmund Ingals, came to America in 1628, and was the first settler of Lynn, Mass. At the age of 14, young Ingals came to Illinois and lived with his brother in Lee County. He attended school

at Princeton one winter, later was a student at Mount Morris seminary, and then took a two years' course at Illinois College, Jacksonville. He taught school two winters, working on the farm during the summers. He began the study of medicine at Rush Medical College in 1845, was a special student in Dr. Brainerd's office, and was graduated in 1847. After graduation, he settled in Lee Centre, Lee County, Ill., and started in practice with Dr. R. F. Adams. Here he remained, living the hard life of the frontier physician, practicing medicine, farming, buying and selling land for ten years, when he came to Chicago, where he afterward made his home. Shortly after his return, he was made associate editor with Dr. Brainerd of the *Northwestern Medical and Surgical Journal*. In 1859 he was appointed professor of materia medica and medical jurisprudence in Rush Medical College and a member of its board of trustees, and these positions he held until 1871, when he resigned. He again accepted the position of trustee of the college in 1896, and was made emeritus professor of materia medica and medical jurisprudence. In 1897, when the college was about to be affiliated with the University of Chicago he made a donation of \$25,000 toward the liquidation of the debts of the college. He also endowed the Ingals professorship

of therapeutics and preventive medicine. He was greatly interested in the advance of medical education and more particularly as regards the affiliation of medical colleges with universities, which he believed could make it possible for the college to accomplish much more than without that aid. He also gave \$30,000 in aid of the laboratories of the Northwestern University Medical School. He was a member of the AMERICAN MEDICAL ASSOCIATION, of the Illinois State Medical Society, of which he once was president, and of the Chicago Medical Society, of which he was a life member and three times president. About ten years ago he gave up active practice. Three years later he began to develop symptoms of weak heart. From that time he had no serious illness, although he was frequently ill and confined to the house for several weeks at a time. He had had, however, at intervals, Cheyne-Stokes respiration for five years. On December 5 he was attacked with what appeared to be influenza, attended by marked Cheyne-Stokes respiration. After a few days the symptoms of heart-weakness increased, and on December 9 he had a severe attack of angina pectoris *sine dolore*, and seemed hardly able to live through the night. During the next three days he had three or four similar attacks a day which were checked by remedies in a short time. He then rallied for three or four days. He had a cough that was continuous, but not particularly troublesome, with slight fever. On December 15 he had a relapse and grew steadily worse, but had a fairly comfortable night December 17. The next morning his pulse was regular, with slight rise in temperature and rapid respiration. At 9:20 he took some milk, and answered questions intelligently. Almost immediately the nurses noticed his pulse was weak, and in a few minutes he died. He looked upon his life-work as done and deprecated any efforts made to prolong his life, feeling that he had earned the right to rest.

EDWARD A. SMITH, M.D., in New York City, where he had lived since 1878, on December 10, aged 70. After graduating from the University of Pennsylvania medical department he became assistant physician in the Worcester (Mass.) State Lunatic Asylum. In 1856 he occupied a like position in the Pennsylvania Hospital for the Insane at Philadelphia. Six years thereafter he resigned to become a surgeon U. S. V. on hospital duty in the same city. After the Civil War he entered upon private practice and at last went to New York, here for several years he was closely identified with the New York Orthopedic Dispensary and Hospital as trustee, treasurer and finally as vice-president.

CHARLES SABIN TAFT, M.D., at his home in Mt. Vernon, N.Y., December 18, aged 65, with cancer of the throat. He was stationed at Washington during the Civil War and was present in Ford's theater when Lincoln was assassinated. He and Mrs. Taft occupied orchestra seats just below the president's box and Dr. Taft was the first surgeon to reach the dying president, with whom he remained until the end.

WILLIAM P. CALWELL, M. D., Washington University, Baltimore, 1867, suddenly at White Sulphur Springs, Greenbrier County, W. Va., December 8, aged 62. He was a son of Dr. Henry Calwell, of the family so long associated with the ownership and management of the Greenbrier White Sulphur Springs.

JOHN C. ACHESON, M.D., College of Physicians and Surgeons, New York, 1859, at his home in New York, December 12, aged 68. He was among the physicians first appointed by the New York health board as at present organized, was a frequent medical society attendant and was active in dispensary work.

CASSIUS C. DAVIDSON, M.D., Western Reserve University, Cleveland, 1876, after an illness of three weeks, at his residence in Akron, Ohio., December 9, aged 50. His fellow practitioners adopted resolutions deploring his death and expressing sympathy with his family.

WILLIAM H. JONES, M.D., University of Pennsylvania, 1858, in Bethlehem, Pa., December 13. In 1873 he was commissioned surgeon on the *Portsmouth* at San Francisco and Philadelphia, and later was stationed at the League Island navy yard, Philadelphia.

LEROY J. BROOKS, M.D., Bellevue Hospital Medical College, New York, 1872, at Norwich, N. Y., December 11, from chronic

nephritis. He was a well-known physician of Chenango county and a member of the AMERICAN MEDICAL ASSOCIATION.

HENRY T. WOODRUFF, M.D., Northwestern University Medical School, 1861, surgeon of the 100th Illinois during the Civil War, died at his home in Harvard, Ill., from Bright's disease, December 17, aged 61.

JOSEPH T. SHOEMAKER, M.D., University of Pennsylvania, 1860, at Philadelphia, December 6, aged 62 years. During the Civil War he served as surgeon of the 88th Pennsylvania Volunteer Infantry.

WILLIAM H. DAUGHTRY, M.D., University of Pennsylvania, 1865, formerly president of the Franklin Agricultural and Mechanical Society, at Sunbeam, Southampton county, Va., December 14.

WINONA JENNINGS, M.D., Laura Memorial Woman's Medical College, Cincinnati, 1899, at the Cincinnati Hospital, December 13, after a lingering illness, the result of a series of operations.

GEORGE C. ROBERTS, M.D., Atlanta Medical College, 1887, a resident and late city physician of Chattanooga, at Memphis, Tenn., December 3, after an illness of two weeks, aged 43.

ELLIOTT BAITON PALMER, M.D., Medical College of Ohio, Cincinnati, 1896, at his home in Avondale, Cincinnati, from influenza complicating heart disease, December 10.

ORLANDO J. HARRAN, M.D., Northwestern Medical College, St. Joseph, Mo., 1890, at his home in West Beatrice, Neb., after a brief illness, December 10, aged 77.

FREDERICK C. W. PLEIBEL, M.D., University of Pennsylvania, 1862, at the German Hospital, Philadelphia, December 6, after a brief illness, aged 66.

O. K. EARLY, M.D., surgeon of a Kentucky brigade in the Confederate service, at his home in Columbus, Miss., after a short illness, on December 11.

JAMES FLEURY STEWART, M.D., junior resident physician at the S. R. Smith Infirmary, New Brighton, N.Y., from typhoid fever, aged 23 years.

FREDERICK A. HOPKINS, M.D., McGill University, Montreal, 1889, instantly, by being struck by a train at Montreal West, December 1, aged 34.

KIRK C. MCKINNEY, M.D., Kansas City Medical College, 1896, from gunshot wound self-inflicted, at El Paso, Texas, December 8, aged 29.

FRANK SCOTT HARKER, M.D., Medical College of Virginia, 1892, at his home in Richmond, Va., after a short illness, December 8, aged 42.

JAMES H. MCDANIEL, M.D., University of Louisville, 1870, at his home, Centerville, Texas, after a long illness, November 26.

ADOLPH F. KRAUSE, M.D., Rush Medical College, 1895, suddenly, during an epileptic attack at Bowdle, S.D., December 5.

RANDOLPH N. HOWARD, M.D., Jefferson Medical College, 1879, suddenly from heart disease at Carrington, N. D., December 7.

P. L. HUDSON, M.D., University of Georgia, 1877, at Cochran, Ga., from an overdose of chloroform, November 30.

JOHN IGNATIUS GROSS, M.D., University of Maryland, 1865, suddenly, from heart disease, December 14, aged 61.

J. PERRIN JOHNSON, M.D., University of Cincinnati, 1860, at his home in Sioux City, Iowa, December 9, aged 72.

ADOLPH PRAMANN, M.D., University of Wurzburg, Germany, 1856, at his home in New York, aged 68 years.

SAMUEL C. TISDALE, M.D., University of Louisville, 1887, at his home, Port Lavaca, Texas, December 4.

J. S. ZUKOSKIE, M.D., University of Poland, 1867, died near Enley, Mich., November 14.

W. G. BIGELOW, M.D., Stormstown, Pa., at Du Bois, Pa., November 28, aged 87.

A. B. KARTERMAN, M.D., at Hepler, Upper Mahantongo Township, Pa.

If there is anything in a name, the title of this book ought to insure it a successful "run." This does not mean that all there is to it is the poetical title. Far from it. There is not a page but is interesting and some of the descriptions are beautiful word pictures, showing that the author, besides his other gifts, has that faculty which few writers possess—the ability to describe a scene or an occurrence so that the reader can see it as the observer saw it. Lyd-ton takes a trip to his birthplace in California by way of New York, and is snow-bound on the way; to Cuba; across the Isthmus of Panama; up the Pacific coast to San Francisco; and, after a ramble through California, home. He takes the reader with him and shows him what he saw—by photographs "taken on the spot," and by his happy way of describing occurrences and places. He visited many and various towns—on the way South, in Central America, and going North—and kept his eyes open and let nothing escape him. Consequently, he had much to tell and tells it in Lyd-ton's style. While he did not intend to do so, he has made his book instructive, and so the time spent in reading it will not be thrown away. But it is also interesting and entertaining, and this is what he intended it should be. While "Panama and the Sierras" is not as pretentious a volume as "Over the Hookah," nor possibly as deserving of praise from the literary point of view, yet it is one that will add luster to the author's name and insure his right to be placed among that steadily increasing class—The Physician in Literature.

THE PHYSICIAN'S VISITING LIST (Lindsay and Blakiston's) for 1901. Fiftieth Year of Its Publication. Price, \$1.00. Philadelphia: P. Blakiston's Son & Co.

As the title-page indicates, this handy little book completes with this year its half century of usefulness. It is in convenient, pocket form, and neatly but substantially bound. It contains: calendar, metric system, table for converting apothecaries weights and measures into grams, dosage table, notes on asphyxia and apnea, comparison of thermometers, and obstetric table. The blank leaves are for visiting list, memoranda, addresses of patients and nurses, accounts asked for, wants, engagements, record of births and deaths, cash accounts, etc.

THE MEDICAL NEWS VISITING LIST. 1901. Thirty Patients per Week. Leather; pp. 192. Price, \$1.25. Thumb-letter index, 25 cents extra. Philadelphia and New York: Lea Brothers & Co.

This annual volume, which is indispensable in its way to every practitioner, has been very neatly gotten out by Lea Brothers, containing an arranged visiting list with the usual accessories, dosage table, poisons and their antidotes, method of examination of urine, a comparative table of the different thermometers and scales, and a table of weights and measures, with also surgical directions as to certain operations, such as ligation of arteries, and a list of remedies for all the disorders commonly met with. The book altogether is conveniently arranged. The thumb index for the departments is a feature which enhances its convenience.

HEART DISEASES IN CHILDHOOD AND YOUTH. By Charles W. Chapman, M.D. Durh., M.R.C.P. Lond., Physician to the National Hospital for Diseases of the Heart. With an Introduction by Sir Samuel Wilks, Bart., M.D., F.R.S., Physician Extraordinary to H. M. the Queen. Cloth; pp. 98. Price, 3s. 6d. London: The Med. Publishing Co., Ltd.

This little book is offered to the medical public as containing an account of the more common forms of cardiac affections as they occur in young persons. The author has omitted a consideration of the acute cardiac disorders which are for the most part complications of the general febrile states, such as rheumatic fever, and are therefore only incidentally touched upon. The book is largely made up of case records, with critical remarks appended, and it will be found an instructive work for reading by the general practitioner. Special attention is given to certain questions, such as education, sports, etc., in children, which are practical points whose inclusion will be appreciated. We agree with Sir Samuel Wilks in the introduction when he says the author has produced a book of great interest and value.

Book Notices.

PANAMA AND THE SIERRAS: A Doctor's Wander Days. By G. Frank Lyd-ton, M.D. Illustrated from the author's original photographs. Price, \$1.75. Chicago: The Riverside Press, 1900.

Association News.

Research Fund.

The Committee on Scientific Research of the American Medical Association desires to announce that it has available the sum of five hundred dollars for the assistance of researches to be undertaken in the next six months, and that the money will be appropriated if applications be received within the month of January, 1901. Applicants should state clearly the character of the research to be undertaken, and the facilities at their command. Address Dr. H. C. Wood, chairman, 1925 Chestnut street, Philadelphia.

Societies.

Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

Medical Association of Nevada, Reno, Jan. 7, 1901.

Pan-American Medical Congress, Havana, Cuba, Feb. 4, 1901.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

THE MARYLAND OPHTHALMOLOGICAL AND OTOLOGICAL SOCIETY, at its annual meeting, elected Dr. Hiram Woods president and Dr. Henry O. Reick secretary-treasurer.

THE KEOKUK (Iowa) MEDICAL SOCIETY has been reorganized and has elected the following officers: Dr. Wilson W. Holmes, president; Dr. R. K. Taylor, vice-president, and Dr. Horace A. Kinnaman, secretary.

THE KENOSHA COUNTY (Wis.) MEDICAL ASSOCIATION met at Kenosha, December 6, and elected Dr. William R. Cheever, president; Dr. Helen Harbert, vice-president; Dr. Paul P. Jorgensen, secretary, and Dr. George T. Kimball, treasurer.

THE SIOUX CITY (Iowa) MEDICAL ASSOCIATION was organized December 7, with the following officers: Dr. George Schott, president; Dr. Van Buren Knott, vice-president; Dr. Marshall E. Silver, secretary, and Dr. John N. Warren, treasurer.

THE SUMMIT COUNTY (Ohio) MEDICAL SOCIETY met at Akron, December 4, and elected Dr. Herman C. Thiess, Akron, president; Dr. Ezra H. Tobias, Inland, vice-president; Dr. Edward A. Monteyoli, Akron, secretary, and Dr. Charles E. Norris, Akron, treasurer.

THE MONTGOMERY COUNTY (Ohio) MEDICAL SOCIETY held its annual meeting at Dayton, December 7, and elected Dr. John S. Beck, president; Dr. Francis C. Gray, vice-president; Dr. Horace Bonner, secretary; Dr. David C. Liehlter, treasurer, and Dr. Duff W. Greene, censor.

THE DELAWARE COUNTY (Ind.) MEDICAL ASSOCIATION at its annual meeting held at Muncie, December 7, elected Dr. George R. Green, Muncie, president; Dr. Charles W. Smith, Selma, vice-president; and Dr. Ulysses G. Poland, Muncie, secretary and treasurer.

THE MINNESOTA VALLEY MEDICAL ASSOCIATION, whose twentieth annual meeting was noticed briefly in the last issue of THE JOURNAL, elected the following officers: Drs. Oliver H. McMichael, Vernon Center, president, Drs. W. S. Fullerton, Minnesota Lake, W. J. McCarthy, Madelia, and Jared W. Daniels, St. Peter, vice-presidents; Dr. George F. Merritt, treasurer, and Dr. Edwin D. Steel, Mankato, secretary.

THE ROCK COUNTY (Wis.) MEDICAL SOCIETY held its annual meeting at Janesville, December 8. The subject for discussion was "Erysipelas," and afterward the following officers were elected: Dr. James Mills, president; Dr. Samuel B. Buckmaster, vice-president; Dr. George W. Field, secretary; Dr. Ransom W. Eldon, treasurer, and Dr. Quincy O. Sutherland, censor, all of Janesville.

THE INDIAN TERRITORY MEDICAL ASSOCIATION held its twenty-fourth semi-annual meeting at Muskogee, December 4. President Dr. Le Roy Long, Caddo, in the chair. In his address, the president recommended that plans be formulated to secure congressional legislation for an insane asylum for the Indian Territory and for a system of public health boards, and a committee was appointed to take these matters in charge. Vinita was selected as the place for the June, 1901, meeting of the society.

THE ORLEANS (La.) PARISH MEDICAL SOCIETY held a meeting, December 8, at which the following officers were elected. Dr. E. D. Denegre Martin, president; Drs. Herman E. Gessner, Louis G. LeBeuf and George Stumpf, vice-presidents; Dr. W. M. Perkins, recording secretary; Dr. Marion H. McGuire,

treasurer and Dr. Sidney P. Delaup, librarian. These officers constitute the executive committee, and, with Drs. Henry D. Bruns, John Callan and Thomas S. Dabney, the board of directors. Dr. Marcus Feingold read an interesting report on the results of the examination of the eyes of 141 Jewish school children. Contrary to the common belief, hyperopia was more prevalent than myopia—a fact which explains the predisposition of the Jewish race to glaucoma. Syphilitic eye disease was entirely absent. Dr. W. M. Perkins exhibited a new plaster knife and demonstrated its application on a cast. The prominent features are: a heavy wooden handle and a strong blade, triangular on cross-section, sloping from back to edge so as to form a projecting point. The blade can be projected from or sunk into the handle by a screw.

Philadelphia Pathological Society.

Meeting Nov. 8, 1900.

President Dr. F. A. Packard in the chair.

Dr. ARTHUR V. MEIGS read a memorial address on the death of Dr. Jacob M. Da Costa.

MECHANICAL IMPROVEMENTS.

Dr. W. M. L. COPLIN exhibited an improved mechanical stage for Dölkens's microscope, which he had devised. To this he had added a wider mechanical stage for studying large serial sections, allowing a movement of $2\frac{1}{2}$ inches horizontally. A fine adjustment may also be obtained. The speaker had also devised a drawing attachment with detachable colored glasses, which slip into the cylinder of the microscope through a slot; it is useful in making drawings. Its disadvantage, however, is that it can not be used with a fluid mount. He had also modified the older form of dissecting microscope so that the elbow of the instrument allows the lenses to be rotated horizontally without changing the focus up or down. The instrument also has the advantage of an extremely long arm, thus allowing for examination of embryonic specimens.

A POSSIBLE SOURCE OF INFECTION.

Dr. M. P. RAVENEL devised a kind of nose-bag to be placed over the head of cattle so as to catch the mucus expelled by them. The nose-bag consisted of a piece of thick canvas with a rounded elbow of such size as to admit the apparatus being adjusted. It was divided into two compartments at the bottom by means of a wire screen so that on one side guinea-pigs could be placed and left exposed to the infective material ejected by the diseased cattle. He had at times examined certain solid particles coughed up by the infected cattle and found them loaded with tubercle bacilli. Of five animals he had made thirty-four examinations of such particles and found tubercle bacilli twenty times. Of forty guinea-pigs left exposed to the material ejected by these animals and confined in the nose-bag twenty became tuberculous.

XYGOTES OF PROTOZOOMA.

Dr. ALBERT WOLDERT exhibited a specimen of middle intestine of amoebae infected with the xygotes of protozooma Labbé, which had been loaned through the courtesy of Dr. Ronald Ross, of the Liverpool School of Tropical Medicine. The specimen had been obtained by Ross in 1898 during some of his earlier work in regard to the subject of the inoculation of malarial fever through the medium of mosquitoes. In this specimen there were upward of 200 xygotes. They could be plainly discerned with a low power lens, but studied to greater advantage with a 1 12 oil-immersion. With the oil-immersion they might be described as being cells more or less round in shape, having a thick, yellowish or hyalin capsule, and in the interior containing a few bright reddish pigment granules, and numerous fatty particles having a yellowish or hyalin tint. The protoplasm had a reticulated appearance and in a few localities slit-like vacuoles could be seen. The xygotes were located somewhat superficially and seemed to lie within the muscular layer of the middle intestine, that is, they were usually found lying on the epithelial cells of this organ. They were from two to three days old and ranged from 7 to 15 microns in size.

Dr. SIMON FLENNER saw recently in Cambridge, Eng., Dr. Nuttall's specimens showing the xygotes of the malarial parasite in all stages, in the middle intestine of the mosquito.

MICROSPORON FURFUR.

DR. M. B. HARTZELL made some remarks relative to the finding of the spores of the microsporion furfur in a case of tinea versicolor, and exhibited photomicrographs. Some writers had said that this organism did not invade the hair follicle, but in one case which he had recently examined and stained with gentian-violet he had been able to detect the spores extending downward throughout the hair follicle as well as in the horny layer. These findings were important from the standpoint of treatment.

PRESENTATION OF SPECIMENS.

DR. A. O. J. KELLY presented specimens from a man who had died of sepsis due to an injury of the bladder received several years ago. The bladder walls were almost an inch thick. The man was also suffering from ulcerative colitis.

DR. WM. G. SPILLER exhibited specimens stained by the Mallory method for neuroglia tissue.

DR. W. M. L. COPLIN exhibited a specimen of perforation of the esophagus. In this instance the opening was almost 2 inches in diameter.

Meeting Nov. 22, 1900.

President Dr. Frederick A. Packard in the chair.

GLIOMA OF RETINA.

DRS GEORGE E. DE SCHWEINITZ and EDWARD A. SHUMWAY reported two cases of glioma of the retina. Dr. De Schweinitz states that in Case No. 1 the posterior region of the eyeball was filled with a grayish mass, which also involved the optic nerve. In certain areas there were deposits of lime salts. In other regions were thick masses of cells, some of which had lost their staining properties. The blood-vessels were thickened and showed hyalin degeneration. The cornea was thin and showed staphyloma. None of the rosette formations described by Wintersteiner had been observed.

The second case was that of a boy who had been suffering for about a year. The anterior chamber was filled with the grayish mass. Stained with eosin and hematoxylin, one portion of the mass stained well, while others had lost this property. The sclera was infiltrated, lens cataractous. None of the masses showed the rosette formations which had been described. As to the etiology of this condition Virchow holds to the belief that they spring from the neuroglia cells. Wintersteiner lays stress on the rosette-shaped cells. He calls such formations neuro-epithelioma of the retina. Of 550 cases there had been metastases to the liver in 61 instances. Besides this locality metastasis had also occurred in the brain and mesenteric glands.

DR. SIMON FLEXNER stated that these formations differed considerably from what is known as tubular sarcoma. This is best studied when the tissue is mounted in glycerin. The rod and cone formation differs widely from that of sarcoma. He had examined a brain and found that the structure was the same as that stated elsewhere.

PARASITIC HEMOPTYSIS.

DR. CHARLES WARDELL STILES, Washington, reviewed the history of the subject and stated that Kerbert in 1878 in examining the lungs of a tiger found a peculiar parasite. In 1880 Manson also found a parasite of a similar kind in man. Writers in Japan and China had reported similar findings. Comparing these reports, it was found that the parasite which had been first found in animals and later in man, by many other observers, was identical. Examining the question further it was found that the parasite was what is termed *paragonimus westermanii*, which is very common among hogs in this country and is communicable to man. Post-mortem the disease might be mistaken for that of tuberculosis. It is essentially an Asiatic disease, and is very common in the Philippine Islands. The latter fact should cause the physicians of America to become acquainted with the condition, since there are now in those islands 65,000 soldiers, and it is safe to say that some of them will bring the disease home with them. Some believe that it is contracted by drinking contaminated water. The intermediate host has been proved to be a snail. As the disease mostly attacks the lungs the infectious agent is thrown off in the sputum, which should always be disinfected. The

dry cuspidor should be employed, since it thrives in liquids. Dogs are also susceptible to the disease, and in eradicating it infected dogs should be destroyed. It has been proved that the parasite must first pass through a snail before it can infect man. In England the disease is termed parasitic hemoptysis, a term proposed by Patrick Manson. It is very common in Japan, Korea, China and in the Philippines, where there is a kind of endemic hemoptysis. As to its frequency it is stated that in Japan there are certain towns in which 15 per cent. of the inhabitants are infected. In other places it is believed 25 per cent. are infected. The speaker had collected 59 cases. Of these 45 persons affected had been between the ages of 11 and 30 years. In the majority of instances the disease occurred among men; 38 persons had been farmers, which may be accounted for on the nature of its cause. The disease is of a chronic nature and may last for 20 years. The treatment is absolutely hopeless. There may be some cough, slight fever and cough, hemoptysis with cavity formation. The disease can be quickly diagnosed by examining the fresh sputum, when the eggs of the parasite may be found. The eggs are oval or elliptical in shape with a more or less darkened extremity. The full-grown parasite is somewhat elliptical in shape, $\frac{1}{2}$ inch long and probably $\frac{1}{4}$ thick in the middle. It is greenish-white in color. While the disease occurs most frequently among hogs, cooking will always destroy the eggs of the parasite. On this account the government could not go so far as to have these infected animals killed. [See editorial comment in this issue.—Ed.]

DR. HENRY BEATES believed the time was near at hand when the medical schools of this country should give a course in medical zoology.

EXHIBIT OF SPECIMENS.

DR. F. S. PEACE presented a specimen of hemorrhage into the pons and crus, with paralysis. The symptoms were simply those of cerebral hemorrhage.

DR. JOSEPH MCFARLAND exhibited a specimen of intestine in which the patient died from intestinal obstruction from a Meckel's diverticulum which had been simply inverted into the gut. He also showed a detached thrombus which had formed in the auricle, and another which had formed in the ventricle of the heart.

Philadelphia Academy of Surgery.

Meeting held Nov. 5, 1900.

President Dr. De Forest Willard in the chair.

INFECTION BY THE AEROGENES CAPSULATUS.

DR. JOHN B. ROBERTS reported a case of infection by the bacillus aerogenes capsulatus in an open fracture of the radius and ulna. The patient last August fractured both bones of the forearm, one bone making a small opening externally. The fracture had been dressed antiseptically. Dr. Roberts had seen the case three days after the injury occurred, at which time there was a small focus of skin near the edge of the wound that had a gangrenous appearance. The wound was opened, the gangrenous area cut away, wound thoroughly drained, and afterward dressed. High fever followed a few days later, and rubicasts were found in the urine. The wound was again examined, and it was found that the gangrenous process had extended higher up the arm, and amputation became necessary. The tissues had a crepitating feeling, as though a large amount of gas had formed in them. Two days after the amputation had been done, urticaria developed, and a small area of gangrene was on one of the flaps. The flaps were opened and the wound drained. Within a day or two the black gangrenous area became mummified. He had dissected the portion of arm removed and found that the blood-vessels had not degenerated, but clots were present in the arteries. Cultures had been made of the fluid from around the wound and smear preparations were also examined. In the former instance Drs. Flexner and Kness had found pure cultures of the bacillus aerogenes capsulatus recently described by Welch. He believed that infection by this organism had occurred at the time of fracture.

DR. MILLER thought it was strange we did not see more cases of infection by this bacillus.

DR. ROBERTS, in reply to a question, stated that he was unacquainted with that form of rapidly spreading gangrene, such as seen during the Civil War, so that he could not answer the question definitely. He believed that there might be some relation existing between this form of gangrene reported and malignant edema.

DR. F. T. STEWART (by invitation) reported two cases of appendicular abscess in the left side, in one of which there was abscess of the lung and pyothorax.

DR. H. A. WILSON reported a case of fracture of the femur in an infant, with osteotomy for deformity. He further reported two other cases operated on by Dr. H. M. Sherman, of San Francisco.

The patient had been an infant three months of age, in which there was found marked fullness just below the great trochanter with apex pointing forward. There had been no shortening. On May 5 an incision showed that the mass was a large callus. Osteotomy was done and the parts put in good position. A plaster-of-paris bandage was applied and good union followed.

DR. E. P. DAVIS gave a demonstration of how fractures in these cases might occur, and how best to prevent them. In doing version it is sometimes exceedingly difficult to prevent fracture of one of the long bones. In podalic version, one should be careful to rotate the head upward as far as possible before bringing the feet downward. In one case he had intentionally fractured the clavicle so as to permit the shoulders to droop forward and thus assist birth of child. In one case about ten days after birth he had found a fracture of the femur, and had last year seen a case in which the humerus had been fractured at birth caused by traction on the arm, made by an inexperienced person.

DR. W. REYNOLDS WILSON spoke of the manipulation necessary in these cases. In one case of breech presentation he had felt something give, and on examination found that this sensation had been due to the slipping of the child's head through a contracted pelvis. He believed that many cases of fracture occurring during birth were due to faulty development of the bony structures.

DR. J. H. JORSON spoke of a case which he had treated by means of a posterior splint, with good results.

DR. H. R. WHARTON believed that many of these cases of fractures supposed to occur during labor were really due to falls after birth.

DR. L. W. STEINBACH had seen one case of fracture at the upper third of the femur. He had used an inclined plane in the treatment with a wire on the posterior surface, with good results.

DR. DE FOREST WILLARD, in cases of fracture of this character, was in favor of making traction applied to the foot. In most cases which he had known, such had been caused by traction made on a hook placed in the groin.

DR. GEORGE G. ROSS read a paper entitled "Angina Ludovici with Report of a Case."

Meeting held Dec. 3, 1900.

President Dr. De Forest Willard, in the chair.

EXCISION OF LYMPHOSARCOMA OF NECK.

DR. W. JOSEPH HEARN reported a case of operation for lymphosarcoma of the neck, in which it was necessary to sever the pneumogastric, phrenic, recurrent laryngeal and sympathetic nerves and part of the thoracic duct.

The patient was a physician aged 50 years, who had first manifested symptoms of the disease in July, 1898. At this time the face became swollen, which he attributed to catching cold. In the fall of the same year he observed that a small tumor made its appearance under one ear, which was later followed by enlargement of the glands of the neck. In July, 1899, some of the enlarged glands of the neck were removed, and on microscopic examination the disease proved to be one of sarcoma. In September, 1899, the glands were again enlarged, and an operation was decided on. The speaker had been assisted in the operation by Drs. Kean, Taylor and Roe. After the incision had been made the carotid artery and jugular were located and separated. The tumor had so involved the pneumo-

gastric, phrenic, sympathetic and recurrent laryngeal nerves that it was impossible to dissect them out, so they had all been severed. It was observed that when the pneumogastric had been cut, the pulse, which had been immediately before somewhat slow, immediately afterward became rapid. When the phrenic was served the abdominal muscles showed a somewhat spasmodic movement. After the thoracic duct had been severed only little chyle escaped, which was probably owing to the small amount of food taken by the patient previous to the operation, but it became more abundant about the tenth day. The patient made a good recovery from the operation and subsequently lived in comfort for many months, but owing to a recurrence of the growth in the region of the sternum and evidences of toxemia death ensued in March, 1900. One interesting feature was that there had been no aphonia, which is said to follow section or disease of the recurrent laryngeal nerve.

DR. W. J. TAYLOR stated that he had assisted at this operation, and believed that it had been the most extensive dissection he had ever seen.

CASE REPORTS.

DR. H. R. WHARTON reported; 1, a case of cholecystotomy; 2, a case of compound fracture of the tibia and fibula, with complicated fracture of the condyle of the femur; 3, a case of left inguinal colostomy for imperforate rectum; 4, a case presenting intermittent symptoms of appendicitis due to a fibrous band. In the cholecystotomy case it was found that a stone had lodged in the cystic duct, while others had been found in the gall-bladder and in the common duct. A biliary fistula had been established and good recovery ensued. In Case No. 2 the X-ray had shown the inner condyle imbedded in the knee-joint, which was opened, and the fragments removed. The limb was afterward kept in an extended position and recovery followed with moderately good motion. Case No. 3 was that of an infant three days of age on whom a left inguinal colostomy had been done. At the end of three months the child appeared to be in good condition. In Case 4 a fibrous band had been found to be attached to the head of the colon and extended downward across the appendix, thus causing either its obstruction or that of the bowel. The speaker also referred to a case of double hare-lip that he had treated in which he had freshened the edges of the wound and allowed the bones to fall inward, thus making a moderately good septum.

OPERATIVE TREATMENT OF CIRRHOSIS OF LIVER.

DR. CHARLES H. FRAZIER reported a successful case; with exhibition of the patient. He was beyond middle life and had suffered from the disease for several years, and on account of the obstinate ascites and other manifestations had been regarded as an incurable one. He had been sent from the medical side of a hospital to the surgical department. An incision had been made extending for several inches, beginning at a point in the median line and below the umbilicus. The fluid had been evacuated, after which the peritoneum over the region of the spleen, near the liver and near the points of the incision, had been rubbed with a gauze pad so as to guarantee adhesions. The diaphragm had also been scarified. The patient had made a good recovery from the ascites. This operation seemed justifiable because it promoted a better venous circulation.

DR. JOHN B. DEEVER had seen a cure of ascites result from simple tapping, and Dr. H. R. Wharton had once done an abdominal operation on a patient suffering with ascites, resulting in a cure of this condition.

TORTICOLLIS.

DR. DE FOREST WILLARD exhibited several cases of torticollis of different types. He believed that one should not be hasty in making a prognosis of such cases when seen for the first time. Many of them seemed obstinate. In some instances a system of gymnastics would be beneficial, while in others it did little good. If there is a neurotic element present, the case will be more refractory. He had seen one interesting case in which there had been marked retraction and rigidity. An operation had been decided on, but on giving an anesthetic all deformity had disappeared, and the operation was deterred. It was believed the case had been one of hysteria.

FRACTURE BANDAGE.

DR. WM. G. PORTER made some remarks on fractures of the leg and exhibited a plaster-of-paris bandage. In cases of fracture he now rolls the parts with a flannel bandage, applies a tin plate and invests the whole with a plaster-of-paris bandage. After this dries somewhat, it is split down the middle and thus conforms to the parts very accurately. It may also be used in injuries of the joints.

Chicago Society of Internal Medicine.

Regular Meeting held Oct. 25, 1900.

President Dr. John A. Robison in the chair.

MEMBRANOUS COLITIS.

DR. JOHN A. ROBISON delivered the Presidential Address, and chose the above subject. He divided the causes into primary, as enteroptosis, infection, bacterial fermentation, intestinal calculi and lack of digestive ferments; and secondary causes, as dyspepsia, traumatism and grave cachectic conditions. The disease most frequently attacks young women who are small-boned, muscular, neuropathic individuals. The face and conjunctivæ are pale and eyes bright, the lips and mucous membrane bluish, and the face is an anxious one. Eruptive skin diseases are frequent. The pulse is usually normal and there is seldom fever in uncomplicated cases. Orthopnea, muscular weakness and insomnia are common and distressing symptoms. Neurasthenic symptoms, especially those of a peripheral neuritis, are frequently met with. The tongue is dry, covered with a thick coating and bleeds easily. The gums are spongy. The breath has a fecal, sometimes urinous, odor, especially in the morning. There may be a peculiar persistent, metallic taste in the mouth. Appetite is good; rarely vomiting, but nausea is common. The stools are most frequent in the early morning and vary from 10 to 40 per day. They are thin, foamy, watery, sometimes bran-like. They may contain much mucus and shreds of tissue. Severe rectal tenesmus frequently precedes the discharge of the membranes. Epigastric pain frequently occurs soon after taking food. It is described as a gripping, contracting feeling. It is usually followed by a bowel movement. The abdomen is more or less tympanic and very tender along the outline of the colon. In cases of enteroptosis there is a dragging sensation with pain in the lower abdomen. Pain is increased by pressure and relieved by heat. Intestinal peristalsis is usually palpable. The urine is scanty, high-colored, of high specific gravity, and frequently contains indol. Transient albuminuria occasionally occurs. Renal insufficiency is exceedingly common. The blood is leukemic in character in severe cases. The venous congestion under the finger-nails is more intense when there is much tympany present. Chemically, the membrane consists of albumin; there is no fibrin. There may be fresh blood on it and it usually contains the bacillus coli communis. Women often have amenorrhœa, ovaritis and left salpingitis. The discharge of membranes may occur at intervals, the patient enjoying good health during the interval. Business cares and domestic worries aggravate the case. A disturbance of the nervo-secretory balance is probably the usual underlying cause of the affection. Although the disease is almost invariably a chronic one and the mortality rate low, the prognosis must be guarded. Medicinal treatment is of no avail. Enteroptosis must be treated surgically. Dyspepsia of the gastro-intestinal tract and intestinal infections should receive appropriate treatment. The diet, in most cases, should be ample, varied and easily digestible. The food should be well cooked and nourishing. Rich soups, gravies, sweets, greasy meats and indigestible fruits and vegetables, as well as pastry, should be avoided. Wines containing tannin are allowable. A flannel abdominal bandage should be worn continuously to avoid chilling, as it increases intestinal congestion. Exercise in the open air and sunshine should be insisted on. The mental condition must be well looked after. Renal insufficiency calls for saline diuretics and an occasional hot-air bath. Hot water flushings through a soft rubber tube tend to relieve rectal irritation and in all but the severe cases high, hot colonic flushings are very beneficial. Great care must be exercised in

the giving of the flushings. Never give opiates, astringents or irritating drugs. Intestinal antiseptics, digestive ferments, and partially digested foods are valuable. The best intestinal antiseptics, in these cases, are bismuth salicylate, salol, benzoic acid, menthol, guaiacol carbonate, betanaphthol and creosote. Each individual case requires separate treatment according to the symptoms present.

DR. J. M. PATTON reported a case in which the course of the disease was as described by Dr. Robison.

DR. ROBERT H. BABCOCK said that he had a case three years ago which he thought was one of membranous colitis. The patient had suffered from diarrhea for years and every possible treatment had failed to produce any result. His breath had a peculiar odor; the colon was contracted and easily palpable and tender, and he had lost control of his sphincters. He had been on an absolute milk diet at one time and a nearly absolute meat diet at another without benefit. Dr. Babcock put him on a diet of vegetables, fruits, nuts and cereals, prohibiting all animal food, and a simple intestinal antiseptic was given as a placebo. At the end of a month he had improved considerably, all symptoms having disappeared and the discharges were limited to four a day. At the end of five or six months he was perfectly well. The trouble recurred with a slight lapse in diet. A year and a half afterward the man returned, presenting every symptom of pulmonary tuberculosis. He died some time afterward, and on post-mortem a large retroperitoneal carcinoma was found.

DR. EDWARD F. WELLS referred to a class of cases in which the false membrane has a fibrinous appearance and is discharged in large quantities and in long cords.

SOME CARDIOPATHIES OF THE DEVELOPING PERIOD.

DR. A. C. COTTON read this paper, and urged the importance of a more systematic study of the heart during infancy and childhood. Knowledge derived exclusively from the study of adult hearts is too frequently misapplied in the consideration of disorders of early life. The normal progressive changes in the young heart in its relationship to the other vessels and organs during the growth period are either not sufficiently understood or too often overlooked in our efforts at clinical differentiation. There are two classes of heart lesions, namely, the congenital and acquired, or post-natal. Of the congenital class Osler makes three divisions, which the author quoted.

The author reviewed the signs and symptoms of congenital cardiac disorders. He also quoted Townsend's report of 30 cases with regard to duration of life, presence or absence of cyanosis, cardiac signs, blood findings, and cited his own clinical records on these points. Concerning acquired or post-natal heart disorders, he believes their frequency in infancy is not fully appreciated; that their presence is frequently unrecognized in children, because, 1, they are not always sought for; 2, the young are examined with difficulty; 3, lesions are often masked by more obvious symptoms of the primary infectious disorders; 4, the symptoms are often indefinite, merely a listlessness or indifference to play, often only dyspnea, or merely tachypnea.

As to treatment, the writer emphasized the need of heart rest, to be secured by any means of procedure that is not contraindicated. Drugs, having an alleged direct influence upon the heart, are to be kept in the background.

