The Public Service.

Army Changes.

- Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Oct. 4 to 10, 1900, inclusive:
 - Charles N. Barney, acting asst.-surgeon, member of a board at Fort Monroe, Va., for the examination of officers for promotion, vice Leigh A. Fuller, lieutenant and asst.-surgeon, U. S. A., relieved.
 - William C. Borden, captain and asst.-surgeon, U. S. A., member of a board at Washington, D. C., to examine medical officers of the army for promotion, vice E. L. Munson, captain and asst.-surgeon, U. S. A., relieved.
 - Harry A. Cossitt, acting asst.-surgeon, previous orders, directing him to proceed from Morris Plains, N. J., to San Francisco, Cal., for assignment with troops going on foreign service, revoked.
 - James H. Hyell, major and surgeon, U. S. V., former orders revoked; he will report to the commanding officer, Department of Eastern Cuba, for duty as chief surgeon of that department, to relieve Major Lawrence C. Carr, surgeon, U. S. V.
 - Burke L. Johnson, acting asst.-surgeon, relieved from duty in the division of the Philippines to report to the Surgeon-General at Washington, D. C., for instructions; leave of absence granted.
 - Frank H. Keefer, captain and asst.-surgeon, U. S. A., member of a board at Fort Monroe, Va., for the examination of officers for promotion, vice R. M. O'Reilly, lieutenant-colonel and deputy surgeon-general, U. S. A., relieved.
 - Louis S. Tesson, major and surgeon, U. S. A., to report to the commanding general, Department of the Columbia, for duty as chief surgeon of the department in addition to his duties as surgeon, Vancouver Barracks, Wash.
 - William R. Van Tuyl, acting asst.-surgeon, from Jefferson Barracks, Mo., to post duty at Fort Thomas, Ky.
 - Nelson W. Wilson, acting asst.-surgeon, leave of absence granted.
 - A. A. Woodhull, lieutenant-col. and deputy surgeon-general, U. S. A., leave of absence granted.
- Navy Changes.
- Changes in the Medical Corps of the U. S. Navy for the week ending Oct. 13, 1900:
 - P. A. Surgeon T. W. Richards, detached from the *Indiana* and ordered to the *Albatross*, Oct. 16.
 - P. A. Surgeon L. Morrill, ordered to the Naval Academy.
 - Asst.-Surgeon D. H. Morgan, detached from the *Fernant* and ordered to the *Pensacola* navy yard.
 - Asst.-Surgeon J. A. Murphy, detached from the *Pensacola* navy yard and ordered to the Asiatic station for duty on the *Don Juan De Austria*, to report at San Francisco, Cal., Oct. 30, for passage on the *Salace*.
 - Asst.-Surgeon H. H. Haas, detached from the *Don Juan De Austria*, and ordered home and to wait orders.

Orders Issued by Commander-in-Chief of Asiatic Station.

P. A. Surgeon G. A. Laug, detached from the *Monocacy* and ordered to the Cavite naval station.

Asst.-Surgeon J. C. Thompson, detached from the *Monocacy* and ordered to the Cavite naval station.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service, for the seven days ending Oct. 11, 1900:

P. A. Surgeon W. G. Stimpson, granted fifteen days' extension of leave of absence.

Asst.-Surgeon W. C. Hobdy, granted leave of absence for one month from Oct. 3.

Asst.-Surgeon G. M. Corput, relieved from duty at Mullet Key Detention Camp, and directed to proceed to St. Louis, Mo., and report to the medical officer in command for duty and assignment to quarters.

A. A. Surgeon S. B. Hunter, granted leave of absence for seven days.

A. A. Surgeon J. C. Rodman, granted leave of absence for seven days.

Hospital Steward S. W. Richardson, upon expiration of leave of absence, to rejoin station at St. Louis, Mo.

Surgeon G. W. Stoner, granted leave of absence for seven days. Surgeon C. E. Banks, four days of leave granted by department letter of June 5, revoked.

Surgeon J. H. White, granted leave of absence for one month.

Surgeon R. M. Woodward, detailed to represent the service at the meeting of the American Public Health Association, at Indianapolis, Ind., Oct. 22-26.

P. A. Surgeon J. O. Cobb, to proceed to El Paso, Texas, on special temporary duty.

Asst.-Surgeon H. C. Mathewson, relieved from duty at Philadelphia, Pa., and directed to proceed to San Juan, Porto Rico, and assume command of the service, relieving Asst.-Surgeon C. H. Lavinder.

Asst.-Surgeon C. H. Lavinder, on being relieved from duty at San Juan, Porto Rico, to proceed to Washington, D. C., for orders.

Asst.-Surgeon R. L. Wilson, relieved from duty at San Francisco, Cal., and directed to proceed to Honolulu, H. I., and report to Surgeon Carmichael for duty.

A. A. Surgeon F. M. Clarke, granted leave of absence for twenty days from Oct. 15.

A. A. Surgeon P. W. Goldsborough, granted leave of absence for one day.

A. A. Surgeon Fay Tuttle, granted leave of absence for thirty days from Oct. 24.

Hospital Steward C. C. Allen, granted leave of absence for six days from Oct. 22.

Hospital Steward F. A. Southard, granted leave of absence for fifteen days from Nov. 5.

APPOINTMENT.

Harrington Marr, of Tennessee, appointed acting asst.-surgeon.

RESIGNATIONS.

Asst.-Surgeon Elmer R. Edson, Sept. 22, 1900.

Acting Asst.-Surgeon A. G. Greenstreet, Sept. 30, 1900.

Hospital Steward C. P. Crowley, Sept. 4, 1900.

Acting Asst.-Surgeon Richard Douglas, Oct. 7, 1900.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 12, 1900:

SMALLPOX—UNITED STATES.

Alaska: Nome, Oct. 7, 1 case (in barracks).

Kansas: Wichita, Sept. 29-Oct. 6, 1 case.

Ohio: Cleveland, Sept. 29-Oct. 6, 10 cases.

Pennsylvania: Philadelphia, Sept. 29-Oct. 6, 4 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 8-15, 1 case.

Brazil: Pernambuco, Aug. 24-31, 4 deaths.

England: Liverpool, Sept. 15-22, 1 case; London, Sept. 15-22, 2 cases.

France: Paris, Sept. 15-22, 3 deaths; St. Etienne, Sept. 1-15, 1 case, 1 death.

Germany: Koenigsberg, Sept. 8-15, 2 cases.

Mexico: Vera Cruz, Sept. 22-29, 1 death.

Russia: Odessa, Sept. 15-22, 11 cases, 2 deaths; St. Petersburg, Sept. 8-15, 9 cases, 5 deaths.

Scotland: Glasgow, Sept. 21-28, 22 cases, 3 deaths.

Yukon Territory: Dawson, Sept. 8, present.

YELLOW FEVER.

Colombia: Barranquilla, Sept. 16-23, 1 death; Cartagena, Sept. 1-14, 3 cases, 3 deaths.

Cuba: Havana, Sept. 22-29, 19 deaths.

Mexico: Vera Cruz, Sept. 22-29, 10 deaths.

PLAGUE.

Paraguay: Asuncion, July 21-28, 2 deaths.

Scotland: Glasgow, Sept. 15-22, 3 cases, 2 deaths.

Wales: Llandoff, Oct. 9, 1 death (imported from Rosario).

CHOLERA.

Straits Settlements: Singapore, Aug. 11-25, 1 death.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION. The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-Laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

ACUTE SENILE ENDOMETRITIS.

CASES AND PATHOLOGY.*

L. H. DUNNING, M.D.

INDIANAPOLIS, IND.

Professor Diseases of Women, Medical College of Indiana, University of Indianapolis.

Since the publication of Skene's notable¹ article in 1894 on "Senile Endometritis," the lesion has attracted considerable attention, and text-books now include this form in the classification of endometritis. The disease as described by Skene is essentially a chronic one, and while his exposition of the subject is true and graphic, it can not be made to include cases of the type of those, the histories of which I shall present to-day.

In his admirable² article entitled "Post-Climacteric Endometritis," Sexton treats of the same lesion described by Skene and calls it a chronic inflammation. His cases were in one particular different from those here presented, in that there was no hemorrhage; indeed, he emphasizes the fact that there is an absence of hemorrhage.

Mundé, in his article³ read before the American Gynecological Society in 1896, wrote very clearly on the clinical history of this class of cases, but he does not attempt to add to our knowledge of the pathology of the lesion.

The author believes the pathologic findings in his cases clearly indicate that those described by Mundé, as well as his own, are at the onset acute in character and must, if properly classified, be denominated acute senile endometritis. The sole object of his paper is to endeavor to demonstrate this fact.

It has seemed to the writer that the histologic study of endometrium in senile endometritis has been limited to microscopic examination of scrapings, and he deems himself fortunate in being able to present the results of a microscopic study of the endometrium in two cases in which the uterus has been removed by hysterectomy.

So important has the writer deemed this subject that he has been minute in his descriptions of the histories of his cases and the pathologic findings, at the risk of subjecting himself to the charge of being tedious.

CASE 1.—Mrs. M. M., aged 63 years, was referred to me by Dr. J. S. Sherfee, of Fairland, Ind., Jan. 22, 1900.

She presented the following history: She had never borne children, though married since early womanhood.

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

¹ Trans. American Association of Obs. and Gyn., Vol. viii, pp. 314-319.

² New York Gyn. and Obs., June, 1891, p. 611.

³ Gynecological Transactions, Vol. ii, p. 29.

Her health had always been good until the time of menopause, which occurred at 40 years of age. At that period she was confined to her bed for six months on account of illness, the nature of which I am unable to ascertain; but subsequently she enjoyed fairly good health until six months ago, when without apparent cause she began having a seropurulent discharge from the uterus.

In spite of general and local treatment this discharge continued, and finally became bloody and exceedingly offensive. She complained of backache, pain and soreness through the pelvic organs and inability to walk or stand many minutes at a time. She had lost several pounds in weight and was noticeably anemic.

The sanguineous discharge was not profuse, but was of dark color and exceedingly offensive. A physical examination showed a small, short vagina, here and there in patches, eroded and quite sensitive to the touch. The cervix uteri was atrophied and was but slightly invaginated. The uterus was small and retroverted, though not adherent. There was no difficulty in passing a uterine sound. The withdrawal of the sound was followed by the discharge of probably two drams of dark, offensive fluid. The left Fallopian tube and ovary could be easily palpated. They were thought to be enlarged. Their palpation caused a great deal of pain.

My diagnosis was senile endometritis and inflammatory lesions of the left tube and ovary. Hysterectomy was recommended. It was performed at the Deaconess Hospital, Jan. 23, 1900. The operation was an easy one and the patient made an excellent recovery.

The left tube was considerably thickened but was not distended, and the left ovary contained two or three small cysts. Unfortunately before I saw the importance of a microscopic examination of the tube, it was lost. There were found evidences of a slight, recent, pelvic peritoneal inflammation manifested by adhesion of the diseased tube and ovary.

With the aid of my assistant, Dr. R. L. Ritter, a critical and microscopic study of the uterus was made, with the following results: In general appearance, it exhibited the characteristics one would expect to find in the uterus of a woman at the age of the patient. The organ was pale and perceptibly smaller than a sexually active one. It measured $2\frac{1}{2}$ inches in length, $1\frac{3}{4}$ inches in width at its widest points, and about $\frac{3}{4}$ inch at its thickest portion anteroposteriorly. The cervix was short, quite dense; the external os was rather flaring, the cervical canal patulous. There was no evidence of laceration of the cervix. There was absolutely no sign of disease of the organ to be seen externally, with the exception of a thick, dark-colored, granular material which exuded from the external os on pressure. On splitting the organ longitudinally the walls were found to be firmer or denser than the muscular tissue of a functioning uterus, and the muscular tissue somewhat paler in color. The walls were about $\frac{3}{8}$ inch in thick-

ness. Covering the entire mucous surface and filling the uterine cavity was the same material which could be forced out of the cervical canal by pressure. Part of it was breaking-down, liquefying blood-clot, diluted with what seemed to be pus colored by liberated hemoglobin of the clot. This material was thick and sticky, but could be scraped off easily, leaving a roughened, reddened endometrium below. The cervical mucosa did not seem to be greatly affected. When this material was thoroughly washed off, the surface of the mucous membrane was seen to be studded apparently with little nodules resembling somewhat the skin of a frog's back.

Thin sections stained with hematoxylin and eosin, photomicrographs of which are herewith submitted, show an endometrium thickened, densely infiltrated with leucocytes and highly vascular. All the superficial epithelium is lost, the roughened surface being covered

Figure 1.

Case 1.—Section showing mucosa and a portion of the muscularis. 1 Endometrium. *a*. Free surface of mucosa. *b*. Degenerating and disintegrating glands of mucosa. 2. Upper layers of muscularis, showing round-celled infiltration. 3. muscularis.

with a layer of material composed of granular debris, epithelial cells and leucocytes of various kinds, chiefly of the small mononuclear variety, "lymphocytes," and polymorphonuclear or pus corpuscles.

The epithelial cells are found chiefly near the orifices of the glands. These latter are greatly diminished in number, their course is quite tortuous and their epithelium in many cases is desquamating, filling the lumen of the gland with a mass of granular debris and cells in all stages of degeneration. There is no sharp-dividing line between the intact mucous tissue and the material on the surface. The minute blood-vessels with which the endometrium is abundantly supplied often run to the surface and seem to end at the surface. From these changes I am led to believe that there exists a purulent inflammatory process in this endometrium, subacute in character, or else at the time the organ was removed there was an acute exacerbation of a more chronic process. I believe the hemorrhage which had evidently taken place from the mucosa was due to the erosion of the minute blood-vessels described and whose blind ends may be seen at the surface. It has been a direct hemorrhage rather than a diapedesis.

The musculature of the organ shows evidences of atrophy such as normally takes place after menopause. The arteries found chiefly in the middle layer of muscle also show degenerative changes. Their tunica intima is markedly thickened and consists of a rather homogeneous structureless material showing here and there a few small, shrunken, free-lying nuclei evidently of degenerated subendothelial connective-tissue cells. All the changes I have described are found best shown in the body of the organ proper.

In conclusion I would say, we have a uterus showing decidedly the atrophic changes of senility, yet with a mucosa the seat of an active persistent inflammatory process.

CASE 2.—Mrs. V., aged 63 years, was referred to me by Dr. Theodore Potter, Dec. 5, 1899. She gave the following history: She had been married 42 years and was the mother of 8 children, the youngest 24 years

Figure 2.

Case 2.—Endometrium. *a*. Free surface of mucosa. *b*. Remains of glands.

of age. She passed the menopause twenty years ago. Her health had always been good. She had the first leucorrhoeal discharge of her life four weeks ago.

One week later, viz., three weeks previous to my examination, a bloody discharge appeared. It was slight at first, but had gradually become more abundant. This discharge had an offensive odor from the first. The discharge was thick and dark, and seemed to me to be pus stained by the coloring matter of blood. On examination the vagina was found small but elastic. The upper portion was slightly reddened and showed slightly ulcerated patches. The uterus was in normal position, the cervix short, and gave evidence of having been lacerated bilaterally. The external os was of sufficient size to admit the end of the small finger. The internal os, while not patulous, permitted the easy passage of an ordinary uterine sound. There seemed to be a considerable cavity in the body of the uterus and the uterine walls were thin and elastic.

A considerable amount of dark-colored sanguinopurulent fluid flowed out of the os on withdrawal of the sound. A small, sharp curette was introduced into the uterine cavity and an effort made to remove portions of tissue for microscopic examination. Only small shreds

of tissue and dark-colored blood-clots and débris were obtained. I was inclined to believe that we had to deal with a case of incipient cancer. Dr. Potter assented to this view, and we agreed upon a hysterectomy.

The operation was done at St. Vincent's Hospital, Dec. 22, 1899. No neoplasm was found in the uterus. The appendages were removed. The right ovary and tube showed the atrophic changes incident to the age of the patient. The left ovary contained a small cyst not larger than a hazel-nut. There was no pelvic peritonitis.

On examination the uterus was found to closely resemble the preceding one in appearance. There was the same thickened endometrium densely infiltrated with small round cells. This infiltration involved also the upper layers of the muscularis. The superficial epithelium normally present was entirely gone, and the surface covered with an indefinite layer of a confused mass of small round cells, larger connective-tissue cells,

The writer greatly regrets not having procured a bacteriological examination of the contents of the uterine cavities in these cases and the loss of the diseased tube and ovary in the first case.

Fortunately in Case 2, one tube and ovary were still attached to the uterus and were examined microscopically. The endometrium surrounding the entrance of the tube into the uterine cavity showed marked inflammation. While it was impossible to pass even a bristle through the uterine portion of the tubal canal, yet on microscopic examination its lumen was shown to be pervious. For a short distance away from the horn of the uterus the mucous membrane of the tube showed round-cell infiltration and other slight evidences of inflammation. This the writer regards as important, as it demonstrates the spread of the inflammation by continuity and clearly indicates the necessity of the extirpation of the uterus, tubes and ovaries in cases of

Figure 3.

Case 2.—Endometrium.

Figure 4.

Case 2.—Opening of Fallopian Tube into uterine cavity. Thick section, to show merely patulous condition.

polymorphonuclear leucocytes, commonly called pus-corpuses, and epithelial cells, the latter more numerous in the vicinity of the mouths of the glands. The glands were greatly diminished in number and there were very few which do not show some pathologic changes.

In some, the epithelium was exfoliated and the lumen of the gland filled with a granular mass containing many of these epithelial cells, and often "pus corpuses." Others appeared to be disintegrating and appeared merely as little islands or masses of epithelial cells buried in the mucosa. Still others deep in the mucosa showed a dilated lumen with an epithelium intact. The arteries of the muscularis show the same thickened intima of the first uterus and even more of the hyaline material in their walls.

There was evidently here a very acute inflammatory process or an acute exacerbation of a chronic inflammatory process. There could hardly be a chronic inflammatory process of any long standing without development of connective tissue unduly in the mucosa, though in this specimen the infiltration of the mucosa by small round cells is so dense as to obscure almost entirely the structure of the mucosa, yet any pronounced increase of connective tissue would be apparent as it would to a certain extent limit the infiltration.

senile endometritis where there are evidences of involvement of the appendages.

The writer will not attempt to discuss the etiology of the lesion in these cases further than to say he believes that gonorrhœal infection can be excluded in both. The histories of the cases, together with the pathologic findings, will, I think, justify me in making the following summary and conclusions:

1. The lesion found in both uteri was an acute inflammatory process. It may be properly denominated acute senile endometritis.

2. The characteristic pathologic features of the inflammation are: *a*, A thickened endometrium, the free surface of which is devoid of its epithelial layer; *b*, increased vascularity with peculiar arrangement of small blood-vessels; *c*, small round-celled infiltration; *d*, diminished glandular elements: while a few glands are to be distinctly seen in many of them, their epithelium is desquamating and their lumen filled with granular débris; they may be said to be functionless glands; *e*, degeneration of the coats of the arteries of the muscular layer of the organ; in one specimen (Fig. 2) this degenerative process is distinctly hyaline; *f*, in not one section examined from various parts of the organ could there be found any increase of connective tissue.

3. The mucosa of both the cervix and body is involved in the inflammation, but is most marked in both cases in the body of the uterus.

4. The small round-celled infiltration extends into the upper muscular tissue, though the inflammation is more marked in the mucosa.

5. In both cases one uterine appendage was diseased: in one the ovary was cystic; in the other, one ovary cystic and the Fallopian tube inflamed. In this case there were slight recent peritoneal adhesions.

6. The microscopic appearance in these cases bears but slight resemblance to that found in case of interstitial endometritis.

7. In one case the acute inflammation seems to have developed without any preceding chronic inflammation.

Figure 5.

Case 2.—Cross-section isthmus of Fallopian Tube, showing slight round-celled infiltration of mucosa and some desquamation. Remaining portion of tube perfectly normal.

In the other case the acute attack may have been an acute exacerbation of a chronic inflammation.

8. In one case there was marked retroversion of the uterus, in the other the uterus was in normal position, and in neither case was there marked stenosis of the internal os; yet there was a considerable accumulation of fluid within the uterine cavity.

9. The presence of diseased appendages in both cases, and of pelvic peritonitis (mild) in one, seems to indicate that the inflammation is prone to extend beyond the limits of the uterus, and if such extension is demonstrable by combined examination, an extirpation of the uterus and appendages is probably the best form of treatment.

Iodoform Intoxication.—A 20 per cent. emulsion of iodoform and glycerin was injected into a cold abscess below Poupert's ligament in a male patient 30 years of age. The amount injected was 80, 90 and 100 c.c. at intervals of two to four months. The temperature rose after the third injection, the patient became confused, comatose, and the nose was remarkably swollen and red, while acne pustules appeared on the skin of the face and trunk, and dry, brown scabs obstructed the mouth and nose. Death followed in ten days. The autopsy disclosed total tuberculous caseation of the suprarenals, although there had been no clinical manifestation of this lesion. The communication in *Beitrag z. Klin. Chir.* xxviii, 1, describing this case states that it is the first on record in which iodine acne has been observed from iodoform intoxication.

DISEASE OF THE FALLOPIAN TUBES.

WITH SPECIAL REFERENCE TO SPECIFIC INFECTION.*

J. R. GUTHRIE, M.D.

DURBUQUE, IA.

No structure of equal pathological interest and of such vital clinical importance to the medical profession was so long and so persistently neglected as the Fallopian tube. In the older medical literature it received only the briefest mention, and then the reference was most superficial. Little attention was given its anatomy or physiology, while its histology was wholly neglected. Nothing was known of its pathology and no symptoms were attributed to diseases of this important structure. What a marvelous development in pathological interest and clinical importance during recent years! Careful research will disclose the fact that generations ago the clinicians described disease in the Fallopian tube, but through lack of both anatomical and pathological precision their teaching made practically no modification in either the medical thought or practice of the day.

Perhaps the first well-authenticated account of a discussion of the Fallopian tube and its diseases was in the year 1665, and may be well epitomized in this statement "that occlusion of the tube is one of the most fruitful causes of sterility." Nearly a century later, in 1742, Josias Weitbrecht, the great anatomist of St. Petersburg, described the obliteration of the tube in a woman with one child and who was subsequently sterile. In 1766 Astuc gave considerable attention to the Fallopian tube and afforded perhaps the first accurate description of its diseases. He clearly describes hydro-salpinx, pyosalpinx and tubal pregnancy. But, as frequently happens, his teachings seemed for a time to be forgotten, or at least neglected. Nothing new on this subject is found in medical literature for nearly a century. In the writings of that able French observer, Columbat, as translated by Charles D. Meigs in 1845, there is found only a brief mention of this organ, and he practically describes only one disorder of the tube, atresia. Investigation was imperfect, reports contradictory, and knowledge of slow growth.

In 1854, Charles D. Meigs published his brilliant work. He likewise refers to atresia of the tube and to its effect in producing sterility. He speaks of a most remarkable death from what would to-day be diagnosed as a case of pyosalpinx. Acute observer that he was, scholarly and progressive in his field, yet he devoted only five pages to the tube, including its anatomy, physiology, pathology, clinical history and methods of treatment. T. Gaillard Thomas published his work on diseases of women in 1869. He was a bright light in his special field for nearly a generation, and yet he gives only two pages to a discussion of the tube and its diseases. In brief, an examination of older medical works and journals of all kinds, home and foreign, will show absolute want of literature on this important subject.

The medical man of to-day is well informed on all phases of disease of the tube and of the different views of tubal disease, its origin, pathology and methods of treatment. The causes of inflammation are numerous. When the tube is considered as a continuation of the structure of the uterus, the cause of the inflammation is easily understood. Any cause which may produce inflammation of the uterine structure may, by simple extension, cause an inflamed tube. Disease of bacterial

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

origin may readily affect the contiguous structure. Among the exciting causes are those producing endometritis or metritis; direct injury, sudden checking of the flow, pelvic hyperemia, infection with staphylococcus, streptococcus and gonococcus. Of these causes, gonococcus infection is most frequent and important.

Authorities differ widely as to the importance of the gonococcus as an etiologic element in production of tubal diseases. The question regarding this feature is important and difficult to determine. All will agree that the gonococcus is a frequent cause and should demand most earnest attention, and that the profession must be alive to prevent a trouble which, when established, we are so powerless to cure. We all too often meet cases like the following: young lady of good family and personal history, with menstruation regular and painless, who marries; wedding trip is taken and the bride returns home an invalid. She suffers from pelvic distress, and all the usual symptoms of specific infection are plainly evident.

A latent gleet in the male may be the cause of a fresh infection in the mucous membrane of the vagina. There is much speculation in regard to the gonococcus of Neisser as to its possible origin, the manner of its acquiring specific functions, how it may be possible by culture methods to rob it of its specific character, etc. The infectious character of the germ and its peculiar action on mucous membrane is as yet imperfectly understood. The germ is cultivated in laboratory and changed from media to media until it is theoretically sterile, yet deposited on mucous membrane its growth is luxuriant. Only a few germs may be present, yet the development is of almost incredible rapidity. A woman with latent gonorrhoea for years imparts a virulent ophthalmia to her new-born child. This organism has a wondrous grasp upon life, so wondrous, in fact, that one is almost ready to accept the doctrine of Noeggerath, "once infected always infected"; at least one is ready to accept this as a safer rule than that gonorrhoea is no more to be thought of than a common cold. Practical experience and bacteriologic research agree that the gonococcus is tenacious of life in the human tissues.

Bumm transplanted the 20th generation into healthy mucous membrane and produced a virulent gonorrhoea. Warren states that suppurative inflammation of the tube is largely due to the gonococcus. Bernutz's investigation coincides in the opinion. The findings of Noeggerath and Sanger are along the line—the two latter find pyosalpinx in 33 per cent. of women suffering from gonorrhoeal infection.

Goel, after an extensive research, says he was able to discover the gonococcus after a latency of six years. Neisser in 143 cases extending over a period varying from two months to eight years, found the germ in 80 cases. The observation of Wertheim is in the same direction. He reports the finding of the gonococcus in a chronic salpingitis of two years' duration. Neisser insists upon the value of microscopic examinations and makes a strong point of the necessity of frequent tests. Some observers failing in this have much underestimated the frequency of gonorrhoeal infection in diseases of the tube. One must not be satisfied with one or two examinations, but must insist upon repeated careful tests, and the perseverance will frequently be rewarded by the establishment of a positive diagnosis. The failure of some observers to frequently discover this germ in tubal disease is to be attributed to either faulty methods or a lack of perseverance in making investigations. While this germ is practically unlimited as to time, it is very cir-

cumscribed as to tissue invaded. It is limited to usually the epithelial layer. That it may occasionally affect the deeper tissues is denied, yet this is undoubtedly very rare. The cervix stands second in point of the pregnancy of infection and first as to chronicity. By simple extension the tube becomes diseased. The gonococcus finds the epithelial layer of the mucous membrane its favorite habitat, and here multiplies with unaccountable rapidity. There, its irritating effect soon becomes manifest in increased blood-supply, edema, and an enormous leucocytic exudate, followed by round-cell infiltration. This infection may lead to a simple salpingitis or to suppurative disease of the tube, depending on the virulence of the germ and the antimicrobial power of the tissues. There are various modes of infection: sexual intercourse, infection by use of douche tubes, by the careless use of gynecological instruments and by carelessness in making examinations. Has sufficient emphasis been placed on this as a cause of pyosalpinx, confessedly a most serious condition? Has the profession made clear and positive its position in regard to the baneful far-reaching effect of this infection on the health and life of the women of our land?

This is a serious question and one not to be pushed lightly aside, but demands our careful attention. That the profession has not fully appreciated the serious far-reaching effect of this infection, I fully believe. As one of the results of this apathy and indifference, is it any wonder that the laity regard gonorrhoea as a trivial affection? At the meeting of this Association, at Columbus, Ohio, a committee was appointed to investigate and report on ravages produced by syphilis on women; a similar committee should be appointed to investigate and report on the baneful effects of gonorrhoea on the female. While syphilis slays its thousand, gonorrhoea slays its ten thousand. When fully impressed with its true character the conscientious physician will do all in his power to prevent a trouble which when fully established he is powerless to cure. Prevention is the glory of modern medicine—certainly here is a fruitful field for its exercise.

I am convinced that the profession is not impressed with the magnitude of this evil, yet the truth is taught with more or less clearness by leading American authorities. Kelly, Garrigue, Penrose, Baldy, Price, Skene, Dudley and Henrotin mention the gonococcus as an important agent in pyosalpinx. I have had correspondence with a large number of physicians of Iowa and adjacent states, and find there is considerable diversity of opinion, yet the majority place the gonococcus as an important agent in pyosalpinx. From facts collected from fifteen of the chief cities of Iowa, I find 70 per cent. the average estimate of the cases of tubal disease due to gonorrhoea. From correspondence with physicians in small towns and rural districts, I learn of the infrequency of tubal disease in females. An examination of the records of three hospitals doing a good share of work shows a large number of cases of suppurative disease of tube of specific origin. Individual experience is only of value in determining a proper understanding of this question. In my experience during the last year I find 80 per cent. of the cases due to specific infection.

I am of the opinion, therefore, that the importance of gonorrhoea in causing tubal disease has not been properly emphasized; that the question is a serious one and worthy of our careful investigation, and that as earnest physicians imbued with the idea of prevention we should make ourselves felt in behalf of these unfortunate sufferers.

TUBERCULAR PERITONITIS.*

A. H. CORDIER, M.D.

Professor of Abdominal Surgery in University Medical College,
KANSAS CITY, MO.

There are a great many truths in surgery and medicine in which a satisfactory explanation of the manifested phenomena has never been discovered. The explanations of how tubercular peritonitis is cured by a peritoneal opening are many, but none are satisfactory; hence I trust I may be pardoned if I add another, which to me is original.

It would seem from the findings in most of these cases that there was not a local focus from which the disease spread, or if so, that focus was overshadowed by the later and more widespread process. The nodules have been about equally distributed over the peritoneum in most of my cases, both visceral and parietal. Inoculation experiments have demonstrated the extreme susceptibility of the peritoneum to tubercular invasion. This membrane can resist the inroads of most of the pus microbes better than the tubercle bacilli.

Most of my cases have been in females, and as the anatomical conditions are the same in both sexes, except the opening through the Fallopian tubes, this would indicate a causative factor situated at this point. In quite a percentage of the diseased tubes removed by myself there has been a tubercular disease of these ducts, yet it is a remarkable fact that none of my tubercular Fallopian tube cases had a perceptible peritoneal invasion at time of operation. This would seemingly negative the tubes as a source of a general peritoneal infection. The resistance of this membrane may be increased by the presence of the usual pelvic inflammatory complication in tubercular tubes.

A primary tubercular peritonitis may be induced by the presence of tubercle bacilli in the blood, the bacilli being lodged in capillaries on the surface of peritoneum. A remarkable immunity of other organs of the body must exist in these cases, as many subjects of tubercular peritonitis are entirely free from pulmonary or other complications. This freedom from constitutional invasion may be explained by the more or less complete walling in of every little point of infection by the building of a tubercle in which the bacilli are isolated. This coagulation necrosis will not supply nutriment to the bacilli, hence many nodules are sterile, and this may be one of the methods of nature's cures. The cheesy masses may or may not contain living bacilli, but most of them at an early date contain spores capable of reproduction if planted in fertile soil. These tubercles of the peritoneum may, after undergoing this cheesy change, be robbed of their moisture and ultimately become calcareous masses enclosed by a layer of dense connective tissue.

It is universally admitted that the tubercle bacilli are not pus-producing germs. The liquid, turbid or otherwise, in tubercular abscesses is not purulent unless a mixed infection be present. As a result of the intense hyperemia and blood-stasis of the peritoneum, red as well as white corpuscles may escape from the vessel; in that event the fluid becomes sero-sanguinolent. This is usually an evidence of an active, or recently active, stage of the disease. The absorptive powers of the peritoneum are in a measure in abeyance during this acute stage. The lymphatics are more or less compressed and blocked by the escaped blood-cells. The withdrawal of

the fluid and operative manipulations by a laparotomy relieve these conditions interfering with free absorption and thus act as a stimulus to the absorbents to renewed activity both in the destruction of the bacilli and the manufacture of antitoxin.

In those cases in which there exists a large collection of fluid, the intestines are usually free from adhesion and are the more amenable to treatment, surgically. The amount of fluid may vary from a few ounces to several gallons.

In many cases no fluid is found in the peritoneum. As a result of the outpouring of the white corpuscles and serum a false membrane is formed on the peritoneum this becomes organized and cements the intestinal coil together. The fluid in the dry or fibrinoplastic variety is absorbed, thus permitting the intestinal coils to come in contact and become adhered, in many cases producing intestinal obstruction or other obstructive symptoms in ureter, gall-duct, etc. These cases are the hardest to deal with surgically and promise little chance of a cure.

A conflict is waged between the various forms of bacteria and the white corpuscles: the fibrin coagulates and the exudate becomes more or less solidified, or if on the surface of a serous or mucous membrane a false membrane is formed. This organizes tissue through the projection of blood-vessels into the membrane. An adhesion thus formed may become a very serious complication of the original disease, while on the other hand it becomes a conservator of life by preventing the ever-present myriads of bacteria in the intestines from escaping into the general peritoneum, in case of a fistula bi-mucosa. In many cases the disease is not accompanied by any constitutional or other focus of infection symptoms. One author says that in 30 to 40 per cent of peritoneal tuberculosis the Fallopian tubes are affected. This has been my experience only so far as concerns the surface of the tubes. I have found the nodules on tubal peritoneum the same as on the intestinal or parietal layers. The pleura is more frequently involved than the other structures when the disease is located elsewhere.

The small multiple nodules of a widely disseminated cancer of peritoneum may lead to an error at time of operation, but a close scrutiny of all other organs will usually disclose a larger growth. The ascites as a rule in tubercular peritonitis is not as great as in cancer and the fluid is not as likely to be bloody in character.

A tumor may develop from this process by a slow rolling up of the omentum until it makes an oblong mass across the upper abdomen. This condition may easily be confounded with peritoneal cancer. This form of disease usually has little or no liquid in the cavity. The agglutination of coils of intestines may make a solid mass, feeling to the palpating hand like some form of tumor. A careful auscultatory and manual examination will detect intestinal sounds and movements into and through the mass.

In the disease known as *tabes mesenterica* the peritoneum is frequently the origin of the glandular infection, but in the great majority of these cases the infective area is within the bowel. Coils of adherent bowel may be diagnosed as enlarged mesenteric glands even at time of operating, unless a careful and experienced examination is then made. An intestinal ulcer may be found as the origin of the enlarged mesenteric glands. The omentum may retain its normal position and yet be extensively involved. As a rule, however, it

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the AMERICAN MEDICAL ASSOCIATION, held at Atlantic City, N. J., June 5-8, 1900.

soon adheres to some infected point and forms a mass of greater or less dimensions.

Mesenteric glandular disease—tubercular—may lead to an infection of general peritoneum by breaking down of the glands. Pain, while of frequent occurrence in these cases, is absent in many. The pains in my cases have been those simulating gaseous intestinal colic, coming on at irregular intervals, extending over a period of months. These have usually been relieved in a measure by a free bowel-movement. The cause of these pains is the tension produced by the gas on the constricting, tubercular, hyperemic, peritoneal coat of the intestine. In some cases the pain has acute exacerbations accompanied by tenderness and increased rise in temperature, indicating an acute or active stage of the disease, in fact, simulating an acute septic type of peritonitis, such as might extend from an appendicitis, yet not accompanied by the usual severe constitutional manifestations of the latter disease.

The temperature may remain subnormal for weeks at a time; yet in the majority of instances it is elevated at some time during the twenty-four hours. Discoloration of skin about face and breast is of common occurrence, and is due to action on the sympathetic nervous system. It has no special significance in diagnosis.

The temperature curve is a decidedly variable one, ranging from a subnormal morning temperature to 103 F. or higher in the morning. On the other hand, the temperature and pulse may be such as to lead to the erroneous diagnosis of typhoid or malarial fever. A careful blood examination for agglutination for the plasmodium of Laveran would aid in eliminating these two misleaders. The presence of ascitic fluid, general uneasiness or tenderness over abdomen and the protractedness of the attack favor the diagnosis of tubercular peritonitis. A careful physical examination eliminates pregnancy, ovarian cyst, etc.

The general health in the ascitic type of the disease may not be much impaired in the beginning. In fact, in some cases the patient may take on weight and become very fleshy. I have recently operated on a married woman 28 years of age, who two years ago weighed only 116 pounds, and who at the time of operating weighed 220, and was in appearance in good health. She had an elevation of 2 degrees in temperature and pulse of 90. Pains, colicky in character, occurred every few days, with exacerbations of acute symptoms of pain and tenderness, the attacks usually putting her in bed a week or ten days. At operation I found the peritoneum studded with miliary nodules and the cavity filled with a serosanguinolent fluid. She had quite an attack following the operation, lasting ten days. This subsided, and her recovery from the operation was not further interrupted. The result as to a cure remains to be seen.

Unless encysted, fluid gravitates to a dependent part of the cavity with change of patient's position. The sacculated variety may cause an error in diagnosis, the mistake usually made being that of ovarian cyst. A proper recognition of the pedicle or "diagnostic point," and location of dulness will prevent this error in most cases.

The focal point of all abdominal diagnosis should be reached by excluding other probable sources of symptom-producing pathology, as cancer of liver, spleen, kidney diseases, organic diseases of heart, etc., all producers of abdominal dropsy.

Painful micturition is mentioned by many writers as a prominent symptom, without giving any definite explanation of its cause. While this symptom has been

present in two or three of my cases it was not a marked feature in them.

Where a doubt exists in the mind of the surgeon of it being tubercular peritonitis a small amount of the fluid may be collected with a hypodermic syringe and inoculation practiced on guinea-pigs. All fluids in this disease do not have the bacilli, but in some they are present in abundant numbers; in such cases the diagnosis may be made absolute. This diagnostic test will often show presence of bacilli when the microscope has failed, as is the case in the urine of tuberculosis of the kidney.

My cases have been mostly in females between 20 and 30 years of age. None of them have been of the negro race, yet it is claimed that they are very prone to this form of tubercular disease. The absence of symptoms and the presence of seemingly good bodily nourishment are misleading and often prevent an early diagnosis. In two of my cases the disease was discovered after opening the peritoneum for the removal of an ovarian cyst. Recovery took place in both cases, and the patients have since remained well.

Typhoid fever is the one disease most likely to mislead, but a careful analysis of the presented symptoms will usually enable the physician to determine the actual disease present. The cases in which there is much fluid do not suffer very much, unless in the very acute or active stage of the disease. In the chronic variety diarrhea is a very prominent symptom and usually, if due to ulceration of the bowels, is an unfavorable sign. Tubercular family history is common in many cases, but not with a frequency to be of much value alone as a diagnostic helper.

Vague abdominal pains with no explainable cause, accompanied by irregular febrile attacks, and a gradual loss in weight with an increase in size of the abdomen, are of much value. Yet it must not be forgotten that many of these patients are well nourished. Pain has not been a marked feature in my cases. The suffering has been from gaseous distension of the bowels and the consequent stretching of its coats from the adherent intestines being impeded in their vermicular movements and rubbing of the surfaces infected.

Any pathologic process operated on that symptomatically disappears and remains so should be considered cured. If the disease be a constitutional one and local and distant points become invaded, it may not be a cure in the true sense of the word; yet if the point at which the original operation was performed remains well, the surgery should be considered successful. If a tubercular peritonitis is cured by a laparotomy and the patient dies in three or four years from pulmonary tuberculosis this fact should not be used as an argument against the justifiability of the operation.

Abbe has reported a number of very interesting cases coming under his care, one a child 3 years old, in whom the parietal peritoneum was filled with tubercular nodules, the membrane being one-half inch thick. A laparotomy cured the child. In another case the patient's general condition was such as to prevent an anesthetic being given. An incision was made under cocaine. The patient was cured, as was proved by an examination three years later while operating for a hernia.

According to Osler, in 346 cases, both sexes included, there were under 10 years 27 cases; from 10 to 20 years, 75; 20 to 30 years, 87; 30 to 40 years, 71; 40 to 50 years, 61; 50 to 60 years, 19; 60 to 70 years, 4; above 70 years, 2.

In Kelly's 29 cases, 18 were whites, 11 blacks; average age of white patients, all females, was 29.55 years; average age of black females, 25.63.

Abbe believes that the washing out of the peritoneum is followed by an acute engorgement of the tubercular nodules, followed by rapid envelopment of the nodules with a fibrous tissue, thus destroying the vitality of the bacilli and causing a retrograde metamorphosis of the neoplastic tissue. Weir believes the same process is brought about by the damage done to the peritoneal surfaces at the time of operating.

An exposed mesentery or any surface of peritoneum opened to light and air soon becomes hyperemic. The rapidity of the blood-flow is increased and the blood-vessels visibly become more numerous. This increased flow of blood is transient and in its stead a sluggish circulation is observed. The vessels are literally filled with white corpuscles; even at this time these scavengers are finding their way through the walls of the veins. Fluid exudes into surrounding tissue. If the process stops here we have the parts resuming their normal state. If an infection is added to this hyperemia the process changes to a more severe condition, infectious peritonitis.

The disturbance of circulation in an inflammatory process is slower in its appearance and is of longer duration than that accompanying a simple hyperemia, the exudation being much more pronounced in the former. Cabot's experiments disproved the presence of leucocytosis in tubercular processes, while in septic peritonitis it was usually present in a marked degree, a diagnostic symptom of no small import in suspected tubercular peritonitis. An aseptic hyperemia—inflammation—which is short of any death of the tissues may conserve in a reparative or curative process of the peritoneum in peritonitis of a tubercular character. Accompanying this hyperemia there is an increased flow of lymph, which acts as a diluent to the morbid tubercular product, exercising a more or less antiseptic power. The phagocytes are greatly increased and the attack on disease is more vigorous.

One of the evidences of putrefactive and other bacterial chemical action is the formation of coloring matter by chromogenic bacteria. In a number of the cases of tubercular peritonitis falling under my care there has been present on the face and other exposed parts of the body the brown spots—*chloasmata*—usually attributed by the layman to "diseased livers."

I am disposed to believe that an explanation of how these cases are cured from a surgical procedure may be found in the probable production of an antitoxin within the peritoneum owing to some unknown function of this great lymphatic. In no other way can we explain how a tubercular pleurisy is cured, as is often the case, by an incision into the peritoneum. I am sure I have seen cases of well-marked tubercular disease of the lung with pleural effusion symptomatically cured from the incision made at the time of operating on a similar process within the peritoneum. There exists within all healthy individuals a power of resistance to the invasion of most microbes. This immunity is brought about by some force or action within the body at this time not altogether understood. The theory of Metschnikoff of phagocytosis does not explain all the phases of this subject. I am firmly of the opinion that a chemical agent, call it toxin if you may, is being manufactured within the body constantly. This agent induces an immunity to the invasion of microbes; if this was not the case we would be in constant danger of destruction

from the bacteria that we eat and drink and breathe every day.

The bacilli that are present, it is presumed, are killed, cease to multiply or are held in abeyance in these cases that get well after a laparotomy. The operation stimulates the peritoneum to an increased activity in the production of an antitubercular toxin.

Bacteria that are not pathogenic within themselves—saprophytes—by their action on dead tissue or diseased structures may produce, by decomposition, poisons of a virulent character, the nature of which is not thoroughly understood. It is generally accepted that the product of these germs produces a destructive action on many forms of bacteria. This clinical change, says Pasteur, "may continue until the bacteria are all destroyed and the organic material is completely separated into the constituents of the atmospheric and mineral kingdoms."

An evidence that there is an antitoxin manufactured within the peritoneum in primary tubercular peritonitis is the fact that pulmonary complications are rare, a species of immunity to the disease in distant organs. All surgical treatment should be supplemented by a thorough antitubercular medicinal course.

In some cases the operative indications are for the relief of complications as a result of the original pathology, as abscess formation or intestinal obstruction. The report of cures in even the most unpromising cases from operation, should lend encouragement not to abandon any case as being hopeless. All diseased structures, when possible, should be removed at time of operation, as the Fallopian tubes, omentum, etc. Intestinal adhesions should be separated with great care, less numerous openings be made into the bowel. The usual median incision is made, the fluid is removed by sponging; if no fluid exist, adhesions are carefully separated, if pus is present the pocket is packed with gauze and drained; very rarely is it necessary to irrigate with saline or other fluids. I have in some of my cases used iodoform gauze to brush over the surface of the bowel and peritoneum. In a few of my cases I have used a glass drain, but the cases drained have not done equally as well. My cases were 18 in number in which the diagnosis was certain. Of these, 15 were operated on, with no death from the operation. Three were not operated on; of the latter one died of miliary tuberculosis, one is still under observation and has the disease well marked, the other case has symptomatically recovered, three years since the last evidence of the disease.

One of my cases operated on died eight months after operation, from abscess of the spleen. Another case died from pulmonary tuberculosis several months after operation. In this case three years prior to time of operating for the tubercular peritonitis I removed a large ovarian cyst from the patient; at that time there was no evidence of the disease under consideration. When operating the second time I found very extensive involvement of the intestines with the fibrino-plastic form of the disease. The agglutination was so extensive that I found it necessary to resect 27 inches of the small bowel. She recovered from this operation nicely, but died from the pulmonary complications eight months later. Of the 18 cases there were 14 females and 4 males. The average age of the females was 27 years. The average of the males was 28 years. There were married females, 7; married males, 1. The youngest patient was 14 years, the oldest 45 years. Two of the cases were very fleshy patients, both females. Two were pregnant at time of operating—about fourth month. One of these

cases had a large ovarian cyst. The other had extensive omental and intestinal adhesions binding the uterus in the pelvis. Both of these women went to full term, and were delivered of living children. One case was treated for eight weeks for a condition simulating typhoid fever—tubercular peritonitis active. This case I operated on several months later, doing an abdominal hysterectomy for a fibroid. Her symptoms have all disappeared. The peritoneum was studded with miliary nodules. One case had a large ovarian cyst as a complication. The case that died was a male, aged 45, disease being acute at time I saw him. A post-mortem verified this diagnosis.

In one case I operated for a tubercular peritonitis and three years later opened the abdomen for the removal of an ovarian cyst. No trace of the original disease could be found. Two of the cases were very fat women, yet a very extensive invasion of the peritoneum was found. In one case the operation was performed for an appendicitis. In this case I found the peritoneum filled with a fluid that coagulated as soon as the air came in contact with it. The fluid had the appearance of pus, but was tubercular. This case is entirely well. Pulmonary and pleural complications were noted in a few cases, the exact number my record fails to show.

In only one case was there evidence of Fallopiian tubal disease of a tubercular character. One case had as a complication a tubercular mesenteric cyst the size of a cocoon.

DISCUSSION OF PAPERS OF DUNNING, GUTHRIE AND CORDIER.

DR. PALMER DUDLEY, New York City—With the few moments allowed me to discuss Dr. Harris' paper, I simply want to say that I am doing conservative surgery as much as possible, and so far I have 145 consecutive operations without a death. In 25 of these cases pregnancy followed. I can describe only one case, and I will cite a typical one which will demonstrate the result of such work.

In 1898 a patient came to me with retroversion, double salpingitis, and cystic ovary. I performed a laparotomy, removing one-half of each ovary and tube. The tube was distended on the outer half, the ovary being involved, but the inner half of the tube was healthy. I removed one-half of the ovary and tube on each side, fastening the uterus to the abdominal wall by hysterorrhaphy. Five months afterward she came to me with what I supposed to be extrauterine pregnancy. She had every symptom; I operated and found a large hematocele on one side, involving the whole structure. The patient having asked me to leave some portion of the ovary, I did so. I lifted up the stump of the tube and ovary and found the silk with which I had circumscribed the mouth of the tube. It was still unabsorbed, and I removed it, scraping off the adhesions from the ovary, washed it thoroughly, touched it with carbolic acid, washed it off and returned the tube to the abdomen. The woman recovered, drifted from my care and I did not see her again until last Wednesday, a little over a year after the operation. She came with my office six months pregnant. I outlined the position of the fetus and could distinctly hear its heart-beat. That is one case to prove the theory which I am advocating.

Without drifting from conservatism, I will tell you a little of what I have done. In order to save the female from the reflex symptoms following total extirpation of the appendages, I tried some experiments. I have operated on five cases and previous to coming here I heard from them all. They have all menstruated with the exception of one. This latter is probably due to the fact that I implanted a portion of eirrhotic ovary, which was the best I had to work with. I removed the appendages, sewed over the stump with catgut, leaving a portion

of ovary to be implanted. Then securing the fundus of the uterus to the abdominal wall, I took out a portion of the inner surface of the structure, quickly cut this portion off, implanted it into the fundus and left one-half of the capsule of the ovary dependent in the uterine cavity. One of the cases claims that she has all the symptoms of pregnancy. She visited a physician in New York and he catheterized the uterus, removing the gestation. I have a record of all her menstruations. In none of the five cases was the ovary thrown from the uterus and not one of them had any of the reflex symptoms of total extirpation.

DR. G. I. McKELWAY, Philadelphia—I wish to endorse what Dr. Dudley has just said. Two years ago a lady came and asked me to attend her in her confinement. She told me that she could not understand how it was that she was pregnant as she believed she had no ovaries, as Dr. Barrows, of New York, had removed them. I wrote to him and he answered that he had operated in this way. He had removed the tube and ovary of one side in their entirety and finding a hematoma of the ovary on the other side he had removed a large portion of that ovary. After her delivery she removed from Philadelphia to Long Island, and within the last month I have had a letter from her husband saying she was again pregnant.

Four years ago, I had a patient from whom I removed a cyst of the left ovary, taking away the entire ovary and tube. At the time of operation I found she had a uterus bicornis septus. I left the tube and a small eirrhotic ovary on the right side. Since then she has had on the operated side a pregnancy, which aborted through the tubal end, and within the last three months she was cured, following a criminal abortion, for a pregnancy in the right half of her uterus.

These two cases and the others that have been cited emphasize the importance of leaving a part of the ovary and tube whenever possible.

DR. FREDERICK HOLME WIGGIN, New York City—In connection with the operation for tubercular peritonitis, I think Dr. Cordier was wrong in advising the use of sponges in removing the fluid from the peritoneal cavity. I have found it preferable to remove the fluid by irrigation with saline solution. I believe the use of sponges tends to cause mechanical injury to the parts, thus favoring the formation of adhesions and increasing the danger of intestinal obstruction, while the saline solution, some of which I have been in the habit of leaving in the intestinal cavity, I believe tends to mechanically separate the parts and thus lessens this danger.

I agree with Dr. Harris, that whenever the ovaries are not diseased they should be left; in fact if a portion only of one or both ovaries is healthy such should be left, only the diseased parts being removed. I have found that this can be done with great advantage in many instances. But occasionally, where there is a suppurative disease, it is not wise to do so, and I have, on some occasions, seen cases where secondary operations were necessary because the surgeon had been over-conservative.

DR. EDWIN RICKETTS, Cincinnati—In regard to the case reported by Dr. Cordier, where tubercular peritonitis followed ovariectomy, he says he sponged the fluid out of the abdominal cavity. I wish to ask whether those sponges, which he used in this particular case, were ever used in any other?

As to the plea for more frequent avoidance of excision of the ovary in connection with the diseased tubes, I wish to refer to a case following the delivery of a child four weeks after by a midwife. It was the fifth infection the midwife had on her hand. The patient's temperature had reached 105, pulse 130; there was distension of the abdomen. I saw her in consultation with the family physician. Her condition was bad. We were satisfied that there was fluid in the abdomen; the uterus was fixed. No abscess could be mapped out on either side of the uterus. The abdomen was opened and the fluid wiped out with carbolated gauze. Both ovaries were normal; the tubes were thick, but there was no accumulation of fluid. With my left index finger in the abdominal incision, I carried my right index finger into the vagina and uterus and forced out about two or three ounces of pus. As soon as the pus was evacuated, the peritoneum covering the fundus lay on my finger; we drained the uterus and abdomen with gauze and the patient

[The paper of Dr. A. P. Harris on "Plea for More Frequent Avoidance of Excision of Ovary in Connection with Resections of Diseased Tubes," has appeared elsewhere.]

made a satisfactory recovery. Strange to say her physician delivered her two years ago of a healthy boy baby at full term.

DR. A. H. GOELER, New York City—Senile endometritis is a subject in which I have been very much interested, and I am very glad to hear of the microscopic investigations made by Dr. Dunning. It puts a different light upon the subject. With Dr. Skene, I have been in the habit of regarding this as a degenerative process instead of an endometritis. I am satisfied however, that it is an exception when this condition is an acute inflammatory process. We may find it so in some cases, but usually it is simply a degenerative process following the menopause. In this connection I wish to enter an urgent plea in favor of investigation of all vaginal discharges, particularly of women at and after the menopause. It is a matter which ought never to be neglected. I have had a number of cases sent to me for the removal of the uterus and found nothing but a senile endometritis, a condition very easily cured. The great difficulty in the way of detection of the condition is that the family physician is too apt to disregard it, because of the age of the patient. He is averse to investigating the condition and oftentimes the patient is also averse to it. She believes that when she reaches the menopause she becomes immune to uterine disease. I have found senile endometritis frequently in unmarried women where not even an examination had been made, as in old maids, showing that infection could not have been carried in through the vagina.

Another difficulty about the diagnosis of this condition is its insidious character. It seldom gives rise to symptoms that direct attention to the uterus. But I make it a rule to insist on an examination in all cases where there is marked constitutional disturbance without any other ascertainable cause. Where the patient complains of restlessness, insomnia, nervous dyspepsia and general irritability, and where they have not been relieved by general treatment, I have never yet failed to detect a condition of senile degeneration of the endometrium as the cause.

There is one point in the paper which I wish to speak of. The author insisted that the condition existed in one of his cases where there was no occlusion of the canal, therefore he thought defective drainage was not responsible for the symptoms. But he admitted there was a marked posterior flexion, which would defeat drainage. A cure can be quickly obtained, by establishing free drainage from the uterus. It is just as important where there is a displacement as where there is actual occlusion of the canal.

I agree with Dr. Harris that our work should always be conservative whenever possible, and we should not precipitate a premature menopause when it can be avoided. I recall a case of senile endometritis in a young woman of 30 years, occurring three years after removal of the appendages. She was sent to me by a colleague who had failed to cure her of a very disagreeable discharge though she had been under his care for many months. By maintaining free drainage she was well in two months.

DR. G. J. ENGLEMAN, Boston—There is no longer any question as to the favorable influence of any particle of ovarian tissue remaining, provided it is active, and I wish to add to my testimony as to the result of such conservation and of conservative methods by a few striking cases. One was a case of very large double ovarian tumor; a very large colloid on the left side and a small pedunculated cystic tumor on the left. I removed the colloid, together with the tube, and took off the smaller tumor without any thought as to the possible importance of the pedicle. I certainly must have left a portion of this thin pedicle as it seemed unimportant and as I do not recall paying any particular attention, or in fact giving any thought to it. The patient did well and within five weeks after the time of her last menstruation she bled a little. I did not know what to make of it. Following this she menstruated regularly and then ceased, which I thought a natural sequence to the operation. The abdomen began to enlarge. I supposed the colloid mass to have been malignant and this to be a recurrence, but the physician in Kansas City gave very favorable reports as to her condition, and it finally proved to be a pregnancy. She was delivered of a healthy child and has

menstruated with perfect regularity ever since. The pedicle of the cyst I removed was about the size of a slate pencil. The distal portion removed was examined and showed bits of ovarian tissue. Now then, we have nothing but a stump of a tube on the left side, on the right side a little more, and that piece of tissue in the pedicle which remained active. The ultimate outcome of the case shows the effect of the smallest remnant of ovarian tissue, and also, what we know now, the possibility of the ovula passing through the stump of the tube, which becomes visible.

The other case, which I will cite, clearly demonstrates that the ovum may pass from one side to the other through the abdominal cavity. If a tube is on one side and the ovary on the other, impregnation may take place. The patient, with a double gonorrhoeal salpingitis, was brought to the hospital on a stretcher and remained confined to her bed for three or four months. For more than a year she continued in a very miserable condition constantly under treatment, but supporting herself and slowly improving. Several years later I saw her as the patient of another physician for a possible appendicitis, but I thought she had had a miscarriage. She admitted nothing, and we found no more enlargement than might be accounted for by long continued inflammation of the uterus; there was some blood, which she ascribed to menstruation. Post-mortem examination showed a tubal pregnancy on the right side, the right ovary a fibrous mass, with a corpus luteum on the left, and an impermeable left tube. In other words, the ovum came from one side, the left, and passed through the abdominal cavity to the other side, the right, and passing through the permeable right tube; the left was solid. The appendix was attached to the right ovary, and in the tube of that side was a small ruptured sac. The agglutination of the appendix was, of course, an unimportant complication.

The first case is a striking instance of the activity of small portions of ovarian structure, which I had looked on as nothing but connective tissue, and of the permeability of a ligated tube. The second shows the possibility of the ovum traveling from one side to the other through the abdominal cavity.

DR. G. BETTON MASSEY, Philadelphia—Some years ago we had a similar symposium on the inflammatory diseases of the female pelvis at the Philadelphia Pathological Society. I introduced the subject of inflammation of the uterus, and a member of the society complained that my paper was outside of the subject under discussion. He had forgotten that the uterus was a pelvic organ. There is a little bit of that forgetfulness with us at other times when we confine our discussions to inflammation of the ovaries and tubes, forgetting that the inflammatory diseases of mucous membranes necessarily take up their first chronic habitat in the cavity of the uterus. That endometritis may follow a vaginitis is a well-known fact. We should be interested in this endometritis, particularly as general practitioners rather than as surgeons. It is a little odd, but the medical world looks on inflammatory diseases as closely allied to microbic agencies, whereas surgeons and gynecologists look on them as the result of mechanical conditions. They speak of drainage curing endometritis, forgetting that possibly it was the means employed to secure drainage. They do not tell us that there was an accumulation when they began to drain. They seem to forget that, as a rule, it is a catarrhal disease of the interior of the uterus, which ultimately creeping up the tube, gives rise to the necessity for the operations mentioned this afternoon. I merely wish to direct attention to the wisdom of considering the uterus more than we do, and that we have a microbic condition and not a mere mechanical condition to deal with.

DR. WILLIAM R. PRYOR, New York City—Conservatism is a good term and the man who uses it will always receive a certain amount of consideration at the hands of his confrères and a large amount of applause from the laity. We all believe in conservatism and of two kinds, one of which seeks the preservation of an organ which is diseased and its restoration to a normal condition, and the other concerns the welfare of the individual as a whole by sacrificing a diseased organ which is jeopardizing health. Cystic ovaries, hemorrhages into the

ovaries, hydrosalpinx, ectopic gestation in the early weeks, adhesions and all those conditions which do not show the presence of active pathogenic germs, may be treated conservatively. But I must take issue with Dr. Dudley and those who advocate conservatism in a pus field. The thing to do is to carefully consider every bearing of the lesions before we operate, and when we operate, do it in such a way as to cure our patient. If I had my way I should never take out a pus tube due to gonorrhoea without taking out the tube on the other side as well. If you do not do this the patient will surely come back for a second operation. Practically applied, this belief of mine compels me either to do a purely evacuative operation for gonorrhoeic pus through the vagina or else do a radical operation through the vagina, removing all the organs. If you take out pus tubes, as in the case of Dr. Bóvč, that patient is not cured; you must take out every portion of pus focus, and if you do this by using ligatures you must place these entirely away from the pus field. In employing conservatism in pus foci you must use ligatures and sutures near the infected area. That is why I take issue as strongly as I can with every gentleman who has spoken here in advocacy of conservatism in the presence of pus. If you open the cul-de-sac and drain, that is an evacuative operation, and is not to be styled conservative.