DR. ROBERT H. BABCOCK said that congenital cardiac affections are of interest not only from a pathologic but also from a diagnostic standpoint, because they are so difficult to diagnose. It may be possible for the physician who sees the case from birth to make a rough diagnosis of the existence of a congenital affection, but for the consultant, who sees a child years afterward, it is sometimes exceedingly difficult to give whether the affection is a congenital one, and if it is to give its exact nature. Histories of early infancy are unreliable because of their obscurity. He has seen several cases which he thought were congenital, but owing to the fact that a post-mortem could not be made the diagnosis was not verified. He cited the case of a young woman who complained of rapid heart action. There was a pronounced murmur accompanying the first sound in the mitral area. Over the upper por-

tion of the sternum there was a very peculiar murmur which extended throughout the whole cardiac cycle, presenting periods of exacerbation, but never wholly ceasing. There was a well-recognized hypertrophy of the left ventricle and hypertrophy and dilatation of the right ventricle. It was diagnosed as a case of mitral regurgitation with probably a patent foramen ovale. The blood examination showed a well-marked chlorosis. The patient died three or four years afterward and on post-mortem there was found stenosis of the organ just beyond the point where the ductus is given off; a persistent ductus arteriosus; the valves were all intact; the left ventricle enormously hypertrophied; the right ventricle showed no enlargement. That simply illustrates the difficulty of making the diagnosis of what would seem to be such a simple matter as a patent foramen ovale—one of the commonest congenital defects compatible with life. The frequency with which acquired cardiac diseases occur in children is not recognized, because the rheumatism from which they suffer is so atypical, so insidious, that its existence is not suspected. Very frequently the first manifestation is an endocarditis. Objective symptoms are easily recognized, but subjective symptoms are often wanting. It is remarkable how little dyspnea a child will be conscious of, and yet to the observer the rapid breathing gives ample evidence of the cardiac impairment, to say nothing about the tumultuous action of the heart of which the child is unconscious. Acute myocarditis is also often overlooked in children. We know of nothing that is pathognomonic of it. The instability of the pulse is a very suspicious phenomenon, but if acute myocarditis is overlooked it is not a reflection on the physician because it frequently presents no very manifest clinical features. The prognosis of cardiac disease in children is serious just as in the other extreme of life. Although the heart of a child is capable of wonderful adjustment to difficulty it is, nevertheless, rapidly exhausted. The prognosis is unfavorable also because of the emotional excitable nature of the child. It can not exert the self-control which is so essential for the preservation of compensation. Furthermore, the heart may rapidly acquire a size far out of proportion to the capacity of the child's chest thus disturbing the circulatory balance. Parents are loath to exert the restraining influence on the young child suffering from heart-disease. The child is fretful and the parents are unwilling to insist on such a regimen as will offer a possibility of prolonging life. Rheumatism in children frequently manifests itself as a tonsillitis and the physician should be alive to its dangers.

DR. LUDWIG HEKTOEN said that in speaking of myocarditis in children, reference should be made to syphilitic myocarditis in congenital syphilis, as it may be the cause of sudden death. He has had occasion to study two cases of interstitial proliferations in the myocardia due to a congenital syphilis. Dr. Cotton's first case of aortic-pulmonary communication is, as far as we know, the first one reported in America and the tenth in literature. In all these ten cases the anatomical conditions were the same. The defect is the result of a developmental anomaly in the septum between the pulmonary artery and the aorta. It is to be distinguished from accidental communications, which are much more frequent and are produced by aneurysms, ulcerative aortitis and similar lesions; also to a persistent, large, and unusually short ductus arteriosus. The sexes are equally represented in these ten cases. The age varies from a few days to thirty-four years. Half of the cases live to be more than 4 years of age. Those cases that lived to be older than 4 years presented well-marked symptoms of heart disease, which were in no way distinctive of the existing condition. Many of the writers refer to the presence of double murmurs at the base of the heart. Cyanosis was observed in many of the cases, but it would be difficult to distinguish between cyanosis due to this communication and cyanosis due to failure of the myocardia late in the disease. Sometimes there is a communication between the aorta and the right ventricle which depends on failure of union between the septum of the bulb and the interventricular septum. As regards the second case, while the mitral and aortic valves were irregularly thickened, there is some question as to whether

that could be designated as the result of endocarditis. The valves are smooth and the thickening might be due to irregularity in development. There is a bulging at the junction of the aorta and the interventricular septum and a passage beneath a fully developed anterior aortic valve. In the bottom of this bulging, which is quite aneurysmal in appearance, is situated the opening of the right coronary artery. The smoothness of the wall of this bulging and the perfect condition of the valve seems to speak against aortitis or endocarditis and in favor of a developmental defect. It is impossible to speak definitely on this point, because lesions in intrauterine life heal perfectly. If the defect is to be regarded as being developmental how can it be explained. Dr. Hektoen has studied this question quite thoroughly and has arrived at the conclusion that it is the result of defective development in the septum of the bulb which divides the bulb into the pulmonary artery and aorta, and which, when it unites with the interventricular septum, completes the division of the bulb into the pulmonary artery and aorta and the heart into the left and right ventricle. Two ridges, one anterior and one posterior, help to close the original opening between the two ventricles of the heart. In the case presented there seems to have been delay in the closing of the septum, although the aortic valve developed normally. The embryology of the semi-lunar valves in the human body has not been extensively studied. We know, however, that before the bulb divides into the pulmonary artery and aorta two endothelial cushions appear, one at the beginning of the ridge which forms the beginning of the septum, and as the septum develops these two cushions divide into two additional cushions, thus giving two on each side. These are subsequently hollowed out and form the leaflets of the semi-lunar valves. Vierordt suggested that this hollowing-out process may spread to the septum between the aorta and pulmonary artery and thus give rise to the aortic-pulmonary communication described in Dr. Cotton's first case. It is, however, difficult to understand how the hollowing-out process jumped from a semi-lunar valve to the wall of the aorta. The same explanation might be applied to the defect in the semi-lunar valve in Dr. Cotton's second case, but it meets with the same difficulty there. Defects in the septum between the pulmonary artery and the aorta may lead to three conditions: 1, communication between the aorta and pulmonary artery; 2, communication between the aorta and right ventricle; 3, communication between the aorta and left ventricle under the semi-lunar valve. This is the only case of its kind in medical literature. Bands of different kinds have been found extending across the root of the aorta, but no defect of this character. If these communications are developmental in their origin, they date back to about the sixth week of intrauterine life, because at that time the septum between the pulmonary artery and aorta is complete.

DR. GEORGE W. WEBSTER said that congenital endocarditis occurred with great frequency without exhibiting any known symptoms or reasonable evidence of rheumatism on the part of the mother. These cases of fetal endocarditis involving usually the right side of the heart, contrast strongly with the acquired endocarditis which involves the left side of the heart. The explanation of this probably lies in the fact that the various micro-organisms capable of producing infection and inflammation develop more readily in the venous blood in the left side of the heart after birth, and just as readily in the venous blood found in the right side of the heart previous to birth. It is well known that in cases of congenital or fetal endocarditis they are very prone to attack the pulmonary orifice.

In regard to the diagnosis, he has had three cases under his observation during the last two years and in all of them one of the notable points was the increase in the percentage of hemoglobin, as high as 120 in one case. Another feature was the impaired physical and mental development. One of the patients, a boy of 11, was not larger than a boy of 3½. His intellectual impairment was so great that up to that time he had not been able to memorize all of the alphabet. He would learn three or four letters a day, remember them for that day, but promptly forget them by the next day. He slept most of the time. The cyanosis in all his cases has been more marked

than occurs in any acquired disease of the heart where any other than the pulmonary orifice is involved. He attributes the cause of this to the lessened tissue change which is present in these cases and evidenced by both physical and mental impairment. These cases probably terminate earlier because of the condition of the heart, the impaired circulation and the deficient aeration of the blood. Another reason is that while any defect or deformity or disease of the other valves of the heart rather protects against a pulmonary tuberculosis, with the possible exception of mitral stenosis, stenosis of the pulmonary orifice predisposes to pulmonary as well as to general tuberculosis, from which they are very liable to die. When the heart develops to an extent quite out of proportion to the development of the coronary artery, the tissue of the heart must suffer in its blood supply and this will ultimately destroy life. He emphasized the fact that in children and youths, contrary to what is taught in text-books, the pulmonic second sound is relatively louder than the aortic. As age advances, and as there is lessened elasticity in the systemic arteries and arterioles, the relative pressure in the two systems gradually changes; it becomes higher in the systemic with consequent accentuation of the aortic second tone.

The reason that pericardial effusion is so often overlooked is because the majority of physicians begin the examination of the heart by clapping on a stethoscope as soon as the chest is bared. This is wrong. The diagnosis ought to be made before the stethoscope is resorted to. Careful inspection, palpation and percussion should be made before the stethoscope is used.

DR. ISAAC A. APT, when examining the hearts of newly-born children, has occasionally heard a murmur over the upper portion of the sternum, which disappeared after four or five days. He came to the conclusion that they were due to the temporary patency of the foramen ovale. Rauefuss and Hueh-singer say that accidental murmurs never occur in children under 3 years. Fisher, of Boston, frequently heard a bruit over the fontanelle of children and called it the brain murmur. This can be heard over the back and base of the heart of young children quite frequently.

DR. J. M. PATTON thinks that murmurs ought to be classified, as has been done by several English writers, into those which are due to errors of development and which antedate the period at which the specialization of organs occurs and which embrace errors of development as acardia, dextrocardia, etc., including probably transposition of the two great arterial trunks, and murmurs due to lesions occurring after the specialization of organs has taken place. These conditions may be called pathological, whereas the previous ones belong to the department of teratology. It is in the latter class that the diseases due to fetal endocarditis belong. The middle ground covers the developmental area of the arterial bulb described by Dr. Hektoen and perhaps some of the anomalies which occur in the various valves. Much discussion has taken place as to which class they belong to. Undoubtedly the majority of cases of stenosis of the arterial cone of the right ventricle and of the pulmonary artery are probably due to fetal endocarditis. Those cases arising from failure of the arterial bulb to place itself in proper position from the twisting process it undergoes previous to the union of septum and auricle and the division of the arterial bulb, probably come under the head of developmental errors including those cases where the aorta is in partial communication with the right ventricle.

Under the second class we can take up Osler's classification: Defects of the septum, ventricles, auricles, anomalies of the valves and all the conditions he describes. The most common result of fetal endocarditis is undoubtedly stenosis of the pulmonary artery or the cone of the right ventricle. Rauefuss claims that in the absence of congenital malformation disease of the left side is just as common as of the right, and lesions of the aortic and mitral valves are just as frequent as pulmonary lesions in the absence of congenital malformation. Bouchard claims that all these lesions are due to fetal endocarditis. In regard to the marked degree of hypertrophy of the right side of the heart, we must remember the increased pressure the right ventricle is working under and some of the developmental errors are in a measure due to that cause. The septum, in

its development, is sometimes disposed so far to the left as to open a direct communication between the right ventricle and arterial bulb. The most experienced clinicians have for the last few years dwelt on the development after birth of endocarditis and pericarditis. The preference is generally given to pericarditis. Sturgis says that pericarditis in children is always accompanied by endocarditis, and that endocarditis in early life is certain to bring about a pericarditis. There is a good deal of difference of opinion as to the occurrences of functional murmurs. Senator thought they were frequent; Troussseau thought they might occur; Jacob did not think they were frequent. We must remember that cardiac cavities develop more rapidly in size than in thickness; murmurs occurring under those circumstances should not be considered as functional. If the child is vigorous, murmurs are not often heard, except when the pulse is, for some reason, rapid, when the murmur might be regarded as a functional one, unless there were distinct evidences to the contrary. Inflammations of the heart are not at all uncommon in children who have had rheumatism, according to statistics, 50 to 80 per cent. Cyanosis occurs most often with stenosis of the pulmonary artery. The cause has been attributed to mixture of the blood, but it also occurs in cases in which there is no admixture. Reeves attributed it to want of oxygenation, which probably has something to do with it. The corpuscles of the blood as well as the hemoglobin are increased. The diagnosis of these lesions is extremely difficult. It is possible to map out the heart and tell whether a murmur is present, but it is exceedingly difficult to tell what causes that murmur. We can only conclude that it is a case of congenital disease of some kind.

DR. HAROLD N. MOYER said that during the last fifteen years Rush has had over a thousand cases of chorea in his clinic. The examination of the heart was rather perfunctory at that time and when more careful examination was made they found a much larger number of heart complications than is usually stated by authorities. It is extremely difficult to impress students and assistants with the necessity of correctly examining the heart. They always want to use the stethoscope first, instead of inspecting, palpating, and then listening. The heart is examined in every case of chorea, and more than half of them have heart complications.

DR. WILLIAM J. BUTLER did not agree as to the difficulty of diagnosing congenital heart lesions. Dr. Cotton made some diagnoses and they were proved correct on post-mortem. The presence of a heart murmur in an infant immediately becomes significant of a congenital heart lesion. It is not so difficult to diagnose lesions that come to one's notice later in life as is generally conceived. The most frequent lesion is that of pulmonary stenosis, whether it involves the pulmonary artery, the conus or the valves themselves. The symptoms and signs are occasionally so strikingly typical as to be easily diagnosed. Cyanosis is very characteristic, but is not always present, as in one of Dr. Cotton's cases. The absence of cyanosis was undoubtedly due to the anemic condition of the child. In these pulmonary lesions there is invariably a murmur, sometimes so marked as to be heard some distance from the chest. They are usually accompanied by a marked chill and are heard and felt most distinctly over the pulmonary area.

Cleveland Medical Society.

Quarterly Meeting, October 26, 1900.

President Dr. Henry S. Upton in the chair.

SOME PROBLEMS IN PEDIATRICS.

DR. L. EMMETT HOLT, New York City, dealt with this subject. The present has been called the age of the child. Taking up first the present status of diphtheria antitoxin he pointed out that all its opponents who had consented to give it fair trial had been won over. Reciting the facts and statistics in detail, he showed that the mortality from diphtheria has everywhere been reduced more than one-half by the use of antitoxin, and in each locality in proportion to the vigor and extent of its employment. The proportion of laryngeal cases requiring operation has been reduced one-half, and intubation now saves 70 per cent. of cases instead of the former 30 per cent. The

physician who now treats diphtheria without antitoxin is guilty of as great criminal negligence as is a surgeon who does a laparotomy without sterilizing his hands, instruments or dressings. Immunizing doses have been too small; 500 to 700 units should be given to a child of 5 years, and 250 to 350 to an infant under one year.

Koplik's sign in measles he had found present in 90 per cent. of cases and is almost as characteristic of the disease as the skin eruption. It enables diagnosis in the majority of cases one day before the eruption; and in a few cases still earlier. When recognized there is always found to be some rise of temperature, so that its value in preventing the spread of an epidemic is not sure. It is of great value in differential diagnosis.

Infantile scurvy deserves more attention from the profession than it receives. Frequently it is called rheumatism, and at times neuritis, joint disease, or osteitis, but these diseases rarely occur so early in life—83 per cent. of cases of scurvy occurring at 6 to 15 months. Proprietary foods, sterilized milk, and condensed milk are the chief causes of the disease.

DR. L. B. TUCKERMAN said that any improvement in the feeding of children probably adds more to the sum total of health than the most marked advance in surgery. He asked the essayist if anything was known to the effect on dairy milk, and through it on children, of the feeding of cows on ensilage, a practice which has grown very common with farmers.

DR. OSCAR B. CAMPBELL said that without doubt modified milk was the best food for infants, but that practically the methods are hard to follow. It had been his experience that in very many cases the mother or some other person had interrupted the treatment by the administration of some of the proprietary foods, and had neglected to follow out the prescription. He wished to know how the man in general practice was going to carry out this method of feeding, when he had so little control of the case.

DR. JOHN L. HESS asked what had been the essayist's experience with modified milk as compared with Pasteurized milk. It had been his experience that children had thrived better upon the Pasteurized milk than they had upon the milk from the Walker-Gordon laboratory.

DR. HUNTER H. POWELL said that beyond doubt the modified milk was very superior to the ordinary Pasteurized milk, because the proportions of its constituents can be changed to suit the individual case. He asked the essayist if peptonized milk had any particular action in scarlet fever, as has been claimed by some authorities. His experience with diphtheria antitoxin has been very favorable. While the antitoxin is expensive for the poor, it yet may not cost the poor man as much as a dozen visits from a physician, which he would otherwise probably have to pay for.

DR. NATHAN ROSEWATER said that it should be noted that there are times when no food will agree with children, while after the nervous conditions have passed away the results are much better. Therefore, it should not be expected that even modified milk will on first trial agree in every case.

DR. SAMUEL W. KELLEY said that he had been very much aided in feeding infants by the establishment of the Walker-Gordon laboratory in Cleveland. However, it is possible in many cases to teach the parent to modify milk satisfactorily at home. In regard to the use of diphtheria antitoxin he said that in his practice it had not been increasing as fast as with the general profession, and he had never found it necessary to use such large doses as some recommended. He thought that 2000 or 3000 units would cure the average case. He thought that it was largely due to the influence of the manufacturers that such large doses were being used. He is suspicious that the standard preparations are little more reliable than the concentrated ones, and he wished to know what Dr. Holt's opinion was on this point. He thought that the clinical picture of diphtheria was so plain that it was seldom necessary to wait for a bacteriologic examination.

DR. HOLT, in closing, said that he did not know much about the feeding of cows, but that men who had given the matter attention thought that ensilage was a very good and a very safe food. He thinks there is some misunderstanding as to what

modified milk really is, and it seems that it is anything that the physician wants. The percentage of fat, sugar and proteids can be constantly varied to suit the physician's prescription. He thought that babies in Cleveland must have different stomachs from those in New York if Pasteurized milk suits them better than modified milk. The chief value of the laboratory is that it does things definitely, so that if the baby needs a change of food the physician can get just what he wants. If the child is spitting up milk, we know that probably less fat is required, or if it is getting fat too rapidly we should order less sugar. The milk laboratory occupies the same relation to the physician as does the drugstore.

He thought that most of the antitoxin offered for sale is reliable. It is made mainly by large firms because it requires an expensive outfit, and it is usually fresh when made by such firms as Parke, Davis and Company, Mulford and Company, and Frederick Stearns and Company. The concentration of the antitoxin has much to do with the number of doses necessary. In regard to the few sudden deaths reported from its use, he thought that it was not different from our early experiences with any other remedy.

Denver and Arapahoe Medical Society.

Regular Meeting held Nov. 27, 1900.

SUBARACHNOIDEAN INJECTION OF COCAIN FOR ANESTHESIA.

DR. JOHN S. MILLER thinks that the term "subarachnoidean injection" is more descriptive and more nearly anatomically correct than the terms "medullary injection," "medullary narcosis," "subdural infiltration," "spinal anesthesia," "cocain anesthesia" of the spinal cord, etc. This new procedure will have to pass through the ordeal of probation divided into three stages, viz., enthusiasm, moderation, and finally approbation. He suggested an experimentation on a dog for the purpose of studying the diffusibility of the cocain solution in the lumbar subarachnoidean space. In summing up the advantages of the subarachnoidean method over the general anesthesia he said that the respiratory, cardiac, gastric and renal organs are not so seriously disturbed as by the inhalation method. Still another advantage is that of the ability of the patient to confer with the surgeon during the operation in case a modification of the original plan must be made and the patient's consent is necessary. He referred to the medicolegal aspect of this mode of anesthesia.

DR. J. T. ESKRIDGE does not believe in the theory of diffusion through the spinal fluid. He is of the opinion that the cocain solution is absorbed through the circulation, that in order to produce anesthesia it is not necessary to inject the cocain solution into the arachnoidean space, that anesthesia will follow the injection outside the dura. There can be no anesthesia in any part in which the blood-vessels have been previously cut.

DR. LEONARD FREEMAN would prefer in all major operations complete general anesthesia, so as to insure absolute relaxation of muscles and avoid the possibility of inflicting pain should the action of the cocain for any reason close before the operation is completed. He thinks the method should be used in persons who have a mortal fear of the state of unconsciousness.

DR. C. P. HERSHEY reported two cases in which the subarachnoidean method was used. The first was a painful knee-joint in which the merest touch would produce pain. Ten minutes after the injection the anesthesia was complete. The patient, a lady, became talkative, nervous, then sick at the stomach. The second case was that of fistula in ano in a male. He, too, became very talkative. The anesthesia was not complete and was not equally distributed. There was no headache and no vomiting.

DR. WM. C. MITCHEL exhibited a 2 per cent. solution of cocain which contained numerous colonies of various bacteria. He described his method of preparing sterile cocain solution, which was used in the two cases reported by Dr. Hershey. He filters the solution and then exposes it to a temperature of 176 F. for one hour, which destroys the bacteria, but not the spores. After twenty-four hours he again exposes the solution to a temperature of 176 F. for an hour, and the day following he gives

a final sterilization as before. This method is both scientific and reliable.

DR. VAN ZANT cannot agree with the absorption theory of Dr. Eskridge, since the patients retain their motor functions.

Detroit Medical Society.

Regular Meeting, held November 21, 1900.

SOME OBSERVATIONS ON NORMAL TEMPERATURES IN CHILDREN.

DR. WILLIAM M. DONALD read a paper on this subject. Twenty children, all apparently in perfect health, inmates of the Protestant Orphan Asylum, were selected for the experiment. Temperatures were observed night and morning for fourteen days, giving a total of 28 collective readings. Twelve collective readings, or 42 per cent., gave a constant mean evening temperature of 99 Fahrenheit, or over. Five collective readings, or 18 per cent., gave a higher morning than evening temperature. There were 560 individual readings. On 13 occasions, or .02 per cent. of the 560 readings, a temperature of 100 or over, was found. On one occasion a temperature of 101 was recorded and on another occasion 102 was reached.

Of the 20 children examined 30 per cent. showed a tendency to a constantly high temperature of about 99 to 99.5. Fifteen months after these observations were made these children remained in the same state of perfect health, no pathological condition developing or becoming manifest to account for this aberration from the normal. The conclusions were that a higher or lower temperature may have no pathological significance, being purely physiological.

DR. A. W. IVES read a paper on "Thermotaxis," dealing with the physiological process of heat production and dissipation. Drs G. W. MORAN, M. L. High, Walter J. Wilson, Jr., C. G. Jennings, W. L. Anderson and A. D. Holmes discussed the papers.

DR. ANGUS McLEAN presented an aneurysm removed from femoral artery, with report of case and exhibition of patient.

DR. EUGENE SMITH reported two cases of mastoid disease with operation.

DR. DON M. CAMPBELL reported a case of large foreign body removed from the eye with the Johnston magnet. The piece of iron and magnet were exhibited.

Therapeutics.

Epistaxis.

All that is necessary in epistaxis is to fashion with a pair of scissors a dry plug of prepared sponge, in size and length comparable with the little finger of a 12-year-old boy. Soak this in boiled water, squeeze it dry and insert its full length, gently along the floor of the bleeding nostril. No styptic will be necessary. The expansive pressure of the sponge increased by the coagulation of the blood will check the hemorrhage immediately. Remove it in twelve hours and under no circumstances allow it to remain longer than twenty-four hours.

—*Sajous' Cyclopaedia.*

Removal of Dressings from Wounds.

In order to relieve the pain and irritation caused by the removal of dressings adhering to a wound, pour some hydrogen peroxid over the adherent part of the dressing. This will rapidly soften the coagulated discharges and the dressing will come off readily. This method saves time in prolonged soaking with ordinary solutions, and relieves the apprehension of the patient usually shown at each fresh dressing.

—*Canadian Pract. and Rev.*

Jaundice.

The following prescription for catarrhal jaundice is recommended by the *Riforma Medica*:

R. Resine podophylli	
Ext. hyocyami	
Saponis, āā	gr. ivss
Ext. rhei	gr. xv
M. Ft. pil. No. x.	Sig. One or two pills daily.

Albuminuria of Pregnancy.

JAMES W. McLAINE, in the *Medical News*, orders rest in bed, plenty of fresh air, skimmed milk diet, with no alcoholic liquors, half a gallon of water—not mineral—a day, to flush out the kidneys, a daily warm bath, and the following pill may be given when necessary:

R. Ext. colocynth comp.	gr. ii	12
Massæ hydrargyri.	gr. iss	09
Ext. nucis vomicæ.	gr. 1/6	01
Pulv. alois	gr. ss	03
M. Ft. pilula No. i.	Sig. At bedtime.	

In acute cases, if the patient is plethoric, venesection is advised, or dry or wet cupping over the loins and free catharsis:

R. Hydrarg. chloridi mitis.	gr. x	66
Sodii bicarbonatis	gr. xx	133
M. Sig. At one dose.		

If there is no relaxation of symptoms, induce labor as soon as the child is viable.

To Lessen Labor Pains.

In a lecture on "Mechanism of Normal Labor." Dr. Davis recommends an injection, per rectum, of:

R. Lactis		
Aque. āā	ʒi	32
Chloral hydratis	gr. xxx	2
M. Sig. Administer per rectum.		

The above may be used during the first stage of labor to lessen pain. As the head passes the vulva the patient is given sufficient chloroform to dull the sensibility.

—*Monthly Encyc. of Med.*

Tapeworm.

The *Medical Record* contains the following prescription for tapeworm. The synergistic combination should certainly accomplish the purpose for which it is given:

R. Granati—pomegranate	ʒiv	16
Peponis—pumpkin seed	ʒi	32
Ext. aspidii—male fern	ʒi	4
Pulv. ergot	ʒss	2
Olei tiglii	m. ii	12
Gum arabic	ʒi	4
Aque, q. s., ad.	ʒviii	256

M. Sig. At one dose, followed by a dose of rochelle salts.

The intestinal tract is first relieved as much as possible by giving the patient but little food and a full dose of rochelle salts.

To Retain Nutrient Enemas.

The instillation of a few drops of a 3 per cent. solution of cocaine into the rectum by means of a medicine dropper has been recommended in order to aid a patient to retain an enema when it is given with that object in view; by this procedure the sphincter is partially anesthetized for a period of twenty to thirty minutes.

Wet and Dry Dressings.

R. H. Skillern, as stated by the *Phila. Med. Journal*, advises as to when to use dry and wet surgical dressings in dealing with minor operations, and as the general practitioner is called on to meet such cases frequently, we give his comparison of the efficiency of wet and dry dressings:

1. A dry dressing is superior to a wet one in incised wounds.
2. In contused and lacerated wounds a wet dressing should be employed for a week or two, followed by a dry one.
3. In carbuncles, boils and infected wounds, a wet dressing is indicated.
4. When pus has burrowed and sinuses exist, packing and a dry dressing are preferable.
5. In deep punctured wounds with a small orifice, a wet dressing is better.

In all wounds of the scalp whether infected or not, a dry dressing should be used.

Chilblains.

R. Acidi sulphurosi	ʒiii	12
Glycerini	ʒi	4
Aque destil	ʒi	32
M. Sig. Apply on lint to the affected parts.		

Penna. Med. Jour.

Acute Bright's Disease.

Stevens, in *Phila. Med. Journal*, gives a summary of an article by J. M. Bruce, which appeared in *Practical Medicine*: Rest in bed in a room at not less than 60 F.; flannel garments, blankets, no sheets; careful nursing; warm baths; never cold.

The patient should be placed upon a milk diet—diluted with water if necessary—and as a purgative he advises the following:

R. Potassii bicarb.	5i	8
Sodii tartratis gr. x		66
Tinct. aurantii corticis m. xv	1	
Syrupi aurantii m. xxx	2	
Aque destil. q. s., ad.	5i	32

M. Sig. At one dose.

As a saline diuretic and diaphoretic:

R. Potassii acetatis gr. xx	1	33
Potassii bicarbonatis gr. x		66
Solutionis Am. acetatis 5ii	8	
Tinct. limonis m. x		66
Syrupi m. xxx	2	
Aque q. s., ad.	5i	32

M. Sig. At one dose every six hours.

In the more severe cases vapor and hot-air baths. If the case progresses properly different forms of farinaceous foods may be given in addition to milk. Then in succession, light vegetables, subacid fruits, fish, fowl or game, fat bacon. The urine, heart and general strength should be watched and with the meals an abundance of distilled or vichy water should be given.

AS A DRINK.

R. Potassii bitart.	5v	20
Syrupi. q. s.		
Aque bullientis Oi	5i2	

M. Sig. Drink ad lib.

Give no stimulants and caution patient about sitting up, a return to which should be gradual. And at this time prescribe the following as an unstimulating diuretic mixture:

R. Ferri et ammonii citratis. gr. v	33
Potassii citratis gr. v	33
Ext. scille flu. m. i	66
Spts. etheris nitrosi	
Syrupi aurantii, aa. m. xxx	2
Aq. destil. q. s., ad.	5i

M. Sig. At one dose three times a day after each meal, and give a purgative each morning.

Fetid Bronchitis.

Naphthalin is considered by Dr. Pirnot a most excellent remedy in fetid bronchitis. He relates two cases in which the fetor was so strong that it was dilficult or impossible for people to stay in the same room with the patient. He prescribes the following:

R. Naphthalin	5i	4
Alcoholis—absolute,		
Syr. pruni virg., aa.	5i	48
Ext. scille flu.	5iv	16
Tinct. aceniti m. viii		5

M. Sig. One teaspoonful every three hours.

In addition he ordered the following to be given alternately with the above:

R. Iodoformi,		
Calcii phosphati, aa. gr. xxiv	1	5
Pulv. ipeacacuanhae,		
Ext. hyoseyami, aa. gr. vi	36	
Pulv. opii gr. iv	25	
Olei anisi m. x	66	

M. Ft. capsulae No. xxiv. Sig. One every three hours. One patient was cured within a month and the others within eighteen days.

—*Merck's Archives.*

Crusts and Fissures of the Nostrils.

R. Unguenti hydrarg. ammon.		
Vasolini, aa. 5i	iss	10
Zinci oxidii gr. lxxx	5	
Plumbi acetatis gr. i	4	015

M. Sig. For external application night and morning.

—*Practitioner.*

Venereal Warts.

For a corona of small warts just back of the glans penis, and traced to the irritative action of the vaginal secretions on a surface weakened by too much venery, use the following dusting powder, and insist upon continence for at least three months:

R. Hydrargyri chloridi mitis	5ss	2
Acidi tannici gr. xx		133
Bismuthi subnitratii 5ss		2

M. Sig. Use locally as a dusting powder. —*Shoemaker.*

Acne.

Acne in its different forms is not infrequently met with by the general practitioner. Shoemaker, in the *Medical Record*, advises the following treatment in acne due to digestive derangements:

R. Creosoti	m ss	03
Cerri oxalatis gr. ii		12
Pepsini puri gr. i		06
Strychnina sulphatis gr. 1/60		001
Tinct. belladonnae m. ii		12
Podophylotoxini gr. 1/10		006

M. Ft. capsula No. i. Sig. One such to be taken after each meal and at bedtime if necessary.

R. Acidi salicylici gr. xx	1	33
Olei eucalypti m. x		66
Acidi borici 5ss	2	
Ungt. zinci oxidii		
Ungt. aque rose, aa. 5ss		16

M. Ft. unguentum. Sig. As a local application night and morning.

Hepatic Colic Gall-Stones.

In the treatment of hepatic colic the use of morphin may be avoided by giving other preparations of opium accompanied with some antispasmodic. Baealoghi outlines the following treatment in hepatic colic:

R. Ext. belladonnae gr. ss	03
Ext. opii gr. ii	12
Ol. theobromatis, q. s.	

M. Ft. one suppository—make four such. Sig. One, and in one hour repeat, then every two hours.

Apply over the region of the liver a flaxseed poultice made with laudanum. Give the following internally:

R. Sodii bicarb.	5i	4
Aq. destil 5i	iii	96
Syr. simplicis 5i	32	

M. Sig. One teaspoonful every half hour, alternating with:

R. Acidi citrici	5i	4
Aque destil 5i	iii	96
Syrupi limonis 5i	32	

M. Sig. One teaspoonful at a dose every half hour.

Jaundice in the Newly Born.

R. Ammonii chloridi gr. i	06
Syrupi acacie 5ss	16

M. Sig. A teaspoonful every two hours.

The above is recommended by Musser, who advises it in the mild forms. He first recommends the administration of a mild laxative, as calcined magnesia or calomel, and proper elimination by the kidneys by giving potassium nitrate well diluted.

Vaginal Irrigation in Leucorrhœa.

Lutaud, in the *Medical Record*, gives the following formula:

R. Potassii chloratis gr. lxxx	5
Vini opii 5i	4
Aque picis 5iv	128

M. Sig. Add two or three teaspoonfuls to a quart of warm water as a douche.

The following combination of creolin and hydrastis contains the antiseptic properties of the one and the astringent properties of the other:

R. Creolin	5ii	8
Pulv. ext. hydrastis q. s. ad.	5ii	64

M. Sig. One tablespoonful to a quart of warm water twice a day.

Unpalatable Drugs Made Palatable.

Dr. L. Freyburger, in his "Pocket Formulary of Diseases of Children," offers the following suggestions:

Aloin, one-quarter grain, is disguised by ten minims of fluid extract glycyrrhizæ comp.

Ammonii bromidum, ammonii carbonas, and chloral hydras, one grain, are disguised by five minims of syr. aurantii.

Potassii bromidum, three grains, is disguised by fifteen minims of syr. aurantii.

Potassii iodidum, one grain, is disguised by one-half dram aqua menthae piperita.

Quinina hydrochloras, one half grain, is disguised by twenty minims syr. aurantii.

Sodii salicylas, three grains, is disguised by five minims of syr. simplex and one dram syr. cinnamomi.

Medicolegal.

Admissibility of Declarations of Pain.—The Supreme Court of California holds, in *Green vs. Pacific Lumber Company*, that a nurse being asked to state any complaints of pain and suffering heard is not objectionable on the ground either that the witness is not an expert or of the evidence being hearsay. It says that involuntary declarations and exclamations of a person's present pain and suffering are admissible as tending in some degree to show his physical condition. Of course, when these declarations only amount to statements of his past condition, they should be rejected.

Alcoholic Insanity as Defense to Crime.—In *State vs. Rigley*, the Supreme Court of Idaho holds that where the evidence shows a party made an assault with intent to commit murder, and the defense of alcoholic insanity is set up, it must clearly appear from the evidence that the party making the assault had no deliberate intention of doing so from motive of revenge for a real or imaginary injury. The kind of alcoholic insanity which simply tends to accelerate the party in seeking revenge for either a real or imagined injury, and which is directed solely against the author of such injury, the court declares, is a very different disease from that which is motiveless, and results in a mere "delirious fancy and a muscle raised obedient to its impulse."

Insane Delusions Affecting Wills.—Prejudices, dislikes, and antipathies, however ill-founded, or however strongly entertained, the Supreme Court of California says, in *re Kendrick's Estate*, can not be classed as insane delusions; nor is every delusion an insane delusion. Whenever one's mind is tricked or deceived into a false opinion or belief, it has been played upon; it is deluded. But an insane delusion is the spontaneous production of a diseased mind, leading to the belief in the existence of something which either does not exist in the manner believed—a belief which a rational mind would not entertain, yet which is so firmly fixed that neither argument nor evidence can convince to the contrary. Moreover, such an insane delusion must have operated to cause the production of the will which is under attack to justify a refusal to probate it. Then the court states that it is a characteristic of monomania and insane delusion that, when the conversation turns upon the subject, the patient is dominated by it, and can not conceal his conviction.

Examination Twenty Months After Alleged Rape.—The New York Penal Code contains a provision that no conviction can be had for rape on the testimony of the female defiled, unsupported by other evidence. To meet this, the fourth appellate division of the Supreme Court of New York holds, in *People vs. Butler*, that it was error to permit to be introduced the testimony of a physician to the effect that during the time of the trial, twenty months after the date of the alleged commission of the crime, he made an examination of the person of the prosecutrix, and found that she was not a virgin, because that would not tend to prove that the female had illicit intercourse at or even about the time averred. On the other hand,

the court says that it would undoubtedly have been competent for the defendant to have proved that the genital organs of the prosecutrix at the time of the trial were in such condition as to indicate that she was then a virgin, which, if the testimony was believed, would have exonerated him. Further along, the court says that the crime of rape is a most atrocious one, and one which most naturally tends to enlist the sympathies of all men, and, of course, of jurors, in favor of the victim. In such cases, where, as a rule, the accused has no weapon of defense except his own uncorroborated denial, the courts, it adds, should be extremely careful that no evidence of a tendency to excite or influence the resentment of jurors, and which does not tend to support the evidence of the prosecutrix, or to connect the defendant with the commission of the crime, should be permitted to go to the jury.

Caring for Employees Injured Outside Line of Duty.

The manager of a business corporation, the Supreme Court of Nebraska holds, in the case of *Chase vs. Swift and Company*, has no implied authority to furnish medical aid and assistance to a servant of the corporation who has been injured outside the line of his duties. This was an action brought by a practicing physician to recover for professional services rendered to employees of the defendant corporation who had been injured in some manner during the progress of a strike. The employees in question had been brought from other points to take the places of strikers, and the theory upon which the action was prosecuted was that the superintendent, who had the direction and management of the company's business at that point, had agreed to take care of any of the new men who should be injured by the strikers in consequence of having engaged in the service of the company. But when, where, or why they were injured did not appear. Under these circumstances, after resolving all doubts in the plaintiff's favor as to what the superintendent agreed to do and the extent he was authorized to bind his principal, the court holds that a preemptory instruction was properly given the jury to find for the defendant. It says that it was certain that the men were not hurt while in the actual service of the company, and there being no proof that they were assaulted by the strikers, or that there was an causal relation between their injuries and the service in which they were engaged, it adds that it seems quite clear that it was not within the apparent range of the superintendent's agency to employ a physician to attend them.

Minnesota Law for Treatment of Inebriates Invalid.—Chapter 260 of the Minnesota Laws of 1897, entitled "An act to provide for the treatment of inebriates by counties and prescribing rules governing the same," the Supreme Court of Minnesota holds, in *Murray vs. Board of Commissioners of Ramsey County*, is unconstitutional, in that it is special legislation as to the affairs of counties, and is not uniform in its operation throughout the state. By this act an attempt was made to remove the objections pointed out by the supreme court when it held that a former similar act was invalid which applied to the whole state but attempted to confer powers and duties upon the probate judges beyond the jurisdiction authorized by the constitution. But the limiting, by its terms, of the operation of this second act to counties having a population of 50,000 or more, the supreme court does not think a proper classification for legislation of this character. Nor, if the primary purpose of the law was to protect the public from the results of drunkenness by curing the inebriate, does it think it defensible to limit the cure to one patient to each 10,000 of population. The purpose of the law being to provide a bounty to needy inebriates, to the end that they might be cured of their disease, and the public thereby incidentally benefited, there was, and could be, the court declares, no reason, necessity, or propriety for discrimination against any of them. In short, it considers the classification on the basis of population, for the purpose of legislating for the relief of such indigent inebriates was purely arbitrary, and holds that the act was as clearly unconstitutional as would be a law providing for the care of insane persons or the poor of a limited number of counties at the cost of such counties, and excluding the insane and poor of all the other counties of the state from the opera-

tion of the act. In conclusion, the court says that it is not to be understood as holding that a general act, uniform in its operation throughout the state, providing for the treatment of inebriates at the expense of the public, would not be a valid law; for reclaiming the inebriate, who is incapable of self-respect or self-support, and restoring him to society prepared again to discharge the duties of citizenship, directly promotes the public welfare.

AMERICAN NOTES.

1. **Hypospadias.**—Beck first notices the frequency of this condition and the inconvenience and sterility which usually accompanies it, and discusses the different methods of operation to relieve it. The method that he has followed, of which he reports three cases, consists in dissecting free and dislocating the urethra forward so that a new canal does not have to be created, the existing urethra performing its function. The internal surface of the tube remains intact, the urine does not come in contact with the wound itself and the use of the catheter can be discarded. He gives the technique of his methods in full, for which the reader is referred to the article itself. How apparent are the advantages of his method for forward dislocation is best illustrated, he says, by the many more or less useful modifications which have been proposed during the short space of three and one-half years since its introduction.

2. **Enlarged Prostate.**—The various operative measures for the relief of enlarged prostate are reviewed by Guitéras. The ligation of the internal iliacs is a matter of ancient history; castration has had its day, and vasectomy is little used in this country. The two operations most in vogue are prostatectomy and the Bottini operation, each of which has its advantages. The indications that should help to decide which operation to perform, are: 1, age of the patient; 2, size and shape of the prostate; 3, the condition of the kidneys and liver. Age is important, as the older the patient the less the resisting power; therefore, in very old men if the prostate is of the right variety, the Bottini operation is preferable, though old age is not in itself a contraindication to prostatectomy. Very large prostates, such as have the feel of an apple or orange on rectal examination, are favorable for enucleation, while smaller ones in which there is a distinct impediment in the prostatic urethra on introducing instruments, together with a considerable quantity of residual urine, are the best for the Bottini. The condition of the bladder is less important than that of the kidneys, for treatment will do much to benefit it; but bad kidneys are always contraindications, and if they are damaged in any way and operation is demanded the Bottini should be the choice.

though not itself entirely free from danger. The technique of both operations is described. The author's own method of performing prostaticectomy is by what he calls the rectovesical method, though no part of the operation proper is performed by the rectum, the fingers being simply inserted into it to exert direct counter-pressure and guide the operating finger. He first performs suprapubic cystostomy, putting retention sutures into the bladder wall on each side of the incision. A careful rectovesical palpation is then made with the first and second fingers of the left hand while the right finger is in the bladder, and a visual examination is made with an electric light inserted into the bladder. A pair of closed scissors are then introduced into the surface of the enlarged glands until the blades are felt to press the prostate against the fingers of the left hand in the rectum, which recognize whether the scissors are in the right position or not. The blades are then opened and a cut is made through the bladder tissue covering the gland in a line corresponding with the space between the two fingers and the rectum. The forefinger of the right hand is then inserted into this cut through the bladder and gradually works its way between the capsule and the gland. Counter-pressure with the rectum fingers is kept up and the tumor enucleated by the right forefinger. The gland having been enucleated, there is always free hemorrhage, and very hot water should be injected for two or three minutes through the suprapubic opening while the surgeon washes his hands. He then passes a grooved sound, preferably a lithotomy guide, through the urethra into the bladder; having brought the patient into the lithotomy posture, he rapidly cuts through the membranous urethra and pushes a large perineal drainage-tube into the bladder, which he fastens to one side of the perineal incision. The finishing steps are to put two catheters into the bladder suprapubically, with gauze drain beside them and into the cavity made by the removal of the prostate. Fasten these into the skin of the bladder wall; then sew the bladder wall up to the drain. The surgeon then closes the abdominal wall, including the fascia, muscle and skin, as far as the drain. The floor of the posterior urethra should be cut through from above downward before the perineal tube is left permanently in place, to prevent the formation of a pocket, which would retard the cure. The after-treatment consists in an enema and a hot bottle to the feet, the free administration of water and the hypodermic injection of strychnia, 1/30 of a grain every four hours, with a repetition of hot saline enema alternating with the strychnia. The suprapubic tube can be removed in a week, and the perineal one in two or three weeks. Drainage in these cases through the suprapubic opening is by the siphon method, into bags hanging at the side of the bed. It is well, both before and after the operation, to give urotropin in 10-grain doses three times a day. A milk diet of two or three quarts a day is advisable. The bowels should be moved by some saline water on the second day. In conclusion, he says that he considers the operation of prostatectomy still in its infancy and it will some day be simplified.

4. **Mammary Abscess.**—Field advises the use of general anesthesia in cases of mammary abscess, as the condition may require it. He was brought to this view by the case here reported. It is impossible in deep inflammation to know in what direction the pus has burrowed or how many lobes may be affected, and this can be determined under general anesthesia and operation performed.

5. **Mastoid Abscess.**—Wright remarks on the development of the anatomical conditions of mastoid abscess with special reference to cases reported by Harrigan in a former number of the *New York Medical Journal*. He says early recognition of the site of the perforation with adequate treatment should prevent mastoid complications in those affecting primarily Prussak's space with perforation of Shrapnell's membrane.

6. **Placenta Previa.**—According to Donoghue, in reviewing the opinions of various authorities, together with analysis of cases that are made, Caesarian section is preferable in placenta previa over other operations in: 1, cases of complete previa; 2 in cases of previa in primiparae when signs of fetal or ma-

ternal exhaustion are evident; 3, when the condition of rigid os is present; 4, where there is a history of previous operative delivery; 5, in transverse positions, and in cases of prolapsed cord when the cord is not easily returnable. It is the easiest of all ecliotomies and in nearly every large community it is possible to obtain an operator capable of performing it under strict aseptic and antiseptic precautions, and the second operation is easier than the first. He reports a case where the operation was performed in a 4-roomed country house, with an ordinary country nurse, with such appliances as were readily available, and with complete success.

11. **Tropical Ration.**—In this installment of his paper Kean describes the conditions in the United States army as compared with foreign armies, and notices the required tropical diet. He thinks that the appetite is lessened by long-continued heat and is more capricious, and that there is a greater demand for the carbohydrates in the form of fresh vegetables and fruits, with a less need for fats or the heat-producing foods, and less stimulating proteids in the form of meat. He favors the use of ice freely, holding that this is not merely an acquired habit, but is of value in diminishing the amount of water required, and also as preventing the soldiers from taking water from surface wells, thus guarding against infection.

14. **The Suprarenal Gland in Hay-Fever.**—Somers' experience with twenty-one cases of hay-fever treated by the use of the suprarenal gland internally has not been favorable to this remedy, and not only the hay-fever itself, but the attacks of asthma which occur habitually during the hay-fever season were increased and became more intense. He believes the drug had a causal action in producing this symptom. Other unpleasant symptoms were nausea and a sense of chest contraction preceding the asthmatic attacks. He does not deny the value of the remedy in its local application, but considers it not warranted for internal use.

15. **Sanitation in Havana.**—Bispham gives an account of the deplorable sanitary condition existing in Havana at the time of the American occupation, the unsewered condition of the city, the foul markets, hospitals and unclean stables, cabinets, etc., and the improvement which has been made under the American administration.

17.—See abstract in THE JOURNAL of November 3, p. 1172.

18. **Electrolysis in Tumors.**—Nefel calls attention first to the fact that the originator of electrolysis and galvanization for treatment of tumors was Gustav Crusel, a Russian practitioner. He made his researches in the 40's, but was overlooked, although he completely and correctly laid down the rational indications for the treatment. He attributes the immunity from complications that follow this method largely to the escape of gases developed in the living tissue, especially ozone, peroxid of hydrogen, chlorine, which fact renders the electrolysis process the most efficient antiseptic; the part also played by the acids is mentioned. He considers it an ideal antiseptic, since it can reach the most hidden places and cavities inaccessible to other antiseptics. The article goes into detail as to the chemical and physical action of electricity, the effects of the current on the tissues, the action of the two electrodes, etc. He considers the treatment of benign and malignant tumors to be based on entirely different principles. In the latter our aim is to produce in one operation by the action of the anode, the necrotic destruction of the tumor and all the infectious germs of the surrounding tissues. This must be accomplished in the early stage while the disease is yet local and the lymphatic glands are not infected and deposits lacking in distant organs. The effect of such an electrolytic operation is the relief of all the morbid symptoms and complete recovery. The treatment of benign tumors is based on a different principle, that of inducing by the action of the cathode regressive metamorphosis, molecular disintegration, absorption and atrophy. The remainder of his paper is taken up with a description of cases.

19. **Infant Feeding.**—The most important point, according to Fischer, in infant feeding is to have pure cow's milk, which can only be obtained from a reliable dairy where all the modern sanitary rules are observed and the hygienic condition of the

cows is perfect. Antisepsis in the stable is essential. We should imitate nature in feeding; the infant receives raw milk from its mother, and we should, therefore, follow this in artificial feeding. The principal objection to raw milk is its contamination with various pathogenic bacteria, but this is reduced to a minimum if the above mentioned conditions are observed. The use of sterilized or boiled milk is liable to produce scurvy; it undergoes a sort of deadening in the action of heating or boiling. Phosphorus and ferric proteids are required to be given in a living form. Each child is a law unto itself and we must notice the following factors to be satisfied that it is thriving: 1. The infant must appear satisfied after taking its bottle. 2. No vomiting. 3. No colic. 4. The bowels must move at least once or twice in twenty-four hours with yellowish-white and medium-soft stools. 5. The infant should sleep from four to eight hours at a time during the night. 6. The weight, taken regularly once a week, should show a gain of at least 6 or 8 ounces weekly, and if no increase is observed the reason should be studied and by all means the food changed. He gives a tabulated statement of the quantity, proportion of water and the frequency of feeding for infants of all ages up to six to eight months. He agrees with the sentiments of Professor Jacobi regarding the use of modified laboratory milk. He has not found it so useful to children and the theory does not work well in practice. When the milk disagrees and the infant's stomach will not tolerate it, vomiting is provoked, or bowel disorders follow, milk should be stopped. In such cases he has seen good results in many cases follow the use of almond milk made by scalding or blanching almonds, then heating them up, using an ounce of water for each ounce of blanched almonds, rubbing up this mixture and then expressing it through cheese-cloth. This should yield an ounce of almond milk for each ounce of almonds used and can be made at home, and be found sometimes quite serviceable in the treatment of summer complaints. Dextrinization of foods, chiefly the cereals, is successful in children having subnormal gastric digestion. It should be used during illness only, and is not advisable for healthy children. Frequently the infant's stomach requires assistance in the assimilation of food, and an examination of the stomach contents shows a deficiency of hydrochloric acid. Hence it seems more beneficial to give the infant several drops of diluted hydrochloric acid after feeding. In conclusion he remarks that two drugs must always be considered in the management of infant feeding, especially in difficult cases: *nux vomica* and *mat.*

21. **Rectal Prolapse.**—The method described by Fowler consists in the use of the combined lithotomy and Trendelenburg position during operation under spinal cocaineization, the patient being perfectly conscious and able to extrude the prolapse, thus doing away with the need of traction. A cuff at the mucocutaneous margin was turned back for the purpose of preserving the normal condition at the rectal outlet and at the same time permitting the removal of all relaxed and over-stretched mucous and submucous structures at this point. It also provides a covering for the sutured edges of the stump of the prolapse and diminishes opportunity for subsequent infection. The third advantage in the operation is the step by step application of, first, a suture and then an extension of the incision through both cylinders to correspond with the sutured area, in this manner avoiding exposure of the peritoneal cavity to infection. He does not claim that this operation possesses all these advantages exclusively, but he has not seen these heretofore combined.

22. **The Mosquito Theory of Malaria.**—Grandy, while recognizing and accepting fully the mosquito theory, finds some difficulties in assuming that the plasmodium finds its life cycle exclusively through man and anopheles. If this is true, then the depopulation of a region for a short time would extirpate malaria, which is not the case. He suggests that while in a certain number of cases malaria is directly transmitted through man by anopheles, he thinks the latter can and do obtain the organisms from other sources than the human blood. All the arguments in favor of the mosquito theory apply equally well to this modification of it. The objection that malarial organ-

isms have never been cultured artificially is not sufficient to overthrow the idea. No other parasitic protozoan has been cultured and yet they exist in various conditions. He also thinks that the objection that they have never been found free in nature is of little value, since they might easily be overlooked. This modification he holds comes nearer to filling all the conditions and answering all the objections than the other theory that requires the exclusive transmission of the germs through the cycle of man and mosquito.

23. **Post Operative Complications from Heat-Stroke.**—Gilson believes that heat has caused certain unfortunate complications occurring after operations, and depressing weather should be considered by surgeons in this special point of view. He reports two cases of operations for appendicitis in which he believes the element of heat-stroke produced a very serious complication. In one the symptoms were gradually relieved by the application of cold, in the other the patient ultimately succumbed. He does not wish to say that the summer season is not favorable for operative work; on the whole, cases seem to do better, as they are more free from pneumonic disorders and the increased action of the skin supplements the efforts of damaged kidneys, and good circulation is kept up; but he wishes to call attention to the fact that the beneficial effects of heat may become misdirected when accompanied with unfavorable atmospheric conditions.

24. **Drainage.**—The purpose of this paper is to show that drainage, instead of being a necessity, is of value in comparatively few cases and of damage in others. Pond considers that the idea of drainage to prevent pus formation is unscientific, as its irritating action has actually the opposite effect. While we must still drain some of the septic cases, yet in abdominal injuries for instance, the peritoneum can take care of poisoned cells of infectious material better than it can make immune the surfaces constantly producing sepsis. Salt solution may be valuable in such cases; in sterile cases drainage is not only unnecessary, but absolutely detrimental.

25. **Acute Alcoholism.**—Baudy considers that all forms of acute alcoholism have a tendency to self-limitation; that they always result from an excess or abuse of alcohol, and not from any sudden withdrawal of the stimulant. He therefore claims that it follows as a corollary of the first of these statements that the treatment must needs be expectant. The systematic administration of opiates is unjustifiable and full of danger. He has had 1129 cases with only 14 deaths, a mortality of a little over .015 per cent., as compared with some statistics of others, who had a percentage of even 10 per cent. or more. He also would withdraw all alcoholics during the attack of acute alcoholism; there is no need of adding to the poison. In conclusion he recapitulates his ideas and holds that in this disorder, as in many others, the *vis medicatrix* is fully adequate to produce the happiest results.

26. **Laboratory and Bedside Diagnosis.**—The subject here considered is the comparative value of laboratory and bedside work. The author first notices the over-enthusiasm on the one hand and the ultra-conservatism on the other, and holds that the true position is nearer the former than the latter. He enumerates some of the causes of failure of laboratory work: first among these is the matter of personal skill. There are many physicians who have not the first idea how to recognize what they see under the microscope or in the tests, and he notices a few errors, mistaking leukemia for chronic malaria, rates for albumin in Heller's test, lint or scratches for casts, cretated red blood-cells or even the pale centers of normal red blood for malarial parasites, certain peculiar refracting lines for tubercle bacilli, etc. In the laboratory manager, besides skill, there is another qualifying factor, that of honesty, which requires him to avoid surmises and make sure that nothing that is said is without the limits of absolute certainty. Practitioners also fail to make proper specimens, frequently sending them in conditions in which laboratory examination is impossible; also failure to send the correct history of the case is a common fault, and lastly, he mentions the restrictions under which the laboratorian is often forced to work. Certain possibly useful tests are not desired when the labora-

torian could at once say that nothing could be obtained by the one demanded. To make the results of the laboratory worker in diagnosis compare with those of the clinician, we must first recognize the fact that in certain cases only direct examination of the patient is of value. In another class of cases the laboratory alone can furnish an accurate diagnosis, and this includes diabetes, renal affections, blood diseases, certain neoplasms, etc., and there is still a third class where a combination of both methods is required and certain others in which any given case may vary within wide limits. He sums up the practical points of his paper as follows: 1. Practitioners should possess sufficient knowledge of laboratory methods to apply them for themselves in simple cases. 2. Here, as in all specialties, the general practitioner should promptly recognize the cases which are beyond his own skill and refer them to an expert. 3. The practitioner may simply send material for examination where the nature of the required investigation is clear and where the character of the material permits, but he should at least know and follow the proper method for its collection and preservation, or, not knowing it, should take no step without informing himself on this point. 4. A brief history, containing only salient points, together with the apparent clinical diagnosis, should, if possible, accompany all specimens. 5. The laboratorian should be called in as a regular consultant in those cases in which the diagnosis is very obscure, and should be given full scope to make examinations in whatever direction he may deem best.

47. Transmission of Sound in the Middle Ear.—Zimmermann's paper argues against what he considers fundamental errors as regards the transmission of sound, viz., that sound is transmitted through the channel of the bones to the fenestrum ovale instead of being carried from the membrana tympani to the air of the middle ear and through it conducted to the lobule and capsule without needing any conduction through the channels of the ossicles. He tries to show the inaccuracy of some of the remarks and proofs advanced in the favor of the Helmholtz theory.

56. Malaria Simulating Multiple Sclerosis.—Cases of malaria affecting the nervous system are, as Spiller remarks, not rare, but the case here given is of value as showing the symptoms of multiple sclerosis, as intention tremor, localized ataxia, transitory hemiparesis, headache, vertigo, drowsiness, diplopia, nystagmus, scanning speech and exaggerated reflexes were all present. Malarial parasites were found in the blood-vessels throughout the brain and cord. The case shows that symptoms of disseminated sclerosis, as the author remarks, may result from irritating vascular lesions, imperfect nutrition and poisoning of the nerve cells without the formation of multiple-sclerosis foci. The paper also gives an interesting résumé of the literature of similar cases, and especially notices the paper of Torti and Angelini.

57. Cortical Localization of the Sight and Hearing.—Good reports a case, with post-mortem, in which there was blindness and deafness due to lesions in the left occipital lobe due to old embolic softening caused by blocking of the posterior cerebral artery in the left hemisphere, together with disseminated lesions in the corresponding region of the right. The cortex of the mesial surface of the right hemisphere, together with the greater part of the lingual and fusiform gyri, had been destroyed. On the convex surface the superior and middle occipital gyri were also involved in both. The only part of the brain the author found intact that had any relation with the vision was the right angular gyrus, which he thinks accounts for the little preception of sight the patient retained. The conclusions of his paper are as follows: 1. Destruction of the cortical visual areas will lead to a degeneration of the cells in the geniculate ganglia and the corpora quadrigemina, and to a degeneration of the nerve fibers of the optic tracts and nerves. 2. The macula lutea of one eye is in connection with the opposite angular gyrus.

58. Leucocyte Count in Serous Pleurisy.—From an examination of twenty cases of serous pleurisy where the leucocyte count was made daily, Morse concludes that serous pleurisy is only exceptionally accompanied by an increase in the number of white corpuscles, and then intermittently. The

white count is of value in two ways in the diagnosis of serous pleurisy: If the physical signs are doubtful and there is no leucocytosis the condition is almost certainly not pneumonia or empyema, but serous pleurisy. If there is a serous pleurisy and a continuous leucocytosis, some complication is present. The white count in serous pleurisy affords no information as to the duration of the process, the amount of the fluid, and its increase or diminution. The number of white cells is not influenced by the presence of blood or microscopical pus in the fluid or by the degree of fever.

59. Hepatic Cirrhosis.—Frazier reports a case of liver cirrhosis in which operation was performed to open the channel for the relief of the obstructed portal circulation, and tabulates similar cases that have been reported. The indication for the operation is the presence of ascites due to obstruction of the veins of the portal system when the obstruction itself is due to cirrhosis of the liver, the liver being still functionally active. The technique of the operation is simple. Local anesthesia is preferable. An incision three or four inches in length is made in the median line or on the border of the rectus above the umbilicus. The peritoneum of the adjacent surfaces of the diaphragm, liver and spleen, respectively, and the peritoneum on either side of the wound are sacrificed with a blunt curette or rubbed with a gauze pad. The latter proceeding caused less bleeding, at the same time exciting sufficient peritonitis to insure adhesion. The omentum is sutured to the parietal peritoneum for a distance of three or four inches on either side of the wound, and to the margin of the wound itself. The evacuation of the fluid completes the operation, the wound being closed without drainage. Drainage has been used in several cases, but the author thinks it better to omit it as it can have no good effect on the lesion and introduces an additional element of risk. Frazier, while admitting that experience is as yet very limited, holds in properly selected cases where the liver cells are not yet devoid of function and where internal medication and paracentesis fail or where there is no serious contraindication the operation has a future. It is a last resort in hopeless cases, and it is so simple in itself and the danger so slight that the prospects of the mode of treatment becoming an established one seem bright. In his case the results were good.

61. Irritable Bladder in the Female.—In the conclusions of Bierhoff's article in regard to the question of irritable bladder, he says as follows: 1. The term "vesical hyperesthesia" or "irritable bladder" is in almost every case in the female erroneously applied. 2. As a true neurosis, vesical hyperesthesia rarely occurs. 3. Where vesical hyperesthesia exists it does so only as a symptom; in the majority of cases as a direct result of some change in the vesical mucous membrane, in the minority as an indirect result of change, in other organs adjoining or near the bladder. 4. The diagnosis of the causative factor must rest upon a thorough examination not only of the bladder, but also of the urethra and the genital and pelvic organs as well. 5. The treatment must be directed both against the local changes and the causative factors.

67. Patella Fracture.—The etiology of patella fracture is particularly discussed by Corner, who first notices the structural conditions. The fractures of indirect violence are those that are more particularly noticed. He thinks that the lower portion of the patella is its weakest point, and fractures where the upper fragment is larger are more numerous than those where the lower fragment exceeds. Fractures of the center or lower half of the bone form about 83 per cent. of the cases. Fracture of the patella by indirect violence is really due to exaggeration of natural forces that have given rise to the internal architecture of the bone. This is in accordance with the experience above mentioned. Besides the structure of the bone there is a still more important factor in localizing the situation of the line of fracture. This is the degree the knee is flexed at the time of the accident. The center-point of the bone varies a good deal, but for practical purposes it may be said to be just below the middle of the area of contact in semi-flexion, the condition in which 84 per cent. of the fractures occur. It would also appear that oblique fractures should

be more common, though few are reported, which is explained, he thinks, by the fact that small degrees of obliquity are overlooked. He finds also that fractures of the patella are less common in females than in males in a ratio greater than is the case of other fractures of the lower limb. Fractures are more common in males of the patella and in females of the femur. It is not infrequently the case that the patella is re-fractured, much more frequently than the long bones of the leg. This is explained by the mechanical conditions; its situation over an actively functional joint, and also to two other conditions due to the upright position, namely, an atrophic condition of the bone and the comparatively low situation of the femoral condyles, due to the relatively short ligamentum patellae. Either the bone itself or the fibrous union may be severed, and the same predominance of males occurs in this accident as in the first fracture. He suggests that the failure of ossification of the bone is due largely to the fact that being a sesamoid bone it lacks a periosteum, and the osteogenetic power must therefore be comparatively small unless there is close approximation of the fragments.

68. Suppurative Pericarditis.—After reviewing the conditions and their literature, Porter sums up in the following conclusions: 1. Pericardotomy is indicated in all cases of suppurative pericarditis. 2. Because of the uncertain and varying relations of the pleura, and because of the anterior position of the heart whenever the pericardial sac is distended by fluid, aspiration of the pericardium is a more dangerous procedure than open incision when done by skilled hands. 3. Incision of the pericardium can be done quickly and safely by resection of the fifth costal cartilage, and in many cases under local anesthesia. 4. In many cases of serous effusion, open incision without puncture will offer less risk and speedier cure than aspiration. 5. The method and detailed technique of the writer proposed in 1897 have been followed out by the majority of recent operators. His paper also includes a report of a large number of cases taken from the literature.

69. Inguinal Hernia in the Female.—According to Macready's statistics, 8.5 per cent. of hernia of the female are inguinal, which exceeds the number of femoral hernia in both sexes, and forms 60 per cent. of cases of rupture in women. Coley, from a study of the literature, concludes that the treatment of this condition in the female does not receive the attention it deserves. While most authorities agree that hernia in female children are more amenable to mechanical treatment than in the male, his own experience has led him to consider the difference as very slight, and he favors a more general recourse to operation. He disagrees with Kelly in his statement that the removal of the sac is of little importance, especially in small hernia, and thinks it likely to do much harm. In support of his view he cites a series of cases observed during the year 1888-89. The method he has employed is practically that of the Bassini method employed in males, the only difference being that the transplantation of the cord is naturally omitted. He insists on complete asepsis and the advisability of using rubber gloves. As regards sutures, he thinks that the non-absorbent suture should be omitted in the local cure of hernia. As regards the technique of the operation, he has always believed cutting of the internal oblique muscle not only unnecessary, but likely to weaken the canal, and quotes Turek and Blake as supporting his opinion. He has, since 1892, operated on 123 cases of female inguinal hernia without any mortality; 73 of these patients were under 14 years of age and in only 8 cases did suppuration occur, in these slight and limited to stitch-hole infection. He has been able to trace all but 13 of his patients. The majority of these were well two to seven years after operation. He thinks from his results that prognosis is even better in the female than in the male, and the prospect of cure may be reasonably sure.

70. Echinococcus Cyst of the Liver.—During the past few years Fowler has been able to see five cases of this condition, one of which he reports. The historical data are briefly reviewed. *Tenia echinococcus* derived from the dog is the exciting cause. The diagnosis is easy in fully developed cases. The symptoms are those due to pressure effects. Hydatid fremitus, due to the impulse of the daughter cysts on one another in the

absence of liquid in the parent sac, is noticed, as is also the Santini booming sign, which Fiaschi of Sydney considers a valuable aid in diagnosis. The disease untreated may progress indefinitely. Spontaneous cure may occur, or death may ensue in various ways. The parasite may die, and the sac may contract; but the usual way of spontaneous cure is by rupture into one of the neighboring viscera, stomach, intestine, lung or pleura. In the latter two cases the chances are unfavorable. In rare cases it may occur externally. The growth of the cyst is slow, ranging between fifteen and twenty years, or more. His method of treatment consists in stitching the sac wall to the edges of the wound in the abdominal parietes and then incising it either in one or two stages. In certain cases the cyst may be best reached by the transpleural route or through the lumbar region. The tension of the sac may be lessened by aspiration of a portion of its contents; it is important that none of the fluid escapes into the peritoneum. After incision the lining membrane of the sac is peeled off as completely as possible by a stream of warm solution directed between the lining and the fibrous capsules. The cavity is irrigated and packed daily until only a small sinus is left, which does not usually close readily. The healing process may take many months and a liver fistula may persist indefinitely. In those cases which admit of it, a hepatectomy may be performed to totally eradicate the disease. Cysts which are very large, or where a small amount of liver tissue is involved, may be subject to this procedure, but great care must be taken in selecting these cases. The methods and experiences of various surgeons such as Palleroni, Terrillon, Bergmann, Billroth and others are noted, and the author himself has assisted Professor Fowler in the removal of a large single echinococcus in the left lobe of the liver, which will be reported at a future date.

73. Fracture of the Spine.—Lathrop discusses the conditions and reports cases of spinal fracture, also reviewing the literature to a considerable extent. In conclusion he summarizes as follows: 1. In partial lesions we should operate. 2. Where the lumbar region is involved with lesions of the cauda equina, operation offers the best chance of recovery. 3. In fracture of the spinous process, lamina, or entire neural arch, operation is demanded. 4. Should immediate operation not be done, and we wait six to eight weeks, with the result that paralysis of the bladder and bowel continues, with cystitis and severe bedsores present, we may be sure that nature can not relieve the case, and an operation is not only indicated but demanded.

77.—See abstract in THE JOURNAL of October 20, p. 1051.

85. The Care of the Insane.—The relations of the state toward the insane are discussed at length by Kraepelin, who notices the causes of insanity, alcohol and syphilis especially coming under this general head. The article has been noticed in part editorially already. He also reviews the questions of organizations and says that the public institutions are far more progressive and advantageous to the state than the private ones. The questions of commitment and retention are also treated at length. He would advise retention to be made more difficult and commitment more easy. The backwardness of practitioners in insane asylums and the tendency to isolation and narrowness are mentioned, and he believes that frequent rests and change or travel would be of great value. The idea that places in these institutions are held simply by right of length of service, and not held by competition with others is, he thinks, a bad rule. It would be better to have changes instituted than to consider long services alone as a qualification for retention.

87. The Alcohol Question.—Forel gives his personal experience from a study of alcoholism and his change of view from moderate indulgence to total abstinence. He does not think the prohibition laws do not prohibit from his observation in the United States, but thinks that this country has gone backward a little of late years from the advanced position that it has held. The Americans are, he says, the leaders in anti-alcohol movement, and it is their duty to continue it.

101. Injuries to the Bladder and Ureters.—Bovéc gives a short review of the history of the operative measures for such injuries and discusses their efficiency, which he thinks is hard to

demonstrate, as in ordinary hysterectomy for malignant growths they are seldom disturbed. They are more common, of course, in the vaginal than the abdominal operations. About their frequency, various authorities differ; Byron Robinson considers about 1 per cent. of the operations for hysterectomy are attended with ligated or cut ureters; Spencer Wells that one in every six cases. The treatment consists both in preventing their occurrence and in repairing them after the accident has occurred. He does not favor Kelly's method of catheterization of the ureters, and believes that it is liable to produce complications. He mentions for example urinary hemorrhages which occur sometimes after catheterization, and also a case noted by Cullen of the breaking of the bougie and retention of the fragment. The treatment he has followed has been to isolate the ureter, except from the perineum, early in the operation by making an incision through the peritoneum along its course from the division of the iliacs to the bladder. Then by passing a few pieces of suture material under it along its course and tying the two ends of each together we have the means for pulling it up into view at any time without injury. We can easily ascertain whether any part of the ureter has been removed, and the ureter work, if any, which is always an important complication, can be planned during the operation. The preferable method of ureteral anastomosis is the end-to-end one. Injuries to the bladder usually occur in separating this organ from the uterus and vagina with insufficient care, but in some cases the bladder wall is in a pathologic condition or abnormally thinned, rendering it impossible to avoid the injury. In cases of bladder puncture or incision, immediate closure with permanent bladder drainage for a few days will usually suffice. In late bladder sloughing and injuries discovered after operation, a second operation is usually required, though sometimes permanent catheterization suffices. Many cases of ureteral injury are discovered only after several days. Some of these close spontaneously, and some are cured by vaginoplasty. If the ureteral opening be large the fistula continues and a tedious operation will be necessary. He would postpone this until nine or twelve months have passed and no evidence of return of cancer has appeared.

105.—See abstract in THE JOURNAL of October 27, p. 1105.

113. **Pathology of Adenoids.**—Richardson describes the macroscopic appearances in adenoids, together with their microscopic structure, and analyzes the statistics as regards tuberculosis in these growths from various authorities. He finds that in over 1000 cases subjected to close microscopic scrutiny in only about 5 per cent. was there more or less pathologic evidence of tuberculosis stamped on the glandular hyperplasia. He asks if this is simply an accident or is it a more intense manifestation of the tuberculous condition which is manifested in a fair proportion of the remaining 95 per cent, but not shown by actual pathobiologic changes. He thinks there is some underlying pathologic condition or conditions responsible, called by whatever name you choose, lymphatic diathesis, serofula, lymphatism, etc. In most of these cases the family histories, he thinks, will reveal certain conditions that have made their impress on the case; it may be syphilitic, tubercular, an ill-assorted marriage, or a conception in which one or both of the parents were below par at the time.

114. **Hemorrhage in Adenoids.**—The points which Kimball emphasizes are as regards the occurrence of hemorrhage in operations for adenoids as follows: 1. Thoroughness of removal and carefulness in technique at the expense of time. 2. The selection of instruments the best suited to perform the operation safely and efficiently. 3. The positive exclusion of the hemorrhagic diathesis. 4. Competent supervision of the patient until the danger from hemorrhage is over.

115. **Nasal Synechia.**—The causes of nasal synechia are described by Lederman, who points out the necessity of proper treatment after eauterizing or operating for obstruction to prevent these growths. He thinks the introduction of a certain kind of separator in many cases is very important, and has used the surgical sponge or spunk to advantage. In recent cases nature assists materially by absorption of a portion of the inflammatory exudate, causing a decided shrinking in what at

first appears to be an extensive bridge. It is well to let this process of absorption exert itself to its full extent, as energetic manipulation often makes matters worse. When subjective symptoms are not pronounced it is good judgment to let the nose alone, of course, keeping the passages clean by some antiseptic spray. After a few weeks' rest we will frequently find improvement and better conditions for operation. In conclusion he calls attention to those forms of adenoid occlusions that have assumed extensive proportions, and undergone osseous change. Here the chisel, trephine and rongeur have to be employed before serviceable breathing space can be obtained. In such cases persistent dilatation must be carried out for some time to keep the opposite parts from reuniting.

119.—See also title 129.

123. **Cervical Lymph Nodes.**—The surgery of cervical lymph-nodes is treated by Grant, who sums up his conclusions as follows: 1. The cause of tuberculous adenitis of the cervical region is almost always local, and takes place through the buccal cavity. 2. The glandular manifestation, when it progresses, and especially when it is followed by suppuration, indicates a damaged and usually useless, often dangerous, gland. 3. The removal of such a gland *in toto* and promptly is neither difficult nor dangerous, and is the treatment indicated. 4. Nature will probably provide a new and equally perfect protection in the place of the one that is lost. 5. Multiple enlarged glands indicate a constitutional tendency, which will not be benefited by removal, except when local discomforts and dangers indicate it. 6. Small groups of single, slowly growing glands are subject to the same indication.

129.—See also title 119.

134.—See abstract in THE JOURNAL, xxxiv, p. 1335.

135.—*Ibid.*, p. 1334.

136. **The Sac in Large Inguinal Hernia.**—Harris considers that the removal of the sac in cases of very large inguinal hernia is often inadvisable, or at best it is not advisable to remove the serotal portion of the sac. It may be drained for the first few days from its lowest point if thought advisable. The advantages of thus treating it are the saving of time in the operation, avoidance of danger of sloughing of the testicle and serotal tissues, and lessened danger of sepsis. Of the three cases which he reports, in one, where the sac was removed, there was thrombosis, hemorrhage and infiltration; in the other two, in which it was left, there was no subsequent trouble, no cyst nor hydrocele developed and the sac and serotum diminished remarkably in size by absorption.

142. **Large Umbilical Hernia.**—Wheaton illustrates two cases, before and after operation, of very large umbilical hernia and calls attention to certain points in the treatment of such cases. He thinks undoubtedly a hernia that has existed for a long time has, as an older writer expressed it, lost the right of habitation in the abdomen, but he believes that this can be regained, if not by a first at least by a second operation. The element of resiliency or non-resiliency of the contracted abdominal covering due to protrusion which lessens the resistance from within is the thing to be considered. All large non-reducible hernias, incurable by the truss as a preliminary operation, should have treatment in bed for a sufficient period of time to remove as far as possible the element of resistance before referred to, which is responsible for many failures. He holds that in almost all abdominal hernie of adults which are due to conditions arising after childhood and many of which are technically not umbilical, that point becomes the strongest part of the wall and is responsible for strangulation which results from pressure upon the neck of the extruded contents. The relation which the omentum bears to the floating contents of the abdomen makes it a conspicuous organ in these hernia. As a rule the protrusion comes through the median opening, the omentum first, followed by the floating contents from behind. Gradually as the tumor becomes larger the strangulation at the point of contraction brings about degenerative changes in the omentum and the adhesions between the omentum and intestine result in serious interference with the function of the latter, hence the gastrointestinal disturbance observed in these cases. From a successful experience

which he has had with large hernie he offers the opinion that with good heart and sound kidneys no umbilical hernia is so large as to be the cause of practically bed-ridden existence to the patient. Most of the text-books in surgery advise operation only in favorable cases, but by the preliminary operation before suggested and an operation performed which is ideal as far as its technique is concerned we will save nearly all our patients.

143.—See abstract in THE JOURNAL of Nov. 10, p. 1235.

148. **Tuberculosis.**—The points made by Porter regarding the home treatment of tuberculosis, which is the only kind possible in the great majority of cases, are: The importance of early diagnosis, correct hygienic conditions, clothing, good feeding, exercise suited to the case, hydrotherapy, the control of night sweats, hemorrhage and cough. He speaks particularly of the creosote treatment and thinks there is danger of pushing it too far. It should be given rather in small doses than in large ones.

149. **The Functions of the Ovary.**—Dudley notices the more recent views in regard to the internal secretive functions of the ovary, calling attention particularly to the experiments of Knauer, Marehesse, etc., and especially to the case of Glass where the transplantation of the ovary from another female seemed to re-excite the whole reproductive life. He thinks that the first function of the ovary coincident with its rapid development at the time of puberty is an internal secretion, and reviews the subject of ovarian therapy, quoting various authorities to show its advantages in amenorrhea, chlorosis, dysmenorrhea, cases of loss of ovary, etc.

British Medical Journal, Dec. 1.

Causes and Cure of Insomnia. JAMES SAWYER.—After first noticing the physiology of sleep, in which he rather indorses Foster's view that the essence of the condition is to be sought in the purely molecular changes, Sawyer passes to the etiology of insomnia. Secondary insomnia may be due to various causes such as pain, fever, or dyspnea, and these conditions are frequently met with in medical practice and treated by appropriate remedies. There is, however, a simple incapability to sleep which may be called *insomnia per se*—a kind of wakefulness for which we can find no obvious physiologic cause, and which seems to depend upon the incapability of the brain and nervous system to adapt themselves to sleep-conditions. This is generally met with in well-to-do persons of high mental endowment and neurotic temperament. It is a very important disorder, and if understood and properly managed, there is no disease more amenable to treatment. He divides this type into three classes: psychic, toxic and senile. The first occurs mostly in men of nervous temperament and is often due to shock or mental strain. It would seem that these causes may arouse a given group of cerebral cells into persistent activity or, if the strain has been less intense but long kept up, a monotonous group of ideas is maintained in exhausting recurrence. In either case it would appear that sleeplessness did not appear until there was a partial or complete vasomotor paralysis from exhaustion of the blood-vessels; the arterioles of the brain had lost their normal contractility. This point of view gives the best working hypothesis for the treatment. Toxic insomnia may be due to internal autogenetic poisoning as in cases of kidney insufficiency, or possibly to absorption from the gastrointestinal tract and constipation, but the causes which he holds most responsible are tobacco, tea, coffee, alcohol and gout. In this lecture he also mentions senile insomnia due to lessening resiliency and contractility of the vascular system. Senility is a relative term and it may be properly said that a man is as old as his arteries. The tendency of this condition of the blood-vessels of the brain to prevent, lessen or interrupt sleep is probably counteracted in many cases by the cardiac feebleness which it may be said coexists with the senile vascular changes.

Fundamental Points Connected with the Pathology of Diabetes Mellitus. F. W. PAVY.—The general trend of modern research, according to Pavy, is away from the idea that sugar is carried through the general circulation to be consumed by the tissues. Sugar is disposed of in the system normally

in three ways; by transformation into fat, which is now an accepted fact; and into proteids in the villi; or into glycogen. The latter is not carried on exclusively in the liver; it seems to be one property of protoplasmic matter to form it when suitable conditions arise. If assimilation fails to be carried out in these ways the carbohydrates that can be taken up by a normal person without producing glycosuria can no longer escape doing so, and in proportion as the power is reduced, so is the curtailment of the amount of carbohydrate that can be taken without shoving sugar in the urine. Very varying degrees of impairment of this type are found to exist in different cases, producing varying degrees of severity of the condition to be dealt with, and this needs to be taken into account in treatment intended to adjust the dietetic management. The fact of the avoidance of sugar offers evidence that the system is overburdened with carbohydrate, and anything which conduces to its increase adds to the difficulty. Restoration of the assimilative power is needed and this is managed by the control of transit of sugar through the system from food. This kind of alimentary diabetes has a favorable tendency especially amongst people above the middle period of life, and it is not uncommon to have assimilative power restored so that the ordinary diet may be resumed. In other grave forms of diabetes, the elimination of sugar is in part derived from the tissues of the body as well as the food, and other products also arise from its abnormal tissue disintegration; oxybutyric and diacetic acids accompany the sugar and distinguish this form, which he calls composite as distinguished from the simple alimentary type.

The Face and Pupil in Alcoholic Neuritis.—Brunton calls attention to certain symptoms in alcoholic neuritis which he has not seen described in the literature. The first is the peculiar expression of the face, which becomes mask-like and expressionless; the lips appear to move apart separately from the cheeks, but they sometimes appear very mobile. The eyebrows and eyes may move in accordance with the lips, but a fixed and expressionless band stretches across the nose and cheeks between the eyes and lips. He has been able to diagnose alcoholic neuritis, provisionally at least, from observation in this way. Another point is the condition of the pupil reflex which is just the reverse of the Argyll-Robertson phenomenon. In a number of cases he has noticed that the reflex to light is rapid and extensive, whereas accommodation to near objects was slight and sluggish or entirely wanting, and in one or two cases he has observed dilatation instead of contraction on accommodation.

On the Causation of the Congenital Stridor of Infants. JOHN THOMSON and A. LOGAN TURNER.—The causation of congenital stridor of infants which is observed sometimes during the first, and part of the second, year, has been studied by the authors, who give their conclusions as follows: 1. The primary element in the causation of this condition is a disturbance of the co-ordination of the respiratory movements, probably due to some developmental backwardness of the cortical structures which control them. 2. The change of form found is merely an exaggeration of the normal infantile type, and is mainly, if not entirely, the result of a constantly recurring sucking-in of the upper aperture of the soft larynx, which is induced by the ill co-ordinated and spasmodic nature of the breathing. That it is, in fact, an acquired deformity strictly analogous to pigeon-breast. 3. There is no proof that any congenital malformation of the upper laryngeal aperture exists in these cases. 4. The supposition of a congenital deformity is not essential to account for the symptoms, inasmuch as normal babies crow in a very similar manner when they are coming out of chloroform. 5. The sounds are not produced in the pharynx. This is proved by the high-pitched phonic character of the crow, and also by the fact that the stridor persists, not only when the nostrils are closed, but equally when the mouth is occluded by the nipple, when the tongue is depressed by a spatula, and during yawning. They are not produced in the trachea by compression exerted by a large thymus or enlarged lymphatic glands. The stridor is probably produced partly in the larynx proper, and partly at the abnormally approximated aryepiglottic folds. 6. The neurosis causing the symptoms has not

in our experience seemed to depend on the presence of adenoid growths or other obvious causes of reflex irritation. They differ from Sutherland and Lack, who have written on this subject in not ascribing any primary etiologic importance to the peculiar conformation of the upper aperture found in these cases, and which they consider an acquired deformity and result of ill-co-ordinated breathing.