DR. WALTER B. CHASE, Brooklyn.—Senile endometritis is very apt to be confounded clinically with malignant disease of the uterus. More than one case has come under my observation in which, if I were to make a diagnosis by the general or local symptoms and the character of the discharge, I would say at once that it is a case of malignant disease. Observation proves that there are a large number of cases which give these symptoms, but they are not malignant. If careful investigation is made and appropriate treatment adopted they can be cured. I feel positive that many a woman has lost her uterus after the menopause, because her adviser said she had a malignant disease, although it was not present. The profession should be on the lookout for just such conditions. We must not always adhere to the old theory that when a woman has a foul discharge it is due to malignant disease. Be careful, gentlemen, that it is before you operate.

DR. C. L. BONIFIELD, Cincinnati.—As a great many of the speakers have cited instances of conservative surgery, it is unnecessary for me to do so. The point I wish to make is that we must treat the patient that comes to us and not alone the condition of which she complains. I agree largely with what Dr. Pryor said, that the vast majority of these cases where we have pus to deal with and where we do conservative surgery, will have to be operated on again. There are exceptions to this rule, however. We occasionally have patients whose desire for children is so great that it is worth their while to take the risk of not being entirely well, or of having to undergo another operation at some future time, in order that they may remain in a condition in which pregnancy is a possibility. Most of us have had such cases who became pregnant and were delivered of children which were not freaks. In treating charity cases or others who can ill afford to lie in bed or to be operated on a second time, conservative surgery has no place.

DR. JOHN M. DUFF, Pittsburg.—In regard to conservatism after gonorrhoea, it is a very rare thing if you remove one tube and ovary that you do not have a subsequent operation. When you come to the conclusion that it is best to remove both tubes and ovaries at the first operation, you will have the assurance that your result is going to be a good one.

DR. JOSEPH PRICE, Philadelphia, Pa.—Puriform diseases, in about all cases, are due to gonorrhoea. It is the one disease decimating our women. The other infections are not common. Good physicians of to-day are clean. Most gynecologists in their public and private work are strictly clean, and are not guilty of infecting. The general practitioner is three more careful than he was many years ago, and I think you can fairly say that at least 94 per cent. of all pelvic suppurations are due to gonorrhoea. All of us are perfectly willing to say from personal experience that we have verified the observations of Noeggerath. It is all well enough to talk about conservative work and to pat the general practitioner and the

general community on the back. Few operators in this country or abroad having large experience have very few if any cases of pregnancy following unilateral operation for puriform disease. All of us have made an effort to save the tube and ovary on one side, but later it was necessary for the same or some other operator to remove the ovary and tube on the other side. I have repeatedly operated on my own as well as on the patients of other men, and I have yet to see the first woman to conceive through the tube I made the effort to save. Mr. Tait in Europe, and other men of rare good judgment and experience, tried what I repeatedly try, and they all fail. I wrote Mr. Tait shortly before his death that a patient had come to me from whom he had removed a pus tube and that I had repeated the operation on the opposite side. I do not see why men advocate conservative procedures when their patients go to others for relief afterward. It is a common thing for people to go to some one else for a second operation. They rarely go back to the original operator. I have patients in bed now that other men operated on and I had to repeat the operation on the other side. Pus disease is exceedingly common. Dr. Pryor's statement is correct, and you can not get around it. Clean work is required. We have a baby-show in our city every year. I am satisfied that the best-looking women in our city have had sections. If we had a woman-show in our city I could put up 100 women and win the prize. We have the best-looking women in our city and they have nearly all had their appendages removed. Sometimes when walking on the street I see a pretty woman. I look at her and she comes right up to me and says: "Doctor, don't you recognize me?" She then tells me that I operated on her some four years ago, etc. I know there are hundreds of cases like that in Philadelphia, and I sometimes think that it is a good thing to remove a woman's appendages in order to improve her appearance.

DR. RUFUS B. HALL, Cincinnati, Ohio.—I wish to emphasize the statement made by one or two of the gentlemen that conservative operation in these cases is what best serves the interest of the patient. I have experimented along this line somewhat, but in every instance where I tried to save one tube and ovary in a case infected by gonorrhoea I did not succeed in permanently curing the patient. In many instances they had to be operated on again by myself or some of my neighbors. It is a serious matter to subject a woman to an operation and then leave her in the condition where you must do it over again. In some cases it is desirable and advantageous to leave an ovary or a portion of it. I operated on a case of ovarian tumor eleven years ago. The patient was 32 years old, the mother of one child and exceedingly anxious to have another. Her greatest fear in having the operation done was that she might lose the other ovary; therefore, she begged of me to leave it if I possibly could. I operated and removed one large tumor on the ovary on the opposite side; there was a cyst of the ovary the size of a hen's egg. On top of this tumor there was a piece that we supposed to be ovarian tissue. It was about the size of the end of the little finger. It looked healthy. We cut away the cyst, leaving this little piece and the tube on that side, so that we could conscientiously say that we had not removed all of the ovary. Eleven months afterward she was delivered of a healthy boy baby. She has not conceived since, although she continued to menstruate regularly. This piece of tissue was left simply to gratify the wish of the patient, but illustrates what can be accomplished in some of these cases by saving even a small piece of ovarian tissue.

DR. L. H. DUNNING, closing the discussion.—I expected my colleagues to say more against the extirpation of the uterus in senile endometritis. I was sorry that I did not have time to consider that phase of the subject more than I did. When you read the pathological report you will find that the uterus was infiltrated with pus corpuscles and ordinary leucocytes. If you will examine the picture of the Fallopian tube which was removed, and which section was made from parts of tube taken three-quarters of an inch from the horn of the uterus, you will see it is densely infiltrated with leucocytes. I stated in the paper that it was impossible to pass a bristle through the Fallopian tube, although the microscope showed it to be patulous. Now we would expect to have trouble with the tube in a

case of that kind. The reason I advocated the extirpation of the uterus was that there was a distinct suppurative process going on within the Fallopian tube. That is the only class of cases in which I would recommend extirpation. I have several cases on hand all the time where there is a thin purulent discharge, which is easily cured by dilatation of the uterus, curetting and packing, or by an application of zinc chlorid or carbolic acid, followed by alcohol, and they give no more trouble. In the early stages of the class of cases of which the paper treats the onset is very acute and the patient is real sick. In one case I thought I had to deal with a malignant trouble in its very incipency. I extirpated and found an acute senile endometritis. These cases are not the only ones I have seen, but they are the only ones in which I have been able to obtain a careful pathological examination of the uterus. The specimens distinctly show an acute inflammation. Drs. Skene and Goelet tell us it is a degenerative and not an inflammatory process. The words are really synonyms. I would like to know what form of degeneration is present. My paper endeavors to answer this question. In one of the cases there was a slight mucoid degeneration, but we had all the features of an acute inflammation at the same time.

Dr. HARRIS, closing the discussion—The very limited time at my disposal will not permit me to make replies to all the gentlemen who have spoken. I wish to thank those who supported me in my claims. I selected the subject of my paper after attending a meeting in a physician's house about a year ago, where a friend had just been reading a paper on the removal of the tubes and ovaries. I came in just after he had finished his paper and, being invited to participate in the discussion, asked in what proportion of cases he removed the ovary when excising diseased tubes. He answered that he always removed the ovaries while removing the tubes. As this work is comparatively new, I must express my gratification at having received so much support to-day.

Regarding Dr. Pryor's case, I think the trouble more often comes from amputated and patent tubes than from the ovary. Of course, if the ovary is infected and suppuration goes on we may have to do a secondary operation, but the ovary is not the natural habitat for this inflammatory condition and not likely to continue suppurating.

In regard to Dr. Price's 100 most beautiful women in Philadelphia, it is interesting, but I dare say that most of these women were operated on a long time ago, because beautiful women are scarce, and we must operate on many to have left 100 of the most beautiful. If Dr. Price removed all their ovaries in recent years he greatly invaded their personal rights. As a class they are sadly lacking in some of the particular qualities of woman. I am free to say that if Dr. Price had all these women to operate over again he would leave many of their ovaries in.

I thank Dr. Engelmann for his demonstration of the migration of the ovum from one side to the other. That has been demonstrated in a very few instances and argues in favor of the more conservative practice advocated by my paper and endorsed by so many present.

Dr. COMIER, closing the discussion—I would like to correct the idea of Dr. Ricketts that we use secondhand sponges out in Kansas City. I have never used the same sponge twice in the last nine years. We never cleanse a sponge and use it again. The point I endeavored to bring out especially was that a factor in the cure of the disease was the cure of the peritoneum itself, pumping out the fluid from the peritoneal cavity and pumping in saline fluid and then removing that. The cavity has been filled with air, hydrogen, oxygen and other gases without any benefit. It is possible to cure these cases by opening the abdomen. I do not believe it is due to the sunlight, because the operation can be done just as well in the dark as far as the effect of light is concerned, provided the peritoneum receives the necessary stimulant to excite the latent function. I do believe it is necessary to produce more or less irritation. It

may be the injury to the sympathetic system, or the peritoneum itself that excited the manufacture of this antitoxin, which is no doubt the cause of hundreds of cures. In no other way can we explain how a tubercular pleurisy is often benefited by an incision into it. It undoubtedly attracts an increased amount of fluid to the part, and this in turn brings about an increased activity, the antitoxin is formed and the condition is eventually cured by it. That is the only explanation I can give.

PORTABLE COMPRESSED-AIR ATOMIZER.*

GEORGE F. COTT, M.D.

RUFFALO, N. Y.

This apparatus consists of a tank 6 inches high and 4 inches in diameter. It has a brass barrel running through the center and closed at the lower end by a cone-shaped piece of rubber having a slit in its lower extremity. The piston which runs up and down in the barrel admits air through the rod by drawing it up and is prevented from escaping by a valve which closes when the piston is sent home. The air is then forced through the slit in the rubber stopper and again prevented from returning into the pump, by closing hermetically, as it were. Thus, the cylinder or tank holds the air indefinitely, and a pressure of thirty pounds can be reached, which, however, is not necessary, as fifteen or twenty pounds is

amply sufficient for all ordinary purposes. A peculiarly arranged apparatus is attached immediately above the handle, which acts as an automatic shut-off, permitting just enough air to escape to cause a fine spray to form when forced into a specially-made bottle used as a spray-tube, which can be changed readily, as no cumbersome mechanism causes delay.

The atomizer sprays oil, water, glycerin or any substance ordinarily used for such purposes, and is so small that it can be carried in a small handbag. I have used one in my office, at the hospital and at patients' homes for two years and find it always ready in time of need. It may also be had in an oak case with half a dozen bottles for as many different solutions. The bottles can be changed in a few seconds. The instrument is designed for physicians who have no need of a more elaborate apparatus, or for patients who need a substantial atomizer for long use. Each bottle has a capacity of one-half ounce, which may be emptied with

one filling of the tank; no ordinary spraying, however, requires so much liquid. One bottleful may be used a number of times before it requires refilling.

ESTIVO-AUTUMNAL MALARIAL FEVER.*

SOME TYPICAL CASES OF QUOTIDIAN AND TERTIAN FORMS,
WITH A STUDY OF THE TEMPERATURE CURVES AND
OF THE PARASITES OBSERVED IN THE BLOOD.

CHARLES F. CRAIG, M.D.

Acting Assistant-Surgeon U. S. A.; Pathologist and Bacteriologist
U. S. Gen. Hospital, Presidio, San Francisco; Late Director
Bacteriological Laboratories of the Sternberg U. S. A.
Gen. Hospital, Chickamauga Park, Ga.; Josiah
Simpson U. S. A. Gen. Hospital, Ft.
Monroe, Va., and Camp Columbia
Hospital, Havana, Cuba.

In the following paper I have selected for description a number of typical cases of quotidian and tertian estivo-autumnal malarial fever studied by me in soldiers returning from Cuba, at the Josiah Simpson U. S. General Hospital, Fort Monroe, Va., in 1899. I have selected these cases from hundreds of malarial patients because they were studied for several days before quinin was administered, and thus all the typical phenomena of the paroxysm were exhibited. The quinin was withheld only when the patient consented, and in no case where the symptoms were urgent or suggested a pernicious character. From the charts shown it will be seen that the estivo-autumnal cases conformed to one of two types of fever, quotidian or tertian. In a previous contribution¹ to this subject I have shown that the estivo-autumnal or remittent malarial fevers present either quotidian or tertian paroxysms, and that each form is caused by a distinct and characteristic variety of the estivo-autumnal malarial plasmodia. As stated in that paper, my observations confirm those of Marchiafava and Bignami, who were the first to describe the forms of the malarial parasites mentioned. They gave the names quotidian and malignant tertian estivo-autumnal parasites to the organisms described, but it would seem to be preferable to simply designate them as the quotidian and tertian parasites, because, in reality, the term "inalignant" belongs rather to the quotidian than to the tertian form, as most of the pernicious cases of malaria which I have observed have been infected with the quotidian estivo-autumnal parasite.

I hope by the cases adduced to show the value of a careful study of our cases of malarial fever, both clinically and microscopically, and to demonstrate the occurrence of the two forms of the estivo-autumnal fever mentioned. I shall consider each case separately, giving the clinical history and describing the parasites found in the blood. The cases are arranged as follows:

1. Cases of quotidian estivo-autumnal fever.
2. Cases of tertian estivo-autumnal fever.

In considering the subject in this manner I have aimed to give the salient features, both clinical and microscopical, found in typical cases, but it should be understood that many cases occur which are not typical, where the temperature curve is more or less continuous; cases where there are mixed infections or infections with multiple groups of parasites, which it is impossible to describe in the limits of an article such as this. In such cases the clinical symptoms are often atypical and the temperature curves are most irregular and confusing. But no matter how typical a case of estivo-autum-

nal malaria we may have, it can be easily made atypical by the administration of small broken doses of quinin. Such treatment—far too common—will cause the most typical temperature curve, whether quotidian or tertian, to become irregular and often altogether unrecognizable as one of malaria, and is the most prolific source of the existing confusion regarding the forms of estivo-autumnal fever. In combined infections with both the quotidian and tertian estivo-autumnal parasites, a more or less continued or slightly remittent temperature curve is seen, while in cases in which quinin in unsuitable doses, at irregular intervals, has been given, an irregular, intermittent temperature curve is most common. Where, however, no combination of the two varieties of the parasites exists, and quinin is not administered, it will invariably be found that either a quotidian or a peculiar tertian temperature curve will be observed.

Cases of Quotidian Estivo-autumnal Fever.—There is nothing very peculiar about the temperature curve in this form of malarial fever; it very closely resembles an ordinary double tertian curve. It is a notable fact, however, that most cases of pernicious malarial fever which I have observed have presented this type of temperature curve, and the blood has shown the characteristic quotidian estivo-autumnal organisms. None of the cases described in this paper were pernicious in character, as I have purposely selected those of a milder type, because they are so much more common.

CASE 1, Chart 1—Hamilton. The patient, a soldier, arrived at Santiago during August, 1898. He was there about one month when he was attacked by measles, which was followed by dysentery. About the middle of October he began to have chills and fever. His chills occurred, as a rule, every day, but were sometimes irregular. Besides the chills, he suffered from nausea, vomiting, very severe headache, and diarrhea. Has had several attacks followed by apparent recovery under treatment. He was feeling well on his arrival at the hospital on June 23, 1899. On the 26th he began to run a temperature characterized by quotidian paroxysms, but had no distinct chill until the 30th. Up to the latter date he suffered from nausea, some headache, and general pains. On the 30th he had a distinct chill, suffered from nausea, vomiting, sweating, severe frontal headache, and general pain, especially severe between the shoulders. His bowels were constipated.

Physical Examination: Patient is anemic and emaciated. Skin slightly yellow; face flushed; tongue heavily coated with a thick yellowish fur, and flabby; lungs and heart normal; pulse full and bounding; spleen enlarged and tender, reaching about 4 cm. below ribs; liver normal. Some tenderness over abdomen on deep pressure, probably due to pressure on spleen.

Examination of Blood: The blood was examined daily, at intervals, until the parasites disappeared. It was found that they were the most numerous in the peripheral blood during or just after a paroxysm, but at no time were they numerous enough to show more than one infected corpuscle, on an average, to the field. The parasites were typical of the quotidian estivo-autumnal variety, and two forms were observed in the blood: the ring forms and the pigmented forms. The ring forms (Fig. 1) were very small, indistinct in outline, perfectly circular when at rest, and very actively amoeboid. They never showed any signet-ring appearance, and were never more than one-sixth the size of the infected corpuscle. Some infected corpuscles contained two and a few even three parasites. The pigmented forms were about one-fourth the size of the infected corpuscles, which were always shrunken, brassy green in color, and generally enucleated. The outline of the organisms was much more sharply defined than they were in the case of ring forms, and they were perfectly circular in shape, amoeboid motion having entirely disappeared. The pigment was in the form of one, or, at most, two rather large, almost black dots, either centrally or peripherally situated. The pigment was always entirely motionless. No segmenting forms nor crescents were observed in this case. The parasites dis-

¹ Philadelphia Medical Journal, April 7, 1900.

appeared from the blood two days after the commencement of the administration of quinin.

Treatment: Quinin, in doses of .36 every four hours. Recovery.

On reference to the temperature chart, it will be seen that there is nothing very distinctive about the temperature curve, beyond its quotidian character and the fact that during the first three paroxysms the patient felt slightly chilly, during the fourth even the chilly sensations were absent, and that the first distinct chill occurred during the fifth paroxysm. As far as the temperature curve is concerned, it might very well be that of a double tertian, the microscope alone being serviceable in differentiating the type of infection present. The temperature reached normal after two days' treatment with quinin. The subnormal temperature on the 29th, of 95.4 F., is worthy of notice, as it has been my experience that in no disease does the temperature so often reach low subnormal points as in the estivo-autumnal fevers.

CASE 2, Chart 2.—S. F. Shelton. The patient, a soldier, suffered for several weeks in Santiago, Cuba, from attacks of

hoid motion. The segmenting forms were both intracorpuscular, and in one instance the number of segments was six; in the other eight. In one instance a peculiar double-ring form of the parasite was observed, which suggested a process of division. Numerous corpuscles were observed to contain two ring forms.

Treatment: Quinin .65 every four hours. Recovery.

The temperature chart in this case shows an unusually high range of temperature for the quotidian estivo-autumnal infection, but is not otherwise remarkable. It resembles, even more than that of Case 1, an ordinary double tertian chart, and it would obviously be impossible to make a diagnosis of estivo-autumnal infection from the chart, without the aid of the microscope. The chart is, however, a beautiful example of the temperature curve in the quotidian estivo-autumnal infections, as contrasted with the totally different temperature curve of the tertian type of the infection. It also shows how little a chart can be depended on in making a diagnosis of the type of malaria present in a given case. It is safe to say that on simple inspection, this, or in fact almost any, quotidian estivo-autumnal

CHART NO. 1.—Chart of quotidian estivo-autumnal fever.

fever, accompanied by chilly sensations, headache, backache, slight nausea, and sweating. He grew gradually weaker and was transferred to the United States, arriving at the hospital on Jan. 23, 1899. His temperature remained normal till the 26th, when he had a chill, which was repeated every day for four days. He suffered from severe headache, with much mental depression, nausea, backache, and darting pains down the legs.

Physical Examination: Emaciated; skin of a peculiar grayish-yellow hue, tongue thickly coated and flabby; expression listless and depressed; heart and lungs normal; pulse rapid, full and strong; spleen enlarged and tender, reaching about 6 cm. below border of ribs; liver slightly enlarged; bowels constipated.

Examination of Blood: The blood was examined daily, at regular intervals, and showed very numerous quotidian estivo-autumnal malarial parasites. Ring forms and pigmented forms were common and on one occasion two segmenting forms were observed. The organisms were most numerous during the latter part of the paroxysms. (See Fig. 2.) The ring forms were very minute, indistinct in outline, and actively amoeboid at intervals. The pigmented forms were circular or oval in shape, and contained one or two nearly black pigment dots. The pigment was immobile and the organisms showed no ame-

chart could be considered as a chart of double tertian malaria, and very justly so. The microscopic examination of the blood is the only means by which the diagnosis can be cleared up in such cases, and it should never be neglected, as it is of infinite importance to the patient whether or not he is suffering from the benign double tertian or the too often malignant estivo-autumnal infection. The prompt subsidence of so pronounced an infection, under large repeated doses of quinin is also worthy of attention.

CASE 3, Chart 3—Cecil Taylor. The history in this case is briefly as follows. The patient had never been in Cuba, and apparently his malaria was contracted at Fort Monroe, as he gave no history of previous attacks. His illness began with a slight chill, nausea and vomiting, and severe headache and backache. He also had some abdominal tenderness and a slight epistaxis. His temperature reached 103.8 F. after the chill.

Physical examination showed an enlarged spleen, general abdominal tenderness, dry, hot skin, flushed face, injected conjunctiva, and a pointed, tremulous tongue thickly covered with a white fur; the pulse full and rather slow. The case was regarded at first as one of typhoid fever, but no Widal reaction could be obtained and examination of the blood showed

large numbers of typical quotidian estivo-autumnal parasites.

Examination of Blood:—The blood showed numerous intracorpuseular "ring forms" of the estivo-autumnal parasites of the quotidian type, and also a few crescents. The intracorpuseular parasites (Fig. 3) were very small, rather dimly outlined, actively ameboid at times, and often corpuscles were seen containing two parasites. The infected corpuscles were smaller than normal, dark green in color, and often crenated. No pigmented forms were observed.

The crescents (Fig. 4) were remarkable because of their plump appearance and small size. They contained perfectly motionless, almost black pigment, in the form of short rods; their protoplasm had a peculiar refractive, ground-glass appearance, and in every instance a darker colored, greenish double outline was to be seen surrounding them. They were easily seen to be dissimilar from the more common tertian estivo-autumnal crescents.

Treatment: Quinin, in .40 doses, given every four hours, caused a disappearance of the fever in two days.

In this case the temperature chart is not as typical as in the other cases cited and is therefore more interesting. During the first two days of illness the temperature showed hardly any remission, but after that the

Physical Examination: Patient somewhat emaciated and very anemic. Skin bronzed and rather moist. Tongue flabby and coated. Spleen enlarged. Heart and lungs normal. Abdomen rather tender. Pulse full and rapid.

Examination of Blood: The blood contained large numbers of ring forms of the quotidian estivo-autumnal parasite and a few crescents. In several examinations only two pigmented parasites were seen.

The intracorpuseular rings were similar in appearance to those already described, being minute in size, rather dim in outline and always perfectly round. The pigmented forms (Fig. 5) were circular in shape, more sharply outlined than the "rings," and the pigment consisted of one black dot situated in the center of the parasite. The pigment was perfectly motionless, and the parasites were not ameboid. The infected corpuscles were very dark green in color. The crescents observed were small and very plump, and showed a double outline. An intracorpuseular crescent was observed during one examination.

Treatment: Quinin, .40 every four hours reduced the temperature to normal very promptly.

The temperature curve in this case is remarkable for its regularity, and because of its resemblance to the

CHART No. 2.—Chart of quotidian estivo-autumnal fever.

remissions occurred as usual. It is difficult to explain this by any other hypothesis than a double infection, two groups of parasites reaching maturity within a few hours of each other. This explanation is further strengthened by the fact that on the 29th two paroxysms occurred, but this time the last paroxysm occurred after the remission of the first. As a whole, however, the chart is a fairly typical one of quotidian estivo-autumnal fever. It will be seen that the patient had no distinct chills, but chilly sensations.

CASE 4.—Robert S. Patient was 40 years old and had been in the service for 13 years; had always been well. Had had a slight cough at times during the past two years, but physical signs were negative. The sputum showed no tubercle bacilli. Was taken sick in Tampa, Fla., in 1898. Had chills daily for three or four days. Recovered from this attack and went with his regiment to Santiago, January, 1899, having several attacks of malarial fever and being unfit for duty about six weeks in all. Arrived at the hospital January 23, 1899. While here had a quotidian temperature and chilly sensations, with rarely a distinct chill. Suffered from headache, loss of appetite, pain in back and limbs, and slight nausea. Had no distinct sweats.

temperature curve seen in pulmonary tuberculosis. This resemblance, together with acute bronchitis present, caused the case to be considered as one of phthisis until the microscope cleared up the diagnosis, and quinin wrought a cure. The quotidian paroxysms, it will be noted, occurred with great regularity, and the temperature went below normal after each paroxysm. Without a blood examination it would be impossible, from the chart, to differentiate the two diseases, and it is in such cases as these that the value of a microscopic examination is shown. No distinct chills were noted at any time, the patient complaining only of chilly sensations.

CASE 5.—Charles S. The patient went with his regiment to Santiago in August, 1898. Was there about three weeks when he was taken suddenly ill with fainting spells, as he expressed it. Was taken to the hospital and suffered from severe headache, slight chills and nausea and night sweats. Was in the hospital about two weeks. He then returned to duty, but had several relapses, the last one occurring about five weeks before arrival at this hospital on December 11, 1898. Since being at this hospital he has had two attacks, attended with chilly sensations, nausea, severe headache.

Physical Examination: Patient somewhat emaciated and

very anemic. Skin yellow, tongue flabby and coated. Heart and lungs normal. Spleen not appreciably enlarged. Liver enlarged. Abdomen distended, but not tender. Bowels constipated.

Examination of Blood: The blood contained a few typical ring forms of the quotidian estivo-autumnal parasite, the "rings" being small, circular in shape, dimly outlined, actively ameboid at times, and unpigmented. Pigmented forms (Fig. 6) were also numerous. These were more sharply defined than

curring regularly, and the chart resembling that of a double tertian infection.

From the study of a large number of cases of this type of malaria, of which the five cases given are fair examples, the conclusion is inevitable that there occurs a type of malarial fever, due to an estivo-autumnal parasite, and characterized by quotidian paroxysms. These paroxysms are due to the ripening of a single genera-

CHART No. 3.—Chart of quotidian estivo-autumnal fever.

CHART No. 4.—Chart of quotidian estivo-autumnal fever.

the "ring forms," were less than one-fourth the size of the infected corpuscle, and the pigment occurred as a single dot, situated at the center or at one side of the parasite. The pigment was perfectly motionless and almost black in color. No ameboid motion was noted in the pigmented forms. The infected corpuscles were always shrunken and enreathed.

Treatment: Quinin in 40 doses every four hours reduced the temperature to normal in two days.

The temperature chart in this case is that of a typical quotidian estivo-autumnal infection, the paroxysms oc-

tion of a peculiar and characteristic form of the estivo-autumnal parasite, which completes its cycle of development in the blood in approximately twenty-four hours.

In blood secured by puncture of the spleen all stages of the development of this organism can be studied, and each stage differs markedly from the estivo-autumnal parasite causing paroxysms every forty-eight hours. The points to be noted in the differentiation of the quotidian estivo-autumnal parasite are the following:

1. During its hyaline stage, its minute size, about 1/6 of corpuscle, its perfectly circular ring shape, its very active amoeboid motion, which occurs at intervals and is so rapid that it must be carefully watched for; its indistinct outline; the very dark-green color of the infected corpuscle and its wrinkled or crenated appearance, and the fact that often more than one parasite occurs in a corpuscle.

4. Crescents are small and plump, contain small amount of pigment and always show double outline.

5. The cycle of development, lasting twenty-four hours.

There is no difficulty in securing typical temperature charts of this form of malarial fever if quinin be withheld, but if it be given in small doses, or at long or unsuitable intervals, the regularity of the temperature

CHART No. 5.—Chart of quotidian estivo-autumnal fever.

CHART No. 6.—Chart of tertian estivo-autumnal fever.

2. During its pigmented stage, its small size, about 1/4 of corpuscle; its circular shape and loss of "ring form" before pigmentation; its more sharply defined outline; its pigment, consisting of one or two coarse granules, perfectly motionless; its multiple occurrence in corpuscles and their very dark-green crenated appearance.

3. Segmentation takes place within the corpuscles, and the number of segments is six or eight.

curve is lost and it becomes impossible to tell with what form of malaria we are dealing, from a consideration of the chart. To this is undoubtedly due the fact that this form of malaria has not been more generally recognized.

Cases of Tertian Estivo-autumnal Fever.—In the contribution before referred to I have called attention to the fact that the majority of cases of estivo-autumnal fever present paroxysms occurring every forty-eight hours approximately. These tertian paroxysms are peculiar,

in that while they occur every other day, each paroxysm is prolonged so that it lasts considerably over twenty-four hours, and often almost forty-eight hours. This type of malarial fever is further characterized by a peculiar temperature curve, which was first described by Marchiafava and Bignami. The analysis of the temperature curve in these cases shows the following characteristics: A rapid and sudden rise, a stage with

or, again, by both the quotidian and tertian estivo-autumnal parasites, this peculiar temperature curve will not be exhibited, nor will it be in cases which have received small doses of quinin or quinin at long intervals.

In order, then, to secure a typical temperature chart of the tertian estivo-autumnal fever, we must have a patient infected by a single group of parasites and must withhold all quinin for several days. It is safe to say

CHART No. 7.—Chart of tertian estivo-autumnal fever.

CHART No. 8.—Chart of tertian estivo-autumnal fever.

slight remissions, a pseudo-crisis, a precritical rise, during which the temperature reaches a higher point than it had previously, and lastly, the true crisis, in which the temperature rapidly falls.

This peculiar temperature curve is presented in all uncomplicated cases of tertian estivo-autumnal fever, where quinin has not been administered. In cases which are infected by two groups of the parasites, ripening at different periods, or by the tertian or quartan parasites,

that all the confusion existing today regarding the types of estivo-autumnal fever is due to one of two factors, infection by more than one variety of malarial parasites, or the improper and untimely administration of quinin. The first factor can only be eliminated by the use of the microscope in diagnosis, and the second, only by an earnest scientific spirit on the part of the physician, so strong that he will be willing to withhold quinin long enough to secure a proper knowledge of the character of the

case which he is called on to treat. Medicine, to-day, has reached a stage where the so-called diagnostic terms of "remittent" and "intermittent" malarial fevers are of little exact meaning, and earnest effort should be made to substitute for them, in medical nomenclature, the more scientific terms, tertian, quartan, and quotidian and tertian estivo-autumnal malarial fevers.

The following cases are selected from a large number because they are typical of the tertian estivo-autumnal fevers and because they presented all forms of the tertian estivo-autumnal parasite, for this form of malarial fever is dependent on a characteristic parasite, possessing well-recognized differences from the parasite causing the quotidian form of the fever, and which is easily differentiated by the microscope, when one has become accustomed to appearances presented by it in the blood.

From the following cases, in which I have especially considered the character of the temperature curve and the parasites present, I hope to prove conclusively the occurrence and distinct character of the tertian form of estivo-autumnal fever.

some portion of their periphery, thus causing the so-called "signet ring" appearance. They were very refractive and sharply outlined, looking as though they were cut or stamped into the corpuscle; the protoplasm was clear and the ameboid movements were sluggish. The "ring" form was sometimes lost, a clear circular hyaline disc resulting. No corpuscles were observed to be infected by more than one parasite, and the corpuscle itself, although more greenish in color than the uninfected ones, was very much less altered in appearance than in the quotidian infection, and but seldom created. (Fig. 7.)

The pigmented rings and pigmented bodies were present in small numbers. The pigmented rings showed a few fine pigment granules, generally in the dilated portion of the ring, and these granules were often in rapid motion. These pigmented rings still showed ameboid motion, sometimes very noticeable.

The pigmented rings and pigmented bodies were present in small numbers. The pigmented rings showed a few fine pigment granules, generally in the dilated portion of the ring, and these granules were often in rapid motion. These pigmented rings still showed ameboid motion, sometimes very noticeable.

The pigmented parasites were larger than the rings, being

CHART No. 9.—Chart of tertian estivo-autumnal fever.

CASE 1, Chart 6—Sydney C., aged 23. The patient arrived at Santiago, Cuba, in August, 1898. On September 20 he was taken sick with a chill, which was followed by a high temperature. He had chills every other day for several days, and suffered from nausea and vomiting, severe headache and leg ache, and drenching perspiration. He had several attacks during the next two months and was finally sent to the Simpson Hospital, where he arrived on December 11. On December 17 he had a rise of temperature accompanied by chilly feelings. This paroxysm was succeeded by three others, all accompanied by severe headache and backache, nausea and great nervous prostration.

Physical Examination: Patient somewhat emaciated, skin yellowish, mucous membranes pale, cheeks flushed, eyes bright, tongue broad and coated. Heart and lungs normal. Abdomen rather tender. Bowels constipated. Marked mental depression and general debility.

Examination of the Blood: The blood was examined at frequent intervals and numerous ring forms, pigmented rings, and larger pigmented forms of the tertian estivo-autumnal parasite were found. No segmenting forms were observed. The "ring forms" were larger than those of the quotidian parasites, being about one-fourth the size of the infected corpuscle, irregular in shape, most of them presenting an enlargement at

nearly one-half as large as the infected corpuscle; they were very sharply defined, the protoplasm being very refractive and finely granular in appearance. The pigment was in the form of fine reddish brown granules, and had a marked vibratory motion. The ameboid motion of these parasites was very sluggish, and in some, had entirely disappeared. (Fig. 8.)

Treatment: Quinin, .40 every four hours reduced the temperature in two days and its continued use resulted in recovery.

A consideration of the temperature chart in this case shows a beautiful illustration of the peculiar temperature curve in this type of malarial fever. Quinin was withheld until the occurrence of the fourth paroxysm. It will be seen that the paroxysms occurred at intervals of forty-eight hours approximately and that the paroxysms lasted from thirty-six to forty-eight hours. It also shows well the several characteristics of the curve, noted before. Taking the paroxysm of the 21st for example, we see beautifully illustrated the rise, the period of slight remission, the pseudo-crisis, the precritical rise, in which the temperature reached the highest point, and lastly, the crisis, in which the temperature

gradually returned to normal. The intervals between the paroxysms were short, as shown by the chart. It will also be noted that two of the paroxysms were accompanied only by chilly feelings, while two commenced with distinct chills. As a general rule, the temperature goes to normal or below during the intervals, but in this case it did not.

CASE 2, Chart 7.—Paul R., aged 21. Patient arrived in Cuba on December 17, 1898. Was taken sick March 13, 1899, with severe pain in head, chill, high fever and nausea and vomiting. Was supposed to be suffering from typhoid fever, but felt better after a week in the Hospital and was up and about. On April 6, the day before he boarded steamer, on his way to Fort Monroe, the fever returned, accompanied by the same symptoms. Arrived at the Simpson Hospital on April 12. Since arrival he has had four chills, occurring every other day, but not very severe, accompanied by nausea, vomiting, headache, high temperature and pain in the back and legs.

Physical Examination: Patient looked very ill. Greatly emaciated, skin yellow, cheeks flushed, eyes bright, tongue broad and coated with yellowish fur. Heart and lungs normal. Pulse rather weak. Spleen slightly enlarged. Liver normal. Abdomen rather tender. Bowels constipated.

1899. Has had several paroxysms of fever, accompanied by chilly feelings, but no distinct chill, severe headache and backache, some nausea, and general muscular pain.

Physical Condition: The patient showed but little emaciation and appeared physically well. There was some anemia, the tongue was coated, the bowels constipated. Heart, lungs and liver apparently normal. The spleen was enlarged, reaching half way to the umbilicus. There was much mental depression present.

Examination of the Blood: The blood was examined frequently and numerous pigmented and unpigmented tertian estivo-autumnal parasites were found, most numerous just before or some time after a paroxysm. (Fig. 10.)

Treatment: Quinin, .40 every four hours. Recovery.

In this case the temperature chart is again typical of the tertian estivo-autumnal infection, and would easily be recognized on simple inspection. The occurrence of the paroxysms on every third day, the length of the individual paroxysm, the peculiar curve exhibited, all prove conclusively the type of malarial disease present, even without the aid afforded by the microscope in detecting the characteristic parasite.

CHART No. 10.—Chart of tertian estivo-autumnal fever.

Examination of the Blood: The blood was examined at frequent intervals and always showed numerous ring forms and pigmented rings of the tertian estivo-autumnal parasites, similar in every respect to those described in Case 1. No segmenting forms or crescents were found in the peripheral circulation. The parasites were most numerous just before the paroxysms. (Fig. 9.)

Treatment: Quinin .50 every six hours. Recovery.

The temperature chart in this case is a typical one of the tertian estivo-autumnal fever. It will be seen that there were four paroxysms in all, and that each of them showed the characteristic temperature curve, although the paroxysm of the 23d is slightly atypical, in that after the pseudo-crisis, there occurred a slight remission before the final rise and the crisis. That of the 27th is very typical. In no other malarial disease will a temperature chart like this be seen, and it is actually diagnostic of the type of infection present.

CASE 3, Chart 8.—Hall, A. H. The patient, while in Santiago suffered from malarial fever, having chills nearly every other day, accompanied by high fever, severe headache, backache and nausea. Arrived at Fort Monroe on January 23,

CASE 4, Chart 9.—Sullivan. The patient arrived at Santiago in August, 1898. Was there about two weeks when he was taken suddenly ill, having a chill, high fever, nausea and vomiting and great mental depression. Chills recurred every third day, and were always accompanied by intense headache and fever. Arrived at Simpson Hospital on Dec. 11, 1899, and on the 16th had chilly sensations and a rise of temperature. He had two paroxysms after this, accompanied by fever, intense headache, nausea, general muscular pain and mental depression.

Physical Examination: Patient appears well, save for some anemia and listlessness. Skin is slightly yellow, tongue slightly coated. Heart, lungs and liver apparently normal. Spleen not appreciably enlarged. Bowels constipated. Pulse full and regular.

Examination of Blood: Numerous examinations of the blood were made and pigmented and unpigmented ring forms of the tertian estivo-autumnal parasites were found as well as large pigmented forms. Several segmenting forms were observed.

The pigmented and unpigmented ring forms have already been described under Case 1. The large pigmented parasites were about half as large as the infected corpuscle, and contained numerous fine granules of the pigment, generally col-

lected near the center of the organism. The parasites were very sharply cut and refractive. In some of the pigmented forms the pigment was collected in a solid block at the center, and faint radial striations could be made out dividing the organisms into several segments.

The segmenting forms observed were extracorpuseular and consisted of blocks of pigment with ten or more oval segments arranged around them. (Fig. 11.)

Treatment: Quinin, 40 every four hours. Recovery.

The temperature chart in this case is interesting in that each of the three paroxysms presents a modification of the typical tertian estivo-autumnal curve. In the

first paroxysm we find no stage of slight remission, there being a rapid initial rise and almost immediately a pseudo-crisis, in which the temperature reached normal. This was immediately succeeded by the precritical rise and followed by the crisis.

In the second paroxysm there is also no stage of slight remissions, but the pseudo-crisis is more normal and the precritical rise more gradual.

The third paroxysm is marked by a well-defined stage of slight remissions, but the pseudo-crisis is almost absent.

Such slight modifications as these are very common in certain estivo-autumnal cases, but they do not in the least affect the general character of the temperature curve, nor cause a moment's doubt as to the nature of a case showing such a temperature curve as is here presented. Such temperature curves are uniquely characteristic and are associated only with the tertian estivo-autumnal infections.

CASE 5, Chart 10.—Charles Connor, aged 25, arrived at Santiago, Cuba, in August, 1895. Was there about one month when he had a sharp chill followed by high temperature. Chill oc-

EXPLANATION OF PLATE.

Under each figure the cuts should be read from above downward. The drawings are more or less diagrammatic, but serve to show the chief points in the differentiation of the quotidian and tertian estivo-autumnal parasites.

2. Corpuseule infected by one ring form and one pigmented form of the quotidian estivo-autumnal parasite.

occurred for a while on every third day, but later became irregular. They were always followed by a high temperature. He was admitted to the hospital there five different times, each apparent recovery from the fever being followed by a relapse as soon as he returned to duty. During the paroxysms he suffered from very severe headache, muscular pain, nausea and vomiting. He arrived at the Simpson Hospital on Dec. 11, 1898. Had chilly sensations and headache on the 15th, followed by a rise of temperature. Had three slight paroxysms afterward, accompanied by slight chilly sensations.

Physical Examination: Patient emaciated and anemic; skin yellow, tongue flabby and coated. Heart and lungs normal. Spleen greatly enlarged, reaching nearly to the umbilicus. Liver dullness normal. Bowels constipated. Abdomen tender.

Examination of the Blood: The blood in this case showed numerous pigmented ring forms of the tertian estivo-autumnal parasite and also numerous crescents. The ring forms have already been described under Case 1.

The crescents were very much more slender and larger than those of the quotidian estivo-autumnal parasites, and contained much more pigment of a more reddish color. The double outline was much less common but the quotidian crescents were more refractive.

In this case the temperature chart is not as typical as the preceding ones, but it is typical of the more chronic form of the tertian estivo-autumnal infection. The paroxysms occur every forty-eight hours approximately, but it will be noted that the range of temperature is not as high and that there seems to be a tendency toward a spontaneous decline of the infection. The chart is curious in that there seems to be a reversal of the ordinary temperature curve, the highest temperature being reached during the initial rise, but even in this chart the temperature curve is on the whole so characteristic that a diagnosis of tertian estivo-autumnal fever could easily be made from an inspection of it.

From the cases of quotidian and tertian estivo-autumnal malarial fever considered it will be seen that no differentiation is possible from a consideration of the clinical symptoms save that in the first named the chill or chilly sensations occur every day, while in the latter they occur every other day. A consideration of the temperature charts, however, shows such a marked difference in the temperature curve that we must admit that we are dealing with two distinct types of infection. The quotidian estivo-autumnal type shows a simple intermittent temperature curve, indistinguishable from a double tertian, while the tertian estivo-autumnal type presents a most peculiar and characteristic temperature curve, entirely different from that shown in any other type of malarial fever, and diagnostic in itself. When to this is added the fact that the tertian form is due to a distinct and easily differentiated parasite, as I have shown, the conclusion is inevitable that there are two varieties of estivo-autumnal fever, the quotidian and tertian, and that each is due to a characteristic parasite, as first shown by Marchiafava and Bignami.

The tertian estivo-autumnal parasite differs from the quotidian parasite in the following particulars:

1. During the hyaline stage: the rings are larger, being from $\frac{1}{8}$ to $\frac{1}{4}$ the size of the infected corpuscle; the signet-ring shape: the sluggish amoeboid motion; the clear-cut and refractive outline; the less wrinkled and lighter green infected corpuscle; the occurrence of only one parasite in the infected corpuscle.

2. During the pigmented stage: larger size, $\frac{1}{2}$ of corpuscle; the pigmented ring forms; the continuance of amoeboid motion; more sharply defined and refractive, and the granular protoplasm; the finely granular pigment, which is motile; the occurrence of only one

parasite in a corpuscle and the lighter colored, seldom crenated infected corpuscle.

3. During the segmenting stage: the occurrence of segmentation outside the corpuscle; the number of segments, ten to fifteen.

4. The larger, more narrow, more deeply pigmented crescents seldom showing a double outline.

5. The cycle of development, forty-eight hours.

In conclusion I desire to express my gratitude to the Surgeon-General of the Army for the opportunities offered me for the study of this subject, and to Col. A. A. Woodhull, Col. A. C. Girard, and Major Charles Richard for their interest in, and encouragement of, the scientific study of disease.

CLINICAL OBSERVATION IN MALARIA AS SEEN IN THE MISSISSIPPI DELTA.*

FRANK A. JONES, M.D.

Chief of Clinics, Demonstrator of Physical Diagnosis, Instructor Clinical Medicine, etc., Memphis Hospital Medical College.

MEMPHIS, TENN.

A distinguished diplomat, scholar and statesman has said: "It is too much the habit of men who have more education than experience, more culture than perception, to desire to mold the policy of the future by avoidance of all cases of trouble in the past." This logic can be well applied to-day in medical research. I come before you not to present anything specially new, but to call your attention briefly to some of the clinical features of malaria as seen in the Mississippi Delta. I shall not attempt a dissertation on the life history of the parasites outside the body, nor to theorize on the relationship which exists between malaria and the much talked-of mosquito. We have been taught much about acute malaria. The biology of the parasites causative of the various forms of malarial fevers has been heralded to us from all quarters of the globe, by men in and out of the malarial districts. With the advent of better laboratory facilities, with higher magnifying lenses, the malarial parasites have been exhaustively studied, while their clinical features have in a great measure been neglected and relegated to an obscure consideration, unfortunately. Malaria in the Mississippi swamps often means chronicity, frequently chronicity without there first having existed acute paroxysms. How often do the Delta physicians see a clinical picture something like this. The patient has neither chill, appetite, nor energy; feels wretched; head and limbs ache; has constant thirst; is constipated; urine is highly colored, scant, and often colored with bile; tongue is thick, flabby and heavily coated; skin is pale and muddy, almost cadaveric; eyes are jaundiced. Physical examination shows liver and spleen to be enormously enlarged. Often the patient will say that he has a "spleen in his side." Pulse is rapid with but little tension. Often on auscultation an anemic murmur will be noticed; temperature is normal. The blood shows anemia, also parasites in various stages of development, especially the estivo-autumnal.

The question naturally arises. Why do all these chronic manifestations occur without there first having existed acute paroxysms? The theory of phagocytosis in all probability explains this relative immunity. The corpuscles being able to cope with this gradual infection, so to speak, the parasites can develop and sporulate without giving rise to paroxysms. I have watched this

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

class of patients carefully. Upon sending them to a higher climate, to a climate free from malarial influences, they will in the majority of instances develop paroxysms in a period varying from forty-eight hours to a week.

Why the malaria in this class of patients does not give rise to a paroxysm while in a malarial climate but develops soon after changing to a non-malarial climate remains to be more thoroughly investigated. It is this class of patients who very often become victims of malarial hemoglobinuria.

Of late years authorities have been contending over pneumonia, and the course it pursues when malaria is also present. Pneumonia in the Delta or in any highly malarial climate is necessarily more fatal than elsewhere. Pneumonia in the Mississippi Valley runs an irregular course; the crisis is nearly always delayed; the fever is of an irregular type and not the type of a classical text-book pneumonia. Nausea and vomiting are always well-marked symptoms. I have seen malarial paroxysms occur during an attack of pneumonia. A double infection does very often truly exist.

OBESITY.

I have searched the literature carefully but have failed to find anything pertaining to obesity occurring in malarial climates. It is a morbid condition which attracted my attention when I first began to practice in the swamps of Mississippi. It occurs among persons coming from a climate free from malaria to the Delta. During a short residence in the Delta this class take on flesh rapidly; they seem to be immune to malarial infection. They do not have chills, they proclaim the Delta as a health resort on account of their growing fat. They have no chronic manifestations of malaria. It is this class of patients who become victims of furunculosis during the winter months. These are nearly always blondes. I have long since observed that brunettes are more susceptible to malaria than blondes. In all probability the hemoglobin of the brunette is capable of absorbing more poison than that of the blonde. What the pathology of this obesity is remains to be decided. Is it a fatty infiltration, the result of malarial poison, or is it due to stasis in a lymphatic system? It matters not what the pathology may be, the obesity subsides rapidly by changing from a malarial to a non-malarial climate.

PERNICIOUS MALARIA.

Of the three varieties mentioned in our text-books, the comatose type is most common. Patients are often attacked when there had been no paroxysms or even an initial chill. Temperature generally runs high; it may be subnormal. Prognosis depends on the patient's previous history. If there have been repeated attacks of chills, the prognosis is generally fatal, the system having become so thoroughly surcharged with quinin that the eliminative treatment fails to accomplish anything. On the other hand, we can often effect a cure if the patient's previous health has been good. It is astonishing to note how quickly recovery can sometimes take place by the judicious administration of quinin.

Two-thirds of the population of that portion of the State of Mississippi bordering on the Mississippi River are negroes. The negro constitutes one of the best subjects in which to study the natural course of disease without medication. A large experience in treating the negro has thoroughly convinced me that he is in a great measure immune to malarial infection. He does not suffer from chronic malaria. Acute paroxysms, when they do occur, are easily cut short by small doses of

quinin. I have on numerous occasions seen paroxysms run their course, terminating in spontaneous recovery without any medication. The negro's love for watermelons has been the theme for poets. It is not an uncommon thing for them to have a chill in the early morning hours, pass through the hot and sweating stage by noon, then repair to the patch to partake of a sumptuous feast of hot watermelons which have lain in the sun during the whole day, the repast producing no deleterious effects. Acute nephritis, however, in the negro is quite a common sequel of acute malarial infection. A large clinical experience in conducting an outdoor clinic composed almost entirely of negroes justifies me in making the statement that the negro's kidneys are as vulnerable an organ as his lungs. The negro does not have hemoglobinuria. I have never seen it in the genuine negro; but have in the mulatto. Acute nephritis and glandular fever are common sequelæ of malaria in white children.

HEMOGLOBINURIA.

The much-discussed, one might say the much-abused, subject of hemoglobinuria has come to be fairly well understood by the majority of the Delta physicians. By careful clinical study, by a large bedside experience, assisted by competent pathologists and microscopists, we have learned that it is the product, the sum total of neglected malaria—a malarial toxemia. In the majority of cases a history of prolonged paroxysms can be obtained. One striking feature of this condition is that it occurs most frequently in its most severe forms with the advent of cold weather. It is more fatal than when occurring during the summer months. Where it develops in the summer months as a result of previous paroxysms of short duration it runs a much milder course and is more amenable to treatment. Why hemoglobinuria should occur more frequently after the first frost, and why it should prove more fatal then, are questions which demand much consideration. There are just reasons to believe that the parasites remain dormant in the liver, spleen and bone-marrow, a latent malaria. These organs, reacting to the stimulus of a bracing atmosphere become invigorated, sweep the parasites into the peripheral circulation, and take on new life as a consequence of a better circulation. These latent parasites are aroused to activity, toxins are rapidly formed, spending their force on the blood cells, thus producing profound destruction of the corpuscles. The whole system becomes so overwhelmed that it can not react, death ending the scene. Jaundice in this class of patients rapidly becomes profound within a few hours after the chill and after the characteristic discharge has taken place from the kidneys. This jaundice is so pronounced and striking that the late Dr. Warren Stone, of New Orleans, denominated hemoglobinuria as pseudo-yellow fever. We who have seen both diseases have learned that they have many symptoms in common. Pigmentation, both hematogenous and hepatogenous, or ecchymoses on various portions of the body, especially the face, called by the laity "liver spots," are frequently forerunners and forewarners of an approaching attack of hemoglobinuria.

The Delta physicians as well as the laity have learned by experience that the administration of quinin with these conditions present is fraught with danger, frequently precipitating an attack, whereas, if the eliminative course of treatment is pursued, disengorging the liver, kidneys and gastrointestinal tract, followed by a tonic of arsenic, nux vomica and iron, the attack can be prevented. Nausea and vomiting, a tendency to sup-

pression of the urine and paresis of the bowels, are symptoms which confront the physician and annoy him in treating hemoglobinuria. In those cases in which suppression occurs it appears early in the attack. The nausea and vomiting together with suppression, the patient being either in a comatose or a semicomatose condition, present to the physician a clinical picture of uremia. Whether uremia is due to edema of the brain, as advocated by Traube, or whether it is the result of retained toxin, it matters not. We know that where suppression occurs in hemoglobinuria the patient in nearly every instance succumbs, it matters not how heroic nor how various our therapeutic measures have been. If we accept the physiological teaching that the liver creates urea and that it is eliminated by the kidneys, there is just reason to suppose that this urea-producing function of the liver, by reason of its being congested and engorged, is interfered with; the kidneys are called on not only to eliminate the malarial toxin but also the toxins of imperfect liver functions; hence the suppression, hence the coma. Anuria of several days' duration is not an uncommon occurrence in hemoglobinuria. I have recorded one patient who lived nine days. When I saw him he had had several discharges from the kidneys. He had been living in the swamps of Arkansas and had had numerous paroxysms during a period of several years. The liver and spleen were enormously enlarged. He was profoundly anemic; had no nausea or vomiting, and was in a semi-comatose condition, with temperature subnormal during the whole time. He died on the ninth day after my first visit. He had no convulsions, dissolution taking place by a gradual process. I believe that a true splenic leukemia—which has been so clearly and concisely described by Dr. Osler—much more frequently exists than is generally supposed. What the physicians of the swamps of Arkansas, Louisiana and Mississippi need are better facilities for making blood analyses.

I wish to call attention to a condition which I have frequently observed in hemoglobinuria, and I have seen no mention of it. I refer to paresis of the bowels. Text-books tell us that diarrhea is often present in hemoglobinuria. This has not been my experience. Diarrhea is the exception and not the rule. It seems that with this condition diarrhea in a measure might prove salutary. Very often just as suppression occurs the abdomen becomes distended with gas. The medicine which you have given your patient with a view of arousing the liver and kidneys to action has had no effect. Death takes place, both by suppression and paresis of the bowels. It seems that the same conditions which have produced the suppression have also acted as causative factors of the paresis. Let me admonish you, gentlemen, who are making scientific research in malaria not to journey to Rome to study the Pontine fevers or to South Africa to investigate the black-water fever, but come South to the swamps of Arkansas, Mississippi and Louisiana, where we have malaria in abundance and in all of its forms.

Sanitary Substitute for the Individual Communion Cup.—The *Lancet* suggests the revival of the ancient custom of dipping the bread in the wine or "intinction," instead of the use of the common chalice at the Communion. This is the method still followed in the Eastern Church, and was generally practised until the twelfth century. The editorial earnestly urges ecclesiastical authorities to consider the matter and live up to the traditions of the Church as a leader in sanitary matters. Individual communion cups are not practicable, but intinction has much to recommend it.

HYPERTROPHY OF PHARYNGEAL TONSIL.

ITS ANATOMY AND PHYSIOLOGY.*

NORVAL H. PIERCE, M.D.

CHICAGO.

The pharyngeal tonsil lies above a line drawn from about the middle of the Eustachian cushions in the post-nasal space, and is developed at a very early age, probably coincident with the faucial tonsils. Its ultimate nature is as much unknown as is the ultimate nature of the tonsils. Whether it is an evolutionary vestige or a gland which has still a function is unknown at the present time. Embryologically, it develops with the pituitary body and the pineal gland, and probably there is a relationship existing between these three bodies. It is composed of lymphoid tissue, the mass of the tissue being round cells indistinguishable from embryological connective tissue and lymph nodes, which are in turn indistinguishable from the solitary follicles of the intestine. These, together with the blood-vessels and nerves—for there are nerves in the pharyngeal tonsil and adenoids—are held together by a reticulum of connective tissue, which has a great deal to do with the involution of the organ after hypertrophy. Each of the lymph nodes or solitary follicles is encased in a bag of connective tissue. This connective tissue, at an early date, is embryonal in character and goes onward to adult growth, ripens rather early, and in due course of time matures, and, following the law of connective tissue, contracts, thus squeezing the lymph nodes, shutting off the blood-supply to them, and by pressure atrophy, we may say, producing their shrinkage. This body is covered by ciliated columnar epithelium, which differs from the epithelium of the mesopharynx. However, in the majority of growths that I have examined, I have found as much squamous or cuboidal as columnar epithelium. This transition from the columnar to the cuboidal variety is due to pressure. Adenoids are hyperplasia of this normal tissue. They vary, of course, in size, in consistency, and in color. The surface may be coarsely granular, furrowed more or less, or smooth. The smooth variety very frequently leads us astray in post-rhinoscopic diagnosis, because it forms simply a smooth layer, thus foreshortening the nasal space, and this is difficult to judge in the mirror.

I have under the microscope four specimens which show the various interesting points in adenoids, one particularly which shows the peculiar, fan-shaped distribution of the blood-vessels, which are surrounded by connective tissue; this apparently holds the blood-vessels open, thus increasing the blood-supply to the gland. In this way we may account for hyperplasia in some of these bodies. The hyperplasia, however, is most often caused by a succession of attacks of acute inflammation, just as hyperplasia of the faucial tonsil is caused by hypertrophy.

The infectious diseases, such as measles, scarlet fever, etc., play a very active part in the causation of this condition. Then, too, of the acute inflammations of the gland itself, we have the lacunar variety of inflammation, and the inflammations due to the streptococcus infections, which are very frequently the cause of acute hyperplasia.

Their dependence on tuberculosis is a most interesting and important question, and it is still unsettled. Pansac, in an interesting article which appeared in

*Read in a Symposium on Hypertrophy of the Pharyngeal Tonsil, before the Chicago Climatological and Laryngological Association, July 5, 1900.

1895, divides adenoids into three varieties—the scrofulous, tuberculous, and the syphilitic. It is my opinion that these varieties do not comprise all cases of adenoids. We know that a great number of scrofulous children have adenoids; we know, furthermore, that a great number of children who bear no evidence of scrofulous or chlorosis have these bodies in their postnasal spaces. We must remember, too, that the presence of hypertrophied and lymphatic tissue in the postnasal space and in the fauces may cause a condition which is hardly distinguishable from scrofulous or chlorosis, which condition immediately disappears on the removal of the hypertrophied or hyperplastic gland. Koch has observed the reaction of adenoids after the injection of tuberculin, and he has found that a certain percentage show a reaction which we would expect from true tubercular tissue. These adenoids, after removal, heal, just as other cases of adenoids heal, with no reaction, and with no subsequent tuberculous. George Gottstein, Jr., removed from a girl of 12 a large adenoid mass which showed evidences of tuberculosis, i. e., giant cells, and the like. Another observer examined the girl when 18 years of age, or six years after the operation: she then enjoyed vigorous health and showed no symptoms of tuberculosis in the postnasal space. That these glands do become tubercular there can be no doubt.

Professor Roth has reported a case of tuberculosis of the pharyngeal tonsil which resulted in tubercular infection of the bones beneath, followed by death from tubercular meningitis. A great deal of work has been done on this line by Wendt, E. Frankel, Schlenker, Dmnochowski, and others. Cases of tubercular ulceration resulting from extirpation of the glands have been reported, so that we may assume that the relationship between hyperplastic adenoid tissue and tuberculosis is somewhat close.

Abscesses may develop in this tissue, which may cause septic meningitis. Cysts, and all of the tumors, especially sarcoma, develop from the membrana prevertebralis. The case of a child is reported by Dmnochowski, from whom he removed hyperplastic adenoid tissue four different times, with recurrence after each operation. The child at length died with sarcoma of the dura, and yet after each operation a number of pathologists failed to determine the sarcomatous nature of the tissue.

31 Washington Street.

CONNELL'S OPERATION OF END-TO-END ANASTOMOSIS OF SMALL INTESTINE.

FOR REPAIR OF ENTEROTOMY PERFORMED TO RELIEVE ACUTE OBSTRUCTION.

FIRST CASE REPORTED ON HUMAN SUBJECT.

FRANKLIN H. MARTIN, M.D.

CHICAGO.

W. V. B., admitted to my service April 17, 1900, with the following history: Both parents died of pneumonia; one brother died of epilepsy; one sister died of pulmonary tuberculosis. Has two brothers and two sisters living in good health.

She has had the usual diseases of childhood. Puberty at 13. Menstruation history normal. She has three children. Normal labors, no miscarriages. Last confinement thirteen months prior to her admission into the hospital.