The Lancet, December 1.

Prognosis and Treatment of Pulmonary Tuberculosis.
ROBERT MAGUIRE.—In this first lecture, after some preliminary remarks, Maguire divides pulmonary tuberculosis into three stages: invasion, progress and result. These may be co-existing in the different parts, but the division is really made on the general clinical syndromes. The resistance of the lung and body generally is also to be considered with special reference to prognosis. In the first stage we wish to obtain complete cure of the patient and absolute arrest of invasion and the return of the lung to its normal condition, though there may be remaining some tendency to re-infection. The prognosis is favorable in this stage. In the second stage we still hope for arrest of the condition, but only after a certain amount of damage has taken place which may give the patient no trouble if the tendency to further attacks be kept under control. In the third stage the prognosis is not nearly so good. We have here absolute destruction of lung tissue which can never be made good, and the most favorable outlook is vastly less favorable than that of either of the two preceding. Finally, if actual cure and arrest is impossible, we may still estimate the probable rapidity of the disease processes and the duration of life and comfort of the patient. The physical symptoms of the first stage are noted, the earliest one being a slight attack of resonance and of breathing sounds, limited to one point, usually the apex, showing a certain degree of collapse of the lung. The apex may not be the first point, though it is rare that the disorder commences at the base. The author has seen it in only 60 cases out of about 19,000 that have passed under his hands. It is unfortunate because these basal are much more favorable than the apex tubercloses, and the latter are more so than those which begin in the middle lobe. According to Maguire's experience, which agrees with that of Bruce, tuberculosis beginning near the breast is, as a rule, rapidly fatal, though he would still further limit this by saying tuberculosis beginning in the middle lobe. Cases of multiple lesions indicate a greater intensity of tuberculous poisoning and greater vulnerability of the system in which they occur. These cases are noticed in their height in two forms: in one, which he has never seen described and which he calls the multiple pleuritic onset. The patient may not admit there is anything wrong, but suffers from vague ailments of varying types which are ascribed to rheumatism and neuralgia. A careful examination will show here and there perhaps a slight pleuritic rub, but no apparent consolidation and no respiratory distress. He knows of no beginning which bears a more unfavorable prognosis than this. After a short time patches of consolidation appear, cavities form and the whole system collapses. The next most serious form is what Bruce has called emphysematous phthisis and Jacoud and Stokes named the suffocative form of tuberculosis. The patient complains simply of cough, choking in character, and difficulty in breathing. The physical signs are lacking, but if the physician is on his guard he will find tubercle bacilli; the temperature may be normal, but is sometimes irregular and the patient wastes and becomes gradually weakened. None of the ordinary remedies for bronchitis and emphyema have any effect, and finally there is an outbreak of physical signs, increased weakness and general breakdown. It is one of the most serious forms of beginning tuberculosis. Still another form is mentioned, to which he gives no particular name, and the rule of thumb by which he recognizes it is, if the symptoms are out of all proportion greater than the physical signs, look out. The action on the tissue and its poisoning is in advance of the resisting power of the lung. There is irregularity of temperature sometimes becoming very marked and the patient may be kept in bed, with emaciation, weakness and loss of appetite. There may be

no cough or a very slight one and the slightest possible physical signs. The condition is often attributed to persistent influenza, not infrequently to subacute rheumatism or to sheer neurotism. Time after time he has seen this apparent quiescent state give way to a serious breakdown with lung destruction and early death. If a name were demanded, he would call this latent tuberculosis. The conditions that may precede the outbreak and possibly conduce to its occurrence are noticed. Chlorosis is rarely an antecedent. Florid patients are more apt to be seriously affected than anemic individuals, and he attributes this to a tendency to vasomotor paralysis. Deformity of the chest undoubtedly predisposes to tuberculosis, the more so since it so often depends on primary tubercular disease of the bone and to what we call the serofulous diathesis, but judging from his own experience, Maguire would say that the progress of pulmonary tuberculosis secondary to a pre-existing glandular affection is much slower and more favorable than when the lung tissue is primarily affected. The glands seem to form a resting-place for the disease, which frequently can be extirpated with them. Among the most important disorders from a prognostic point of view which may precede tuberculosis of the lungs are pleurisy, serous or purulent, and pneumonia. He has already mentioned the serious outlook when scattered patches of pleurisy precede the disease, and it is remarkable, judging from the results of many observers, how often an apparently simple pleurisy is really tuberculosis and yet how comparatively seldom pleurisy is followed by pulmonary involvement. From actual observation he does not think breakdown of tuberculosis following pleurisy is so serious in prognosis as those forms that have not been preceded by this affection, and the occurrence of pleuritic effusion in the course of pulmonary tuberculosis, especially in the invasion stage, seems to be actually beneficial provided it is not removed. When empyema occurs and has been removed by operation, it is remarkable how seldom it is followed by pulmonary tuberculosis. Pneumonia is an essential element of pulmonary tuberculosis and gives rise to the physical signs from which we form our diagnosis, but pneumonia, not of itself tuberculous, but occurring in a person predisposed to the disease, does not materially affect the progress of subsequent tuberculosis. Most pneumonias affect the base of the lung, and tuberculosis starting there is, as has already been stated, rare and slow in progress. Pneumonia of the apex not necessarily tuberculous is generally followed by complete resolution of the lung, even more so when the base is affected. Urinary tuberculosis, beginning as such, remains so for a long time as a rule, but near the end of such cases one does meet with lung tuberculosis, but the lung trouble usually plays only a minor part in causing the death of the patient. The influence of hereditary tendency can be by no means ignored, and whenever present he has found it seriously to affect the gravity of the case. While most of his patients were sedentary in their habits, a curious exception is noted among the Polish-Jew tailors of London, who live under most unsanitary conditions, and yet rarely have tuberculous affections, though they suffer greatly from bronchitis and other catarrhs.

The Treatment of Certain Chronic Abscesses by Simple Aspiration. **WILLIAM H. BENNETT.**—After reporting several cases in which aspiration was employed for tuberculous abscesses with good results, the author remarks that he does not wish to advocate the indiscriminate use of this treatment to the exclusion of the more scientific method by free incision and scraping. All he wishes to do is to point out that aspiration in the method here performed is of value in certain cases where treatment by the other method is extremely undesirable and often disastrous. The slight difficulty in the matter of sterilization and slight inconvenience to the patient are its advantages. The essential points are, besides absolute surgical cleanliness, to be sure to cease to withdraw the contents the moment any sign of blood shows itself, and not to allow the abscess to regain more than one-half its former size before aspirating again. This last applies not only to the original tapping, but also to recurrent ones. The more slowly the fluid is withdrawn the better.

Annales de Gyn. et d'Obst. (Paris), October.

Puerperal Sepsis. DRAGHIESCU.—The method of treating puerperal sepsis at Bucharest is by systematic irrigation of the uterus whenever, after delivery, the patient has a chill, temperature of 38 C., and pulse 100. The uterus is then packed with iodoform gauze moistened with a 5 to 10 per cent. solution of phenic acid. The gauze slightly distends the organ and by direct contact cauterizes the surface and promotes uterine contractions. It is renewed twice in twenty-four hours. The patient recovers more rapidly with this than with any other method of treatment, and affections of the adnexa, etc., and phlebitis are much less frequent. The mortality has ranged from .05 to .22 per cent. of all accouchements since this treatment was instituted in 1895. There were 3 deaths, or .13 per cent., of 2047 deliveries in 1899.

Treatment of Puerperal Eclampsia. PORAK.—According to Porak, eclampsia is an auto-intoxication of intestinal origin. He therefore treats it by copious flushing of the bowels, using 30 to 50 liters of tepid, 7 per 1000 salt solution under weak pressure. This irrigation brings at last a discharge of pure bile, and then he desists. Infusion into the blood is also an important aid. He considers the convulsions of reflex origin, and consequently forbids all food or drinks by the stomach, and if obstetrical intervention is necessary, abolishes the reflexes by profound narcosis. Since he has been treating eclampsia on these principles he has had only five die out of forty-seven cases, and two of these deaths could not be attributed to the eclampsia.

Anterior Colpohysterotomy for Chronic Inversion of the Uterus. G. SPINELLI.—The finger is introduced into the inverted organ through a transverse incision in the cervix, and the anterior wall is then incised on the median line to the bottom. The uterus is then turned right side out, the incisions are sutured and the organ is replaced. There is much less tendency to the formation of adhesions by this anterior intervention than by the usual posterior incision.

Malignity of Hydatidiform Mole. F. LA TORRE.—Unless the stroma of the villi is involved, the mole is not malignant, and La Torre cites three cases in which the patients are still in good health two to eight years after spontaneous expulsion of a mole.

Autotransplantation of Ovary. MAUCLAIRE.—It is sometimes impossible to leave a sound ovary *in situ* during a salpingo-ovariectomy. In such cases Mauclaire urges transplanting the ablated ovary elsewhere instead of sacrificing it completely. He has thus transplanted the ovary in seven women under the skin of the median incision or in the inguinal region, but he was obliged to remove it later in four cases, as the organ proved septic. In the three others it healed in place and is still palpable, several months later. Menstruation has continued regular in one of the patients with a transplanted ovary after bilateral salpingo-ovariectomy. Pozzi does not approve of the procedure, as he thinks that the transplanted organ will be absorbed or expelled as a foreign body. He believes that the disturbances attributed to the premature menopause have been very much exaggerated. Bouilly has noticed that women near the menopause are apt to suffer more from these post-operative troubles, suggesting an "ovarian habit." Jayle has recently called attention to the necessity of carefully testing the functioning of the ovary before operating. If there are evidences of ovarian insufficiency there is little advantage to be derived from saving the organ.

Annales de l'Institut Pasteur (Paris), October.

Autosecretions of Microbes. J. DANYSZ.—In the course of attempts to immunize the anthrax bacillus against the bactericidal action of rat serum, Danyasz has become convinced that the microbe is dissolved by a diastase which it secretes itself, and that the action of this diastase becomes pathogenic when it is no longer held in check or compensated. This diastatic action and the appreciable pathogenic symptoms noted in consequence of the supposed action of alexins, and probably also of lysins and toxins, on living organisms or tissues may be produced by this substance secreted by the cells themselves, and in this case specific antitoxins would have no direct in-

fluence on this substance nor on the symptoms which it originates. It follows, therefore, that if there is usually a diastatic element in the action of alexins, lysins or toxins, it need not be inferred that these substances are diastases or that they contain any.

Annales des Mal. Gen.-Ur. (Paris), September.

Neuropathic Hematuria. LANCERAUX.—The hematuria was always preceded by pains in the joints. This suggested that quinin might prove useful, and experience has emphatically confirmed this assumption, the quinin in doses of .8 to 1.5, supplemented by hydrotherapy and rest.

Bulletin de l'Acad. de Med. (Paris), November 20.

Treatment of Cancer With Anticellular Serum. WLAEFF AND H. DE VILLIERS.—With blastomycetes derived from malignant tumors the writers have succeeded in immunizing animals and have produced an active serum in pigeons, hens and geese. This serum injected in patients with inoperable cancer arrests the tumor in most cases and leads to its retrogression for a time. Wlaeff claims that this improvement is sufficient to transform an inoperable into an operable tumor. The serum has been tested by several of the Paris hospital physicians as a last resort in inoperable cases, and all concur in proclaiming its entire harmlessness, and the subjective benefit derived. The pain and functional disturbances are certainly much improved; strength, appetite and sleep return, but these effects may be due to suggestion. On the other hand, the modification in the tumor is objectively apparent. It diminishes in size, contracts, becomes harder, hemorrhages cease or are less frequent. The ulcerations may become partially repaired and the involved ganglia also diminish in size. But this modification is transient, in every case the neoplasm resumed its course sooner or later. The anticellular serum does not have a very firm scientific foundation, as the connection between the blastomycetes and cancer is still disputed. Berger observes, after watching its effects on about a dozen patients, that the precarious character of the improvement attained with anticellular serum should not prevent resort to it when indicated, as even transient improvement is a great boon in many cases.

Presse Medicale (Paris), November 21 and 24.

The Liver Function in Infantile Gastroenteritis. E. TERRIEN.—Exact tests of the absolute functioning of the liver in nurslings have not yet been made on a comprehensive scale, and tests of the urogeenic function have been so fraught with errors that the results have no value. Terrien has been studying the glycogetic function of the liver after establishing that alimentary glycosuria is very frequent in infantile gastroenteritis, and that it can be considered pathologic whenever it appears with ingestion of less than 4 grams of pure glucose to the kilogram of body-weight, or 3.5 of pure lactose. The absence of alimentary glycosuria does not necessarily indicate that the liver function is normal; too many causes outside of the liver may co-operate in this result. But if the test is positive, an insufficiency of the liver is evident, as Terrien has demonstrated that the factors of the renal permeability and the glycolytic power of the tissues are more important theoretically than practically in these cases. The same applies also to the absorbing power of the intestinal walls. Whether the barrier is in the liver, or in the liver and intestines combined, it is evident that this barrier has been broken down and that it allows the glucose to pass and also probably the soluble poisons and intestinal toxins. This is a plausible explanation for the emaciation and cachexia that persist with progressively increasing alimentary glycosuria after cessation of the symptoms of the gastroenteritis.

November 24.

Relations Between the Nitrogen and the Chlorids in the Gastric Juice. J. WINTER AND A. FALLOISE.—The theory generally accepted in regard to the process of digestion is based too exclusively on peptonization *in vitro*, and leaves many of the phenomena of digestion unexplained. Peptonization is in reality merely one isolated phase of gastric digestion. According to the theory advocated in this communication, there is no

true secretion of hydrochloric acid. This acid, free and in combination, is formed in the cavity of the stomach. This theory conflicts with our preconceived ideas in regard to digestion, but it harmonizes with all the known facts, and even allows us to anticipate and foretell the phenomena. It reveals the existence of multiple connections between the organism and the gastric juice. The results of tests are tabulated which show that there is absolutely no proportion between the amount of nitrogen and the amount of hydrochloric acid in the gastric juice. They demonstrate, however, certain laws of proportion between the dissolved nitrogen and the organic chlorine in combination. The amount of nitrogen increases in proportion to the amount of bound chlorides and with the immediate product of their dissociation, the organic chlorine. This dissociation is influenced by the progress of the concentration. The organic chlorine appears as a transient combination correlated to the hydration of the nitrogenized matters. It is, therefore, possible to calculate the amounts of the chemical constituents of the gastric juice when one is known, as they are bound together by close and regular relations. The arguments and data demonstrate that digestion may occur in the total absence of free hydrochloric acid in the stomach contents. The presence of hydrochloric acid is merely an index of the rapid progress of peptonization. The results of the tests also proclaim that the reciprocal dependence between the organs extends also to the most infinitesimal particles dissolved in the gastric fluid.

Revue de Med. (Paris), November.

General Paralysis in Malaria. MONTYEL.—An etiologic connection was apparent in eight cases observed by Montyel. Paralysis on a malarial foundation is almost always rapidly progressive. Acute malarial infection, he asserts, may induce general paralysis or pseudo-paralysis in the predisposed. Chronic malaria may produce the same effect and may even originate general paralysis in the non-predisposed. The malarial infection frequently causes cerebral congestions, which complicate and aggravate the paralysis.

Semaine Medicale (Paris), November 21 and 28.

Toxic Dyscrasia Complicating Diabetes. R. LÉPINE.—Three important works have been published this year on the cyanogen compounds and nitriles. Lépine thinks that the facts presented have some bearing on the etiology and treatment of the toxic dyscrasia of diabetes. Sternberg has suggested that beta-oxylbutyric acid might be derived from beta-amidobutyric acid. He established that the latter acid produces in the dog and cat symptoms resembling those of diabetic coma, acceleration of the pulse, increased amplitude of respiration and coma. It is much more toxic than beta-oxylbutyric acid, as it kills in the dose of one gram per kilogram. It is generally supposed that oxylbutyric acid is derived from the fats, but some experts still maintain that proteid substances are also a source of oxylbutyric acid and eventually of amidobutyric acid. Although Sternberg's hypothesis can not be proved yet it is supported by the similarity in the symptoms, and the fact that as amidobutyric acid becomes hydrated, it generates beta-oxylbutyric acid at the same time that it liberates a molecule of ammonia. This may prove to be one of the sources of the excess of ammonia noted in diabetic urine in case of toxic dyscrasia. The chemical equation corresponding to amidobutyric nitrile and amidobutyric acid suggests a possible origin for the amidobutyric acid. The hydration of a molecule of amidobutyric nitrile generates a molecule of amidobutyric acid and also a molecule of ammonia. There is here a second source for the excess of ammonia in the urine. We know that albuminoid substances contain complex nitriles, harmless originally, but if molecular subtraction occurs by the action of suitable reagents, these nitriles become formidable poisons as they are simplified, as for example cinnamic nitrile, whose toxicity is equal to that of hydrocyanic acid. Applying these data to the question of the toxic dyscrasia complicating diabetes, Lépine asserts that if beta-amidobutyric acid be not the actual causal agent of diabetic coma, the latter is probably due to some other derivative of the complex nitriles which form an integral part of our tissues. Filehne asserts that

the organism becomes accustomed in time to any poison given in repeated doses, but the researches of Heymans and Masoin, reported in the *Arch. Int. de Pharmacodynamie*, 1900, vii, establish that this is not the case with the poisons in question in this case. Fiquet's study of the properties of the nitrile-phenols, (*Jour. de Phys.*, 1900, September) shows that the introduction of a phenol—especially if carboxylated—into the molecule of a nitrile abolishes its toxicity. He suggests the possibility that the phenols will enter into combination with the toxins in the organism and thus annul their toxicity. As some of the phenols are very slightly toxic, Lépine remarks that the various facts cited justify the attempt to utilize the phenols in the treatment of the prodromic stage of diabetic coma. In the meanwhile he advises careful surveillance of the kidney, daily use of a slightly diuretic mineral water, and prolonged, large doses of sodium bicarbonate, inhalation of oxygen, and in case of imminent coma, intravenous infusion of possibly two or three liters of an alkaline salt solution, made very slowly, auscultating the heart occasionally. Subcutaneous injections are dangerous in diabetes.

November 28.

Determination of the Amount of a Pleural Effusion by Methylene Blue. NICLOT.—This colorimetric estimation of the quantity of fluid in the pleura has been found accurate in an experience of three cases. It is based on the principle that a certain amount of methylene blue introduced into the effusion will stain it a lighter or darker color according to the amount of the fluid. By comparison with a test-tube containing some of the unstained fluid, the quantity can be gauged with mathematical exactness.

Archiv f. Ophthalmologie (Leipsic), October 23.

Conjunctivitis Petrificans. T. LEBER.—Since Leber first described in 1895 the acute process of calcification to which he applied the term in the title, he has had occasion to observe and follow three cases of typical and three others which differ in some respects from the exact type described. The process differs from ordinary calcification as the lime is still in an organic, crystallizable combination. Two or three similar cases are on record from preceding centuries, one stated to be the result of witchcraft. The lesion first appears as white opaque spots, with no inflammation nor subjective disturbances, or very slight if they occur. It resembles the action of a caustic, especially of lead-water. The affection progresses spasmodically, new foci appearing and others healing or lingering for weeks, months or even years. The possibility of complete retrogression of the conjunctival process is in striking contrast to its severity. The smaller foci vanish completely by absorption or elimination of the affected tissue but the more extensive leave the membrane slightly thickened and shriveled at the spot, but not at all in proportion to the extent of the lesion. A tendency to recurrence may remain but gradually becomes attenuated, although in some cases the attacks recur in endless succession terminating in blindness. Weak antiseptics may prove useful at first, but later, no irritating substance is tolerated. Warm, moist compresses favor the expulsion of the necrotic tissue. Excision of the focus, when possible, abbreviated the attack and rendered recurrence milder. No microorganisms could be discovered, but the propagation of the lesions by contact favored the idea of a microbial origin.

Congenital Corectopia. E. V. HIPPEL.—Examination of an eye enucleated on account of traumatism showed a condition of congenital corectopia and luxation of the lens, confirmed by investigation of the other eye. The iris had been pulled backward by a connecting strip of solidified vitreous substance containing an artery and two or three veins. The luxation of the lens had been secondary.

Centralblatt f. Chirurgie (Leipsic), December 1.

Improved Technique in Use of Gigli Wire Saw. I. GIGLI.—The fine serrated wire is now supplemented by an improved drill and inserter designed by Gigli for the purpose, which are described and illustrated in this communication. The drill has a large handle projecting outward and downward from one side, with a semicircular portion which fits over the skull of the patient and steadies the whole instrument.

Deutsche Med. Wochenschrift (Leipzig), November 15.

Specific Biologic Test for Albumin. UHLENHUTH.—The biologic method described is said to surpass in accuracy and delicacy any chemical test. Rabbits were treated with a solution of albumin from the eggs of hens or pigeons, injected repeatedly into the peritoneum or ingested per os. The serum of the animals acquired the property of rendering turbid a solution of the albumin and causing a precipitate to be deposited. The reaction does not occur with albumin from any source but eggs. The serum can be heated to 60 C., without losing this specific property.

The Freezing-Point of the Blood in Typhoid Fever. WALDVOGEL.—The results of comprehensive study of twenty-four cases of typhoid fever are tabulated. They prove that a higher freezing-point of the blood is not necessarily indicative of uremia. It is evidently not so much the quantity as the quality of the toxic substances retained in the blood that causes the disturbances in uremia. The freezing-point is higher in certain cases of typhoid fever—probably a phenomenon directly connected with the formation of antitoxin. In the cases in which the freezing-point is only slightly above normal—below .7—the prognosis of the disease is generally unfavorable.

Muenchener Med. Wochenschrift, November 27.

Hereditary, Progressive Spinal Atrophy of the Muscles in Children. J. HOFFMANN.—The disease commences in healthy children during the first year of life, first noticed as a symmetrical, lax, atrophic paralysis of the thigh and pelvic muscles, extending to the muscles of the back, abdomen, neck and shoulders in turn, with a descending course in the legs and arms. Death follows in one to four years from secondary pulmonary affections caused by the paralysis of the thoracic muscles. The intelligence and senses are normal and there are no bulbar symptoms. Hoffmann has had six patients with this disease, all in four families not at all related, but with a record of twenty-one cases in all. Energetic treatment of various kinds proved totally ineffectual. The autopsy findings in three cases out of three families coincided in every respect: symmetrical, very pronounced degeneration of the peripheral neurons of all the motor nerve pairs below the hypoglossus, degeneration of the multipolar ganglion cells of the anterior columns and of the anterior roots, degeneration of the motor peripheral nerves and intramuscular nerve ramifications, with muscular atrophy and degeneration proportional to the lesions in the spinal cord. Bruns has recently reported three cases of the same disease, differing only in the longer survival of the children, who are now 11 to 14 years old. Werdnig published the first description in 1891, with two cases, and two have since been reported.

Three Hundred Autopsies of Suicides. A. HELLER.—The autopsies were made at the Pathologic Institute at Kiel, and the findings demonstrated that nearly 50 per cent. of the so-called suicides had been mentally irresponsible, and consequently not actual suicides. Of the seventy women, 47.4 per cent. were menstruating, pregnant or convalescing from childbirth, the first forming 35.9 per cent. Syphilis seemed to be a factor in the suicides to a certain extent; eight subjects had syphilis and six syphilophobia, fostered by charlatans, frightening, pretending to treat and then collecting blackmail from them. In only 8 per cent. of the entire number of suicides were no traces of pathologic lesions to be discovered, including a few in advanced putrefaction.

Practical Method of Rendering Cow's Milk Easily Digestible. VON DUNGERN.—The cow's milk can be boiled first. Just before using, it is heated to body temperature and slightly coagulated with a small amount of rennet, then stirred to break up the curd, which restores the milk to nearly normal appearance. Children relish it the same as before, but all danger of the formation of large, hard curds in the stomach is entirely obviated. Aseptic rennet for the purpose is now prepared for the market. This method has been extensively tested by von Dungen and others with entire success.

Grece Medicale (Syra), November.

Repeated Laparotomies in Peritoneal Tuberculosis. J. GALVANI.—This communication describes the excellent results

obtained in chronic peritoneal tuberculosis by laparotomy systematically repeated as many times as indicated. In 20 cases he performed a second laparotomy in seven days to twenty-three months after the first. Some died from intestinal perforation, but many were cured. Two patients required three laparotomies, one four and another five. Galvani therefore asserts that systematic repetition of the laparotomy will save many patients now abandoned, as it were, after the surgeon has done one laparotomy.

Annali di Ost. e. Gin. (Milan), xxii, 4 and 7.

Veratrum Viride in Eclampsia. L. MANOIGALLI.—Veratrum has proved unfaillingly effective in arresting the convulsions in eighteen cases of puerperal eclampsia in Mangiagalli's experience during the last four years.

Gazzeta Degli Osp. (Milan), November 25.

Mistakes in Diagnosis from Presence of Pseudo-Tubercle Bacillus. E. BENVENUTI.—A case is described diagnosed tubercular gangrene of the lungs, but the autopsy disclosed the entire absence of indications of tuberculosis. A bacillus was found in abundance closely resembling the tubercle bacillus, but differing in certain points. It is evidently the same bacillus that has been found in butter, in cases of pulmonary gangrene and in the dejecta of animals by Rabinowitsch, Petri, Moeller and others, the pseudo-tubercle or smegma bacillus. In the case described the bacilli might have been derived from the stomach, which would explain the indol reaction noted. Others have probably made the same mistake; for instance, the case related by Tuffier at the Paris Société de Chirurgie last March of a woman with tubercular gangrene of the lungs who recovered completely after pneumotomy. The bacilli found in the sputa and assumed to be tubercle bacilli must have been the spurious variety, as otherwise such complete recovery after mere pneumotomy is inexplicable.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., November 25 to Dec. 5, 1900, inclusive:

- George W. Adair, major and surgeon, U. S. A., member of a retiring board convened in Chicago.
 David H. Coffin, lieutenant and asst. surgeon (recently appointed, with rank from Nov. 19, 1900), is assigned to the 39th U. S. Inf. Vols.
 Daniel C. Cooney, acting asst. surgeon, orders directing annulment of contract revoked, leave of absence granted.
 Charles H. Fischer, acting asst. surgeon, from Fort Apache, Ariz., to Washington, D. C., for annulment of contract.
 Valery Hayard, major and surgeon, U. S. A., leave of absence from the Division of Cuba extended, he will report at Washington, D. C., to the surgeon-general, on official business, thereafter remaining his status on leave of absence.
 James H. Hyasell, major and surgeon, Vols., honorably discharged from the service of the United States, to take effect Dec. 19, 1900.

Theodore C. Lyster, lieutenant and asst.-surgeon, U. S. A., leave of absence from the Division of Cuba extended.

Henry I. Raymond, captain and asst.-surgeon, member of a retiring board convened at Chicago.

Charles W. Thorp, acting asst.-surgeon, from Denver, Colo., to San Francisco, Cal., to accompany troops to Manila, P. I., and for assignment to duty in the Division of the Philippines.

J. Samuel White, acting asst.-surgeon, from Manheim, Pa., to San Francisco, Cal., to accompany troops to Manila, P. I., and for assignment in the Division of the Philippines.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Dec. 8, 1900:

P. A. Surgeon R. S. Blakeman, ordered to be examined December 10, at Washington, D. C., for retirement, and thence home to wait orders.

P. A. Surgeon A. W. Dunbar, ordered to the Vermont for duty with the crew of the *Wisconsin*, revoked; ordered to duty at naval hospital, Mare Island.

Asst.-Surgeon W. M. Carton, ordered to the Washington navy yard.

Surgeon C. Biddle, ordered to the naval hospital, Norfolk, Va., for temporary duty.

Asst.-Surgeon E. J. Crow, detached from the *Monadnock* and ordered to the *Catigua*.

Pharmacist J. Cowan, detached from the *Monadnock* and ordered to the *Catigua*, and to additional duty at the Cavite naval station.

Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine Hospital Service for the seven days ended Dec. 6, 1900:

Surgeon H. R. Carter, granted extension of leave of absence for 15 days from December 1, on account of sickness.

Surgeon C. T. Peckham, granted leave of absence for two months from December 17.

Surgeon S. D. Brooks, granted leave of absence for five days from December 11.

Surgeon V. H. McIntosh, to proceed to Perry, Ga., for special temporary duty.

P. A. Surgeon G. B. Young, granted leave of absence for three days.

P. A. Surgeon H. W. Wickes, granted extension of leave of absence for ten days.

P. A. Surgeon L. E. Cofer, upon being relieved from duty at Los Angeles, Cal., to proceed to Honolulu, H. I., and report to Surgeon D. A. Carmichael for duty.

Asst.-Surgeon H. Hastings, relieved from duty at the Columbia River quarantine, Astoria, Ore., and directed to proceed to Los Angeles, Cal., and assume command of the service, relieving P. A. Surgeon Cofer.

Asst.-Surgeon H. B. Parker, to proceed to Magnolia and Fayette, Miss., and St. Joseph, La., for special temporary duty.

Asst.-Surgeon C. W. Vogel, upon being relieved from duty at the San Francisco quarantine to proceed to San Francisco, Cal., and report to medical officer in command for duty and assignment to quarters.

Health Reports.

The following cases of smallpox, yellow fever and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 8, 1900:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Nov. 12-24, 3 cases.
 Kansas: Wichita, Nov. 17-Dec. 1, 10 cases.
 Kentucky: Lexington, Nov. 17-Dec. 1, 3 cases.
 Illinois: Cairo, Nov. 27, 1 case.
 Minnesota: Duluth, Nov. 8-22, 54 cases; Minneapolis, Nov. 24-Dec. 1, 1 case; St. Paul, Nov. 8-22, 2 cases; Winona, Nov. 24-Dec. 1, 60 cases; the counties of Carlton, Kandiyohi, Le Sueur, Lyon, Meeker, Pine, Ramsey and Wright, Nov. 8-22, 73 cases.
 Missouri: St. Louis, Nov. 23-Dec. 3, 3 cases.
 New York: Nov. 24-Dec. 1, 34 cases.
 Ohio: Nov. 24-Dec. 1, Ashabula, 7 cases; Cleveland, 34 cases, 1 death.
 Pennsylvania: Allegheny, Nov. 24-Dec. 1, 1 case.
 South Carolina: Greenville, Nov. 24-Dec. 1, 3 cases.
 Tennessee: Nashville, Nov. 24-Dec. 1, 1 case.
 Texas: Nov. 22, Blue Springs, present; Sublime, 14 cases; Vashit, present.
 Virginia: Alexandria county, Dec. 5, 1 case.

West Virginia: Harrison County, Nov. 28, 18 cases; Wheeling, Nov. 24-Dec. 1, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 10-17, 29 cases.
 Ecuador: Guayaquil, Oct. 6-Nov. 17, 40 deaths.
 Egypt: Cairo, Nov. 3-11, 1 death.
 France: Paris, Nov. 10-17, 15 deaths.
 Gibraltar: Nov. 3-11, 1 case.
 Greece: Athens, Nov. 10-17, 2 cases, 1 death.
 Mexico: Tampico, Nov. 11-18, 4 deaths; Vera Cruz, Nov. 17-24, 1 death.
 Russia: Moscow, Nov. 3-10, 2 cases; Odessa, Nov. 10-17, 14 cases, 7 deaths; St. Petersburg, Nov. 3-10, 2 cases, 2 deaths.
 Scotland: Glasgow, Nov. 17-23, 24 cases, 2 deaths.
 Spain: Barcelona, Oct. 27-Nov. 3, 48 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: 40 miles south of Natchez, Miss., Nov. 27, 5 cases.
 Mississippi: Natchez, Nov. 27, 1 case; Osyka, Dec. 4, possibly 1, fatal.

YELLOW FEVER—FOREIGN AND INSULAR.

Cuba: Havana, Nov. 17-24, 14 deaths.
 Dominican Republic: Puerto Plata, Nov. 3-17, 3 deaths.
 Mexico: Vera Cruz, Nov. 17-24, 3 deaths.
 PHILIPPINE ISLANDS: Manila, Sept. 29-Oct. 6, 2 cases.
 PHILIPPINE ISLANDS: Manila, Sept. 29-Oct. 6, 2 cases.
 PHILIPPINE ISLANDS: Manila, Sept. 29-Oct. 6, 2 cases.
 Africa: Cape Willamtown vicinity, Nov. 17, 6 cases, 4 deaths.
 China: Hongkong, Oct. 13-27, 6 deaths.
 Japan: Kobe, Oct. 15-27, 3 cases.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION. . . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-Laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the American Medical Association

Vol. XXXV.

Original Articles.

TREATMENT OF INJURIES TO THE URETERS.*

BYRON B. DAVIS, M.D.

Professor of Surgical Pathology and Clinical Surgery, Omaha Medical College; Surgeon to Immanuel Hospital, etc.
OMAHA, NEB.

Feb. 22, 1900, Mrs. B. M., aged 38 years, housewife, with no children, reported that two months before, she began having morning nausea, and supposed she was pregnant, but menstruation continued. Thursday, February 15, one week before I saw her in consultation with Drs. Hoffman and Detwiler, what seemed to be a normal menstruation came to an end, and she felt perfectly well. The next morning she felt a sudden sharp pain in the lower abdomen, radiating toward the left side, and she had to lie down. A little more menstrual blood made its appearance, and she has had a slight flow ever since, but nothing has been found to suggest a miscarriage, and no decidua tissue has been discovered. Pain has been at times severe and cutting. Since February 18, Drs. Hoffman and Detwiler have seen her daily and her temperature has never been above normal, nor has her pulse suggested shock. A mass in the left lower quadrant of the abdomen has been increasing rapidly in size.

When seen by the writer, February 22, she had a normal temperature and pulse, and was a spare but apparently well-nourished woman. A slightly nodular mass was found in the left inguinal region, extending an inch above the umbilicus and more than an inch to the right of the median line. The mass also presented behind the cervix, tense, but slightly fluctuating. It was not very painful on pressure.

Three explanations were suggested to account for the condition: 1, a pelvic abscess caused by an undiscovered abortion; 2, a ruptured tubal pregnancy; 3, an intraligamentous cyst, growing rapidly because of some change in its circulation brought about by trauma or pressure. The first supposition was untenable because of the absence of fever or increased pulse-rate. Neither was the pain significant of a rapid pus formation. Extruterine pregnancy seemed to also be negated from absence of severe collapse, from the fact that the mass was firmer than we usually find in such cases, and from the somewhat nodular form of the growth. The most plausible explanation was that we had to do with a rapidly-growing intraligamentous cyst.

Operation was performed Feb. 26, at 9 a. m., at Immanuel Hospital. Drs. Hoffman and Detwiler assisted, and Dr. Peterson, the house surgeon, gave ether. On opening the abdomen, an adherent, thick-walled cyst was found, the intestines and omentum being firmly adherent to it and to each other everywhere. After loosening the adhesions, some of which were so vascular they had to be ligated and cut, the left tube was found to be tensely stretched over the tumor, proving it to be intraligamentous. As it grew, it had burrowed up behind the peritoneum. The contents—clear serum—were removed by aspiration.

By hard work, lasting an hour, the cyst-wall was completely enucleated, but during this process several clamps had to be put on to stop the free bleeding. Sufficient care was supposed to

have been taken to avoid the ureter, but, after clearing the mass away, a suspicious-looking vessel was found hanging loose in the pelvis. A small Kelly's probe was introduced into its lumen, and passed directly into the bladder. This portion was about 3½ inches long, so search was made for the upper fragment, and it was found within the grasp of a pair of forceps so near the median line that no thought had been present of being in a dangerous locality. The probe passed directly up to the pelvis of the kidney. I therefore united the severed ends of the ureter by an end-in-end anastomosis. The lower end was split for a distance of a centimeter, by introducing one blade of a pair of fine scissors into the lumen. Next, with a fine catgut suture, threaded with a needle at each end, the needles were passed side by side into the lumen of the upper fragment, and from within out through the wall of the ureter about one-eighth inch from the open end. These needles were about one-fifth the circumference of the duct apart, and at an equal distance from the free end. Next the needles were introduced into the lumen of the lower fragment and carried from within out through its wall at a distance of about one-half inch below the lower angle made by the slit in the wall; the needles here being the same distance apart as in the upper portion. (See Fig. 1.) With an assistant holding the free angles made by the slit in the lower fragment by means of small artery forceps, the opening was made more patulous and the duct steadied, while the upper fragment was drawn down within the lower. The catgut suture was then tied, and this held the upper fragment securely invaginated within the lower. With two additional catgut sutures the slit made in the lower fragment was repaired. (See Fig. 2.) The ureter was then covered as well as possible with peritoneum and the abdominal wall closed, but with a strip of gauze extending from the lower angle of the wound to the point of union of the duct.

The patient suffered from shock but quickly rallied. The first urine drawn from the bladder after the operation contained a slight amount of blood. At 6 p. m. of the day of operation, the temperature reached 99.4 degrees, the highest it rose at any time. March 3, the fifth day after the operation, the gauze drain was removed. No leakage of urine had occurred. By March 14 the wound was nicely healed and the patient was allowed to sit up. On March 22, to test the patency of the ureter, a Harris "segregator" was used, and in thirty minutes 18 c.c. of urine was collected from the left—injured—kidney and 16 c.c. from the right. Phosphates were in excess, but otherwise the urine from each side was normal. On March 23, the patient was discharged from the hospital, and on May 29 was doing well, having gained several pounds in weight, and her urine being normal.

The possibility of injury to the ureter in intrapelvic operations has been recognized since the beginning of abdominal operations, but the full extent of this danger seems not to have been fully appreciated until the present decade. Could the whole truth be known, many cases of death reported as "shock" or "exhaustion" would have to be charged to "accidental injury to the ureter." Within a short time the writer learned of a woman dying from suppression of the urine shortly after an abdominal operation. Autopsy revealed the fact that both ureters had been tied and cut. Had no autopsy been secured,

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

this would probably have been reported as a case of the "pernicious effects of the anesthetic." By making a regular practice of careful review after every complicated intrapelvic operation, one would not be likely to close the abdomen without discovering such an injury.

The manner of dealing with a severed ureter, whether it be accidental or because of disease, will depend on the point of division. In the past the treatment advised and occasionally carried out was to remove the corresponding kidney, a measure so radical and so destructive that it had little except necessity to commend it. If the opposite kidney happened to be sound and the patient survived the shock of a major operation after having already endured a prolonged and difficult one, the result was satisfactory, although a person with only one kidney is greatly handicapped. To avoid so radical a procedure, when it was shown by the experiments of R. Harvey Reed and others that ligation of the ureter produced atrophy of the corresponding kidney, this was deemed a distinct gain, and was thought to mark an epoch in the treatment of this class of injuries. But it has been found that the results of ligation are not always the same, that atrophy does not always follow, and, if it does, the patient has the serious disability of having only one functioning kidney.

Fig. 1. Inverting upper fragment into lower.

Fig. 2. Anastomosis completed.

Stitching the severed ureteral end to the skin and thus establishing a permanent urinary fistula is less dangerous, so far as immediate results are concerned, but the disagreeable, not to say disgusting, condition in which the patient with such a fistula is left is enough to condemn it. In addition to the irritation of the skin and the foul odor which prevents the patient from mingling with his fellows, there is constant danger of an ascending infection to the pelvis of the kidney. This procedure has justly fallen into disuse and only the circumstance of this being the only procedure possible would warrant a surgeon in adopting it.

Much experimental work has been done to devise a safe and satisfactory method of implanting the severed ureteral end into the rectum or other part of the alimentary canal, but thus far it has not proved itself of value. Notwithstanding the apparent success of Martin's recent case of implantation of both ureters into the rectum with removal of the bladder for carcinoma, most surgeons would hesitate to follow his example. Theoretically, by imitating the oblique method by which the ureter enters the bladder, it was thought that infection of the kidney might be avoided, but the results in experiments on animals have not been encouraging. Dr. Reuben Peterson's general conclusions

were that the primary mortality of the uretero-intestinal anastomosis, both in experimental work on animals and in man, was exceedingly high; that all efforts to prevent ascending renal infection in animals or in man had proved futile, and that the operation was unjustifiable, either for the purpose of making the patient more comfortable or for malignant disease of the bladder. Van Hook³ says: "Implantation of the ureter into the intestines at any point is, in the writer's judgment, absolutely contraindicated, because of the certainty of infection of the ureter and its kidney." There is only one condition where implantation of the ureter into the intestine would seem justifiable until: 1, the immediate mortality is reduced, and 2, the dangers of an ascending infection to the pelvis of the kidney are lessened. The condition referred to is where the ureter is severed so high up that the proximal end can not be implanted into the bladder, and where there is so much loss of substance that the severed ureteral ends can not be united without too great tension. With this condition present, oblique implantation of the ureter into the colon would be preferable to the establishment of an external urinary fistula, to nephrectomy or to ligation of the ureter.

Implantation of the ureter into the vagina has little to commend it unless, by a plastic operation, it can be made to serve the purpose of a reservoir for the urine and its natural functions be abolished. Except in the event of total ablation of the bladder, no condition that warrants such an operation is conceivable. Even then one might follow the lead of Nicaeus, who successfully implanted the ureter into the urethra.

But two practicable methods are left for disposing of an accidentally severed ureter: Implantation of the proximal end into the bladder and uretero-ureteral anastomosis. The former is only applicable in those cases in which the division occurs low down. In order to prevent retroflux of urine when the bladder contracts, and to minimize the dangers of an ascending infection, the method uniformly adopted is to imitate the natural manner in which the ureter enters the bladder. Novaro, Kelly, Penrose, Price, King and Baldy are some of the men who have successfully implanted the ureter into the bladder.

J. F. Baldwin² reported the details of a case in which he excised 1½ inches of the right ureter while performing a hysterectomy. The lower end was too short for uretero-ureteral anastomosis. The proximal end, under considerable tension, was implanted into the bladder. To lessen the tension the bladder was drawn upward by suturing it to the broad ligament. His patient recovered.

The first to perform the operation of uretero-ureteral anastomosis was Schopf, in 1886. The man who has probably done most to perfect a technique is Weller Van Hook, whose method of ligation of the distal end and implantation of the proximal end through a lateral longitudinal slit into the distal portion, has been practiced successfully in a number of cases. In summing up the advantages of his method, Van Hook³ says: 1. The urine is made to pass through its normal channel. 2. Healing takes place at once, without even temporary loss of function or a temporary fistula. 3. No stenosis occurs, even after a long interval of time. 4. The ureter can always be united, if accidentally injured at any operation, with materials always at hand. 5. Leakage can not occur, because the upper extremity of the ureter acts as an obturator to the lower portion of the tube. 6.

2. Phila. Med. Jour., Nov. 29, 1898.

3. Internat. Text-Book of Surg., iv, p. 572.

Scar-contraction can never injuriously diminish the lumen of the tube, because the scar which encircles the ureter after union by this method is equal in length to twice the extent of the incision in the side of the lower ureteral stump.

Transverse suture is difficult and seems likely to be followed by stricture, unless an effort is made, by splitting the ends, to increase the lumen. Hocheneegg is reported to have made use of this method. Bovée reports having successfully employed direct suture after having divided the ends obliquely.

Paggi is said to have been the first to propose end-in-end anastomosis, but I have been unable to find a description of his method or the technique of the method as carried out by others. The method of end-in-end anastomosis as carried out in this case seems to have all the advantages of Van Hook's method, with one or two additional: 1. It is simple and more quickly done. 2. There is less waste of substance, and it would be available when the Van Hook method would produce too great tension, or where the distal fragment is so short that union by Van Hook's method could not be made. It is much quicker, simpler and surer than by transverse suture or oblique end-to-end suture as employed by Bovée.

When division of the ureter occurs, the following would seem to be the rational mode of choosing the method of repair: 1. When possible to perform uretero-ureteral anastomosis this is the preferable procedure: end-in-end anastomosis, as employed in this case, seeming to me simpler and better. 2. When the distal portion is too short for uretero-ureteral anastomosis, implantation into the bladder should be performed. 3. When there is too much loss of substance to permit uretero-ureteral anastomosis, and the proximal end can not be brought down to the bladder even with the assistance of a diverticulum of the bladder, as devised by Van Hook, the procedure with the least objection is probably implantation into the colon.

EPISPADIC EXSTROPHY OF THE BLADDER COMPLETE.*

AP MORGAN VANCE, M.D.
LOUISVILLE, KY.

Dr. Rudolph Matas,¹ at the last meeting of the Association, gave such a complete résumé of the subject that it would be simply repetition to now enter into a general discussion of the topic—and in his conclusions favored Maydl's operation, holding that the autoplasmic operations could be little more than palliative, and never satisfactory. His paper decided me to report a case and exhibit the patient, showing the result of autoplasmic work. I do not know how original the procedure to be described may be, though I have been unable to find a report of such a one.

Mr. J. McE., aged 17 years, was referred to me by Dr. J. M. Mathews, on Oct. 26, 1897. He had come to Louisville to obtain a urinal and, if possible, get relief from the miserable condition of complete bladder exstrophy. Fig. 1 shows the condition before operation.

He was fairly well developed for his age, but his life was rendered unendurable as the result of excoriations from the urine and the contact of the clothing with the bulging posterior bladder wall, where ulceration with the deposit of calcareous material around the edges rendered the local condition horrible in the extreme. On Nov. 1,

1897, the first operation was done. This was much too soon, as five days was not sufficient to get the parts into proper condition, but it was done at this time because his family physician, Dr. Cowen, of Girard, Ill., who came with him, wished to return.

The epispadic penis was very short and drawn back into a sulcus at the lower part of the opening. The posterior bladder wall, with discharging ureters, presented a convex surface far in front of the abdominal plane, about the size of the half of a baseball or larger—when recumbent or in the Trendelenburg position a concave sulcus of corresponding dimensions presented.

The first step in the operation, as illustrated by Fig. 2, was to score as deeply as possible in a triangular manner.

FIGURE 1.

wide out into the iliac regions, then with strong forceps to drag upward and inward, still further loosening the tissues thus freed, bringing the mucous membrane along with the skin. When this loosening and stretching had been done sufficiently to allow the separated pudendal structure to be brought together in the middle line, the edges down to the end of the penis were vivified by slitting and brought together by two sets of sutures: one line of buried chromicized catgut, No. 1, which inverted the inner or mucous membrane side, and another of interrupted silkworm-gut which everted the outer or skin side. Over this a dressing of collodion and cotton was applied. The button-hole-like opening left above was used to drain the urine away, the patient being required to maintain the Trendelenburg position. No

1 THE JOURNAL, xxxiii, p. 260.

good resulted from this operation, except probably the piling up of tissue to be used to better advantage at the next attempt.

On Jan. 16, 1898, all the parts being healed and the resulting infiltration having disappeared, the above-described flap-splitting and suturing was repeated, the only difference being that I had less tension to combat and was gratified on removing the sutures on the tenth day to find that the penis was united and a fairly good bridge of tissue at the upper part of the pudendal portion also held together. Fig. 3 shows this result.

On July 16, six months later, the third operation was done. It consisted in the closure of the transverse opening at the upper part of the original open space. This

The new bladder has now been performing its function six months and is in a perfectly healthy condition. The penis has developed quite a good deal. The young man has been able to fulfill the duties of a salesman in a store, is able to keep himself dry and, in fact, is altogether a new man in every way. While recumbent about four ounces of urine will accumulate, and this is voided when he arises and can be passed out with some degree of force by voluntary effort. When upright the urine is received into an ordinary urinal. Fig. 4 shows the final result.

I had at the same time a second similar case, but the child was only 7 years of age. The result promised to be quite as good and was almost complete. He was allowed

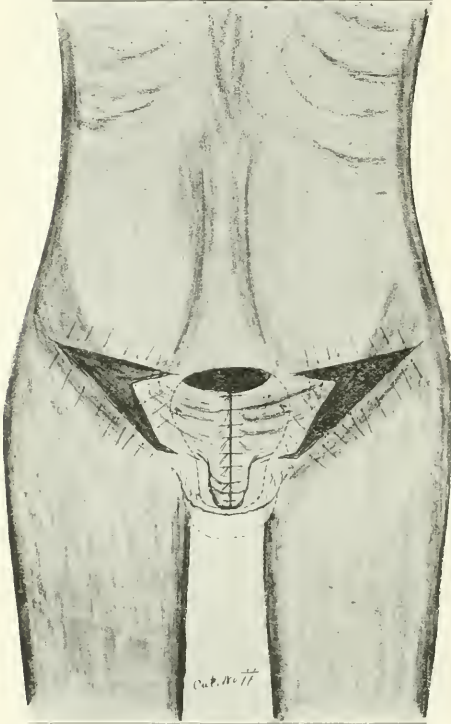

FIGURE 2.

was done by freshening the edges of the bridge of tissue and the line of skin above by splitting, the same method of suturing being used, except that both lines of sutures were buried and both were chromicized catgut. This healed from end to end, leaving a round hole about the size of a silver quarter still uncovered between the lower edge of the bridge of tissue above referred to and the root of the penis.

By this time the young man's improved condition encouraged great hopes of final success, but four other attempts at closure were made before I succeeded, and another year was required. These last procedures were done by splitting the edges of the opening and suturing, and each trial was followed by a decrease in the uncovered area. The last operation, done just two years after the first, finally finished the case.

FIGURE 3.

to return home on a visit, and has never returned for the finishing touches, much to my disappointment.

In this kind of work much patience is required both on the part of the patient and the surgeon, and many difficulties are to be overcome, principal among which are the septic surroundings, the difficulty of drawing away the urine, and the constant lack of rest of the parts due to the tendency to erections. Notwithstanding all the difficulties, the benefits justify one in the efforts at autoplasmic work.

Maydl's operation, in the light of future experience, may prove better, but I am inclined to believe that in the hands of the rank and file of surgeons it is a very grave procedure, to say nothing of the possible future complications that may arise in the way of disease of the kidneys due to septic invasion from below.

DISCUSSION.

DR. DEFOREST WILLARD, Philadelphia—I desire to congratulate Dr. Vance on the excellent results obtained in this case, which is certainly as satisfactory as I have ever seen. In spite, however, of the good results obtained in some of these cases, I think all of us will agree that operation after operation frequently fails to secure success. This class of patients are so disgusting to themselves and to others that they deserve the most careful attention, and none require more surgical skill. Nearly all of the external plastic operations are faulty from the fact that we turn our flaps with skin surface inward. Concretions on the inner surface of the bladder follow from deposition of urinary salts on the hairs, and subsequent opening of the bladder is sometimes necessary. This difficulty Dr. Vance wisely avoided by leaving the skin face of the flaps external.

FIGURE 4.

On the whole, I am convinced that the formation of an intestinal reservoir is better. To obtain this it is preferable to abandon the rectum and go higher up above the sigmoid flexure, since this flexure is a valve and helps to retain the urine. Such a reservoir permits the patient to void urine and feces at stated intervals, and seems at present the best result obtainable under the circumstances. The insertion of the ureter into the bowel is so liable to be followed by kidney infection that it is wiser to remove, at the same time, a portion of the bladder wall, in order to obtain the normal valve of the ureter, since we can never secure a similar valve after division of the tube.

DR. HOWARD A. KELLY, Baltimore—The condition of these exstrophic patients is indeed a sad one. The only operation we can do with certainty of immediate success, is to put the ureter with the neighboring portion of the bladder into the rectum, according to Maydl. The condition of this patient is how-

ever, remarkable, and does Dr. Vance great credit. I have a case under my care somewhat similar, and I have done a number of these skin-flap operations and tested their utility thoroughly, and have come to reject all operations that turn the skin in with the hair. I broke up the sacro-iliac joint to approximate the symphysis (Trendelenburg), but still it failed; and I then tried what has given me the best result, that is, skinning out the muscular bladder from the peritoneum (Sonnenburg). I dissected it loose from the underlying surface and brought the lax muscularis together. I was thus able to secure a reservoir of considerable size, which has held fairly well so far. I was also able at the same time to form a good penis. I could not have done Dr. Vance's operation in this case, as there were such extensive areas of scar tissue. Skinning up the bladder should be given a more careful trial.

DR. W. J. MEANS, Columbus, Ohio—At the Columbus meeting of the Association I exhibited a case of exstrophy of the bladder, on which I had operated a few weeks previous, similar to Dr. Vance's. The result obtained by the Doctor in this case is certainly excellent, and he is to be congratulated. The operation in my own case was successful in covering the bladder and making a pouch, but a failure in relieving the epispadias. I operated again two months ago for the latter condition with good success. If the patient has the fortitude to persevere, I am satisfied I can still further improve his condition. It was my desire to perform the Maydl operation, but when I mentioned the dangers attending it, his friends objected. It is my opinion that of all the methods tried for the relief of exstrophy of the bladder, none equal that of Maydl.

I had the pleasure of meeting Dr. Allen a few weeks ago. He informed me that the patient on whom he had performed the Maydl operation and presented to this section, was still in perfect health.

The method adopted by Dr. Vance in covering the exposed bladder is certainly ingenious, but I doubt if success follows in many cases. In my case I used the double skin flap. The patient has not had the difficulties from lime deposits that usually follow when the skin is used to form the internal layer of the covering. These plastic operations are, at best, only palliative. A natural reservoir for the urine, that can be emptied at the will of the person, can not be formed by artificial work. The only natural sphincter muscle contiguous to the ureters is the sphincter ani; but to utilize this the urine must be carried into the bowel. The longevity of patients where the rectum is used as a reservoir is a matter of the future to determine.

DR. MAXMILIAN HERZOG, Chicago—Dr. Jacob Frank, of Chicago, has recently devised an operation for exstrophy of the bladder. His operation consists of an anastomosis by the aid of his absorbable bone coupler. Frank has made his operation on a number of dogs, and I have myself made the post-mortem examination and histologic and bacteriologic examination on the animals operated on. Dr. Halstead of Chicago has had a chance to perform Frank's operation on the human being. When operating for exstrophy of the bladder it is undoubtedly very desirable to procure for the urine a receptacle which can be voided at will at certain intervals. The great trouble in making part of the intestines a receptacle for the urine is that the procedure as a rule leads to infection of the kidneys from the gut. Several of Dr. Frank's dogs, however, remained free from infection of the kidneys so that it appears that anastomoses of the bladder and rectum may be made, even in dogs, where the conditions are not as favorable as in the human being, without a subsequent infection of the kidneys.

DR. J. RILUS EASTMAN, Indianapolis—It may interest those members of the section who were present at the Columbus Meeting to know that the case of bladder exstrophy which I reported at that time is still doing well. One of the kidneys in this case was much disorganized and was removed. I removed the bladder mucosa and implanted the end of the ureter from the remaining right kidney at the tip of the clubbed epispadic penis, the penis having been dorsally split in the median sagittal line for reception of the ureter. All the work of secretion of urine has therefore devolved upon the one kidney.

but the boy has enjoyed good health at all times since the operation (eighteen months.) He wears a specially-constructed silver and rubber urinal and is apparently unhampered in work and play by his deformity.

DR. F. G. CONNELL, Chicago—During the last year I have had occasion to look up the literature on exstrophy of the bladder, in connection with some experimental work along this line upon the lower animals, and have found that the methods of treatment have been, for convenience, divided into palliative and radical. Under the former are included all those methods which, when completed, do not give to the individual, absolute control over the evacuation of urine. And those methods wherein the result does admit of this control by the patient are classed as radical. This is accomplished by the utilization of the sphincter ani as a substitute for the sphincter vesicae—which is beyond repair—and the rectum, or some portion of the alimentary canal as a receptacle.

DR. J. E. SUMMERS, JR., Omaha—I have operated on four patients for exstrophy of the bladder. Three of these operations were done on the old-plan methods and were unsatisfactory in results; however, they were as good as could be obtained by such makeshift plastic work. In the fourth case, a female, little trouble was experienced in fixing the ureters in the vagina. If we pass a probe into each ureter, as a guide, there is no difficulty in exposing the ureters and draining them into the vagina. The ureteral openings into the bladder are easily closed by ligation, the ligation being carried, by a full-curved needle, from the vaginal side. The bladder mucous membrane can be excised in whole or in part, and the wound closed after the manner adopted by Dr. Vance.

DR. A. M. VANCE, closing—I think this case is about as extreme a one as we ever meet, but I think the same procedure can be carried out in all cases. I use every precaution to avoid any hair-bearing tissue being introduced into the bladder. It requires great care and all the ingenuity one can bring to bear to combat the many difficulties of such a case. In bringing together the edges of these flaps I do not destroy any tissue but use the flap-splitting method. I believe my experience in these two cases will enable me to do better work in the future.

HEMORRHAGIC INFECTION IN AN INFANT DUE TO THE TYPHOID BACILLUS.*

(GEORGE BLUMER, M.D.)

DIRECTOR OF THE BENDER HYGIENIC LABORATORY,
ALBANY, N. Y.

The case herein reported, while differing in some respects from the hitherto recorded ones of congenital typhoid infection, probably belongs in the same category. It seems proper, therefore, before detailing the history and findings to review briefly the literature of this somewhat rare class of cases.

It seems hardly necessary to refer to the cases reported in the pre-bacteriologic era, inasmuch as they are so imperfectly recorded, according to modern standards, that considerable doubt must necessarily hang over their authenticity. Even the earlier cases recorded after the discovery of the typhoid bacillus are open to question, on account of the difficulty at the time of their discovery of distinguishing the typhoid bacillus from the organisms of the colon group.

Eberth¹ indirectly hints, and Dürk² positively states that the cases of Reher,³ Neuhaus⁴ and Chantemesse and Widal⁵ are open to doubt on these grounds, and this being the case, but eight or nine positive cases of congenital typhoid fever are left on record. There is a good deal of similarity in all these cases. The infection in all instances occurred in children born at the time that the mother was actually suffering from an

attack of typhoid fever. Many of the cases were premature births, though one or two had gone on to term. The cases of Eberth, Giglio,⁶ Freund and Levy,⁷ and Etienne,⁸ were abortions at about the fourth or fifth month; the cases of Hildebrandt⁹ and Janiszewski¹⁰ were miscarriages at about the eighth month, while in the cases of P. Ernst¹¹ and Dürk the children were born at or near term. Most of the children were born dead, though Dürk's case lived nine hours. Ernst's four days, and Janiszewski's five days. In most cases where the child had only reached the fourth or fifth month of development the post-mortem findings were entirely or almost entirely negative and the diagnosis rested on the bacteriologic findings. In some of the later cases definite macroscopic lesions were present, though in all instances except one the intestines were spared, and in that one, Hildebrandt's case, the lesion consisted of a single swollen solitary follicle.

Several of the authors point out that the disease at this age takes the form of a general infection rather than a local one, and the lesions found were those suggestive of such a state. The most constant lesion was slight enlargement of the spleen. Other lesions present in occasional cases were slight icterus (2 cases), hemorrhages into the skin, liver or kidneys (2 cases) and slight swelling of the mesenteric glands (1 case). The condition of the placenta was recorded in 4 cases and was normal in each instance. The typhoid bacilli were constant in the spleen and frequently present in the blood; they were occasionally present in the lung (2 cases), the kidney and mesenteric glands (1 case) and the liver (1 case). The placenta when examined bacteriologically showed the presence of typhoid bacilli.

In none of the reported cases is there a satisfactory description of the histological lesions in the organs of the child.

The case which I wish to report occurred in the practice of Dr. W. B. Sabin, of Watervliet, N. Y., to whom I am indebted for the clinical notes, and who kindly procured permission for the autopsy.

The mother of the child was apparently in perfect health at the time of its birth, but it was subsequently determined that about four and a half months previously she had had an acute illness, severe enough to confine her to her bed for a period of twenty-one days, characterized by a remittent form of fever, associated with occasional chills and with constipation. As the neighborhood is a non-malarious one, and the history characteristic, the presumption is that the attack was one of typhoid fever. The history of the child was as follows:

Baby H., a female child, was born at term after a difficult labor, the delivery being effected with forceps. Three days after birth the child had a slight convulsion after nursing. At each nursing after this convulsion the child would stiffen out as if in pain. On the fifth day the nurse noticed some spots of blood on the child's diaper, the amount of blood lost gradually increasing so as to become alarming on the sixth day. At this time a consultant was called in, and it was decided that the blood came from the vagina. The vagina was packed with cotton, but the cotton was soon expelled and with it some large blood clots. A further examination was made, and an eroded cervix was discovered, from which the bleeding seemed to come. This was cauterized with nitrate of silver and the vagina was again packed. The packing was again forced out, and hemorrhage from the vagina continued until the death of the child on the ninth day. Before death there also

*Presented to the Section on Pathology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

developed slight bleeding from the gums, and a petechial eruption over the forehead. There were slight rises of temperature during the attack.

The necropsy was performed nine and one-half hours after death, in cool weather. The following are the main points of interest abstracted from the necropsy protocol.

Macroscopic Findings.—Body 47 cm. long; strongly built; well nourished. Rigor mortis marked. Post-mortem lividity of dependent parts. Papulo-hemorrhagic eruption on forehead. Dried blood on the gums and around the vulva. Surface in general pale. Remains of umbilical cord completely dried up except for a small excretion near its insertion. Mucous membranes extremely pale. No visible hemorrhages into the gums; subcutaneous fat moderate in amount. Muscles well developed; pale.

Peritoneal cavity is dry. Mesenteric lymph-glands are all markedly hemorrhagic; on section blood red in color.

The heart is normal except for cloudy swelling of the muscle. The lungs show hypostatic congestion.

Spleen is free from adhesions; measures 5x3x2 cm.; capsule normal; consistency soft; on section very dark; trabeculae and malpighian bodies just visible.

Liver is free from adhesions; surface smooth; measures 12x7x3 cm.; has a mottled reddish-yellow appearance; consistency soft; on section very cloudy; looks as though it had been boiled.

Gall-bladder contains thick, opaque bile; walls are normal.

The kidneys are normal except for a few hemorrhages into the cortex.

Bladder shows one large—2 mm. in diameter—hemorrhage beneath mucous membrane and numerous small ones, pin-head in size.

Vagina shows one or two submucous hemorrhages; contains blood clots. Os is greatly dilated, 6 mm. in diameter.

Uterus is 4 cm. in length; cavity much dilated. Just above the internal os there is a blood clot, the size of a pea, and there is a strip of endometrium 1 cm. wide, which is intensely hemorrhagic. Tubes and ovaries appear normal.

Esophagus shows one or two diffuse areas of submucous hemorrhage. The stomach, aorta, pancreas, adrenals and ureters are normal.

Duodenum is slightly bile stained; jejunum the same. No signs of hemorrhage in upper part of small intestine. In the ileum the solitary follicles are swollen; some of them hemorrhagic. All through the large intestine the solitary follicles are much swollen; many of them contain hemorrhages. The mucous membrane between the follicles is swollen in places.

Anatomical Diagnosis.—Hemorrhagic follicular colitis and ileitis. Swelling of the spleen. Swelling of the mesenteric lymph-glands with hemorrhage. Cloudy swelling of the liver and kidneys. Congestion of lower lobes of lungs. Dilatation of uterus with hemorrhage into endometrium. Hemorrhages into kidney and submucosa of bladder.

Microscopic Findings.—Heart is normal except that in the blood in the cardiac vessels in one or two places there are to be seen large, irregular cells, a good deal larger than the white blood-cells, and similar in appearance to cells to be described later in connection with the intestine and spleen. Some of these large cells are distinctly phagocytic.

The pleura is normal. The pulmonary aveoli in places are slightly dilated; in places normal in size. They are for the most part empty, but in some areas contain a pink-stained granular material and a few red corpuscles. The bronchi and blood-vessels are normal in appearance. In a few of the smaller blood-vessels there can be seen large cells similar to those described in the cardiac vessels.

Capsule of the liver is normal; connective tissue not increased. The liver cells are greatly swollen, so much so that the lumen of the capillaries is markedly diminished. The protoplasm of the cells is in part replaced by medium-sized fat globules. Where not so replaced it is extremely granular. Occasionally a single liver cell has lost its nucleus and takes a more intense stain with the eosin than its fellows. There are

present in the capillaries of the liver a few large phagocytic cells similar to those seen in the vessels of the heart and lung. In no place are these cells seen except as single elements, and in no place do they appear to interere with the circulation. The larger blood-vessels and bile-vessels are normal in appearance.

Capsule of spleen is normal; trabeculae not increased. The pulp contains an excessive amount of blood, sometimes free in the blood spaces, sometimes contained in large phagocytic cells. The endothelial cells lining the vessels of the spleen show evidences of proliferation, karyokinetic figures being occasionally made out, and the proliferated cells are greatly increased in size, so that they almost block the smaller vessels in places. They show evidences of phagocytic properties. In many of the malpighian bodies the lymphoid cells are much reduced in number; their place is taken by larger cells of an epithelioid type; the latter have an irregular shape with a large rounded or oval nucleus which stains moderately intensely with the nuclear dyes, and which is generally extra-centrally situated. At times these cells contain darkly stained degenerated material, apparently nuclear substance.

Kidney capsule is normal; connective tissue not increased. Many of the glomeruli retain the fetal form. The cells lining the convoluted tubules and the ascending branch of Henle's loop are swollen and granular, and often almost fill the lumen of the tubules. There is evidence of karyokinesis in the endothelial cells of the kidney vessels, and in some places large cells similar to those already described in the other organs almost block the blood-vessels. The larger kidney vessels appear normal. The adrenals appear normal except that changes in the walls of the blood-vessels similar to those seen elsewhere are to be made out. In this organ the large phagocytic cells appear in some instances to have developed beneath the intima and have pushed this before them.

The pancreas shows auto-digestion in places. The same process in the blood-vessels is seen here as elsewhere.

The greater part of the uterine musculature is normal. The most marked change is in the endometrium and in the portion of the musculature which lies just beneath this. In the stroma of the endometrium there are a great many karyokinetic figures between the cells, and in between the muscle fibres of the uterus marked hemorrhage has taken place in some areas. The endothelial cells lining the uterine vessels in these areas, and also to some extent outside of them, show marked proliferation, with the formation of large phagocytic cells, which often almost entirely fill the smaller vessels. Similar proliferation of the cells is seen in certain spaces between the musculature, which do not contain blood, and which are apparently lymph spaces.

The affected intestinal follicles, as well as the mucous membrane covering them, show very characteristic changes. These consist in the partial disappearance of the lymphoid cells making up the follicles, and in the appearance of large, irregular, epithelioid cells with a large amount of protoplasm, and an extra-central rounded or oval nucleus containing a moderate amount of chromatin. These cells in places show phagocytic properties; some of them containing red blood-corpuscles, others portions of nuclear substance, presumably from destroyed lymphoid cells. Besides these changes the endothelial cells lining the vessels show fairly well-marked proliferation with increased size and the assumption of phagocytic powers. In no instance was there any actual blocking of the vessels to be made out, nor necrosis present over any large area, though single necrotic cells could at times be made out. A process similar to that just described was made out also in the inter-glandular tissue of the mucous membrane, and in the mesenteric lymph-glands. Both in the intestine and in the lymph glands the process was in places accompanied by an infiltration of blood in the affected tissue. In sections stained by Flexner's method, and methylene blue and eosin, a fair number of short bacilli were to be made out in the sections of the intestine, most of them near the surface, however, so that it could not be determined with certainty whether they were typhoid bacilli. A few were seen in the depth of the lesions. In the spleen also a few bacilli could be seen in the blood-vessels, but none were made out in the other organs.

Bacteriologic Findings.—Cultures were taken from the heart's blood, lung, liver, spleen, kidney, colon, umbilical cord, and bile, on blood-serum and agar slants.

The cultures from the blood of the heart, liver and kidney remained negative after six days' incubation at 37.5 C. The culture from the lung contains from 80 to 100 pin-point to split-pea sized, round or oval, grayish-white, elevated, moist colonies. The culture from the umbilical cord contains 120 to 130 similar colonies; that from the bile 10 to 20, whilst the spleen contains 35 to 38 colonies of similar appearances.

Cover-slips from all these cultures show an identical bacillus, which is short, rather thick; no characteristic disposition in cover-slips. The organism stains evenly and deeply with gentian-violet and rapidly becomes decolorized when treated with Gram's solution. On media the organism behaves as follows:

Agar slant.—A gray, filmy, moist, translucent growth, moderately profuse.

Milk.—Slight acidification, but no coagulation.

Bouillon and Dunham.—Uniformly cloudy in twenty-four hours. Actively motile bacilli in both media. No indole reaction obtained in Dunham's solution after four days' incubation.

Gelatin.—The organism produces a grayish-white growth along the line of inoculation, but at no time showed evidence of liquefaction.

Potato.—The growth on this medium is scarcely perceptible. A moisture along the line of inoculation alone indicates multiplication of the organism on the potato.

Stabs of glucose-agar.—Produces growth along the inoculation line, but no development of gas can be made out.

The organism gave a positive Widal reaction, with blood from a known typhoid cure.

The culture from the colon in addition to a few colonies of the bacillus typhosus, contained a predominating organism which was identified as the bacillus coli communis.

Bacteriologic Diagnosis.—Typhoid infection of the lung, spleen, bile and umbilical cord. Presence of the typhoid bacillus with the colon bacillus in the large intestine.

It will seem that this case differs from all those reported, in one main fact only, namely, that the child was born, not while its mother was in an attack of typhoid fever, but four and a half months later. The question, therefore, naturally arises whether this is really an example of congenital typhoid fever at all. If it is taken for granted that it is we must assume either that the typhoid bacillus was present in the mother's circulation for four and a half months after the attack, and only gained entrance to the blood of the child shortly before birth, or that it was transmitted to the child at the time of the mother's attack and remained latent in its tissues until just before birth. The latter probability would seem more likely on account of the fact that the typhoid bacillus is seldom found in the blood of adults in any number, even during the attack, and it would, therefore, seem extremely unlikely that it is ever present four and a half months later.

There seems to be no reason to doubt that other organisms than the typhoid bacillus remain latent in the tissues for long periods of time, and certain authors seem to regard such latency as probable in some cases of typhoid. Thus Chantemesse¹² in referring to the incubation period of the disease says: "Certain individuals retain for a long time in their intestine, and perhaps even in the interior of their tissues, typhoid germs, which develop poorly until some favorable circumstance arises." Experimentally, Wyssokowitsch¹³ and the above-named investigator have verified this possibility, by finding the typhoid bacillus in the bone-marrow of animals several months after its inoculation into the circulation.

There would seem to be a bare possibility in this case, however, that the disease was not congenital, but was acquired after birth. The disease did not show itself until the third day, and according to Murchison¹⁴ the period of incubation is in rare cases only two to three days. The child, however, was fed by its mother only, and so far as we have been able to determine, the typhoid bacillus has not been isolated from breast milk. Certainly in this case it would seem as unlikely that it was present in the milk as it was that it was in the blood since it would have to be carried to the mammary gland by the circulation.

The excretion at the base of the cord must be mentioned as a possible source of entrance for the bacilli, though I know of no case of typhoid on record which was contracted by inoculation of a wound. This method was suggested on account of the fact that the bacilli of typhoid fever are in some cases present in the urine for months after an attack, and it was thought possible that contamination of such a wound of the cord by the mother's urine might occur. Examination of the mother's urine in this case was, however, negative, as far as the presence of typhoid bacilli was concerned.

It would seem likely then that the case was one of congenital typhoid fever in which the bacilli had remained latent in the fetal tissues for a period of 4½ months. The septicemic character of the disease is characteristic of this class of cases, and the hemorrhagic tendency is seen at times both in children and in adults. Among the congenital cases, P. Ernst had a hemorrhagic eruption during life, and in Janiszewski's case there were hemorrhages in the kidneys and in the connective tissue in the neighborhood of the esophagus. In Dürk's case also there were hemorrhages beneath the capsule of the liver. In discussing the hemorrhagic form in adults, A. G. Nicholls¹⁵ thinks it generally due to secondary infection with pus cocci. The only case of mixed infection in the congenital form is Dürk's case, which was one of those showing hemorrhages.

Finally, it is interesting to note in the case reported that the histological findings almost exactly correspond to those recently described by Mallory,¹⁶ though much slighter in degree than those seen in adults.

MORPHOLOGICAL VARIATION IN THE PATHOGENIC BACTERIA.

WITH TWO PRONOUNCED EXAMPLES.*

A. P. OHLMACHER, M.D.

GALLIPOLIS, OHIO.

From the Pathological Laboratory of the Ohio Hospital for Epileptics.

Variation in pathogenic bacteria is a biological fact scarcely second in importance to any question now before the pathological mycologist. It is a matter of great moment to the bacteriological systematist; but it

*Presented to the Section on Pathology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

further has a vital practical application since much knowledge of infectious diseases remains hidden because of our ignorance of the factors which underlie natural and artificial variation among the microbes concerned in these morbid processes. Considerable progress has been made along certain lines, especially toward determining some of the agencies concerned in producing variation under laboratory conditions. But very little is known of the influences at work within the saprophytic or parasitic environments of the facultative bacteria, by an adaptation to which pronounced morphological or physiological modification is induced. That this subject is by no means a new one is evident when we recall Rodet's classical treatise on variation in bacteria, published in 1894, which includes numerous observations made previously to this time by its author and others. That the topic of morphological or physiological microbial variation is far too large a subject to more than touch on at this time need scarcely be urged.

I shall, therefore, invite your attention to a brief description of two very pronounced examples of bacterial polymorphism which have come under my notice, feeling that data of this character, even if of little significance in themselves, are valuable when accumulated and analyzed.

The first observation was made in Cleveland, in December, 1895, on a streptococcus obtained from a case of follicular tonsillitis by the diphtheria-culture test. The organism was isolated in purity, and gave the physiological reactions of streptococcus pyogenes. In the original culture on Loeffler's medium it took so peculiar a shape as to be confusing, and to lead me to withhold the diagnosis. In seven subsequent generations, during which the isolated streptococcus was grown on ordinary Loeffler's medium, it took the unusual form; seven times returning to the ordinary shape when grown in broth. The Loeffler serum was in no way peculiar, and samples of two distinct lots, both moist and quite fresh, were used in these experiments. The cultures were kept both at the room temperature and that of the incubator (37.5 C.): in a word, there was nothing out of the ordinary about the laboratory conditions under which this phenomenon occurred.

The remarkable feature about these experiments was the polymorphism of the streptococcus, which, in each transplantation to the serum, took an irregular bacillus-like form resulting in the production of short and long straight rods, rods with swollen centers, rods with clubbed ends, rods with spherical ends, and so on in a bewildering series of most fantastic objects. All much longer and thicker than the normal elements of a streptococcus chain. In preparations made with reasonable care the linear continuity of these bizarre bacilli-like forms was retained, assisting somewhat in identifying the organism, but the chains were readily broken, and the scattered individual elements were then indistinguishable from bacilli and the polymorphism was such as to suggest the diphtheria bacillus. It is easy to see how such a specimen might be mistaken for diphtheria, and Babes, who describes a less marked instance of this kind of variation in a pathogenic streptococcus, draws attention to the possibility of this error. Returned to broth this organism resumed the morphology of an ordinary streptococcus longus, the elements of the chains becoming very much smaller and taking the ovoid, spherical, or diplococoid condition commonly seen. In the first generation in broth an occasional rod-like member could be found, but in two or three genera-

tions in this medium all trace of a bacillary condition disappeared.

A member of the colon-bacillus group, recently obtained from the gall-bladder, bile-ducts and viscera in a case of gangrenous cholecystitis and cholangitis, is the second example. My colleague, Dr. W. G. List, will describe the clinical and pathological features of this case, in which the hepatic infection was complicated by a colon-bacillus septicemia. Although the polymorphism of this organism was evident to a marked degree in the pure cultures obtained from the kidney, spleen, and heart's blood, it reached its perfection in the original smears and sections from the gall-bladder and bile-ducts, and the first generation of cultures from these sources. In the second to fourth generations of early broth cultures, the ordinary colon-bacillus form was established. I shall not weary you with an attempt to make a detailed description of the variations assumed by this bacillus; indeed, the task is well nigh impossible. But in a general way allow me to say that all gradations from minute coccoid or diplococoid to long, coarse filamentous forms were observed in the smears and sections from the biliary apparatus. The coccus, diplococcus, and short streptococcus-like individuals corresponded precisely to those recently described by Adami, Abbott and Nicholson, being often so small as to tax the amplification of the 1/12 inch objective. On the other hand, some of the quite thick, filiform individuals, even after the breaking suffered in smearing or sectioning, were long enough to be traced through three or four fields of the 1/12 inch objective. Other threads were very thin and delicate, and some of the shorter ones showed a row of deeply stained inclusions. These filamentous forms often aggregated into groups, several times appearing as a mass of tangled threads. Some seemed to branch, but whether this dichotomy was real or apparent I was unable to decide. Some of the filaments, or the long rods, had median swellings, some clubbed ends; many were bent at various angles; some stained uniformly and intensely, others were faint and shadowy; and still others stained unevenly, and had metachromatic, or unstainable portions. While quite familiar with the ordinary range of morphological variation which colon bacilli show, I was forcibly struck by the truly remarkable character of the organisms in this case, and a few years ago I would not have had the temerity to conclude that a single bacterial species was under observation, but rather that some error in my technique was to be held accountable. Certainly, any one would be justified, at first sight, in believing that the infection was a mixed one, in which a streptococcus, a bacterium, and a filamentous organism were concerned. I am, however, quite positive as to the reliability of my technique, and with the somewhat similar observations of Schmidt, Rodet, Livingood, Dunbar, Adami and others as precedents, I am emboldened in pronouncing this simply a case of extreme variation in a bacillus of the colon group.

DISCUSSION.

DR. LEO LOEB, Chicago.—Not only may the colon bacillus take on the appearance of a diplococcus, but we must expect the same of the typhoid bacillus. I lately observed that on certain chemically changed culture-media the typhoid bacillus, after one or two days, may appear as a diplococcus and streptococcus-like organism. Some of the diplococci have almost the appearance of gonococci. Also long threads appear. When bacteria change morphologically in the living body, it is by changes in the chemical and physical conditions of their surroundings.

LOCAL USE OF GUAIACOL IN THE TREATMENT OF FREQUENT, PAINFUL URINATION.

JESSE HAWES, M.D.
GREELEY, COLO.

I wish to present guaiacol as a remedy for the treatment of painful urination, which, so far as I am aware, has not been mentioned in the therapeutics of this annoying disorder.

Frequent urination is a symptom of various affections, but guaiacol is applicable only to those cases in which the cause of the symptom is located in the extreme inner portion of the urethra, usually in a space $\frac{3}{4}$ to $1\frac{1}{4}$ inches external to the urethrovaginal orifice. Many diseases of the genitourinary system cause urgent micturition, yet it is probable that all other causes combined furnish fewer cases of frequent painful urination than the one condition under consideration.

Disease of the deep urethra is, I believe, usually mistaken by the majority of general practitioners for cystitis or "irritable bladder." I am quite sure that nearly all the cases which years ago I called cystitis and irritable bladder were not such. I suspect that most of the cases treated with buchu, rhus aromatica, uva ursi, belladonna, etc., and called cystitis, should be called disease of the deep urethra and treated locally.

The morbid condition is usually confined to the mucous membrane and submucous tissues. In almost all cases there is a heightened color of the mucous membrane, varying between a rose or pink and slight purple, some cases presenting a granular surface. The diseased part will often bleed on touch. There may be, and usually is, some uneasiness about the base of the bladder, and when the desire to urinate is decidedly present, the discomfort is marked, nagging and exceedingly uncomfortable.

It is only necessary to place the positive physical signs and symptoms of cystitis, diseases of the prostate and kidneys, gonorrhoea, contracted and adherent prepuce, stricture of the urethra, etc., in contrast with the physical signs of inflammation of the deep urethra, to put the physician on his guard against confusing these diseases. I have called attention thus briefly to some of the symptoms and signs of deep urethritis to emphasize the fact that it is often mistaken for other diseases.

The diagnosis having been settled, an ordinary urethral speculum of a caliber as large as can be borne with comfort should be passed through the deep urethra. With absorbent cotton on a cotton-carrier the mucus at the bottom of the speculum should be taken up, and if any blood has filled the lumen it should be mopped away until the mucous membrane is dry. Another carrier, having a small ovoid of cotton on its point, nearly saturated with guaiacol may be used to make applications to the congested membrane.

Guaiacol in a fluid condition should not be permitted to cover the mucous membrane; barely enough to make a surface application is all that is desirable; thus applied, it is an anesthetic and mild stimulant. It gives rise to much less pain than the usual local applications. No stranguary results, as is usually the case when silver nitrate is used. The patient will often retain the urine for hours after the application. Its use is often followed by a lessening of the perineal and suprapubic discomfort after a few hours, and a few applications, from five to ten days apart, in my experience, have been more satisfactory to patient and physician than any remedy previously used. It has cured 20 per cent. of my patients.