Her puerperium was pathological and for a period of six weeks she had chills and fever, and pain in the pelvis, losing much flesh and color. At the end of the third month after her confinement she was able to attend to light household duties.

In August, 1899, she entered a hospital and underwent an operation for the repair of a lacerated cervix and perineum. Her general condition improved somewhat after this until Decem-

ber, 1899, at which time she began to lose weight and suffer from pain in the pelvis; she also noticed some enlargement in the right lower part of the abdomen above Poupart's ligament.

She menstruated two months after her last confinement and has been regular every twenty-eight days since, with the exception that there had been none during the six weeks prior to her admission to the hospital.

Physical examination of the pelvis shows the cervix low in the vagina, fundus uteri in retroversion, immovable, flanked with an indurated mass that fills the entire pelvis and extends upward into the abdomen behind Poupart's ligament on the right side.

Examination of her blood shows: Hemoglobin 62 to 65 per cent.; erythrocytes, 3,100,000 per cubic millimeter; leucocytes 118,000 per cubic millimeter, marked leucocytosis being present

Plate 1.—The mesenteric, or suspending loop, in position; to insert which the needle with thread is passed through all coats and the V-shaped mesenteric space of each cut end. Its object is to bring this part of the mesentery and intestinal wall into perfect apposition, and thus secure a sero-serous approximation throughout the line of union.

in this case. Together with the above described condition in the pelvis and marked emaciation, a diagnosis of pelvic abscess is made.

Physical exploration of the chest was negative; analysis negative; her pulse ranges from 88 to 100; temperature normal, no history of recent chills nor sweating, bowels constipated, appetite poor, no irritation vesical symptoms.

April 18, 1900, the patient was prepared for an operation. An abdominal incision was made, and the large swelling which filled the entire left side of the pelvis, and which was buried in omental and intestinal adhesions was discovered. Because of the complicated condition of the tumor, and the unsatisfactory physical condition of the patient, it was determined to drain

the abscess through an incision in the vaginal vault, rather than attempt its enucleation. An incision was therefore made in the vaginal vault, the abscess drained and the abdominal wound closed. The patient made a very satisfactory and rapid recovery, and since the evacuation of the septic material in the abscess, the patient's general condition has rapidly improved. Her temperature immediately dropped to normal; her pulse dropped below 100, and with a ravenous appetite she began to improve in general nutrition.

Her bowels, since the operation, were in perfect condition until the night of May 5, when the patient complained of sudden onset of pain of a very excruciating

of May 5. From the pain and vomiting acute obstruction was immediately suspected, and an effort was made to overcome the constipation. First, an enema containing glycerin two ounces, sulphate of magnesia two ounces, and water two ounces, with a dram of spirits of turpentin, was administered, employing for the purpose a tube which carried the enema about eighteen inches into the lower bowel. This stimulating enema, which in the previous history of the case had been very effectual in each instance, causing a free discharge of gas and fecal matter from the bowel, had absolutely no effect. The patient was then placed in Sims' position and a large enema of two quarts of soapsuds, with

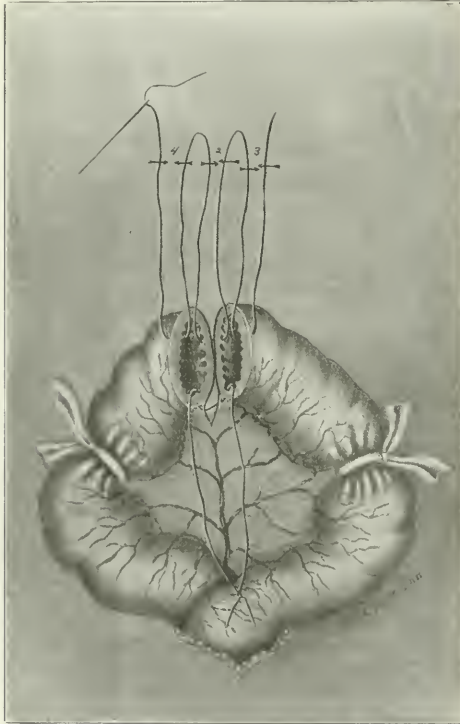

Plate 2.—Suspending loops 2, 3 and 4 are made with one thread inserted at a point two-thirds distance from mesenteric to convex border. The needle with suture is passed through the four walls of the cut ends, and that portion of suture within each lumen is drawn up to a sufficient length, then cut and the contiguous threads tied at the points indicated by the serous, thus having as a result four suspending loops, dividing circumference of each cut end into thirds.

character. She characterized it as that of intestinal colic. The pain did not cease with the application of heat and the administration of stimulants, and finally became so severe that one of the internes administered a hypodermic of morphia and atropia. While this benumbed sensibility somewhat, the pain continued. In about three hours the patient began to have eructations of gas, and in an hour or two began severe retching and occasional vomiting.

The pain and vomiting continued from that time. It was soon noticed by my assistant, Dr. Cooney, that the patient had not passed gas through the rectum or had a movement of the bowels since the afternoon

Plate 3.—Suspending loops 1 and 2, held by an assistant, bring into apposition the one-third of the intestinal walls between these two points. The needle (of suture proper) enters the mucosa from the lumen of one cut end, near loop 2, penetrates all coats of both walls, passes into the lumen of opposite cut end, where it is reversed and made to traverse again the intestinal walls, but in an opposite direction, parallel to, and about one-eighth of an inch from, the first half of the stitch just described. This first stitch is then secured by tying on the mesoneurium, and the free end of the suture not cut, but held by the assistant, with loop 2. The operator then unites the apposed walls with a to-and-fro, or running, suture until he reaches loop 1, where a back stitch is taken to prevent puckering.

four drams of spirits of turpentin, was employed, every effort being made to get the patient to retain the enema for some little time. After retaining the enema for a period of five or ten minutes, the patient was allowed to expel it, but here too again, there was absolutely no result as far as causing the discharge of gas or fecal matter. Later on, the patient was placed in knee-chest position and the large intestine filled with an enema of normal salt solution. More than a gallon of fluid was retained for several minutes. The

enema was finally expelled without result. During the time these enemas were administered, efforts were made to get the patient to retain a laxative, but the vomiting was almost incessant and the result nil. About six hours after the initial pain, considerable distension of the abdomen was noticed and, on percussion, tympanites. Twelve hours after the initial pain, the patient was observed to be in a condition of continuous shock; her temperature ranging from 96 to 97, and her pulse from 130 to 150. In order to sustain her strength and prepare her for an operation, should it become necessary, a pint of normal salt solution with an ounce of brandy was injected into the subcutaneous

pointed directly to such a condition: 1, pain; 2, vomiting; 3, constipation; 4, distension, and 5, collapse. The obstruction was undoubtedly either in the cecum or entirely above the large intestine, as the retained enemas were of large size, thereby demonstrating that the large intestine was empty. The obstruction was undoubtedly in the small intestines, probably rather high in the alimentary tract, inasmuch as the vomiting, which had been quite severe, had resulted in no fecal matter.

OPERATION.

After carefully watching the case for forty-eight

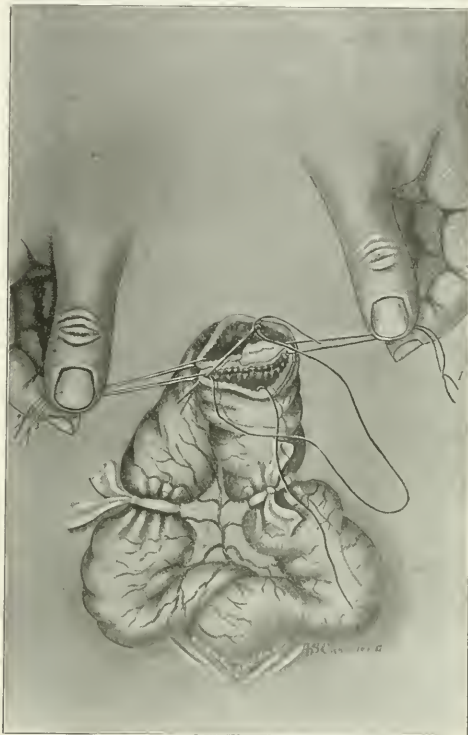

Plate 4.—Loop 2 has been cut away and loop 1 takes its place in the band of the assistant, with loops 3 and 4 held in his other hand, thereby bringing into apposition that portion of the walls to be included in the second third of the suture. The operator continues the suture to the points of insertion of loops 3 and 4, where again a back-stitch is taken, to fix the suture and prevent a purse-string contraction of the same. The white elevation in the center of illustration, representing mesentery, shows that that portion of the intestinal wall not covered by peritoneum, at the mesenteric border, has been secured in the suture.

Plate 5.—At this point the needle for the first time is made to emerge from the lumen of the bowel, at a point corresponding to where the next stitch would be taken, and appears on the serous coat of one cut end of the intestine. Two-thirds of the circumference of the intestine have been sutured. Suspending loops are now cut and removed.

tissue beneath the breast. This caused the temperature to improve and range between 97 and 98. The pulse became stronger, slower and somewhat fuller. In four hours the transfusion was repeated. In the meantime, stimulating enemas of a character similar to those already described were administered to the patient in different positions for at least four hours, her general condition being in the meantime very carefully watched.

DIAGNOSIS.

Symptoms in this case pointed unmistakably to acute obstruction of the intestine; all classical symptoms

hours, after adopting all means ordinarily employed to overcome an obstructed condition, after thoroughly stimulating the patient into a condition of the highest possible tone, we felt that we were justified in making an abdominal incision, and attempting to locate and overcome the obstruction. As the woman had only recently had a laparotomy, a small incision in the abdomen immediately to the right of the recent abdominal wound was made, in order to be in a position to separate the intestines from the old wound, should the cause of obstruction be the result of adhesion of the intestine to the old line of incision. The omentum was adherent to the old wound. The intestines were more or less adherent and fixed to the anterior abdominal

wall and to the omentum, which was attached to the old wound. The omentum was separated from the anterior abdominal wound, and the coils of intestines exposed were also adherent to the omentum. They were large, thin and thoroughly distended with gas, indicating that they were portions of the intestine above the obstruction. By observing the coil of intestine directly beneath the wound, it was noticed that it was turned acutely on itself, and the two arms below the knuckle were closely adherent to the extent of about six inches. The adhesions between the opposing surfaces of the bowel were easily separated, but the fold of intestine remained distended, indicating that

considered it unsafe and unwise to unnecessarily manipulate the intestines, because of the low condition of the patient, a coil of the distended bowel was brought out and enterotomy performed, in order to give the patient temporary relief. A small knuckle of intestine was brought through the abdominal wound, and beneath the knuckle, through the mesentery, a sound was placed to prevent the intestine slipping back into the abdominal cavity. The sutures were inserted into the abdominal wound. A pair of clamps were placed about three inches apart, between which points the gut was opened. One portion of a Murphy button was placed in the intestine and coupled to the other half of the button,

Plate 6.—There remains now only the last or convex-third of the walls to be closed. What was a complete section of the bowel has been transformed into a transverse incision, extending only one-third of the circumference, at the convex border. Owing to the impossibility of holding the divided edges of the last third in serous apposition, and yet unite this third in the same manner as the previous two thirds, it is necessary to proceed somewhat differently to achieve this same result. The suture itself, being fixed at each end, can now be utilized as suspending threads, the free end in one hand of an assistant and the needle end, where it emerges from the bowel wall, in his other, while the operator is free to proceed with the suture. This he does by passing the needle from where it emerges on one cut end to the other cut end, there to be inserted, from without inward, at a point corresponding to that which would be pierced if the walls were in apposition, serous coat to serous coat.

the gas did not pass on. There were several adherent coils, which, however, were easily separated. At a point low in the pelvis, small ribbon-like intestines resembling the ileum were observed; this was the portion of the small intestine below the obstruction. A band, around which a small intestine was twisted, required considerable force to break, and the intestine which was bound brought to the surface. As I con-

Plate 7.—The needle, after having entered the lumen, is passed out again on the same side, one-eighth inch distant; then over to the opposite cut end, where it is inserted from without in and again emerges from within out, on the same side. This step is repeated alternately on opposing margins until the necessary number of stitches have been inserted. It will be observed that when the needle enters the lumen the last time it makes what might be termed a half-stitch, as it does not return again through the wall, but having reached the point where the suture was commenced, the free end and the needle end will complete the last stitch, when tied, on the mucosa. The needle at this point is then brought out of the lumen alongside of the free-end of the suture. The cross-over stitches are next carefully drawn up, thus bringing into contact the opposing serous surfaces at every point except where the suture ends still protrude.

to which was attached a long rubber tube, the clamps loosened and the abdominal wound closed in such a way that the knuckle of intestine was free from pressure. No gas passed through the tube at first. This fact was very disappointing and extremely puzzling. Dressings were placed about the intestine in such a way as to form no constriction and the long tube buried in a liberal pad of loose antiseptic gauze.

Four hours after the operation, when she was fairly out from the anesthetic, gas began to pass by the anus. Directly after this a large amount of fecal matter was found in the dressings surrounding the tube. Large movements of the bowels by the rectum, and a considerable flow of fecal matter from the artificial anus followed. Her temperature soon rose to normal, and her pulse reduced from 150 to 88. The condition of shock entirely disappeared. Three pints of normal salt solution were injected beneath her skin. The pain and vomiting entirely ceased. The patient was fed peptonized milk by the stomach. The subsequent results in this case showed that the obstruction of the

of the knuckle of intestine projecting through the abdominal wound. I carried this incision on either side until I came to the intestinal tube at the upper and lower extremity of the incision and the mesentery near the center of the incision. Now, with great care, I proceeded to separate the knuckle of intestine from the abdominal wall, employing a sponge for the purpose of pushing aside the adhesions. Having accomplished this I found myself in the peritoneal cavity. Here, beneath an adherent omentum, was a mass of adherent intestine extending for a considerable distance. At first it was very difficult to outline any particular coil of intestine, and especially the one with which we

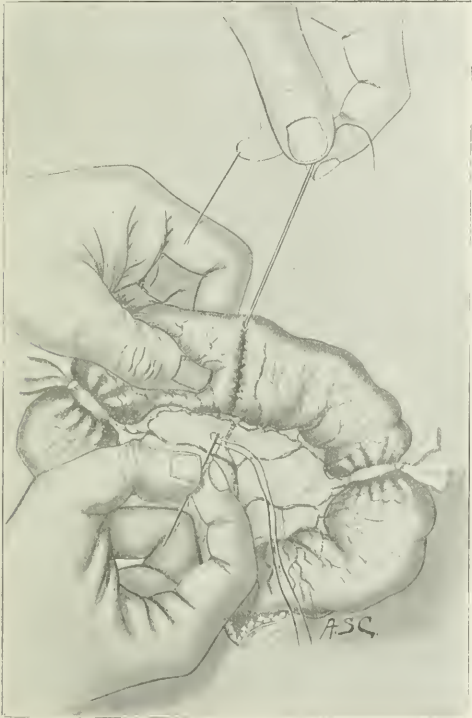

Plate 8.—The suture ends are held by an assistant, while the operator inserts the eye-end of a threaded needle between any two of the previously inserted sutures, preferably about opposite the point of emergence of the suture ends.

Plate 9.—The eye-end of threaded needle is made to emerge alongside of the suture ends, and is then withdrawn a little, which causes its thread to form a loop, through which the assistant passes the ends of the suture. The operator next withdraws the threaded needle, at the same time bringing with it the suture ends, and they present externally at the point of withdrawal of the needle. The serous coats throughout the entire circumference are now in apposition and the suture ends can be tied.

bowel was relieved in the manipulation at the time of the operation and also proved that the enterotomy would have been unnecessary if we had possessed a sure method of ascertaining that the obstruction had been overcome.

On June 1, 1900, I proceeded to restore the intestines as far as possible to their natural condition. The patient being anesthetized, the abdomen cleansed as carefully as possible, I inserted through the artificial anus into the caliber of the intestine in both directions, extending for about three inches, a packing strip of iodoform gauze. I then closed the artificial anus with a large pair of clamp forceps; the parts were then thoroughly disinfected, and I proceeded to open the abdomen by drawing a circular incision on either side

were seeking to deal. I finally accomplished a separation and was enabled to eliminate several inches of the diseased intestine above and below the artificial anus. After freeing their adhesions and packing around the intestines hot-gauze compresses, I brought out through the abdominal incision several inches of the intestine to be operated on, and clamped either arm above and below the incision, and behind the gauze packing previously placed in the intestine with suitable clamps for keeping the intestine closed during the procedure which followed. The clamp from the incision, and the gauze which was placed in the intestine, were removed and as thoroughly as possible the por-

tion of intestine to be excised was cleansed by pressure between the liberal gauze compresses. Next, the intestine was excised to the extent of two or three inches on each side of the opening which formed the artificial anus, removing in all about five inches of the gut. The intervening mesentery was tied in three sections. The end of the intestine representing the portion of the gut above the artificial anus was larger than the coil below that point. An oblique incision of the smaller one was made in order to increase the diameter of its free end. This was done at the expense of its convex border. An end-to-end anastomosis, after the method described by Dr. F. G. Connell, of Chicago, was then

between the approximated serous surfaces. This operation seems to me to have all the advantages of the Murphy button, with none of its serious faults. The abdomen was closed after dropping the intestine, and a small wick of iodoform gauze was left for drainage. The patient, after thorough stimulation, having received a pint of normal salt solution subcutaneously, was sent to bed. The actual time consumed in the anastomosis was between fifteen and twenty minutes, and was done with great deliberateness.

I have to thank Dr. Connell for his very kind assistance during the operation, and for his timely suggestions at different times. Dr. Connell informs me

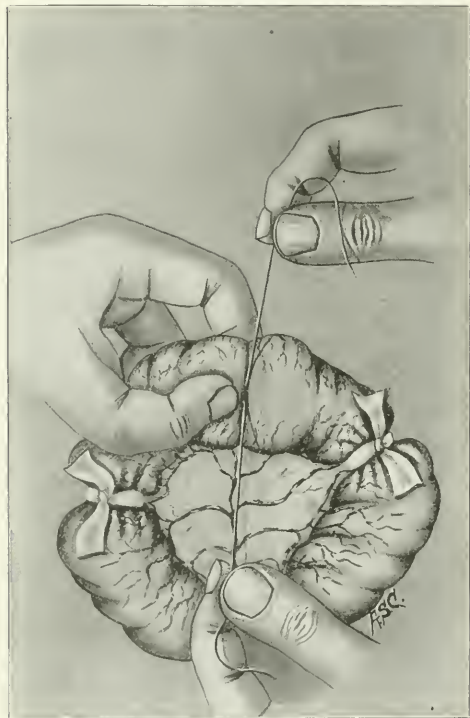

Plate 10.—By slight traction on the suture ends the opposing mucous surfaces are brought in close contact; the suture ends are then tied firmly, burying the knot deep between the serous coats, thus tying the knot upon the mucous coat and the ends then cut off short.

Plate 11.—The intestine, which has been flattened while tying the knot, is now relieved of pressure and allowed to assume its normal cylindrical contour, when the suture ends are seen to slip within the lumen; the enterorrhaphy complete, all knots inside, no stitches visible on the outside.

accomplished. This method is easier to execute than to describe, and I would suggest that the method be practiced on the dog, as while the method is somewhat difficult to understand from description, it is extremely easy to execute. The method consists of a modification of Maunsell's procedure, the original feature of importance being an ingenious method of tying the last suture in a way which effectually places all knots on the mucous surface of the bowel without the necessity of making the ordinary extra incision employed in Maunsell's operation. (See illustrations.)

When the operation is finished, the intestine has very much the appearance of one after an end-to-end anastomosis with the Murphy button. While the sutures included all coats of the bowels, no sutures were visible

that he has no record of the operation having been done before on a human patient. The operation has been done many times on the lower animals, almost uniformly with perfect results.

The following note of the subsequent history of this case is appended by my assistant, Dr. H. C. Cooney:

The patient was returned to her bed with normal temperature, pulse 128; respiration, 28. Subcutaneous transfusion of a pint of normal salt solution under each breast. No vomiting followed the anesthetic, the small gauze drain carried down to the sutured bowel was removed in forty-eight hours, and the provisional sutures were tied, which closed the abdominal incision entirely. Some flatus passed per rectum after twelve hours. No attempt was made to move the bowels for sixty hours, then a small stimulating enema of glycerin, magnesium

sulphate and water—one ounce each—was given under low pressure; this was repeated every twelve hours.

There was no nausea, and the abdomen was only moderately tympanic. Flatus was expelled with the return of the first enema and seventy-two hours after operation a normal bowel movement was obtained.

From this time on, her clinical history contains nothing of especial interest, as her convalescence was uninterrupted. She gained rapidly in strength, flesh and color.

A blood examination made June 20, five days before her departure from the hospital, showed: Hemoglobin 78 to 80 per cent.; red blood-corpuscles per cubic millimeter 3,910,000; leucocytes 8000 per cubic millimeter. Appetite was good, and bowels were regular.

RECEPTIVE QUIESCENCE OF THE STOMACH DURING MASTICATION.

GASTRONOMIC PHENOMENON NOT PREVIOUSLY DESCRIBED.
EVAN O'NEIL KANE, M.D.
KANE, PA.

The muscular coat of the stomach is inactive during mastication. This appeared clearly demonstrated as a physiological fact in a patient on whom I recently performed a gastrotomy. The patient was gradually starving from stricture of the esophagus due to a cancer at the cardiac orifice of the stomach. I operated in order to introduce food directly.

A large part of the posterior wall, as well as the cardiac extremity of the stomach, proved to be involved in the carcinomatous mass, thus greatly reducing the capacity of the viscus. Great difficulty was at first encountered in introducing more than a very small amount of fluid-food at a time, as it was promptly rejected through the peristalsis thus evoked. The question arose: How can a full meal be introduced and the retaining pad replaced over the opening before it can be regurgitated? The solution of the difficulty was arrived at by the very intelligent nurse, who observed that if the patient was chewing anything while being fed—for his appetite was ravenous and he fancied that he slightly appeased it by chewing morsels of food—his stomach would remain quiet, thus allowing her to fill it and secure the retaining pad before muscular activity recommenced. The difficulty with this additional mouth-feeding was that the patient could not be trusted not to swallow what he held in his mouth. This food, lodging in the dilated lower part of the gullet, decomposed and was with difficulty withdrawn. Chewing gum was substituted for food and no further trouble was encountered from this source.

If the state of receptive quiescence above described were a common physiologic phenomenon it would seem strange that no one has as yet observed it. It is possible, however, that in this case the greatly reduced internal capacity of the viscus made the muscular contractions more apparent than they would have been in other cases where gastrotomy has been performed.

Material for reflection is afforded if, as I presume, this condition which I have termed "receptive quiescence" is common in healthy as well as morbid conditions of the stomach. Thus, it would be suggested that mastication of an inert substance after meals might prove beneficial where the stomach is over-active, or prejudicial where there is atony.

Here, the chewing-gum habit should be considered. Again, we might thus explain the injurious effect on the stomach digestion of infants of permitting them

to retain the nipple in their mouths after nursing, or of letting mothers quiet their babies with a sugar-teat, or a "delight," as they call the mock nursing apparatus sold for quieting restless children. Seasickness, unless extreme, is often benefited and the tendency to vomit prevented as long as something is being chewed. How may we apply this principle to the vomiting of pregnancy? These women frequently find relief from chewing or sucking a lemon rind.

The beneficial influence of vinegar inhalations on the nausea following anesthesia may be due to the excitation of the salivary glands by the acid fumes.

I regret that I was unable to ascertain what effect mastication had on the gastric secretion.

[Mastication stimulates reflexly the salivary, gastric, and pancreatic glands. The liver is also stimulated, as shown by experiments, but this is not so conclusive as the stimulation of the stomach and pancreas.

The motor power of the stomach usually acts by the same stimulation that provokes secretion. The marked movements of the stomach, observed by Dr. Kane, were due to the action of the abdominal muscles and the diaphragm in the same manner as the muscles involved in vomiting, and chewing may have produced a condition that withdrew the stimulation from these muscles. This is especially proved in his illustration of vomiting, as vomiting is chiefly an extragastric muscular effort. The stomach muscles are too sluggish in their action to take much part in the act of vomiting. The anxiety and hunger of the patient might, and probably did, cause his abdominal muscles and the diaphragm to contract and expel the food from the contracted (small) stomach.—Ed.]

Prophylaxis Against Venereal Disease.—The International "Prophylaxis Congress" last year established a permanent committee for sanitary prophylaxis of venereal diseases and propagation of morality. The Belgian minister of state, Le Jeune, is president, Dr. Beco, vice-president and Dr. Dubois-Havenith, secretary. The aim of the committee is to found an international society for the study of the hygienic and moral questions which can serve in the prophylaxis of venereal diseases. The constitution and by-laws of the new society have already been formulated and the central committee is appointing national and state sub-committees. Physicians and all other persons who, by their writings, their occupation or their special knowledge are qualified for efficient co-operation, are invited to become members of the society. The annual dues are \$5. An official organ is to be published three times a year. The secretary, 19 rue du Gouvernement Provisoire, Brussels, Belgium, is glad to answer questions and receive suggestions at any time.

Can Valvular Lesions Be Cured?—Petrovitch has been studying for ten years the possibility of recovery from valvular lesions, carefully following all patients with endocarditis and organic affections of the heart. He stated at the International Medical Congress that in seven of these cases the mitral or aortic insufficiency had completely disappeared in ten months to three years after the commencement of the symptoms. They had persisted at least six months with the usual physical signs and functional symptoms of cardiac affections. Treatment was merely the prolonged administration of potassium iodid in small doses with intervals of repose and the application of dry cups to the precordial region. The *Progrès Médical* adds to its abstract of his communication that Rendu has observed two cases of recovery from valvular lesions and Potain one.

ETIOLOGY OF YELLOW FEVER.

Much controversy has been occasioned by the claim of Sanarelli and others that the bacillus *icteroides* is the causative agent of yellow fever. Surgeon-General Sternberg has persistently opposed Sanarelli's claims. Reference to this controversy has been made in these columns from time to time.¹ Reed and Carroll, of the U. S. Army, came to the conclusion that the bacillus *icteroides* is a variety of the bacillus of hog cholera. The commission of medical officers, United States Marine-Hospital Service, which studied yellow fever in Havana and elsewhere, reported favorably to Sanarelli, having succeeded in isolating the bacillus *icteroides* from all the cases of yellow fever studied in Havana. This commission also claimed to have discovered the manner of primary infection, namely, through the respiratory tract, but this claim did not meet with general favor among bacteriologists, as the evidence presented hardly seemed sufficient to justify the statements of the commission.

And now Surgeon Reed and his associates present a preliminary report of their investigations into the etiology of yellow fever in Cuba during the past summer.² The failure to find the bacillus *icteroides* in the blood during the life of yellow-fever patients, as well as the failure to obtain it from the blood and the organs of yellow-fever cadavers, admit of no other reasonable interpretation than that this much-exploited organism is not the cause of yellow fever, but at the most a secondary invader, when present.

But Finlay's theory of the propagation of yellow fever by mosquitoes receives experimental support. Mosquitoes—*Culex fasciatus* Fabr.—that had bitten yellow-fever patients were allowed to bite non-immune persons, and of eleven thus inoculated two developed yellow fever within the usual period of incubation and under circumstances that were not favorable for infection from other sources. One of these patients was Dr. James Carroll, acting assistant-surgeon, United States Army, and one of Dr. Reed's co-workers, who thus passes into history as another example of unselfish devotion to the cause of humanity. No less honor is due the young American who serves as the subject of the second experiment, as well as the other nine persons that escaped

the disease though bitten under the same circumstances. It also appears that the late Dr. Jesse W. Lazear probably acquired the fatal disease—yellow fever—through accidental infection by a mosquito, but under such conditions that the manner of his death becomes heroic. These observations are surely destined to excite renewed interest in the mosquito as the intermediate host of yellow fever. The facts at hand accord well with the observations of Henry R. Carter in regard to the period between the introduction of the first case and the development of secondary cases of yellow fever.

THE RECOGNITION OF FUNCTIONAL INSUFFICIENCY
OF THE KIDNEYS.

Scarcely less important than the recognition of organic disease is an appreciation of the degree of functional derangement present. Some attempts in the determination of the latter have been attended with success, and the kidneys, by reason of the opportunities for comparison they offer, would seem to be especially suitable for this means of study. The information thus gained would be useful from both the prognostic and the therapeutic point of view. Two questions will at once arise: 1. What is the functional efficiency of the kidneys; and is it sufficient for the purposes of the organism? 2. What part does each kidney take in this function? The desired information may be gained by catheterizing the ureters, which will permit not only a study of the microscopic and chemico-constitution of the urine, but also an estimate of the functional activity of each kidney. Caspar and Richter¹ report the results of a large number of observations made in this connection in the course of two years. It was found that under normal conditions, healthy kidneys excreted simultaneously, during a period of from thirty to sixty minutes, almost exactly the same amounts of solids, as determined by the molecular concentration of the urine. In the presence of disease of one kidney—tumor, calculus, pyelonephritis, pyonephrosis—the elimination of urea was almost invariably less on the affected, as compared with the healthy, side. When both kidneys were diseased, as indicated by microscopic and chemico examination of the urine from each, this difference was reduced in greater or lesser degree. In this way it is possible to determine with approximate certainty the respective share taken by each kidney in their total functional activity, as measured by the amounts of urea eliminated and the molecular concentration of the urine.

Efforts were made further to estimate the degree of functional sufficiency of each kidney, and for this purpose phloridzin was administered, with the development of glycosuria. It was found that healthy kidneys, after subcutaneous injection of phloridzin, excreted the same amount of sugar in the course of from thirty to sixty minutes, while a diseased kidney excreted distinctly less sugar than a healthy kidney. In the presence of

1. Berliner klin. Wochensh., 1900, No. 29, p. 643.

marked disease of the kidney involving a large part of the parenchyma—neoplasm, pyonephrosis, severe nephritis—the elimination of sugar may be minimal or wholly abolished. The onset and cessation of the glycosuria may be different in diseased than in healthy kidneys. When both kidneys were diseased, the differences disappeared, as they do with regard to the elimination of urea. As a rule, the elimination of sugar is slight or absent on both sides. With a few exceptions, the degree of glycosuria, of urea-elimination, and the molecular concentration of the urine, pursue parallel lines. While, therefore, the coincidence of these three indicators is important, viewed separately, the phloridzin test appears to be the most delicate reagent for the determination of the degree of renal activity.

THE DANGERS OF LUMBAR PUNCTURE.

In a critical summary of the literature on the diagnostic and therapeutic value of lumbar puncture, Alfred Hand¹ reaches the conclusions that lumbar puncture has a wider field as a diagnostic aid than as a therapeutic measure. As so often is the case it is not safe to draw conclusions when the examination of the fluid withdrawn gives negative results—positive results only are of decisive import. Lumbar puncture is of therapeutic value in cerebrospinal meningitis—the withdrawal of fluid promotes recovery; in tuberculous meningitis it gives comfort; and in other forms of excessive pressure it may remove conditions immediately threatening to life. Nothing is said of the dangers of this procedure, the technique of which is so simple: the introduction of a needle, under conditions of surgical cleanliness, “between the third and fourth lumbar vertebrae, 5 to 10 mm. to one side of the median line, the direction of the needle being slightly toward the median line, and in older children and in adults, slightly upward.” The sense of touch will tell when the cavity is reached. In children 2 cm., in adults 4 to 6 cm. are the depths ordinarily required.

Gumprecht² considers the dangers of lumbar puncture. On the whole the dangers are small. There seems to be no record of infection of the meninges following puncture. The needle may break, owing to muscular contractions in restless patients. Gumprecht mentions an instance of this, but fortunately the loose fragment was easily removed. Perfect quiet should be secured during the little operation, as movement may bend the needle against the vertebral arches. Sudden and profuse escape of cerebrospinal fluid rarely does harm; it may be guarded against by placing the finger over the canula. The headache that so often follows puncture is generally evanescent; in exceptional cases spinal pains and staggering have been noted on the second day. Sudden death may follow withdrawal of cerebrospinal fluid through lumbar puncture. There are 17 recorded instances in which this has happened.

In some cases this may have been a coincidence. In practically all cases it concerned instances of cerebral tumors, especially in the posterior fossa. Symptoms of increased intracranial pressure were present. In these cases the fatal issue is caused almost without exception from paralysis of respiration. After death the ventricles above the tumor have been found greatly dilated; below, the spaces were narrow or but moderately distended, because of pressure on the aqueduct or on the foramen of Magendie. Probably the disturbance of the hydrostatic equilibrium caused by withdrawal of the cerebrospinal fluid is the cause of the paralysis of the respiratory center. There are a number of observations recorded by high authorities to the effect that respiratory paralysis is the mode of death in many intracranial affections associated with increased pressure. Macewen records a remarkable case³ of cerebral disease in which life was maintained by artificial respiration for twenty-four hours. In a second case—cerebral abscess—he opened the skull of a moribund patient during artificial respiration and accomplished a temporary improvement. Trepanation has been proposed by Sir Dyce Duckworth as a therapeutic measure in respiratory paralysis from increased pressure within the skull, and Gumprecht now suggests its employment in cases of paralysis of breathing following spinal puncture.

There is, therefore, but little or no evidence that spinal puncture is of itself a dangerous procedure. In cerebral tumor it should probably not be used; at all events the possible danger of its use in such cases should be clearly understood.

A NEW PATHOGENIC MOLD.

Recently two reports have emanated from San Francisco of a peculiar disease caused by a fungus. Ophüls and Moffitt,¹ in their preliminary report, describe an irregularly febrile disease in a young man of 19, from the Azores. There was abundant exudation in the left pleural cavity and successive painful inflammations of various joints and other regions, irregular consolidations in the lungs, and leucocytosis. The clinical diagnosis was septicopyemia. The autopsy showed pneumonic infiltrations with abscesses, abscesses in the diaphragm, miliary abscesses and nodules in the kidneys and the liver, purulent inflammation of the frontal bone, the tibia, and various joints, with necroses in the regional lymph-glands. In all the diseased foci examined there were found encapsulated quite large organisms, whose protoplasm breaks up into numerous spore-like bodies. In addition to chronic suppuration, the organisms induce the formation of granulation tissue with giant cells often enclosing one or more parasites. In cultures a distinct mycelium developed. Inoculations of material from the lungs of the patient produced suppuration and formation of nodules in guinea-pigs, and from these

2. Deut. med. Wochenschr., 1900, June 14.

3. Oeoid. Med. Times, 1896 (Quoted by Gumprecht).
1. Phila. Med. Jour., June 30, 1900, p. 1471.

lesions the same organism was obtained in pure culture. The development of mycelium from the round bodies was followed in the hanging-drop cultures; repeated examination showed that mycelium develops only from organisms free in culture-medium. Mycelium inoculated into a rabbit produced nodules containing the round bodies; hence it is concluded that the round bodies and the mycelium are developmental stages in the same fungus. Typical spheres probably do not develop on artificial media. The development of spheres from mycelium in the bodies of animals remains to be studied.

The second case is reported by D. W. Montgomery.² It concerns a man of 21 who had lived in various parts of California since infancy. Here there were nodular ulcerations in the skin over various parts of the body, resembling somewhat mycosis fungoides, and other efflorescences; large subcutaneous abscesses, which communicated with the right lung and pleural cavity; there were other smaller abscesses in this lung and an immense abscess in the right lobe of the liver. In the pus and in the cutaneous abscesses coccidia-like bodies were present in large numbers. Here also the granulation tissue contained giant cells enclosing organisms. Endogenous spore formation was observed. Inoculation into a rabbit failed; cultures yielded a filamentous mold, which unfortunately was not further studied.

Similar cases are described by Wernicke, Gilchrist and Rixford (two cases), and Posadas. These authors failed in their culture and inoculation experiments and regarded the disease as of protozoan origin on account of the similarity of the bodies present to certain protozoa. So far, the disease has occurred only in men: three cases were in Portuguese from the Azores.

In all cases so far recorded the disease has marched steadily on to fatal determination regardless of treatment. In Ophüls and Moffitt's case the peculiar skin lesion was absent. Future investigations are sure to clear up many obscure places in the natural history of this interesting malady, which as yet has not received any distinctive name.

THE ROMAN MALARIA EXPERIMENT.

The experiment of a residence in the most malarious region of the Roman Campagna, using only protection against mosquito bites to ward off the fever, has been a complete success. So far as such a practical test can go, it demonstrates the mosquito theory, which already has been fairly proved in other ways. There are still some who hold to the water-borne theory of malaria, but if there is any basis for such theory it has not been proved on the Campagna, because the same water that was drunk by the malaria afflicted natives was used by the experimenters. The Roman anopheles is apparently only a nocturnal biter, and this is the only weak point in the experiment. If this were the case with all mosquitoes it would be possible for persons to live in every malarial region, but it will probably be found that in some parts

the malaria-bearing insects ravage also during the day and must then be protected against as well. If, as reported, Koch has discovered a certain method of prevention in his New Guinea experiences, it will open parts of the world to civilization that have heretofore been thought hopelessly unhealthy for the white race. It is well, however, to reserve our enthusiasm for the present, though the success of the Roman experiment is a decided step toward the practical prophylaxis of malaria.

THE FEMALE ATHLETE.

Women are not usually supposed to excel in athletics, but it appears that a woman has lowered the world's record in long-distance bicycling and yet not done her utmost. After completing her 2000th mile, she had excelled the best male performance in century-riding by several hours, and was ready to keep on when the local authorities interfered. Why they did so is not manifest, as according to newspaper reports, she was taking things easy and only riding to fill out the time. This is evidence that civilized woman is occasionally in some respects physically equal to her more rugged competitors, a fact that rather goes against our preconceived notions based on the average performances of her sex. Nevertheless, this and other such achievements implying continued endurance are not so incompatible with femininity as it at first appears. The average frail-appearing mother can stand the strain of carrying about a heavy child far better than most men, and it has repeatedly happened that delicate women have exceeded men in passive endurance in conditions of special stress and hardship. Among savages it is known that females have habitually the hard manual labor to perform, but the above-mentioned feat of Miss Gast is noteworthy as showing what civilized women can do in athletics when she chooses. It is evident that the civilized female is not necessarily a physical degenerate, at least as regards muscular strength and endurance. While the profitability, or even the propriety, of such performances is somewhat questionable, the results are sometimes, as in the present instance, worthy of note.

PHYSICIANS' INFLUENCE FELT.

At the last session of the Iowa legislature, a certain prominent senator was notably the champion of osteopathy, and succeeded, in spite of opposition, in obtaining its legal recognition. His political ambitions have since expanded and he was recently a prominent candidate of his party for a congressional nomination. Notwithstanding the excellent prospects in his canvass he failed, and the cause of this, according to the *Iowa Medical Journal*, was the opposition of the medical profession, which was combined against him on account of his legislative record. Though in this case perhaps only the empty honor of a nomination was lost, it is satisfactory to know that one advocate of quackery had his aspirations quenched by medical influence, which might oftener be employed in this way for the public good. As the editor of the *Iowa Medical Journal* says: "The friends of the general practitioner are numbered by hundreds, yes by thousands, and that same influence can be exerted for other things that he exerts in his

every-day life. There is no class of men that have as many friends and acquaintances hanging on their words and opinions as the physician; it only remains for him to use this influence with his member in the legislature to bring about a better class of legislation." When legislators are made to recognize the influence of the medical profession unselfishly exerted in favor of right objects they will be less ready to follow the dictation of quacks than they seem too often to be at present. That influence can be exercised when the profession is organized.

MEDICAL MEN IN POLITICS.

There appear to be but two men in the present national Congress who can or care to represent themselves as physicians. It seems strange that a profession so close to the people and representing such an aggregate of culture should furnish hardly the half of 1 per cent. of our lawmakers, while the other learned secular profession, the law, furnishes over nine-tenths of the total number. It is not because there is no need for their services in that capacity; there are ample opportunities for the utilization of medical knowledge in our legislative halls. No other country with legislative government, so far as known, so practically excludes the medical profession from its law-making bodies, and it has not always been the case with us. THE JOURNAL has more than once called attention to the fact that medical men took a prominent part in the First Continental Congress, and some of the names we delight to honor on the Declaration of Independence were those of physicians. There is no good reason why they should not still have their representation in Congress for the good of the country. It is true that traditions have grown up that politics and medicine should be things apart, but there is no real force in them and no reason whatever why a good physician can not be a good legislator. We are now proving that the physician can be the best of military governors, and there is no public office, not even excepting the highest, that could not be worthily filled by medical men now living. It would be to the credit of many constituencies could they be represented by men educated to the ethical standards of the medical profession rather than those of the practical politics in vogue.

DIPLOMA-MILL ARMSTRONG INDICTED.

A federal grand jury has indicted the notorious James Armstrong of "Independent-Metropolitan, etc." medical college fame with two of his associates, for improper use of the mails. While this shows that these impostors can be reached by the United States law at present probably more effectively than by existing State laws, it ought not to suggest any relaxation of efforts to make the latter more efficient. Illinois owes it to herself to see that her good name does not suffer further from the operations of such frauds, and a law like the one proposed at the last session of the legislature would best strike the evil at its root. If present laws were supplemented by one providing that no institution with less than a legally specified minimum endowment and a thorough equipment for teaching all branches of modern medical science, including clinical facilities, together with an efficient and genuine curriculum, could confer medical

degrees, there would be far less chance for Armstrong and others like him to carry on their nefarious occupation. At present it is possible to enjoin them by chancery proceedings, subject to all the law's delays, but there is no prevention of their immediate reorganization and no personal penalty except such as may be inflicted for violation of the federal laws. While the Metropolitan or any other similar concern is being enjoined it can immediately reorganize under a new name and, so long as the attorney-general's attention is not called to its performances, keep on sending out its prospectuses, and so on ad infinitum. To many people all diplomas look alike and so long as a diploma is anywhere either legally or popularly held to be a qualification to practice there will be a field for these impostors. The real remedy will be to invalidate them at their inception.

INSANITY IN LEAD-WORKERS.

Increasing knowledge of the deleterious effects induced by the toxic products of bacterial activity has contributed in no small degree to enlargement of our conceptions of the influences exerted by toxic substances of other origin—organic and inorganic, generated within the body or introduced from without. To all of these, as to all stimulation and irritation, the nervous system is especially sensitive, and it responds variously to different poisons. The commonest form of industrial poisoning is that of lead, and neuritis is the lesion to which this most often gives rise. Although saturnine encephalopathy was described by Tanquerel in 1836, the references to the subject since that time have not been at all numerous. In a paper read before the Section of Psychology at the recent meeting of the British Medical Association, Jones¹ reported 133 cases of various forms of insanity occurring among artisans in various pursuits entailing exposure to the risk of lead-poisoning and received into the London County Asylum. The following occupations were represented: painters, 75; plumbers, 18; decorators and gasfitters, each 13; laborers in lead-works, 6; grainers, 3; gas-meter makers, 2; and 1 color-grinder, file-cutter, and tea-lead roller each. Of this number, 19 exhibited signs of lead-poisoning on admission and 22 others gave a distinct history of that condition at some time or other. The different varieties of mental disease exhibited were as follows: Mania, 37; melancholia, 33; dementia with general paralysis, 24; dementia, 19; dementia with epilepsy, 10; general paralysis (?), 7; alcoholic mania, 3. Recovery took place in 9—47.3 per cent.—of the 19 cases in which definite symptoms of lead-poisoning were present. A careful study of the whole number of cases would make it appear that lead-poisoning is a contributory factor in the causation of insanity and that in lead-workers there is a higher average of general paralytisms than in others of the population. The cases exhibited a tendency to cardiac, renal and arterial degeneration, with complications due to syncope or epileptiform attacks. Most of the cases presented marked signs of anemia and ill health, with unsteadiness of gait and general impairment of muscular strength, and frequently a history of temporary failure of vision.

1. Brit. Med. Jour., Sept. 22, 1900, p. 794.

The mental symptoms observed may be grouped among one or the other of the following varieties: 1, those in the nature of toxemia with sensory disturbances, and which tend rapidly to get well; 2, those with hallucinations of sight and hearing, more chronic in their nature and which may be beyond recovery; the delusions of this class are almost invariably those of being poisoned or followed about, and are in the main persecutory; 3, those resembling general paralysis, with tremors, increased knee-jerks, inco-ordination and accompanied by listlessness amounting to profound dementia, but which tend to get well. It is believed that in most lead-cases presenting mental symptoms the tendency is to recovery, unless the patient dies early.

THE SECTION ON STOMATOLOGY.

Nearly twenty years have passed since the AMERICAN MEDICAL ASSOCIATION created a Section on Dental and Oral Surgery, now the Section on Stomatology. Since its beginning, this section has made admittedly valuable contributions to stomatology and has exerted a wide influence in elevating the dental branch of the medical profession. While dentistry, or stomatology as it is now more appropriately termed, was a very old branch of medicine, still, as the oath of Hippocrates shows, lithotomy was the earliest specialty to separate from the medical profession. Dentistry, however, during the last three centuries, had become a simple mechanical occupation practiced by blacksmiths, traveling quacks, barbers and "wise women." As many of the men, educated as barber-surgeons, like Ambrose Paré, advanced themselves and the science of surgery by their skill and study, so many of the men trained only in the mechanical part of dentistry in its limited sense did much to elevate oral and dental surgery. The feeling had grown, even among men educated in mechanical dentistry or at dental colleges alone, that a medical education is as needful to the stomatologist as to other specialists in medicine. To this feeling the work of the Section on Stomatology has given a great impetus. It is obvious from the proceedings of the Section for 1900, which has just been republished in book form, that the strongest possible reasons exist for this feeling. The discussions on dental education and the relationship of dental and oral surgery indicate that the work of the Section has developed a wide-spread interest among dentists and physicians as to their mutual relations. The views advanced by Dr. N. S. Davis more than 40 years ago seem about to be realized. The same trend is shown in the discussion of interstitial gingivitis from the constitutional, pathologic and prophylactic standpoint in lieu of the simple therapeutic or operative. One reason for the successful work of this Section is, that its secretary has been the same for fifteen years, and has thereby been able to keep in touch not only with the current questions of the day but with the most prominent practitioners of stomatology and their researches. The Section has eminently deserved the praise of being, in the best sense of the term, practical.

Electric Attraction of Dew.—Some recent experiments seem to indicate that electric attraction has something to do with the collection of dew and hence with the water supply. Much more dew collected in basins connected with the ground by a conductor than in similar basins completely insulated.

Medical News.

CALIFORNIA.

THE BERKELEY HOSPITAL directors have selected a site for the new building and hope to be able to receive patients before the end of the year.

A SITE has been offered the San Francisco Board of Health for a pest-house, consisting of a three-acre isolated tract on the bay shore in South San Francisco.

THE LOMA LINDA ASSOCIATION has been incorporated with a capital stock of \$200,000, to build and operate a sanatorium at Mound City, five miles south of San Bernardino.

THE FRESNO COUNTY HOSPITAL was burned to the ground October 18. Fortunately all the inmates were removed in safety. The loss was \$80,000, insured for \$27,500.

THE OAKLAND COLLEGE OF MEDICINE AND SURGERY filed its incorporation papers October 19. The incorporators are Drs. Frank L. Adams, Carl R. Krone, Dennis D. Crowley and Hayward G. Thomas, Oakland, and Joseph S. Eastman, Berkeley. The decision in the Garelon will case, announced in THE JOURNAL last week, has brought this matter to a head, and the college will probably be ready in January, long before the hospital will be built.

ILLINOIS.

THE WILL of the late Jacob Fromm, Moline, which was probated October 18, bequeaths land valued at \$3000 to the city hospital.

Chicago.

NORTHWESTERN UNIVERSITY WOMAN'S MEDICAL SCHOOL has opened with a large freshman class.

"TRUE BILLS" were found by the federal grand jury, October 25, against "James Armstrong, Thomas Armstrong and John H. Randall, officials of the Metropolitan Medical College, known as a 'diploma mill,' charged with using the mails to defraud." They are said to have defrauded the following men by selling them worthless diplomas: D. M. Mott, Fairplain, Pa.; Joseph De Barthe, Baker City, Ore., and H. Almstedt, St. Charles, Mo. The accused are at liberty under bonds.

INDIANA.

DR. W. R. PAGE, formerly of Middlebury, who has been in charge of the medical department of the Mennonite missions at Dhambari, India, has returned home to recuperate.

THE LOGANSPORT board of health rescinded, on October 19, the order for general vaccination of pupils and teachers of schools, as it considers that the danger from smallpox has passed.

MADISON COUNTY, during the quarter ended September 30, had 50 cases of typhoid fever, 25 of diphtheria, 39 of scarlatina, 20 of measles, 24 of smallpox, 3 of cerebrospinal fever, and only 1 of phthisis.

DR. MAVITY J. SPENCER, Indianapolis, has been appointed superintendent of the city hospital, vice Dr. Charles H. C. Poucher, resigned. Dr. John F. Benham succeeds Dr. Spencer as superintendent of the city dispensary, and Dr. Ernest C. Reyer takes Dr. Benham's place on the board of health.

MICHIGAN.

NOTICE. Having received complaint from several Detroit physicians that one Frank B. Kenneth is claiming that he is authorized to solicit and make collections for THE JOURNAL, we desire to state that this person is not connected in any way with this publication. At one time he was authorized to solicit subscriptions, but never to make collections.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION has decided to disband and to join the Detroit Medical Society.

THE SECRETARY of the State Board of Health has called attention to the necessity of a law which shall vest in some competent authority the power to determine what diseases are dangerous and communicable within the meaning of the health laws of the state.

THE DETROIT MEDICAL SOCIETY, which embraces in its membership physicians residing in Wayne County, at its October 24 meeting appointed a committee consisting of Drs. J. Henry Carstens, David Inglis and Louis J. Goux to study the plan of the contemplated reorganization of the Michigan State Medical Society.

THE CONSIDERABLY DISCUSSED physicians' business association had its preliminary meeting for the organization in Detroit, October 29. Several modifications were made in the previously published plan. The word "business" was left out of the title of the organization, the black-listing feature was abolished, as

were also the fines for non-attendance at meetings. As it now stands, according to reports, the designation of the association is "The Physicians' Association of Detroit," and its organization is purely on professional and ethical lines.

NEW JERSEY.

THE GRAHAM MEMORIAL operating pavilion of the general hospital, Paterson, the gift of Mrs. John Graham, New York, in memory of her husband, was thrown open to public inspection October 18.

THE JERSEY CITY BOARD OF HEALTH has decided to hold systematic inspections of all school children in order to guard against the spread of infectious disease. Six local physicians have been assigned to this duty.

NEW YORK.

THE FLUSHING HOSPITAL is again in financial distress, and has issued an appeal for \$5000 which, it thinks, the 13,000 people living tributary to it should raise.

THE SUPREME COURT, Appellate division, first department, has decided, in the case of Helen D. Ward vs. the St. Vincent's Hospital, in the city of New York, that "a charitable hospital corporation is liable to a 'pay' patient for personal injuries sustained through the negligence of a nurse, it having agreed to provide proper care and attendance."

Buffalo.

DR. HARRY MEAD has returned from Europe.

DR. P. W. VAN PEYMA has returned from a three-months trip to Europe.

DR. JOHN H. GRANT has been appointed assistant commissioner of agriculture for the Ninth Division.

DR. NELSON G. RUSSELL, as the result of a competitive examination, has been appointed city district physician, to succeed the late Dr. George W. Lewis.

A NUMBER of rooms at the Service Building of the Pan-American Exposition have been utilized as temporary quarters for the medical department of the Exposition. Each day a number of emergency cases occur in the army of 3000 workmen, which require the attention of the surgeon, Dr. Victor Kenerson.

New York City.

DR. J. RIDDLE GOFFE has returned from his European trip.

BY THE explosion of chemicals and fire in the Tarrant Building at Greenwich and Warren streets, October 29, the M. J. Breitenbach Company and other pharmaceutical houses suffered to a considerable extent.

THE ANNUAL REPORT of the New York Eye and Ear Infirmary for the year just closed shows that 30,878 new cases were treated in the eye department and 9710 in the ear and 7000 in the throat departments. There were 2257 patients cared for in the hospital wards. The institution now has a pavilion for the reception of cases of contagious ophthalmia.

THE COMMITTEE having in charge the selection of a suitable site for the new State Hospital for Tuberculosis has again looked into the Dannemora site. The chief objections mentioned were the inaccessibility of this place, and the unpleasant connection of the name of the place with the state prison. The Chateaugay Railroad Company thereupon offered to extend their railroad to the hospital grounds, and, if need be, to build a separate station on the grounds, the committee being allowed to select the name for this station.

DR. WILLIAM T. JENKINS, health commissioner, has just returned from a tour of inspection abroad. His object was to study methods employed in British cities for the disposal of garbage, but he embraced the opportunity to go to the plague hospital at Glasgow and see the eighteen cases of bubonic plague there under treatment. He described them as having the anxious face seen in typhus fever. He was favorably impressed with the results obtained with Haffkine's serum, so much so that he procured a dozen bottles for use at this port should the emergency arise. All physicians attached to the Glasgow hospital use the serum on themselves for self-protection, but the injection of the serum leaves them with very stiff and swollen arms.

OHIO.

DR. C. W. TANGEMAN has been elected professor of ophthalmology in the Cincinnati College of Medicine and Surgery.

THE SCHOOL COUNCIL of Cleveland has tabled the resolution calling for the appointment of three medical inspectors of schools on account of scarcity of funds.

THE EMERGENCY HOSPITAL at the Columbus city prison has been completed, inspected and accepted by the city. It contains six wards, operating-room and store-room.

On October 10 the semi-annual change of internes to the Cincinnati Hospital took place. Of the out-going staff Drs. Wylie

Aytes and Allan Brankamp leave for study in Europe. Drs. Frank Lamb, Albert Gustetter, F. C. Vogen and O.P. Coe were installed as junior internes.

PENNSYLVANIA.

DR. HARRY W. DECHERT, Tamaqua, for five years medical examiner of the Philadelphia and Reading Relief Association, has resigned.

THE CHESTER HOSPITAL reorganized its staff at a meeting, October 12, at which Dr. J. L. Forwood was elected president; Dr. Robert S. Maison, secretary; Drs. J. L. Forwood, F. Farwell Long, Samuel R. Crothers, F. Otis Bryant, and Robert S. Maison, on the surgical staff, and Drs. Hannah J. Price, Ellen E. Brown, W. Knowles Evans, Ellis M. Harvey, and Harry Horning, on the medical staff.

October 21 the Philadelphia *Press* again began an attack on the State Medical Examining Board and the methods pursued by that body. The paper claimed that it sent a representative to Harrisburg to look over the examination papers of the men who had gone before the board at its meeting in June, and the results of this inspection had shown that, although certain of the men had not obtained the necessary general average (75) at the examination, their marks were afterward carried up or were "padded" and that these men were afterward given certificates to practice medicine. It also claims that at the examination, 23 per cent. of the men had failed to attain the general average of 75, but according to the report of the board filed six weeks later, only 13 per cent. had failed. This paper, in its editorial columns charges that this result has been brought about by pressure exerted by relatives and friends of the applicants. The next semi-annual meeting of the board will be held in December, when action will be taken on the charges.

Philadelphia.

LAST WEEK, 3 new cases of smallpox were reported to the board of health, all of these cases occurring among white people. They are being cared for at the municipal hospital.

A *RUST* by John J. Boyle, of this city, of Dr. George B. Wood, formerly professor of practice of medicine, and trustee in the University of Pennsylvania, has been bought and will be placed in the library building.

DR. JAMES M. ANDERS entertained Dr. Maurice H. Richardson, of the Harvard Medical School, at a dinner given at the Union League Club on October 26. Afterward Dr. Richardson attended a reception given in his honor by the Philadelphia Medical Club.

DIPHTHERIA has greatly increased since the opening of the public schools in September. The board of health decided not to close the schools, but the buildings will be thoroughly cleansed. A study of the statistics shows a rapid increase in the number of cases of this disease. Thus, for the week ended August 25 there were only 38 cases, for that ended September 8, there were 94 cases; September 22, 102 cases; October 20, 110 cases. Scarlet fever has also increased. For the week ended September 15, there were 13 cases, but in one week of October 30 cases were reported.

TENNESSEE.

THE CHATTANOOGA MEDICAL COLLEGE opened for its twelfth annual session, October 10.

THE TENNESSEE MEDICAL COLLEGE opened on October 9 for its annual session.

THE MEDICAL DEPARTMENT of Knoxville College has been discontinued, and its students will be transferred to Meharry Medical College, Nashville.

DR. THOMAS W. GALLION, who has practiced in Dandridge for twenty years, will soon leave for the west. He will be succeeded by his brother-in-law and former student, Dr. Samuel W. Fain, of Chattanooga.

AS A RESULT of the investigations of the State Board of Health, an order has been issued by the board whereby Maury County, where smallpox has been found and where proper precautions against its spread had not been enforced, has been quarantined until further notice.

TEXAS.

DR. MORTON, who lost heavily in the recent Galveston disaster, has located in El Paso.

QUARANTINE is still maintained at El Paso against bubonic plague in San Francisco. To enter Texas, one must have been away from San Francisco for fifteen days. Many passengers are turned back at the state line.

A COMMITTEE of the El Paso County Medical Society has been appointed to invite the members of the regular medical profession of Texas, New Mexico, Arizona and Mexico to meet

in El Paso, Jan. 17, 1901, for the purpose of organizing a tri-state or territorial medical association.

THE TRUSTEES of the medical department of the University of Dallas have elected the following faculty: President, Dr. J. Edward Gilcreest, Gainesville, gynecology; vice-president, Dr. Berthold E. Hadra, Waco, surgery; Dr. Samuel H. Stout, obstetrics; Dr. Samuel E. Milliken, surgery; Dr. Joseph D. Beckton, Greenville, physiology; Dr. Lawrence Ashton, principles and practice of medicine; Dr. Egbert Dunlap, materia medica and therapeutics; Dr. Vene P. Armstrong, diseases of women; Dr. A. F. Beddoe, diseases of children; Dr. Charles M. Rosser, mental and nervous diseases and clinical medicine; Dr. David Davidson, New York City, pathology and histology, and Dr. Jesse B. Titterington, anatomy and diseases of the eye, ear, nose and throat.

UTAH.

THE BOARD OF HEALTH of Salt Lake City has passed a rule requiring physicians to report cases of chickenpox and measles, and quarantining such cases.

THE DEATH-RATE of Salt Lake City for September was 13 per 1000 per annum. The deaths were 58 and the births 114. During the month, 21 cases of smallpox, 17 of scarlet fever, and 32 of typhoid fever were reported.

DR. THEODORE B. BEATY, secretary of the State Board of Health has lodged two complaints against Dr. Wiley E. Ferreebe, Murray, charging him with violating the quarantine laws by failing to report two cases of smallpox to the local health officer. Dr. Ferreebe states that in accordance with instructions from the county physician, he reported the cases to him.

WASHINGTON.

DR. HAMILTON STILLSON, Seattle, has returned from a five-months' tour of Europe.

SEATTLE reports for September a death-rate of only 6.6 per 1000 per annum. There was a marked decrease in the number of cases of communicable diseases during the month.

THE DEACONESSES' HOSPITAL, Seattle, will be opened early this month. It is a substantial four-story building, erected at a cost of \$35,000, and will be equipped according to modern methods.

OUT OF 55 candidates who took the state examination in July, 50 have been granted license to practice, which demonstrates either that the examination was easy or that the candidates possessed talents of an unusually high order.