About 70 per cent. of the cases are improved markedly. Some cases that would seem to fall fairly within our field are not improved. It applied every day or two it will produce local tumefaction, causing a diminished size of the urinary stream; this tumefaction passes away in a few days.

The application will not cure frequent and painful urination due to an enlarged prostate, but in so far as a congested prostatic urethra accompanying prostatitis is a factor in enuresis, the application of this agent is indicated. There are other diseases that cause enuresis which will not be improved by this treatment.

The following cases illustrate its effects. No description of the morbid condition in these cases will be given, as all come within the bounds previously described:

CASE 1.—A. W., male, aged 40, had gonorrhoea fifteen years ago and has since then had an "irritable bladder," has suffered many things from many physicians. When he consulted me the chief cause of complaint was the perineal discomfort and the annoyance of being compelled to void urine on very short notice. He was compelled to pass urine two or three times each night, and frequently during the day. Four applications, a week apart, made him nearly well. He comes to me once in about six or ten months for two or three local treatments, and is kept much more comfortable by them.

CASE 2.—M. E., a girl 10 years old; has been obliged to pass urine very often since babyhood. In the past three years she has got up on an average of six times a night, and passes urine ten or twelve times a day. One local application reduced the nocturnal number to four times a night; the second application reduced it to twice; the third and fourth gave improvement, a whole night being passed sometimes without disturbance of sleep. Although the patient was not fully cured, she has failed to continue treatment.

CASE 3.—MRS. L. T., a widow, aged 72, since 1898 has averaged getting up to pass urine five times a night. Three local applications have reduced the number to about two. This improvement has continued for four months without other attentions.

CASE 4.—MRS. F. J., married, aged 50, has passed urine four to five times a night for many years, and frequently during the day. Medicines by mouth were preferred by patient until it was evident to her that she obtained no benefit therefrom. Local treatment with guaiacol five times in five weeks restored the micturitions to normal number; patient has been in normal condition for a year.

CASE 5.—D. J., male, aged 28, had gonorrhoea one year previous to treatment; was confined to his bed one week with orchitis. During the year before treatment, after all gonorrhoeal discharge has ceased, he had a constant weight in the perineum, and above the bladder, with very frequent urinations; nocturnal enuresis occurred about three times a night. One thorough application was made; that night he urinated once only, and, in the six months since then, has been perfectly normal. The perineal and suprapubic pain has entirely ceased.

CASE 6.—MRS. P. J., aged 28, has had an "irritable bladder" since childhood. For twenty years at least she has passed urine ten or fifteen times a day, and three to five times a night. An examination showed the typical condition described above. A topical application was made at once; that night she passed urine only once for the first time in her recollection. She has never been obliged to get up in the night since that date, and urinates only four or five times a day. As the urethra was a little abnormal I made a second application, ten days after the first.

Medical Editor in Lay Journal. A special supplement to the German magazine the *Kleiner Journal* is to be published by a medical editor, with the title the *Kleiner Journal f. Hygiene*. The purpose is not merely to disseminate knowledge in regard to hygiene, but to educate the public in regard to quacks.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

SATURDAY, DECEMBER 29, 1900.

THE large amount of space occupied by the Index in this issue necessitates the entire omission of some of the departments and a reduction in the amount of space devoted to others. We would again call attention to the Index of Current Medical Literature and to the Authors' Index, which cover all the medical literature of the United States and Canada for the past six months. These follow the General Index.

LABORATORY INVESTIGATION AND ITS EFFECT ON
CLINICAL DIAGNOSIS.

It is a common human characteristic to seek that which is new and to believe in new things without subjecting them to the criticisms which are advanced against older facts. Medical literature teems with instances in which medical men have been carried away by their enthusiasm over methods of diagnosis or treatment which experience has proved to possess no advantages, but rather disadvantages, over more well-trying measures. This desire for the new, however, is responsible for many of the advances which have been made, for were all men satisfied with that which they possess, seekers after additional facts would be few.

During the last few years the profession has been more or less carried away by the tendency to resort to laboratory methods of diagnosis, 1, because many of these are associated with the new science of bacteriology, and 2, because the results obtained have seemed more scientifically accurate and certain than those which were obtained by our predecessors, who were forced to reach their conclusions from a careful study of the symptoms and signs presented. The result has been that the physician of the present generation, at least the younger ones have been taught to rely more on chemical tests and on investigations with the microscope than on auscultation, palpation and inspection. While the newer methods possess advantages which can not be overestimated, still it would be unfortunate if modern physicians should lose the skill so often possessed by their predecessors, who had to rely on what seemed to be more crude methods of investigation, and yet which require on the part of the physician as broad an education, as great skill, and a degree of training which, after all, command the highest respect in the diagnostician and therapist.

We should cultivate the habit of keeping our eyes open to everything that is presented to them or that passes before them; and Dr. Mitchell Bruce¹ enters an earnest plea for the training of the eye, ear and touch in the investigation of disease. These were the portions of the physician's training in earlier times of which he was most apt to boast when his skill was well developed; and, as Dr. Mitchell well says, we ought to be ashamed to confess that a condition which was elucidated by Stokes, Skoda, Walshe and other masters of clinical medicine forty or more years ago, has lately become what might be called a "fashionable disease." "Were there no dilated hearts before the time of Schott, or was it that we did not trouble to find them or that we had forgotten to find them?"

There is still another factor in diagnosis to which Bruce has called attention, namely, the value of negative signs. Too often physicians are inclined to reach no conclusion unless definite positive signs are presented on making an examination. The reason of this is obvious. The presence of a murmur in the heart, of blowing breath in a lung, of tremor in a hand, or some similar definite symptoms leads one naturally to certain conclusions. But if on listening to a chest we find distant or feeble breathing, or on palpating a heart we get an insufficient impulse, or, again, if on taking the grasp of a patient, we find it not as strong as it should be, are we not inclined to regard these signs as of little importance, and to base our diagnosis on others which are really of less value, but which are more marked? This fact is well emphasized by Bruce when he says: "How often have not you and I turned from the auscultation of the posterior base of the chest in acute pneumonia at our first visit, and said: 'There is nothing wrong there,' when we ought to have said, 'I hear nothing there, the lung must be engorged.'"

It was said of the late Dr. Da Costa, than whom there has never been a more skillful diagnostician in our country, that on many occasions he seemed to make a diagnosis by instinct even before he had examined a patient. But those who were accustomed to meet him at the bedside soon learned that his apparent instinctive deductions were really based on an extraordinary power of observation, and he would frequently pass direct to the path which would lead him to a diagnosis by the facies of the patient or by some other superficial sign which the more careless and less experienced practitioner might have overlooked.

THE TREATMENT OF TUBERCULOSIS.

The nineteenth century has witnessed great advances in the treatment of tuberculosis. The epochal discovery of the bacillus of tuberculosis and the numerous painstaking investigations into the mode of infection and of spread of the disease, have given us a firm and scientific basis for effective preventive measures. The sur-

1. *Clinical Journal*, Oct. 31, 1900.

gical treatment of local tuberculosis in glands, bones and joints, as well as elsewhere, is surely accomplishing great results. The recent method of treating lupus by means of the actinic rays of light, introduced by Finsen, seems destined to become an effective and recognized procedure. The climatic and hygienic treatment of pulmonary tuberculosis is saving many a life. The idea that tuberculosis is necessarily a fatal disease is giving way to a more hopeful view. Actual clinical experience, and especially the anatomic evidences of healed tuberculous processes that are being gathered at autopsies, tend to show that in view of its well-nigh universal frequency, tuberculosis must be regarded as one of the decidedly curable chronic infections when not too far advanced or generalized, and not associated with secondary mixed infections, as so often is the case in pulmonary tuberculosis. Pulmonary tuberculosis, when at all advanced, and meningeal and generalized tuberculosis, still baffle treatment. Even here there is hope, because are not cases of healed tuberculous leptomeningitis occasionally reported?

At present the faith in specific, antitoxic and antibacterial treatment, analogous to the serum treatment of diphtheria, is without much real support. The actual results do not correspond to the expectations. In the case of pulmonary tuberculosis, even when advanced, something may perhaps be expected from intrapleural injections of nitrogen gas. At all events, this method now and then may save a life from fatal hemorrhage. It is, as yet, too early to pass final judgment on the merits of this method, which, so far, is somewhat too cumbersome and formidable to receive general application at the hands of practitioners. The recent discussion of this procedure before the Chicago Medical Society¹ is quite timely and interesting.

In the Harveian lecture of the Harveian Society, of London, briefly referred to in an editorial notice in *The Lancet*,² Dr. Robert Maguire suggests an entirely new treatment, of which we are probably destined to hear further, namely, the intravascular injections of formaldehyde solutions. This suggestion is based on the consideration that injections into the blood would have a more direct effect than the introduction of germicidal substances by means of other routes. Maguire has found by experiment that it is safe to inject 50 c.c. of a 1 to 2000 solution daily. It is stated that this method has been carried out with quite favorable results in 70 patients, and one case apparently fully cured was exhibited by the lecturer. It is needless to say that this novel method is yet wholly in the experimental stage. The suggestion may be allowed, however, that a safe method of introduction into the blood of germicidal substances, in quantities sufficient to render the whole blood germicidal, is likely to find a large field. Maguire suggests its probable usefulness in bronchiectasis, and pneumonia. To these may be added general infections,

endocarditis, meningitis, etc. There is a likelihood that much experimentation may be done along these lines in the near future. The "fight against the white plague" is on in dead earnest. Special societies for the study of tuberculosis in all its phases, the general awakening of public and professional interest in the disease, and the untiring efforts of scientific workers everywhere will be sure to result in much good. On the whole the outlook is promising.

IDIOPATHIC TRANSITORY OBSCURATION OF CONSCIOUSNESS.

Despite the study that has been given the subject, the physiology of sleep and of waking, of consciousness and of unconsciousness, has not yet been fully cleared up. Metaphysics has been replaced by psychology, and it has become necessary to explain function by cellular activity, and aberration of function by derangement of that activity. It may, therefore, be conceived that the waking state is dependent on the existence of certain nutritive conditions in the cortical cells and their processes, and that the various departures from that state, namely, sleep, coma, delirium, etc., result from alterations in those nutritive conditions. These may be brought about by the action of metabolic products of physiologic (fatigue) or pathologic origin (uremia, fever, diabetes), or of drugs employed for therapeutic purposes (anesthetics, hypnotics, anodynes).

In the development of these manifestations the motility of the neuron, with variations in the relations of its terminal processes, may play some part, but this must be due finally to influences acting on the cell, either from within or from without. In the absence of demonstration, the explanation suggested may, for the time being at least, be accepted as a working hypothesis, even though it leaves certain points unilluminated. Thus, perturbations of consciousness, with sharply limited impairment of memory, are known to attend hysteria and epilepsy, as well as injuries to the skull, and recently Placzek¹ has reported two cases in which such disturbances were observed apart from these disorders. One occurred in a widow 40 years old who, while engaged in conversation, complained of sudden loss of memory, of which she exhibited unmistakable evidence. Consciousness became clear in the course of six hours, and only a confused recollection of some of the events that had transpired remained. Twenty-four hours later a severe attack of migraine set in, with hyperesthesia for sound, light and touch, muscæ and numbness, disappearing soon under appropriate treatment. The patient presented no neurotic or hysterical stigmata. The second case occurred in a fireman who had had bilateral clonic spasm of the masseter muscles in connection with trigeminal neuralgia and who, after an outburst of anger while on a railroad journey, became taciturn, and subsequently had no recollection of what had happened. There had been no indulgence in alcohol.

1. See THE JOURNAL, A. M. A., Dec. 15, 1900.

2. *Lancet*, Nov. 24, 1900, p. 1514.

1. *Berliner klin. Wochenschrift*, 1900, No. 32, p. 705.

Though in neither were conditions present with which perturbation of consciousness is ordinarily associated, this was in one followed by an attack of migraine, of which the sensorial disturbance might be considered a prodrome or aura, while in the other, emotional influences were operative. The result in both instances is attributed to transient, diffuse changes in the cerebral cortex, possibly vascular spasm. Similar manifestations have been observed in those resuscitated from hanging. Apart from its psychopathologic interest, the question under consideration has a medicolegal significance, as not rarely defense for crimes committed is based on want of responsibility in consequence of disturbances of consciousness.

FRENCH METHODS TO INCREASE BIRTH-RATE.

The proposed tax on bachelors and old maids and upon childless couples in France will, if carried out, be an interesting experiment. If it succeeds in arresting the decrease of the birth-rate it will show the possibility of the more economic method. In any case it is the pecuniary consideration that is involved; if the thrifty French peasant, who under the bounties for children is a regular proletarian in Canada, can be made such in France by the reversed inducement by fines, the problem is solved. The question is essentially an economic one, but it has some medical interest also, and the experiment if tried will be worth watching.

PRETENDERS VS. HUMBUGS.

There are quacks and quacks, and while all are objectionable to decent and enlightened people, some of them are even a thorn in the flesh to other quacks. So it happens that we find the osteopaths in Missouri devising how to put down those whom they consider unauthorized pretenders to qualifications in their "science"; and in the extreme east the osteopaths that massage the faddists of the Back Bay, of Boston, are similarly troubled with what they call "fake osteopaths." It is a case of "bigger fleas have smaller ones to bite them," but they probably utilize the fact to exploit their own virtue and show that there are others really inferior even to themselves in medical qualifications.

PATHOLOGY OF ACUTE ASCENDING PARALYSIS.

There is considerable diversity of opinion as to the nature of the form of acute ascending paralysis described by Landry and known by his name, the disorder being unattended with macroscopic lesions of the nervous system; although of late, with the aid of refined methods of preparation and staining, microscopic alteration have been discovered in nerve-cells and nerve-fibers, sometimes in the periphery, sometimes in the cord and the brain. The belief is gaining ground that the disorder is an infectious one, but the final proof in this connection has not been brought forward. It is true that micro-organisms have been cultivated from the nerves, the cord and the spinal fluid, but these have exhibited no constancy and none of them can be looked on as

specific. Such histologic changes as have been found have involved principally the ganglion-cells of the anterior horns of the spinal cord and the peripheral nerves, and the lesions have been thought to consist essentially in a parenchymatous degeneration of the peripheral motor neuron. Schwab¹ has, however, recently reported a case, the histologic conditions in which lead him to believe that the process is rather an interstitial one, as exhibited mainly in an abnormal condition of the blood-vessels. The nerve-cells present only such slight alterations as could be explained by preagonal or post-mortem chromatolysis. The cord presented no degenerative or inflammatory alteration; there was no neuritis; but the blood-vessels and the perivascular lymph-spaces were in a condition of intense congestion, with thinning of the vessel-walls and escape of free blood into the nervous structures.

ACUTE INTERNAL HYDROCEPHALUS

The credit of having established internal hydrocephalus as a distinct disease belongs to Quincke. While hydrocephalus from mechanical causes is frequent, the so-called idiopathic hydrocephalus seems rather infrequent, appearing in two forms—acute and chronic. The acute form is more frequent in children. In adults the disease may follow injury to the head, infectious diseases and alcoholic poisoning. The case reported by Burr and McCarthy² is a good illustration of the clinical course of the acute form in adults: "A man is suddenly seized with fever, bradycardia, constipation, rigidity of the muscles of the neck, headache, stupor and delirium. After three weeks, during which the intensity of the symptoms varies greatly, he improves very much physically but shows many of the mental symptoms of parietic dementia. A week later fever and the meningeal symptoms return, last about a week, again intermit for four days only to return again and end in death." Post-mortem there was found a moderate internal hydrocephalus, sclerotic changes in the choroid plexus, proliferation of the ependyma, and perivascular cell accumulation in the subependymal tissues. In the early stages the case was diagnosed as a meningitis. Kernig's sign was present throughout the whole course of the disease. The absence and return of the knee-jerk and plantar reflex are interesting phenomena that await explanation. There also developed deafness, probably caused by degeneration of the eighth nerves. The parietic mental state has been noted in this disease by other observers, and the diagnosis of parietic dementia has been held in such cases. The limitation of the inflammatory changes to the ependyma pointed to some toxic or irritating action of the ventricular fluid on the ependymal membranes. Injecting sterile urine, tuberculin, carbolin, carbonic acid and other substances into the ventricles of kittens caused microscopic changes in the ependyma resembling those observed in the case reported, but no increase of ventricular fluid. The mental condition and the curious exacerbations in the symptoms are best explained by the hypothesis of auto-intoxication. Chronic internal hydrocephalus may

1. Journal of Nervous and Mental Diseases, Dec., 1900, p. 619.
2. Jour. Exp. Med., 1900, v. 196-205.

follow the acute. The symptoms are often vague; neurasthenia or brain tumor may be suspected; optic neuritis is rather constant. The long course of the disease with remissions and the good effects of lumbar puncture may lead to correct diagnosis. The spinal fluid will be found most likely under high pressure.

Medical News.

CALIFORNIA.

SAN BERNARDINO has a case of smallpox imported by a tramp, who is isolated and quarantined in a tent near the local hospital.

DR. JOHN D. DAMEBOY, Stockton, was elected health officer of San Joaquin County and Walter D. Stannard re-elected special health officer of Lodi, on December 4.

THE ALAMEDA BOARD OF HEALTH, recognizing that consumption is a contagious disease, has passed resolutions asking the co-operation of the State Medical Society, the local medical boards and the physicians throughout the state to urge upon their representatives in the coming legislature a bill providing for appropriation of sufficient money to erect, equip and maintain sanatoriums for the care of tuberculous patients who are unable to secure the necessary surroundings and treatment at home.

THE MANAGEMENT of the municipal hospitals in San Francisco has been greatly improved since the new charter became operative. Efficiency has increased, and expense decreased. The Receiving Hospital, Harbor Hospital and Detention Hospital are now conducted at an expense for maintenance of \$7200 a year. Under the divided control of the supervisors and the board of health under the consolidation act the maintenance expense was \$17,000. In place of worn-out instruments and lack of surgical supplies, the hospitals have now a modern equipment and supplies for an emergency. Furthermore, at this lessened expense the hospitals are treating about 950 patients a month, where they formerly treated 750. The salary roll has not increased.

PROPOSED MEDICAL PRACTICE ACT.

A law was drafted and presented to the legislature of California in 1898 governing medical practice in that state, but too late for passage that session. It is now proposed to reintroduce it at the coming session in January, 1901. The requirements of the law are simple: A diploma from a recognized school with letters of recommendation from two reputable persons constitutes the first requirement, as given by the *Occidental Medical Times*. The second demands an examination before a board of medical examiners from the three principal schools of medicine, composed of nine members, five regulars and two each from the homoeopathic and eclectic bodies and selected by the state societies of these bodies. The examinations in therapeutics and practice of medicine are to be separate. Six members of the board are to constitute a quorum, and the examination is to be practical and not technical in its character. The bill, if it passes, will not affect any one holding a certificate under the present medical-practice laws. The laxity of requirements in California at the present time is, as the *Medical Times* says, "making the state scarcely more than a place of refuge either for those who have proven themselves unfit to practice under the laws of other states or for the refuse of the second and third-rate colleges of the country." It is to be hoped that the bill may pass, both for the sake of medical progress in the country generally and for the benefit of the practitioners of California.

ILLINOIS.

THE PEORIA MEDICAL SOCIETY has given credentials to Drs. Bradley, Emerson M. Sutton and Thomas M. Melvaine, who are aspirants for state preferment.

DR. GEORGE A. ZELLER, Peoria, superintendent of the asylum for the incurable insane at South Bartonville, has surprised many aspirants for his position by announcing his early return from the Philippine Islands, and is a candidate for re-appointment.

Chicago.

DR. COLFMAN G. BYFORD was elected president of the Missouri Club, December 19.

THE ESTHER FREER HOME and training-school for nurses connected with Provident Hospital was dedicated December 21.

DR. HEZEDIAH T. CRAWFORD has been appointed resident physician at the Children's Hospital, San Francisco.

THE INCORPORATION of the West Side Hospital Training School for Nurses, by Drs. D. A. K. Steele, William L. Noble and George W. Newton, is announced.

ST. LUKE'S HOSPITAL is reported to have more than a dozen of the attendants, nurses, etc., ill with typhoid fever, the cause of which has not been ascertained thus far.

URING the last few days physicians have not been spared by burglars. Drs. E. Fletcher Ingals, Lyman Ware and H. C. Mackey are the latest victims.

DR. ANNA GLOSS, who has been a missionary in China for thirteen years, and who went through the siege of Peking, has returned to her home in Evanston for a period of rest, after which she proposes to return to her work in China.

"DR." DON SANG, the Chinese physician, who claimed to have lost his diploma and received a copy from China duly attested by the consul-general of China, is to be arraigned for practicing medicine without first having been registered.

DR. MATHEUS F. BOZINICH had a desperate fight on December 19 with a collector whom he had employed some time before but had prosecuted for embezzlement. Dr. Bozinch fortunately succeeded in overpowering his assailant and turning him over to the police.

NEW YORK.

DR. FREDERIC C. PETERSON, Watertown, has been elected county physician of Jefferson county.

SEVERAL additional cases of smallpox have been reported in Schenectady, and the public schools have been ordered closed by the board of health.

THE CONTRACT for building the new medical college at Cornell University, Ithaca, has been awarded. The building will cost \$125,000 and is to be completed in time for the fall term of 1902.

AN ISOLATION WARD for the city hospital of Binghamton, is to be erected in the fifth ward of that city, subject to the consent of the residents of that ward, which is to be decided by an election called for that purpose.

IN VIEW of the fact of the prevalence of smallpox in New York City and other parts of the state, namely Schenectady, the State Board of Health recommends to local health officers general vaccination throughout the state.

THE GOVERNOR has removed Dr. Peter M. Wise, State Lunacy Commissioner, on the specific charges of having solicited state employes in the asylums to take stock in a corporation in which he was interested, and that he obtained the installation of an ice plant in which he had an interest at the Long Island State Hospital. The Governor will not fill the vacancy caused by this removal, but will allow Governor-elect Odell to make the appointment. The salary is \$7500 and \$1200 traveling expenses.

Buffalo.

THE NUMBER of school children vaccinated by city physicians was 2612.

WILLIAM CARPENTER, an old man, was arrested December 12 on the charge of illegal practice of medicine. He was arrested last summer on a similar charge.

SOON AFTER January 1 the coroners will be able to move their offices into the new Morgan building, which is expected then to be ready for the reception of the city's dead. When finished it will be one of the most modern and complete buildings of the kind in the United States.

REV. MOSES HULL preached on Sunday last "On the Evils of Vaccination." In the course of his tirade he said that compulsory vaccination is not only unwise, unconstitutional and un-American, but dangerous to health, causing eczema, erysipelas, cancers, tumors and often death. He said that vaccination is the cause of more pulmonary consumption than any other thing in the world; that one-half of all cases of consumption originate in vaccination, and that vaccination fees a gang of hungry doctors at the expense of the public and so on ad nauseum.

MARINE-HOSPITAL SURGEON WASHBURN, in charge of the United States Marine-Hospital service at this port, hopes to secure from Congress at this session an appropriation of \$125,000 for a new marine-hospital at Buffalo. He is supported in this matter by the Buffalo Merchants' Exchange and other commercial organizations in the city, the Lake Carriers Association, and other organizations of lake men. The need of a marine hospital at Buffalo is generally recognized, as to this port come every season the great majority of men employed on vessels on the lake.

New York City.

THE FORMAL OPENING of the new building for Cornell Uni-

versity Medical College, on First Avenue, took place to-day with appropriate ceremonies.

A GIFT of \$75,000 has been made by William C. Schermerhorn, second vice-president of the New York Eye and Ear Infirmary, to be used for constructing a pavilion for ear-patients.

COMPULSORY vaccination is being practiced in the negro quarters of Williamsburg and vicinity. The presidents of two of the large life-insurance companies have issued orders that all their employes in the city are to be vaccinated.

DR. WARREN N. REYNOLDS, a medical school inspector, has had mandamus papers served on him to compel him to certify that the daughter of Edward Crystal, the plaintiff, is not suffering from any contagious or infectious disease which should bar her from attending school.

A SUIT for \$75,000 damages against the Charles Bessler Company has been commenced by Miss Frances Russell Taintor, who claims her physician prescribed the inhalation of oxygen gas; that she procured from the defendant company a tank of gas which, instead of oxygen, contained chlorine and oxid of nitrogen gas, "by which she was permanently injured and her life put in jeopardy."

OHIO.

DR. WILLIAM H. FALLS, Cincinnati, is lying in the Presbyterial Hospital in that city seriously ill with typhoid fever.

IN ONE cheap lodging-house in Cleveland, the city health department vaccinated in a single night 235 men, most of whom were tramps.

NO OSTEOPATHS appeared to take the examination at Columbus, December 10-13. They prefer to fight the state law and are said to be preparing a test case.

IN THE MEDICAL DEPARTMENT of Western Reserve University, Cleveland, on December 12, Dr. Frederick C. Herrick was made demonstrator of surgery; Dr. Frank J. Geib, demonstrator of medicine, and Dr. William E. Bruner, demonstrator of ophthalmology.

DR. ALEXANDER GRITZA, Toledo, has been attained by the State Board of Medical Registration, on the charge of unlawfully practicing medicine without a license. The defense contended that Dr. Grytza had been graduated from the Russian imperial medical college, that he had served as a surgeon in the Russian Army and that he had been physician for the poor at Bay City, Mich. It was claimed that he had not obtained a license to practice medicine, as he was not familiar enough with English to pass an examination held in that language. The jury returned a verdict not guilty.

PENNSYLVANIA.

OWING to the law which it is supposed will be passed by Congress in regard to the sale of oleomargarin, it is believed that no new bill on this subject will be presented before the next session of the legislature of this state.

DR. BENJAMIN LEE, of the State Board of Health, in his report to the governor stated that the number of cases of small-pox reported to the board from the first appearance of the epidemic, Dec. 11, 1898, was 1429, of which 18 were fatal. During the past year contagious diseases over the State have been suppressed as follows: Diphtheria at 38 places; typhoid fever, 40 places; scarlet fever, 19 places; complaints of pollution of drinking water, 20 places. Inspections have been made at 57 places. The board is in favor of placing tuberculosis on the list of contagious diseases and requiring physicians to report all cases to the local boards of health.

THE STATE INSANE ASYLUM at Norristown has entered suit against the city of Philadelphia to recover the sum of \$52,651.72, which is the balance of a total of \$103,331 expended in caring for the indigent insane persons in 1896 and 1897. At that time a total of \$2 per day was charged, but later the amount was reduced to \$1.75 for each patient. It is claimed by the city that the total amount overpaid during the intervening years was sufficient to equal the amount sued for; that the hospital gained by this agreement and that a surplus was formed which was spent for improvements on the hospital that therefore the Commonwealth reaped a profit.

Philadelphia.

DR. MICHAEL O'HARA has been very ill for the past few days with appendicitis, for which an operation was performed. He is doing well.

THE FINANCE COMMITTEE of the city council allowed the following appropriations for the Philadelphia Hospitals: For a new children's hospital, \$35,000; a new maternity house, \$10,000; and for other wards, \$35,000. An appropriation of \$35,000 was asked for to enlarge a ward in the insane department, but was not granted.

THE CITY COUNCIL of Philadelphia has refused to pay for

medical inspection of the public schools. There are more than 230 medical examiners of schools, most of whom have been doing work for a year without remuneration. When they accepted the positions it was hoped that in some way while good would result to the city, their practice might increase. The latter has not been the case. On the contrary some enemies to the movement consider it an affront to have their children sent home, for they have their own family physician to look after health matters. This action of the council has been taken, too, in the face of the fact that school medical inspection has been indorsed by the College of Physicians, the County Medical Society and the Philadelphia Pediatric Society.

GENERAL.

MAJOR TIMOTHY E. WILSON, surgeon, U. S. A., has been relieved from duty at Columbus Barracks, Ohio, and detailed to duty as chief surgeon, Headquarters Department of the Lakes, Chicago.

A BILL has been introduced by Senator Warren, of Wyoming, authorizing the free admission of honorably discharged soldiers and sailors into any hospital of the United States for medical or surgical treatment.

A FRAUD ORDER has been issued by the postoffice department against James Armstrong, 886 West Van Buren street, or 881 West Monroe street, Chicago; J. or James Armstrong, M.D., Dr. J. E. Armstrong, or any other modification of that name which is clearly intended for the James Armstrong described above; the Health University of Chicago, the Independent Medical College of Chicago, the Metropolitan Medical College of Chicago, the Scientific Medical College of Chicago, and the International Medical College of Chicago, and modifications of these names which are clearly intended for either of them at Chicago. The James Armstrong referred to is the president of the notorious diploma-mill, who, on December 15, was sentenced to fine and imprisonment for using the mails to defraud.

PAN-AMERICAN MEDICAL CONGRESS.

OWING to the postponement of the meeting in Havana to February 4, the transportation rates have been changed to the usual winter transit rates. The committee on transportation is, however, urging a reduction. We shall keep our readers posted on whatever changes are made.

SMALLPOX IN ALASKA.

The Yukon Council, the legislative body of the region, has passed an ordinance requiring all persons in Yukon territory, extending from White Horse to Forty Mile, to be vaccinated just as soon as the vaccin arrives. This order affects from 10,000 to 15,000 persons. The Council has appointed six Dawson physicians to make a house-to-house visit throughout Dawson and along all the Klondike creeks and vaccinate all persons who have not been vaccinated within the last seven years. The government bears all cost of vaccination under this compulsory order, and the doctors are paid \$30 a day for their services. A mounted policeman will accompany each doctor to see that his mission is not abused. Any one refusing to submit to vaccination will be liable to a fine of \$250 or three months in jail, and any one not reporting cases of rash or anything looking like smallpox will be subject to a much heavier penalty.

QUARANTINE PROCLAMATION OF STATE BOARD OF HEALTH OF KENTUCKY.

Whereas, official information has come to this board that smallpox is prevailing in epidemic form in several portions of Greenup County and in a population almost entirely unprotected by vaccination, and, whereas, after repeated notice and urging from the duly constituted Board of Health from the county, the Fiscal Court has persistently refused, and still refuses to provide funds for the proper control of such disease, or for necessary nurses, guards, provisions, or even for the vaccination of those exposed to contagion, or in any other way to cooperate or take any of the steps required by law to prevent the spread of this highly contagious and loathsome disease, within said county, or to adjoining counties or states, until the County Board of Health has been forced to resign and leave their jurisdiction without even the semblance of protection, thus greatly endangering the health, lives and business interests of the people of the entire state, and of adjoining states. Now, therefore, be it known, that the State Board of Health of Kentucky, in the exercise of authority vested in it by law, hereby declares Greenup County, Kentucky, and each of its inhabitants to be in quarantine, and establishes a quarantine line along the entire boundary of said county, and forbids any person to enter or leave, except to pass through, and forbids any railroad, steamboat, or other transportation company to make any stops, or to deliver any passengers or freight to

from said county, without a permit from this board, under the pains and penalties of law. The town of Russell, having an independent board of health, and having enforced compulsory vaccination, and complied with the other requirements of law for the suppression of smallpox, is hereby exempted from his quarantine. Boards of health and other officials of adjoining counties are requested and directed to enforce this order of quarantine at their respective county lines bordering on Fremont County, and to cause the prompt arrest, vaccination and prosecution of any and all persons violating the same. This proclamation of quarantine will take effect and be in force from noon on Sunday the 23d instant until officially raised or modified by this board. By order of the Board, J. M. Mathews, I.D., president, J. N. McCormack, M.D., secretary.

Army Efficiency Bill.

The following substitute for Section 18, senate bill 4300, has been approved by the surgeon-general of the army, and proposed by the committee on national legislation of the AMERICAN MEDICAL ASSOCIATION:

Section 18. That the medical department shall hereafter consist of one surgeon-general with the rank of brigadier-general; 10 surgeons with the rank of colonel; 20 surgeons with the rank of lieutenant-colonel; 80 surgeons with the rank of major; 200 surgeons [in lieu of 8, 12, 60 and 240 respectively of the original bill] with the rank, pay and allowances of first lieutenant of cavalry for the first five years' service and with the rank, pay, and allowances of captain of cavalry after five years' service; the hospital corps as now authorized by law, and the nurse corps; Provided, That all vacancies in the grade of colonel, lieutenant-colonel and major, created or caused by this section, shall be filled by promotion according to seniority, subject to the examinations now prescribed by law, and that all vacancies in the grade of surgeon with the rank of lieutenant shall be filled by selection after competitive examination: Provided, That the period during which any surgeon shall have served as a surgeon or assistant-surgeon of volunteers, or as a surgeon under contract, since April 21, 1898, shall be counted as a portion of the five years' service required to entitle him to the rank of captain, but that after he attains the rank of captain his relative rank for subsequent promotion shall not be disturbed by anything herein. That on and after the passage of this act the President may appoint, for duty in the Philippine Islands, fifty surgeons of volunteers with the rank, pay, and allowances of captain of cavalry: Provided, That so many of these volunteer medical officers as are not required shall be honorably discharged from the service whenever, in the opinion of the secretary of war their services are no longer necessary, and that the period for which they are appointed shall be limited to two years from the passage of this act. That on and after the passage of this act the President may appoint contract surgeons who have rendered faithful and satisfactory services for a year or more to be surgeons of volunteers with the rank, pay and allowances of first lieutenants of cavalry, subject to honorable discharge whenever in the opinion of the secretary of war their services are no longer required. Provided further, that all surgeons appointed shall be of good moral character and shall have passed a satisfactory professional and physical examination: Provided, That the surgeon-general of the army, with the approval of the secretary of war, be, and he is hereby authorized to employ dental surgeons to serve the officers and enlisted men of the regular and volunteer army, in the proportion of not to exceed one for every one thousand of said army, and not exceeding thirty in all. Said dental surgeons shall be employed as contract dental surgeons under the terms and conditions applicable to army contract surgeons under the terms and conditions applicable to army contract surgeons, and shall be graduates of standard medical or dental colleges, trained in the several branches of dentistry, of good moral and professional character, and shall pass a satisfactory professional examination: Provided, That three of the number of dental surgeons to be employed shall be first appointed by the surgeon-general, with the approval of the secretary of war, with reference to their fitness for assignment, under the direction of the surgeon-general, to the special service of conducting the examinations and supervising the operations of the others; and for such special service an extra compensation of \$60 a month will be allowed: Provided further, That dental college graduates now employed in the hospital corps who have been detailed for a period of not less than twelve months to render dental service to the army and who are shown by the reports of their superior officers to have rendered such service satisfactorily may be appointed contract dental surgeons without examination.

FOREIGN.

PROF. H. FEHLING, of Halle, has accepted a call to the chair of gynecology at Strassburg as the successor of Prof. Freund.

THE DEATH of Dr. E. J. Bergeron is announced. He was perpetual secretary and ex-president of the Paris Académie de Médecine. He was born in 1817.

VON LEYDEN reports that 8393 physicians in Prussia and 5584 in the rest of Germany replied to the circulars distributed by the Cancer Investigation Committee—about half the total number of physicians in the empire. As many of the rest are no longer practicing or have no cancer patients, the results are considered extremely gratifying—*Deu. Med. Woch.*, December 6. The circular enquired for the number of cancer patients being treated October 15. The total is 11,246 cases of cancer; of these 1141 are in the Rhine province of Prussia and 719 in Berlin alone. The information obtained from the replies to the other questions in the circular will require some time to sift and tabulate.

THE *Press Médicale* of December 5, calls attention to the extra-medical achievement of Dr. Boyé, the surgeon of the French body of 220 men, which recently captured Samory, chief of the rebellious tribes in the Soudan. Dr. Boyé accompanied the party, which made its way stealthily into the midst of the native village of 60,000 souls, including 12,000 armed warriors, and took the chief captive, holding him as a hostage until all had surrendered.

THE INFLUENZA epidemic in St. Petersburg is so severe that the mortality returns for the week preceding December 22, have been the highest for a decade. A meeting of physicians was summoned to discuss remedies, but scarcely half a dozen responded to the call, the rest being overworked, or themselves victims of the malady. The weather is conducive to the spread of the disorder, being changeable, snow and slush alternating.

THE STUDENTS of the Latin quarter in Paris have organized a co-operative restaurant, which is cordially encouraged by the authorities. The leading spirit is the son of Professor Hayem, and the executive board includes the professor of social economics in the law school, who has been instrumental in organizing successful co-operative associations elsewhere. The shares are \$5, but only 50 centimes is required at first, and the balance can be paid at the rate of five centimes a month. The dividends are not to be paid to the shareholders but to those who use the restaurant, pro rata for the number of meals taken.

DR. CLEMON states in *Janus* that before the time of Peter the Great the only representatives of medical science in Russia were the foreign physicians attached to the court. In 1707 Peter the Great inaugurated the first hospital and the first school of medicine and placed it in charge of his Dutch private physician. He was succeeded by Blumentrost, by the French Lestocq, and the English physicians Erskine, Rogerson and Dimsdale. The latter was raised to the hereditary nobility for his success in inoculating the Empress Catherine with variola.

Correspondence.

Status of Medical Officers in the Volunteer Army.

MILWAUKEE, Dec. 20, 1900.

To the Editor:—I desire through the columns of THE JOURNAL to communicate with the gentlemen who served in the Volunteer Army with State Volunteers during the war with Spain and who held the rank of captain and assistant-surgeon. These gentlemen were commissioned captains by authority of the act of April, 1898, calling into service volunteer armies. They were paid as first lieutenants, in accordance with a decision of the comptroller of the currency. Notwithstanding this, they are undoubtedly entitled to the pay of the rank of captain mounted, as is evidenced by the wording of the Law of Congress and the opinion of the surgeon-general and adjutant-general in respect to the law which was passed giving the captains and assistant-surgeons of the volunteers raised under the act of March 2, 1899, the pay of their rank.

It will be necessary, however, to induce Congress to pass a bill on the subject. Senator Hansborough, of North Dakota, has kindly interested himself in the matter at my request. If necessary I will submit correspondence which I have had up to date, and desire that all the gentlemen interested correspond

with me to the end that a proper bill may be drawn up and influence be brought to bear that will secure the passage of the same. We are asking no more than we are clearly entitled to and no more than has been accorded to the Volunteers of 1899. Any suggestions from the gentlemen interested will be greatly appreciated. Very truly yours,

NELSON M. BLACK, M.D.
Late Captain and Asst-Surgeon, U. S. V.

Association News.

Research Fund.

The Committee on Scientific Research of the American Medical Association desires to announce that it has available the sum of five hundred dollars for the assistance of researches to be undertaken in the next six months, and that the money will be appropriated if applications be received within the month of January, 1901. Applicants should state clearly the character of the research to be undertaken, and the facilities at their command. Address Dr. H. C. Wood, chairman, 1 - Chestnut street, Philadelphia.

New York Academy of Medicine—Surgical Section.

Meeting Nov. 12, 1900.

HEAT-STROKE AS A POST-OPERATIVE COMPLICATION.

DR. CHARLES L. GIBSON said that while one must not be too ready to attribute to heat-stroke various constitutional disturbances after operations that might perhaps be the result of sepsis, iodoform poisoning or other causes, still he felt sure, from his own experience during the past summer, that heat-stroke is a real and an important post-operative complication. One case reported as an illustration of what he meant, was that of a boy who had reacted well immediately after the operation, but had developed on the following day a temperature of 104 F. and a pulse of 148, associated with delirium. The fever, rapid pulse and delirium had all quickly subsided under cold sponging, and the boy had made an excellent recovery without further incident. A second case had occurred on August 10, a day long remembered in the hospital, because of the oppressive heat of the operating room at that time. If the nature of this complication were recognized, the treatment would be evident. As a matter of prophylaxis such cases emphasized the importance of having a good circulation of air in hot weather, and where this could not be easily attained by the ordinary methods of ventilation, electric fans would be found a valuable auxiliary.

DR. A. B. JOHNSON cited one of his experiences of last summer. The operation had been done on a day when the temperature of the operating room had reached 102 F. It was a trivial affair, simply the excision of a sear on the lower lip and the application of a single skin-graft. Very little chloroform was used, and the child seemed in good condition when returned to the ward, but within a few hours the temperature had risen to 108 F. As the case was not regarded at the time as one of heat-stroke, cold applications had not been used, and death occurred during the night. A few days later he had two similar cases, and by exclusion had made a diagnosis of heat-stroke. The treatment for that condition having been instituted, there was a rapid subsidence of all bad symptoms. Looking back over his past experience, he now felt sure that he had met with several other cases in which the sudden onset of these urgent symptoms and the fatal termination had been explained at the time in other ways.

DR. GEORGE E. BREWER said that last July he had done a rather severe operation for sarcoma of the tonsil on a lad of 19, on a day when the temperature in the operating room had been 99 F. Within two hours the temperature was 105, the pulse 150, and the patient restless and delirious. At the suggestion of Dr. Gibson he had treated this case as one of heat-stroke, and with the most gratifying result.

DR. ROBERT T. MORRIS said it was well known that those who indulged freely in alcoholic drinks were most liable to heat-stroke, and this led him to query whether the anesthetic, like alcohol, might not, by lessening the powers of resistance, pre-dispose operative cases to this complication. He had met with a case two years ago which he had been inclined then to consider an example of heat-stroke, and now he felt more than ever convinced that this diagnosis was correct.

DR. JAMES P. TUTTLE said that he had met with several cases in the past summer in which there had been a sharp rise of temperature after operations, and he had been in doubt as to the cause. In one of these the temperature had rapidly risen to 107, and had reached 109 at the time of death. Chloroform had been the anesthetic employed in this case, and as there had been suppression of urine the natural supposition had been that death had been the result of nephritis. However, the autopsy had failed to confirm this view.

DR. A. V. MOSCICOWITZ said that last summer he had amputated in a case of Reynaud's disease, and in four hours thereafter the temperature had reached 109 F. A diagnosis of heat-stroke had then been made, but in spite of treatment death had occurred five hours after operation. A complete and most careful post-mortem examination had been made, but all that had been found was a hyperemia of the meninges and a marked rigidity of all the cerebral vessels—a condition pointing to heat-stroke.

DR. WILLIAM H. THOMSON asked if any surgeon present had had similar experiences in cool weather.

DR. ALEXANDER LAMBERT said that the very rapid rise of temperature in the cases just reported would be enough to exclude septicemia and even kidney disease. The common practice of swathing patients in towels and bulky dressings prior to an operation seemed to him to conduct to heat prostration. It should be remembered that while heat and moisture are contributing causes, the chief determining meteorological factor of heat-stroke was the absence of air in motion. Thus in the awful period of heat in 1896, when there were so many cases of heat-stroke, there had been less than the average humidity, but for ten days the velocity of the wind had not exceeded six or eight miles an hour. The practical application of this knowledge in instituting effective prophylaxis was obvious. It took exception to the statement that rigidity of the blood vessels of the brain indicated heat-stroke; a large experience had convinced him that there were no post-mortem findings aside from changes in the nerve cells, which were characteristic of heat-stroke. A most potent means of controlling the hyperpyrexia in these cases was by the administration of ice water enemata.

DR. W. E. STUDDIFORD reported a case of heat-stroke occurring last July within a few hours after a total hysterectomy. The temperature had reached 107.6 F. in thirty-six hours, but had yielded promptly to the ice-pack. There had been nothing about the abdominal wound or about the vaginal drainage to indicate sepsis, and after this time recovery had been uninterrupted.

CONSTRUCTION OF AMPUTATION STUMPS.

DR. A. V. MOSCICOWITZ read a paper on this subject, with a report of two cases of amputation by the osteoplastic method of Bier. He said that since he had become interested in this subject he had examined many amputation stumps made by a great variety of methods, and had convinced himself that every stump made by other than Bier's osteoplastic method or by a disarticulation, was more or less painful. It was true that sometimes, owing to the very bad condition of the patient, the longer operation of Bier would be contraindicated, but there could be no doubt about the superiority of the stump which it gives. In amputating the leg by this method, the periosteum of the anterior surface of the tibia is circumsised, the edge of the periosteum are raised for a short distance, and a thin plate of bone is sawn out, preferably with a saw specially devised for this purpose. A skiagraph taken eighteen days after such an amputation showed perfect union between the osteoplastic flap and the tibia, but not between this flap and the fibula.

Therapeutics.

Pichi in Subacute Urethritis.

Dr. Aronstam, in *The Physician and Surgeon*, contributes a very extensive article on the materia medica of pichi. He states that it should always be prescribed with an alkali, preferably the potassic salts:

R. Extracti pichi fluidi	5iv	16
Potas-ii citratis	3iii	12
Tinct. hyosyami	3ii	8
Spts. etheris nitrosi	3iii	12
Elix. aurantii q. s. ad	3ii	64

M. Sig. One teaspoonful in water one and a half hours after meals. —*Theor. Gazette.*

[He describes pichi as a stimulant and alterative to the secretions in general and a sedative to the mucous membranes, especially to the urethral mucosa, as well as a urinary antiseptic. It is also recommended in dysmenorrhea in combination with viburnum prunifolium and potassium bromid.]

Spasmodic Cough in Bronchitis.

R. Codeina	gr. v	33
Acidi hydrocyanici dil.	m. xl	266
Acidi phosphorici dil.	3i	4
Syr. toluanti	3ii	64
Aque q. s. ad	3iv	128

M. Sig. One teaspoonful every three or four hours. —*Merkel's Report.*

Scabies in Children.

The following ointment is recommended by Perrin:

R. Olei anethem camphorata	5v	20
Unguenti storacis	3i	4
Balsami peruviani	m. xv	1

M. Sig. To be rubbed on in the evening; the next morning cleanse the skin with warm soap and water and sprinkle it with starch, or, if the skin is inflamed, continue the treatment one week or ten days. —*N. Y. Med. Jour.*

Treatment of Lobar Pneumonia.

Louis F. Bishop, in *The Medical Times*, states that the relief of pain is the most important thing; and this can be accomplished by immobilizing that side of the chest and applying warm soothing poultices. If necessary a small amount of morphia may be permitted. The following formula is given by him in some cases, although the treatment as a rule is expectant:

R. Tinct. acetonit	m. i	66
Tinct. digitalis	m. iii	18
Spts. frumenti	3iii	12

M. Sig. One such dose to be taken every three hours.

Sterilization of the Hands.

J. Hahn, in *Chil. f. Chir.*, describes the following method of treating the hands before an operation:

In running-sterile water at about 40 C. with common yellow soap and sterile nail brushes, the hands are scrubbed hard and systematically in four sittings of a few minutes each. After the second scrubbing the nails are cleansed and trimmed. Next immerse the hands, for four minutes, in a 1 to 1000 solution of mercury bichlorid in 95 per cent. alcohol, followed by washing in a 1 to 1000 aqueous solution of the same until the alcohol is washed off. Finally, rinse the hands in the alcoholic solution and begin the operation. —*Med. News.*

Incontinence of Urine in Children.

The following combination is recommended by Mme. Perlis, in *These de Paris*:

R. Ext. rhus, fluidi	m. v to xx	3
Syrupi aromatici	m. xx	133
Aque destil. q. s.		

M. Sig. One such dose to be given three times a day. The amount of the fluid extract to be taken three times a day is five to ten drops for a child between 1 and 5 years of age; ten to fifteen for a child between 5 and 10 years old and fifteen to twenty for children over 10 years of age. —*N. Y. Med. Jour.*

Treatment of Arteriosclerosis.

The Canadian Practitioner contains a very interesting article on treatment of arteriosclerosis; stating the importance of its early recognition and treatment. It is much influenced by habits and occupations and is frequently an early intimation of what may prove to be serious heart or kidney trouble.

The outline of treatment suggested: In the first place alcoholic drinks should be prohibited; caution against violent exercise or overwork; reduction of the amount of meat consumed; proper attention to the emunctories—the skin and kidneys should be made to do active duty by inducing the patient to drink plenty of water. It dilutes and washes out the compounds of uric acid which is so injurious to the liver, kidneys and arteries. One drug alone is mentioned and that is potassium iodid in small doses, two or three grains after meals in water three times a day.

Bismuth Subgallate in Gonorrhoea.

Dr. Dokerchaieff states that he has had brilliant results from the use of bismuth subgallate in both acute and chronic cases.

In the acute cases he first washes out the urethra with a boric acid solution or a 2 per cent. solution of potassium permanganate. Then he injects the following:

R. Bismuthi subgallati	3ii	8
Pulveris acacie, aa	3iii	96
Aque destil.		

M. Sig. Use as an injection every two hours and retain the liquid each time for five minutes and allow it to escape drop by drop.

In the chronic cases the urethra is well irrigated and a bougie made up as follows is introduced:

R. Bismuthi subgallati	gr. xx	66
Wool fat	3iiss	10
Cerae alba—white wax	3ss	2

M. Sig. Insert and lightly massage the penis to bring the mucous membrane in contact with the bougie.

—*Merkel's Archives.*

Bed-Sores in Spinal Cord Troubles.

J. H. Lloyd recommends the following dressing, to be applied as long as the skin remains unbroken:

R. Ol. ricini	3i	32
Collodion, aa.		

M. Sig. Apply locally to the affected part. If the skin is broken add to this a little iodoform. When sloughs have formed treat the same as any other wound.

—*Text-Book of Applied Ther.*

Bronchitis in Children.

Solis-Cohen uses counter-irritation to the chest, inhalation of creosote or formalin, eulomol gr. ¼ when needed and:

R. Tinct. acetonit	m. i	66
Tinct. opii camphorata	m. ii	12
Vini ipecacuanhe	m. v	33

M. Sig. At one dose, to be repeated every two or three hours. He states that alcohol or quinin does but very little good. —*Med. News.*

Cod-Liver Oil Injections in Tuberculosis.

Dr. W. Zenner, in *Theor. Monats.*, advises the employment of the following combination to be given per rectum:

R. Pancreatin pur	gr. xlviiii	320
Fel bovis—inspissated	gr. v	33
Sodii chloratis	gr. xlviiii	320
Dissolve in water	3iii	96

and allow to digest for two hours with
Cod-liver oil 5xvi 512

M. Sig. Cleanse the bowel by enema and inject two or three ounces of this emulsion, previously warmed, through a rectal tube each night, the patient being placed in the knee-chest position. This formula is designed to possess easy absorbability and high nutritive value. —*Amer. Jour. Med. Science.*

Alcohol Dressings.

Freese, in *Munch. Med. Woch.*, reports very favorably on the use of alcohol dressings in inflammatory troubles, phlegmons, buboes, felonis, mastitis, etc., providing the treatment on this line is begun sufficiently early.

AMERICAN.

2. **A Tropical Ration.**—In this continuation of his article Kean gives the essentials, as he sees them, of the different kinds of food in the tropical region. He thinks that there is too much pork and bacon used, especially in garrisons, and that fresh fish and mutton should be substituted for the present monotonous diet of beef and bacon to a certain extent. The vegetable he would discard in the tropics is the ordinary potato, and he would substitute for it rice, sweet potatoes, etc. The vegetable components should be rice 2½ ounces, or macaroni 2 ounces, fresh vegetables in appropriate variety, 16 ounces, purchased if possible, in the vicinity of the post or command. Rice should be a daily, not an alternative issue. Dried fruits are a valuable addition, and the commanding officer in the field should be authorized to increase the fruit component to 3 ounces when deemed necessary. The great perils of the tropics, aside from infectious disease, are from digestive disorders and these decrease the resistance to infectious disease; hence the importance of proper attention to this point.

5. **Aural Hygiene.**—In this paper Amberg deals with the hygiene of the ear: 1. In connection with the proper care of the nose and throat; 2, with general diseases, and 3, in general daily life. The dangers to the ear from nose and throat troubles are noticed and a special point made of the danger of the nasal syringe, the effects of coryza in infants, etc. Sixty per cent. of all ear affections, he says, are caused by disorders of the nose and throat, and yet the common combination of eye and ear instead of nose, throat and ear diseases exists. He also speaks especially of the dangers of intermarriage in those families where deafness exists, as affecting the chances for functional ear troubles. The dangers of dust are also remarked, the need of equable temperature for the best hygienic conditions of the ear, the abuse of drugs such as quinin, by the public and often by physicians, the Fourth of July nuisance, to which he attributes some aural troubles, and the possible dangers of piercing ears for ear-rings.

6. **Chronic Villous Arthritis.**—This peculiar morbid process occurring usually in young adult life, rarely after the 40th year and usually polyarthritic, is confined principally to the villi of the synovial membrane, producing chronic hyperplasia and seldom or never involving the ligaments, cartilages or bones. This is one of the strongest points of differentiation from chronic or other forms of arthritis. The villous hyperplasia produces a fringe-like growth much larger than is found in other forms of arthritis. The family history is usually negative. Trauma may be a causative factor. It does not depend on a strumous diathesis or general ill-health. It is attended by pain, enlargement of joints, impaired motion and usefulness, possibly deformity, and rarely shows any elevation of temperature, heat or discoloration. In chronic arthritis the family history is usually negative. It attacks both youths and adults. Usually there is a history of previous attacks of arthritis or infectious disease. There is fever, swelling, enlargement of the joints, etc. In tuberculous arthritis there is usually a history mentioned, it generally occurs in early childhood and the other symptoms are characteristic. Syphilitic arthritis is ordinarily polyarticular with a history of infection and other signs. Rheumatoid or gouty arthritis may be monoarticular or polyarticular, with history of previous attack, rheumatoid or gouty diathesis, proliferation, enlarged epiphyses and deposition of lime salts in the joint. In arthritis deformans there may be heredity or trauma; it may occur at any period of life; there is hyperplasia, proliferation and thickening of synovial membrane, thickening of capsule, degeneration of ligaments, distortion of joints, etc. For the treatment of villous arthritis, rest, regulation of the bowels and secretions,

and proper treatment to meet the complications are indicated: locally, ichthyol, mercury and belladonna, with dressings to immobilize the joints. Of surgical methods, free opening of the joints under thorough asepsis and excision and removal of hyperplasia, washing out of the cavity with antiseptics, etc., are employed. Later, massage and passive motion are practiced to restore the function.

12. **Uterine Fibroids.**—Segur is an advocate of the electric treatment of uterine fibroids, and sums up his paper as follows: 1. Electricity properly applied may be considered a specific for the treatment of uterine fibroids. 2. A moderate dosage, 40 to 50 milliampers, applied for 20 to 30 minutes relieves pain and influences a diminution in size. 3. There are no dangers to be feared from its use if carefully conducted. 4. Puncture is not necessary in order to obtain practical results. 5. No serious operation should be undertaken until after electricity has been tried.

14. This article has appeared elsewhere. See THE JOURNAL of August 25, title 100, p. 519.

16. **Autointoxication and Visual Disorders.**—Woodward divides these into two classes: 1. Those where the derangement is purely functional, and 2, where there is demonstrable structural lesion. Of the first, the most common and prominent, as well as the most therapeutically perplexing, is neurasthenia, and in its treatment he believes that attention to assimilation and excretion is the first consideration in the great mass of cases. It is true there may be cases where the difficulty is purely in the nervous system, but their number is limited. He does not lay too much stress on eyestrain in these cases. Migraine is another condition which he thinks is often due to slow poisoning by some noxious substance. Among organic derangements he mentions rheumatism producing rheumatic iritis especially, and Bright's disease. Diabetes and gout are omitted because he thinks the ocular manifestations in these conditions are more properly subjects for discussion before a society of ophthalmologists.

17. **Trachoma.**—In view of his later experiences, Pooley summarizes his conclusions as to the value of the improved method of treatment of trachoma as follows: 1. Of all the mechanical methods expression in suitable cases is the most efficient remedy yet discovered; effecting, in a large percentage, a more or less complete cure with better preservation of the conjunctiva than any method hitherto described. 2. It must, however, in every instance, be carefully followed by local treatment until all tendency to relapse has disappeared. 3. The success of the method depends on the conscientious removal, so far as possible, of all the trachomatous bodies without injury to the conjunctiva. 4. In any event, so far as the writer's experience goes, more or less frequent relapses will occur.

19. **Chloretone.**—Hirschman's paper on the prevention of nausea and vomiting during anesthesia is a recommendation of chloretone for this purpose. Out of thirty cases in which he has had experience with this drug, in only three, or 10 per cent., were the patients nauseated. In two of the three the chloretone was not given until just before the administration of the anesthetic, and he thinks the taste in the patient's mouth, together with the fumes of chloroform, caused the nausea, which in both cases was slight. The drug was given in 10-gr. doses to women and boys under 16 years of age, and 16-gr. doses to men, one-half hour, as a rule, before the anesthesia. He prefers to give it dry on the tongue, following the administration with one to two ounces of warm water. It may also be given in capsules, but he does not recommend the sugar coated tablets.

21. **Wounds of the Heart.**—Hill reports two cases of traumatism of the heart, one of penetration by a needle, which was extracted without any bad effects, and the other a wound of the heart muscle causing hemorrhage into the pericardium with serious symptoms, which were relieved by incision and emptying of the pericardium. The patient recovered, though he subsequently had traumatic pericarditis. The author notes the methods of cardiac suture, the interrupted-silk suture being preferable, the needle being introduced and it tied during diastole. Anesthetics are condemned by some, but it is pos-

sible according to some authorities to use good chloroform. He details briefly the seventeen cases of heart suture that have been reported.

22. **Hemorrhage from Ruptured Meso-Appendix.**—The case reported by Ladinski is of a boy 11 years old who apparently suffered from a mild attack of appendicitis and later from a fall, which produced serious symptoms of abdominal hemorrhage or rupture of some important viscus. The prognosis was unfavorable, but the operation seemed to be the only choice and celiotomy was performed. The abdomen was found full of blood which had escaped from the ruptured meso-appendix. The appendix, which was unusually long, was doubled up like the letter U, being held in this position by adhesions, and in the end of the meso-appendix there was a rent to the extent of one-half inch in which there were several small spurting vessels. The meso-appendix was ligated, the appendix separated from the adhesions and removed, the blood and clots wiped away, the peritoneal cavity washed out with saline solution and the wound closed. Recovery was uneventful. The author thinks that this is the only case on record of such a hemorrhage, and it is of interest also on account of its close similarity to general peritonitis, the result of perforation.

23. **Causes of Insanity.**—Jones' article is a review of the opinions of many authorities in regard to the causes of insanity. She does not emphasize the gynecologic causes, though she quotes the authors who have made much of these and reports cases where benefit has been observed from operations. The element of heredity is fully estimated in her article.

24. **Spinal Analgesia in Children.**—Seven cases of operation under medullary anesthesia are reported by Bainbridge, all of which seem to have been satisfactory. The author is rather inclined to favor cocaine over eucaïn in this method, and gives the following method of sterilizing the former, which he thinks is satisfactory so far as experiments can show. About a dram of ether is poured over 5 gr. of powdered cocaine or eucaïn in a measure-glass which has been boiled as well as the glass rod used to mix the ether thoroughly with the powder. The mixing process is continued until all the ether has disappeared, when one ounce of boiled, filtered water is added. The solution should be made fresh before each operation. All the after-effects of cocaine were temporary in his cases. He concludes that no final verdict for or against spinal injection can be reached without further experimental evidence, and the remote after-effects are yet to be determined.

25. **Influenza in Children.**—In this article, only a part of which is published, Jacobi says that the use of water slightly acidulated with hydrochloric acid will be useful as a prophylactic as well as for irrigation of the nose. There is no specific for the disease, and only rational, hygienic, symptomatic and sustaining treatment can be beneficial. He does not find the testimony as to the use of quinine uniform. He would reject acetanilid absolutely, but antipyrin has good effects in some cases, while its undesirable effects are also numerous. Phenacetin, salicyrin, and the salicylates are also mentioned, but none of these drugs should be given without the addition of stimulation. This should rarely be alcoholic, caffeine preparations are vastly preferable, and the use of strychnia is so well understood that he needs only to mention it. One of the best stimulants, but one sadly overlooked is Siberian musk. A child of two years should take of the 10 per cent. tincture five to ten minims every half hour until from half-a-dozen to a dozen doses have been given. In conclusion, he mentions a singular experience in Madeira, where vaccination seemed to be a preventive of the disease.

27. **Influenza and Nervous Symptoms.**—Practically every form of nervous disease has been attributed to influenza, and Mosher here gives an account of the symptoms, observed by him largely among the insane. He ends his paper with the following conclusions: 1. The infection of influenza produces a toxin, which has a severe and selective action upon the nervous system. 2. The immediate effects of this toxin are shown in affections of the peripheral nerves and the cerebro-

spinal centers. 3. The remote effects are manifested in lowered tone of the nervous system, predisposing to other diseases. 4. These ensuing diseases arise in weakened or predisposed organs, giving rise to the different classes of "respiratory," "alimentary," "genitourinary," and "circulatory" forms of influenza. 5. Postinfluenzal insanities are also a complication of the postinfluenzal states of nervous debility, in patients mentally predisposed. 6. The postinfluenzal insanities are not essentially different from other insanities due to vital depression. 7. The prognosis of influenzal affections is generally good, under proper management. 8. Exception to this is in influenzal affections arising during the course of other severe diseases, as pneumonia and general paralysis, and during senility complicated by mental or physical deterioration.

29. **Influenza in Adults.**—According to Wilcox the important matters in the treatment of adults suffering from influenza are: 1. The avoidance of opium, and, 2, all measures that depress the circulation. The affection is severe for a time, but is soon past and should, when properly treated, leave no trace. Elimination of toxins should be insured and diarrhea should be considered beneficial. In the respiratory type he would use ammonium carbonate in 5 to 10 gr. doses, given in 2 ounces of milk, as frequently as the situation may require, antiseptic sprays to the nose and throat and stimulation by strychnia, etc. If pneumonia occurs, the nitrites, preferably nitroglycerin, and strychnia are used. For a slowly-resolving pneumonia and tardy convalescence from bronchitis, creosote carbonate, 30 to 40 drops, several times a day is of value. In the gastrointestinal type, calomel and intestinal antiseptics are indicated with high intestinal irrigations if needed. In the neuro-muscular type, he rather advises against the use of coal-tar analgesics, though he uses them to some extent, and recommends stimulation by caffeine at the same time. Gelsemium is a remedy which he thinks offers great benefit if pushed until slight ptosis appears.

30. **Hydrotherapy in Influenza.**—The use of hydrotherapy for eliminative purpose, such as hot vapor baths, is favored by Shurly, though the employment of the cold pack should take precedence whenever the temperature is very high. With these measures he would give quinin in 3-gr. doses every two hours and opium to relieve pain. For the relief of debility and nervous perturbation after the first stage, he recommends phosphorus .001 grain in capsule in oil, also strychnia. Coal-tar products are generally condemned.

33. **Acute Oral Inflammation.**—The records of the Boston City Hospital for the severer forms of mouth disease are analyzed by Munro, including twenty-nine cases of ulcerative stomatitis chiefly treated in successful cases by washes containing myrrh, chlorate of potash, permanganate of potash and hydrogen peroxid, in addition to a vigorous and supporting diet. In twenty-eight cases of acute glossitis all but five were in males about 30 years of age. The causes were sometimes very obscure and swelling very rapid. In most cases the swelling increased until it almost filled the oral cavity. The history of the cases impressed him with the fact that the phlegmonous type is much severer than the abscess type. In some cases it was difficult to distinguish between true glossitis and Ludwig's angina. The two conditions may co-exist or the disease may start as a cellulitis of the floor of the mouth and extend to the tongue. Only nine cases of Ludwig's angina were recorded, one fatal. The clinical picture is very characteristic; a brawny fulness beneath the chin, an elevation of the floor of the mouth to the level of the edge of the teeth, pushing the tongue upward and backward, and in some cases a cellulitis extending in various directions as far as the shoulder or chest. In all these cases of oral disease the treatment must be vigorous, if it is severe. Where immediate operation for the discharge of the pus or blood is not required, medical treatment must be energetic. Catharsis, abundant food, rest, cleansing antiseptic washes and large hot poultices to the neck and chest will often abort a case that threatens to become rapidly serious. Where there is doubt, however, or delay would seem dangerous, free incision is advisable, whether pus is present or not. In glossitis, unless there is a well-defined, localized collection of

pus, incision is best made in the dorsum on the right side of the median line. In angina cases the incision should be made in most instances in the median line below the chin as from this each lateral space can be easily explored with a blunt instrument until the small focus of pus, if present, is found. These cases are frequently distressing and the condition is grave, but under good treatment they are of brief duration and without sequelæ as a rule.

34. **Varicose Veins.**—The conclusions as to the operative treatment of varicose veins are given by Blake as follows: 1. Operation for radical cure of varicose veins by dissection is not successful in every case. 2. To obtain successful results, cases must be selected and certain conditions avoided, and recommended to palliative treatment. 3. The condition which will probably militate fatally against satisfactory results are: *a*, old age, or an extremely debilitated condition; *b*, excessive and very extensive varicosity; *c*, occupations which to an extraordinary degree favor the development of varicose veins. 4. Cases which may be cured by a thorough and careful operation are: *a*, Local varix, even of marked prominence, particularly if thrombosis has occurred, either in thigh or lower leg; *b*, extensive varix, limited to a single venous stem; *c*, varicosities which are a bar to passing civil service, military or naval examination; *d*, cases in youth and middle life; *e*, cases in which the development of the permanent varicosity was at least partially due to more or less removable conditions—flat foot, garters, etc. 5. Operation, even if not entirely successful, will usually relieve such complications as thrombosis, hemorrhage and ulceration. 6. The usual conditions which follow unsuccessful operations are: *a*, Pain in and around the scar; *b*, general swelling and tenderness of the leg; *c*, development of varicosities above or below the operation scar, but not at the site of the operation itself. 7. In all operated cases, general systemic treatment as well as local treatment should be prescribed, together with exercise and the avoidance of a continued upright position whenever possible. 8. Cure of symptoms does not necessarily mean the removal of all visible varicosities. 9. Comparison of relative methods of multiple ligation and continuous dissection must be based on a larger number of cases than are here recorded. 10. Bennett's conclusions and his extreme limitation of the indications for successful operation are too sweeping.

35. **Heroin.**—Lazarus reports a number of cases of respiratory disorders producing cough or other symptoms and also one of intercostal neuralgia relieved by heroin. He considers the drug a most valuable aid which should rank as a specific in pulmonary affections combined with cough, while its analgesic qualities in neuralgia and its antispasmodic effect in asthma and whooping cough have been well established.

36. **Rectal Stricture.**—Monroe considers stricture of the rectum largely due to poor rectal surgery, especially to the amount of carbolic acid formerly used in the treatment of rectal disease. He has also seen it follow meddlesome procedures on the rectum by so-called official surgeons, and Whitehead's operation. Other causes mentioned are constipation, foreign bodies, syphilis, etc. He discusses the symptoms and diagnosis. The prognosis is, he thinks, generally unfavorable. We can usually alleviate but not often completely cure.

37. **Aspirin.**—Aurbach reports several cases treated with aspirin, which he thinks is a valuable remedy in the treatment of rheumatism. The method of administration is usually 10 gr. powders three times, or less, daily. In addition he gives supporting treatment.

39. **Abdominal Relaxation and Gall-Stones.**—Meyer's paper is summed up in the following: 1. Visceral ptosis consequent upon abdominal relaxation and other causes results in stagnation of the bile through interference with its normal expulsion. 2. The inactivity of the gall-bladder and stagnation of the bile predispose the mucous membrane to infection. 3. The infection may be either hematogenic, through the portal system, etc., or ascending from the duodenum. 4. This results in catarrhal inflammation of the mucous membrane, an albuminous exudate, and the exfoliation of epithelial cells.—According to Naunyn, the addition of albumin to the bile

produces a copious precipitation of the stone-forming elements. This precipitate, with clumped bacteria—Blachstein—and degenerated-cell masses as nuclei, forms biliary calculi.

40. See abstract in *THE JOURNAL*, xxxiv, p. 1133.

41. **Ectopia Vesicae.**—Halsted reports a case of operation for ectopia vesicae by Frank's method of anastomosing the bladder to the rectum by means of his decalcified-bone coupler. The operation per se was successful, but the patient died of shock due to long operation, which he thinks can be avoided in future cases.

45. **Cerebrospinal Rhinorrhea.**—One of the three cases reported by Philip and Brown is considered by them to be a true case of escape of the cerebro-spinal fluid through the nose, similar to that reported by St. Clair Thompson. The patient was a young woman, 25 years old, and the condition was first noticed some months previous. The flow was intermittent, sometimes from one nostril and sometimes from the other. It was preceded by no headache, but a dull frontal pain followed it for several hours. The only premonition was a tickling sensation between the eyes followed by sneezing. It would begin on awakening whenever that might be and last two or three hours, when it would stop for a few hours and begin again later in the day. The flow was enough to saturate a number of handkerchiefs, which would become stiff enough to stand alone, but in no way discolored. On examination of the fluid it was found sterile, and feebly alkaline in reaction; there was a slight and retarded reduction of copper when boiled with Fehling's solution. Atropin was the only drug that gave her any relief and finally led to a stoppage of the flow in the patient's opinion. Two other cases are reported that are considered to be of the ordinary rhinorrheal type.

Surgical Treatment of Essential Epilepsy. VIDAL.—Reviewing the various operations that have been performed for the relief of essential epilepsy, Vidal concludes that resection of the skull or of the sympathetic is the only rational procedure known to date. The epilepsy resulting from direct or indirect pressure on the brain is the only form amenable to craniectomy. Resection of the sympathetic should be reserved for certain epilepsies of toxic origin, especially those in which the primary hyperexcitability of the cortical cells is reinforced by ischemia from excitation of the cervical sympathetic by lesions in or near it. This auxiliary factor of irritation of the brain should be suppressed, as aside from its direct share in the genesis of the convulsive symptoms, it entails in time definite histologic and physiologic alterations in the motor cells, which suffice in themselves to perpetuate the affection. On the other hand, resection of the sympathetic will be ineffectual in reflex epilepsy, in epilepsy from pressure on the brain or from intoxication by an indifferent or vasodilating poison. The nature of the essential epilepsy may possibly be determined beforehand by a preliminary test with amyl nitrite. In patients refractory to this substance administered at the premonitory symptoms of a seizure, it is probable that the disturbances in the circulation have no share in determining the seizure, which is probably a reflex neurosis or vasodilating intoxication, and consequently, resection of the sympathetic would have no effect on the epilepsy, as there is no anemia in the brain. In other patients in whom the seizure is favorably influenced by amyl nitrite, the epilepsy would probably be favorably influenced by sympathicotomy. Done in time, it might arrest the seizures and preserve the gray matter from the serious consequences of an insufficient blood supply. Resection of the sympathetic is, however, formally contraindicated in cases in which the amyl nitrite induces a seizure in the absence of premonitory symptoms. The above assertions are the result of reasoning, much experimental research and study of physiologic and pathologic conditions, but they lack clinical confirmation.

Immunization Against Tuberculosis. TATSU-BABO.—The writer of this communication is a medical officer in the Japanese navy who has been completing some research lately under Roux at the Paris Institut Pasteur. He proclaims that

he has succeeded in immunizing guinea-pigs against tuberculosis and curing already established infection, by a new system of serotherapy. It is founded on the attenuating influence of a first tubercular infection on a second, and the discovery of two substances in dead Koch bacilli, which possess a bactericidal and antitoxic power against the pathogenic agent of tuberculosis. None of the serums hitherto prepared, he states, have possessed the essential properties of the tubercle bacillus. His first substance or tubercle-mycoprotein, induces a leucocytosis at the point of injection, which is an essential property of the live bacillus. The second substance or tubercle-bactericidin, causes vascularization in the tissues and the genesis of perivascular, microscopic granulations. It is a true toxin, endowed with the essential pathogenic properties of the bacillus. Injection of the first confers antitoxic immunity and of the second, bactericidal immunity. No clinical tests are reported.

Bulletin de l'Acad. de Med. de Belgique, 1900, Nos. 7 and 8.

Lesions of Nerve Cells Induced by Acute Anemia. D. DE BUCK.—This experimental study of the conditions caused by acute anemia of the lumbosacral spinal cord, shows that disturbances in nutrition induce an exudation of the migrating cells of the blood, with possible phagocytosis and neuronophagia. This is followed by proliferation of the connective tissue and neuroglia elements. They may participate in the phagocytosis and neuronophagia, but their chief task is the production of the sclerosis which substitutes the destroyed tissue.

No. 8.

Tobacco for Persons Under Sixteen. MASOIN.—Among the points in the report of a committee appointed to consider this subject in response to the request of the government, we note that moist tobacco should always be avoided, as the nicotine escapes from it without being decomposed. As nicotine vaporizes at 250 C., the portion not decomposed by the heat accumulates in the unburned portion toward the mouth, and the last quarter of a cigar should never be smoked. Pipes should have long stems. The cigarette is, of all the methods of smoking, the least harmful. No one should smoke before meals nor on an empty stomach, nor in a close room. Young people should be effectively warned at home and at school of the dangers of excess and abuse of tobacco. Tobacco should be regarded as possibly dangerous at all ages and especially during the period of active growth.

Echo Med. (Lille), December 2.

Apocodein for Hypodermic Administration of a Laxative. RAVIART.—The drugs that can be administered hypodermically to control the functioning of the intestines are not numerous. The hydrochlorate of apocodein has proved that it possesses remarkable evacuating properties, laxative rather than purgative, and an experience of thirty-four cases shows that it can be used without fear of the slightest accident. Two cgm. were injected at a time of a solution of apocodein hydrochlorate: 50 cgm. in 50 gm. water. Raviart's experience has been in reality much more extensive, but thirty-four cases are related in detail. A few proved rebellious to the small dose injected, one a patient with chorea, others with hemiplegia or delirium tremens, malarial fever, neurasthenia, hyperchlorhydria or tuberculosis. The apocodein is a sedative and hypnotic with a peculiar, stimulating effect on the peristalsis and glandular hypersecretion. Toy announced at the Bordeaux Congress of Alienists that he had been invariably successful with apocodein in soothing the patients and procuring several hours of sleep for them; one, and sometimes three, stools occurring during the night, with no vomiting nor other inconvenience.

Corr. Bl. f. Schweiz. Aerzte (Basle), October 1 and November 1.

Spinal Cocainization. F. DUMONT.—The results of spinal cocainization were discouraging in the three cases in which Dumont used it. He injected 15 mg. in each case, one a carcinoma mammae, another an umbilical hernia, and in neither was analgesia obtained. The operation had to be completed with ether. The third patient was much debilitated from tubercular lesions in foot and hand. One knee had been re-

sected a few months before. In each patient intense headache and nausea persisted for four days, and the third patient died the fifth day. The autopsy showed the spinal membranes apparently normal, the cord moderately anemic. Tubercular lesions in lungs and intestines explained the fatal termination which, Dumont believes, was undoubtedly hastened by the cocaineization. He adds that the little patient who continued eating candy while Koehner was resetting his foot under spinal analgesia, has since died of meningitis.

November 1.

Carcinoma of the Stomach. L. RUETIMYER.—In fourteen cases carefully studied no free HCl was found in 84 per cent., while it was discovered in 16 per cent. Lactic acid was found in 87 per cent. and long bacilli in 80 per cent. Three patients with carcinoma of the stomach were 14, 19 and 23 years old. Ruetimyer reviews the statistics of various cities during the last few decades and points out that not only is the frequency of carcinoma of the stomach increasing, but that the average age is less than it used to be, the majority now occurring between 40 and 50, instead of between 60 and 70 as formerly. The statistics for Basle of 666 cases occurring during the last twenty-eight years are 102 between 40 and 50; 141 between 50 and 60; 182 between 60 and 70; men, 311; women, 355.

Deutsche Med. Wochenschrift (Leipzig), November 22.

Bactericidal Powers of the Ultra Violet Rays. H. STREBEL.—In this preliminary communication Strebel, of Munich, states that the invisible ultra violet rays of the spark of a powerful induction coil are strongly bactericidal. They killed a flourishing colony of the micrococcus prodigious for instance, at a distance and even through thick media of quartz, in twenty minutes. The ultra violet rays are especially numerous in the induction spark and the number can be increased by using aluminum and cadmium electrodes and a Leyden jar to accumulate and regulate the electricity. With this combination the ultra violet portion of the invisible spectrum can be seen with the barium-platinum-cyanid screen to be more than four times the length of the visible portion of the spectrum. Finsen uses chiefly the blue violet rays in his radiotherapy, which are weaker chemically than the ultra violet. Any one owning a Roentgen induction coil outfit, Strebel adds, can establish the truth of his assertions and give radiotreatment himself.

Exclusion of a Kidney. L. LANDAU.—During the extirpation of a carcinoma of the cervix in a woman of 38, the ureter was resected. The proximal stump was merely ligated and replaced. The patient recovered with no disturbance on the part of the urinary system. Landau has excluded the kidney in this way three times, and has found it a harmless procedure when unavoidable.

Traumatic Diabetic Coma. W. SPITZER.—An intelligent man of 46 had been diabetic for six years, but the affection was kept well under control. At the end of this time he met with a slight fall which caused him a severe fright. The sugar rose from 25 to 250 gr. a day and only by strenuous efforts was the threatened coma averted.

Deutsche Ztit. f. Chir. (Leipzig), October.

Lung Affections After Operations. M. GERULANOS.—Out of the ninety-five deaths at Heflerich's surgical clinic at Kiel during 1899, pulmonary complications were observed in eighteen. In seven of these the lung affection was evidently directly connected with the operative intervention. By detailed study of these seven and the reports from Mikulicz and other clinics, Gerulanos finds that pulmonary complications are at least as frequent after infiltration anesthesia as after general narcosis. He considers the emotions of the patient as he consciously follows the operation, a factor in determining physical disturbances later, quoting Riesel and Aufrecht, who have observed cases in which violent emotions were the cause of pneumonia with severe cerebral symptoms. This factor possibly predominates in pulmonary troubles after infiltration anesthesia. The insensible aspiration of particles from the secretions of the mouth probably co-operates, finding a soil altered by the effect of emotion or from the irritating action of ether. A macroscopic or bacterial embolus may also be the

source of infection. But the principal cause of post-operative pneumonia is probably hypostasis from the continuous reclining, the paresis of the intestines and meteorism pushing up the diaphragm and consequently crowding the lungs. This hypostasis should be prevented by frequently changing the position of the patient, with the trunk slightly inclined to one side or the other. The patient should be urged to breathe deep, with morphin if necessary to reduce the painfulness of deep breathing. All binding bandages should be avoided. Gas should not be allowed to distend the abdomen; a mild purgative is preferable to opium for this reason even after a laparotomy. An expectorant should be administered in case of existing bronchial symptoms and all other means should be used to prevent hypostasis, which is especially dangerous in debilitated, elderly persons, and after laparotomies in particular, as the patient is inclined to hold himself as immovable as possible. Chilling during the operation is also a factor in post-operative pulmonary troubles. At Kiel it is now the practice to cover the patient warmly or pack the extremities in cotton. A bath just before the operation is also warned against. Narcosis should be avoided as much as possible, particularly in elderly, debilitated persons. For minor operations infiltration anesthesia is preferable, but for serious operations the patient's distress of mind is more injurious than the shock of general narcosis. Ether should be used only exceptionally and for strong patients, on account of its more intense and injurious action on the lungs and circulation, especially to be feared in case of existing bronchial affections. In narcosis with chloroform, it should be completely suspended in a laparotomy for instance, as long as the manipulations are restricted to the intestines. By this means the patient gets very little chloroform and the actual narcosis is much abridged. The head should be lowered to prevent aspiration of secretions from the mouth.

Clinica Med. Italiana (Milan), 1900, No. 8.

Hematogenic Value of the Metals. F. APORTI.—Copper, zinc, gold and mercury proved to have no hematogenic action in the extensive experimental research described in this article. Iron proved to have a marked influence in this respect, most intense when introduced directly into the blood. Manganese has also a hematogenic action, but it is much slower and less pronounced than that of iron. But it does increase the hemoglobin and also the number of red corpuscles in time. Aporti is inclined to believe that this is accomplished by the manganese substituting the iron in the tissues and thus restoring it to the blood.

Vratch (St. Petersburg), November 24.