WISCONSIN.

DR. STEPHEN S. STACK returned to Milwaukee after a five-months' stay in Europe, and assumed charge of the Sacred Heart Sanatorium on November 1.

LICENSES for 62 physicians in various parts of the state were granted by the State Board of Medical Examiners, October 10.

THE OSTEOPATH who was charged with violating the law by using the title of doctor and practicing medicine without a license, was found guilty by Justice Neelen, of Milwaukee, October 20, and fined \$50 and costs.

PECULIAR PROVISIONS of the will of the late John Plankinton, Milwaukee, whereby the reversion to the Milwaukee Hospital is made terminable on Miss Elizabeth Plankinton's reaching the age of 55, will probably result in that institution being deprived of several million dollars, as Miss Plankinton is nearing that age and is in good health.

GENERAL.

SURGEON W. H. RUSH, U. S. Navy, who was ordered before a retiring board, has been found disqualified for further service and has been retired.

THE ANNUAL MEETING of the Southern Medical College Association will take place in Atlanta, Ga., on November 13, at the Kimball House. The meeting will be called to order at 10 a. m.

THE JOSIAH SIMPSON HOSPITAL, comprising 37 buildings at Old Point Comfort, Va., in which more than 2000 sick and wounded were cared for during the Spanish-American war, has been sold at public auction.

CONTRACT SURGEONS in the army, or acting assistant-surgeons with the honorary rank of first lieutenant, have been decided by the comptroller of the treasury to be neither officers nor enlisted men, and hence not entitled to the 10 per cent. increase in pay provided under the law of May 26.

DR. WOODS HURCHINSON, Buffalo, who has been in England for several years, has gone to Oregon to recuperate. He was threatened with nervous exhaustion and his medical friends insisted on his giving up work for the present. He will probably remain in Oregon during the winter, returning to Buffalo next summer.

THE VITAL STATISTICS of the Sisseton and Wabpeton Sioux Indians emphasize the fact that civilization has its compensatory disadvantages in the case of aborigines. During the last year 56 deaths occurred in the combined bands, which numbers 1900 individuals. This means an annual death-rate of nearly 30 per 1000. It is reported that 90 per cent. of the deaths occur from consumption.

A FILIPINO LAD, Arturo Midel, son of the native president of Zamboango, has been sent to this country to be educated. He expects after his school work is done, to take a "thorough course in medicine and surgery and return to dispense medicine and perform operations among his people." The reason of the quotation will be apparent when it is understood that this embryo doctor is now only 10 years old.

THE *American Journal of Nursing* is a handsome new publication issued by J. B. Lippincott & Co., and under the editorial charge of Mrs. Sophia F. Palmer and an ample staff of assistants. It will be the organ of the trained nurses of the United States. The first number contains, together with contributed articles, a large amount of news items and editorial notes and comments, besides a report of the proceedings of the Third Annual Convention of the Associated Alumni of Trained Nurses of the United States, held in New York last May. The new journal begins well and has, we trust, a useful future before it.

THIRD PAN-AMERICAN MEDICAL CONGRESS.

This congress will convene at Havana, Cuba, Dec. 26-29, 1900. The Committee on Transportation has made the following report on rates for the delegates: The Southeastern Passenger Association has authorized a rate of one fare for the round-trip to Port Tampa, Fla., plus \$2 (exclusive of Pullman berths and meals), connecting with the Peninsula & Occidental Steamship Company at Port Tampa, which has authorized a rate of \$36.50 round-trip from Port Tampa to Havana, including meals and berths in each direction. This makes the rate through to Havana, from Washington, \$70.05; from Cincinnati, \$68.30; from Louisville, \$67.55, and correspondingly low rates from intermediate points. The Trunk Line Association has authorized excursion fares to Washington, added to the fares authorized by the Southeastern Passenger Association, which includes all regular ticketing routes. The Central Traffic and Western Passenger Associations have authorized regular winter tourist rates. Delegates from these territories may find it to their interest to pay local fare to Cincinnati or Louisville and use the authorized rates from those points as outlined above. The Ward Line steamers from New York, have authorized a rate, including meals and state-room in each direction, of \$60 round trip from New York to Havana, sailing Wednesday and Saturday; time, five days in each direction. Passengers who use the Ward Line to Havana, paying \$60 for the round trip and desire to return either from Port Tampa or Miami by rail, will receive a refund of \$20 by returning the unused return portion of the ticket. This will necessitate the purchase of tickets from Havana over the Peninsula & Occidental S. S. Line to Port Tampa or Miami and thence by rail. No rates have been authorized from the New England territory thus far. The United States Fast Mail leaving Washington via the Southern Railway at 11:15 a. m., Dec. 21, arrives at Port Tampa, Fla., 10:30 p. m., Dec. 22, making immediate connection with the steamer leaving Port Tampa, 11 p. m., which arrives at Havana at 5 a. m., Dec. 24. Extra sleepers will be run through from New York over the Pennsylvania Railroad, Southern Railway and Plant System to Port Tampa. The train leaving Cincinnati, over the Queen & Crescent route, at 8:30 a. m., Dec. 21, will arrive at Port Tampa 10:30 p. m., the following day, connecting with the same steamer. The train leaving Louisville over the Southern Railway at 7:45 a. m., connects with the Cincinnati party at Lexington, Ky., at 10:45 a. m. These schedules all unite at Jacksonville, Fla., and go through to Port Tampa and Havana together. It is suggested that the delegates from the East mobilize through Washington and those from the West through Cincinnati. The rates used above apply via all lines in the territories designated. Delegates are requested to send their names and the names and relationship of those who will accompany them on this trip, to Dr. H. L. E. Johnson, chairman Committee on Transportation, International Executive Committee, at the earliest possible moment, that sleeping car and steamer accommodations may be arranged in advance.

FOREIGN.

PROF. C. TERMI has completed his study of yellow fever and the plague in Brazil and returned to Italy.

THE PLAGUE in India is on the increase, but the famine situation is improving. Cholera is raging in Kashmir.

PROF. J. HOCHENEGG is conducting Albert's clinic at Vienna for the present until a successor has been officially appointed.

A "FESTSCHRIFT" was presented to Professor Kaposi, of Vienna, on the occasion of the twenty-fifth anniversary of his professorship.

THE golden professional jubilee of Dr. Kuenne, of Elberfeld, Germany, was celebrated, October 15, with much ceremony, and the title of Geheimer Sanitätsrath conferred upon him.

YERSIN has returned to Paris after four years of research in the Orient. He expects to go back soon to the Tonquin, after presenting his official report of his antiplague serum to the authorities.

THE *Gaz. Méd. de Paris* reports the eighteenth case that has been published of sudden cyanosis and symptoms of general intoxication, traced to the wearing of tan shoes that had been dyed black with an anilin tincture.

A SUSPECTED case of bubonic plague has been found in a sailor on the steamer *Ben Lomond*, which arrived in London, October 26, from the Philippine Islands. The patient is in a hospital near the mouth of the Thames.

THE talented young editor of the Russian medical journal, *Ejendebnik*, and privat docent of pharmacology at St. Petersburg, Dr. E. Kotlyar, died October 7. The death of Dr. Cordés, formerly of Alexandersbad, is also announced.

PROFESSOR RIEDER, of Bonn, who has been entrusted with the reorganization of the Turkish medical department, met recently with a serious accident in Constantinople, a fall of 45 feet, involving injury to the spine and fracture of a foot.

THE TRADES COUNCIL of Bradford, Eng., has petitioned the municipal authorities to provide a public pathologic and bacteriologic laboratory for that city. At present Cardiff is the only town in Great Britain that has established its own health laboratory.

IN IRELAND there appears to be just now a dearth of physicians. Good medical vacancies, extensively advertised, have gone a begging and practitioners have in some cases had to forego their vacations from inability to find substitutes. This is partially accounted for by the demand for the South African war.

IN THE new senate of the reconstituted London University the following have been elected as representatives of the medical faculty: Dr. Rose Bradford, physician to University College Hospital; Dr. Kingston Fowler, physician and lecturer of medicine at Middlesex Hospital, and Dr. E. C. Perry, superintendent and physician to Guy's Hospital.

THE STOCKHOLM MEDICAL SOCIETY will give a gold medal every tenth year to honor the memory of Pasteur; the recipient must be the scientist whose works have done most to promote bacteriology or hygiene. The first medal has recently been bestowed on Max von Pettenkofer, the venerable hygienist of Munich.

PROF. MAX VON NIESSEN has founded a new periodical devoted exclusively to syphilis, the *Beitraege z. Syphilis-Forschung*. The expenses are paid by an anonymous friend. Contributions are invited from persons interested in the study of syphilis, and will be published with translation, in either English, German or French.

IT APPEARS that the entries into the medical schools of England are notably fewer this year than previously. In St. Bartholomew's Hospital there was a falling off of 28 from the number of the previous year; at St. Thomas', 12; at St. George's, 10; at London, 9, etc. In a few there was a slight increase, but the net decrease was 102, a comparatively formidable figure in England, where the annual entries are counted by the hundreds rather than the thousands as in this country.

THE MEMBERS of the profession in Spain and Spanish-speaking America have organized for closer fellowship. The president of the association is J. Calleja, of Madrid, and a prominent physician in each country has been appointed to found local societies in affiliation with the central committee—Dr. Ulecia, for Cuba; Cajal, for Mexico, etc. The new Union Medica Hispano-Americana hopes to publish an official organ in time. The triennial meetings will occur on the occasion of the international medical congresses.

THE RECENT PLAGUE case at Cardiff has suggested some unpleasant possibilities. The patient, while suffering from the early stage of the disease made a railway journey from King's Lynn to Cardiff, where his case was diagnosed. This implies the possible infection of one or more probably unidentifiable third-class railway carriages that may still be spreading the infection. The possibility of undiagnosed plague scattered throughout England and Wales, through such an unfortunate

accident, is not at least a pleasant one to contemplate, though it is one that has to be rationally considered.

THE STOCKHOLM *Dagblad* states that it has taken four years to realize and bring into shape the vast estate of the inventor of dynamite to comply with the conditions of the will in regard to the endowment of the famous Nobel prizes, each of which is a fortune in itself. It is anticipated now that the five prizes can be awarded in 1901. Physicians are interested, as one of the five is for "progress in medicine." No notice will be taken of personal applications. The committee in charge of the physics and chemistry prizes has already requested suggestions from the professors of these sciences at the principal universities of the world, including Rome, Leyden, St. Petersburg and Chicago.

Correspondence.

Dr. Oliver's Article on Tuberculosis.

SARANAC LAKE, N. Y., Oct. 25, 1900.

To the Editor.—In connection with my article which appeared in THE JOURNAL, October 20, it has been suggested to me that I did not succeed in making it clear that the article was not "inspired" by Dr. Trudeau, nor written in any sense with a view to flattering him. A failure to understand this might lead to serious misinterpretation of him and his motives, and perhaps hamper the work he is doing.

Let me state the fact plainly, therefore, that the article was written without his knowledge, and he knew absolutely nothing of its contents until he saw it in print. If in your estimation there was possible such a misinterpretation, I beg you, in justice to him and to me, to publish this statement at your earliest convenience.

EDWARD S. OLIVER, M.D.

Sanitary Condition of Atlantic City.

ATLANTIC CITY, N. J., Oct. 26, 1900.

To the Editor.—"The sanitary condition of Atlantic City at the present time is said to be bad, and this is especially due to the defective sewerage system and the lack of attention from the board of health." THE JOURNAL, page 760.

This unfortunate misrepresentation of the sanitary condition of Atlantic City is evidently founded, as it says, on hearsay and not on facts and vital statistics. When Atlantic City has just closed the healthiest season in the history of the resort it is unfair to allow this statement to go unchallenged.

All contagious and infectious diseases must be reported to the board of health immediately on their diagnosis, under heavy penalty. Houses are not placarded, but are properly quarantined when occasion demands. No epidemics of any kind have occurred during the past year, nor in a number of years.

The sewerage system of Atlantic City is known as the West system and is constructed the same as that used in Pullman, Ill., and Norfolk, Va. The plant has been working perfectly, except for two days during last August, when an obstruction in one of the mains in the upper section of the city caused a temporary annoyance to a very small section, but from which no evidence of disease or sickness could be traced. The sewage, when filtered of all large objects, is carried in pipes over one mile from the city limit to a thoroughfare of swift tidewater, where 800 million gallons of seawater pass a given point in twenty-four hours. This thoroughfare flows five miles before it reaches the ocean before the city and the current goes directly to sea so that the sewage is so thoroughly diluted and destroyed by the salt water that it is absolutely harmless. No sewage refuse has ever been known to wash up on the beach in front of the city from the present system. My own residence is situated in the center of the city, where the system is probably most taxed, and in the last three years I have not had the first fault to find with its service.

There is probably no healthier city in the United States than Atlantic City. Our death-rate, while low, is not the lowest, but this is due to the large number of deaths among non-resident visitors who come here in the last stages of disease—many to die as they would in any other place. By eliminating these cases our death-rate will compete for lowest place with the most favored cities.

The administrative ability of the board of health has never been better, and if there have been a few cases overlooked, not reported, or concealed they should not come in for unjust censure. Every case coming under their care has been properly handled, and they stand ready to meet any emergency and to protect the city against any imported or local diseases.

W. BLAIR STEWART, M.D.

Was "Commercialism" Its Basis? A Protest.

ASHEVILLE, N. C., Oct. 24, 1900.

To the Editor:—It seems to me most unfortunate that you should have allowed your excellent tuberculosis number of October 20 to be spoiled by giving access to it, of a paper which, apparently—for I do not want to do its author an injustice in case it was meant well—is a purely commercial advertisement of a special method of treatment so indistinctly described that those wishing to test its reputed virtues will have to write to its author for particulars. I refer to the paper by Dr. Lisle, of Columbus, on the Treatment of Pulmonary Tuberculosis. I believe that any one who reads it will be convinced that, however honest the intention of its author, he has been unfortunate in the way in which he wrote, if he wished to "avoid the appearance of evil."

When one comes forward with a new treatment it is customary to state fully and clearly each detail, and when its central point is a prescription to give its ingredients specifically. In Dr. Lisle's case, however, he gets no nearer to it than to mention that it is "a solution of unstable carbon compounds of the aromatic series," and in mentioning the apparatus necessary in the use of this compound he is too indefinite for any one to be sure whether a special apparatus known only to himself or the ordinary nebulizing apparatus, is required.

While one could easily criticize any treatment which shuts a consumptive away from the fresh air and substitutes an artificially medicated air for it, it is not to criticize its medical features that I write but to protest against the publication in THE JOURNAL, which should be above every other in the ethical and scientific standard of its papers, of articles which justify cause outsiders to sneer and fortifies the unjust belief that the American profession is a commercial one. If the essayist is innocent of any commercial intent, which I would gladly believe, I regret that he gives such cause for suspicion. Nebulous statements, such as here made, lead the least suspicious to think that to get the results spoken of the patient must put himself under the charge of the author, the only man who can know, from what he writes, how to carry out this new specific treatment. A clear and distinct statement of what drugs and apparatus he uses, thus opening his treatment to the possibility of verification and control by others, without the necessity of recourse to some special source of supply, would at least free him from any accusation of self-interest, though it may not cause the medical world to abandon the admirable method so unanimously advocated by the other writers in this number, or to believe that he any more than the thousands who have preceded him have found drugs which can compare with fresh air and hygiene in the treatment of pulmonary tuberculosis. Grateful as are all our members to you for the great improvement you have worked in THE JOURNAL, I think I can safely undertake to speak for many of them when I hope that articles of this type may not be able to slip in unawares, but that everything published in it may be as excellent as are the balance of the papers in the number in question. Yours sincerely,

CHARLES L. MINOR, M.D.

Association News.

American Medical Association Medal.

The Committee on the award of the ASSOCIATION medal desires to call attention to the following: The AMERICAN MEDICAL ASSOCIATION offers annually a gold medal valued at \$100.00 for the best essay on any subject relating to medicine or surgery. At the last meeting of the ASSOCIATION it was

decided that hereafter the recipient of the prize should be given the option of the gold medal or a bronze replica of the medal and the balance of the appropriation in money.

The competing essays must be typewritten or printed, and bear no mark revealing their authorship; but instead of the name of the author, there must appear on each essay a motto, and accompanying each essay a sealed envelope containing the name of the author and bearing on its outer surface the motto of identification. No envelope is to be opened by the Committee until a decision has been reached as to the most deserving essay, and the other essays have been returned to their respective owners. The Committee has authority to reject and return all essays in case none have been found worthy of the ASSOCIATION medal.

The Committee suggests as one of the important topics of the day that of Tropical Diseases, but, while suggesting this, does not wish to dictate in the slightest degree that this branch of medicine must be the subject discussed.

Competing essays must be in the hands of the Committee not later than March 1, 1901. For further information address any member of the Committee, which consists of the following: Dr. William Osler, Baltimore, Md.; Dr. C. W. Richardson, Washington, D. C.; Dr. Rudolph Matas, New Orleans, La.

Nicholas Senn Prize Medal.

The committee on the Senn Medal beg leave to call attention to the following conditions governing the competition for this medal for 1901:

1. A gold medal of suitable design is to be conferred upon the member of the AMERICAN MEDICAL ASSOCIATION who shall present the best essay upon some surgical subject.

2. This medal will be known as the Nicholas Senn Prize Medal.

3. The award shall be made under the following conditions:

a. The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. b. All successful essays become the property of the ASSOCIATION. c. The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the ASSOCIATION. d. The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the AMERICAN MEDICAL ASSOCIATION. e. The competition for the medal will be closed three months before the next annual meeting of the AMERICAN MEDICAL ASSOCIATION, and no essays will be received after March 1, 1901.

Communications may be addressed to any member of the committee, consisting of the following: Dr. Maurice H. Richardson, Boston, Mass.; Dr. Frederick Holme Wiggin, New York, N. Y.; Dr. Clayton Parkhill, Denver, Col.

Marriages.

DR. ELGIN O. BINGHAM, Niagara Falls, N. Y., to Miss Florence Estelle Young, Loekport, N. Y., October 17.

DR. ALBERT R. DA COSTA, Jr., Chicago, to Dr. Helena K. Gray, Princeton, Ind., October 17.

DR. GEORGE W. DUFFICY, Sacramento, Cal., to Miss Alberta Evelyn Rackliffe, at San Francisco, October 24.

DR. WAYLAND S. HUGH, Cuyahoga Falls, Ohio, to Miss Sadie F. Johnston, Ironton, Ohio, at Tolono, Ill., October 22.

DR. ROBERT E. McCANDLESS, Perry, Okla., to Miss Esther Harwood, at Cedar Rapids, Ia., September 27.

DR. GEORGE A. HOLLISTER to Miss Mary Lamb, both of Toledo, Ohio, October 6.

DR. PAUL MITFORD MCCRAY, to Miss Jane Elizabeth Boyer, both of Camden, N. J., October 18.

DR. JOSEPH R. MOUNTAIN, Connorsville, Ind., to Miss Elizabeth Clark, Cincinnati, Ohio, October 16.

DR. THOMAS G. ODELL, Butte, Mont., to Miss Maude F. Hardy, Salt Lake City, Utah, October 16.

DR. PEARL E. SOMERS to Miss Nellie Morrison, both of Des Moines, Ia., October 10.

DR. EDGAR A. STEWART, Dayton, Ohio, to Miss Mary Chenoweth, of Fairfield Township, Madison County, Ohio, October 17.

DR. RICHARD CHARLES THOMPSON, Pine Bluff, Ark., to Miss Anita Kellogg, Cincinnati, October 24.

DR. HAROLD WILSON to Miss Nellie I. Dorman, both of Conneaut, Ohio, October 11.

DR. JOHN W. WRIGHT to Miss Clara Katherine Keller, both of Erie, Pa., October 15.

DR. J. F. NOOL, Boerne, Tex., to Mrs. Mary Hutchings-Spencer, Galveston, Tex., October 17.

DR. P. S. KEOGH to Mrs. Nellie Fulton, both of Salt Lake City, Utah, October 20.

DR. PERCY C. PROCTOR, Gloucester, Mass., to Miss Mary H. Marlin, Boston, Mass., October 18.

DR. WILLIAM C. NEWTON, Revere, Mass., to Miss Elizabeth Starwood Perry, Worcester, Mass., October 16.

DR. JULIUS FRIEDENWALD, Baltimore, Md., to Mrs. Esther L. Reinhard, Baltimore, October 25.

DR. PHILIP F. ROGERS, Milwaukee, Wis., to Miss Cornelia N. Meinhardt, Burlington, Wis., October 25.

DR. ALBERT E. BLACKBURN, Philadelphia, Pa., to Miss Myra Holliday, Bellefonte, Pa., November 7.

DR. BURT L. EASTMAN, Kansas City, Mo., to Miss Grace Lucile Denslow, October 22.

Deaths and Obituaries.

EDWARD R. SQUIBB, M.D., Jefferson Medical College, 1845, died at his home in Brooklyn, October 26, aged 81 years. He was born in Wilmington, Del., and was in charge of the medical station at the Brooklyn navy yard when the Civil War broke out. On his resignation from the navy he started a private laboratory in Brooklyn. He retired from business about fifteen years ago. He was a member of THE AMERICAN MEDICAL ASSOCIATION, New York State Medical Association, etc. Dr. Squibb was an authority on pharmaceutical subjects.

LAURENCE TURNBULL, M.D., Jefferson Medical College, 1845, died at his home in Philadelphia, October 24, after a long illness, aged 79 years. He was born in Lanarkshire, Scotland, and came to this country in 1833. He was the author of many contributions to the literature, and his text-book on anesthesia is a standard. He claimed the distinction of being the first in America to open the mastoid process. He was a member of THE AMERICAN MEDICAL ASSOCIATION, ex vice-president of the Pennsylvania State Medical Society, etc.

MOSES C. WHITE, M.D., Yale University, 1854, died at New Haven, Conn., October 24, aged 81 years. He was born in Paris, N. Y. He first studied for the ministry, and was a missionary in China from 1847 to 1853. He was secretary of the Connecticut State Medical Society from 1864 till 1876. In 1867 he was appointed professor of pathology and histology in Yale Medical College. His active duties continued until last June, when he resigned and was made professor emeritus.

JOHN G. GRIGGS, M.D., University of Pennsylvania, 1853, died at Birmingham, Ala., from heart disease, October 21, aged 70 years. At the outbreak of the Civil War he enlisted as a private in an Alabama regiment, but was soon made surgeon of the 5th Georgia. For thirty years thereafter he practiced in Tuskegee, Ala., and then moved to Birmingham.

WILLIAM F. REILY, M.D., University of Pennsylvania, 1875, died at Carlisle, Pa., October 19, aged 48 years. He had been assistant surgeon of the 8th Infantry, N. G. Pa., for ten years, and served in the Spanish-American War, where he contracted the malady which caused his death.

WILLIAM T. NEWTON, M.D., Medical College of Ohio, 1876, died at Indianapolis, October 22, from Bright's disease. He was professor of materia medica in the Central College of

Physicians and Surgeons, and a member of the AMERICAN MEDICAL ASSOCIATION.

WILLIAM H. STURGEON, M.D., Jefferson Medical College, 1849, died at Uniontown, Pa., October 15, aged 74 years. He was one of the oldest practitioners in Fayette County, and a member of his county and state society and of the AMERICAN MEDICAL ASSOCIATION.

CHARLES S. FERRELL, M.D., University of Wooster, 1890, died at Wheeling, W. Va., from consumption, October 22, aged 35 years. He went, several months before, to China as superintendent of a hospital, but was forced to return on account of the Boxer uprising.

CHARLES ST. JOHN, M.D., University of Buffalo, 1898, shot while attending to the wounded on the firing line in a scrimmage with the Filipinos. Dr. St. John had been an interne at the County Hospital at Buffalo previous to becoming contract surgeon.

GEORGE EASTMAN, M.D., Dartmouth Medical College, 1844, died at his home in Platteville, Wis., October 24, aged 76 years. He was medical inspector of 17th Army Corps in the Civil War.

HENRY MORETON, M.D., College of Physicians and Surgeons, New York, 1845, died in New York City, October 25, aged 93 years. He was a son of a British army surgeon.

BENJAMIN BROOKE, M.D., University of Pennsylvania, 1889, died, October 18, at Radnor, Pa., aged 34 years. He was late a surgeon and captain U. S. Army.

JOHN W. ROBINSON, M.D., College of Physicians and Surgeons, New York, 1867, died at Lyons, N. Y., from heart disease, October 21, aged 57 years.

ROBERT J. BAGBY, M.D., Washington University, St. Louis, 1863, died at Roanoke, Mo., from cancer of the stomach, October 15, aged 68 years.

WILLIAM HOLLAND, M.D., Rush Medical College, died at Crawfordsville, Ind., from rheumatism and exhaustion, October 20, aged 84 years.

GUILIAM A. ZABISKIE, M.D., College of Physicians and Surgeons, New York City, 1882, died in New York City, October 25, aged 42.

EDWIN S. THOMAS, M. D., University of Maryland, 1849, died at Philadelphia from hemorrhage of the lungs, October 17, aged 72 years.

WILLIS L. MAY, M.D., Rush Medical College, 1858, died suddenly of heart disease in his office at Crawfordsville, Ind., October 24.

DAVID PELLMAN BOYER, M.D., Jefferson Medical College, 1846, died at Philadelphia, of Bright's disease, October 15, aged 76.

PHILIP ROTH, JR., M.D., University of Vermont, 1884, died at Newark, N. J., from cardiac disease, October 21, aged 36 years.

BENJAMIN M. TURNER, M.D., University of Vermont, 1889, died at his home in Gardiner, Me., October 25, aged 36 years.

GEORGE A. MUEHLECK, M.D., University of Heidelberg, 1883, died at his home in Philadelphia, October 25, aged 40 years.

EDWARD A. HERVEY, M.D., New York University, 1859, died at his home in Rossville, N. Y., October 26, aged 76 years.

HUGO FREDERICK MAYER, M.D., College of Physicians and Surgeons, New York, 1882, died in New York, October 21.

WILLIAM B. WILSON, M.D., New York University, 1852, died at Cape Girardeau, Mo., October 18, aged 69 years.

GEORGE H. W. MUSEKAMP, M.D., Medical College of Ohio, 1884, died at Cheviot, Ohio, October 22, aged 59 years.

WILLIAM J. NELSON, M.D., University of Maryland, 1883, died at Middletown, N. Y., October 26, aged 40 years.

WILFRED C. MUSE, M.D., Baltimore Medical College, 1892, was accidentally drowned, October 22, aged 32 years.

HIRAM W. RITTER, M.D., Jefferson Medical College, 1877, died at Souderton, Pa., October 9, aged 47 years.

CHARLES ROEMMELT, M.D., University of Buffalo, 1898, died recently of dysentery in the Philippines.

EDWARD H. CUTTER, M.D., Harvard University, of Leominster, Mass., died October 23, aged 45 years.

WILLIAM T. PRENTISS, M.D., Jefferson Medical College, 1884, died at Lewisport, Ky., aged 73 years.

ALICE B. BAIRD, M.D., Woman's Medical College, Chicago, 1883, died at her home at Pierre, S. D.

G. W. ROTHWELL, M.D., University of Virginia, died at Sedalia, Mo., aged 88 years.

Miscellany.

MARINE HOSPITAL NOTES.

ASST.-SURGEON CARROLL FOX, who has been on duty during the past summer at the national quarantine station, Dutch Harbor, Alaska, returned to Port Townsend, and has been assigned to duty in charge of the service at Portland, Oregon.

ASST.-SURGEON H. S. MATHEWSON has been detailed as chief quarantine officer for the Island of Porto Rico under the provisions of department circular relating to the establishment of the quarantine service in the Island of Porto Rico.

PLAGUE SITUATION IN GLASGOW.

REPORTS from P. A. Surgeon Thomas at Glasgow show that for the week ended October 27 there were no new cases and no deaths from plague; four cases were discharged and ten remain.

CHOLERA IN THE EAST.

In a special report, the U. S. Consul at Bombay says that cholera is raging in India, that it is of a very fatal type, prevailing among all classes in all sections of the city and generally throughout the famine area of Western India. Eight hundred and thirty-four cases and 751 deaths were reported for the week ending August 22 in the city of Bombay alone. In addition to the above official reports, the press reports state that there have been 4500 deaths from this disease in Kabul, Afghanistan. It is therefore likely that it will soon be necessary for health officers to give special attention to vessels coming from ports of the Black Sea, Persian Gulf and the Red Sea. In this connection, the report of the commission of the Marine Hospital Service, appointed in 1892 to investigate the cholera epidemic and the danger of contagious diseases from foreign countries, is of particular interest at this time. This report, with maps showing the usual routes of cholera, is published in full in the annual report for 1893.

Hurdwar, in India, where a great annual fair is held, seems to be the starting distributing point, for it is to Hurdwar that traders come from all parts of India to meet a like stream from Persia and Afghanistan, where they exchange the products of the two countries. Hurdwar is on the Ganges, and the religion of the Hindoo makes it obligatory to bathe in the stream at this point, and when there is a drouth the stream is nothing but a series of pools, in which every one must bathe. It becomes a focal point from which disease radiates. Then along the routes of travel the disease spreads from India to Afghanistan, thence to Persia, thence into Turkey in Asia, Turkey in Europe and thence to other portions of Europe and the civilized world.

Societies.

Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.

Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.

The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.

Indian Territory Medical Association, Muskogee, Dec. 4-5.

THE CHESHIRE COUNTY (N. H.) MEDICAL SOCIETY, at its annual meeting elected Dr. Gardner C. Hill, Keene, president; Dr. Charles H. Cutler, Peterboro, vice-president, and Dr. John D. Proctor, Keene, secretary and treasurer.

THE NORFOLK (Va.) MEDICAL SOCIETY has elected Dr. Charles R. Grandy, president; Drs. Benjamin M. Baker and Israel Brown, vice-presidents; Dr. Philip St. L. Moncreu, secretary, and Dr. W. Levi Old, treasurer.

THE PAWTUCKET (R. I.) MEDICAL SOCIETY was organized, Oct. 10, with the following officers: Dr. William H. Heimer, Pawtucket, president; Dr. Eugene A. Kennedy, Central Falls, vice-president, and Dr. Joseph E. Duxbury, Lonsdale, secretary.

THE PORTSMOUTH (Va.) MEDICAL SOCIETY elected the following officers at its annual meeting, held Oct. 16: Dr. Joseph

Grice, president; Dr. Otto C. A. Bindewald, vice-president, and Dr. Vernon G. Culpepper, secretary and treasurer.

THE EAST TENNESSEE MEDICAL SOCIETY held its semi-annual meeting at Bristol, Sept. 27 and 28, and elected Dr. David M. Miller, Indian Springs, president; Dr. Charles J. Broyles, Johnson City, secretary, and Dr. William J. Matthews, Johnson City, treasurer.

THE PHYSICIANS' PROTECTIVE ASSOCIATION has been organized at Dunkirk, Ind., with the following officers: Dr. Jonathan B. Garber, president; Dr. J. S. Lytle, vice-president, and Dr. Donn P. Murray, secretary.

THE EL PASO COUNTY (Texas) MEDICAL SOCIETY held its second annual meeting at El Paso, Oct. 13, and elected Dr. Howard Thompson, president; Dr. Stephen T. Turner, vice-president; Dr. Junius A. Rawlings, secretary, and Dr. Herbert E. Stevenson, treasurer.

THE DENVER AND ARAPAHOE MEDICAL SOCIETY met on Oct. 23. An address was made by Dr. Josiah N. Hall, on "Enteropneusts," and papers were read by Dr. A. Mansfield Holmes on "Some Problems Pertaining to Tuberculosis," and by Dr. Frank E. Waxham, on "Mycosis of the Throat."

THE LUCAS COUNTY (Ohio) MEDICAL SOCIETY met Oct. 10. Dr. W. J. Gillette read a paper on "Uses of Forceps in Labor Cases;" Dr. J. H. Jacobson made a report of "Three Cases of Aneurysm," with demonstration of a case. The treatment of hernia was generally discussed.

THE MILITARY TRACT SOCIETY held its annual meeting at Kewanee, Oct. 18 and 19, at which the following officers were elected: Dr. Robert E. Lewis, Macomb, president; Dr. Robert A. Kerr, Peoria, first vice-president; Dr. H. Nelson Heflin, Kewanee, second vice-president, and Dr. Charles B. Horrell, Galesburg, secretary-treasurer.

THE HAMDEN DISTRICT (Mass.) MEDICAL SOCIETY met at Springfield, Oct. 16. Dr. Daniel E. Keefe read a paper on "Typhoid Fever," and Dr. Louis A. Prefontaine discussed the connection of diseases of the eye with ordinary diseases. President Frank W. Draper, of the State Medical Society, then gave a short informal address.

THE NEW HAVEN COUNTY (Conn.) MEDICAL SOCIETY held its semi-annual meeting at New Haven, Oct. 18. The president, Dr. Carl E. Munger, Waterbury, read a paper on "The Prevention of Consumption," in which he advised the segregation of consumptives. The following officers were elected: Dr. Henry L. Swain, New Haven, president, and Dr. Frank B. Tuttle, Naugatuck, vice-president.

THE INLAND EMPIRE CLINICAL SOCIETY held its first semi-annual meeting at Spokane, Wash., Oct. 11, and elected the following officers: Dr. J. B. Morris, Lewiston, Idaho, president; Dr. Henry G. Mauzey, Spokane, vice-president; Dr. Charles P. Thomas, Spokane, secretary, and Dr. Alexander F. MacLeod, Spokane, treasurer.

THE SCOTT COUNTY (Iowa) MEDICAL SOCIETY held a symposium on "Tetanus," Oct. 23, at Davenport, at which Dr. John A. DeArmand considered the history of the disease; Dr. William L. Allen, its pathology; Dr. Jennings P. Crawford, the etiology and symptomatology; Dr. Edward S. Bowman, the medical treatment, and Prof. Walter L. Biering, Iowa City, the history and results of serumtherapy.

THE MISSOURI VALLEY (Mo.) DISTRICT MEDICAL SOCIETY met at Marshall, Mo., Oct. 16. Dr. William A. Braeklin, Higginsville, reported a case of peculiar injury to the shoulder joint; Dr. L. A. Bazar, Shackelford, read a paper on "Typhoid Fever;" Dr. John Puntun, Kansas City, one on "Epilepsy," and Dr. Frank J. Lutz, St. Louis, on "Needed Legislation in Matters Medical, and How to Obtain It."

THE CEDAR VALLEY (Iowa) MEDICAL SOCIETY met at Waterloo, Oct. 23. Papers were read by Dr. Paul E. Gardner, Hazelton, on "Xerostoma;" Dr. John Hamilton, Cedar Rapids, "Typhoid Fever;" Dr. Amos G. Shellito, Independence, "Appendicitis;" Dr. A. R. Rogers, Osceola, "Ethics in Venereal Diseases;" Dr. Charles S. Chase, Waterloo, "Therapeutic Considerata," and Dr. David S. Fairchild, Clinton, "Observation in Intestinal Obstruction." Drs. James W. Heustis, Dubuque, and Dallas M. Wick, Cedar Falls, reported interesting cases.

THE FRANKLIN COUNTY (Pa.) MEDICAL SOCIETY held its annual session in Chambersburg, Oct. 16, and elected the following officers: Dr. Joseph K. Snively, Shady Grove, president; Drs. Ambrose W. Thrush, Green Village, and Alvin B. Dalbey, McConnellsburg, vice-presidents; Dr. John J. Coffman, Scotland, recording secretary; Dr. Henry C. Devillbiss, Chambersburg, corresponding secretary, and Dr. David Maclay, Chambersburg, treasurer.

THE JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY met at the hospital Oct. 15. Dr. William H. Welch was elected

president, and Dr. James F. Mitchell, secretary. Resolutions of regret were adopted on the death of the late Dr. J. W. Lazear, a former teacher in the medical school, cases were exhibited and papers read by Drs. Osler, Platt, Kelly, Mitchell and Opie.

THE WYOMING STATE MEDICAL ASSOCIATION met in annual session at Cheyenne, Oct. 9 and 10. The meeting was well attended, and the papers read and discussed were of high merit. The following officers were elected for the ensuing year: Dr. Ernest E. Levers, Piedmont, president; Drs. Samuel B. Miller, Laramie, William A. Jolley, Rawlins, and Charlotte G. Hawk, Green River, vice-presidents; Dr. Isaac B. Swiggart, Laramie, secretary and editor, and Dr. Joseph L. Wicks, Evanston, treasurer. The next meeting will be held at Evanston, in October, 1901.

THE TRI-STATE MEDICAL SOCIETY OF ALABAMA, GEORGIA AND TENNESSEE, held its twelfth annual meeting in Chattanooga, Oct. 11, 12 and 13. The president's address, by Dr. Rufus R. Kime, Atlanta, Ga., was entitled "The Relation of the Profession to the Public." He dwelt on the duty of the profession to protect the public against their own folly in the use of dangerous drugs, coal-tar derivatives, opium, alcohol, etc., and suggested that a committee be appointed for the study of social problems affecting the development of the race. The following officers were elected: Dr. Matthew C. McGannon, Nashville, president; Dr. Walter G. Bogart, Chattanooga, Dr. S. Harris, Union Springs, Ala., and Dr. Michael Hoke, Atlanta, vice-presidents; Dr. Frank Trester Smith, Chattanooga, secretary, and Dr. George R. West, Chattanooga, treasurer. Nashville was selected as the next place of meeting.

THE UTAH STATE MEDICAL SOCIETY met for its sixth annual session at Salt Lake City, October 2 and 3, president Albert S. Bower in the chair. Papers were presented by the following: Dr. Harry S. Scott, on "Smallpox, With Special Reference to the Prevailing Mild Type of the Disease"; Dr. Leslie W. Snow, on "The Pupil and Its Derangement in Diseases of the Eye"; Dr. Alexander C. Ewing, "Do Doctors Disagree?" Dr. Walter S. Ellerbeck, "Observations on Formaldehyde," and Dr. Edward V. Silver, "Diseases in Schools." Cases were reported by Dr. William T. Dalby and Emerson F. Root. Dr. Donald Maclean, Detroit, was introduced by the president and gave an informal reminiscent talk. The following officers were elected: Dr. John W. Aird, Heber, president; Drs. Milton H. Hardy, Provo City, and John S. Gordon, Ogden, vice-presidents; Dr. J. C. E. King, Salt Lake City, secretary and Dr. Union Worthington, Salt Lake City, treasurer. The next meeting will be held in Provo City in October, 1901.

THE VERMONT STATE MEDICAL SOCIETY held its eighty-seventh annual meeting at Rutland, October 11 and 12. President Dr. M. Richards Crain, Rutland, in the chair. Dr. George H. Gorham, Bellows Falls, delivered an address on "The Treatment of the Eye by the General Practitioner"; Dr. Sumner E. Darling, Hardwick, reported the recent epidemic of smallpox in and around that place; and Dr. Ashbel P. Grinnell, Burlington, read a paper on "The Use and Abuse of Drugs in Vermont." Dr. M. Richards Crain, Rutland, then delivered the president's address on "Location of the Lesion in Paralysis." On the second day the proceedings opened with election of officers, which resulted as follows: Dr. William D. Huntington, Rochester, president; Dr. E. Merriman Brown, Sheldon, vice-president; Dr. Donly C. Hawley, secretary, and Dr. Elmore S. Allbee, Bellows Falls, treasurer. The following papers were then presented: "Dr. Willis G. MacDonald, Albany, N. Y., "Diagnosis of Extra-Uterine Pregnancy"; Dr. Edmund M. Pond, Rutland, "Puerperal Septicemia"; Dr. W. L. Heath, Richmond, "Pneumonia"; Dr. Charles M. Strobell, Rutland, "Hysterectomy"; Dr. J. Sutcliffe Hill, Bellows Falls, "Some of the Evils of Aseptic Surgery"; Dr. Frederick E. Clark, Burlington, "Abdominal Palpation in Obstetrics"; and Dr. Lewis H. Hemenway, Manchester, "Rupture of the Uterus During Childbirth." The next meeting will be held at Bellows Falls.

American Public Health Association.

Twenty-Eighth Annual Meeting, held at Indianapolis, Ind., Oct. 22-26, 1900.

President Dr. Peter H. Bryce, Toronto, in the chair.

Addresses of welcome were delivered by ex-President Benjamin Harrison, Governor James A. Mound, and Hon. Addison C. Harris, Minister to Austria. The response to these addresses was made by Dr. Charles A. Lindsley, New Haven, Conn.

CAR SANITATION.

PROF. S. H. WOODBRIDGE, Boston, presented the following report of the committee on car sanitation:

1. When a passenger is known to be contagiously ill he should be isolated in a compartment appropriately equipped and ventilated in such a manner as to separate it from the rest of the car. Through trains should be provided with rooms for the sick as well as staterooms, interchangeable in use.
2. The interior of passenger cars should be plain, finished with hard, smooth and polished surfaces.
3. All furnishings should be as non-absorbent as possible.
4. Coaches should be furnished with effective means for continuously supplying not less than 1000 cubic feet of warm air an hour for each single seat and for distributing and removing the air without troublesome draught.
5. The temperature should be regulated.
6. The cleaning of cars should be frequent and thorough.
7. Floors and sanitary and laboratory fixtures should be frequently treated with a disinfecting wash.
8. All fabrics in cars should receive sterilizing treatment. All bed and laboratory linen should be thoroughly sterilized in the process of laundering.
9. Sewage tanks and earth closets should be provided under the cars. The practice of disposing of excreta by scattering it over road-beds is dangerous.
10. Water and ice should be obtained from the purest available sources. The use of tongs in handling ice should be insisted on.
11. The water tank should be frequently cleansed and periodically sterilized with boiling water or otherwise.
12. The public should be educated to use individual cups. Paper paraffined cups might be provided by a cent-in-the-slot device.
13. The use of canned goods in buffet car service makes careful inspection of such goods imperative. Fruits and all eatables before and after purchase should be stored with care to avoid all unnecessary exposure to street and car dust.
14. The filthy habit of spitting on car floors should be dealt with in a manner to cause its prompt discontinuance. It should be punished as one of the most flagrant of the thoughtless offenses against the public right to health.
15. Station premises should receive attention directed to general cleanliness of floors, furnishings, air, sanitariums, lavatories, platforms and approaches, and should be plentifully supplied with approved disinfecting material. The recommendations of the committee were concurred in by the Association.

DR. J. N. HURTY, Indianapolis, said that if the Association would make a vigorous demand for white blankets for sleeping cars, instead of colored ones, it would be a great reform. The white blanket would tell its own story. Colored blankets are frequently saturated with filth.

DR. H. M. BRACKEN, Minneapolis, said that inasmuch as the traveling public pay a good price for Pullman cars, it is only right that the cars should be kept clean and in good condition. The beds are made up, people sleep in them, the next morning the linen is removed, while the mattresses and blankets are thrown into the upper berths and remain there until the next night, then used again. It is not uncommon for people, on entering Pullman cars, to complain of the odor of stale bedding, etc.

DR. C. H. JONES, Baltimore, referred to tuberculous patients who travel long distances. When the greatest care and caution are observed, the blankets used on Pullman cars are now and then spat on by them. The attendants can not always be with such patients to cover their mouths with handkerchiefs. Railway managers should be notified of the great danger to the public from this source. When the public is educated in this matter a great reform will have been inaugurated.

DR. C. P. WILKINSON, New Orleans, stated that the chief objection to the equipment and furnishings of railway cars is that they are upholstered in absorbable material. In the extreme South rattan and steel springs are now used instead of plush and woollen furnishings.

DR. U. O. B. WINGATE, Milwaukee, referred to the work that is being done in this direction by the International Association of Railway Surgeons, and suggested that it might be well to appoint a committee to co-operate with a similar committee of that Association to do further work in car sanitation.

DR. HURTY spoke of one railroad which is now constructing seven cars with perfectly plain interiors. The bottoms and backs of the seats can be taken out and thoroughly sterilized at the end of every run.

DR. DOMINGO ORYANANOS, Mexico City, Mexico, read a supplementary report on car sanitation. Boards of health in the territories covered by the Association ought to try and obtain support from the different legislatures so as to make certain provisions obligatory on railway companies, as, for instance, 1, the isolation in special cars of any persons suffering from transmissible diseases; 2, to supply guaranteed filters in the tanks of drinking water; 3, the disinfection of bed clothes, hangings, curtains and towels; 4, all sleeping cars should be provided with small disinfectant stoves for small toilet articles; 5, the absolute prohibition under severe penalty of expectoration on pavements; 6, all railroad cars should be provided with a sufficient number of cuspidors containing a strong disinfecting solution.

NEW QUARANTINE METHODS AND CHANGES CALLED FOR IN MARINE SANITATION.

DR. ALVAH H. DOTY, New York City, said that, contrary to the popular belief, the most careful investigation both from a scientific and practical standpoint, has demonstrated that the clothing actually worn by well persons is not a medium of infection. This is also true of the cargoes of ships. In making this statement, the author does not mean to imply that infection from these sources is not within the realms of possibility. Evidence was adduced that the cargo of a ship does not act as a medium of infection. If exceptions exist, they have not been revealed to practical sanitarians. Outbreaks of bubonic plague in European and other ports have brought prominently before our notice the question of the transmission of this disease by rats and other vermin. Information on this subject at present is incomplete, although Kitasato and Yersin have demonstrated the presence of the disease in rats during the epidemic of bubonic plague in Hong Kong in 1894. Beyond this, sanitarians have but little authentic information on this subject. It is reasonable to believe, however, that in such communities as are found in India and China, where filth, overcrowding and bad sanitary regulations exist to an extent which is almost beyond belief, the dissemination of infection is so general that even vermin are involved. In civilized communities, however, where the ordinary sanitary regulations are carried out, the danger from this source would seem to be very limited. No authentic reports exist which show that cargoes of vessels have transmitted bubonic plague through the medium of infected rats or other sources.

In the inspection of persons coming from infected ports, the ordinary examination, which includes a statement from the person concerned, is not sufficient at all times to detect mild or ambulant cases. The most practical and important addition to the ordinary method of inspection is the use of the clinical thermometer. This has been in operation for the past two years in New York, and the most satisfactory results have been obtained in detecting mild or ambulant cases. While the essayist is convinced that the maximum period of incubation of yellow fever is five days, there is no doubt that during the first day or so of the disease persons affected may present themselves and pass the ordinary inspection. The use of the thermometer at this time, however, will almost always show an elevation of temperature sufficiently high to justify the physician or health officer in causing a longer detention.

PROF. F. C. ROBINSON, Maine, said that formerly a great deal of paper was made from rags, and he was surprised to hear that there was no danger from infectious diseases from cargoes of rags. He believes outbreaks of smallpox and other contagious diseases have been traced to rags.

DR. H. M. BRACKEN vigorously controverted the statement of the essayist that healthy persons are not liable to carry disease in their clothing. Every physician of experience could cite instances of physicians who have carried contagion to healthy people.

The paper was further discussed by Drs. Wilson, Montzambert, the President, Lee, Durgin, Jones, most of whom protested against the idea that physicians could not carry infection in their clothing.

REPORT OF THE COMMITTEE ON CAUSE AND PREVENTION OF INFECTIOUS DISEASES.

DR. A. WALTER SUITEZ, Herkimer, N. Y., read the above report. Reference was made to smallpox, which he said was on the increase, and he cited copious statistics to prove his assertion. He added the pleasing assurance that the death-rate from this malady is decreasing. The latter fact must not be viewed too optimistically, because smallpox is certain, if an epidemic of it continues long enough, to develop its greatest degree of virulence. He showed the value of sanitary precautions and of vaccination by citing the fact that Porto Rico, since the United States has dominated its government, has rid itself of the disease, which, before the war, was very prevalent in that island. He also discussed malaria, scarlet fever, typhoid fever, and declared himself a believer in the theory that the germs of malaria are transmitted by mosquitoes in many instances. In discussing typhoid fever he referred to the declaration of Dr. Vaughan, that more than 80 per cent. of deaths among American soldiers in the Spanish War were caused by typhoid fever, and emphasized the necessity of cleanliness about military camps. He touched on bubonic plague, and said he did not anticipate a scourge of this disease here, but urged great sanitary precautions.

ETIOLOGY OF YELLOW FEVER.

DR. WALTER REED, Washington, D. C., read a paper on this subject, it being the joint production of himself, Dr. James Carroll, Dr. A. Agramonte, and the late Dr. Jesse W. Lazear. A series of clinical, bacteriological and pathological observations was narrated, comprising 18 cases of yellow fever. Of this number 11 were designated as severe cases of the disease, with 4 deaths; 3, as well-marked cases, with no deaths, and 4 as mild cases with no deaths. Blood cultures were made of 18 cases during life, and of 48 separate cultures made from the blood on various days of the disease and representing 115 bouillon inoculations, and 18 agar plates, they failed to find the bacillus *icteroides* in any of the tubes or plates. They failed to isolate the bacillus *icteroides* in 11 autopsies of yellow-fever patients. Having failed to isolate this bacillus either from the blood during life, or from the blood and organs of cadavers, two courses of procedure appeared to be worthy of attention, namely, 1, a careful study of the intestinal flora in yellow fever in comparison with the bacteria that might be isolated from the intestinal canal of healthy individuals in this vicinity, or of those sick with other diseases; or, 2, to give attention to the theory of the propagation of yellow fever by means of the mosquito. The essayists pursued the second line of investigation by reason of the well-known facts connected with the epidemiology of this disease, and by the brilliant work of Ross and the Italian observers in connection with the theory of the propagation of malaria by the mosquito. Their observations point to the presence of an intermediate host, such as the mosquito, which having taken the parasite into its stomach soon after the entrance of the patient into the noninfected house, was able, after a certain interval to convey the infecting agent to other individuals, thereby converting the noninfected house into an infected house. This interval would appear to be from nine to sixteen days, allowing for the period of incubation, which agrees fairly closely with the time required for the passage of the malarial parasite from the stomach of the mosquito to its salivary glands. In view of the foregoing observations they tested the theory of Finley on human beings. Experiments were made on 11 nonimmune individuals. The mosquito used in all cases was *Culex fasciatus*, Fabr. Results: nine negatives, two positives. The two cases reported as positive, the authors detailed at great length.

Since they record one case in which a typical attack of yellow fever followed the bite of an infected mosquito within the usual period of incubation of the disease, and in which other sources of infection could be excluded, they feel confident that the publication of their detailed observations will excite renewed interest in the mosquito theory of the propagation of yellow fever, as first proposed by Finley.

From their studies thus far of the disease, they conclude that the bacillus *icteroides* stands in no causative relation to

yellow fever, but, when present, should be considered as a secondary invader in this malady. The mosquito serves as an intermediate host for the parasite of yellow fever.

REPORT OF THE COMMITTEE ON THE ETIOLOGY OF YELLOW FEVER.

DR. HENRY B. HORLBECK, Charleston, S. C., made reference to previous contributions on this subject by the committee, and a digest given of the labors of bacteriologists who have during the past twelve months devoted themselves to the study of the bacillus icteroides. The report closed with the following conclusions from an article by Pronst and Wurtz, published Sept. 7, 1900:

1. The bacillus icteroides of Sanarelli seems to be the specific agent of yellow fever. That micro-organisms injected into certain animals, especially dogs, reproduce symptoms and lesions strikingly analogous to those observed in man. The toxin of this bacillus produces in animals the same effect as the microbe. The injection of this toxin into five individuals reproduced in man typical yellow fever, accompanied by its symptoms and anatomical lesions. The serum of individuals attacked with yellow fever agglutinates cultures of the bacillus icteroides. 2. The bacillus has a prolonged vitality both in air and water (fresh and sea). It is certain that it is the same in the soil. Molds favor its development. These facts confirm conditions that have been known a long time. They explain the reawakening of yellow fever a long time after the extinction of an epidemic, and the longevity of the disease aboard vessels in bad hygienic condition. No new prophylactic measures have come out in this knowledge of the etiology of the disease. As formerly, the prevention of yellow fever consists in applying the measures of isolation and of disinfection, and of improving the hygienic conditions.

DR. J. P. BERNALDEZ, of Mexico, spoke of human vaccin as a prophylactic of smallpox, and discussed its advantages and disadvantages.

DR. M. S. IGLESIAS, Vera Cruz, Mexico, spoke of the elements of defense against infection-contagious diseases at the port of Vera Cruz.

PRESIDENTIAL ADDRESS.

DR. PETER H. BRYCE, Toronto, sketched at great length the progress of sanitary science from its birth in the period of the Renaissance down to the present time and declared that scientific workers ought to take courage from what they have seen accomplished in this century. The address was an admirable compact sanitary digest.

REPORT OF THE COMMITTEE ON POLLUTION OF WATER-SUPPLY.

This was presented by the chairman, Mr. George W. Fuller, of New York City. The report took the form of records and summaries showing recent progress in the more important branches of the subject. With regard to quality, the water-supply of the future should meet the following requirements: It shall be free, or substantially free, from disease-producing germs. It shall be clear and colorless, containing no noticeable turbidity or vegetable stain. It shall be free from objectionable tastes and odors, as supplied to the consumer. It shall be free from noticeable amounts of dissolved iron, such as unfit for household use. It shall be free from excessive amounts of lime and magnesia, such as make water too hard for ordinary use. It shall be carefully examined with regard to constituents capable of dissolving metals used in distributing pipes.

(To be continued.)

New York State Medical Association.

(Concluded from p. 1105.)

AN EPIDEMIC OF DIPHThERIA TRACED TO A MILK SUPPLY.

DR. CHAUNCEY P. BIGGS, Ithaca, gave a brief review of the literature on milk supply and epidemics of diphtheria. He then described a recent epidemic in Ithaca, pointing out how the infection of the milk supply had been traced, and narrated some experiences in the control and management of an epidemic in a small town.

THE MANAGEMENT OF DIPHThERIA IN SMALL CITIES FROM A BACTERIOLOGICAL STANDPOINT.

PROF. VERANUS A. MOORE, Cornell University, showed how

the bacteriological examinations instituted by the Board of Health of Ithaca at the time of the epidemic had proved useful both in controlling the disease and tracing the sources of infection.

THE TONSILS AS PORTALS OF INFECTION.

DR. JULIUS ULLMAN, Buffalo, referred more especially to such septic diseases as malignant endocarditis. He regarded rheumatism as a mild form of pyemia in which the staphylococci and their toxins become attenuated.

DR. DE LANCEY ROCHESTER, Buffalo, reported three cases of scarlatina without eruption.

PRESENT STATUS OF JONNESCO'S OPERATION.

DR. MARCEL HARTWIG, Buffalo, reviewed the history of neurectomy of the cervical sympathetic, and reported the results obtained with it in epilepsy, exophthalmic goiter and glaucoma.

THE TREATMENT OF PULMONARY TUBERCULOSIS, WITH SPECIAL REFERENCE TO THE CLIMATE OF ARIZONA.

DR. CLARENCE G. CAMPBELL, New York City, held that the chief advantage of all climatic treatment is the discouragement of germ life. The apparent discrepancy between treatment in a dry rarified atmosphere, such as that of Colorado, and treatment on the open sea is because the distribution of germ life is inhibited on the sea by the absence of dust and of a population calculated to spread the infection. He could not help thinking that too much stress had been laid on the value of high altitude, and that the good results secured in such altitudes had been in spite of the altitude and because of the high percentage of sunny days. He had had a large personal experience with the treatment of phthisical patients in the lowlands of Arizona, which present a nearly ideal climate for such persons between October and June. In midwinter one may remain out-doors with comfort and benefit for many hours each day. The region is sheltered from winds, and there is a great volume of sunshine. An individual whose tuberculosis has been arrested under climatic treatment should remain in the same climate for at least one year after cough and expectoration have ceased. Strict obedience should be the motto of the patient, and infinite care that of the physician. Modern methods of treatment, when aided by a suitable climate, would save many cases that would otherwise succumb.

PRESIDENT'S ADDRESS—THE SURGICAL MANAGEMENT OF UMBILICAL HERNIA WITH LARGE RING.

DR. E. D. FERGUSON, Troy, described his method of closing the opening by means of lateral tendinous flaps turned over to the median line and held at their free borders by the cobbler's stitch.

TUBERCULOSIS; ITS GENERAL ETIOLOGY, GENERAL PATHOLOGY AND GENERAL PROPHYLAXIS.

PROF. VICTOR C. VAUGHAN, Ann Arbor, Mich., opened the symposium on tuberculosis. He said that some observers had stated that tubercle bacilli are capable of living abundantly and indefinitely outside the body as saprophytes, but this was a mere assumption, and had no scientific basis. The transmission of the tubercle bacillus is rarely direct, but may be so occasionally, as in the inoculation of wounds. When the infectious matter is introduced under the skin, the first sign of infection is in the adjacent lymph-glands. He was more than ever convinced that every dairy cow should be tested with tuberculin. Tuberculosis always begins as a local disease, and most of the deaths from tuberculosis of the lungs are the result of mixed infection. Very little could be accomplished in the way of treatment outside of special hospitals, but he firmly believed that in time the human race could be rid of this plague just as it had been of leprosy.

THE DIAGNOSIS AND TREATMENT OF LARYNGEAL TUBERCULOSIS.

DR. JONATHAN WRIGHT, Brooklyn, pointed out the great risk of confounding laryngeal phthisis with syphilis, and in connection with the treatment, expressed the opinion that a radical cure was rarely secured by surgical means. The local application of iodoform or orthoform emulsion would be found soothing if not curative. Submucous injections of creosote or lactic acid did not appeal to his knowledge of the pathology.

TUBERCULOSIS OF THE EYE; ITS DIFFERENTIAL DIAGNOSIS, PATHOLOGY AND TREATMENT.

DR. CHARLES STEDMAN BULL, New York City, discussed separately and exhaustively the effect of tuberculosis on each of the more important structures of the eye.

THE PATHOLOGY, DIAGNOSIS, SPECIAL PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS OF THE EAR.

DR. SEYMOUR OPPENHEIMER, New York City, said that in making the diagnosis in tuberculosis of the ear it was often necessary to examine microscopically the pus from the deeper structures, or even to make inoculation experiments.

ACUTE TUBERCULOSIS OF THE MESENTERIC LYMPH-GLANDS.

DR. MAURICE H. RICHARDSON, Boston, said the symptoms are most obscure. The prognosis had always been considered very grave, but with earlier surgical intervention it should improve.

SURGICAL TREATMENT OF URINARY AND URO-GENITAL TUBERCULOSIS.

DR. S. ALEXANDER, New York City, dealt successively with tuberculosis of the kidneys, epididymis, testicle, prostate and bladder. He said that to succeed in finding the tubercle bacilli in the urine it was necessary to collect the sediment, with the aid of the centrifuge, from freshly voided urine.

DR. E. H. NICHOLS, Boston, discussed "The Pathology, Diagnosis, Special Prophylaxis and Treatment of Tuberculosis of the Bones and Joints," with the aid of many lantern slides.

THE PATHOLOGY, DIAGNOSIS, SPECIAL PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS OF THE SKIN AND SUPERFICIAL FASCIA.

DR. JOHN A. FORDYCE, New York City, discussed the principal features of lupus, and exhibited some lantern slides to show the differences and points of resemblances between lupus and syphilis.

THE TREATMENT OF ICHTHYOSIS HYSTRIX BY ELECTRIC LIGHT.

DR. GEORGE W. COLER, Rochester, gave a brief account of a rapid cure effected in a case by exposure to electric light.