Injurious Effects of Excessive Spitting. P. P. GELLAT.—Five cases are described of what Gellat terms "psychic salivation," which he considers is quite frequent. In a typical case a middle-aged woman applied for relief from an excessive secretion of mucus in the nasopharynx which prevented her from sleeping. She became frightened during the local irrigation and resorted to a newspaper "specialist." He treated her for a year. When she applied to Gellat the secretion of mucous saliva had become excessive and the patient was spitting or wiping her mouth every minute, with nausea at the idea of swallowing "the horrible stuff." Gellat told her she must not spit, and ordered 20 drops of hydrochloric acid in a glass of water. Whenever she felt an inclination to spit she must sip from the glass and swallow instead of expectorating. In three days she was very much better and was soon completely cured. Her general health, which had been much debilitated was restored to normal at the same time. The loss of the oxydases in the saliva, which are wasted in the excessive spitting, depresses the metabolism and leads to local and general disturbances and neurasthenia. He therefore suggests that the more correct term for the condition would be "aptalya," and that the public should be warned of the injury resulting from the perverted use of the saliva.

Upsala Laek. Foerh., July and August.

Gall Stones from Polar Bears. O. HAMMARSTEN.—The bile and gall stones found in an old and a young female polar bear contained from nearly 4 to more than 6 per cent. of bili-

rubin. The presence of urobilin, Hammarsten observes, indicates that putrefaction must have occurred in the intestines, which conflicts with the recent statements that the intestines of animals in the arctic regions are nearly or entirely sterile.

Actinomycotic Appendicitis. G. EKEHORN.—The slow, gradual course, the insidious commencement and the constantly progressive tendency while still the patient feels comparatively well, are important points in differentiating actinomycotic appendicitis. Ekehorn has observed four cases. The last was treated by resection of the appendix and of a portion of the cecum. The patient was a married woman of 53, who had noticed a small tumor in the right iliac fossa for two years. It had never caused serious inconvenience, but it was diagnosed and removed as an evening temperature of 38 C. was noted at times. Complete recovery after the operation. The preceding cases were in a much more advanced stage when first seen.

August.

Operative Treatment of Prolapsus Uteri. A. O. LINDFORS.—Twelve personal cases of ventrofixation for prolapse are described and twelve by other Swedish surgeons are analyzed. Sixty-eight cases in which this operation was followed by more or less interference with pregnancy are also tabulated, including some published in American journals in the last few years. In the Swedish statistics the mortality has been nil, and in the foreign, 2.9 per cent. Lindfors concludes from a general review that the benefits of operative intervention in case of genital prolapsus are uncertain and relapses frequent even at the best. Consequently, he thinks that pessary treatment combined with a strengthening regime, will prevent the necessity of an operation in many cases, at least among patients in easy circumstances. Among the operative procedures vaginoplasty takes an important if not the most important rank, but severe, primary antelexion may require a high fixation rather than vaginoplasty. The Alexander-Adams operation proved insufficient in some cases, and ventrofixation accessory to vaginoplasty, is preferable. Indications vary with the sexual age of the patient. He prefers a combined Martin-Fehling or Tait-Fehling for his personal technique in vaginoperineal plastic operations. Total extirpation is only indicated in case of tumors or gangrene or in elderly women whose tissues have lost their tonus to such an extent that plastic operations have little chance of success. Neurasthenic patients should never be operated on when possible to avoid it. Whichever method is chosen the surgeon should be prepared for relapses or all kinds of complications. He should always be guided by the principle that a relapse is much less to be feared than serious interference with pregnancy or delivery.

New Patents.

Patents of interest to physicians, etc., Dec. 4 and 11 inclusive: 663,224. Bunton or corn shield. John J. Georges, Washington, D. C.
663,088. Apparatus for making chlorin. Paul Naef, New York City.
663,089. Making chlorin. Paul Naef, New York City.
663,723. Design, casing for disinfecting apparatus. Emil Tausig, New York City.
663,691. Syringe. Robert N. Barber, Hopedale, Ill.
663,723. Apparatus for making and dispensing infusions. Wm. J. Brown and J. R. Beer, London, England.
663,427. Invalid bedstead. Ida D. Eddy, Quiner, Ill.
663,536. Hemoglobinometer. Samuel L. Fox, Haverford, and E. S. Clare, Philadelphia.
663,754. Unstable acetonalikamins and making same. Carl Harries, Berlin, Germany.
663,825. Shoulder-brace and anti-snoring attachment. Leonidas E. Wilson, Broken Bow, Neb.
33,684. Design. Albert L. Gray, St. Louis, Mo.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Dec. 6 to 12, 1900, inclusive:
Edward G. Beeson, captain and asst.-surgeon, 39th U. S. V. Inf., now at San Francisco, Cal., to join his regiment in the Philippine Islands.
John G. Byrne, acting asst.-surgeon, from San Francisco, Cal., to Fort Wright, Wash., for duty in the Department of the Columbia.
T. F. Goulding, acting asst.-surgeon, leave of absence, from the Department of Western Cuba, extended.
William L. Keller, acting asst.-surgeon, from temporary duty at Fort Logaa, Colo., to San Francisco, Cal., for duty with troops en

route to Manila and subsequent assignment in the Division of the Philippines.

James P. Kimball, lieut.-col. and deputy surgeon-general, U. S. A., member of a board at Des Moines, Iowa, to examine sites for a military post at or near that place.

Francis M. McCallum, acting asst.-surgeon, now on leave of absence at Kansas City, Mo., to report for temporary duty at Jefferson Barracks, Mo.

James K. Stockard, acting asst.-surgeon, leave of absence, from the Department of California, extended.

Sanford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., relieved of further duty in the Department of Porto Rico; on the expiration of his present leave of absence to report at Columbus Barracks, Ohio, for post duty.

Philip G. Wales, captain and asst.-surgeon U. S. A., from San Francisco, Cal., to Fort De Chesne, Italy, for post duty.
Timothy H. Wheat, major and surgeon U. S. A., from Columbus Barracks, Ohio, Chicago, for duty as chief surgeon, Department of the Lakes.

Abraham D. Williams, acting asst.-surgeon, to proceed from New York City to Washington, D. C., and thence to San Francisco, Cal., for duty with troops en route to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

Compton Wilson, acting asst.-surgeon, leave of absence granted.
Richard Wilson, acting asst.-surgeon, leave of absence granted.

Navy Changes.

Changes in the Official Corps of the Navy for the week ending Dec. 15, 1900:

Pharmacist J. F. Pearson, ordered to the Naval Academy.
Asst.-Surgeon J. C. Pryor detached from the *Albatross* on reporting of relief and ordered home to wait orders.

Asst.-Surgeon W. Butler, detached from the *Independence* and ordered to the *Albatross*.

Asst.-Surgeon J. B. Dennis, detached from the *Wheeling*, on reporting of relief, and ordered home and to wait orders.

Asst.-Surgeon C. S. Fliske, detached from the naval hospital, Mare Island, Cal., and ordered to the *Wheeling*.
P. A. Surgeon W. M. Wheeler, detached from the *Kearsarge* and ordered to the *Alabama*.

P. A. Surgeon T. W. Richards, detached from the *Alabama*, and ordered to the Bureau of Medicine and Surgery, Navy Department.
P. A. Surgeon F. L. Piedwell, detached from the Bureau of Medicine and Surgery, and ordered to the *Kearsarge*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Dec. 13, 1900:

Surgeon H. W. Austin, detailed as medical officer in command of the station quarantining service at the Delaware Bay and River.
Surgeon P. W. Mead, granted leave of absence for one day.

A. A. Surgeon R. C. Craig, granted leave of absence for seven days from Dec. 13.

Senior Hospital Steward M. Steward M. Valerius, granted leave of absence for seven days from Dec. 4.

CASUALTY.

Senior Hospital Steward James Craig died at Key West, Fla., Dec. 2, 1900.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Dec. 14, 1900:

SMALLPOX—UNITED STATES.
California: Oakland, Nov. 24-Dec. 1, 4 cases.
Georgia: Houston, Dec. 1-7, 24 cases, 1 death.
Illinois: Chicago, Dec. 1-8, 1 case.
Kansas: Dec. 1-8, 9 cases.
Kentucky: Lexington, Dec. 1-8, 2 cases; Russell, Nov. 20, epidemic.

Michigan: Detroit, Dec. 1-8, 2 cases; Grand Rapids, Nov. 24-Dec. 1, 1 case; reported present at 28 places Nov. 25-Dec. 1.

Minnesota: Minneapolis, Dec. 1-8, 1 case.
Nebraska: Omaha, Nov. 24-Dec. 1, 3 cases.

New Hampshire: Manchester, Dec. 1, 8 cases.
New York: New York, Dec. 1-12, 12 cases, 3 deaths.

Ohio: Dec. 1-8, Ashtabula, 4 cases; Cleveland, 32 cases; 2 deaths.

Pennsylvania: Steelton, Dec. 1-8, 1 case.
Tennessee: Memphis, Nov. 24-Dec. 8, 5 cases; Nashville, Dec. 1-8, 1 case.

Utah: Salt Lake City, Nov. 24-Dec. 8, 69 cases.

SMALLPOX—FOREIGN.

British Columbia: Nov. 21, Gabriola Island, 1 case; Nanaimo, 13 cases.

Egypt: Cairo, Nov. 1-18, 1 case.
France: Paris, Nov. 18-25, 8 deaths.

Mexico: Tuxpam, Nov. 19-26, 4 deaths.
Russia: St. Petersburg, Nov. 10-17, cases, 1 death; Vladivostok, July 1-30, 1 case; Warsaw, Nov. 10-17, 32 deaths.

Scotland: Glasgow, Nov. 23-30, 30 cases, 1 death.
Spain: Barcelona, Oct. 6-Nov. 11, 49 deaths; Valencia, Nov. 4-18, 1 case.

Yucatan: Merida, Nov. 15-30, several cases.

YELLOW FEVER—FOREIGN AND INSULAR.
Cuba: Havana, Nov. 24-Dec. 1, 7 deaths; Puerto Padre, Dec. 3, 1 case.

Mexico: Mexico, Nov. 18-25, 1 death; Tampico, Nov. 18-25, 6 deaths; Yeta Cruz, Nov. 24-30, 12 deaths.

CHOLERA.
India: Bombay, Oct. 30-Nov. 6, 3 deaths; Madras, Oct. 27-Nov. 2, 10 deaths.

PLAGUE—FOREIGN AND INSULAR.
Egypt: Alexandria, Nov. 5-12, 1 case, 1 death.

Germany: Bremen, Nov. 6, 1 death.
India: Bombay, Oct. 30-Nov. 6, 84 deaths; Madras, Oct. 27-Nov. 2, 1 death.

Madagascar: Tamatave, Oct. 15-29, 2 cases, 1 death.
Philippine Islands: Manila, Oct. 13-20, 3 cases, 2 deaths.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one head, etc., and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles, editorials, society reports, abstracts, and miscellaneous matter appearing in the Journal, the book notices, deaths, societies, correspondents, discussions, authors, and titles of articles mentioned in the "Current Medical Literature" department being indexed and arranged under their separate headings instead of in the body of the "General Index."

- ABDOMEN, retrenchment of, 1376
 Abdominal operations, vaginal and 258
 relaxation and gall-stones, 1689
 practice, physician and surgeon in, 121
 section in women, post-operative treatment of, 1313
 surgery, hemostasis in, 1304
 Abductor paralysis, bilateral, 909
 Abortifacient, diachylon as, 193
 Abortion and second degree murder, 298
 criminal, 943
 rapid induced, 850
 rational treatment of, 447
 threatened, hemostatics in, 161
 to prevent, 30, 968
 treatment of, 456
 Abraham, J. H., acute tonsillar diseases and their sequelae, 152
 Abscess, acute tympanic, 1057
 cerebellar, differentiation of, 32
 cerebral, 766
 cerebral, following typhoid, 1282
 in bones, tunnel treatment of, 912
 mammary, 1658
 mastoid, 1658
 of liver, 117
 retro-ocular, 904
 retropharyngeal, 1296
 subdiaphragmatic, 1119
 subpericne, 257, 779
 subphrenic, following appendicitis, 651
 traumatic pancreatic, 326
 tropical liver, 779, 780
 tubo-ovarian, 904
 Abscesses, Douglas' treatment of, chronic, treatment of, by simple aspiration, 1664
 in perityphilitis, 1122
 fixation, 247
 Absorption under influence of massage, 1379
 Accident cases, harmful suggestion in, 83
 Accidents, railway, 378
 Accommodation, theory of, 979
 Acid, carbonic, 649
 carbonic, homicide by, 1029
 curative in hip-joint disease, 1049
 climatic, and leucocytosis in tuberculosis, 954
 hydrochloric, in sciatia, 984
 phenic, cure of tetanus with, 914
 Aene, chloric, 590
 dyspepsia accompanied by, 296
 necrotic, treatment of, with sea salt, 593
 simple, 161, 1654
 sulphur in, 263
 Acromegaly and gigantism, 320, 326
 lesions in, 1588
 Acromion, luxation of, 264
 Actinomycosis, 845
 Address, American Public Health Association, 1171
 in medicine, Mississippi Valley Medical Association, 1043
 in surgery, Mississippi Valley Medical Association, 1049
 Presidential, Mississippi Valley Medical Association, 1046
 Address, section on ophthalmology, 335
 section of materia medica, pharmacy and therapeutics, 331
 Toronto Clinical Society, 1296
 Adenocarcinoma of gall-bladder, 320
 Adenoids, 201, 588
 anesthesia in, 1302
 etiology and prognosis of, 1207
 hemorrhage in, 1662
 in nasopharynx, treatment of, 1340
 influence of, in morbidity, 851
 pathology of, 1662
 Adenoma malignum, 954
 sebaceous of face, 654
 Adhesions, tubo-ovarian, their re-leases, 539
 Adipositas ossosa, 587, 1178
 Adirondack, cottage sanitarium, 1227
 Adrenals, comparative anatomy of, 851
 Marchand's, 168
 Adulis, influenza in, 1689
 Advancement operation, double book for, 1270
 Advertising, abuse of medico-pharmaceutical, 446
 After-pain from tooth extr'n, 519
 After-pains, instant relief of, 230
 Aegle, 30
 Aerial, refresh memory on, 1111
 of consent, 646
 Aged, heart failure in, 1183
 pneumonia in, 780
 Agglutination in pneumococcus infection, 716
 in typhoid, 1512
 mechanism of, 58
 of bacteria, 1374
 of tubercle bacillus, 1352
 with blood of mother and fetus, 127
 Air passages, best anesthetic for operation on, 391
 passages, catarrh of, 984
 passages, neuropathic hemorrhages of, 849
 passages, upper, obstruction of, 777
 tract, upper, syphilis of, 1327
 water, bacteriologic examination of, in Atlantic ocean, 1445
 purification of, 1042
 suppressed, treatment of ulcers by, 984
 Akins, Dr., president's address, 1296
 Alabaster, medical news, 505, 693, 1033, 1286, 1486
 Alaska, Marine-Hospital service in, 636
 smallpox in, 904
 Albumin, artificial oxidation of, 1440
 specific biologic test for, 1667
 transformation of, and elimination of sugar, 1122
 transformation of, influence of oophorin on, 1309
 Albuminuria of pregnancy, 1653
 Albumosuria myelopathic, 1378
 Alcohol, a food or a poison, 718
 and ether intoxication, 444
 as a food, 110, 521
 bacterioid power of, 262
 dressings, 1689
 Alcohol habit, bromids in, 388
 influence of, on susceptibility to infection, 928
 in carbolic acid burns and poisoning, 1557
 in criminality, 1561
 in therapeutics, 316
 substitute for, 589
 pathology of, 1308
 question, the, 98, 1661
 subcutaneous injection of, 1303
 utility of, for the treatment of the indiscriminate use of, 1632
 utility of, as disinfectant, 433
 Alcoholism (see insomnia), 536
 in Russian army, 100
 treatment of, 232, 1659
 treatment of, by digitalis, 337
 Alexander, S., urinary and prostatic tuberculosis, 1172
 Alkalinization, renal, 387
 Alkaline diuretic mixture, 1236
 Allen, S. E., bacteriology and serum treatment of diphtheria, 940
 Alloxiuric bases in nephritis, 1375
 bases in nephritis cardiovascular changes, 1352
 Allport, F., visual defects in rail road service, 920
 Alopecia, 30, 376
 hysterical ciliary, 904
 syphilitic, 770
 Altitude and insanity, 457
 Alum and bacterial growth, 1495
 baking powder, 1243
 Alvarenga prize, 965
 Amblydexterity, 886
 Amblyopia, tobacco, 457
 Ambulance work in South Africa, 37
 Amelia, 714
 Amenorrhoea, 385, 1110
 Amputation at hip-joint, 359
 intrascapular, thoracic, 189
 interscapulo-thoracic and scapular, 236
 Mauer bullet wounds and 59
 retractor for soft parts in, 935
 subcutaneous, for diffuse carcinoma, 1474
 stump, construction of, 1685
 Amputations, osteoplastic, 654
 Amygdalitis, follicular, 1577
 scarlatinal, carbolic injections in, 1577
 Amyloid bodies, 1376
 Amyotrophy, scapulohoracic as sign of tuberculosis, 1513
 Anacrobiosis, 394
 Analgesia from cocaineization of spinal cord, 559, 1301, 1689
 in obstetrics, 1301
 medullary, in obstetrics, 1232
 medullary, observations on, 1222
 spinal, and labor, 650
 Anaphrodisiac, 1110
 in gonorrhoea, 1380
 Anasarca, surgical treatment of, 1380
 treatment of by siphon cupping glass, 1185
 Anastomosis, intestinal, 121, 323, 1051, 1052
 Intestinal, end-to-end, 1151
 ureterointestinal, 1056

 Anders, J. M., hereditary factors in tuberculosis, 1001
 Andersen, P. H., spinal cocaineization, 1045
 Anderson, C. H., gunshot wounds of bladder, 184
 H. B., displacement of liver, 1296
 J. C., contusion of brain, 900
 Andrews, E. W., reeving operation for movable kidney, 877
 Anemia, 1043
 acute, lesions of nerve cells from, 189
 anti-treptococcal serum in, 321
 migraine accompanying, 230
 pernicious, 689, 1105, 1375, 1433, 1581
 pernicious, blood in, 1319
 pernicious, with spinal symptoms, 1436
 with dysmenorrhoea and constipation, 1111
 Anesthesia, 498
 and circulation and respiration, 969
 appliance for, 325
 chloroform, death during, 38
 discoverer of, 1421
 discoverer of, and Hall of Fame, 1226
 general, 775
 importance of arterial pressure in, 1059
 in aneoids, 1302
 lasting, 230
 local and regional, 1301
 medullary, 1308
 medullary, in gynecology, 1251
 medullary or subarachnoid cocaine, 572
 spinal, 1178
 spinal, danger of 1329
 subarachnoid, history of, 1439
 to membrane of stomach, 1428
 thyroidectomy without, 1438
 upright position in, 1114
 Anesthetic, 974
 management of, 59
 Aneurysm, aortic, 1510
 cure of, by ligation of axillary artery, 529
 cured by electrolysis, 718
 gelatin injections in, 980
 of renal artery, 1118
 pedicled, 974
 syphilitic aortitis and, 433
 thoracic, diagnosis and treatment of, 1641
 Aneurysms, diagnosis of, 149
 differentiation of, with radio-graphy, 781
 treatment of, with gelatin, 460, 851
 Angina leucanaris, acute poly-arthritis following, 752
 pectoris, 354, 654, 848
 pectoris, gory, 1120
 pectoris, uremic origin of, 1308
 Angina membranacea, 1584
 Angioma in abdominal surgery, 267
 in vaginal sclerotomy, value of, 153
 use of, 188
 Anglo-Saxon race, is it degenerating, 588
 Aniline blue, treatment of malaria with, 1122

AMERICAN MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index covers titles and subjects of original articles published in the medical journals of the United States and Canada during the past six months. The titles, and the journals in which they appeared, were published weekly in the Current Medical Literature department, to which references are made. The figures in parentheses refer to the paragraph: the number following, to the page in The Journal. For instance, "Abortion (139) 187" refers to page 187 of The Journal, on which is found opposite paragraph 139 the title and name of author, viz., "Abortion. Dr. E. T. Dickinson." This title is listed under the journal in which the article appeared: The Carolina Medical Journal for June, printed at Charlotte, N. C.

- Abdomen, gunshot wounds of, (32) 1113
bad penetrating wound of, (115) 1581
- Abdominal cavity, drainage and closure of, (31) 318
cavity, drainage of, (104) 711
dropsy, curious case of, (31) 186
practice, co-operation of physician and surgeon in, (39) 114
- section, points in management of, (56) 905
section, suppurative wound after, (54) 187
sections, lessons learned from, (85) 583
sections, post-operative treatment in, (78) 1176
surgery, work in, (139) 1657
wall, repairing of, in ventral hernia (21) 1239
wounds, closure of (122) 187
- Abduens paralysis, action of obliquus in, (81) 1240
- Abortion, (139) 187, (163) 188, (129) 711, (136) 1373
criminal, medicolegally considered, (131) 1301, (139) 1657
medicolegal status of, (59) 453
observations on, (76) 648
rational treatment of, (107) 884
treatment of, (55) 453
treatment of, in country practice, (133) 976
views on, (92) 773
- Abrasion, laryngeal (48) 384
- Abscess, cerebral, following chronic otitis media purulenta (139) 1301
cerebral, bacterial infection cause of, (54) 284
cerebral, of otitic origin (21) 1391
ischio-rectal (63) 842, (82) 1431
lacrimal, (68) 711, (133) 1391
left bio-ovarian, and right pyosalpinx (101) 1373
mammary, anaesthesia in treatment of, (165) 1053
mastoid, case of, (6) 1373, (32) 1595, (5) 1656
of brain, (22) 518, (94) 1113
of lung, (96) 518
pelvic (35) 118
pelvic, rupture of, (61) 648
perinephritic, with myxedema, (88) 583
peritonissal, in children (29) 905
post-otitic cerebral with amnesic aphasia, (82) 319
retroauricular, etiology of, (70) 905
subpectoral (45) 1372
subphrenic, (71) 648
subphrenic, following appendicitis, (38) 186, (26) 254, (118) 976
tuberculous, (115) 843
tubercular, how best to deal with, (64) 1431, (60) 1505
- Abscesses, classification and symptomatology of, (107) 874
pathology and symptomatology of, (125) 385
- Accidents and errors, (110) 118
and "blinds," (81) 1176
- Accommodation in glaucoma relieved by eserin, (75) 711
theory of, (57) 975
- Acetabular habit, case of, (113) 187
- Aene, (63) and 73) 583
- Acromegaly, pituitary gland in, (7) 318, (1) 283
associated with low grade of gigantism, (45) 1636
- Actinomycelial processes and ray fungi (102) 187
- Actinomycosis, (21) 842
cases of, (23) 82
hominis, case of, (60) 1372
of udder of cow, (139) 54
- Addison's disease, (14) 186, (10) 118
disease, report of case of, (111) 54
- Address, (95) 118, (125) 774
- American Dermatological Association, (44) 452
- American Laryngological Association, (13) 647
- American Laryngological, Rhinological and Otolological Society, (112) 1657
- AMERICAN MEDICAL ASSOCIATION, (111) 384, (122) 648
- American Public Health Association, (89) 1581
- Canadian Medical Association, (101) 1053
- Cleveland College of Physicians and Surgeons, (51) 1052, (80) 1176
College of Physicians and Surgeons, (16) 255
degrate, (36) 647
executive health officer of Ontario, (40) 1372
Grady Hospital Training School for Nurses, (99) 519
Hempstead Memorial Academy of Medicine, (116) 976
in medicine, (50) 1113
in surgery, (115) 1177, (126) 1240
- International Association of Railway Surgeons, (129) and 1372

- upon Dr. Dessenden Nott Otis, (20) 53
- University of Denver, (120) 54
- University of Toronto, (115) 1431
- Yale Medical Alumni Association, (35) 519
- at banquet tendered A. Jacobi, (93) 118
- Babies' ward of the Post-Graduate Hospital, (42) 384
- Adenocarcinoma of gall-bladder (2) 318
- of gall-bladder with secondaries in adrenals, (13) 186
- pylorotomy and, (15) 975
pylorotomy for, (166) 188, (66) 1053
- of recto-vaginal septum, (73) 975
- Adenocystoma of kidneys, (84) 384
- Adenoid growths in vault of pharynx, (152) 188
- growth, pathology of, (113) 1656
vegetations, (83) 583
- Adenoids, (65) and 127) 255
angels in children with, (5) 1299
- from standpoint of hemorrhage, (114) 1657
- pharyngeal, (111) 976
curette forceps for removal of, (139) 519
- Adenomyoma uteri diffusum benignum, (117) 384
- Adhesions about the stomach, (71) 187
- Adiposis dolorosa, (67) 583
dolorosa, case of, (45) 1176
- Adolescent period, medical treatment during, (42) 1300
- Adrenals, malignant disease of, (10) 254
- Adulterations, food, (103) 1113, (123) 1431
- Adults (see tonsils)
- After-pains from extraction of teeth, (10) 518
- Age, influence of, upon production of nervous diseases, (18) 1300
- Aged, medicolegal responsibility of, (122) 583
- Agglutination, studies in mechanism of, (134) 54
- Air-passages, foreign bodies in, (58) 118, (1) 1687
obstruction of, (81) 773
- Albumin, cases without, and encephal nephritis, (94) 1431
- Albuminuria, clinical importance of, (107) 583
- Alcohol and heredity, (15) 1430
and medicine, (117) 255
as a food, (40) 319, (27) 518
as etiologic factor in diseases of nervous system, (125) 1373, (163) 1300
damage of daily use of, (109) 1200
effect on human system, (92) 976
effect on nervous system, (98) 1300
in diseases of children, (156) 1176
influence of, on living animal body, (45) 452
is it a food? (153) 188, (49) 453
of the brain, effect of, (48) 453
physiologic chemistry of, (96) 1300
question, the, (87) 1656
subcutaneous injection of, in saline solution, (33) 1300
- Alcoholism, (97) 1300
acute, reduction of mortality in, (32) 1656
treated by digitalis, (24) 583
vegetable digestive ferment in treatment of chronic, (39) 905
- Alexia, case of, (8) 1656
- Alimentation, artificial, (39) 1430
- Alkaloidal medication, (143) 1431
poisoning, cases of, (18) 186
- Alkaloids, (102) 1240
- Allen, J. M., vice-president A. M. A., (121) 118
- Alloxoric bases in cardio-vascular changes of nephritis, (47) 1372
- Alopecia areata, (41) 905
- Altitude, is it an etiologic factor in insanity? (84) 453
- Alum, (127) 1431
baking powder, effects of digestion of food prepared with, (7) 1239
- Amaraosis, hysterical, (70) 583
- Amblyopia, physical, (101) 648
- Ambrico, (76) 463, (119) 1373
- Amenities, professional, (105) 255
- Ambulatory treatment of fractures, (137) 187
- Amenorrhoea, (10) 383
- American Gynecological Society, personal factor in the work of, (59) 319
- Ammonio-formaldehyd, clinical effects of, (18) 975
- Amputation, intra-abdominal of uterus, (51) 219
- Amputations in children, (31) 1505
- Amygdalitis, acute follicular and suppurative, (16) 429
- Amylene-chloral in private practice, (156) 1177
- Analgesia, (34) 583
cocaine, from subarachnoid spinal injection, (2) 1299, (24) 1687
in obstetrics produced by injections of cocaine, (14) 1299
- Intraspinal, "Duffer's method of," (138) 1301

- Analgesia of tissues below the diaphragm by injection of cocaine hydrochlorate into spinal canal, (47) 1421
 produced by mediastinal injection of cocaine, (39) 1372
 Analgesic, heroin as, (24) 1580
 Analgesics and anesthetics in traumatism of extremities (136) 1114
 in children, (153) 1177
 Anasarca, total and strangulation, (80) 1466
 Anastomosis, new instrument for forming, (98) 319
 uretero-intestinal, (60) 1052
 vesico-rectal, (153) 54, (41) 1657
 Anatomy, teaching of, (19) 710
 Anemia and indigestion, (43) 975
 and loss of weight, treatment of, (141) 1249
 Aneplogy and treatment of, (47) 1580
 pernicious, (50) 453, (22) 1430
 pernicious, disease of, organs of, (2) 1239
 pernicious, etiology of, (63) 648
 pernicious, infection and sub-infection in, (6) 905
 pernicious, relation of, to inheritance, (1) 1580
 pernicious, study of, (60) 453
 progressive, pernicious, (2) 1116, (11) 1229
 pernicious, with reference to blood-findings, (41) 1372
 secondary, treatment of, (172) 1243, (143) 1241
 splenic, (118) 1301, (112) 1506
 study of, (38) 1430
 treated with antistreptococcus serum, (2) 318
 Anemias, appearance of blood in, (51) 1176
 Anesthesia by coacination of spinal cord, (7) 1299, (34) 1246
 by intraspinal injections of cocaine, (8) 1372
 by nitrous oxid gas and ether, (36) 956
 chloroform, cessation of respiration in, due to chewing-corn in larynx, (30) 1589
 congenital, of spinal cord, (10) 1300
 general, cases of, (87) 319
 in children with adenoids, (5) 1299
 in labor, (144) 1431
 in treatment of mammary abscess, (4) 1656
 infiltration, (121) 453
 influence of sensory irritation on, (50) 905
 new method of, (121) 711
 prevention of nausea and vomiting during, (19) 1687
 spinal, conservative jottings apropos, (19) 1176
 status of general, (40) 773
 with cocaine, (11) 1299, (38) 1505
 with eucain, operation for hernia under special, (5) 1299
 Anesthetics, administration of, (84) 711
 and analgesics in traumatism of extremities, (136) 1114
 and anodynes in midwifery (167) 188
 Anesthetizer, patient and operator, relation of, (115) 111
 Aneurysm, aneurysm, cases of, (62) 1053, (60) 1656
 cases of, (95) 255, (119) 1431
 dissecting, of aorta, (119) 1113
 of aorta treated by insertion of permanent wire and galvanism, (73) 1505
 of heart with thrombosis of left coronary artery, (44) 1372
 of spermatic artery simulating oblique inguinal hernia, (17) 1430
 on necessary branch of right renal artery (18) 1430
 popliteal, cured by digital pressure of femoral artery, (163) 1372
 traumatic, of left internal carotid artery, (4) 1595
 treated with gelatin injections, (13) 976
 Aneurysms, multiple, case of, (25) 1580
 Angina pectoris, (15) 53, (7) 118

diseases of, suprarenal capsule in, (8) 1052
disease and pregnancy, (55) 1271, 842
disease or epilepsy, (61) 1431
disturbances of, (110) 519
disturbed pelvic mechanism on, (27) 842
inhibition of, as aid in diagnosis, (16) 975
in influenza of children, (3) 518
lesions and measures for their relief, studies of, (95) 1581
lesions following acute specific fevers, (104) 1176
necessity of, (82) 1113
physical sign in dislocation of, (16) 772
transposition of, (114) 843
treatment, physics of, (138) 1431
trouble, functional, (135) 1240
valvular diseases of, (54) 254
winds of, cases of, (21) 1687
- Heat-stroke as post-operative complication, (23) 1656
- Height and weight table, (119) 900
- Helmholtz's theory of transmission of sound in middle ear, (47) 1656
- Hematemesis, post-operative, (27) 900
- Hematopathy, (66) 1176
- Hematocele, pelvic extraperitoneal, following dilatation of cervix and curettage, (76) 1300
pelvic, and its relation to tubal pregnancy, (100) 1657
- Hematocolpos et hematometra, (55) 319
- Hematoma of vulva and vagina, (44) 583, (75) 1581
puerperal, case of, (53) 1052
traumatic, (126) 1177
Hematuria, (177) 188, (143) 319
does quinin produce, (141) 119
malarial, (129) 255, (36) 975, (105) 773
malarial, unique case of, (125) 1177
- Hemipia, following poisoning by illuminating gas, (47) 254
temporal, 17, 1112
- Hemiplegia, diagnosis of organic and hysterical, (93) 1053
left and right-sided, (59) 518
- Hemochromatosis, etiology of, (63) 648
and diabetes, cirrhosis of liver and pancreas with, (42) 1687
infection and subinfection in, (69) 905
- Hemoglobin, relation of specific gravity of blood to percentage of hemoglobin, (124) 1246
- Hemoglobinometer for examination of undiluted blood, (3) 900
- Hemoglobinuria, death from, (90) 976
- Hemolysis, (95) 1113
- Hemophilia, case of, (100) 976
- Hemorrhage, (87) 1113, treatment of, (130) 648
treatment, (128) 1657
- Hemorrhage, accidental, and placenta previa, (113) 1246
after menopause, (102) 118
after operations on throat and nose, (5) 772, (114) 1657
aphasia due to, (81) 518
during catarract extraction, (87) 1240
from anus and rectum, (21) 383
gastric, (24) 53
in extrauterine pregnancy, (69) 255
internal, result of rupture of adhesions due to appendicitis, (22) 1687
intestinal, of new-born infant, (127) 1177
occurring after menopause, (1) 1053
occurring in ulcer of stomach and duodenum, surgical treatment of, (113) 1113
post-operative, (32) 1430, (15) and (27) 1505
postpartum, (80) and (24) 255, (60) 711, (87) 905, (126) 1431, (54) 1580
postpartum, prevention and treatment of, (67) 1300
- Hemorrhoids, (173) 188, (174) 902, 583, (113) 1373, (151) 1657
etiology, pathology and treatment of, (17) 975
surgical treatment of, (102) 1113
submucous ligature for rectal, (134) 453
surgical treatment of, (25) 842, (78) 975, (39) 1580
treatment of, (24) 118
- Hemostasis in abdominal surgery, (17) 842
- Hepatitis treated by abdominal section, (95) 905
- Herd's inspection of, (59) 384
deficiency among women, study of, (73) 902, 905
and alcohol, (45) 1430
defective, degenerative results of, (11) 1657
- Hernia, anatomical construction predisposing to, (24) 1112
cure of, by surgical means, (76) 1177
diaphragmatic, (101) 773
diaphragmatic, and goiter, (68) 648
double inguinal, with prolapse of rectum, (34) 186
gangrenous and intestinal obstruction, (41) 1052
intra-arterial, operation for cure of, (63) 1573
in children, (52) 710
indications for cure of, (92) 255
inguinal, (44) 319
inguinal, in male, cure of, (120) 1113
inguinal, reflex phenomena of, (93) 648
inguinal, relative bearing of conjoined tendon and oblique muscle to, (1) 710
inguinal, treatment of sac in, (10) 842
injection treatment of, (118) 711
- Hernia, large scrotal, (6) 1299
Marcy-Bassini operation for, (51) 1372, (82) 1505
of bladder in femoral ring, (140) 1177
of bladder through pelvic floor, (49) 905
of diverticulum of chorion, (62) 1340
operations for, (138) 1240
operative treatment of, (47) 975
Phipps operation for, (18) 905
post-operative, prevention of, (42) 1176
radical cure of, (61) 518, (20) 442, (69) 1656
strangulated, in infant, (83) 773
strangulated inguinal, containing oecum and appendix, (24) 1687
strangulated obturator, (37) 518
treatment of by buried, continuous silver wire suturing, (47) 53
treatment of sac in, (136) 1657
umbilical, treatment of, (8) 975
undiluted with large ring, management of, (8) 1176, (142) 1657
ventral, case of, (59) 1052
ventral, improved technique for cure of, (23) 710
vesical in child (67) 319
- Heroin, as analgesic, (132) 648, (157) 1657
hydrochlorid, therapeutic studies of, (38) 1580
in coughs, (56) 187, (9) 772, (153) 1687
and aene rosacea, (131) 1114
- Higher altitudes, medicine and surgery in, (122) 118
- Hillman, H., (13) 1113
- Hints gathered while in New York City Lying-in hospital, (5) 1687
- Hip (see ankylosis, fracture), joint, dislocations of, bloodless treatment of, (40) 905
joint (see dislocation, osteoarthrosis)
- History-taking, obstetric, in practice, (89) 976
- Hodgkin's disease, remarks on J. W. White, (18) 842
- Hog cholera or bacillus enteritidis, (40) 518
- Holocain, (111) 118
- Home, the physician's, (29) 318, (36) 1113
- Homeopathic department of state university, (58) 905
- Hoosier doctors, (78) 773, 842
Hoosier building for insane, (39) 1200
governor and his staff, (8) 186
- Hospitals, private, and their management, (18) 842
Hot air in treatment of rheumatic affections, (21) 318
air treatment of nervous and joint affections, (102) 319
air treatment of rheumatic and allied affections, (125) 54
douche, gynecologic, (117) 1240
- Hour-glass stomach, surgical treatment of, (69) 187
- Human milk, pathology of, (77) 384
- Humens (see sarcoma), (79) 519
compound fracture of, (57) 1580
dislocation of, complicated by fracture at neck, (11) 1113
of neck, (43) 1652
- Hunter, William and John, and medicine of their time, (53) 1300
- Hyalin casts in puerperal eclampsia, (10) 1687
- Hydatid disease, case of, (86) 1372, 1581
- Hydroencephalocele, superior occipital, successfully operated on, (53) 710
- Hydrophobia, (58) 583
- Hydrophrenia, acute internal, (75) 1372
case of concealed, (155) 54
internal, following cerebrospinal meningitis, (84) 1113
treated by craniotomy, (83) 319
- Hydrochloric acid and hyperacidity of stomach, (91) 884
hydrochloric acid, examination of stomach contents with, (specimen to, (44) 1687
- Hydrogen dioxide in pyorrhea alveolaris, (152) 54
Hydrophobia, (79) 453
- Hydrophobia, nasal, cases of, (45) 1176
Hydrothorax, in pneumonia, (2) 452, (15) 1176
influenza treated by employment of, (39) 1687
- Hygiene, methods of teaching, (18) 710
modern public, (96) 384
practical, (35) 976
- Hygroma, syphilitic, prepatellar bursa, (147) 255
- Hymosa in rheumatism, (102) 843
- Hyperacidity of stomach, symptoms and treatment of, (32) 1680
- Hyperchlorhydria, (70) 773
- Hyperplasia, endothelial, of spleen, (78) 1113
of uterus and Emmet's operation, (106) 384
- Hypertrophy of prostate gland, castration and vasectomy in, (45) 905
of leg, case of, (117) 1581
of tonsils, (54) 583, (48) 1656
of uric acid bodies, (9) 975
prostatic, present status of treatment of, (2) 1656
- Hypnotic new, (18) 582
without sleep, (general medicine), (143) 119
Hypnotism and general medicine, (3) 452
in general practice, (141) 774
in therapeutics, (29) 318
medical aspect of, (47) 118
painless labor under, (120) 711
- Hypodermomyelitis, (163) 1657
- Hypostaphylos, (14) 318, (1) 1656
operated on, Beck's method, (18) 583
- Hysterectomies, fifty-seven, (145) 1200
- Hysterectomy, (102) 773, (75) 1300
for fibroids, mortality of, (22) 447
for myoma, (23) 647
pan and supravaginal, (151) 255
sequele and indications for, (22) 905
unique, (123) 1113
- Hysteria, (34) 384
association of, with organic disease of nervous system, (169) 1506
and neurasthenia, treatment of, (45) 1113
etiology and cure of, (10) 318
manifestations and treatment of, (65) 384
nature and etiology of, (13) 1300
simulation of organic disease of nervous system by, (46) 1200
with larval general manifestations, (28) 905
- Hystero-myectomy, (85) 519
complicated with pregnancy, (54) 842
vaginal, and morcellation of myomatous uterus, (69) 1300
- Ichthiban in intestinal diseases, (94) 711
- Ichthiform as an antiseptic, (120) 1581
ideals, professional, (124) 118
Idiocy, anauric family, (29) 254
anatomical anatomy of, (94) 1053
- Idiosyncrasy to quinin, peculiar manifestation of, (75) 1431
- Ileocecal affections and its bearing on constipation, (48) 905
- Immunity, (29) 842
acquired, against zymotic diseases, (120) 905
in tuberculosis, (81) 1300
Impacted cases, management of, (41) 254, (94) 319
- Impetigo vesic. (68) 582
- Impetigo adenosa, (63) 118
contagiosa bullosa, (34) 1372
contagiosa, epidemic of, (114) 118
- Impotence (see potency)
and vesiculitis, (19) 518
impotency and sterility, (65) 1372
spinal meningitis, (84) 1113
Inanition vs. earth sinks and chemical disinfection, (22) 1687
- Inciser, cystoscopic prostatic, for Bottini operation, (53) 1372
- Incision, abdominal, closure of, (18) 452
incisions, exploratory, (140) 1301

- Incontinence of urine, treatment of, (140) 119
- India, opium in, (91) 1581
- Indigestion, intestinal, (87) 1176
- Inebriety, curability of, by medical treatment, 26 and 28