THE DIFFERENTIAL DIAGNOSIS OF ECTOPIC GESTATION WITH SPECIAL REFERENCE TO EARLY ABORTION.

DR. HIRAM N. VINEBERG, New York City, pointed out the liability of confounding ectopic pregnancy with irregular saculation of a pregnant uterus, with elongation of the cervix and with a retroflexed uterus. In doubtful cases he advocated exploration through a posterior vaginal incision. DRs. F. H. WIGGIN, C. C. FREDERICK and E. V. DELPHEY related cases which they had seen, and which well illustrated the difficulties of diagnosis in this class of cases.

THE RESOURCES OF MODERN MINOR GYNECOLOGY.

DR. AUGUSTIN H. GOELET, New York City, exhibited some laminaria tents which he had had covered with rubber sheaths to do away with the objection that they are prone to cause infection. He holds electricity, both faradic and galvanic, in high esteem in the treatment of endometritis and pain and tenderness arising from the presence of pelvic exudates. He had found a combination of potassium bromid and iodid useful in this last class of cases.

STRABISMUS AND ITS MANAGEMENT.

DR. JULIUS H. WOODWARD, New York City, described the symptomatology and treatment of both paralytic and non-paralytic strabismus. He favored early operation, pointing out the disastrous effect on the temperament of the person if the deformity were not corrected at an early date.

INVESTIGATIONS UPON SPECIFIC CORPORAL GRAVITY AND UPON THE VALUE OF THIS FACTOR IN PHYSICAL DIAGNOSIS.

DR. HEINRICH STERN, New York City, pointed out that the important thing for the physician or life insurance examiner to know was not the body weight but the specific gravity of the body. It could be most easily determined by dividing the amount of absolute weight of the body by the loss of weight sustained when submerged in water. It is less in children than in adults, and is greater in the aged than in middle life. His studies had also brought out the fact that it was perfectly possible to estimate the specific gravity of the body by determining the specific gravity of a drop of blood.

ASEPTIC MINOR SURGERY.

DR. DOUGLAS AYRES, Fort Plain, gave a view of the surgery

of the past, and then described the arrangements in the office or home by which one can most easily and successfully practice modern aseptic surgery.

DR. JOHN A. WYETH, New York City, presented a paper, "Amputation at the Hip-Joint: A Report of 200 Cases in Which the Author's Method of Hemostasis was Employed," which will appear in a later issue of THE JOURNAL.

REPORT OF THREE CASES OF INTESTINAL OBSTRUCTION DUE TO MECKEL'S DIVERTICULA.

DR. JOHN F. ERDMAN, New York City, called attention to the similarity in symptoms in these three cases to those of appendicitis, and also to the difficulty of early differential diagnosis between these two conditions.

INTRASPINAL COCAINIZATION FOR THE PRODUCTION OF SURGICAL ANESTHESIA.

DR. S. ORMOND GOLDAN, New York City, detailed his experience with this new method of inducing anesthesia. He advises the use of specially-made needles of gold, and the injection at one time of not more than 20 minims of a freshly prepared and sterile solution of cocain. The syringe should not be removed from the needle for at least two minutes after making the injection. Anesthesia will be complete in from four to twelve minutes. It was his practice now to give whiskey in every case before resorting to intraspinal cocaineization.

DR. J. A. BODINE suggested that some of the failures might be explained by the too rapid diffusion of the solution, and suggested as a remedy the addition of salt solution. In any case, he looked upon this method of inducing anesthesia as by no means free from danger.

DRS. DAWBARN and HARTWIG counseled the exercise of a reasonable conservatism in this matter, the former remarking that he had known of the method being used for the opening of a large boil on the thigh.

DR. GOLDAN replied that he had tried the salt solution, but with a negative result.

THE TECHNIC OF BLOODLESS WORK.

DR. ROBERT H. M. DAWBARN, New York City, described some of the simplest and most practical methods of reducing to a minimum the amount of blood lost in surgical operations of all kinds. Special emphasis was laid upon the great value of temporary ligation of the extremities in hemorrhage from the lungs.

OPERATIVE TREATMENT OF SYMBLEPHARON BY THE USE OF THIERSCH'S GRAFTS.

DR. WILBUR B. MARPLE, New York City, described his method of using a glass shell, something like an artificial eye, as a means of holding the graft in better apposition than was possible by the methods heretofore employed.

Therapeutics.

Dyspepsia.

Sir T. Lauder Brunton, in the *Clinical Journal*, emphasizes the following points in instructing patients troubled with dyspepsia:

1. Eat slowly, masticate and insalivate thoroughly. And, if necessary, follow Sir Andrew Clark's rule—count the bites.
2. Take the solids and liquids separately, so as not to dilute the gastric juice nor weaken the digestive ability of the stomach.
3. If necessary, let the patient take his farinaceous food and the proteids at different meals.
4. The best fluid is hot water, taken early in the morning and an hour or two before lunch and dinner.
 - a. Alkalies before meals stimulate secretion of gastric juice.
 - b. Acids before meals check acid secretions of the stomach.
 - c. Where the food remains in the stomach an unusual length of time lavage should be resorted to.

ERUCTIONS, REGURGITATION AND RUMINATION.

Lincoln, in the *N. Y. Med. Journal*, advises removal of the cause and, next to that, a strong will-power. Have the meals served in company with some one whom the patient respects. Use food, as much as possible, which remains in the stomach

only a short time and use a bitter preparation at meal-times as follows:

R. Ext. condurango fluidi

Medicolegal.

Suspending Trial for Examination by Physician.—One of the grounds on which the Supreme Court of Georgia was sought in *Herdon vs. State*, to reverse a conviction of murder, was that the trial court had refused to allow a medical expert, who had been introduced by the accused, and who was on the stand testifying as a witness, to examine an indention or depression in the skull of the accused, and then testify as to the effect it would produce on his mind. In his statement to the jury, the accused had stated that the depression had been made in his early youth by a falling stone, that he had subsequently had a severe case of typhoid fever, and that since then he had been at times ignorant or unconscious of what he said and did. But the matter of suspending the trial for the purpose mentioned, the supreme court holds, was entirely within the discretion of the trial court. It says that a trial court may or may not suspend a trial for such a purpose, according to the circumstances of each particular case, and that where a matter of practice is within the discretion of the trial court, the supreme court will not interfere unless such discretion is manifestly abused. Continuing, it says that it can not establish

any fixed rules to govern courts in this respect. In some cases an examination of an injury might be made in a few minutes. In others, hours might be consumed before the expert could come to any definite conclusion as to the nature and character of the injuries. Besides, it makes a point here of the fact that this appeared to have been the second trial of this case, and that the accused and his counsel had had abundant opportunity to have had the examination made before the trial. Had he done so, then the expert, it holds, could have testified as to his opinion of the effect the injury would have produced upon the mind of the accused.

Pain and Suffering in Malpractice Case.—A boy bruised his right leg, or shin bone, just below the knee. After about a week, considerable pain ensuing, a physician was called in to treat the wound. According to the allegations, he persisted in diagnosing the case as one of inflammatory rheumatism, and in treating it as such until after a great quantity of pus had formed, and the leg had finally to be amputated. But the physician denied all the allegations which attempted to charge him with liability on account of malpractice. He contended that, although he had made a mistake as to the first diagnosis and treatment, that did not result in the necessity for the amputation, but that the amputation resulted from an entirely different disease, which would have been the result notwithstanding the original mistake. Quite a volume of evidence was introduced pro and con, and the jury returned a verdict for the defendant. However, the Supreme Court of Georgia holds, *Moon vs. McRae*, that the judgment in the physician's favor must be reversed, and a new trial had, on account of an erroneous instruction to the jury. It holds that it was error to charge the jury, in effect, that if the amputation itself did not result from the defendant's treatment there could be no recovery of damages, or, in other words, that damages could not be recovered for pain and suffering from unskillful treatment by the physician, unless such treatment was the cause of the loss of the limb. And it holds that, as elements of damages claimed, pain and suffering were sufficiently set forth in the petition, which set forth the extent of pain and suffering and contained allegations which clearly attributed much of it to an improper diagnosis, and to the delay in administering the proper treatment until pus had so accumulated in the diseased leg as to unnecessarily add to the pain and suffering, the damages claimed in the petition being not only for the loss of the leg by amputation, but also for pain and suffering occasioned by the alleged mistreatment.

Not Liable for Trespass of Health Officer.—A theatrical troupe left New Orleans for San Antonio on the last train before a quarantine was declared in Texas against New Orleans on account of yellow fever. On arrival at San Antonio, several of the members of this troupe registered at a certain hotel, the others taking quarters elsewhere in the city. In the afternoon of that day, under direction of the mayor and city physician, all were taken in charge by police, and taken to the hotel mentioned, where, without the consent and over the protest of the proprietor, they were quartered as yellow-fever suspects and detained by police officers for six days. This greatly injured the business of the hotel, and the proprietor sued the city for damages. The allegation was that the city, by and through its mayor and health officer, committed the acts complained of. It is probable, says the Court of Civil Appeals of Texas, *City of Antonio vs. White*, that this was a sufficient allegation that the city caused the acts to be done. It further says that the acts detailed above constituted an unwarrantable trespass, for which the mayor and health officer were probably liable. But it holds that a fact that is essential to the city's liability in cases of this kind was wanting, namely, the fact that the city was, or had made itself, a party to the trespass. It says that there was absolutely no evidence from which it could be found that the city directed, or had ratified, the proceeding, and a city, it holds, is not liable for acts of its health officers, or for malfeasances. At least it is of the opinion, it says, that, without some testimony connecting the corporation with the transaction complained of, either by showing its previous direction, or participation therein, or

ratification, there was no basis for any claim of liability against it. Again, the court says that it is of the opinion that a city could not, under the guise of exercising a strictly governmental power, evade the constitutional provision that private property is not to be appropriated for public use without just compensation, but it says that it is clear that the act must be the act of the city in such a case. A city can not be held liable for property taken or appropriated by a trespass with which it has no connection at all. Wherefore, it holds that it was error to refuse to charge the jury in this case that the city was not liable for any wrong or trespass committed by its mayor, city physician, or police officers, and therefore to return a verdict for the city.

Husband's Liability for Care of Insane Wife.—The Supreme Court of California has rendered decisions in two cases brought by the St. Vincent's Institution for the Insane vs. John T. Davis. One was for boarding and clothing his insane wife prior to June, 1894, and the other was for keeping and caring for her, providing for her suitable boarding, lodging, clothing, washing, medicine, and medical and other attendance after that date. In both cases, the court cites section 174 of the California civil code, which provides that, when a husband fails to make adequate provision for the support of his wife, then—except in certain cases—any person may supply her with necessaries, and recover the value thereof from the husband. Under this rule, applied to the different circumstances of the two cases, in the first-mentioned case the supreme court affirms a judgment in favor of the St. Vincent's Institution for the Insane, and, in the other case, in favor of the husband. In the first case, there was a very strong presumption that the husband had left his wife in a small town in Illinois, intending that her identity should be lost, that she might no longer be a charge upon him. Under such circumstances, the court holds, the husband would be liable for necessaries, even though the parties supplying them did not know of his existence, or that the woman was married. And with regard to the contention that the evidence was insufficient to sustain a finding that the service was rendered on the credit of the husband, it being argued that it did not appear that he was even aware that she was being kept and provided for by the institution at all, the court answers that, even if he had no such knowledge, it would not follow that he was not liable, or that the service was not rendered at his request. But, in the second case, there was a finding that the husband, desiring in good faith to care for his wife elsewhere, had, in June, 1894, demanded of the institution that she be delivered to him, and that the institution, without legal cause or excuse, had refused to comply with such demand, and against the will of the husband had thereafter retained the wife in its custody. Such being this second case, the court holds that no recovery for keeping and caring for her could be had therein, the section of the civil code quoted requiring that whoever supplies necessaries to a wife must, in order to recover therefor, show neglect on the part of the husband to make adequate provision for her support, which was not shown in this case, it not being enough for the purpose that some suspicion was cast upon the motives of the husband, there also being some evidence tending to show good faith on his part.

1.—See abstract in THE JOURNAL of October 20, p. 1049.

2. **Asthma.**—Wells thinks that asthma, above all other diseases, requires strict individualization in its treatment, and regard must be had for the existence of complications. He concludes that it has so many points of resemblance with migraine, angina pectoris and epilepsy that it may be reasonable to suspect that they have a similar pathology. Of all the theories of the pathology of the paroxysm, none harmonizes so well with all the facts as the vasomotor theory, and this, when we consider the disturbance as essentially that of arterial contraction, not dilatation. Asthma occurs in reflex neuroses from diseases of various organs, but especially from those supplied by the vagus nerve. The nasal trouble which is so frequently its cause, may not be an obstruction and may often be very difficult to detect. Nearly all cases show evidence of a pronounced psychic element in the curious character of the exciting causes, the capriciousness of the disease and its dependence on emotional states. In the treatment of the paroxysm strict individualization needs to be observed. The best remedies are those which overcome arterial spasm, such as morphin, nitroglycerin, atropin and chloral hydrate. The treatment between the attacks must be directed first, to removing the cause and, second, to the institution of sound hygienic and prophylactic measures as regards the mind, diet, air, exercise, etc. The medicinal treatment is addressed to improving the constitutional state, for which the best remedies are piperazin, potassium iodid and other iodids, the alkalies, and tonics.

3. **Electrization of Lachrymal Passages.**—After noticing the history of the method, technique, opinions and results of authorities, Mial reports his own experience. He used applications of the electric current with the Bowman probe at intervals of a week in six cases, with results so encouraging that he has had constructed a special set of lachrymal electrodes. At present it seems to him that in simple stricture of the lachrymal ducts, the knife is unnecessary and should be wholly replaced by the electric bougie. The chief indication is to keep the passages open; electrization does this speedily, painlessly and without hemorrhage, and is furthermore antiseptic. In his opinion the strength of the current should not exceed 3 milliamperes. The positive pole is a flat sponge applied to the back of the neck, and two minutes is long enough under all circumstances. Short and frequent sittings are preferable to longer ones. After withdrawing the probe, it is well to wash out the canal with a 4 per cent. solution of protargol.

5. **Concha Bullosa.**—Bullous enlargement of the middle turbinate bone or concha bullosa is described by Clark, who reports two cases and mentions the symptoms and treatment. The condition seems to occur almost exclusively in women, a fact which can not be explained. The diagnosis is not difficult. A rounded swelling situated in the region of the middle turbinate should be distinguished by a probe from a polyp or hypertrophy of the mucous membrane. The symptoms are chiefly headache, obstruction to respiration, sometimes, though not commonly, deformity of the nose, reflex symptoms, such as vomiting, etc. The only rational treatment is the removal with the cold-wire snare, conchotome, or cutting-forceps. Hemorrhage is usually insignificant.

9. **Yellow Fever.**—Smart reproduces Sternberg's reply to Sanarelli in the *Centralblatt fuer Bakteriologie*, Bd. xxvii, No. 20-21, and also gives a translation of a letter from Dr. Adolphe Lutz, published in the *Revista d'Igiene e Sanita Publica*, Torino, 1 July, 1900, supporting the views of Sternberg as opposed to those of Sanarelli.

14. **Suppurative Pericarditis.**—The following are the conclusions of Porter's article: 1. Pericardiotomy is indicated in all cases of suppurative pericarditis. 2. Because of the un-

certain and varying relations of the pleura and because of the anterior position of the heart, whenever the pericardial sac is distended by fluid, aspiration of the pericardium is a more dangerous procedure than open incision, when done by skilled hands. 3. Incisions of the pericardium can be done quickly and safely by resection of the fifth costal cartilage and in many cases under local anesthesia. 4. In many cases of serous effusion open incision without puncture will offer less risk and speedier cure than aspiration. 5. The method and detailed technique of the writer proposed in 1897 has been followed out by the majority of recent operators.

15.—See THE JOURNAL, August 18, p. 454.

16. **Rheumatic Diathesis.**—Porter argues against the assumption of the existence of uric-acid diathesis and thinks it reasonable to assume that continued errors in the diet, the action of the various micro-organisms on the intestinal canal and the production of an almost endless variety of these toxic products may be easily made to explain the many symptoms and types of so-called rheumatism, even from a slight neuralgia down to the most extensive destruction of the joint structures. Uric acid, when it rises above the normal in the urine, is simply a symptom of the imperfect state of proteid oxidation and the general condition of malnutrition.

17. **Septic and Gonorrhœa Joints.**—In the paper on this subject, Porter attempts to show that gonorrhœa alone can cause arthritis which may be purulent without the presence of other organisms, and that this gonorrhœal arthritis occurs not only in acute gonorrhœa but in chronic and latent stages and is more permanent than is usually believed. The signs of such chronic infections are often slight and overlooked. Therefore, not a small proportion of cases are diagnosed as arthritis which are really of gonorrhœal origin. He thinks the best treatment in the acute stage is absolute immobilization, and after its subsidence advantage can be taken of the period of diminished sensibility to pain which usually follows the hot-air bath, to employ massage as a preliminary to passive movement. The question of operation is rather coming to the front, and he thinks with proper precautions the danger of sepsis is slight compared with the advantage to be gained, but for general adoption immobilization is the best treatment. Only when pus can be demonstrated by fluctuation, edema and redness, or aspiration, should operation be resorted to.

19. **Spinal Anesthesia.**—Coring notices first the history, with special reference to his own part in the origination of the method, and then describes the technique of spinal cocainization, calling attention to the necessity of antiseptics. He maintains that the outflow of the cerebrospinal fluid is not absolutely essential to ascertain whether the needle has entered the spinal cord. This can be determined by measurements and a tentative injection of a small quantity of the anesthetic. He cautions against too free recourse to the method and believes that deaths will be reported from its use in the hands of unskilled practitioners. He does not think that it will ever supplant entirely or seriously the methods of cerebral anesthesia though it may curtail their use somewhat.

23. **Surgery of the Gall-Tracts.**—The special points emphasized by Jones are: 1. The diagnostic value of the point of maximum tenderness on pressure, which is over the gall-bladder or at near the costal margin of the ninth rib. This point in disease of the gall-tracts corresponds in importance with McBurney's point in disease of the appendix. 2. The diagnostic value of the presence of bile in the urine excreted during or immediately after a very brief obstruction of the common duct. 3. Disease of the gall-tracts is of very common occurrence, and is liable to be mistaken for other troubles which it closely imitates. He urges the physician to observe and recognize early the effects due to diseases of the gall-tracts.

24. **The Soldier's Rations.**—Seaman thinks that the soldiers' ration used by the United States is altogether too rich in proteids and severely taxes the digestion of soldiers in the tropics. He maintains that a small amount of fresh meat or its equivalent in dried and smoked beef with a more ample

allowance of succulent and green vegetables and sugar with chocolate would be a great improvement and would afford the possibility of selecting a light portable ration which would be ample for hard campaigning in hot countries.

27. **Typhoid Fever.**—The principles of the treatment of typhoid fever are: Put the patient to bed at the beginning, as any other course is perilous. Then provide a non-irritating and preferably liquid diet. The mild cases will get well without medication, but Burt does not recommend that altogether expectant course. He is of the opinion that alcohol is used too freely, but there are cases where it is required. The actual tub bath he thinks is less advisable than an application of cold water otherwise. A sponge bath, one-third alcohol and two-thirds cold water, will accomplish the desired results in the majority of cases. He is inclined to believe that where the fever remains within bounds, it is not a matter of much concern, if the pulse remains good and nervous symptoms are absent. If any intestinal antiseptic remedies are to be tried, he considers mild laxatives the best. Where the bowels move more than three or four times in the twenty-four hours he gives bismuth in large doses with a small dose of morphia. The supporting remedies are strychnin, ammonia, alcohol, bismuth, etc. When the fever has gone, he would keep the patient still in bed until the muscular symptoms and heart are in a suitable condition for his getting up, and he would prescribe a soft diet for a week or ten days.

31.—See abstract in THE JOURNAL of October 20, p. 1050.

37. **Tuberculosis.**—The diagnosis and prognosis of pulmonary tuberculosis are discussed by Dock, who insists on the importance of sputum examinations as well as of physical and rational signs. The former appear to him to be very much neglected by general practitioners, not over 10 per cent. of the patients coming to the University Hospital (Ann Arbor) having had their sputa tested. Too much reliance, however, should not be placed in this alone, nor on a good family history; a negative family history should of itself carry no weight. Among the early symptoms he specially notes anemia, dyspepsia, etc. Cough does not always receive the attention it deserves, and hoarseness is also important. Tuberculosis of the genito-urinary tract is commoner than is supposed and pus from it should be examined like sputum. Percussion and auscultation must be comparative to be of value, and attention must be given to the proper use of interrupted breathing, prolongation of expiration and the voice signs. The prognosis depends upon various factors. The condition of other organs than the lungs must be regarded. The abundance of bacilli in the sputum is significant; often a large number may come from a quiescent cavity, and though this may be liable to be lighted up, their presence does not necessarily imply that this has occurred. The condition of the larynx is important, but less so than formerly supposed. Complicating pleurisy is not necessarily a hopeless symptom. Dock lays special stress on the significance of the diazo reaction; when it is positive the outlook must be considered bad.

38.—**Graves' Disease.**—Inglis' theory of Graves' disease is that it is a group of symptoms due to the entrance into the blood of an altered secretion of the thyroid gland. The normal secretion is, he holds, an enzyme affecting tissue growth. In this disease a poison is secreted having an elective action on the nervous system, and especially the sympathetic. In the common cases with early thyroid enlargement, the gland is diseased and its toxic secretion irritates the gland itself. In the rarer cases without enlargement, the gland is not so directly affected by its abnormal products. This theory explains more readily the occurrence of exophthalmic goiter from nervous shock. A comparison of the symptoms with those observed in other disorders assumed to be due to toxins, such as tuberculosis and cholera throws light on the disease.

45. **Adiposis Dolorosa.**—Burr reports a case in a woman thirty-six years of age, weighing three hundred pounds, with symptoms of lethargy, weakness, spinal paralysis, who had lost control of the bladder and rectum. She was in the hospital in a semi-conscious condition for several weeks, and then died with edema of the lungs and acute Bright's

disease. At the necropsy, a tumor of the pituitary body about as large as a walnut was found, involving the optic chiasm and penetrating upward into the ventricles. There was a marked internal hydrocephalus. The thyroid gland was normal in size, and contained a secretion about as large as a chestnut. The lungs were edematous and the ovaries small and hard. Microscopic examination showed a high grade of interstitial neuritis in the nerve filaments and muscles and in the various nerves examined. At the seat of the pituitary body was a glioma. There was marked degeneration of the thyroid gland and absence of the secreting cells. The ovaries were non-functional and sclerotic. The case is of interest as showing the combination of adiposis dolorosa with neuritis and organic brain disease, together with ovarian complication which may have had a bearing on the beginning of the trouble.

54. Treatment of the Breasts.—Brodhead advises that nothing be done during pregnancy in most cases, beyond the precautions for cleanliness, bathing each day with warm water and castile soap and a little massage if the nipples are small; albolene on sterile gauze applied at night is also advisable. With nursing women the nipples should be kept covered with albolene on sterile gauze between nursings, and never handled. If they become cracked or eroded there is nothing equal to a 10 per cent. nitrate of silver solution applied on clean cotton. After two or three applications the crack usually heals. After each nursing the nipples should be bathed with boric acid and the child's mouth treated in the same way. Where the patient does not nurse, a tight breast-binder should be applied after nursing has ceased, and in many cases this alone will suffice and the milk will dry up. In other cases it may be advisable to limit the amount of fluids taken and in all cases where the breasts are caked large doses of Rochelle salts should be given. In very few cases will it be necessary to use massage. In nursing women, where there is extreme over-secretion, a little pressure may be applied, but in ordinary cases this should be avoided. In all cases the breasts should be supported in some way to prevent caking, and the use of Rochelle salts in cases of over-secretion is good practice. Abscess of the breasts is very rare with perfect cleanliness, but when it occurs massage should be used to force the pus out through the nipples and nursing should be stopped. Here also large doses of salts are useful. When this treatment fails, the treatment is the same as for abscesses in other parts of the body.

60. Nephritis Following Influenza.—From the observation of a certain number of cases in the literature, as well as one observed by himself, Freeman draws the following conclusions, premising that they are based on a very limited number of cases: 1. Although albuminuria is fairly frequent with influenza, nephritis is a rare complication. 2. The nephritis complicating influenza is clinically of the acute hemorrhagic type and morphologically shows toxic lesions. 3. It apparently attacks children more often than adults. 4. The kidney disturbances may appear a few days after the acute symptoms of the influenza, or as long as a month later. 5. The prognosis is good.

70. Pelvic Reflexes.—Howe reviews the anatomy of the nervous system briefly to explain the possibilities of pelvic reflexes and insists on close observation of these latter in nervous manifestations in women. If the cause is not found there, seek it elsewhere, but by all means find the cause and remove it. He reports several cases illustrating ovarian and uterine reflexes and the benefit derived from operation.

71. Gonorrhoea.—Residuary pathologic conditions following gonorrhoea are noted by Ill. He finds among the most frequent and persistent forms about the vulva, what has been called a macular vulvitis. The Bartholinian gland itself will often be found as a hard nodular mass and its cysts are commonly the result of gonorrhoeal obliteration of the duct. At the meatus we have the macules, and purulent discharges from the ducts of Skene and stringy mucus showing in the urine-like threads, are prominent residuary symptoms about the urethra as well as stricture of the urethra and periurethral thickening. The same macules and papules are found in the vagina. The very

chronic form of endometritis, where there is a copious mucopurulent discharge from the cervix in which gonococci can no longer be demonstrated, might also possibly be classed under this head. It is this form that baffles our skill in treatment. He has also seen a chronic atrophic endometritis, which he has reason to believe is a very remote residuary symptom of gonorrhoea. The residuary symptoms found in the tubes, ovaries and pelvic peritoneum need no lengthy description. The chronic thickening of the tubes with their adhesions is commonly the result of gonorrhoeal infection, as likewise is the thickened albuginea of the ovary. When these conditions are found with the macules already mentioned we may feel very sure of their cause. Septic puerperal infection rarely leaves such thickening in the pelvis as does gonorrhoea. The writer has often been astonished to find how frequently a granular colitis accompanies the residuary symptoms in other parts. Finally, he cautions circumspection in the diagnosis and close observation before decision.

76. Surgical Treatment of Hernia.—Parker describes his method of treating hernia, which is largely that of Bassini, and sums up the indications as follows: 1. Close the sac. This is accomplished by pulling down the sac and sewing it so that when it retracts it will rest against the abdominal wall. 2. To close the internal ring by sewing together the transversalis fascia and securing a firm union of the internal oblique and the transversalis muscle to Poupart's ligament. 3. The displacing the cord on to the pubes and uniting the pillars of the external ring closely over it. 4. The operation is not to interfere with the functions of the cord or testicle. No veins are removed. No tension is put on the cord and atrophy of the testicle should not occur.

78. Post-Operative Treatment.—Robb's practice in abdominal operations is to give for the restlessness which occurs for the first twenty-four hours after the operation, when the attentions of the nurse are not sufficient, an enema consisting of 2 ounces of milk of assafetida, to be repeated in an hour if necessary, sometimes adding $\frac{1}{2}$ dram or more of potassium bromid. If the restlessness persists and the patient suffers pain it may be necessary to give $\frac{1}{6}$ to $\frac{1}{4}$ gr. of morphin, but it should never be used unless all other measures have failed. Where the pain is excessive and relief by the simpler methods have failed, a drop of the tincture of capsicum in a teaspoonful of hot water every half hour for two or three doses is ordered, or if this fails, fifteen to twenty drops of deodorized tincture of opium is added to a nutritive enema which the patient receives as a routine practice after the operation. Only exceptionally is morphin given hypodermically. Strychnin sulphate, $\frac{1}{30}$ of a grain by the rectum, is given as a routine practice after every abdominal operation, and when the patient arrives in the ward, $\frac{1}{30}$ grain hypodermically, with $\frac{1}{75}$ grain of atropin sulphate every half hour for two doses. After that she is then given strychnin— $\frac{1}{30}$ to $\frac{1}{60}$ gr.—hypodermically every three to six hours, according to the character of the pulse, and in a condition of marked shock six to eight doses may be employed. If the pulse is under 110 on the morning after the operation, as a rule, no strychnin is given, but if it is over 120, $\frac{1}{40}$ to $\frac{1}{70}$ of a grain is given hypodermically every three or four hours until the pulse is reduced. For the tympanites which sometimes occur after abdominal operation, 1 to 2 drops of tincture of capsicum in a teaspoonful of hot water every half hour for three or four doses, or 15 to 20 drops of essence of peppermint, will often prove effectual. A turpentine stupe or a mustard leaf over the epigastrium is a useful adjunct. If these measures do not relieve, a rectal tube is introduced high up in the rectum and is allowed to remain from fifteen minutes to half an hour, or until tympany disappears.

89. Puerperal Eclampsia.—Posey reports a case of puerperal eclampsia in which great relief was obtained from blood-letting, and argues, therefore, from experience in this and other cases that it will greatly modify the mortality of the condition if blood-letting were oftener resorted to.

91. Erichsen's Disease.—Goss' article is written entirely from the standpoint of a railway surgeon, and he has very

little belief in the genuineness of the great majority of cases that come up for damages against railroads. He thinks that in such cases greater weight should be given to the testimony of the surgeon than to that of the neurologist on account of the greater experience of the former with this class of cases.

92.—See abstract in THE JOURNAL of October 20, p. 1048.

99. **Malignant Growths.**—Pearse reviews the various methods of treating malignant growths, especially the non-surgical methods. He recalls a case of sarcoma reported by Dr. E. J. Kuh, pronounced inoperable, cured by alcohol injections, and mentions the value of internal medication with nucleiin, also the advantages from the use of opium and cocaine in the after-treatment of operated cases, as recommended by Herbert Snow. The value of escharotics as testified to by such men as Bernays, Lewis, Wyeth and others is also mentioned; also the use of electricity and the cataphoric method with oxychlorid of mercury, employed by Dr. G. Betton Massey, which he seems to consider promising, though too dangerous to be employed about the head and neck.

107. **Fracture of the Humerus.**—Jepson reports a case in which he diagnosed fracture of the humerus through the anatomical neck and in which he cut down on the head of the bone and removed it with good results. He remarks that it is commonly assumed that all dislocations at the shoulder-joint are classified as occurring either at the anatomical neck or surgical neck, and are presumed to be amenable to the same treatment, viz., reduction of the dislocated head irrespective of line of fracture. He protests against this view and says if the fracture is at the anatomical neck the head will be severed from all blood-supply and is liable to necrosis, and union could not take place unless impaction occurs. Consequently he would lay down the following rule: In fractures through the anatomic neck where a fragment is separated from all blood-supply, the proper procedure is to remove the dislocated head of the bone at as early a period as may be justified by circumstances, and that passive motion be undertaken early with a view of securing a nearthrosis, for if the bone were returned it would not unite and would ultimately have to be removed, and if left in its abnormal position it would in all probability induce deleterious effects. On the other hand, if the fragment had adequate blood-supply—as is possible in a fracture involving the tuberosities or the surgical neck—every effort at reduction should be made by direct manipulation, while the patient is under an anesthetic. If this should fail, then McBurney's method may be called into requisition. When it is impossible to bring about reduction of the upper fragment, then it would appear that removal of the fragment would lead to results superior to those which would follow in event of its being left in situ.

109.—Ibid., p. 234.

112.—See THE JOURNAL of October 13, title 40, p. 975.

114. **Medicolegal Experiences.**—In this address Mills gives some interesting experiences in medicolegal cases showing the tricks of lawyers and the peculiar position in which the medical witness often stands. He cautions witnesses against giving views regarding the books used by the examining counsel, as it is common practice to try to catch the doctor in endorsing what does not there exist. He shows the defects of expert testimony and the probable reasons why it is ineffectual in many cases; prejudice is one of those, as in the celebrated Giteau case. He thinks that the official expert system will never succeed in this country. The real way would be for the experts on both sides to examine the case together and consult about the condition frankly and freely without any effort to come to an agreement for the mere sake of doing so. While the present system is probably the best it is not always properly made use of. Very much depends on the competency of the experts, which it is needless to say is not always provided for. In conclusion he speaks about the physician's conduct as a witness, making the following points: 1. That the witness should not go outside of his own province. 2. That his testimony should

be relevant and his manner respectful. 3. That he should always tell his story in plain language. 4. That he should never pose as an expert outside of his special line of work. When asked about the responsibility of persons on trial he has on one or two occasions himself found it advantageous to disclaim being an expert on responsibility. While as a rule repartee is not advisable there are cases where it may be advantageous, but they are not common. The witness should learn not to say too much. It is exceptional, but it is also possible for the witness, through nervousness or modesty, to be too brief.

115. **Asepsis.**—The history of asepsis is briefly noticed by Nancrede, who insists on absolute asepsis by means of gloves, giving details as to their use. They can be best put on by filling with sterilized water or a germicidal solution and then turning down the gauntlet part, slipping the fingers in carefully, following with the thumb. After both the gloves are on rinse off their outer surfaces with a germicidal solution or sterile water for fear the water escaping from the interior contain germs from the imperfectly cleaned hand. After removing them, dip them in water and turn inside out, dry carefully and dust with powdered talc. If punctured during the operation a thin finger cot must be pulled over the finger. After the operation most tears and all punctures can be readily repaired with cement obtainable from the makers. He concludes his paper with the following recapitulation of its chief points: 1. Air-germs can be ignored if strong currents of air be avoided. 2. The field of operation can be rendered practically aseptic, especially as the deeper layers of the epidermis, which contain the germs impossible to remove, are usually mechanically excluded from the wound proper by the apposition of the derm by suturing. 3. Mechanical removal of germs by friction, assisted by agents such as alkalies, which tend to disintegrate the superficial layers of the epidermis should be the chief means employed to secure asepsis of the field of operation and the hands. 4. Alcohol is preferable to ether for the removal of grease, as it destroys the deeper layers of the epiderm, thus tending to destroy or inhibit the growth of the germs there resident. 5. Caloric is the only thoroughly reliable agent for the sterilization of ligatures, dressings, and sponges. 6. There is no certainly reliable method of sterilization of the hands which renders it safe under all circumstances to tie the ligatures with bare hands. 7. Hence it is our duty to use gloves when tying ligatures and, when possible, at every stage of all operations and during the dressing of all open wounds. Armed with a pair of these gloves, the practitioner can be independent of everything but water and soap, and can protect his patients from the chief danger, viz., his hands. 9. Obstetrical cases can be most safely handled with gloves especially if active intervention, as the mechanical removal of the placenta, be necessary.

119. **War Experiences in South Africa.**—Ryerson gives the results of his observations in South Africa during the late unpleasantness. He found, as others have found, that the Mauser bullet is not as serious in its effects as the older missiles. He also noticed that lyddite was not especially destructive, and the Boers found that the escaping gas could be counteracted by a few drops of vinegar. He remarks also on the good results following penetrating wounds of the abdomen, and says that while usually interference was not advisable he saw one case where excellent results were obtained by section. In conclusion he remarks on the hospital management in South Africa, vindicating the medical corps from the charges that have been made.

122. **Procidencia Uteri.**—Laphorn Smith reports results of the treatment of cases with complete procidencia. We have two operations, he says, to choose from, according to the degree of the prolapse and the size of the uterus. If the latter is small and not so far out of the body as to become ulcerated, the safest operation is to make a small incision in the abdomen, and catching the fundus with the bullet forceps, draw it up to the incision and scarify the whole anterior surface and then sew it to the abdominal wall with buried chromicized catgut, after which the vaginal outlet is narrowed by a large anterior and posterior colporrhaphy. If, however, the uterus is very

long, especially if it is badly ulcerated, it is better to amputate all but the upper two inches of it and then narrow the outlet. There is one advantage which ventrofixation and amputation of the cervix have over complete removal of the uterus; namely, that the bladder and vagina are drawn up by ventrofixation better than when the uterus is removed. However, by doing a Stolz operation to narrow the anterior vaginal wall, and a Hegar operation to narrow the posterior one, the outlet generally becomes quite small enough to keep the cystocele and rectocele in. In some cases, however, the cystocele is one of the most difficult conditions to cure.

129. Asthma and Hay-Fever.—Asthma is a symptom not a disease. We must look for the cause of it in some tissue or tissues supplied by the vagi and sympathetic. With the wide range of these nerves the organs supplied by them are numerous. We may, therefore, have cardiac asthma, bronchial, hepatic, pelvic, renal, splenic asthma, etc. There are three pretty constant factors, however, in all cases of asthma of long standing, viz., cardiac dilatation, acute vesicular emphysema, and chronic hepatic congestion. They must be relieved to cure the patient. As regards cardiac dilatation, Kingscote has endeavored to show in previous papers how the dilated organ may impinge on the vagi and so irritate them as to produce asthmatic spasm. Emphysema tends to produce asthma by dilating the heart and interfering with pulmonary circulation. In some cases these may be the only remaining causes of asthma, the original cause having worn itself out. It is easy to diagnose emphysema, but the exact amount of cardiac dilatation is difficult to determine on account of the former. If we can find the origin, whatever it may be, gastric trouble, or oral or nasal irritation, proper treatment is called for. To reduce the cardiac dilatation Kingscote knows of no better or surer means than the Schott treatment, while the emphysema may be reduced by the breathing exercises suggested by Harry Campbell. These are intended to induce thoracic respiration by fixing the lower ribs after expiration and slowly inhaling through the nose. The upper thorax is thus compelled to expand. He has seen many cases where this method produced several additional inches expansion of the chest. He has also been in the habit of giving these patients showing suboxidation of blood and anemia, inhalations of pure oxygen gas several times a day, and peptonate of iron, which is not assimilated until it reaches the alkaline influences of the intestines and, therefore, does not disturb the stomach and is not astringent. The patient is also encouraged to be in the open air as much as possible. In a period extending over six years, 10 per cent. of his patients suffering from asthma have been improved and 90 per cent. cured by the foregoing treatment. Hay-fever is allied to asthma and all his patients suffering from that symptom have been cured.

130. Cardiac Stimulants.—Flare calls attention to the disregard to essential details as to the action of this important class of drugs. In many cases he finds that symptoms supposed to be serious heart trouble that are entirely due to the excessive use of digitalis. Not infrequently is the cardiac distress augmented by the use also of strong coffee. He therefore thinks it well to call attention to the fact that the best medicine for a tired heart is rest, not stimulants, unless they be conjoined with rest. Another misuse of cardiac stimulants is their employment in states of undue excitement of the heart when cardiac sedatives are really needed. They are also often given without regard to the state they are expected to meet. The degenerated heart muscles can gain no advantage from the drug, and it actually increases the labor of the heart by contracting the blood-vessels. If any drug is used in such conditions it should be one like strophanthus or cactus, in its action only slightly, if at all, vascular. It is not rare to find digitalis given in full doses in cases of failing heart where the chief trouble is not in the heart itself but in the condition of high arterial spasm or atheroma. If it is given in such cases, its vascular effect must be relieved by vascular relaxants such as the nitrites. In all heart disorders it is well to make an effort to discover if any cause exists which may be removed before using powerful heart tonics. Not rarely the stopping of

tobacco, alcoholic drinks, over-eating, sexual excitement, etc., will relieve the condition without the use of drugs.

132. Strychnin.—Potts reports two cases in which he used hypodermic injections of large doses of strychnin, together with rest in bed, light diet, diuretics, the use of potassium iodid, and tincture of iron for neuralgia as advised by Dana. The results obtained show that, within the limitations detailed by Dana, the treatment is of value and should always be given a fair trial.

136. Antistreptococcic Serum.—Experience with this serum by Hunter has not led him to be very enthusiastic in regard to it, though in his tabulated statement it would appear that in some cases at least the results following the treatment were good. He is inclined to think that the serum is comparatively inactive and says that the useful judgment of the value of these remedies can not fairly be expected from the general practitioner. He thinks the movement which he understands is on foot to refer such remedies to some authoritative body before their general recommendation would be a very excellent thing.

137. Diphtheria Antitoxin.—England's article is a plea for the pharmacopoeial recognition of a standardized preparation of diphtheria antitoxin instead of having to depend solely upon the manufacturers' standards.

147.—This article has appeared elsewhere. See THE JOURNAL of September 1, '95, p. 582.

148.—Ibid., August 25, title 25, p. 518.

149.—See abstract in THE JOURNAL xxxiv, p. 1130.

150.—This article has appeared elsewhere. See THE JOURNAL of July 14, title 14, p. 118.

156. Dormiol (Amylene Chloral).—The value of a hypnotic is determined: 1, by its reliability and promptness in action; 2, by the duration of its effects; 3, by its harmlessness as regards by and after effects. Goldmann remarks that it is an excellent idea to combine chloral, which is rather toxic and the unfavorable action of which is not always controlled, with the harmless and reliable amylene hydrate and thereby obtain a preparation uniting in itself the qualities of a good hypnotic. This combination, which has been called dormiol by its introducer, Dr. Fuchs, is a mixture of a molecule of chloral with one of amylene hydrate. It is a colorless oily fluid of a camphor-like odor and peculiar though not very unpleasant pungent taste. Fuchs and Koch found that about 24 per cent. more chloral was borne in this combination than when taken uncombined. From this they deduce that "the lesser toxicity of dormiol is due to the gradual occurrence and slow progress of disunion of the preparation." Goldmann reports his experience with this remedy as a hypnotic in a number of cases, including insomnia from various causes and finds that it has a prompt and reliable hypnotic action and also an undeniable sedative effect. It can be called upon to manifest itself in the relatively small dose of 5 min. and in larger doses up to 24 min. or more, has apparently no depressing action. As compared with other hypnotics it is well borne on account of its slow absorption, is more harmless and more durable in its effects. The desired sleep often sets in in a quarter of an hour without any preliminary excitation and continues undiminished for several hours. It has no cumulative action, establishes no tolerance by its long-continued use, agrees well with the patient and has no untoward by- or after-effects.

158. Quinin as an Antipyretic.—Egbert finds quinin a valuable antipyretic, especially so in lobar pneumonia and idiopathic peritonitis. It should be administered early and freely. He does not recommend its promiscuous use nor advise that it be given preference to other remedies even in the diseases mentioned. For example, in pneumonia diaphoretic measures must not be neglected. We are treating in its first stage active congestion rather than virulent inflammation and such can be done to modify the occurrence of the disorder by measures which dilate the peripheral capillaries and further the excretions. In peritonitis he would strongly recommend the quinin

treatment in preference to that by opium. Excessive pain may demand the latter, but the less the amount of opium, the better the results. He favors moderate doses of quinin; over 5 gr. for an adult is seldom called for, and then when we have to press the drug the point of tolerance will be found to be removed by the exigency of the case. Quinin pills should be tabooed if other forms are available, capsules and cachets are preferable, and it is still more regular in its action in solution. Its activity is greatly augmented by combining it with aromatics, cholagogues and a moderate amount of alcohol, and it can also be aided by combining or administering it with remedies that relax capillaries, such as Dover's powder and those which have such a definite antifebrile effect by acting on the nervous centers, such as acetanilid, atypyrin, etc.

162.—This article has appeared elsewhere. See THE JOURNAL of August 25, title 45, p. 518.

FOREIGN.

British Medical Journal, October 13.

A Discussion on the Treatment of Internal Hemorrhages.—DR. W. G. SMITH opened the discussion by noticing the various remedies recommended for internal hemorrhages and remarked that drug treatment, simply because there is hemorrhage, is often superfluous and sometimes mischievous. There is no doubt as to the efficiency of local styptics, but the principle of their action does not apply to the remedies given internally for hemorrhage. After discussing the action of ergot and other drugs, he details the rational treatment in an urgent case of hemoptysis as follows: 1. Reassure the patient and calm his natural alarm and excitement and that of his friends by a few judicious words and simple directions, and emphasize the fact that hemorrhage *per se* is rarely a matter of urgency. It is curious to observe that gastric hemorrhages, which are often of much more serious import, have not the same depressing effect upon the patient as a slight tinge of blood in the expectoration. 2. Avoid irritation of the gastric ends of the vagus nerve. Therefore do not administer cold drinks or pieces of ice to patients suffering from phthisis complicated with hemoptysis. Cold drinks irritate the gastric branches of the vagus, give rise to cough and thus aggravate bleeding. Moreover, by causing contraction of blood-vessels of the stomach they may tend to increase the flow of blood to the lungs, and intelligent patients the subject of hemoptysis, usually discover the truth of this by experience, and avoid cold drinks (Eklund). Allow, on the contrary, warm mucilaginous drinks. An icebag to the outside of the chest is perhaps of use. 3. Keep the patient absolutely quiet in mind and body. 4. Give morphin hypodermically; this is the best thing of all to do. 5. Relieve the bowels freely by magnesium sulphate or by calomel. 6. Let the diet be simple and nutritious, reduce the amount of fluid, and give no alcohol. In the discussion which followed, Dr. Wynter referred to the use of gelatin for increasing the coagulability of the blood and suggested that this means had been employed in internal hemorrhage.

A Contribution to the Study of the Vascular Mechanism of the Testis. WALTER E. DIXON.—This article gives the results of experimental researches in the laboratories of the Royal College of Physicians and Surgeons of London. The author employed the plethysmograph to record the vasomotor changes of the testis, experimenting chiefly on dogs, and gives skiagraphs showing the effects of cantharidin, nicotin, etc. He says that it shows that the testis is supplied with vasomotor nerves; that it undergoes changes in volume passively with the blood-pressure, and actively as a direct result of vasomotor activity. These alterations, although well defined, are insignificant in comparison with the changes in other organs, such as the kidneys. The testis does not necessarily follow the vascular alterations of either the kidney or splanchnic areas; thus, after the injections of testicular substance, the volume of the testis and intestine expands, while the kidneys contract. On the other hand, after smaller injections of euntharidin, the testis and kidney contract while the splanchnic area becomes dilated; in contrast to both these, nicotin usually produces immediate constriction of both in-

testines and kidney, but induces dilatation of the testis. Of the substances inducing vasodilatation of the testis the following are among some of the most defined: Cantharidin (late), valerian, gold (late), spermin and allied bodies, caffeine, and fresh extracts of testis. The question of "internal secretion" and the significance of a dilated condition of the testis need not be discussed, but it is evident that, as in other glands, an active dilatation of vessels will lead to increased activity.

A Discussion on Serumtherapy.—After first giving a review of the theories of immunity in which he mentions the greater probability of Ehrlich's side-chain theory, Bokenham remarks that serumtherapy is no longer considered a treatment coming from haphazard experimentation, but one based on strictly sound scientific principles, that the specificity of any given serum is absolute and it is illogical to expect the least benefit to follow the use of, say a diphtheritic serum in whooping-cough, or any other disease than diphtheria, and that the benefits said to follow the use of specific serum in uncorresponding affections might be due to the alexins present in all serum, but certainly not to any specific element contained therein and absent from normal serum. He notices the antidiphtheritic serum, remarking that his experience, covering 500 inoculations, is altogether in its favor. One point of direct importance is the rash-producing effect and no method is at present known to obviate this unpleasant difficulty. The makers should eradicate all serums found to contain rash-producing products, even if satisfactory in other respects. As regards antistreptococic serum he found, with Professor Denys, of Louvain, that the way to secure the best results is to immunize the animals against as many strains of streptococcus as possible. In this way they have both obtained serums of far greater activity than can be gained otherwise. His own clinical results were very encouraging so long as he had at his disposal a fresh active serum recently prepared by himself, but it appears that it rapidly deteriorates, hence the uncertainty of the results of commercial serums. It should be used within three or four weeks after having been obtained from the animal. He has had no clinical experience with anti-pneumococic serum and suggests that what it apparently does is to prevent a general septicaemia and in this way is held to save life. He remarks, in conclusion, that no doubt research will lead to the addition of other serums to those now available in clinical use, but that at present we must not expect too much from applications of serumtherapy to the treatment of typhoid fever, cholera and the plague. Preventive inoculation rather than serumtherapy should for the present be our sheet-anchor.

The Treatment of Gouty Eczema. GILBERT J. K. MARTYN.—The eczema associated with gout is one of the most irritating troubles of the disease and Martyn confines his remarks to avoidance and prevention of irritation of the skin. The types of eczema met with in gout are, roughly: acute dry, acute moist, chronic, and what he terms latent. By the last he means the burning, itching sensation of the skin, with nothing visible on the surface. The treatment consists in regulation of the diet and the avoidance of everything that would produce dyspepsia, alcohol especially. Bismuth and the alkalis must be freely given for periods of three weeks, with short intervals. To relieve the intense burning and itching nothing does so well as a lotion or ointment containing carbolic acid. The clothing of the patient subject to attacks of eczema should be such as will assist healthy action of the skin, avoid extreme loss of heat, constant chillings, and reduce irritation to the minimum. The changes between winter and summer should be confined to the outer garments. Woolen is apt to be irritating and is made denser in the wash. The most rational is cotton or cotton with wool, which allows ventilation of the skin. The extremities must be especially protected with warm socks and mittens. The climate is of importance; a sea-climate is the worst; the best is an equable, fairly bracing one where the action of the skin will not be suddenly interfered with. Of the articles of diet which should be especially avoided, the first and foremost is alcohol; then all forms of raw or cooked food containing much fermentable

sugar or acid, such as strawberries, gooseberries, apples, lemons and rhubarb. All stimulating foods should be avoided. The patient can judge for himself what aggravates his case and what does not. Martyr has never seen colchicum, lithia or piperazin have the least effect on the eczema. The only valuable drugs are those that relieve the indigestion and increase the alkalinity of the blood. In some extreme cases morphin may be required to relieve the irritation. Arsenic is difficult to handle, but the nearer the eczema approaches the dry or scaly type the better its effects. The use of aperient water in the morning before eating should never be omitted. The local treatment is more important. For the acute, moist, inflammatory type, soothing lotions with lead and opium should be used constantly. When the irritation begins to disappear and the exudation lessens, he substitutes a dusting powder of carbonate of magnesia and Fuller's earth. For the dry irritating type nothing excels the old-fashioned tar in the form of liquor carbonis detergens. It should be used in a very diluted form as an ointment, 10 minims of the liquor to an ounce of lanolin. Owing to the great extent of the eczema, baths are very valuable, though when there is much irritation or inflammation they only serve to make matters worse. A lime sulphur water is admirably adapted to the dry, irritating, scaly eczema. In the more obdurate types he orders an addition of sulphur-water, prepared by boiling sulphur and slaked lime. The temperature of the bath should never exceed 98 F. In the aged the treatment must be, as a rule, palliative. Daily sponging with warm sulphur-water is of the greatest value and free use of dusting-powder after drying. Sleep must be procured, with mild sedatives if necessary.

Contribution to Our Knowledge of Proteid Metabolism in Children. F. W. TUNNICLIFFE and OTTO ROSENHEIM.—The authors made experimental investigations on the value of a special substance, prepared from skimmed milk, called plasmon, which is really a milk-proteid, with special reference to determining whether milk-proteid is capable of replacing meat in the diet of children between 3 and 6 years of age. Their article is illustrated by diagrams and their conclusions are: 1. Milk-proteid (plasmon) is capable of replacing meat as a nitrogenous food in the mixed diet of children according to its nitrogen percentage. 2. A greater increase in body weight took place during the milk-proteid periods in all three cases than during the meat periods. 3. The phosphorus of the milk-proteid is capable of being assimilated and retained in the body.

The Medicinal and Dietetic Treatment of Heart Failure in the Aged. F. W. FORBES ROSS.—This article deals with the results observed and maintained with strophanthus and digitalis, and the modifications of their action likely to occur under the influence of certain dietaries. The author finds that digitalis stimulates the vagus, depresses the reflex action of the cord and motor nerves, prolongs the cardiac diastole, increases papillary resistance, is irregular in results, is cumulative, irritating to the alimentary canal and induces suppression of the urine in the aged. Strophanthus does not stimulate the vagus, prolongs the cardiac systole, renders the nervous system hyperæsthetic and does not have any effect on the peripheral circulation till long after it increases the force of the cardiac systole, is unaccumulative, is not any more than if as irritating to the alimentary canal as digitalis, and acts regularly. It can be given with benefit for very long periods, even up to four years, without any other than good effect. Its cardiac stimulant dose does not affect the nervous system adversely unless administered with a mineral acid. Finally, strophanthus does not act like digitalis on the heart, as it can be given at once even after digitalis has produced ill effects, and these effects pass off while the patient is actually taking strophanthus. The drug, next to a direct cardiac stimulant that can be classed as most useful is mercury. In high-tension cases it acts as a strong diuretic, opens up the peripheral circulation and is said by some to be an actual heart tonic. It relieves portal engorgements in this, and in conditions of low tension and feeble pulse with cardiac embarrassment. Diarrhea is rather an indication for its use than the contrary.

Ross has found potassium iodid beneficial as a diuretic and cardiac tonic. Potassium and sodium nitrate will be found of great service from their dilating action on the peripheral circulation. He mentions here an undescribed physiologic effect of potassium nitrate and potassium citrate given in combination as a nocturnal dose, which seems to him very interesting. If given to even healthy persons whose hair is white, it will be noticed that within a week or ten days the hair over the ears, nape of the neck and beard begins to be restored to its natural color, and this progresses all over the scalp until the color is in a great part restored, but streaked with gray. This he takes as his barometer, and as long as he can see this continuing he feels confident of good results. He says one can prove this for himself. He raises a warning voice against the employment of rapid and violent arterial dilators such as the nitrites. The aged must receive the wherewithal to renovate the cardiac machine, and muscular-tissue building material must form a part of the dietary.

Journal of Laryngology, Rhinology and Otolaryngology, October.

A Plea for Early Naked Eye Diagnosis and Removal of the Entire Organ, With the Neighboring Area of Possible Lymphatic Infection, in Cancer of the Larynx. JOHN NOLAND MACKENZIE.—This article is a plea for greater attention to the naked-eye appearances in the diagnosis of malignant disease of the larynx, and the author protests against removal of tissue for diagnostic purposes, holding that it gives the disease a start. The moment the continuity of the growth is broken, the pathway for self-poisoning is opened. Early diagnosis and early radical treatment are of prime importance, especially in this condition. When the diagnosis is made, of course total extirpation should be the rule. He maintains that operations for laryngeal cancer through the mouth, so universally done at the present time, should be abandoned. No operation for laryngeal cancer is completed without removal of the neck lymphatics.

Annales de l'Institut Pasteur (Paris), April to September.

Microbe Pathogenic for Rats. J. DANYSZ.—A coccobacillus with all the characteristics of the bacillus coli was isolated from a spontaneous epidemic among field-mice and tested on rats after its virulence had been enhanced. The results have convinced Danyesz that rats could be completely exterminated by the systematic inoculation during a year or two of the young generations, which are most susceptible. Only eight were found alive out of 200 rats placed in a closed portion of a sewer and given bread smeared with the cultures.

Experimental Research on Symptomatic Anthrax. E. LECLAINCHE and H. VALLEE.—The research reported establishes that the bacterium of symptomatic anthrax is capable of producing an active toxin. Spores free from the toxin are unable to germinate and produce infection when introduced into an organism. The resistance to infection is connected with phagocytosis and everything that tends to inhibit it favors infection. Vaccination of cattle with pure cultures heated at 70 C. for two hours, supplemented by inoculation of a pure, non-heated culture, enables the animals to bear without reaction extremely large amounts of virulent juices. The pure vaccin can be prepared in the form of a powder. An effective immunizing and preventive serum can be produced, but its effect is transient.

Improved Differentiating Process for Typhoid Bacillus. L. REMY.—The formula of the differentiating culture-medium urgently recommended by Remy is as follows: Distilled water, 1000 gm.; asparagin, 6 gm.; oxalic acid, .5 gm.; lactic acid, .15 gm.; citric acid, .15 gm.; bisodium phosphate, 5 gm.; magnesium sulphate, 2.5 gm.; potassium phosphate, 1.25 gm.; sodium chlorid, 2 gm. The different salts, with the exception of the magnesium sulphate, are pulverized; mixed with a liter of distilled water and 30 gm. of peptone, heated in the autoclave for fifteen minutes, and poured, while boiling, into another vessel containing 120 to 150 gm. of gelatin. When dissolved, soda is added until the mixture is slightly alkaline. It is then cooked in the autoclave under pressure for fifteen minutes and rendered acid with a demi-normal solution of sulphuric acid in the proportion of .5 gm. of sulphuric acid to the liter. After stirring it is returned again to the autoclave for

eight to ten minutes, then filtered and the acidity tested by adding 10 c.c. of the gelatin to 100 c.c. of distilled water and 4 to 5 drops of phenolphthalein. The demi-normal solution of soda is then dropped from a pipette until the red tint appears, which should be when 2 c.c. of the soda solution have been added to 10 c.c. of the gelatin. The magnesium sulphate is then added—2.5 to the liter of the gelatin—which is distributed in the tubes and sterilized three times. To each tube is added 1 c.c. of a 35 per cent. solution of lactose and 1 c.c. of a 2.5 per cent. solution of phenic acid. Colonies both of the bacillus coli and Eberth's bacillus appeared in two days and differentiation was possible by the third, fourth and fifth day in six out of the twenty-three cases described. The colonies of Eberth's bacillus are a bluish white, with no gas-formation nor fermentation of lactose, and do not give the indol reaction. The bacilli are motile and agglutinate at 1 to 80,000. The colonies of the bacillus coli are yellowish-brown.

September

Spermotoxin. S. MATALINKOFF.—Further extensive research on the cell poisons has confirmed Metchnikoff's theory that they are formed inside the phagocytes and are merely intracellular digestive ferments. Spermatozoa introduced into the peritoneum of a spermotoxic guinea-pig are rapidly destroyed when there is phagolysis, but not when it is prevented by any means. On the other hand, they survive in the peritoneal fluid when the leucocytes are intact. Another argument is the prolonged resistance of the spermatozoa when introduced subcutaneously without phagolysis. Also the fact that it is easy to obtain an autopermotoxic serum by injecting spermatozoa from one guinea-pig into the peritoneum of another.

Archives de Med. Exp. (Paris), II, nos. 1 to 4

Saponifying Power of Serum in Pathologic Conditions. CH. ACIARD.—Research on seventy-two patients with various affections demonstrated that hyperlipasias is frequent in diabetes, and established the grave significance of any marked decrease in the lipasic activity of the serum.

Influence of Food on the Excretion of Urea. E. MAUREL. This monograph is based on years of study of guinea-pigs as herbivorous animals, hedge-hogs as carnivorous, and of man on a mixed diet. The chief practical conclusions are that urea in health is derived from the disassimilated albuminoid substances, from combustion of the excess of the nitrogenized elements of the food in the blood and from the excess of albuminoid substances in the blood found in certain pathologic conditions. The quantity of urea excreted has no diagnostic value unless the character of the food is known, as it varies with the latter more than is generally recognized. The minimum of urea from disassimilation is about .15 to .2 gm. per kilogram in a healthy, active man. This includes .07 to .09 gm. of nitrogen. The excretion of urea can be increased at will by increasing the amount of nitrogenous food. The normal average is .25 to .35 gm. This leaves a balance of .10 to .15 gm. for the urea derived from the food above the disassimilation urea. To maintain this normal average and supply the calories required the food should contain one part of nitrogenous ingredients to four of the carbohydrates. This proportion of nitrogen is ample in health, and in case of defective elimination should be diminished rather than increased.

Toxins of the Pneumococcus. P. CARNOT.—The toxins were obtained for this research by dialysis. The pneumococci were cultivated on the usual media, but in a long, slender bag of collodion, tied to the end of a glass tube passing through the cork of a large vessel filled with the same fluid, in which the bag was suspended. A second tube through the cork regulates the atmospheric pressure. The pneumococcus develops with exceptional luxuriance under these conditions, while the toxins escape by dialysis through the bag into the surrounding fluid.

July.

Septicopychemia in Man, Simulating Plague. BONDET.—A young Parisian was taken with a rapidly fatal septicemia, characterized by signs of "dramatic general infection," pulmonary symptoms and a supraclavicular adenophlegmon with multiple abscesses in the lungs. A small anaerobic bacillus was

found in large numbers, pathogenic and pyogenic for the rabbit, guinea-pig and dog, but not for rodents.

Buccal Leucoplasia. E. GAUCHER.—When the patch is smooth, Gaucher gently paints it once or twice a day with an aqueous 2 per cent. solution of potassium bichromate. This treatment should be continued patiently, as instances have been known of a cure after three years. If the patch is papillomatous, the excrescences should be removed with the galvano-cautery and the mouth frequently rinsed with a 10 per cent. solution of magnesium chloride. The patient should be kept under surveillance to detect incipient cancerous degeneration.

Action of Purgatives on Nutrition. H. MOREIGNE.—This study scientifically demonstrates the general hyperactivity of the phenomena of disassimilation and increase of the oxidations which are caused by a purgative, in addition to its action in stimulating peristalsis. The purgative used in the tests was .25 gm. of aloes with .02 gm. of podophyllin. Research on the action of sodium salicylate was reported by the same writer in the preceding number. This stimulates the biliary functions while it does not diminish the intraorganic phenomena of oxidation and hydrolysis.

Bulletin de la Soc. Med. des Hop. de Paris, August 2.

Typhoid Pleurisy. F. WIDAL.—Eleven writers have reported cases of typhoid pleurisy, but Widal has observed the astonishing number of eleven during the last year. He describes three in detail. They establish that the effusion may be serofibrinous, hemorrhagic or purulent. A slight, apparently insignificant effusion may rapidly become hemorrhagic or purulent, with a grave prognosis. The effusion is more or less bactericidal and Eberth's bacilli may be discovered in it only now and then or not at all. The three cases described terminated in recovery with absorption of the effusion. The agglutinating power of the latter was usually less than that of the serum, but occasionally equalled it. In one case exploratory punctures of different portions of the pleura showed the three types of an effusion developing simultaneously in the different regions.

Bulletin Medical (Paris), October 3.

Circumcision in the Senegal. LASNET.—All the native races in the Senegal practise circumcision with more or less ceremony. Bands of a hundred boys between 10 and 15 are circumcised in public, each lad sitting astride a log in turn for the operation. A thread is passed through the prepuce and the village blacksmith or shoemaker performs the operation. Girls are circumcised in private at home by the excision of the clitoris before the fourth year.

Nouvelle Iconographie de la Salpêtrière (Paris), March to August.

Seven Months' Sleep From Tumor in the Hypophysis. F. SOCA.—The case was observed at Montevideo. A young woman entered the hospital complaining of progressive blindness, and slept for seven months continuously, when death occurred, the autopsy disclosing a tumor in the hypophysis. The sleep was apparently physiologic during the first months. The patient could be aroused and would sit up, stretch, yawn and reply intelligently to questions and then drop off to sleep.

Fracture of Jaw First Sign of Tabes. SABRAZES.—A healthy workingwoman began to suffer with intense toothache, the pains radiating through the head and face. The teeth and gums appeared normal in every respect, but she applied to a dentist to have the right canine extracted, from which she suffered most. As he pulled it, the entire alveolar process of the upper maxillary bone broke off with it, with all the solidly-implanted, sound teeth. Two years later unmistakable symptoms of progressive tabes appeared.

Myxedema in Children. E. HERTOGHE.—The photographs of several children in different stages of thyroid treatment illustrate the remarkable benefits to be derived from it in benign, chronic hypothyroidism or latent myxedema, and in Lorain's infantilism. Falling of the hair and incontinence of urine are among the signs of the latter. Hertoghe adds the photograph of the mother in nearly every case as an important factor in the study of the child, pointing out in them the characteristics and defects that distinguish the parents of cretins.

The last illustration in each case represents an intelligent, normally developed boy or girl. In one case of pronounced myxedema, an umbilical hernia receded spontaneously under thyroid treatment.

Presse Méd. Belge (Brussels), August 12.

Errors of Diagnosis in Syphilis. MATAGNE.—The writer describes several unusual cases in his experience in which unrecognized syphilitic lesions were vainly treated for years until accident suggested the true treatment. In one a woman had a supposed white swelling of the foot and multiple tumors in the rectum, all of which promptly yielded when specific treatment was instituted. In another case, a pulmonary lesion simulated tuberculosis, and a few years later an intracranial affection was diagnosed as cancer, but both subsided on mercurial treatment, which also cured lupus and pleurisy in another and intense, incessant cephalgia which had persisted for months in two young women.

Semaine Médicale (Paris), October 10.

Phlebitis in Tuberculosis. E. LESNE.—It is evident from the experimental research reported that the tubercle bacilli may pass into the blood in a consumptive, but not remain in it, settling promptly in some vein and inducing an ordinary phlebitis without tubercle formation. No bacilli could be found in the vein or its contents in the cases examined. No cultures could be derived from them of any kind, but guinea-pigs inoculated with them soon succumbed to pure tubercular infection.

Arch v f Klin. Chirurgie (Berlin), lxxi, 1.

Absorbable Metal for Suture of Blood Vessels and Nerves. E. PAYR.—Magnesium is the absorbable metal referred to. It can be filed, turned, polished and drawn into a wire or rolled in a sheet. At the same time it dissolves in water and still more rapidly in alkalis and diluted acids. Payr has been using a short tube of this metal in suturing arteries. He slips the tube over the central stump and turns the end of the stump up over the tube, which he then invaginates into the distal end. The intima on both stumps is thus brought into contact. He sutures a nerve by inserting both stumps into a short magnesium tube and passing a thread through each, beyond the tube, and tying it above, or by slipping the tube on one stump and after suturing the two ends together, bringing the tube over the spot to protect the suture. The time required for the absorption of the magnesium tubes varies with their size and thickness.

Surgery of the Spleen. F. BESSEL HAGEN.—Three cases are described which emphasize the necessity of surgical intervention in primary or idiopathic hypertrophy of the spleen as the only rational treatment, and this should not be delayed until a serious stage has been reached. The mortality during the last decade has been only 2 in 15 cases, and one of these deaths was due to another cause. Recovery followed splenectomy in 13 out of 16 cases in which a primary hypertrophy of the spleen accompanied cirrhosis of the liver. In one of the observations reported by Hagen primary hyperplasia of the spleen with interstitial hepatitis, was cured by splenectomy. In another, suppuration and necrosis of the spleen consecutive to a gangrenous chancre was cured by splenotomy and extensive resection of spleen tissue, which also cured a third case with multiple intrasplenic abscesses following appendicitis. The spleen was reached by an incision along the tenth rib with resection of a portion of the rib. All of his cases have been carefully followed to date and no disturbances have been noted that could be imputed to the loss of spleen tissue.

Beitragce z. Klin. Chirurgie (Tuebingen), xxvii, 2.

Tetanus Nearly Six Years After a Gunshot Wound. H. KAPOSI.—A young man carried a bullet in his abdominal wall for five and a half years without symptoms. The region then became sensitive and the bullet was extracted. During the operation at Czerny's clinic a deep abscess was discovered and evacuated. The intervention was followed in ten days by a rapidly fatal tetanus. This is the first case of post-operative tetanus which has ever occurred at the clinic, and the only plausible explanation of the infection seems to be that a non-virulent tetanus germ was carried into the wound by the bullet

and became encapsulated with it. The operation opened a passage for the germ into the circulation and the conditions aroused it to virulence.

Berliner Klinische Wochenschrift, September 24.

Treatment of Anasarca by a Siphon Cupping-Glass. K. MIURA.—A small cupping-glass with a spout in one side, is applied on a spot where the edema is prominent, usually on the thigh, after a few incisions have been made. It is important to avoid drawing blood, as a clot might stop the flow of the serous fluid. A rubber tube is put on the spout and both cup and tube are filled with salt solution. When the serum is escaping from the incisions the cup is turned over the spot and the salt solution allowed to flow out of the tube. It acts as a siphon and aspirates the serous fluid from the tissues. In one case the fluid was siphoned out in this way fifty times between February and June and the patient improved remarkably. The amount withdrawn at a time was 1600 to 2800 c.c. in about eight hours.

Virchow's Archiv (Berlin), September.

Percussion in Diagnosis of Affections of the Frontal and Maxillary Sinuses. LIPOWSKI.—Hajek has called attention to the almost invariable occurrence of a lesion of one or more of these sinuses in influenza, typhoid fever, erysipelas, measles, scarlet fever and croupous pneumonia, but experience shows that spontaneous recovery is frequent. The signs of an affection of a sinus are a polyp, swelling of the middle turbinated bone, hypertrophy of the concave surfaces of the middle turbinated bone in the septum, where it is bathed by the secretion, scabs, atrophy of the inferior turbinated or fetidities. Resection of the front end of the middle turbinated bone affords convenient oversight of the hiatus semilunaris and the openings into it. Electric trans-illumination of the frontal and maxillary sinuses is an important aid to diagnosis. All these means, however, frequently fail and Lipowski announces that valuable supplementary information can be derived from percussion and auscultation of the cavities, the resonance in the nose, mouth and throat being increased by inserting a "sound-funnel" in the nostrils. Direct percussion of the antrum of Highmore is most instructive when the phonendoscope is placed on the nasal process, and the upper lip drawn upward and outward to expose the anterior wall of the sinus on the side toward the mouth.

Gazzetta Degli Ospedali (Milan), October 7.

Disturbances in Respiration in Hemiplegia. G. BOERI.—Examination of sixty-one patients with hemiplegia showed that the respiration was diminished in nearly all, but there was a difference between the excursions of the sides of the thorax in more than 80 per cent. of the cases. In more than 63 per cent. the respiration was less on the hemiplegic side, but in 16.4 per cent. the respiration was much more intense on the hemiplegic than on the sound side. Tracings of the involuntary respiration in one case showed curves on the paralyzed side nearly four times the length of those on the other, and slightly anticipating them, although the latter were physiologic. Boeri is inclined to attribute this phenomenon to irritation of the respiratory center, as in six of the ten cases of this kind convulsive phenomena were noted, and in three on which autopsy was made, an intraventricular effusion was found. Exaggerated respiration in these cases may prove an aid in diagnosing the cerebral affection.

New Patents.

- Patents of interest to the medical profession, Oct. 2 to 9:
 659,130. Syringe. Charles A. Bucklin, New York City.
 659,058. Surgeon's case. Emil A. Elden, Moline, Ill.
 658,889. Heriatic truss. John F. Kampf, Toledo, Ohio.
 658,998. Pocket case for thermometers. Wm. A. Randall, Swampscott, Mass.
 659,112. Device for emptying leeches. Benjamin Sykes, Curwensville, Pa.
 659,188. Inhaler. George B. Underwood, New York City.
 658,903. Massage apparatus. Franz L. Ungethum, Oetzsch, Germany.
 33,320. Design. Abdominal band. Adele M. Kauffman, St. Paul, Minn.
 659,513. Device for inducing artificial respiration. Eugene L. Doyen, Paris, France.

659,470. Syringe. Anton C. Eggers, New York City.
 659,621. Disinfectant. David M. Kelsey, Saratoga Springs, N. Y.
 659,308. Invalid-bed. John A. Lemmons, Anderson; J. J. Hubbard and E. C. Hummel, Juggals, Ind.
 659,542. Inhaler. Harry A. McTosh, Liberty, Ind.
 659,551. Vapor-treatment apparatus. Fortnee R. Ryan, Memphis, Tenn.
 659,422. Surgical instrument. George W. Shidler, York, Neb.

Change of Address.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Oct. 11 to 17, 1900, inclusive:
 Lewis Hulch, major and surgeon, Vols., honorably discharged from the service of the United States to take effect Nov. 7, 1900.
 William H. Corbuser, major and surgeon, U. S. A., member of a board at Governor's Island, N. Y., to examine officers as to their fitness for promotion; also member of an army retiring board at Governor's Island, N. Y., vice Major John L. Phillips, surgeon, U. S. A., relieved.
 Guy C. M. Godfrey, captain and asst.-surgeon, U. S. A., now in Brooklyn, N. Y., to report to the commanding officer, Department of the East, for assignment to duty with recruits en route to the Philippine Islands on the transport *Kipatrick*; on arrival at Manila, P. I., to report to the commanding general for further orders.
 Joseph M. Heller, acting asst. surgeon, member of a board at Governor's Island, N. Y., to examine officers as to their fitness for promotion.

James H. Hysell, major and surgeon, Vols., previous orders revoked; he is relieved from duty in the Department of Eastern Cuba to report to the Surgeon-General.
 James E. Pilcher, captain and asst.-surgeon, U. S. A., to report at Fort McHenry, Md., for examination by a medical officer as to his physical condition.
 Dwight B. Taylor, acting asst.-surgeon, member of a board at Columbus Barracks, Ohio, to examine officers as to their fitness for promotion.
 Timothy E. Wilcox, major and surgeon, U. S. A., member of a board at Columbus Barracks, Ohio, to examine officers as to their fitness for promotion.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Oct. 20, 1900:
 Medical Inspector E. S. Derr, detached from the navy yard, Portsmouth, N. H., on reporting of relief, and ordered home to wait orders.
 Surgeon P. B. Stephenson, ordered to the navy yard, Portsmouth, N. H.; commissioned, medical inspector from May 31, 1900.
 Asst.-Surgeon H. E. Odell, order to the Asiatic station modified; to take passage on the *Solace*.
 Asst.-Surgeon H. A. Dunn, detached from the *Dorothea* and ordered to the *Frolic*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Oct. 18, 1900:
 Surgeon J. A. Gassaway, leave of absence for four days from Oct. 15, 1900, under provisions of paragraph 179, Regulations, M. H. S.
 Surgeon G. W. Stoner, granted three days' extension of leave of absence.
 P. A. Surgeon J. B. Stoner, granted leave of absence for twenty-two days.
 P. A. Surgeon G. B. Young, granted leave of absence for one day.
 Asst.-Surgeon D. H. Currie, to proceed to Indianapolis, Ind., in charge of the laboratory exhibit of the service to be shown at the meeting of the American Public Health Association.
 Hospital Steward E. B. Scott, granted leave of absence for twenty days.

BOARD CONVENED.

Board convened to meet at the Purveying Depot, New York City, on Wednesday, Oct. 24, 1900, for the purpose of revising the official supply table of the service. Detail for the board: Surgeon G. W. Stoner, chairman, and Surgeon C. E. Banks.

APPOINTMENTS.

Albert M. Roehrig, appointed temporary hospital steward and assistant chemist for duty at Immigration Depot, New York City.
 W. F. Schlar, reappointed senior hospital steward.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 19, 1900:

SMALLPOX—UNITED STATES.

Kentucky: Lexington, Oct. 6-13, 1 case.
 Louisiana: New Orleans, Sept. 30-Oct. 13, 1 case, 1 death.
 Minnesota: Minneapolis, Oct. 6-13, 2 cases.
 Nebraska: Omaha, Sept. 30-Oct. 6, 1 case.
 Ohio: Cleveland, Oct. 6-13, 9 cases.
 Utah: Salt Lake City, Oct. 6-13, 10 cases.
 West Virginia: Wheeling, Sept. 30-Oct. 6, 1 case.
 SMALLPOX—FOREIGN AND INSULAR.
 Brazil: Rio de Janeiro, Aug. 1-Sept. 15, 57 deaths.
 England: London, Sept. 22-29, 2 cases.
 France: Paris, Sept. 22-29, 6 deaths.
 India: Bombay, Sept. 6-18, 3 deaths; Calcutta, Sept. 1-15, 17 deaths.
 Philippines: Manila, Jan. 1-Sept. 8, 35 cases, 1 death.
 Russia: Moscow, Sept. 8-15, 4 cases; Odessa, Sept. 22-29, 9 cases, 4 deaths; St. Petersburg, Sept. 15-22, 9 cases, 4 deaths.
 Scotland: Dundee, Sept. 22-29, 1 case.

YELLOW FEVER—UNITED STATES.

New York: New York, quarantine, Oct. 9, 1 case on steamship *Havana*, from Havana.
 YELLOW FEVER—FOREIGN AND INSULAR.

TUBERCULOSIS OF THE TESTICLE.

WITH SPECIAL CONSIDERATION OF ITS CONSERVATIVE
TREATMENT.

JOHN B. MURPHY, M.D.
CHICAGO.

Before entering into our subject, let us briefly review the anatomy and physiology of the testicle, that we may better understand the pathologic changes and processes of repair which take place when it is the seat of tubercular infection.

The testes are suspended in the scrotum by the two spermatic cords, the left being slightly lower than the right. Each is oval in form, compressed laterally, and occupies an oblique position in the scrotum, the upper extremity being directed forward and outward, the lower downward and a little inward. The surface of the gland, excepting its posterior border, is free, smooth and covered by the visceral layer of the tunica vaginalis. Lying along the posterior border is a narrow flattened body, the epididymis, which consists of three parts, namely, first, the upper enlarged extremity, globus major; second, the pointed lower extremity, globus minor, and, third, the intermediate portion, or body of the epididymis. The globus major is intimately connected with the upper end of the testicle proper by means of its efferent ducts, while the globus minor is attached to its lower end by cellular tissue and a reflection of the tunica vaginalis. This membrane, the tunica vaginalis, as it leaves the testicle proper at its posterior border, is reflected on to the epididymis, covering its outer surface and upper and lower extremities and completely investing the body, excepting along its posterior border, from which it is again reflected on to the inner surface of the scrotum. It will thus be seen that a sort of mesentery is formed by the membrane between the testicle proper and the epididymis. Attached to the upper end of the testicle or epididymis are one or more small pedunculated bodies, the most constant of which is called the "hydatid of Morgagni."

Besides the tunica vaginalis, which is the most external, the testis is invested by two tunics, the tunica albuginea and the tunica vasculosa. The tunica albuginea is beneath the serous coat and surrounds the glandular structure of the testis. It is thick and dense, and composed of white fibrous tissue. At the posterior border of the gland it is reflected into the interior, forming an incomplete vertical septum, the mediastinum testis, or corpus Highmorianum, from the edge and lateral surfaces of which numerous fibrous trabeculae pass, to be attached to the inner surface of the tunica albuginea. These trabeculae divide the interior of the gland into a number of cone-shaped spaces, the bases of the cones being at the periphery and the apices at the mediastinum.

The tunica vasculosa consists of a plexus of blood-vessels, which line the inner surface of the tunica albuginea and the fibrous trabeculae.

The glandular structure of the testis (Fig. A) consists of numerous cone-shaped lobules (lobuli testis), each contained in one of the spaces described above and composed of one or more convoluted tubules, $2\frac{1}{4}$ feet in length and $1/150$ inch in diameter, the convolutions being held together by an intertubular connective tissue. The connective tissue presents large interstitial spaces lined with endothelium, the rootlets of the lymphatic vessels, and masses of large cells—the interstitial cells—accompanying the finer blood-vessels.

Fig. A.—Showing testicle partly macerated in KOH solution, which has loosened the connective tissue framework. (After Todd.) 1. Tubuli seminiferi coarctati. 2. Body of epididymis. 3. Coni vasculosi. 4. Vasa efferentia. 5. Tunica albuginea at hyalum. 6. Lobuli testis. 7. Tubuli seminiferi.

Each seminiferous tubule consists of: 1, a hyaline membrana propria; 2, several layers of epithelial cells—the seminal cells—which are usually arranged as follows: *a*, an outer (deeper) layer of polyhedral cells, the spermatogonia; *b*, an intermediate layer, the cells of which are in active proliferation, the spermatogenic cells; *c*, an inner layer, the spermatoblasts. The latter are granular, indistinctly outlined, and show no signs of proliferation.

At the apices of the lobules the tubes become straight,

join together to form larger tubes (vasa recta), and enter channels in the mediastinum (rete testis). At the upper end of the mediastinum the channels of the rete unite to form from 13 to 20 larger tubes (vasa efferentia), which perforate the tunica albuginea and enter the epididymis. At first straight, they become convoluted and form a series of cone-shaped masses (coni vasculosi), which together form the globus major. Opposite the bases of the cones the efferent vessels open at narrow intervals into a single duct, which constitutes, by its complex convolutions, the body and globus minor of the epididymis. This tube, the convolutions of which are held together by fine arcolar tissue, is about 20 feet in length, and is continuous at the globus minor with the vas deferens.

The vasa recta and channels of the rete are lined by a single layer of flattened epithelial cells. The vasa efferentia and tube of the epididymis are lined by columnar ciliated epithelium, and their walls contain circularly arranged muscular fibers.

The vas deferens is a continuation of the tube of the epididymis. (See Fig. 1.) Commencing at the lower part of the globus minor, it ascends along the posterior border of the testis and inner side of the epididymis, and along the back part of the cord to the internal ring. From the ring it curves around the epigastric artery and descends into the pelvis at the side of the bladder to its base. In this situation it lies between the bladder and

Fig. 1. Skiagraph showing Vas and Tube of the epididymis injected with mercury. *a* Vas. *b* Tube of epididymis.

rectum and along the inner border of the seminal vesicle of the same side. Here it becomes enlarged to form the ampulla, then narrows and unites with the duct of the vesicula seminalis to form the ejaculatory duct. It is about 2 feet in length, the walls are thick and the lumen small, measuring $1\frac{3}{35}$ of an inch. The vas consists of three coats: 1, an external or cellular coat; 2, a muscular coat; and, 3, an internal or mucous coat, arranged in longitudinal folds and covered by columnar epithelium.

The blood-supply of the testis is principally from the spermatic artery, which arises from the abdominal aorta, and accompanies the other structures composing the cord through the canal. As it approaches the testicle it divides, some small branches continuing onward to supply the epididymis, while the larger ones perforate the tunica albuginea and enter the mediastinum to supply the glandular portion through the vessels of the tunica vasculosa. The vessel does not always divide so high as is pictured in the text-books. This is shown in Fig. 2, where the artery was injected with mercury and then skiagraphed. The bifurcation takes place close to

the testicle, a fact to be borne in mind when operating.

The spermatic veins commence in the testis and epididymis, pass out at the posterior border and ascend in the cord as the pampiniform plexus. (See skiagraph Fig. No. 3.) Finally, two or three larger veins are formed from the plexus, pass into the abdomen with the artery and unite to form the spermatic vein. This, on the left side, empties into the renal vein, and on the right side into the ascending vena cava.

The lymphatics of the testicle (see Fig. 4) commence as minute vessels around the seminal tubules. These coalesce and most of them pass through the septa into the mediastinum. Others pass outward to join the plexus beneath the tunica albuginea, which plexus also communicates with a more superficial one beneath the tunica vaginalis. In the mediastinum the deep and superficial sets unite to form from four to six trunks, which pass upward in the cord into the abdomen. On the left side these vessels enter the glands near the aorta and left renal vein, while on the right they empty into the lumbar glands just above the bifurcation of the aorta. Afferent vessels from the glands of both sides empty into the receptaculum chyli.

Fig. 2. Skiagraph of Spermatic Artery injected with mercury. *a* Spermatic Artery. *b* Branch to epididymis. *c* Branch to testicle papae.

The nerves are derived from the sympathetic system, branches from the aortic, renal and hypogastric plexuses, forming the spermatic plexus, which descends upon the spermatic artery and artery of the vas deferens. They are not provided with ganglia and have not been traced into the tubules. The terminal filaments ramify on the surface of the tubules and are distributed to the blood-vessels.

Physiology.—The functions of the testicle are two in number: 1, the production of spermatozoa; 2, the formation of an internal secretion, which is necessary to normal metabolism.

The spermatozoa are formed in the seminiferous tubules by a series of changes which take place in the spermatoblasts, or cells of the internal layer. These changes are as follows: The cell first assumes a pear-shape, the pointed end containing the nucleus, being directed toward the basement membrane. This portion forms the head of the spermatozoon. By a drawing out or elongation of the broad part of the cell the middle piece and tail are formed.

After puberty the semen is probably being constantly secreted, although most of the time in small quantities. As the spermatozoa are formed they are forced along the tubules by the pressure of accumulated secretion, aided by the ciliary movements of the cells lining the vasa recta, vasa efferentia and tube of the epididymis. In the two latter its expulsion is also aided by contraction of the muscular fibers in their walls. From the vas deferens the semen passes into the ejaculatory duct and seminal vesicle, in which latter, unless discharged immediately by emission, some of it is retained. It is probable, however, that the principal function of the vesiculæ seminales is secretory and that the ducts of the testes, rather than they, act as reservoirs for the semen.

The second and more important function of the testicles is the formation of an internal secretion. While the active principle of this secretion has never been isolated, nor the secretion itself been definitely proved to exist, experimental and pathologic evidence leaves

little doubt as to its presence under normal conditions. Its importance to the normal development of the body is shown in cases of cryptorchidism, or where both testicles have been destroyed or removed before the age of puberty. These cases invariably show a lack of the sexual characteristics which are normally developed at this time. Its influence is also shown, though to a lesser degree, in cases where both organs have been removed after puberty in early and middle adult life. In many of these, sexual desire is entirely lost, the prostate and other parts of the remaining genital apparatus atrophy, and in a few there is a loss of the sexual characteristics which were formerly possessed. The experiments of Zath, reported in 1896, are interesting in this connection. Under daily injections of testicular extract the working power of a man's neuro-muscular system was increased 5 per cent., and during rest his powers of recuperation were greatly increased.

It can thus be seen that the preservation of this normal secretion is worthy of careful consideration, and the purpose of this paper is to emphasize its impor-

tance. In addition to the physiologic effects on the general metabolism produced by the removal of the testes, in many cases grave mental states, such as melancholia, are induced. Finally, there is the practical side, that many patients will not consent to the removal of both testes for tubercular disease until the bladder and prostate have become involved, or until they realize that death will result if the diseased organs are retained, while they will readily consent to the removal of both epididymi, upon the physician's statement that the testicles proper will be preserved.

Etiology. Age.—Tuberculosis of the testicle may occur at any age, but it is much more common during early adult life, between the ages of 20 and 35 years,

Fig. 3.—Spermatic Veins injected with mercury.

Fig. 4.—Lymphatics of testicle. (Heitzmann.)

when the activity of the sexual gland is at its height. In Koenig's cases the different decades were affected as follows: Under 4 years, 3; between 20 and 30 years, 24; between 30 and 40 years, 8; between 40 and 50 years, 4; between 50 and 60 years, 4; between 60 and 80 years, 2. Of the latter, one was 67, and one 72 years of age.

The age statistics quoted by Senn from the various authorities are as follows: Salleron in 17 cases observed the period of greatest liability to be between 20 and 30 years. Kocher from 50 cases also between 20 and 30 years, while Simonds, from an analysis of 69 cases, found the greatest number between the ages

of 20 and 30 years.

of 20 and 30 years.

of 40 and 50 years, with 20 to 30, and 30 to 40 years coming next in frequency.

Jullien reported 16 cases of tubercular testicle in infants, 6 of which were under 1 year of age, and Dr. Dreschfeld a case where the disease was present at birth. In one of Koenig's cases the disease was noted a few days after birth.

As regards the other extreme of life, Gibson has reported a case in a man aged 81 years. In the cases here reported the average age was about 33 years.

Hereditary Influence.—This may be shown in two ways: 1, where the disease is present at birth or develops very soon after; 2, as an inherited condition of lowered vitality, in which there is a tendency to the development of tuberculosis, due, probably, to a lessened resistance of the tissues.

In perhaps the majority of the cases no tubercular family history can be obtained, this absence of hereditary influence being especially marked in cases which develop in adult life. In 10 cases of testicular tuberculosis in children, reported by Jullien and Lannelongue, 4 presented a distinct family history. In 5 of Koenig's cases, in which the disease was distinctly localized in the testis, and in which he believed it to have originated from pre-existing tubercular deposit, there was a family history in 3.

In 16 cases reported by Jullien, 6 were in patients less than one year of age. An inherited tendency is probably present where the disease develops so soon after birth.

Injury.—In many cases there is a history of traumatism preceding the onset of the disease. The injury in most cases, slight and insignificant, may be forgotten by the patient, who does not connect it with the onset of his trouble. In other cases the relation between the two is so striking and direct that it can not be overlooked. This etiologic factor is beautifully illustrated in Case 10, where the disease developed almost immediately after a kick in the testicle. The rule is that the tubercular process does not manifest itself conspicuously until at least six weeks or more have elapsed from the time the injury was received.

Previous Inflammatory Processes.—Of all affections of the genito-urinary tract, which predispose the testicle and epididymis to a subsequent tubercular infection, gonorrhoea is the most important, either a gonorrhoeal epididymitis or a posterior urethritis. In 52 cases collected by Kocher, 14 had suffered from it previously. The tubercular process may follow the gonorrhoeal immediately, while the latter is yet in the acute stage, or at any time after the subsidence of the active symptoms. It must not be forgotten, however, in this connection, that the gonorrhoeal inflammation may be simply the means of lighting up a latent tubercular focus, which had been lying dormant in the epididymis for years, without, perhaps, the patient being aware of its existence.

The explanation of this phenomenon is simply that of a *locus minoris resistentie* left after subsidence of the acute inflammatory process. This area of diminished resistance may perhaps in some cases be a defect in the mucous lining, through which germs may enter from the surface. Tuberculosis of the testicle does not commonly follow the acute infectious diseases, even when these have been complicated by an orchitis. J. B. Shaw reports a case where it was supposed to have followed an attack of measles.

Atrium of Infection. This at the present time is undergoing most rigid scientific investigations. The

channels through which infection may take place are, in order of frequency, as follows: 1, respiratory tract; 2, gastrointestinal tract; 3, genitourinary tract; 4, skin.

That the respiratory tract, with arrest of infecting organisms in the mediastinal glands, is the most frequent atrium of infection, is shown by the researches of Jens Bugge. This investigator has shown that 75 per cent. of all human beings who come to the post-mortem table have had mediastinal glandular tuberculosis. As is well known, this disease may exist without producing any symptoms, and it will therefore be seen how readily a crypto-tubercular infection in this locality could precede a localized infection of the testicle. It is our belief that the mediastinal glands are the most common sources of supply for tubercle bacilli in the body.

Carious teeth with ulceration of the gums about them, and defects in the mucous membrane of the nose, mouth, tonsils and middle ear, with subsequent infection of the cervical lymph-glands may, especially in children, be the primary sources of infection.

That the gastrointestinal tract admits of infection from tuberculous material taken in as food, can not be questioned, but that it is attacked much less commonly than is generally supposed is proved by the infrequency of tuberculosis of the mesenteric glands. (Northrup and Boviard.) Dr. W. J. Mayo, of Minnesota, has found that in the rural districts, where milk is largely used as an article of diet, a localized tuberculosis of the intestinal mucosa is not very uncommon, but that the mesenteric glands are very rarely involved without a demonstrable lesion in the intestine. In this respect the intestinal tract differs from the respiratory, where in many cases no physical changes can be demonstrated at the point where the bacilli have gained entrance.

That infection can take place directly through the urinary outlet, the urethra, or through the genital outlet, the vagina, is generally admitted, and cases have been reported where it was transmitted from a tubercular uterus or vagina to the glans penis, or prepuce (Jonin, Cornet.) Reclus denies that infection ever takes place in this way.

That tubercular infection is often admitted into the system through the skin is shown by the number of cases of the local disease among physicians, and in the children of tuberculous parents, these children so often developing lesions about the cheeks, lips and mouth.

The tubercle bacilli having gained entrance into the system, the next subject for consideration is: How do they find localization in the testis? There are a number of routes by which the infection may be carried to the sexual glands: 1, by the blood-stream; 2, along the surface of the mucous membrane of the genito-urinary tract; 3, by the lymphatics.

1. Transmission by the blood-stream has been, by most authors, considered to be the most important. The bacilli contained in the blood localize in the epididymis at some point where there exists a focus of diminished resistance, either congenital, or produced by previous injury or disease. The frequent localization in the epididymis is accounted for by the fact that the spermatic artery divides opposite that organ, and that the vessels of the epididymis are smaller and more tortuous than those of the vas or testicle proper, the current therefore being slower. (Saltzman.)

2. In some cases the infection undoubtedly travels along the surface of the mucous membrane. This view

is supported by Koenig in his recent paper on the subject. He believes that in a very great majority of cases the testicular affection is preceded by tubercular disease higher up in the genito-urinary tract, especially in the vesiculae seminales and prostate. In the 45 cases reported by him, these organs were involved 31 times. In the majority of cases, however, there were distant foci in the lungs, bones, glands, etc. Kocher holds the same view. Cayla thinks that a descending infection along the mucous membrane is most common, and believes that the infection travels in the same direction as the current of urine, and against that of the semen. His views are based on 100 sections, in which he observed that tubercular disease of the genito-urinary organs was always preceded by tuberculosis higher up.

Guyon and Lancereux have observed that the process often begins in the vesiculae seminales. Virchow has always held that the infection was a descending one, beginning in some of the higher genito-urinary organs. Saleron is opposed to this view, as in 51 cases examined by him, organs, other than the testicles and epididymis, were involved in only one case. Senn states that frequently the infection descends from the prostate, seminal vesicles or kidneys. Weigert (cited by Kocher) thinks that the prostate favors localization of all kinds of micro-organisms, and Keziwicki, in 15 autopsies on cases of genito-urinary tuberculosis, found the prostate involved 11 times.

M. Verneuil believes that infection often takes place during coitus, and gives anatomical reasons for his views. This seems very doubtful, however, when we consider the frequency of tubercular epididymitis in children. Furthermore, if this were the case, we should more frequently meet with tubercular lesions of the penis and urethra, for there must be ample means for inoculation in the abrasions of the urethral mucosa so commonly found in gonorrhoea.

While we can undoubtedly have a descending infection, it is our observation and that of many other investigators, that the disease is usually an ascending one, the epididymis being affected primarily and the bladder, prostate, etc., secondarily, the process extending upward along the surface of the mucous membrane of the excretory duct.

3. Transmission of the infectious material to the testicle by the lymph channels, while usually given as one of the routes, must be very rare, as the lymph-current is directed away from the organ rather than toward it. No cases have been reported which show the infection to have taken place in this way.

Koenig thinks that in some cases the disease begins as a primary tuberculosis of the testicle, the infection having been carried to the organ some time before and remaining dormant until lighted up by the occurrence of one of the exciting causes, such as injury, acute inflammatory processes, etc. This view is based on the studies of Jani, who found bacilli in apparently healthy testicles of patients suffering from pulmonary phthisis. Koenig thinks that this may explain some cases where no atrium of infection can be demonstrated.

(To be continued.)

TUBERCULAR TUMOR OF THE ORBIT.*

HOWARD F. HANSELL, M.D.

PHILADELPHIA.

In the spring of 1899, a small tumor appeared between the upper lid and the superior margin of the right orbit in a girl of 13. It received no medical attention until the autumn, when she applied to the out-patient department of the Jefferson Medical College. She stated that recently the tumor had increased in size and that the lid was swollen and drooping. The growth was painless and insensitive except on hard pressure; it was hard and inelastic, and projected about two millimeters beyond the vertical plane of the anterior margin of the orbit. The tumor was partly movable and was attached to the roof of the orbit a few millimeters back of the bony margin. Its anterior edge was rounded, quite smooth and thin, as though it belonged to a flat tumor about the size of a silver dollar. The lid was edematous and its elevator parietic. The eyeball was not discolored nor were its movements abnormally restricted. Refraction was low myopia. The media were clear and the fundus was healthy. The left eye was normal in all respects except the refraction, which was slightly myopic.

The parents of the girl are living and healthy, and there is no family history, however remote, that shows a trace of tuberculosis. The patient is anemic, but makes no complaint of disordered health. The lungs are sound and the abdominal organs free from disease. She had not menstruated.

The diagnosis of the nature of the growth could not be determined. After several weeks of observation and treatment the tumor was enucleated without disturbing the eye or its muscles.

The report of the microscopic examination, made in the laboratories of the college by Dr. H. F. Harris, is as follows:

The specimen as received consisted of two masses of tissue. The larger was irregular in form. On section, this piece of tissue was found to be quite firm and to present a uniform pinkish-gray color. It has an average length of 3 cm., an average width of 1.5 cm., and a thickness of about 5 mm. Weight was 4 gms. The smaller piece of tissue was irregular in form, being about 12 mm. long, 5 mm. thick and 6 mm. wide. This piece of tissue did not weigh more than 1 gm.

Specimens were fixed in Heidenhain's solution, embedded in paraffin, sections stained with hematoxylin and eosin, carmalum and picric acid, toluidin blue alone and with eosin, and by the method of Weigert for bacteria.

On microscopic examination the specimen is found to be made up of a basis of collagenous tissue intermingled with a considerable quantity of adipose tissue and involuntary muscle fibers. Around the edges of the specimen the tissue is for the most part practically normal, although in some situations the changes presently to be described extend to the very margin. In the upper portions of the specimen there are two well-defined and undoubtedly separate processes to be observed. Especially in the regions occupied by fatty tissue there is every evidence of the action on the tissues of some agent which produces suppurative change. The tissues here are infiltrated with, and in a measure replaced by, masses of polymorphonuclear leucocytes which show the usual fibrillar properties of these cells. Intermingled with these cells are some red cells, some mononuclear leucocytes and quite a number of plasma and mast cells. Here and there may be observed a swollen connective-tissue cell in addition, though they are comparatively rarely seen. The blood-vessels in this situation do not show change of any kind. The fibrils of collagenous tissue which pre-exist in the part are practically unaltered.

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Senile Alterations in Ganglion Cells.—The *Berliner Klin. Woch.* quotes Marinisco to the effect that the atrophy of the ganglion cells from advancing age is manifested first by chromatolysis, then pigment-formation and shrinking of the processes. He has suggested that this senile atrophy of the nerve cells might be prevented by introducing into the organism the serum of young animals as dynamogenic substances.

In other parts of the specimen, and at many points merging into the altered tissues, as just described, there are changes which are characteristic of bacteria and other disease-producing causes which do not cause the leucocytes to be attracted to the part, but which, notwithstanding, produce a low degree of inflammatory change. These alterations are most numerous in the perivascular lymph spaces, where there are enormous collections of lymphoid cells. These lymphoid cells do not remain confined to the lymph spaces, but may be seen to permeate the surrounding tissues. In these regions the cells show an increased protoplasm which is faintly basophilic—the daughter plasma cells of Unna—and still farther outward perfectly characteristic plasma cells are seen in considerable numbers. Mixed with them are a considerable number of mast cells. The connective-tissue cells in the vicinity are often swollen and many present the peculiarities of fibroblasts. The walls of the blood-vessels, which lie generally eccentrically placed in these masses, appear but little altered. Some of the fibrils occurring in these walls seems to have undergone a slight degree of hyaline change, and the number of nuclei in the muscle walls appear to be increased in many cases, but these changes are by no means constant and are of a not pronounced kind. The endothelial lining of these vessels appears normal. The connective tissues which lie in the vicinity of these blood-vessels do not show appreciable alteration, though it is quite possible that the amount of this tissue is increased. This appears to be unmistakably the case in the adventitial coating of some of the smaller vessels around which there is no collection of lymphoid cells. In these cases the amount of collagenous tissue is, in the situations mentioned, undoubtedly increased. The inner coats of these vessels show no alteration. In the central portion of this specimen there is a comparatively large area in which the tissues have undergone complete necrotic change. What still remains of the original tissue in the part takes intensely the acid stain, while there are a few fragments of nuclei included in the mass which still retain the power of reacting to basic dyes. At one side of the necrotic area there are found three large and very typical giant cells, the nuclei of which, as is usual, lie toward the periphery of these bodies. Forming a well-defined border to this area are tissues undergoing necrobiotic change. In this area the nuclei of the cells, which are for the most part in a fragmented state, still stain intensely with basic dyes, and the protoplasm and intercellular substance with the acid dyes with a little more than the usual intensity. A little farther outward there is a wall composed almost entirely of fibroblasts intermingled with which are a few lymphoid cells. In this region and in the area of necrobiotic change just referred to, there is an amorphous, intensely basophilic, intercellular substance in many situations, which appears to be mucin. Still farther outward the fibroblasts are gradually replaced by the normal fibrous tissue of the part, but even here there are found lymphoid cells, plasma cells, mast cells, and an occasional bit of mucin. On one side of this area the involuntary muscle fibers, which were at first referred to, are seen to be considerably altered. The fibers are ill-defined and the nuclei are enormously increased in number, and are exceedingly irregular in form. Mucin is also found in these situations.

Specimens stained for bacteria were very disappointing, inasmuch as no bacteria could be found in any part of them. Many sections were stained and organisms were carefully searched for, but as none were found it seems obvious that though tubercle bacilli must be present they are in such small numbers that they were overlooked. As regards the cause of the suppurative change nothing can for a like reason be definitely said, though it seems in the highest degree probable that some of the pyogenic organisms must have been, at least at one time, present in the mass.

Diagnosis: The tumor is beyond doubt primarily of tuberculous origin, added to which there has been some cause inducing a mild degree of leucocytic infiltration. The mass may be said to be at present both tuberculous, and, parts of it, in a condition akin to abscess formation.

A short time after the operation the case passed under the care of my colleague, Dr. de Schweinitz, who has repeatedly examined her during the past three months and

to whom I am indebted for the opportunity to make a final examination, April 19. The ptosis that had been made complete by the operation was slowly recovering. The skin at and near the scar of the incision was slightly pigmented, but the tissues were healthy. A small hard mass could be readily felt at the previous site of the tumor, but it had fewer of the characteristics of a recurrence than of solid exudation from the incised and wounded periosteum. My colleague believes this new tumor has decreased in size under arsenic.

I have been unable to find the record of a single case in ophthalmic literature of tubercular tumor of the orbit. The nearest approach was the description of a case of tuberculosis of the orbit by Sureau¹. A 13-year-old boy had a persistent fistula and discharge from the upper part of the right orbit since the opening of an abscess seven months before. The pus that had collected in the fistula contained numerous bacilli of Koch. The incision was enlarged and the roof of the orbit and the adjoining soft parts were curetted. Cure was complete in three months. There was no sign of disease of the sinuses, although Panas believes that caries of the orbit always has its origin in sinus disease.

DISCUSSION.

DR. G. E. DE SCHWEINITZ, Philadelphia—I had the pleasure of examining this growth before it was operated on by Dr. Hansell, and, as he says, I have subsequently seen the patient very often. Certainly, it is a most unusual neoplasm, which I was inclined to regard as a lymphoma before the report of the pathologist was made. The question of recurrence is a little difficult to decide. There is present at the seat of operation a swelling, which has decreased somewhat in size, but there is still a hard flat nodule in the upper and outer part of the orbit, and with the concurrence of Dr. Hansell I shall remove it very soon.

DR. HANSELL—It was surprising to me to find that there were no similar cases reported in literature. I found some cases of tubercular abscess, and plenty of tuberculous disease of the eyeball and lachrymal gland, but nothing like this tumor.

OSSIFICATION OF THE CHOROID LEADS TO THE IDENTIFICATION OF THE BODY IN AN INSURANCE CASE.*

ROBERT L. RANDOLPH, M.D.

BALTIMORE, MD.

Early in October, five years ago, a well-known wholesale clothier of Baltimore telegraphed to his wife from a point in Canada to meet him on a Saturday, at 4 p.m., in the Grand Central Station, New York. She was there on time, but failed to find her husband. She ascertained from the sleeping-car conductor and porter that her husband had occupied a berth on the train, and some of his clothes were found in the berth. The porter said that he had seen Mr. A. passing through the car door, presumably on his way to the car ahead, and that the train at this time was crossing the Niagara River. The following week the wife appeared at the office of the insurance companies and claimed the insurance, which the companies refused until more conclusive evidence was forthcoming of the man's death. Weeks passed and still the family were unable to bring forward absolute proof of Mr. A.'s death. A minute description of him was put in all the papers in that section of the country, rewards were offered and notices posted throughout a stretch of country along the Niagara River.

Nine months after Mr. A.'s disappearance, his wife

1. *Annales d'Ophthalmologie*, cxvi, p. 367.

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

received notice that the body had been discovered and that all this time it had been in the river. The body was brought to Baltimore, and as it was in an advanced state of decomposition it was promptly buried. It might be well to state here that when found the body had on a pair of drawers, an undershirt and a collar which was marked with his initials. The companies then came forward and claimed the right to inspect the body, at the same time asserting that the latter in all likelihood was unrecognizable from having been nine months under water. I need not go into the details of the autopsy, which was made by a prominent pathologist in Baltimore. It can easily be imagined, however, that a body which had been exposed to such conditions would have lost many of the physical characteristics peculiar to it before death. It may be sufficient for me to say, however, that much of the flesh on the face and head was gone, and this brings me to the eyes, which were submitted to me for an examination. It was remembered by his family that he had lost his left eye as a child from a blow with a stick. This eye then had been blind for many years, and I elicited the fact that it had a whitish appearance in the pupil, which no doubt was a shrunken lens capsule, probably the result of a traumatic cataract.

The question then was, if it were possible to find in the left eye anything which would indicate that the man had been blind in that eye for most of his life. The following was the result of my examination:

MACROSCOPIC EXAMINATION.

Right Eye: Cornea perfectly and uniformly opaque. This opacity was remarkable for its density and it evidently involved the entire substance proper of the cornea as well as the epithelial layers.

The cornea was sunken in the middle, and this was explained by the loss of the intra-ocular fluids, a fact revealed when the eye-ball was opened. The eye-ball was soft and mushy and its sides could be pressed together at any two opposite points, just like a collapsed balloon or bag. On opening the eye-ball there was no evidence of vitreous body or crystalline lens. The retina and choroid were not separable, but they formed a dark, indistinguishable mass that went to pieces when picked up with the forceps. These two coats seemed to be absolutely disorganized. The iris seemed devoid of pigment and was recognized as a delicate, colorless membrane, resting against the posterior surface of the cornea. This membrane, too, like the choroid and retina, was decomposed. The optic nerve was shrunken.

Left Eye: The cornea was hazy and faintly transparent over an area comprising about two-thirds of the entire surface. This transparency allowed one to see beyond, and on pressing the eye-ball at its posterior pole a grayish mass could be seen to advance toward the cornea. This mass occupied the position of the crystalline lens. The entire periphery of the cornea was opaque. This opacity was not sharply cut as to its inner borders, as is the case with the arcus senilis, but had a ragged inner edge with here and there a more marked jutting out into the clearer cornea.

This eye-ball, too, was collapsed like its fellow. On cutting open the eye-ball, both retina and choroid were found in a condition similar to that of the right eye. The iris, too, lay against the posterior surface of the cornea and appeared devoid of pigment. When picked up, this part of the eye fell to pieces. The grayish mass mentioned as being visible through the cornea proved to be a small body about the size of a grain of rice and of irregular shape and nearly solid. In the posterior part of the eye a hard substance was felt. This substance was apparently loose and lying in disorganized choroid and retina. It was picked up with the forceps and seen to be a thin sheet of what was evidently ossification of the choroid. It was 7/16 of an inch long and about 3/16 of an

inch wide, and posteriorly it was perforated by a round hole. The optic nerve was shrunken. Nothing further was noteworthy in this eye.

The striking points about this part of the examination were, 1, the dense and uniform opacity of the right cornea, and, 2, the existence of the plate of bone in the posterior part of the left eye-ball.

MICROSCOPIC EXAMINATION.

Cornea of Right Eye: Impossible to get any reliable differential stain. The tissue could be recognized as that of the cornea, but beyond this nothing could be said of its ante-mortem condition.

Left Cornea: The same want of definiteness existed as was seen in the cornea of the right eye.

Grayish mass in left eye-ball, composed of a cloudy, round large center, made up largely of bands looking like the layers of the lens. This mass was surrounded by clumps of pigment. All that could be said of this mass was that it resembled lens substance more than it did anything else. The retina, choroid and iris stained so diffusely that nothing valuable could be made out. This was the case in both eyes. It was impossible to demonstrate the existence of cataract.

The substance removed from the left eye-ball, and pronounced by me to be the condition known as ossification of the choroid, was shown under the microscope to be bone, as I had said.

It will be seen from this that while the small body, of irregular shape and about the size of a grain of rice, might reasonably be regarded as a shrunken lens the result of a traumatic inflammation, it could not of itself be regarded as positive evidence that the man had been blind for many years, for such a condition of the lens can be brought about in probably one or two years. With the discovery, however, of the plate of bone there was immediately obtained unmistakable evidence that the man had been blind in that eye for many years before his death. In those cases of ossification of the choroid which I have seen, the patient had been blind from early childhood. This conclusive proof then that the left eye had been blind for a long time, was evidence enough in the opinion of the insurance companies to establish the identity of the body, and the money was paid.

It is clear from all this that the microscopic examination of an eye which has been exposed to such conditions reveals nothing of any value, owing to the post-mortem changes in the cell structure. Indeed, the disintegration of the various parts of the eye is so far advanced that it is impossible to draw any conclusions as to the ante-mortem condition, even as to the color of the iris. The effect of the water on the eye for so long a period was to completely obliterate ante-mortem characteristics, with one exception, ossification of the choroid. There was present in this case then, the only ocular condition which would have been valuable in establishing the identity of the body.

MEASLES AND THE EXANTHEMATA.

SHALL CHILDREN BE KEPT THEREFROM? LIKEWISE FROM DIPHTHERIA AND PERTUSSIS.*

C. F. WAHRER, M.S., M.D.
FORT MADISON, IOWA.

It might be stated as an axiom, that as long as a child does not have a disease, it can not die from it; and the first step to prevent such a death, is to prevent a child from acquiring the disease. Hence, we have now in nearly all the states quarantine laws that prevent largely the spread of all contagious diseases, and this

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

is certainly, in the vast number of cases the proper thing to do, namely, prevention is much better than cure, at least for the patient, if not for the physician. There is one element in many of these diseases we can not control, namely, the epidemic element; but in a municipality placed under strict health laws, put into ideal sanitary conditions, even the epidemic element will thus be largely modified. Could these ideal sanitary regulations be everywhere enforced, and always exist, then it were worth while to quarantine against everything to which the least suspicion of contagion is attached, even such mooted diseases as consumption, cancer, typhoid fever, cerebro-spinal meningitis, and many more whose status is not yet fully defined. But I have thought a great deal about the matter; if it is with as good a show of reason that we keep our children from measles as we do from röteln, variella, variola, scarlatina, diphtheria and pertussis, and to this purpose this paper is dedicated.

I have no desire to say anything for the purpose of evoking useless criticism or captiousness, or to be in anywise pyrotechnic or make a display of being queer or finicky, but to honestly make an inquiry whether we are acting wisely or not.

I shall hold that it is not always best to keep our children from acquiring measles, at least not with as good a reason as we have for preventing their acquiring such virulent diseases as scarlatina, variola or diphtheria, for the following reasons:

Röteln and variella may at once be dismissed, as it matters little whether a child has them or not, as neither is ever fatal, only chicken-pox may leave a few disfiguring scars, or even blindness in some remote cases by a scar remaining on the cornea in the pupillary axis of vision.

Now, we have weighty reasons as to scarlatina. First, because it is always a dreadful disease that not only kills thousands of our children, but no one can ever tell what fatal or troublesome sequelæ or complications it may have with it. Many children who do not die outright, may afterward have diabetes, Bright's disease, or paralysis of one or more limbs, from which they may die after lingering illness, or remain hopelessly diseased all their lives.

Also, another reason for quarantine against scarlatina is that this affection is not likely to be acquired after one has reached adult life, and even if acquired, runs usually a much milder and less complicated course.

While diphtheria is not an exanthem, I should like to include it in my list of diseases, and will just mention that what I have said of scarlatina is largely true of it, with the exception that since we are using diphtheria antitoxin, it is not so fatal a malady as before.

In variola we have at all times of life a dangerous, loathsome malady, which has a large mortality, with intense suffering to the afflicted one, and even those who recover are forever horribly disfigured on account of the ugly pockmarks it leaves. So terrible is this pestilence that we are not only content to quarantine against it, but in this case we fight fire with fire; we substitute another disease for it, namely, vaccinia, by vaccinating ourselves with the virus of cowpox, and though this is by no means a pleasant disease to have, yet we prefer it to its horrid analogue, one of the scourges of mankind. And here we have a hint in fighting the measles of adult life, always a dangerous affection, by substituting the measles of childhood, which is less dangerous.

While pertussis is not an exanthem, I desire to mention it because it comes under my line of reasoning also, for we know this often proves not only a long and tedious malady of childhood, lasting, according to the season of the year, from three to seven weeks, and often longer, but is in early life very fatal, and frequently accompanied by complications, such as pneumonia, bronchitis, pleurisy, emphysema and others, and often when recovered from leaves the child weak and of frail constitution, making it an easy prey for other diseases. Again, as in some of the others mentioned, adult life, while not entirely exempt from it, does not become so easily affected, nor is the mortality nearly so great nor do adults easily acquire it, if exposed thereto.

Now, premising that these foregoing statements are true or as nearly so as we can gather from our varied experiences, and a summary of the knowledge we can obtain from our most reliable sources, let us see whether the same reasoning holds good as to measles, or whether we can show good reasons for a different or modified course.

That measles is always to be regarded seriously on account of the possibilities with which it is surrounded or associated, no one can successfully deny. The mortality from this affection in the aggregate is great, but mostly during adult life, and that it is often associated with ugly complications we all must admit, also the same is true of some of its sequelæ; are they not principally true during adult life? I do not mean to obtain your assent by begging the question, but by suggesting your assent or denial according to your varied experiences. Many epidemics of measles are so mild, especially during the warmer seasons, that the majority of those sick, if children especially, never go to bed, but remain outdoors and play, and scarcely show any signs of distress. When a mild epidemic shows its character, why not expose all children above 2 years and under 12 to 14 years to it? Measles, ever so mild, is prophylactic against any future exposure, as much or more than vaccinia is against smallpox. Whatever phase measles exhibits during childhood, we will all admit that generally it is very severe among adults, causing a great mortality *per se*, and still greater on account of its complications.

It is true the hygiene of prisons and camps, as well as other places of detention such as the various hospitals, is to-day more perfect, yet much is to be desired, and we know that if measles breaks out in such places, especially among adults, the mortality is usually great and the epidemic hard to manage. But my observations on a large number of epidemics, it is true, in Iowa, where we have small cities and many small country towns and rural districts, have invariably shown very light mortality among children under 14 and a much greater number of deaths among the adults. It is undeniably true also that the very young, say under 2 years of age, also bear the disease very poorly.

In the discussion before us, of course, much must be considered. I think the disease should always be quarantined against in children's hospitals, in private schools, in severe winters, and in the unsanitary districts of crowded tenement wards or other unhealthy communities, since in these cases complications are easily evoked, especially tuberculosis following the disease as a sequela. But when we can expose children in ordinary health to a mild epidemic of measles, there would probably be the same gain as we experience in the substitution disease of cowpox for smallpox.

Even in an epidemic recently observed in a small rural community, where there were 68 cases of measles, no one under 15 years of age died, but 3 adults died out of 23 cases over 25 years of age. This epidemic is a fair sample out of many I have observed in rural districts, villages and small towns from 2000 to 30,000 inhabitants.

In case the susceptibility to acquire measles diminished much, as adult age is reached, it would be more worth our while to quarantine, but such is not the case; adults are just as likely to acquire measles as children, when exposed to the contagion or an epidemic, and when acquired become usually more dangerous. I am aware that while I had my experiences with thousands, there are those here who have had theirs with tens of thousands, yet I hope that no javelins will be thrown on account of the difference, rather if my suggestions appear weak before the strong let them deal kindly with the erring, and thus show us the better way. There is, however, a margin always in favor of quarantine, and that margin is the doubt in diagnosis. Until that is fully established, while we fear a case of measles or varicella may be scarlatina or variola, a mistake that not only happens to the neophyte but to the oldest veteran in practice at times, it is best not to allow patients to come in contact with others.

I now submit these few premises for your conclusions, and trust you will accept them in the spirit offered, namely, let our contentions be in quest of truth, and the greatest good for all. Undoubtedly your varied experiences may cause you to differ as the parallax depends on the different stations occupied by different observers viewing the same object. One may see the same shield black that another sees white and if it were turned, opinions as to color would change. As for me I am glad I had the measles when I was a child, and so are all of you who are in the same boat.

ROETHELN.

ITS DIFFERENTIATION FROM MEASLES OR SCARLET FEVER.*

HENRY KOPLIK, M.D.

NEW YORK CITY.

It is very difficult, even from a historical standpoint, to accept a description of an epidemic, exanthematous affection of a century ago and try to adapt this description of disease to what we see to-day. Our point of view is entirely at variance with that of observers of an early clinical school. With such a disease as roetheln or rubella our confusion is more marked if we study the epidemics of this disease described by Hildebrand in 1832, Heim in 1812, and Forney in 1784-1796. It is not surprising that such a writer as Jurgensen is thrown into doubt. It would be well if we should reject all but the most modern descriptions of epidemics of roetheln, as these modern writers can be more easily understood by us to-day. We do no injustice then to older, or we may say to antiquarian, historians: their descriptions are obscured by lack of accurate clinical methods. Even in such simple matters as the description of an eruption, its location and characteristics, with roetheln, the lack of explicit and modern description, in older writers can only be appreciated by any one who will study the history of this disease. As far back as the 18th century we find

descriptions of a disease which often accompanied or occurred, as it were, on the outskirts of epidemics of measles and scarlet fever. Though resembling cases of both diseases, they could not be classed as belonging to either of the well-known exanthemata. The early descriptions of this disease are marred by bitter polemics, some physicians contending that they were in the presence of a distinct disease, roetheln; others, that the disease in question was but a mild measles or scarlet fever. To-day we find such observers as Hensch and Jurgensen still in doubt as to the entity of roetheln.

These are the considerations which have induced the writer to present his views on this subject. He agrees with Trouseau, Cheadle, Thomas, Baginsky and Eminghaus, that roetheln is a distinct and definite disease, independent of measles or scarlet fever. It has a distinct semeiology, and can to-day be differentiated especially from measles or scarlet fever. Trouseau describes under the heading of roseola, rubella exanthema fugax, a disease which he places in the same relation to measles or rubella that varicella holds to variola. He describes the exanthem, lays stress on its evanescent character, its characteristic location, the absence of affections of the mucous surfaces—conjunctiva, nasal passages, and lungs—and the absence of any sequelae or complications. He calls attention to the fact that an attack does not prevent subsequent attacks, nor protect against measles. It occurs epidemically and is contagious. Thomas¹ gives the most modern, and to me a very classical, description of some epidemics of roetheln which he has observed. His descriptions, to which I will freely refer, have done much to place the disease on a firm, independent basis. He describes two forms of exanthem, the small and the large papular. He describes minutely the appearances, if any, on the mucous membranes, the temperature and course of the disease. Eminghaus² also describes an epidemic of roetheln and concludes that it is a disease sui generis. His descriptions are not as definite nor as simple and classical as those of Thomas. In the transactions of the International Congress at London, 1881, a full discussion of the position of roetheln to the other exanthemata took place. The disease was discussed by various leading authorities of the times, most of whom are living to-day—Cheadle, Shuttleworth, William Squire, Kassowitz, Baginsky, Jacobi, and Lewis Smith. Smith's description of a New York epidemic is particularly full and definite. The consensus of opinion was that roetheln, rubella sine catarrho, rubella, was a disease, giving no protection from measles or scarlet fever and distinct from them. Returning to the textbooks, Barthez and Rillicz, 1861, acknowledged the great difficulty in distinguishing between roseola and rubeola—measles. They place more reliance on the absence of marked general symptoms than on characteristics of eruption for a diagnosis. Kaposi (1887) is inclined, with Hebra, to look on roetheln as a mild or anomalous form of measles, and denies its right to the dignity of a distinct disease sui generis. He cites Kassowitz, who at first disapproved the view that roetheln was a distinct disease, but subsequently observed an epidemic which caused him to rather support the view of its being a disease distinct from measles or scarlet fever. Gerhardt, in 1881, believes that roetheln is distinct from measles or scarlet fever, though he admits that roetheln occurs epidemically with measles. Gerhardt mentions the school of Shoelenin, which regards

*Presented to the Section on the Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

1. Jahrb. f. Kinderheilk., 1869.

2. Jahrb. f. Kinderheilk., 1871.

roetheln as a mixed or bastard form of measles or scarlet fever; on the other hand, he is inclined to side with Thierfelder, Koestlein and Thomas, who regard the disease as distinct from measles and scarlatina, which it resembles in several characteristics. E. Husset,³ regards roetheln as distinct from measles and scarlet fever. In closing this historical review we need but mention the work of Griffith, of Philadelphia, who describes a severe form which occurred epidemically and which seems to have been observed by few other authors. Forcheimer, in the "Transactions of the American Pediatric Society," has recently described an epidemic in Cincinnati in which he made a minute study of the appearances on the mucous membrane of the soft palate, to which we shall return again.

Looking over the work of those who have studied roetheln in large or small epidemics, we are struck by the incompleteness of most of these studies. The number of cases observed by each author is not only small, but limited for the most part to one epidemic. The experience of many writers numbers at most only 50 or 100 cases. A great number of observers do not seem to have approached their cases with sufficient experience in the diagnosis of skin eruptions which might resemble that seen in roetheln. In one case we find an author a violent opponent of the view of roetheln being an affection independent from measles or scarlet fever; a few years later this same author has had an opportunity to observe an epidemic and he straightway becomes convinced of the specific nature of the affection.

During the past seven or eight years the author of this paper has made a special study of the relationship of roetheln to measles and the other exanthemata. During these years, and especially later in his studies, the exact characteristics of roetheln have formulated themselves in his mind. He has seen probably as large a number of cases as has fallen to the lot of most writers on the subject, having passed through many small local outbreaks of the disease. Though it may occur in cities at a time when measles is epidemic or prevalent, roetheln has no relation to this disease. It does not protect the patient from measles; it may occur in subjects who have had measles. It may even occur in the same patient a number of times. In other words, one attack does not give immunity from subsequent attacks. Though highly contagious, the author has met children who have been exposed and yet did not develop the exanthem.

Age.—It attacks every age from the youngest infant to adult life. The author has, as Thomas also records, seen the disease in adult life. Unlike in measles, adults do not seem to be any sicker than children, when attacked with roetheln. The throat in adults appears to present the only disagreeable symptom. Personally, I have met roetheln in nurslings as young as 7 weeks of age, as well as in adults. Thomas' youngest case was 19 months old. It shows no predilection for sexes. The prodromal period in the children I have observed gives no symptoms, except that for a few days previous to the outbreak of the eruption I have noted in the last epidemic a suffusion of the eyes, such as is often seen in an attack of grieppe. The conjunctival folds have a deep-scarlet color. There is, however, no marked conjunctivitis. The children do not complain. This was so in a case I recently met in a public conveyance: the boy's eyes were of a deep-pink color. I told the mother of this fact. Four days after this, the eruption broke out on the body. In adults I had occasion to note

an interesting case in a nurse who had been in an assistant capacity in a large children's clinic. For six days previous to the outbreak of the eruption she came to me to ask about a chain of glands on both sides of the neck behind the sternomastoid. Those glands had enlarged to the size of a half bean, were not painful, but only aroused uneasiness by their peculiar abrupt appearance. Six days after daily observation of these glands the exanthem appeared. There was absolutely no fever in this prodromal period. In another case, a boy 6 years old, who had been exposed, his sister having a decided attack of roetheln, the lymph-nodes along the posterior border of the sternomastoid were distinctly enlarged at the time of the appearance of the exanthema in his sister. The boy had no other symptoms. He had no fever and was at play. Two weeks after this the eruption appeared on the body of the boy and was out only one day.

The period of incubation, which may include these mild affections of the prodromal period, is placed by Thomas and Eminghaus as varying from 15 to 20 days. Eminghaus says that before the outbreak of the eruption there is some headache, nausea and irritation of the bronchial mucous membrane. Forcheimer, who was able to observe the disease in his own family, says that his child complained of slight malaise just before the outbreak of the eruption. In the largest number of cases, however the eruption is the first symptom and will bring the patient to the physician.

The Exanthema.—We may say that the exanthema of roetheln resembles that of measles so closely that at the time of onset it is quite common with physicians to mistake the one for the other. The mode of appearance is also similar to that of morbilli, in that it is first noticed around the *alæ nasi* and on the upper lip in an indistinct way, as is seen in the invasions of morbillous exanthema. All writers who have to-day retained any authority on the subject of roetheln agree that the exanthema appears first on the face. It is seen on the forehead at the side, at the temporal region, on the cheeks and chin. It is preceded in some cases by an erythematous flame-like blush, which is diffused over the whole face. This deep erythematous blush was described by Eminghaus. The writer has had a very good opportunity to observe it also. It breaks out on the face; it may again in a few hours disappear and reappear, to finally, in six to twelve hours, disappear and leave the real exanthema in all its characteristics spreading on the face and neck. In all the epidemics which I have observed this exanthema has the same characteristics. It is papular, of a deep rose-red color. As a rule, it remains discrete. The rose-red or roseolar papules are distinctly arranged in a crescentic manner. This arrangement can always be made out where the exanthema is spreading. On the face and neck at the outset this crescentic arrangement, present at first, gives place to a blotchy appearance characteristic of measles. At this stage, if we look at the trunk, where the exanthema is advancing, we see the crescentic arrangement of rose-red papules above referred to. The skin between and in the center of the crescentically arranged papules has a normal hue. Sometimes, in the parts where the eruption has become confluent, I have seen an appearance, punctate in character, which may be mistaken by the superficial observer for scarlet fever. In such cases, a study of other parts of the body will immediately reveal the above papules disposed in a crescentic fashion. I have been able to verify, with Thomas, that in many cases the individual rose-red papules are punctate in size all over

the body. These cases might be mistaken for mild scarlet exanthema; but here, as in the larger form of rose-red papules or roscola, the crescentic arrangement on the other parts, as the thorax, back, buttocks, and extremities, has in all my cases been very apparent and a distinct element in establishing the diagnosis. In other words, this crescentic arrangement is exactly similar to what is seen in measles in the discrete stage of the exanthema. The exanthema will in many cases fade on the face while it spreads from the trunk to the lower extremities. In the parts in which it is spreading the exanthema retains its discrete form and crescentic arrangement. Thus it happens, if the eruption is diffuse on the face and trunk after it has been out a few hours, to the superficial observer it looks like a typical case of measles, with certain very important diagnostic reservations, which the writer will emphasize. After remaining out in full efflorescence on the face and trunk only from a few hours to a day, the exanthema begins to fade, first from the face and then from the trunk. A patient may in the next twenty-four hours present a perfectly normal skin. As a rule, evidences of the eruption continue for two or three days, especially on the extremities and lower trunk. In some cases the disappearance of the papules is complete, leaving a white skin. In other cases, though the exanthema has completely disappeared, it leaves after forty-eight hours indistinct bluish or brownish crescentic pictures occupying the place of the roseolar spots. This reminds us quite forcibly of what is seen in cases of simple erythematous eruptions. After another twenty-four hours no trace of the eruption is left. I have never seen the pigmented spots seen in true measles, which persist for days or weeks on the skin. After the disappearance of the exanthema—one to three days—there is in some few cases an indication here and there as though there might be attempted desquamation. It is not always easy to decide this point. For, among the poor, it is impossible on account of filth to decide the presence or absence of so delicate a matter as desquamation after roetheln. In the better class I have found it equally difficult to come to any definite conclusion. Thomas accepts the presence of a fine desquamation of the skin.

Mucous Membranes.—My own studies have convinced me that, unlike measles, roetheln is not a disease of the mucous membranes. In all the cases I have studied, their number is large and the severity varied, I have never seen the coryza, cough and bronchitis as it is seen in measles, even of the milder types. We find a mild and evanescent cough, seemingly caused by the injection of the pharynx and enlargement of the tonsils, which is always present. In other words, the conjunctivæ are injected, as in grippé, but there is no secretion or conjunctivitis, nor even photophobia, as in measles. In fact, the children will ask to be permitted to read. There is no conjunctival inflammation; it is simply an injection. This injection will sometimes persist for days after the exanthema has disappeared from the skin. The eyes will retain a sleepy look, but give no symptoms. If we look into the mouth at the outset of the disease we see a varying redness of the pharynx, pillars of the fauces and enlarged red tonsils. It is rather an angina that we see, similar to what is seen in very mild scarlet fever or simple angina. The glands at the angle of the jaw may be enlarged, also, as mentioned, those behind the posterior border of the sternomastoid muscle. The disease seems to have spent itself, as in scarlet fever, on that part of the chylipoietic

system connected with the skin, as the lymph-nodes, rather than on the mucous membranes.

Thomas speaks of a spotted appearance of the mucous membrane of the soft palate and cheeks. The individual spots are not raised as those on the skin. They do not resemble the skin eruption. Eminghaus mentions the discrete red spots of the soft and hard palate. Thomas, in another article,⁴ characterizes the appearance of the mucous membrane of the hard and soft palate as streaked in red in some places, in others spotted. Kassowitz, in the discussion at the International Congress, mentioned the presence of isolated red spots on the mucous membrane of the hard palate on the first day of the disease in a small percentage of the cases. Jurgensen describes an exanthema on the soft and hard palate similar to what is found in measles. Gerhardt, also, while calling attention to the injected pharynx, describes a spotted hemorrhagic eruption on the palate. Forcheimer is the most recent writer to describe a characteristic exanthema on the soft palate, consisting of a "macular, distinctly rose-red eruption on the velum of the palate and uvula, extending to, but not on, the hard palate." These spots were arranged irregularly, not crescentically. The author of this paper wishes to emphasize the fact that he does not consider any eruption on the soft or hard palate as pathognomonic or characteristic of roetheln. He has observed all of the above eruptions. In some cases the soft and hard palate are irregularly spotted or streaked red in places. In other cases, he has observed small stellate or round rose-red spots. In other cases again, the soft palate was studded with an eruption of red spots, in the center of which could be seen small vesicular formations. None of these are characteristic. They are met with in other exanthemata, such as scarlet fever or measles.

The buccal mucous membrane, however, is the crucial test in making a diagnosis of roetheln in the vast majority of cases. We never see in this location the characteristic measles spots described by the author as pathognomonic of measles. The buccal mucous membrane in most cases of roetheln is of a normal pale-pink hue. In some few cases, a vanishing percentage, I and my assistants at the clinic have observed and subsequently studied cases of roetheln in which a few rose-red spots were seen on the buccal mucous membrane. In no case, however, of true roetheln have I observed the rose-red spots with the bluish-white speck in the center seen in measles. From a study of a large number of classical and doubtful cases, the author has come to rely on the buccal mucous membrane as the only reliable means, with other symptoms and skin eruption, of distinguishing roetheln from measles. The cases of roetheln observed in New York show the buccal mucous membrane free from any eruption or exanthema throughout the disease. The buccal mucous membrane retains its pale-pink normal hue.

We find in roetheln that the temperature is highest at the outset of the disease, when the eruption has appeared on the face. The temperature does not rise when the eruption spreads on the trunk, but falls, within a few hours from the outset by a sort of crisis (Thomas), to within one or a half degree of the normal. Or the temperature may be normal in the rectum and still the eruption be at its florid state on the face or trunk. The eruption, spreading as it does in stages from the trunk to extremities, does not cause any marked disturbance of the temperature curve at the time of its spread to

4. Jahrb. f. Kinderheilk., 1872.

other parts. The temperature at the outset may be 99.8 F. in the rectum, or it may reach 102 in the rectum. I have rarely seen cases in which it was higher. It falls fully within twelve hours to 100 F. in the rectum, and may continue for a day or two at that temperature in the rectum and then fall to the normal. I have noted in those cases in which the evening rectal temperature remained 100 or 100.4 for a day or more, the throat was inflamed more than usual or the lymph-nodes at the side of the neck persisted longer.

The Lymph-nodes.—In the cases of roetheln which I have observed, the lymph-nodes behind the sternomastoid muscle, both in children and adults, were enlarged. The enlargement in the prodromal stage has already been mentioned. I have seen cases in which the patients have been distinctly exposed to the disease, who for days or weeks showed enlarged lymph-nodes in chains exactly similar to those who presented the exanthema. In these cases, in spite of daily observation, the exanthema never was seen on the skin and the nodes gradually returned to the normal without temperature. In these cases I have wondered whether the exanthema might not have been so slight and evanescent as to escape observation and disappear within a few hours. The enlargement of the nodes denotes to me an infection only of an abortive character. In one adult case, the lymph-nodes were much enlarged and the angina was marked. The exanthema appeared for only a few hours on the face and nowhere else. It was not apparent to others in the family, but was very characteristic to me. It had the papular, roseolar, circinate character.

In a recent outbreak of roetheln I and my assistants have made a study of the lymph-nodes elsewhere than in the neck. In the eleven appended consecutive cases studied in my clinic the lymph-nodes were enlarged at the bend of the elbow, the axilla and the groin. The nodes were the size of a bean or pea, in some cases larger. In all cases the lymph-nodes remained enlarged long after the eruption had disappeared from the skin. The nodes may sometimes be felt for weeks after. In other cases they rapidly grow smaller. I append the following cases simply as a matter of record:

CASE 1.—Male, 6 years; temp. 100.2; eruption full; general lymph-node enlargement.

CASE 2.—Male, 6½ years; temp. 100; eruption; general lymph-node enlargement; disappeared in two days.

CASE 3.—Male, 1 year, 2 months; temp. 99.8; eruption; lymph-nodes generally enlarged.

CASE 4.—Male, 7 years; temp. 98.5; eruption; lymph-nodes generally enlarged.

CASE 5.—Female, 5 years; temp. 99; eruption; lymph-nodes generally enlarged.

CASE 6.—Male, 6 years; temp. 100.8; eruption; lymph-nodes generally enlarged.

CASE 7.—Male, 5 years; temp. 100; eruption; lymph-nodes large.

CASE 8.—Male, 4 years; temp. 100.2; eruption; lymph-nodes large.

CASE 9.—Female, 19 months; eruption; lymph-nodes large.

CASE 10.—Female, 7 weeks old; temp. 98.6; only lymph-nodes of neck large.

CASE 11.—Male, 2 years; general enlargement of nodes.

The Angina.—In the great majority of cases there is a distinct enlargement of the tonsils; they are red and inflamed, and the pillars of the fauces are inflamed also. The lymph-glands at the angle of the jaw may be slightly enlarged. The angina is never as severe as in scarlet fever. The patients do not complain much of

the throat if they are older children; adults complain of slight pain in swallowing and a feeling of "cold in the head." In no case have I seen any membranous formation on the tonsils. I have examined a number of cases with special reference to the size of the spleen. In varicella the spleen is sometimes palpably enlarged. In roetheln I have never noted this. In one case of roetheln, occurring in a girl of 7 years, in whom the exanthema was profuse, there was dysuria of a very annoying character. In this case an examination of the introitus vagina revealed intense redness and slight secretion. The symptoms disappeared without further treatment.

Eruptions Resembling Those of Roetheln.—There are some forms of erythema multiforme, which by an inexperienced observer might be mistaken for that of roetheln. I refer to the forms of erythema which occur in small papules. These erythemas fail to show the crescentic arrangement of papules, and in places will have a blotchy character to the eruption. Erythemas also have an ecchymotic or bluish color, especially at the center of the papule. In some cases we can understand how a papular rose-colored eruption caused by a drug or antitoxin might be mistaken for the exanthema of roetheln. Scarlet fever does not affect the face so distinctly, and on the trunk scarlet fever shows the acute dermatitis as a background for the punctate character of the general eruption. In scarlet fever the small punctate spots have no particular arrangement; in roetheln, if the papules have the minute size of those of scarlet fever, the skin between the papules has a normal color. In all of these cases, also, we can make out a crescentic arrangement of the papules.

The exanthema of measles of the discrete type is the only eruption which so closely resembles that of roetheln as to be constantly mistaken for it. In fact, I have frequently seen physicians unhesitatingly pronounce a case of measles and insist on the diagnosis when only roetheln was present. In all such cases the buccal mucous membrane has been the crucial test for me. It has invariably maintained the truth of the diagnosis in the subsequent course of the disease. As the disease progresses I have never noted in roetheln the tendency of papules to become confluent over any great extent of surface as seen in measles. At least in the New York cases we have always seen the skin not affected by papules of a normal color and consistency.

Roetheln deserves the dignity of a disease distinct from measles or scarlet fever. It does not protect the subject from either of the two affections named. This will, in my mind, account for a vast number of cases in which there is said to have been two attacks of measles. Roetheln is a mild affection, resembling very much varicella. There have never, to my observation, occurred complications which could give rise to any uneasiness. The temperature at the very highest never goes beyond 103 F., and in most cases in New York the temperature never mounts above 101 F. The general condition of a patient is that of a person suffering only a slight malaise. I have never seen nephritic complications in this disease. It requires little or no treatment. I advise the parents to keep the children indoors until all signs of the exanthema have disappeared; the children are then allowed in the open. In the winter months the children are kept indoors about a week after the first day of the eruption. I have seen no sequelæ in any of my cases. The most important point to me has always been the positive differentiation of this disease from measles or morbilli. We may thus avoid

isolation of the children for three weeks in summer and four weeks in winter, which is necessary in measles. This, in private families, and even in institutions, is a most important matter.

As the writer closed this article he received a reprint of an article by Ad. Schmidt, coming from Escherich's clinic. Among some very interesting data, we find that in a roetheln epidemic in Graz, the "Koplik spots" were studied as to the frequency of their occurrence or absence. It was found that they were invariably absent. Schmidt concludes that the absence of this sign is valuable in building up the diagnosis of roetheln. It will be admitted on all sides that in marasmic children, in whom the mucous membrane has been the subject of prolonged traumatism, the diagnosis of "Koplik spots" may at times be difficult.

A CLINICAL AND PATHOLOGICAL STUDY OF THE RASH OF SCARLET FEVER.*

WITH ESPECIAL REFERENCE TO THE ORIGIN AND CHARACTER OF THE DESQUAMATION.

JAY F. SCHAMBERG, A.B., M.D.

Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine; Fellow of the College of Physicians, Philadelphia.

PHILADELPHIA.

The eruption of scarlet fever is a dermatitis presenting a remarkable constancy in its general characteristics. This is true to such an extent that the clinician has in his mind a concrete picture of this efflorescence. Yet, like inflammation in any other structure, this pathologic process in the skin varies in severity in different patients. There must therefore be a certain degree of variation in the clinical appearances of the eruption.

The redness of the skin of scarlatina has been variously described as bright red, scarlet, raspberry-juice tint, boiled-lobster tint, etc. It is a matter of the greatest difficulty to carry color valuations in one's mind. It is an impossible task for the artist to view a sunset, and then at some future time transfer its coloration to canvas. It is equally impossible to view an eruption and later accurately compare its color with that of some other object. One must have both colors simultaneously before the eye. When pieces of the shell of boiled lobster are compared at the bed-side with the color of the rash of scarlatina a wide difference in the tints is observed. So, too, is it impossible to match the eruption of scarlet fever with any of the shades of bright red or scarlet. In order to accurately reproduce the tint with water-colors one must employ an admixture of red, burnt sienna, yellow and blue. The color of any inflammatory eruption is due to the blood appearing through the texture of the skin. The amount of blood in the part, as determined by the caliber of the cutaneous blood-vessels, and the character of the blood itself influence this coloration. It is therefore evident that the color must vary within certain limitations in different individuals. The color of the eruption in scarlet fever is reddish, sometimes bright, at other times dull or dusky, with an appreciable element of brown. Sometimes the eruption is so brownish-red as to almost approach a bright terra-cotta. Sometimes the element of blue is so well marked, particularly in dependent areas of the skin such as on the back, as to be quite purplish, owing to

venous congestion. The majority of eruptions, it appears to me, would deserve the description of dull-red rather than bright-red. The color varies not only in different individuals, but at different stages in the same individual. A bright-red eruption may become dusky or brownish-red in the course of a few days.

On close inspection the rash of scarlet fever is seen to be made up of small deep-red puncta surrounded by erythematous areolæ of somewhat brighter hue. When the areolæ coalesce, as is usually the case, a diffuse eruption is presented. At times, however, there is some intervening normal skin giving the eruption a more or less speckled appearance. This is more particularly noted upon the flexor surfaces of the fore-arms, in which region the efflorescence may be so blotchy as to excite a suspicion of measles. These deep-red puncta represent, for the greater part, inflammatory cellular infiltration about the hair follicles, and will be discussed more fully in the pathological report to follow.

Many scarlatina eruptions exhibit small pin-point to pin-head sized elevations occurring, in the main, at the sites of hair follicles. This condition has been termed by the older writers "scarlatina papulosa." In addition to these elevations, an appearance not infrequently noted is a general "goose flesh" condition of the skin. This is best marked upon the abdomen and chest, and is characterized by numerous pin-head sized papules bearing a close resemblance to the "cutis anserina" evoked in the normal skin by exposure to either extreme of temperature. These papules may be of the normal skin tint or reddish. They may make their appearance a day or two after the onset of the disease, and usually persist from three to six days. At times this condition is so marked as to give the skin a "nutmeg grater" feel and appearance.

In the older descriptions of the scarlet fever eruption, one reads of the occurrence of sudamina. Inasmuch as the skin in scarlet fever is hot and dry, with no tendency to sweating, one would scarcely expect to find such lesions present. Sudamina are dew-drop like vesicles with an extremely thin roof, occurring at the mouths of the sudoriferous ducts, and merely represent drops of sweat retained by an obstructive epithelial pellicle. That true vesicles do occur, however, in scarlet fever has been noted by numerous observers. To this condition the term "scarlatina miliaris" or "scarlatina vesicularis" has been given. The term miliary vesicle should be understood as referring to a vesicle the size of a millet seed, and in no way related to miliaria or prickly heat, which is an affection associated with disorder of the sweat glands and ducts.

The vesicles of scarlet fever are conical, epidermal elevations, pin-point to pin-head in size, with turbid contents, and usually disseminated, although they may occur in groups. They are commonly situated on the abdomen and chest, to a lesser extent on the extremities. On the back they are less common. The region in which they are frequently most profusely present is the mons veneris, for here the erythema is apt to be most intense. In this region they are prone to develop into well-marked yellowish pustules. The accompanying photograph shows a group of these vesicles occurring about the anterior axillary folds in a well-marked eruption in an adult. (Fig. 1.) Rarely these vesicles may coalesce, forming blebs of the size of a pea or larger, constituting the "scarlatina pemphigoides" of the older writers.

What is the frequency of these vesicles and what is their nature? Do they, or do they not bear a relation-

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

ship to the intensity of the scarlet fever eruption? Do they influence the desquamation? These are questions which have a direct practical import, and have been argued variously. During the past few years I have had the opportunity of examining several hundred cases of scarlet fever, with the object of studying the character of the eruption in general, and the vesiculation in particular. From these observations I should conclude that vesicles are present in the vast majority, if not all of the cases, of scarlatina. In decidedly exceptional cases they are so marked as to confound the clinician in the diagnosis, by suggesting a disease other than scarlet fever. Dr. J. P. C. Griffith, of Philadelphia, has recently reported several such cases. In these cases the vesicular character of the eruption is its most striking feature. In perhaps 20 per cent. of all the cases, and 50 per cent. of well-marked eruptions, vesicles are visible if looked for. Ordinarily pin-point or pin-head sized lesions do not intrude themselves upon one's vision

Fig. 1.—Grouped military vesicles about the anterior axillary fold in a case of scarlet fever.

and are apt to be overlooked in a cursory inspection of the rash. In a large number of the remaining cases they can only be seen by the closest scrutiny of the skin under the best possible illumination. Finally, there are some which can not be seen with the naked eye but are demonstrable under the microscope. In certain excised sections of the skin, I found vesicles microscopically which I could not previously detect by the closest examination of the integument.

Vesicles are more often and more prominently visible in severe eruptions than in mild rashes. It is true that they may be quite conspicuous at times in patients who have but little rash, and this has led some observers to conclude that they bear no relation to the intensity of the eruption. A study of a large number of cases will, however, demonstrate that they are more copious in intense eruptions, and this is confirmed by the appear-

ances under the microscope, demonstrating the vesicles to be distinctly inflammatory in character.

I believe the intensity of desquamation to be directly proportionate to the amount of vesiculation. If one will watch for the first appearance of desquamation on the trunk, it will be noticed as a number of discrete, pin-point, powdery scales. These represent the summits of the desiccated vesicles. In a day or two this scale is cast off, thus producing a small jagged ring of desquamation. The horny layer of the epidermis is now lifted off by centrifugal extension of these rings, which grow constantly larger. On meeting enlarging rings of neighboring lesions they produce gyrate and geographic configurations resembling the contours of a map. This is

Fig. 2.—Unusually intense desquamation in a severe case of scarlet fever. Ring character of desquamation shown.

well illustrated in the photographs (Figs. 2 and 3) which I herewith present for your inspection. In this manner the entire corneous layer of the skin is removed.

This I believe to be the almost invariable character of the desquamation on the trunk. On the hands and feet the desquamation is different, and this because of a difference in the anatomical structure of the skin. The horny layer of the epidermis on the hands and feet is tougher and thicker than elsewhere on the body. Inasmuch as a serous exudate from the blood-vessels travels in the direction of least resistance, it burrows its way beneath the horny layer instead of lifting it up at different points in the form of vesicles. In this manner, in severe eruptions, the horny cuticle is raised *en masse*, with the result that there is shed an entire epidermal cast of the hands or feet. The photograph (Fig. 1) herewith shown well represents this type of

desquamation. In less severe cases the epidermis of the hands peel off in lamellae or flakes. This, beginning at the free border of the nails or at the nail folds, constitutes a highly diagnostic picture. (Fig. 5.)

I am convinced that too much stress in the diagnosis of scarlet fever has been placed on the mere occurrence of desquamation. Desquamation is the terminal stage of certain inflammatory changes in the skin and is not at all peculiar to any one disease. The rash of scarlet fever is an infectious dermatitis. There are other forms of eruptions of infectious origin bearing such a striking resemblance to scarlet fever that they can not by themselves be differentiated. They are grouped under the

Fig. 3. Desquamation upon the neck and chest in an average case of scarlet fever.

one term "scarlatiniform erythema," although there may be a variety of causes giving rise to them. One distinguishing feature of these rashes is a tendency to recurrence.

The persistence of the scarlet fever desquamation and its special characteristics are of more diagnostic importance than the mere existence of scaling. It is rather remarkable that a rash lasting but five or six days should continue to scale for seven, eight or nine weeks. This may be explained by certain pathologic phenomena presently to be described. At the same time it should be borne in mind that it is possible to have a rash so extremely mild and fugacious as to be followed by a barely detectable desquamation.

I am not able to say to what extent vesicles occur in the erythematous resembling scarlatina, and the differential importance of the "jagged-ring desquamation" is

therefore still to be determined. I have occasionally seen a few small vesicles in severe cases of measles, and these may account for the scaling that sometimes takes place in this disease.

HISTOPATHOLOGY.¹

The pathology of the skin in scarlatina has been investigated by Kaposi, Klein, Neumann, Delafield and Prudden, Unna, Pearce and others. They all agree, in the main, as regards their findings: There is a dilatation of the blood-vessels and lymphatics; an infiltration of lymphoid cells and polymorphonuclear leucocytes into the papillary layer; later an invasion of the rete mucosum by leucocytes; mitosis and proliferation of the deeper rete cells. Neumann mentions slight proliferation about the hair-follicles. All of these observers evidently excised for examination areas of the smooth skin. The sections referred to in this paper represent papules, vesicles, puncta, etc., as well as the erythematous rash surrounding them. My results are in accord with those above mentioned, but in addition I have attempted

Fig. 4. Pair of epidermal casts of the hands cast off in a fatal case of scarlet fever.

to describe the histopathology of these other elements of the rash.

The histopathologic data herewith presented are based on a study of about 400 sections of skin representing 13 specimens removed during life from 12 cases of scarlet fever. The skin was excised by means of a Keyes skin-punch, after previous injection into the subcutaneous tissue of a 1 per cent. solution of cocaine. The excisions were performed upon patients representing stages of the disease from the second to the seventh day.

The sections were hardened in successive strengths of alcohol, imbedded in paraffin, and stained in hematoxylin-eosin, thionin, eosin-polychrom-methylene blue and the Weigart-Gram stain. A brief description of the different specimens is herewith appended, with a clinical note describing the lesions before excision.

CASE 1.—J. B., age 6. Profuse erythematous-vesicular rash. Redness very vivid and vesicles remarkably numerous. Area showing a pin-head central vesicle with a hair perforating, and a few smaller peripheral epidermal elevations, excised from the trochanteric region.

Under low power the section is seen to contain four hair follicles. At the mouth of the central follicle is a

¹ From the Polyclinic Laboratory, Philadelphia.

large crateriform cup filled with a mass of leucocytes and epithelial débris. (Fig. 6.) This connects with the lumen of the follicle. The epithelium of the hair-follicle is infiltrated with numerous polymorphonuclear leucocytes. To the right of this is another smaller hair-follicle, which is also the seat of extensive pathologic change. At the surface of this follicle is a small horizontally oval space containing serum and a deeply-stained mass of cells, and covered by the horny layer of the epidermis. The lower half of the follicle is extensively disintegrated by a serous exudate, which has broken into the follicle, separated the epithelial cells and formed a lake in which may be seen numerous leucocytes. (Fig. 7.) The follicle is furthermore infil-

Fig. 5.—Marked desquamation in large flakes upon the hands.

trated with and surrounded by a dense mass of lymphoid cells and polymorphonuclear leucocytes. At the extreme end of the section is another follicle showing a circular space at the surface, filled with serum and leucocytes. The middle third of the follicle exhibits a serous and leucocytic invasion, which surrounds the hair seen *in situ*. (Fig. 8.) Between the two follicles just described there is seen a circular abscess in the epidermis filled with fluid and densely packed with leucocytes. This occupies an area between the horny layer above and the lowermost strata of cells of the rete mucosum. Numerous rete cells are seen detached and floating about in the exudate. The neighboring portions of the Malpighian layer are invaded with polymorphonuclear leucocytes. (Fig. 9.) The specimen, furthermore, shows a dilatation of the blood-vessels and lymph-spaces, a deep-cell infiltration throughout the corium and about the coils of the sweat glands.

CASE 2.—S. M., age 7. Well marked rash. Superficial vesicle excised from abdomen on fourth day of disease.

Sections were stained in hematoxylin-eosin and eosin-polychrom-methylene blue. Under low power the center of the section is seen to be occupied by a vesicle having its seat in the rete mucosum and its roof formed by the horny layer. Directly contiguous to this is a hair-follicle which shows extensive serous exudation and leucocytes in its lower extremity deep in the corium. (Fig. 10.) The papillary layer is the seat of an extensive infiltration of lymphoid cells and polymorphonuclear leucocytes. There is marked dilatation of the papillary blood-vessels, which are seen to be filled and surrounded by cell exudate. In sections stained with hematoxylin-eosin, are seen numerous multinucleated perivascular cells with red granular protoplasm. These are eosinophile cells. Sections stained with the eosin-polychrom-methylene blue show numerous mast-cells, particularly about the blood-vessels and walls of the hair-follicles. The epidermis exhibits a marked invasion of migratory cells which may be seen at all levels. There are also visible mitotic figures in the prickle-cells of the Malpighian layer. The accompanying photograph (Fig. 11) represents a section which shows several nuclei undergoing karyokinetic change. The daughter asters are well seen in the lowermost of the cells. These mitoses occupy cells about the center of the Malpighian layer.

CASE 3.—B. S., age 12. At the outset, a typical punctiform rash. On the sixth day the patient was seen again and showed a distinct goose-flesh papular appearance. A goose-flesh papule of normal skin tint was excised from the lateral aspect of the chest. Several smaller papules present.

Under low power the center of the section is seen to be occupied by a hair-follicle. Smaller follicles are situated at either end. About the central follicle is a well-marked infiltration of lymphoid cells and polymorphonuclear leucocytes. The epithelial cells of the follicles are broken into and pushed aside by a serous and cellular exudate. The same process, omitting the serous effusion, is present in the smaller follicles. The papillary and subpapillary vessels are dilated and filled and surrounded by lymphoid cells. There is a moderate number of oval and stellate mast-cells in the neighborhood of the walls of the follicles. In the perivascular infiltration may be seen small numbers of eosinophile cells. Sections stained in hematoxylin-eosin, thionin and polychrom-methylene blue.

CASE 4.—F. H., age 10. Well marked rash, punctiform with scattered small vesicles. An area of skin, on which was seated a barely discernible vesicle, was excised from the side of the chest about the seventh day. (Lesion is probably a vesicle, but can only be detected on close scrutiny of the skin.)

Under low power there is seen in the center of the section a superficial hair-pocket, the lumen of which is dilated and filled with leucocytic débris. The epithelial walls are disintegrated by an invasion of leucocytes. (Fig. 12.) The papillary layer of the corium is the seat of an intense infiltration of lymphoid cells and polymorphonuclear leucocytes. There is a dilatation of the blood-vessels and lymphatics and a marked perivascular cell infiltration. Leucocytes are visible between the prickle-cells of the rete mucosum. Mast-cells are present in small numbers. Sections stained in hematoxylin-eosin and eosin-polychrom-methylene blue.

CASE 5.—B. C., age 29. Eruption intense with hemorrhagic tendency. A punctuated spot, not disappearing on pressure, excised from right side of chest on fourth day of disease.

Fig. 12.—Hair follicle showing vesicular summit and serous cellular infiltration. Magnified 70 diameters.

Fig. 13.—Vesicle at mouth of hair follicle connecting directly with the lumen. Magnified 70 diameters.

Fig. 15.—Circumscribed vesicle in the epidermis. Magnified 140 diameters.

Fig. 14.—Circumscribed vesicle deep in the epidermis. Magnified 140 diameters.

Fig. 16.—Flat superficial vesicle in the epidermis. Magnified 70 diameters.

Fig. 6.—Large vesicle at the mouth of a hair follicle. Magnified 145 diameters.

Fig. 7.—Hair follicle showing superficial vesicle, disintegration by severe exudate, and surrounding cell infiltration. Magnified 115 diameters.

Fig. 8.—Two hair follicles with vesicles at the surface; both follicles disintegrated by serous exudate and surrounded by cellular infiltration. Also small vesicle in epidermis. Magnified 70 diameters.

Fig. 9.—Vesicle in epidermis showing circumscribed lake of serum filled with leucocytes. Magnified 300 diameters.

Fig. 10.—Serous and cellular infiltration involving the base of a hair follicle. A superficial vesicle contiguous to the hair follicle is not shown in the cut. Magnified 145 diameters.

Fig. 11.—Karyokinetic figures in the prickle cells of the rete mucosum. Magnified 1150 diameters.

In the center are a hair-follicle and sebaceous gland seen in cross section. These are surrounded by an extensive infiltration of polymorphonuclear leucocytes. The papillary blood-vessels are dilated and surrounded by an exudate of lymphoid cells and polymorphonuclear leucocytes, chiefly the latter. The rete mucosum shows leucocytes infiltrated between its cells.

CASE 6.—R. O., age 4. Well-marked eruption. Small epidermal elevation (vesicle) was excised from lateral aspect of chest on the second day of the disease.

The center of the section is occupied by a hair-follicle. In the mouth is seen a vesicle filled with serum and leucocytes. In some sections the vesicle is shut off from the lumen of the follicle; in others, however (Fig. 13), it is seen directly communicating with the lumen, so that there is practically a clear space extending from the horny layer to the base of the follicle. The epithelium of the follicle is disintegrated as a result of serous and cellular infiltration. The walls of the hair-follicle are surrounded by an extensive cell infiltration running parallel to the walls. The papillary blood-vessels are enormously distended and are filled and surrounded with lymphoid cells and polymorphonuclear leucocytes. Sections stained with the Weigert-Gram stain were examined for micro-organisms, but none were found.

CASE 7.—R. O. Same patient as Case 6. Redness fading. Minute vesicle with scaly summit was excised from the side of the chest on the fourth day.

The center of the section is occupied by a hair-follicle, which is surrounded by an intense lymphoid cell and polymorpholeucocytic infiltration. The papillary and subpapillary blood-vessels are dilated and are surrounded by an intense cell exudate. Mast-cells are present in small numbers.

CASE 8.—E. C., age 25. Well-marked eruption. Skin infiltrated. Section of skin with small vesicle on it excised from anterior surface of forearm.

Under low power, are visible two large circumscribed vesicles occupying the rete mucosum, which is cut obliquely and appears to be considerably hypertrophied. The larger of these extends from the horny layer to lowermost strata of rete cells. It is filled with serum, in which are visible densely packed leucocytes. The walls of the vesicle are made up of several layers of flattened rete cells. The other vesicle occupies an area of the rete mucosum at the nether extremity of a prolongation, and appears almost to be snared off in the corium. (Figs. 14, 15 and 16.) There are visible in different places, in the upper portion of the rete, in the granular layer and even in the horny stratum circumscribed masses of leucocytes, without serous effusion. It is possible that desiccation has taken place through absorption of the fluid. Polymorphonuclear leucocytes are seen in abundance invading the rete mucosum. The papillary and subpapillary blood-vessels are distended and surrounded by a marked cell infiltration. The entire corium is infiltrated with cells, many of which appear to be derived from fixed connective-tissue cells. No hair-follicles or sebaceous glands are visible in the section.

CASE 9.—M. M., age 25. Well-marked rash. Reddish elevated punctum (apparently at the site of a hair-follicle), excised from the lateral aspect of the chest on fourth day.

In the center of the section are a hair-follicle and sebaceous gland in cross section. The follicle is surrounded by considerable cell infiltration. Many of the cells of the sebaceous glands are undergoing fatty degeneration; their nuclei are shrunken and distorted. The subpapillary blood-vessels are greatly distended and

exhibit an intense perivascular infiltration. The lymph spaces are dilated and contain a cell infiltration.

CASE 10.—J. N., age 4. Well-marked eruption. A papule (possibly papule-vesicle), excised from thigh on second day of disease.

Under low pressure there is visible a cell infiltration in the papillary layer and throughout the entire corium. In the center of the section is a hair-follicle surrounded by an intense cell infiltration. The sweat coils are likewise infiltrated. No evidence of any vesicle present.

CASE 11.—H. M., age 6. Well-marked eruption. Section of skin 6 mm. in diameter, on which were several small puncta but no vesicles, excised from trochanteric region on third day.

Section shows an enormous dilation of the blood-vessels and lymph spaces. These are surrounded with lymphoid cells and polymorphonuclear leucocytes. A large hair-follicle in the section is surrounded by a moderate cell infiltration. There is also visible a sweat duct, the lumen of which is blocked with endothelial cells. Free blood is seen in many of the lymph spaces.

CASE 12.—R. F., age 4. Little or no redness present. Small area of skin excised third day, on which were seated two or three goose-flesh papules.

The papillary layer of the corium shows an infiltration of lymphoid cells, chiefly about the blood-vessels. Blood-vessels and lymph spaces are dilated. No hair-follicles present in the sections examined.

CASE 13.—H. G., age 22. On entrance to hospital she presented a deep, diffuse, smooth eruption over entire body. No visible elevations at this time. On sixth day redness largely faded. Scattered pin-head translucent vesicles (with difficulty visible). One of these excised from lateral aspect of trunk.

Cell infiltration appears in papillary layer of corium; likewise dilatation of blood-vessels, which are filled and surrounded by lymphoid cells and polymorphonuclear leucocytes. Small number of mast-cells and eosinophiles are present. There is no evidence of vesiculation. (It is possible that the central sections which should have shown the vesicle, were lost in the section cutting.)

Let us now interpret the clinical lessons in the light of the histopathological findings. When an area of skin representing a smooth erythema is excised, one finds the common phenomena of an acute simple dermatitis. There is dilatation of the blood-vessels, an exudation of lymphoid cells and polymorphonuclear leucocytes into the papillary layer, with some invasion of the epidermis by the migratory cells.

The goose-flesh population is not a mere temporary condition due to contraction of the hair-muscles, but results from an extensive infiltration in and about the hair-follicles, and therefore persists until the inflammatory phenomena subside.

Papules represent cellular infiltration, for the greater part in and about hair-follicles. The transition from a papule to a vesicle is a comparatively rapid one, and papulo-vesicles are of common occurrence.

Vesicles are invariably characterized under the microscope by a lake of serum containing a leucocytic infiltrate. These vesicles may have their seat in the deeper layers of the rete, or they may be intrafollicular, involving the hair-follicles. In either case there is a pushing aside and disintegration of the cells of the rete layer by a fluid exudation from the papillary blood vesicles. The turbidity of the contents of these vesicles is due to their invasion by leucocytes. In the attempt on the part of nature to eliminate the materies morbi, the leucocytic mass travels toward the surface lifting up the horny layer. Desiccation of the liquid contents of

the vesicles now takes place. This is immediately followed by a throwing off of the effete products. At this stage, clinically, the small powdery scale is seen at the summit of the dried vesicle. The leucocytes in the epidermis wander laterally as well as directly toward the surface, and lift off the horny layer on the periphery of the vesicle. In the section from Case 1, which represented an area of skin $\frac{1}{4}$ of an inch (6 mm.) in diameter, there were four vesicles, only one of which could have been seen by a casual inspection of the skin; two were visible on close scrutiny, and one not at all with the naked eye.

The punctated spot in several sections proved to be a hair-follicle surrounded by marked cell infiltration. The punctum may, however, show merely dilatation of the blood-vessels, with intense perivascular cell exudation. The number of puncta examined was too small to form any absolute conclusion as to the frequency of their occurrence about hair-follicles.

It will be noted that the hair-follicles and sebaceous glands suffer very greatly in the inflammatory process in the skin in scarlatina. It would seem that goose-flesh papules, puncta, and vesicles all occur more frequently about the pilary pockets than elsewhere in the skin. The depth at which these follicles are involved explains the persistence of desquamation. The walls of the hair-follicles are made up largely of cells corresponding to the rete layer of the epidermis. These being disintegrated by the leucocytic infiltration, must be thrown off with it. The depth from which these cells are derived necessarily makes the process a slow one. The persistence of the infectivity of the scales is explainable on the same grounds. There is every reason to believe that the infectious principle is contained in the leucocytes or epithelial debris cast off from the skin. Unfortunately but a few sections were stained for microorganisms and in these none could be discovered with the ordinary stains employed for this purpose.

In none of the sections was there any enlargement of the papillæ, and therefore the statement made to the contrary in some text-books would seem to have no basis in fact.

Karyokinetic figures are seen in many sections and indicate a proliferation of the epidermal cells, which are perhaps stimulated by the leucocytic invasion. Attacks of second and third desquamation may possibly be due to this cause.

The foregoing observations suggest the following inferences:

1. The color of the rash in scarlatina varies in different individuals, and at different times in the same. Accurately speaking, it is never scarlet and only occasionally bright red. More commonly it is a dull red with an appreciable element of brown.

2. There are other elements of the eruption of scarlet fever besides the erythema, namely, puncta, vesicles and goose-flesh papules, and these lesions occur with a considerable degree of constancy.

3. Vesicles are far more common in the rash of scarlet fever than is ordinarily believed. They are more profuse in intense eruptions, although they may be present in mild ones. The amount of desquamation is as a rule proportionate to the degree of vesiculation. Vesiculation may be so copious as to deceive the physician in his diagnosis.

4. Desquamation on the body begins as pin-point, powdery scales at the summits of the desiccated vesicles. Irregular or jagged rings of desquamation then form, which enlarge until the horny layer is completely shed.

5. Histologically, the rash of scarlet fever is a dermatitis exhibiting deep and extensive changes in the corium. The greatest degree of inflammation is exhibited about the hair-follicles, which are frequently disintegrated by a serous and cellular exudate. Vesicles have their seat either in the epidermis or in the walls of the hair-follicles. The persistence of desquamation and of the infectivity of the scales is to be accounted for by the depth of the pathological process in the skin.

I desire to express my most cordial thanks to my friend Dr. William M. Welch, Chief of the Municipal Hospital for Infectious Diseases, of Philadelphia, for the privilege of studying the valuable material which that institution affords.

DISCUSSION ON PAPERS OF DRs. DANIEL, SMALL, WAHRER, KOPLIK AND SCHAMBERG.*

DR. C. F. WAHRER, Fort Madison, Ia.—I have read descriptions in the various text-books of the exanthemata, and I think they vary almost as much as physicians do. Painters have used their art to paint sunsets, yet one sunset does not look like another. It is very difficult to teach a beginner in medicine, from description alone; it is really only by actual clinical observation that any one can learn. It is possible that with the aid of color photography we may be able to accomplish this, but I doubt it. It is difficult for most of us to recognize the fine distinctions made. If you will read in different text-books the description of the eruptions of scarlatina, measles and röheln, I think you will agree with me that it will take more than a Philadelphia doctor to distinguish between them. In many texts a description of one may easily suit the description of another by some other writer. Skin diseases can be learned only by accurate observation of patients having the diseases.

DR. J. P. C. GRIFFITH, Philadelphia—I think that the doctrine advanced by Dr. Wahrer will hardly meet with the approval of the Section. I doubt if very many of us would be willing to expose our children to the infection of measles. It looks to me very much like doing evil that good may come. I have been very much impressed with the fact that one of our large European cities has recently shown more deaths from measles than from scarlet fever or diphtheria. Such statistics, moreover, do not express, of course, the full number of deaths from measles, because pneumonia, bronchopneumonia and various other complications of measles cause death, which are assigned in the certificates to these causes and not to measles.

A good many years ago I became interested in röheln, or rubella as it is better named. I have repeatedly seen a desquamation in rubella, although it is oftener absent than present. This desquamation resembles closely that of measles, though it is not so marked. The rash in the mouth, described by Dr. Forchheimer, I have seen and described, but we can not say that rubella is absent because the rash is not present. The temperature curve has not seemed to me to be at all characteristic. It is true the temperature very frequently falls early, but not always. The rash often runs over the body like a "wave," as someone has described it, being gone from the face when it reaches the feet, and having disappeared from the body, with the exception of a yellowish stain, within twenty-four or forty-eight hours.

About ten years ago my attention was called to the enlargement of the superficial cervical glands in the cases of measles. I was soon struck with the fact that in the majority of cases of measles in which I looked for this enlargement I found it. A writer in Wood's "Reference Handbook" has called attention to the same fact. I admit that the enlargement is greater, more characteristic and more common in rubella, but it not sufficiently so to form a positive diagnostic feature.

The diagnosis of rubella is often extremely puzzling to all of us. In institution work I have had in one bed a child with a rash resembling measles so exactly that in private practice I would not have been able to differentiate it, and at the same

*The papers of Drs. Daniel and Small, discussed here, were printed in THE JOURNAL of Oct. 27.

time in another bed a child with a rash apparently perfectly typical of scarlet fever. This fact has also been noticed by other observers.

Dr. Schamberg's paper is one of the most valuable I have listened to for a long time, and I would feel a hesitancy about opposing it in any way were it not for his statement that widespread development of vesicles depends on the intensity of the rash. If this were not so, then every child having the deepest and most intense efflorescence should have the greatest development of vesicles, which, I think, you will all say is not so. The same thing is true of the desquamation. Some children will peel and peel, although they have not had an especially severe eruption. My own opinion is that of Thomas, who wrote the article on "Scarlatina" in Ziemssen's "Cyclopaedia," namely, that the degree of the development of vesicles depends on some peculiarity in the skin of the individual child.

DR. LOUIS FISCHER, New York—I have been extremely interested in the three foregoing papers. I would endorse what Dr. Griffith has said about Dr. Wabrer's paper. Those of us who have seen a great many cases of measles know what a dangerous disease it is at times. In the past winter I have seen more cases of otitis media and of empyema following measles than I have seen in the past five or six years. Many other pediatricians with whom I have spoken have noticed the same thing. Measles itself is not dangerous, but its complications are often beyond our control. With proper nursing, good sanitary surroundings and wise symptomatic treatment there should not be a fatal outcome, but we do know that apparently for no reason, in a carefully guarded case of measles, the chest may become filled with serum or pus several weeks after an apparently favorable termination. We all know that laryngeal stenosis occurring in measles is the most dangerous kind, and those who have had occasion to intubate, I think, will agree with me that we should look on such cases as almost always fatal. I have collected a series of 25 cases of children in whom I have performed intubation for laryngeal stenosis during an attack of measles, and out of this number there were 20 deaths. All of the fatal cases were as carefully treated as any of the successful ones.

The paper of Dr. Koplik is an exceedingly valuable contribution to the literature of the clinical manifestations of rubella. Last winter I was greatly puzzled to find a child with coryza, cough and fever, and an eruption, and in the same family, a few days later, a child without catarrhal symptoms and without these distinctive spots on the buccal mucous membrane, but with an eruption on the head, face and thorax and extremities, and a temperature of 102 F. There were lymphatic enlargements, and on examining the throat I found a slight tonsillitis, with some pharyngitis and uvulitis. The behavior of the second case was entirely different from that of the first one, and I made a diagnosis of rubella. We should note most carefully the distinctions drawn in Dr. Koplik's paper regarding the appearance of the spots found on the buccal mucous membrane in measles and in rubella. I should like to ask Dr. Koplik whether he has noticed as severe catarrhal symptoms, and also whether he has seen the usual complications of pneumonia—chiefly those of a streptococcal nature. In one case of rubella seen by me last winter, there was an exceedingly severe complicating vaginitis, which lasted for several months, and is, in fact, still under treatment. The complication came on very suddenly. I saw the case on the third day, when there was a rash and a temperature of 102 F. On the following day the temperature was normal. The enlargement of the superficial cervical glands, I have noticed in almost every case of rubella. In almost every case of measles associated with severe eruption I see some desquamation, but I have never seen desquamation in rubella. Professor Baginsky lays stress on the whitish coating surrounding the teeth and adjacent gums, and believes this to be almost characteristic as a diagnostic sign. There is a small white film, looking like a mass of epithelium situated at the junction of the teeth and the gum. I have seen that with him time and again, one or two days before the eruption, and have also seen the characteristic spots described by Dr. Koplik.

DR. KOPLIK—I never contended that in every case of röttheln one can make the diagnosis; my paper simply shows that röttheln to-day is a definite entity, and that there should be no question about its existence, though Jurgensen and Henoch still doubt it. Concerning Dr. Fischer's question, I would say that in my paper a case is quoted in which the vaginal orifice of a child of 6 years became inflamed. The child was well cared for and in a good family. She complained first of dysuria, but this passed off in twenty-four hours, leaving a vaginitis. My cases of röttheln have been practically free from complications. I isolate all cases, but allow the children to go on the street as soon as the eruption has disappeared; in winter I keep them indoors for about a week. I do not lay any stress on the enlargement of the post-cervical glands; I spoke more especially of the axillary and inguinal glands.

DR. SCHAMBERG—The mortality statistics of measles that have appeared during the past five years have been astounding to those who formerly looked on measles as a trivial affection. Dr. Griffith has erred somewhat in quoting the statistics of measles in Europe, but the error has been on the side of making the mortality less than it really was. In Paris the average mortality from measles during the past five years has been greater than from diphtheria and scarlet fever combined. In the city of Philadelphia in the past six months the mortality from measles has been larger than from diphtheria or scarlet fever.

I desire to endorse the statement made by Dr. Fischer concerning the malignity of laryngeal stenosis in measles. I have had, through the courtesy of Dr. W. M. Welch, the opportunity of observing the course of six or seven cases within the past few months, and one of them recovered. One still wears an intubation tube, and one, when last seen, was dying from a pneumonia complicating a tracheotomy.

Concerning the whitish film along the gum, referred to by Dr. Fischer, I wish to say that I have repeatedly seen it both in measles and in scarlet fever. It is nothing more than a mass of epithelium which becomes whitish through infiltration with moisture. It is really a desquamation of the epithelium of the gum, and, inasmuch as the rash in the mouth precedes the desquamation on the skin, so does the desquamation in the mouth precede the desquamation on the skin. It can not be considered diagnostic of measles, as it is frequently seen well marked in scarlet fever.

In regard to the various cutaneous lesions that I have referred to in my paper on scarlet fever, it may seem to some that their description is an unnecessary refinement. That may be so; nevertheless Dr. Griffith and others have seen cases of scarlet fever in which the vesicular element of the rash has been so striking as to cause the observer to think at first that the case was not one of scarlet fever. It may, therefore, be of some value to call attention to some of the less conspicuous features of the scarlatina eruption. Cases of scarlet fever frequently occur that are not diagnosed, and on the other hand the diagnosis of scarlatina is often made in the presence of some other toxic rash. I have examined the various superficial lymphatic glands of the body—the postcervical, axillary, maxillary, submental, epitrochlear and the inguinal glands—in 100 cases of scarlatina, and I have found the glandular enlargement constant. In scarlet fever there is a recent enlargement of the inguinal glands in 100 per cent.; of the axillary glands in about 96 per cent., and of the epitrochlear in about 25 per cent. of the cases.

Perineal Prostatectomy.—Rydgier advocates treatment of appropriate cases of hypertrophied prostate through a longitudinal perineal incision. He cited several cases successfully treated in this way in the course of his address at the recent Polish Medical Congress. J. Verhoogen has also recently published a case in which he excised 75 gm. of the hypertrophied gland through a right-angled incision in the perineum. A metal catheter has been inserted in the urethra and perforated the rear wall. Through this opening he pushed out more of the prostate tissue for resection. The elderly patient is completely relieved of all prostatic symptoms. Kuidinzel's experience with resection of the vasa deferentia has been that 9 have been cured, 8 much improved and 7 not benefited. Three of the latter were subsequently cured by epicycstotomy.

SOME EXPERIMENTS ON THE RELATION
BETWEEN AUDITION AND THE CIR-
CULATION OF THE BLOOD IN
THE HEAD.*

HAMILTON STILLSON, M.D.

SEATTLE, WASH.

A year ago the writer had a period of fortunate misfortune. His left ear had for a time a slight tinnitus with slight lowering of hearing acuity. It enabled him to institute a series of simultaneous experiments on a normal and on an abnormal ear. He thus has been enabled on his own person to confirm or refute statements made by others concerning tinnitus and its allied states and to institute comparison between effects of similar causes in healthy and in unhealthy ears.

This tinnitus, it should be stated, was caused by tubal edema. This is known not only by self-inspection of the pharyngeal orifice of the tubes, but by palpation, so to speak, of the tube by means of the tongue thrust into the post-nasal space. The writer is able to insert the tip of his tongue into the nasopharynx even to the vault of that cavity, and so far as he is aware, he was the first to teach patients to make use of the tongue in cleansing and medicating the mucous membrane of the nasal pharynx in the treatment of postnasal catarrh.

Now, with the tongue thus placed in the nasopharynx, the writer compared the right tube with the left, and found that the superior segment of the left tube was softer and more swollen than that of the right, and posteriorly, where the cartilaginous plate impinges against the salpingopharyngeal fascia, there was a groove, in the bottom of which were a few tender granulations. It was doubtless caused by tubal catarrh.

Poltizer states that often in a tinnitus caused by tubal catarrh, brushing the cuticle in the region supplied by the trigeminal will cause the tinnitus to disappear, but in the writer's experience such treatment caused the tinnitus to increase.

Merely fixing the attention on the tinnitus would increase its intensity, and brushing the hairs at the external orifice of the auditory meatus would cause a different tinnitus, which was found to be caused by the contraction of the muscles in that vicinity, especially by the contraction of the salpingopharyngeus of the side experimented on. This tinnitus occurred in the healthy ear in a like experiment.

All the authors call attention to the fact that firm pressure on the mastoid bone, or, indeed, on any of the neighboring bones, will increase the tinnitus, but in the writer's experience it not only increased the tinnitus but raised its pitch, and this increase of tinnitus was greatest when the pressure was exerted against the tip of the left mastoid. Pressure against the right mastoid caused no tinnitus at the time of pressure, but a temporary tinnitus with mental hebetude occurred several times after the pressure against the sound mastoid had been greatly prolonged.

One fact not mentioned by any of the authors with whom the writer is conversant is that pressing against the mastoid lessens the hearing acuity. This is particularly so with reference to high-pitched sounds. Seated before an open wood fire, for instance, where the range of sounds varies from that of the low-toned flap of the

flames to the high hiss of escaping vapors from the wood, one can easily repeat the experiment. Pressing firmly against the tip of the mastoid of the normal ear, shuts off the sound of the steam, only the lower-pitched tones being heard. This applies only to the normal ear. And after repeating the experiment a number of times the high-pitched sounds are no longer heard by it for a while and a heavy dulness preceded by subjective noises steals over the hearing. Not so, however, with the tinnitic ear. Pressing against its mastoid tip causes it to hear objective sounds louder and in a slightly higher pitch, and no fullness or dulness follows.

Another experiment easy to perform is testing the hearing while standing or lying down. Any constant sound, like that made by escaping steam, can be approached from a distance until it is first perceived. The distance is marked and the experimenter then recedes and lies down supinely; while in that position he approaches or is caused to approach the source of sound until he again perceives it, keeping the ear directed toward the source of the sound all the while. The hearing distance will be found to have increased. Regaining a standing posture at the distance at which he heard the sound while lying down he will discover that he no longer hears it at that distance. This experiment entirely agrees with Abercrombie's case, cited by Lucas and Politzer—p. 7011—of a man aged 30 years, debilitated by an affection of the stomach, who was deaf while sitting or standing, but who could hear quite well when he was in a horizontal position. Not having access to Abercrombie's original report, the writer is not informed whether Abercrombie's case suffered from tinnitus, but if the latter was the fact, that case does not agree with the writer's experiment on the tinnitic ear. On the contrary, lying down increased the tinnitus and lessened the hearing distance. It is possible, however, and altogether probable, that in cases of congestive tinnitus lying down would increase the hearing distance, especially if the objective noise was similar to the subjective noise. In a case occurring in my own practice recently the hearing distance was greatly increased by lying down. The patient was of robust health, with no disease of the stomach, liver or kidneys, no rheumatism, and no specific infection, and, of course, no anemia. He was a logger, aged 52 years, with otitis media and postnasal catarrh. Both tubes were moderately patent; there was some sclerosis and some atrophy of the membrana tympani, particularly the left one, there being a quadrant fold extending from the short process of the malleus horizontally backward. There was also a crescentic fold in the lower quadrant. Shrapnel's membrane was somewhat congested. The membrana tympani was movable with the otoscope, but the excursions of the malleus were not extensive. There was no tinnitus. There was no fluid observable in the middle ear. Three years previously the patient had had a severe attack of grip followed by a temporary deafness. One year ago he had another attack of grip, followed by what was presumably abscess of the frontal sinus, right and left. The deafness resulting from that attack of grip remained and steadily increased. Hearing distance was about doubled by politzeration. I judge the increase to be as much due to the increased tension placed on the membrana tympani as to the opening of the tubes. The range of hearing was, when sitting: right hears Galton whistle 1; when lying down, 2; left hears Galton whistle, sitting 9, lying down 17. The lowest fork he was tested with was a C fork, which he heard

*Presented to the Section on Laryngology and Otology, at the city's first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

distinctly, and all tones were heard in pitch about a half-tone higher when sitting up than when lying down, although more feebly when sitting up than when lying down. The increase in hearing produced by reclining supinely was, with the acoumeter, for the right ear from 15 inches to 40 inches; in the left from 15 inches to 70 inches. The hearing was decreased in both ears by a prone position. Weber's test was negative. Rinne's test for C and C¹ negative, for C² positive. In the right and in the left the Schwabach test resulted somewhat peculiarly. For C, AC and BC both were 15; for C¹, both 22; for C², AC was 40, and BC 18, in the right ear; and in the left ear C was 21 for AC and BC, C¹ 18 for AC and BC, and C² was 25 for AC and 20 for BC. Tabulating, it was as follows:

Right.			Left.		
Rinne	—	+	Rinne	—	+
AC	15	22	AC	21	18
BC	15	22	BC	21	18
	C	C ¹		C	C ¹

After one week there was found the following condition: When patient is in prone position the right ear hears the acoumeter at 6 feet, when sitting, 7 feet, when supine, 7 feet. When patient is in prone position the left ear hears the acoumeter at 11 inches, when sitting, 26 inches, when supine, 80 inches.

Schwabach table is as follows:

Right.			Left.		
Rinne	—	+	Rinne	—	+
AC	28	15	AC	15	20
BC	26	20	BC	28	20
	C	C ¹		C	C ¹

Another experiment showing the relation between audition and the circulation of blood in the head, consists in testing the hearing while suspended head downward. The writer found it sufficient to hang head downward from a table, the thighs flexed on top of the table, the body depending without touching the head to the floor. To press the head against the floor causes confusing tinnitus in both ears. Now, while thus suspended, at first the power of audition in the healthy ear is increased. Presently a slight subjective noise is heard, after which a dulness of hearing follows, accompanied by a cessation of even the subjective noise. With a sufficient number of repetitions of this experiment the phenomena mentioned become less noticeable. One peculiarity needs to be mentioned in passing; just before the objective noise ceases to be heard a slight rhythm of sound is noticeable synchronous with the pulsations of the heart, and this rhythm is noticeable not only in the faint objective sound but also in the subjective sound produced by this passive congestion. The effects of this experiment on the tinnitic ear were somewhat different from those on the sound ear. In the tinnitic ear the hearing power seemed at first slightly diminished and then increased but no rhythm in the objective sound could be noticed.

One more easily performed experiment will complete our list. It consists in moving the head more or less rapidly to and fro, either on the vertical or on its horizontal axis. Oscillating it on its vertical axis for a minute or two causes dizziness, a nausea, a lowering of the hearing acuity, a peculiar bell-like tinnitus in both ears, more noticeable in the tinnitic one. This tinnitus is greatest at the end of the oscillation, and in the sound ear the tinnitus was greatest at the end of the oscillation that turned the right side backward. In the left ear it was greatest at the end of the oscillation that turned the left side forward. Nodding the

head violently up and down causes the same phenomena, but to a much less degree, and the tinnitus is not bell-like but rasping in character, as though caused by the rubbing of the bones of the neck and the muscles against their sheaths.

The writer will not attempt to draw any practical conclusion from these simple experiments, nor, indeed, even to explain the causes concerned in the phenomena. They will, however, he feels sure, suggest to aurists many things both of practical and theoretical interest.

DISCUSSION.

DR. JOSEPH H. HOFFMAN, Pittsburg.—As the writer has given us some personal experience I will relate a little of mine. I have not made any exact experiments, but I have observed some things rather constantly. I have suffered from tinnitus some fifteen years, and it is continuous. It is not very annoying, but it is always present. My hearing is considerably impaired. I have observed, however, that on lying down I can hear much better than when sitting erect. Some years ago I tried my hearing and I have observed generally that when I lie down I can hear things in the house and external to the house that I am entirely oblivious to when I am up, and this is just as true when everything is quiet, before I retire as afterward. I wish to say too that my capillary circulation is not very good.

DR. C. M. COBB, Lynn, Mass.—I think it very often occurs, if not always, that in the beginning of a one-sided tubal catarrh the tone flats for that ear. Men who are musicians will tell you that the tone is practically a half-tone lower on the affected side than on the other.

ETIOLOGY AND PROGNOSIS OF ADENOIDS.*

A. M. CORWIN, M. D.

CHICAGO.

To gather and set in orderly array the different states and conditions that have been observed and recorded as etiologic agents in the production of adenoid hypertrophy is not difficult, for the literature of the subject is extensive and at hand. Age, sex, heredity, scrofula, the lymphatic temperament, frequent colds, nasal deformities, acute infectious fevers, microbes, climate, and social condition are the chief factors that have been named. But after these have been elaborated and analyzed, we are still far from a satisfactory solution of the problem of ultimate causation in many cases. Why does it occur in one child and not in another under similar circumstances, perhaps in the same family. Why does it occur in several members of the same family, otherwise apparently healthy? What is the reason for its frequent congenital occurrence? These and other queries still clamor for solution. In the present instance we have but to read the classic thesis written in 1863 by Wm. Meyer, of Copenhagen, and the writings of Lowenberg, J. O. Roe, Bosworth, Fraenkel, Chatellier, Hooper and others. Numerous writers of the last decade have also enlarged the subject, chiefly from a statistical aspect and by the device of new instruments and special methods of operation. Enlargement of hypertrophy of the lymphoid structure situated in the pharynx as a part of the general lymphatic system is common in childhood. Of 1000 pupils in Copenhagen examined by Meyer, 1 per cent. were so affected. Chappell found adenoids present in 3 per cent. of 2000 New York school children, while Harrison Allen observed the affection in 33 per cent, of 21 apparently healthy Indian girls. The truth as to frequency the world over, probably lies far under the greater of these figures and far exceeds the

*Read in a Symposium on Hypertrophy of the Pharyngeal Tonsil, before the Chicago Otolaryngological and Laryngological Association, July 5, 1900.

lesser. Up to the age of puberty enlargement of the faucial tonsils is usually accompanied by more or less involvement of the pharyngeal.

It is pre-eminently observed in those between the ages of 3 and 15, and is not uncommon in persons from 15 to 20. It is occasionally seen at birth and often in infants, as exemplified in 6 cases under 6 months of age reported by Huber. Though unusual, it has been found in adults even as old as 65, as in a case reported by Coutoux, and in a woman 70 years old, referred to by J. Solis-Cohen. Roulin, of Marseilles, observed cases in persons 60 and 70 years of age. Lennox Browne removed adenoids from a person of 40 years of age. Bryson Delavan has cited instances in which enlargement of Luschka's tonsil persisted in middle life and others in which hypertrophy had seemingly begun after puberty. I remember in this connection a man of 55 who had had nasal polypi for many years and in whom I found the pharyngeal tonsil of very considerable size and the faucial tonsils but slightly enlarged. Sex seems to bear but little etiological relation to adenoids, though according to some authorities, the males affected seem to outnumber slightly the females under 15 years, after that age the latter appearing to predominate.

In childhood, lymphoid tissue is very abundant in the vault of the pharynx, and this kind of tissue is prone to active inflammation and hypertrophy, as shown by the occurrence at this age of cervical and faucial adenitis, seemingly from slight causes. And owing to the small caliber of the respiratory passages in children, functional interference occurs from glandular enlargements which would be scarcely noticeable in adults. The increase in the dimension of the postnasal and pharyngeal spaces, which takes place rapidly during adolescence, as pointed out by Bosworth, may overcome a marked obstruction produced in childhood by an adenoid mass, should this remain stationary or slightly increase in size. This in part may account for the prevalent opinion that adenoids invariably disappear or rapidly decrease in size at puberty. Up to the age of 20 and 25 these growths are occasionally observed of considerable size, and more frequently of relatively small size. The fact is, however, that in the majority of cases not only does the compensation in the increased size of the cavity take place at puberty but the lymphoid hypertrophy tends to undergo retrograde metamorphosis due to obliteration of blood and lymph channels, and pressure atrophy of the follicles, attending maturative shrinking of the connective tissue, and more or less actual increase of fibrous elements. Kyle speaks of a "natural increase of structure" or hyperplasia of the gland "due to increased blood-supply," and of hypertrophy resulting from inflammation. Increase or enlargement of this lymphatic tissue from one or many causes near or remote is always a morbid condition, the normal structure remaining practically invisible. It simply becomes then a matter of degree of abnormality: on the one hand being remarked clinically by reason of symptoms and requiring operative interference; on the other remaining unnoticed because of the relative smallness of the growth, which finally disappears altogether.

Conditions of general circulation favoring venous turgescence, such as intestinal torpor and other abdominal irregularities or thoracic diseases, are occasional factors in affecting adenoid hypertrophy, but as Kyle points out, occasional evanescent enlargement of these structures from passing congestion or watery infiltration, as a result of reflex or other causes acting transiently, should not be mistaken for true hypertrophy and needs

no surgical measures for its correction. Meyer's researches show that these vegetations are common in all climates and affect all peoples and classes, although the Jewish race has appeared to be especially susceptible. A changeable climate, however, exhibiting great humidity and sudden variation from heat or cold, certainly favors their development, no doubt owing to the greater liability to the occurrence of acute catarrhal affection of the upper air-passages. These sudden congestions in turn favor adenoid activity, for the circulation in these tissues is particularly rich in childhood. In warm, dry climates, on the other hand, the disease seems to be less common. Massi remarks that it is rare in Italy in any marked degree. Children in the cities are if anything more markedly affected than those born and reared in the country, very likely because of the dust, smoke and fume-laden atmosphere and bad hygienic conditions favoring lower body resistance and disease.

Several cases of adenoids are often seen in the same family with a history not infrequently of a like trouble in some of the forebears, so that heredity is considered as a prominent element in their causation. In truth there would seem to be back of all other factors some transmitted condition not necessarily the same in every case, and not well understood, as evidenced by such vaguely comprehensive terms in our vocabulary as scrofula, strumous, dyscrasia, lymphatic temperament, diathesis, cachexia and the like. The so-called lymphatic temperament, the diatheses of rheumatism and struma are, so far as the terms are significant, considered predisposing factors. Furthermore, the tubercular and syphilitic dyscrasias excite chronic lymphatic glandular enlargement. Harrison Allen calls attention to a group of cases which he calls adenoid disease and suggests that it does not excite to mischief by reason of its influence upon respiration or by the setting up of catarrhal trouble, but that its effects are noted in disturbed general nutrition, and would infer that it belongs to the same class of diseases as myxedema and acromegaly, and advises the study of the relation of the pineal gland and pituitary body to adenoids. Such suggestion might be fruitful of results. But the fact that removal of adenoids and re-establishment of perfect nasal respiration effects marked benefit in even the worst example of mal-development connected with adenoids, strongly suggests that their presence mechanically is the efficient cause. We mention in this connection a hypothesis somewhat ingenious, but lacking in the elements of proof, advanced by Hill, that the adenoid overgrowth is due to the prevention of the normal tonsillar function of leucocyte migration by diapidesis into the pharynx by reason of the thickening and impermeability of the mucous covering of the tonsil induced by contact of irritating contamination of the nasal secretions. Potain considers that the tendency to the involvement of lymphatics in morbid processes seen in childhood is but a normal condition which, carried one step further, gives the true pathologic condition of scrofula; but why this tendency, and what is this "one step further," and what is the reason for it? We are as much in the dark as ever, though furnished with another brilliant combination of words. At all events it is recognized that certain constitutional states carry with them greater liability to mucous-membrane inflammation—catching cold—whether depending on vasomotor disturbance from faulty excretion and autointoxication, or on direct specific action on the mucous membrane of some morbid element, chemic or microbic, reaching the part through circulation. Frequent acute

and prolonged subacute or chronic inflammations or colds are, it would seem, very important actors in this drama of adenoid growth, but they do not explain its presence in all cases, as, for example, its congenital and very early occurrence before the exhibition of inflammatory states. All the causes of so-called catching cold may then be considered active influences at times in the life history of this affection. The presence of nasal hypertrophy, septal spurs and deflections is commonly found in those with enlarged tonsils. They may be occasional causes, and are always aggravators of the trouble in so far as they excite postnasal catarrh, which gives rise to imperfect ventilation and faulty drainage with retention of irritating secretions. Possibly the growth of adenoids is also invited by the increase of congestion of the mucous membrane which may attend rarefaction of air in the postnasal space during deglutition and incident to a faulty method of breathing and the tendency to frequent hawking, when there is nasal stenosis. But these same nasal irregularities can not be considered as invariable causes, because they are also seen in other children without adenoids.

Bacterial agents unquestionably exert marked influence on lymphoid tissue; hence the frequency with which adenoids date from an attack of diphtheria, whooping-cough, measles, scarlet fever, and other exanthemata and from influenza. In these cases it would seem that the disorder is produced by the irritating effect of the specific germs or their toxins or both on the highly impressible lymphoid cells, readily exciting them to proliferation. Of specific germs many have been demonstrated on the surface and within the crypts of the tissues in question, although the results of various observers differ so widely that no definite conclusion can yet be drawn as to the frequency, the mode and the specificity of their operation. A few of these may suffice as examples. According to Lermoyez, 1 in every 17 cases of adenoids is tuberculous. P. McBride with A. Logan Turner found tubercle in 3 per cent. of 100 glands removed and carefully examined, and in the majority of cases numerous micrococci and other bacteria lying on the glands and within their crypts. Pleuder and Fischer, studying statistics of 161 cases in which adenoids were examined for tubercle, found 17 cases of its primary development. Pilliet found 7.5 per cent. of adenoids tuberculous; Dieulafoy by inoculation experiments 20 per cent., by histologic examination 5.7 per cent.; G. Gottstein, 12 per cent.; Breudel, 12.5 per cent. On the other hand, Goure found no tubercle bacilli in the tissues in the examination of 201 separate specimens of adenoid vegetation, but in many cases staphylococci, streptococci alone, or mixed and associated with other germs.

It is at present uncertain from a bacteriologic and histologic standpoint just what relation bacteria have to adenoid overgrowths, and our chief practical information may be said to have come from the clinical observation that symptomatic disturbances ascribed to adenoids frequently date from an attack of one of the infectious diseases, notably those, however, the bacterial causes of which have not yet been identified.

PROGNOSIS.

When adenoids are of sufficient size to produce distinct symptoms and when they are left unoperated on, more or less serious effects on general health are certain to follow. The stunting of growth with chest deformity, the dulling of intellect, the unfortunate facial aspect of the chronic mouth-breather and the production of various disturbing and dangerous reflex

phenomena may be confidently expected in greater or less degree and number, and the general practitioner has come in these latter days to recognize their importance as well as their origin. As to local disturbances, impairment of hearing is a result in a large proportion of cases, 74 per cent. as reported by Meyer. In some instances, the mental dulness referred to is apparent rather than real, owing to defective hearing. Without trespassing on the discussion of symptomatology and diagnosis it is proper to mention in this connection the great liability which exists to otitis media, the occurrence of laryngitis and croup through mouth-breathing, the establishment of nasal and postnasal purulent discharges with danger of involvement of accessory sinuses. It is to be remembered that luxuriant adenoids favor the localization and entrance of various infectious diseases, especially diphtheria. The prognosis, then, from the standpoint of non-interference, is unfavorable.

The question naturally arises, Do all adenoid hypertrophies require removal? Bosworth answers in the affirmative, owing to the liability to active inflammation, because they may be the source of chronic postnasal discharges and because there is no harm done by operation. Most observers, however, would seem to favor the negative. Where no symptoms or signs are apparent other than slight or moderate enlargement of the adenoid tissue and no history of past trouble of serious import, there is no more call for operative interference than in the case of faucial tonsils under like condition of enlargement without evidence of follicular or other diseases or record of former disturbance; or for the removal of the appendix vermiformis of every child. On the other hand, in a child nearing puberty with glands of considerable size, but showing slight or moderate functional disturbance, we should not wait for relief to accompany the probable spontaneous subsidence of the growth with advancing adolescence. Never in any case delay operating where there is the slightest interference with the hearing. Neither can we rely alone on the administration of internal remedies. Their action, to say, the least, is uncertain and slow. The promise of permanent relief through radical and thorough removal of adenoids is good. Recurrence practically never happens. In case of partial removal the inflammation may apparently set up rapid development of the portions of the growth remaining or slower development under the influence of the various subsequent exciting causes, so that in not a few instances there is return of more or less trouble. As a rule, however, there is a gradual atrophy and final disappearance of any remnants. That operation which compasses through removal would seem to commend itself as the better practice.

The possibility expressed by Délie of the transformation of the remnants of adenoids into sarcoma is too remote to admit of serious comment. Lermoyez, judging from two cases in which upon return of the growth it was found on bacteriologic and histologic examination to be undoubtedly tuberculous, would almost infer that in some cases adenoids are but the expression of local tuberculosis and that there is a modicum of danger that general dissemination might follow their removal. This conclusion based on very exceptional experience in the light of actual results of operation is likewise hardly worth a passing notice. Usually the chief local signs of post-operative interference subside within 48 to 72 hours, and in many cases within a few weeks or months the influence upon the general health, physical and mental, is so marked for the better as to seem little short

of a miracle. The relief of simple catarrhal symptoms, postnasal dropping, nasal obstruction from intumescence, which is common in these patients, is usually rapid. The cure, also, of more persistent catarrhal discharges from nose and naso-pharynx may be effected frequently without special measures of after-treatment directed to them, though these are always advisable.

The improvement to hearing when the disturbance has been of short duration, and therefore not incident to organic changes in the inner ear, is often striking and sometimes instantaneous. When there is present chronic purulent otitis, often the benefit alone from removal of adenoids is considerable and is an important measure in the treatment of this affection where so complicated. In many cases it is safer to postpone inflation of the Eustachian tubes until the subsidence of acute inflammation following operation. Prognosis should be guarded where deafness, tinnitus aurium, etc., are results of chronic postnasal obstruction.

Functional defects of articulation, month-breathing, snoring, etc., are also commonly corrected spontaneously; though the greater the age of the patient the more fixed the habit, the greater the liability that separate measures shall be demanded for their correction.

As to the dangers from surgical interference, immediate fatal hemorrhage or even serious bleeding is not of frequent occurrence in proportion to the large number of patients operated on, especially if the cases of hemophilia be excluded. In one of the latter reported by Hooper, fatal bleeding followed digital examination. However, in view of the considerable number of fatalities which have been recorded from this source by Knight, Delavan, Newcomb, Hooper and others, every operator must bear in mind this possibility. It has followed injury to the carotid arteries of abnormal course. It has usually been primary, but has also occurred as secondary hemorrhage as long as two days after operation. It seems to bear no special relation to manner of operating or use of anesthetics.

Death from the general anesthetic is among the immediate sources of anxiety, whether the agent be chloroform or bromid of ethyl, the two most recommended. These agents fairly represent the two schools of operators, the one advocating in every case profound narcosis to permit the most thorough removal of the growth, the other preferring the more rapid and perhaps less dangerous method of operating, relying on manual dexterity to remove the major portion of it. Among the other immediate dangers may be mentioned the occurrence of convulsions from shock or hemorrhage, and asphyxia from spasm excited by the passage of blood into the larynx, or occlusion of the glottis by a portion of the gland. Injury to the orifice of the Eustachian tube or extensive stripping off of mucous membrane is certainly to be feared from overzealous or bungling manipulation of instruments.

Secondary or remote unfavorable results of operative interference, in addition to hemorrhage, are bronchitis or pneumonia from aspiration of the blood, etc., into the bronchial tube; accidents which may be avoided by keeping the pharynx lower than the larynx while the patient is under the influence of a general anesthetic like chloroform or ether or by proper manipulation of the patient in case of laughing gas and other anesthetics of transient action. Finally there is some danger of the occurrence of otitis media, crsipelas and deep cellular inflammation followed or not by pyemia or meningitis. Without infringing upon the subject of treatment, it may be remarked from a prognostic point of view that

not only are the ordinary measures for surgical cleanliness to be employed against the infection of the wound at the time of operation, but to reduce to a minimum the danger of otitis the use of syringe and douche should be avoided, both in preparing the patient and in after-treatment. It is far wiser to rely on no application, or better to employ bland oleaginous preparations with perhaps the occasional use of a powder containing a small amount of cocain.

Even young children can be quickly taught to keep the nasopharynx relatively clear of secretions during repair by occasional voluntary forced inspirations through the nose with vibration of the soft palate as in snoring. This procedure is especially effective in dislodging secretions if one nostril at a time be closed, the draft of air being confined to the other.

TREATMENT OF LUPUS VULGARIS WITH X-RAYS.

REPORT OF A CASE, WITH CURE.

J. T. KNOX, M.D.

CINCINNATI, OHIO.

The case of lupus which I report as cured by the X-ray treatment first came under my care in May last, being referred to me by Dr. W. L. Taylor, this city, who

Fig. 1. Before treatment.

had it under treatment at that time. Recognizing his inability to cure the disease by any of the ordinary methods, the X-ray treatment suggested itself to him, but not being equipped with the necessary apparatus, he consulted me. I informed him that I had never treated a case of lupus by this method, and it was with some hesitancy that I assumed the charge of the case.

I was very conservative in the beginning of the treatment, but resolved to carefully observe the effect

of each sitting on the patient, until such time as I could decide as to the proper length of time of each exposure, the most desirable distance to place the patient from the tube—in fact to carefully note all phenomena arising during the treatment of the case.

Although effecting a cure in this case, I could not consistently formulate rules that would apply to the treatment of all cases of lupus, from the fact that the effects of the rays vary, according to the idiosyncrasies of different persons. This fact is an important factor in the application of the X-rays for any purpose, and can only be overcome by the most careful experiments on the part of the operator at the beginning of each case.

The subject, Miss C., of Cincinnati, aged 20 years, weighing 125 pounds, of decided phlegmatic temperament, had no tubercular or other transmissible history, as far as I have been able to trace. The family history was negative. The disease was first recognized as being lupus about two years prior to the time I assumed charge of the case. The patient had been treated for disease of the lid margins and occlusion of the tear-duct of the left eye, for some five years previous to that time, which may have been the primary lesion of the lupus, although I do not think it was. During the past two years she has been treated by some

Fig. 2.—After treatment.

of our most capable dermatologists, and was an inmate of St. Mary's Hospital for seven months of the time, under the care of the staff physicians. The disease steadily progressed, never at any time exhibiting symptoms of improvement.

The location of the disease, as will be observed by the accompanying photograph¹ (Fig. 1), involves the

¹ Taken two years ago by Dr. E. H. Shields, who kindly furnished the plate from which the picture is made. Her condition was much more aggravated when I began treatment.

nose and upper lip, and had so far progressed as to cause perforation of the nose septum. The photograph, Figure 2, taken since the X-ray treatment, shows almost entire absence of scars, or any condition of the tissues that would indicate that the disease had ever existed.

The treatment consisted of the application of the rays for from six to ten minutes each sitting, every other day, placing the affected parts from 4 to 8 inches from the tube, according to the density of the rays. The whole number of applications made during the treatment was seventy-four, and improvement was apparent very soon after beginning the treatment. The unaffected parts of the face and head were shielded by means of a mask, thus preventing the possibility of producing dermatitis and loss of hair, incident to the use of X-rays.

Although this is the first case of lupus I have treated by this method, I have no hesitancy in stating that I regard it as an infallible one, if properly applied and continued a sufficient length of time.

The only cases heretofore reported cured in the United States by the X-ray treatment, were those by Dr. Philip Mills Jones, of San Francisco, Cal., who reported two cases treated and cured by him during the early part of the year 1899, and which have shown no signs of recurrence.

In closing this paper I can not refrain from adding a word in favor of this wonderful and mysterious force in the light of a therapeutic agent, and it is my opinion that there are possibilities within its range that as yet have not been dreamed of. Its uses in surgery have been fully demonstrated; yet there seems to be an apathy on the part of many members of our profession regarding its use, which, as I can testify, is very discouraging to those of us who are devoting time and money to its development. We should at least expect the support to which we are entitled from the profession, especially in those branches of the work in which we have gained proficiency, which cover a wide field.

DISCUSSION.*

DR. W. H. BATES, New York City.—The title of the paper is "Secondary Operations on the Capsular Membrane," and I am going to say something that will probably provoke a great deal of criticism. In all the text-books I have examined, secondary cataract is described as being due to a thickening or wrinkling in the posterior capsule of the lens. I have not been able to find any one who has ever seen under the microscope a cataract caused by any thickening or any change in the posterior capsule of the lens alone. But we do find in every case of secondary cataract that I have been able to see in the human subject, a posterior capsule which may be thrown into folds or may be flat, with a layer of connective tissue on its anterior surface. I have specimens in which this layer of connective tissue is fifty times as thick as the posterior capsule itself. This tissue is a fibrous tissue and furthermore contains blood-vessels. Many of these membranes when cut or incised give you a certain amount of hemorrhage from those blood-vessels and in a few instances a clot. I have studied this matter of secondary cataract on animals, rabbits especially, and might talk to you for a long time concerning my investigations. In rabbits I have never seen a case of secondary cataract after removal of the lens caused by a thickening of the capsule itself. It is always due to connective tissue. In the limited number of human eyes I have been able to examine the secondary cataract is caused in the same way.

If you will give me just a moment I would like to give my theory on the formation of secondary cataract after extraction

* Dr. Callan's paper, together with Dr. Knapp's discussion thereof, appeared in the issue of October 13, p. 927.

of the lens, which suggests at the same time a method for its prevention. When the anterior chamber of a rabbit's eye is evacuated and a drop of the aqueous placed on a glass slide you will find at the end of fifteen or thirty minutes no change; after a lapse of five minutes the anterior chamber refills with a second fluid, and if a drop of that be placed on a slide it clots like blood, and if examined with the microscope the clot shows the well-known structure of fibrin. If the rabbit's lens is extracted, then the eye enucleated, at once one finds in the area of the pupil corresponding to the position of the secondary cataract and covering the posterior capsule a layer of fibrin. Two weeks after an extraction this layer of fibrin is partly replaced by new connective tissue. I am positive about this. I have been working over it for four years and have demonstrated it repeatedly to men better versed in pathology than I am.

I have been able to prevent the formation of a secondary cataract in the rabbit on this theory. Instead of allowing the anterior chamber to refill with a fibrin-forming fluid, I fill it with normal salt solution and secondary cataract does not follow. I have applied this principle to human eyes, refilling the anterior chamber with normal salt, or boracic acid solution, and I believe I succeeded when drainage was prevented. Three corneal sutures were necessary in rabbits.

DR. URIBE TRONCOSO, Mexico—The subject of secondary operations on capsular membranes is a very important one. My experience has been much similar to Dr. Callan's. I think for the membrane operation the DeWecker capsule scissors is the best instrument. I have met with some cases of secondary glaucoma after needle operations, and trying to explain to myself the pathology of this accident, I have reviewed the entire literature of this subject. The different opinions advanced are not satisfactory; the most general one is that the traction produced in the ciliary body by the knife leads to increased tension. I do not think this is the probable cause, but that it is due to a wounding of the vitreous body, which, filling the anterior chamber, changes the chemical composition of the aqueous and makes the exosmosis through the Schlemm channel very difficult. For that reason glaucoma is not so liable to occur when, instead of a simple puncture with the knife, which heals rapidly, an incision in the cornea is performed; for instance, when using De Wecker scissors.

This pathogenesis is also applicable to primary glaucoma, and I am now pursuing a series of experimental researches in this direction. My chemical analyses of the aqueous humor in several cases of primary glaucoma have always shown me that the quantity of albumin is considerably increased. This albumin comes probably from the diseased vessels of the ciliary body and retina and its presence in the aqueous, lessening the excretion, leads to hypertonia and its consequent effects.

When the capsule is thin I find that it is only necessary to make a little incision, whether with one or two needles, but when thick it requires the De Wecker scissors to cut the capsule, or the use of forceps for its removal.

DR. JOHN E. WEEKS, New York—I agree with the speakers that one method of operating is not applicable to all cases of secondary cataract. Where the membrane is thin and we have to deal with a wrinkling of the posterior capsule with perhaps some adventitious tissue, the Knapp needle is sufficient to make the necessary incision. As regards the percentage of cases in which it is necessary to operate, I myself operate in at least 90 per cent. of my private cases that are uncomplicated, and in the hospital it reaches about 70 per cent. As regards the time of operation, I have attempted it in one case within ten days after the extraction. I think, however, that from three to six weeks is the proper time to operate. If we operate after three weeks, the condition that Dr. Bates referred to is not present to any great extent, that is, the membranes are not toughened the connective tissue has not had time to become dense.

The operation that Dr. Callan has described, I use very much, but I use the angular broad needle, piercing the capsule at the opposite side to the entrance of the needle, then with the

De Wecker scissors I excise a triangular piece of the capsule, removing it with the forceps.

In regard to the formation of secondary cataract, it is true that there is a deposition of connective tissue and that the capsule itself is not much thickened. The capsule of the lens is an epithelial product. When we extract the cataract we have removed the bulk of the lens, but have left more or less cortex which is irritative. In the removal of the cataract we also wound the iris more or less and induce some exudation, if not a hemorrhage. It is well known that fibrous material coming into contact with the natural aqueous humor produces a coagulum—the phenomena that Dr. Bates has spoken of. The observation of this phenomena is not original with Dr. Bates, but has been known for many years and is familiar to all advanced students of ophthalmology. With the presence of fibrin on the posterior capsule, we have the same process that is found in retinitis proliferans, the presence of a clot that may or may not contain blood-corpuscles; this clot gradually becomes organized and forms a pseudo-membrane. The pseudo-membrane may be extremely thin or quite thick, the density depending largely on the amount of coagulum deposited.

In regard to the use of salt solution or boracic acid solution for preventing the formation of secondary cataract—if they prevent it at all, which I doubt very much—they do so only to a very small extent. I have used them both for a long time in washing out the debris of the lens after cataract extraction. The capsular cataracts are, I think, less dense, because I have removed more of the irritating material, but they still form.

DR. A. W. CALHOUN, Atlanta—Formerly I used to make a simple extraction, but I have gone back to the operation with iridectomy, largely because of the fact that I could not get my patients to come back to me, many of them living at great distances, to submit to the secondary operations. As a result of that operation I do not have so many of the capsular membranes remaining, and when I do have them, their removal is simple. I penetrate the lower portion of the cornea with a very small Graefe cataract knife, and passing it up into the pupil I cut the membrane, at the same time extending the incision down into the iris, making an iridotomy. The iris, of course, pulls apart and helps to keep the membrane apart. My experience with the needle is that when you begin to tear you do not know where you will end, and the pulling is apt to set up inflammation. Occasionally I pass my forceps through and take out a portion of the iris. I also at times use the De Wecker scissors, making the corneal incision with the knife and, passing the blades of the scissors through that opening, make the iridotomy. I should like to confine myself very largely to the simple extraction, because the pupil looks better, but I do not believe it makes any difference in the vision whether you have a round pupil or not.

DR. J. L. THOMPSON, Indianapolis—Do you not sometimes have subsequent hemorrhages after cutting the iris that way, which interferes with the wound?

DR. CALHOUN—I do have a little hemorrhage, but it disappears within twenty-four hours and leaves no bad effects.

DR. WILLIAM THOMPSON—Can you always make a sufficient iridotomy with the Graefe knife?

DR. CALHOUN—Yes, sir.

DR. C. F. CLARK, Columbus—There is one instrument that has proved, in my hands, of great value and I think it has some advantage over the De Wecker scissors; it was introduced some years ago by Dr. Noyes. I have had Tiemann make these scissors curved on the flat and they are more easily commanded than the De Wecker scissors. Since traumatism is the main cause of failure in these cases, it has been my aim to simply outline as far back from the edge of pupil as possible as large a space as I can in the capsule and then endeavor to remove the central portion. When the cortex is soft I practice curveting the soft substance of the anterior portion of the lens and removing it by irrigation before attempting the delivery of the nucleus. I think you will find this most valuable in a number of cases. I practice the simple

extraction by preference, as I consider it easier and safer in the majority of cases.

DR. MILES STANDISH, Boston—I simply want to add a word for the Noyes seissors. They are very easily used, give greater motility in the anterior chamber, and the handiness with which you can use your fingers is much greater than with the De Wecker seissors.

DR. FRANK ALLPORT, Chicago.—I would like to ask Dr. Knapp what he would do in a case as follows: Numerous attacks of iritis had produced complete occlusion of the pupils of both eyes. Practical blindness resulted. I made an upward iridectomy and found a cataract. In a few weeks, in spite of all efforts, the iritic wound drew together, and the pupil drew up and became obliterated. Later I made a downward iridectomy and extracted the lens. This wound also drew together, leaving a linear cicatricial healing from the upper to the lower portion of the cornea. What would Dr. Knapp advise as the next step?

DR. KNAPP—It is just those cases that I should like to speak of. Dr. Callan has seen me operate on one of this kind. I used the De Wecker seissors and made a triangular pupil. It gradually closed from an inherent tendency to cicatricial contraction. I do not know what to do with them and the only good thing about them is that they are rare.

DR. S. LEWIS ZIEGLER, Philadelphia—In the beginning of this century there seemed to be two schools, divided just as they are now, one in favor of the knife and the other preferring the seissors. The great fault of the latter is the necessity of opening the eye and the danger of losing fluid vitreous. The limited way in which we can use the seissors is also against them. About eleven years ago I devised an operation for use with the knife-needle. I made the incision in this way: Standing at the head of the patient puncture-incision was made in the periphery of the cornea and the needle passed across the anterior chamber to the left of the median line about 3 mm.; by a quick thrust the membrane was penetrated and by delicate manipulation, without any pressure, the incision was carried by a sawing motion until it came opposite the point of puncture. This made an opening which was oval, and the knife raised through this opening was swung across to a point 4 mm. on the right side of the median line, to allow for about 1 mm. sagging of the membrane. When this latter incision was completed you had a triangular flap. This flap withdrew at once and formed something approaching a triangular opening. Usually the membrane turns directly down behind. If, however, the membrane is very stiff, and it was in these cases, that I was first led to use this method, you can either with the point of the knife press it down and back, or make another puncture in the base of the flap and by a cross incision break it back, so that it will fall down.

DR. J. L. THOMPSON, Indianapolis—Are you able to make that sawing motion with a collapsed anterior chamber?

DR. ZIEGLER—Yes, but you should preserve the aqueous if possible. The secret lies in making no pressure at all. There is no traction on the ciliary body and therefore only little danger of subsequent glaucoma. I have always used by preference the Hays knife-needle, which is an heirloom from one of the early surgeons of the Wills Hospital. It has the general form and shape of Beer's knife, but on a very small scale. The knife-needle of Dr. Knapp is also quite efficient.

In regard to the opening of the capsule by the cystotome, prior to extracting the lens, I always make an incision resembling the Greek letter pi, the first incision from below upward on the right side, second the left side, and a third connecting these two at the top. This forms a capsular flap that rolls down behind the iris as the lens is extruded, avoiding the gluing together of the anterior and posterior layers of the capsule, and often preventing the formation of secondary capsular cataract.

DR. WALTER B. JOHNSON, Paterson—One operative procedure has not been mentioned and that is the operation suggested by Dr. Agnew, I think called the hook operation, in which the hook was passed in and turned so as to twist the membrane on the hook, which was then withdrawn with the

membrane. This operation has been satisfactory to me, as it was to Dr. Agnew.

DR. CALLAN, closing the discussion—There is no question whatever that we can tear an opening by some method, but the whole subject depends on the traumatism we make. My point is this, that in the simple thin membranes we are safe with the knife-needle, but in the thickened membranes no man can tell how much resistance he will meet with. If we could see what the membrane back of the pupil was we would know what to do with it, but we can not. Granted that we can make an opening, no matter by what means, the question of traumatism is the one to be guarded against, and if you have ever lost an eye after the simple operation for secondary cataract perhaps you would feel as strongly about it as I do.

In regard to Dr. Allport's case, I should say that I would have made a section like the ordinary extraction and gone in with seissors to loosen up the iris on each side. I would not attempt to make an extra traumatism by making an iridectomy the whole length of the mass.

BUBONIC PLAGUE IN SAN FRANCISCO.

The following three cases of bubonic plague have occurred in San Francisco since the last report on this subject by THE JOURNAL:

CASE 16.—Lea De Hen, aged 50, Mongolian, cigarmaker, had lived in California 28 years. His residence was 710½ Dupont street. Patient died Oct. 5, at 10 p. m.

Examination of the body revealed a large bubo in the right inguino-femoral region. Incision disclosed a lymph node about the size of an egg, surrounding which the tissues were filled with a chocolate-colored fluid. The cut surface of the gland was very dark, purple and mottled, but substance fairly firm. A microscopical examination showed numerous bipolar-staining bacilli, decolorizing by Gram's method. Two guinea-pigs were inoculated with a glandular emulsion on Oct. 7.

One of the pigs lived four and one-half days after inoculation. On examination there was found a large area of coagulation necrosis surrounding the point of inoculation on the anterior abdominal wall. There was widespread edema and hemorrhages into the subcutaneous. The lymph nodes were enormously enlarged in both groins, the mass on each side being about the size of a lima bean. Both lungs were studded with yellowish-white nodules. Each pleural cavity contained about 2 c.c. of pinkish mucilaginous fluid. The liver was greatly enlarged, congested and mottled. Spleen was about fifteen times its normal size, dark and friable, and covered with yellowish specks. The vessels of the mesentery were injected. There was a small amount of pinkish fluid in the peritoneum. The suprarenal capsules and pelvis of both kidneys were hemorrhagic. The organs of the animal contained the plague bacillus in great numbers, and it has been obtained in pure cultures from them.

CASE 17.—Chun Yen, male, aged 37, Mongolian laborer, had been in California 10 years. Residence was 767 Clay street. Patient died Oct. 10, at 2 a. m. According to the statement of a white physician who lives and practices among the Chinese, he was sick two weeks and died of typhoid pneumonia. The body was that of a very large, fat and well-nourished man, who would probably weigh 200 pounds. An enlargement of the glands of the left femoral region could be detected through the thick layer of fat. These were removed and found to be about the size of hazel-nuts, very dark and necrosed. Smears showed the typical bipolar bacilli in large numbers. Two guinea-pigs were inoculated on Oct. 11, with an emulsion of the glandular tissue, and both lived about three and one-half days.

Autopsy: Guinea-pig No. 1. Large areas of coagulation necrosis surrounding the point of inoculation; marked subcutaneous edema; enlargement of the lymph nodes and hemorrhages in the left groin and axilla; lungs normal; spleen about three times normal size; very dark and soft, but no yellow spots; punctiform hemorrhages in peritoneum covering small intestines.

Guinea-pig No. 2.—Large area of coagulation necrosis at

the point of inoculation, surrounded by a zone of edema and subcutaneous hemorrhage; a marked hemorrhage in the left groin, but no enlargement of the glands; lungs normal; spleen about three times normal size and shows a few yellow spots; same condition of peritoneum as in first pig.

The plague bacillus was recovered in pure culture from both pigs. It is worthy of note that Chun Yen contracted the disease in the same house as the thirteenth case, that of Lee Wing Tong. This house was quarantined and thoroughly fumigated in the interval between the two cases.

CASE 18.—Tai Dong Leong, male, aged 39 years, Mongolian, had lived 25 years in California. Residence was 905 Clay street. Patient died Oct. 14, at 11 p. m.

The diagnosis of this case was established by a clinical examination of the blood during the life of the patient, who was attended by a reputable white physician, who reported the case

to the health department as suspicious, as soon as he had seen it.

On Oct. 14, the patient was seen by a number of physicians, among them were Drs. Ryfkogel and Kinyoun, and blood, as well as some fluid from the bubo, were secured for examination. These samples both showed the specific bacillus in large numbers, and it was also secured in pure culture from both sources.

Two guinea-pigs were inoculated, one with the pure culture grown from the blood, and the other with spleen obtained at the autopsy.

The guinea pig inoculated with the pure culture died in four days of a typical plague infection, there being the usual coagulation necrosis at the site of inoculation; a moderate amount of subcutaneous edema; and an enlarged spleen; the latter however, in this instance, containing much larger numbers of the plague bacillus than usual.

TESTIMONIAL BANQUET TO DR. CHRISTIAN FENGER.

A testimonial banquet was tendered Dr. Christian Fenger, Nov. 3, his sixtieth birthday, at the Auditorium Hotel, Chicago. It was a representative gathering of over five hundred, characterized by good-fellowship and good feeling. The tables were tastefully arrayed with roses, chrysanthemums and other flowers.

After the banquet Dr. Murphy called the assembly to order and said he was proud of the opportunity to pay tribute to Dr. Fenger. As an executive officer, it was his pleasant privilege to tender the compliments of the assemblage. In honoring Dr. Fenger, they accentuated the ideal of the medical profession, for he had been emblematic of all that was pure, noble and truly scientific in medicine in this section for the last quarter of a century. He thanked the honored guests from abroad for being present. He was not unmindful of the many personal sacrifices they had made in leaving their homes and labor to assist in making this testimonial a fitting tribute to this master mind. He then presented Dr. Charles A. L. Reed, of Cincinnati, Ohio, president of THE AMERICAN MEDICAL ASSOCIATION, as the toastmaster of the evening.

Dr. Reed expressed his cordial appreciation of the compliment of being called on to preside over such a large and brilliant gathering. He said they had met not merely for personal gratification, but for the splendid purpose of paying tribute to a man who had won a race by vigor, and not by vaunt. They had assembled to pay respect to a man who by stately stride had ascended a lofty hill, one who by the spirit of truth was made free—Christian Fenger.

Letters and messages of regret were read from the officers of various state, county and local medical societies in the east, west, north and south, the contents of some of them revealing great admiration for Dr. Fenger, others breathing such expressions of gratitude as are rarely written of living men.

Dr. W. W. Keen, of Philadelphia, presented the loving-cup. He said that friendship was one of the things that adorned and sweetened human life the most. Its delights had been pictured by the Roman orator in an immortal essay. It lived in the heathen legend of Damon and Pythias; it reappeared in the Holy Writ, where David and Jonathan were knit as one soul together. It began with youth; it heartened and cheered our manhood, and even in our declining years it illumined the last days with the glories of a setting sun, and after we were gone the memory of our friendships was as the afterglow which perpetuated the glory of a departed friend. He said they had met to bear witness to the value of this friendship and to pay honor to one who was among our foremost fellow citizens, our best-known and our best-loved colleague. He congratulated Dr. Fenger on the wonderful success that he had achieved. He had founded surgery on its true scientific basis, namely, on surgical pathology. Posthumous honors were very good in their way, but there were occasions on which it was proper, while the subject of them lived, that honor should be done to one who had won a conspicuous place in the medical profession not only

by his attainments, but by his modesty and his uprightness of character, and that we should in our friendship greet him during his lifetime and shower the honors of the profession on him.

On one side of the cup is inscribed:

"This great, good man for noblest cause displays,
What many labors taught and many days."

On the other side:

"To Dr. Christian Fenger, on the sixtieth anniversary of his birth, from those who know and love him best—THE MEDICAL PROFESSION."

Dr. Fenger, in accepting the loving-cup, said: "What you, dear friends, here present have done for me to-night surpasses anything that I at any time in my life ever dreamed of. It is the milestone in my life, compared to which all other events sink into insignificance. You have certainly passed far beyond any ambition that I ever had, and as to the effect on the remainder of my life, it will of course be that it will make what work yet remains to me pleasant, and when this work is finished, I shall be contented in looking back to your kindness to-night, and shall feel that I, perhaps, have not lived in vain. The chief value of this honor to me is the kindness of heart which inspired the gift. For this token of friendly love I wish to express my heartfelt thanks, not alone to those in whose kind hearts this thought originated, but to those who carried it out, and to all present who joined them and have left their homes, both far and near, to be present here to-night."

Dr. Edwin Ricketts, of Cincinnati, Ohio, responded to the toast, "Physicians as Leaders of Men." He said that the Trojan war could never have been so successfully fought had it not been for the valuable counsel and medical advice of trusted physicians. In the history of the world there were a few men who stood as great landmarks that distinguished the time in which they lived and gave prominence to the age. Some led in conquest; others in the arts of peace. New York has had her Sayre; Kentucky her McDowell; Louisiana her Stone; Ohio her Blackman; Missouri her Hodgen; Pittsburg her Murdoch, Virginia her McGuire; Illinois her Parkes; Philadelphia her Agnew; Georgia her Westmoreland; Nashville her Eve, along with thousands of glorious American immortals in our profession, who were leaders of men, and who, "like pillars of fire in a sea of darkness," were the light, the signal, the guide for all time. Fenger is a leader of men; a diligent worker, and a charming companion. For this charitable man, he closed with the following expression: "May life's evening shadows be gentle and restful; may they silently give place to the golden ray of sunshine that shall welcome his glorious morning."

Dr. W. H. Earles, of Milwaukee, Wis., in responding to the toast, "The Physician in Times of Plenty," said the physician of to-day, whether in plenty or in want, was one of the greatest products of modern evolution, and at the same time he was sorry to say too often one of its greatest failures. He was great as a product because of the favorable conditions under

which he had been evolved, and he was great as a failure because in recognizing he ignored the necessities of the time in which he lived. The physician should learn early in life that he had to assume the double responsibilities of citizen and doctor, and his duties to the state were of no less value than his duties as a physician in the community in which he lived. The physician should learn early in life that his reputation to be lasting must not rest on the shifting sands of fleeting popularity, but on the solid rock of integrity, industry, practicability, and worth.

Dr. Joseph M. Matthews, of Louisville, Ky., spoke of "The Physician in Times of Adversity." He said that compared with the great men of the past, with those of the present, or

those that are to come, he was willing to express the sentiment that Christian Fenger was as great as any of them. When a young man began to practice medicine he imagined that there were three main objects in view. One was to make money that he might support his family; second, to be a public benefactor, namely, to cure all those who were sick and sought his services; third, to make a reputation. These objects were discussed at length by the speaker. He would that every young man in the profession in America could be present to-night and see in what honest work, honest endeavor could culminate. Fenger did not belong to Chicago or Illinois; he was favorably known for his surgical work in the East, West, North and South. He was a shining example of what could be accomplished by honest, modest, tireless work. He would rather have given to him the tribute that had been paid to Christian Fenger than to wear the crown of a king or scepter of an emperor.

Dr. Nicholas Senn, of Chicago, followed Dr. Matthews, responding to the toast, "The Physician as a Scientist." This will be published in a future issue of THE JOURNAL.

At the close of Dr. Senn's remarks he presented Dr. Fenger with an album, beautifully illustrated and engrossed, which contained the autographs of all present.

Dr. Charles A. Wheaton, of St. Paul, Minn., responded to the toast, "The Physician as a Good Fellow." The speaker had known Fenger for twenty years, and it was he—Fenger—who had taught him most of his surgical pathology. Fenger had made himself peculiarly closely related to the younger members of the profession. He was a charming companion, and a conspicuous example of a great surgeon.

Dr. C. B. Nancrede, of Ann Arbor, Mich., discussed "The Physician in Times of War"; while Dr. William E. Quine, of Chicago, spoke of "The Physician in Times of Peace."

Dr. Fenger spoke of "The Period of Awakening and the

Period of Progress." He divided the time since 1877, when he came to Chicago, into two distinct epochs: the first prior to 1880, of which he saw only a few years, and which he called the period of awakening; and, second, the period from 1880 till 1900, which he called the period of uninterrupted progress. During the first period so little interest was manifested by many men in scientific medicine that it was difficult at society meetings to obtain a fair hearing or any discussion when any other than strictly medical matters were brought up. In 1880 there were about 18 medical journals in the middle West; to-day there are 81. In 1880 there were less than 20 medical societies; at present there are nearly 400. The speaker then spoke of the increased number of professors, demonstrators and lecturers in

the medical colleges of Chicago. In 1880 there were not more than 25 hospitals in the middle West; the largest of these was the Cook County Hospital, at which time it had a capacity of 250 beds; to-day there are about 150 hospitals, aside from private institutions, with a capacity amounting to more than 14,000. The difficulties physicians had to contend with in America in years gone by were: 1, the little help from the public funds; 2, the low standard of preliminary education, the betterment of which was first urged by Dr. N. S. Davis; 3, the prejudice in the public mind against autopsies, even of paupers, and against the use of patients for teaching purposes.

The advantages were the personal energy and willingness to learn—to be thorough, which was the dominant characteristic of the best medical students, whose terms of preliminary study terminated in internships in hospitals.

It is a satisfaction to the speaker to have done his life work in Chicago, witnessing and taking as best he could a small part in the growth of the West.

Stories were told by Drs. Frank Billings, Archibald Church, S. C.

Plummer, Fenton B. Turck, and Harold N. Moyer, which brought out the many good and variable traits of Dr. Fenger.

Dr. G. Frank Lydston, of Chicago, recited in an admirable manner a humorous, but eulogistic, poem, written in Hoosier dialect, on Dr. Fenger. Dr. L. H. Watson, of Chicago, likewise paid a tribute to the distinguished guest by reciting a poem.

Dr. F. E. Lange, of New York City, and Dr. Victor C. Vaughan, of Ann Arbor, Michigan, made brief speeches in which they paid homage to the illustrious guest.

Christian Fenger

Denmark. Following in the footsteps of his uncle, Professor Emil Fenger, he decided to study medicine. While still a student, war broke out between Denmark and Germany, and he served as surgeon throughout that campaign. In 1867 he received his diploma. For two years he was assistant to Wilhelm Mayer, in his ear clinic, and during 1868 and 1869, an interne in the Friedrich's Hospital, Copenhagen. When war was declared between France and Germany, Dr. Fenger became surgeon in the Red Cross ambulance corps and served in that capacity during the war. He then studied in Vienna under Professor Billroth, and returned, in the winter of 1871, to Denmark, and was prosecutor at the Copenhagen City Hospital from 1871 till 1874. In 1874 he presented and defended a monograph on "Carcinoma of the Stomach, Its Anatomy, Development and Extension," which gained for him the position of lecturer at the University. At the end of 1874, he was made extraordinary professor of pathological anatomy. In 1875 he went to Egypt, was made a member of the Conseil Militaire and surgeon in charge of the Khalifa quarter of Cairo. Two years later he came to America and settled in Chicago. In 1878 he was appointed to the attending staff of Cook County Hospital, and in 1880 was made curator of the Rush Medical College Museum. In 1884 he was elected professor of clinical surgery at the College of Physicians and Surgeons; nine years later he was made professor of clinical surgery at the Chicago Medical College, and in 1899 he was appointed to the same chair in Rush Medical College. During the last twenty-three years he has been or is now surgeon to Cook County, Presbyterian, Mercy, Tabitha Norwegian, Passavant Memorial, Lutheran, German, and German-American Hospitals.

Dr. Fenger has contributed extensively to the literature. Since 1870, more than eighty articles testify to his persistent and careful work. Its scope has been broad. His researches on tuberculosis of bones and joints, abscess and gangrene of the lungs, abscess of the brain, and his more recent work in surgery of the kidneys, bile-ducts and ureters are among his most important additions to medical literature.

The following were among those present from places outside of Chicago:

ILLINOIS.

Chas. C. Carter, Carl Bernhardt, Geo. L. Eyster and J. R. Hollowbush, Rock Island; Benjamin F. Uran, Charles True, Emmet F. Enoa and C. F. Shrouts, Kankakee; J. A. Egan, Walter Ryan and G. N. Kreider, Springfield; C. A. Palmer and J. A. Vixtrum, Princeton; C. E. Starrett, J. Forrest Bell and William S. Brown, Elgin; R. L. James, Blue Island; J. F. Barton, Shawneetown; E. F. Burton and Arthur Loewy, Oak Park; F. W. Werner, Joliet; E. R. Miller, Sullivan; W. R. Livingston, Maywood; Carl E. Black, Jacksonville; B. L. Evans and G. R. Browne, Waukega; H. C. Fairbrother, East St. Louis; Frank G. Norbury, Jacksonville; Frank Anthony, Sterling; Clarence A. Earle, Des Plaines; W. S. Pickard, Maywood; W. F. Grinstead, Cairo; W. L. Smith, Streator; C. C. Hunt, Dixon; Edmund W. Weis, Ottawa; J. F. Percy, Galesburg; H. C. Howard, Champaign; W. H. German, Morgan Park; W. A. Brennecke, Aurora; E. B. Montgomery, Quincy; William M. Richards, Joliet; E. J. Brown, Decatur.

WISCONSIN.

O. Thlenhaus, Lewis G. Nolte, D. J. Hayes, William E. Durr, L. Boorse, G. D. Ladd, R. G. Sayle, H. H. Hagerman, H. A. Sifton, W. F. Malone, Thos. Fitzgibbon, Jas. A. Bach, G. J. Kaunheimer, Thos. C. Phillips, D. Baldwin Wylie, Chas. H. Lemon, A. J. Burgess, Joseph H. Wallis, S. B. Sperry, Lawrence Hopkinson, F. C. Moeck, Byron O. Nobles, Chas. J. Coffey, W. H. Earles, Norman Hoffman, Otho Schorsch, Waverly B. Hill, W. C. F. Wild, Ralph Chandler, H. F. Kortbein, E. Wells Kellogg, Aug. Doerr, Geo. V. I. Brown, Geo. L. Alexander, John M. Beffel, Louis F. Jermain, H. M. Brown, D. Merenasa, A. H. Levings, G. J. Hirth and W. H. Washburn, of Milwaukee, Edward S. Hayes and J. V. R. Lyman, of Eau Claire; W. F. McCabe and F. T. Nye, of Beloit; W. B. Lyman, Mendota; Wm. H. Palmer, Janesville; L. N. Hicks, Burlington; P. S. Wiley, Fond du Lac; D. A. Myers, Trenton; L. H. Trince, Palmyra; Wm. E. Doid, Lake Geneva; Chas. W. Oviatt, Oshkosh; Charles S. Sheldon, Madison.

IOWA.

D. W. Crouse, Waterloo; D. M. Wick, Cedar Falls; D. S. Fairchild, Clinton; C. W. McGavren, Missouri Valley; A. L. Wright, Carroll; Frank T. Breene, Iowa City.

MINNESOTA.

J. B. McGaughey and E. D. Keyes, Wlnoona; C. H. Mayo, Rochester; James H. Dunn, Minneapolis; R. S. Dugan, Eyota; Charles A. Wheaton, St. Paul.

INDIANA.

A. W. Brayton, Joseph Eastman and Guido Bell, Indianapolis; H. C. Sharp, Jeffersonville; I. B. Washburn, Benssalaer; Aldine J. Dooley, Marion; Jaa. M. Dinneen, Fort Wayne.

MISSOURI.

Chas. Wood Fassett, O. Beverly Campbell and Jacob Geiger, St. Joseph; Charles G. Chaddock, H. W. Loeb and H. L. Nietert, St. Louis; L. W. Luscher, Kansas City.

NEBRASKA.

Jno. E. Summers, Jr., W. O. Henry, J. P. Lord, A. F. Jonas, Charles C. Allison, Omaha.

NEW YORK.

F. E. Lange, New York.

MARYLAND.

Guy L. Hunner, Baltimore.

MICHIGAN.

Charles B. Nancrede and Victor C. Vaughan, Ann Arbor; Angus McLean, Detroit; Eugene Boise, Grand Rapids.

KENTUCKY.

Dudler S. Reynolds and Joseph M. Mathews, Louisville; J. M. McCormack, Bowling Green.

KANSAS.

J. P. Kaster, Topeka.

OHIO.

Charles A. L. Reed, Edwin Ricketts and B. Merrill Ricketts, Cincinnati.

PENNSYLVANIA.

W. W. Keen, Philadelphia.

MISSISSIPPI.

R. E. Howard, Durant.

Disinfection by Sulphur Dioxide.—In Bulletin No. 3 of the Hygienic Laboratory of the U. S. Marine-Hospital Service, P. A. Surgeon H. D. Geddings makes the following statements and draws the following conclusions as to the efficiency of sulphur dioxide as a germicidal agent, and its employment for disinfecting purposes. After a brief résumé of the chemical and physical properties of the gas, and the various methods of production, he discusses the limitations of the agent, and arrives at the conclusion that it is open to the serious objections of slight penetrating power, and destructive action on textiles and fabrics. He shows however that the infection of the communicable diseases is seldom deep seated, and comes to the conclusion that the destructive effects of the gas are the strongest arguments against its employment. He distinctly recommends therefore that sulphur dioxide should not be employed for the disinfection of textiles and fabrics when it is possible to employ other agents of known efficiency. He shows however that the gas is cheaply and easily produced; that the materials for its production can be procured almost everywhere, and recommends it for the disinfection of ships' holds, freight cars, etc. He lays stress on the importance of accomplishing a hydration of the gas when employed as a disinfecting agent, detailing an experiment in which it is shown that a 10 per cent. volume of the gas failed to exert a germicidal influence not only on a spore-bearing germ, as anthrax, but also on the bacteria of cholera, yellow fever, typhoid fever, diphtheria and bubonic plague, when exposed for forty-eight hours. He then goes on to show that these same organisms, with the exception of anthrax, were killed by an exposure of twenty-four hours to a 0.6 per cent. atmosphere of the gas in the presence of moisture, in other words demonstrates the high germicidal value of hydrated sulphur dioxide or sulphurous acid. Several experiments are then detailed showing the germicidal effect of the gas in various percentages for varying lengths of time, always in the presence of moisture. He arrives at the conclusion that a 5 per cent. atmosphere of sulphurous acid for sixteen hours would be a perfectly efficient germicidal measure as applied to quarantine practice. He further details the amount of sulphur necessary to produce a given percentage of gas in each 1000 cubic feet of space, and a consideration of the quantity of water which must be volatilized during the process of the combustion of the sulphur to effect a hydration of the product. He then closes the article by two practical suggestions as to the position of the sulphur-containers in the holds of ships, and lays stress on the desirability of effecting the combustion of the necessary quantity of sulphur in a number of small containers, rather than in one of large size.

DR. SENN'S GIFT TO RUSH MEDICAL COLLEGE AND
HIGH STANDARDS OF MEDICAL EDUCATION.

Friends of high standards in medicine will rejoice to learn that Dr. N. Senn has given \$50,000 to Rush Medical College for building purposes. This is not his first gift to medicine. A few years ago he gave to the Newberry Library, of Chicago, a unique and remarkable collection of medical books—that of Baum and du Bois Reymond. When Rush College became affiliated with the University of Chicago he contributed \$25,000 toward wiping out the debt of the college. And only the other day, a gift of \$10,000 was announced to St. Joseph's Hospital, in which Dr. Senn for years has done a large share of his private work. This makes a substantial return to the profession in which but few acquire abundance of worldly estate. It is given only to few to further the medical weal as Dr. Senn is doing. The example is one that others will do well to follow, and it is to be hoped that this gift of \$50,000 may mark the beginning of a series of endowments in the interests of higher education in medicine.

The foremost medical colleges in Chicago have received, up to this time, far less endowment than similar institutions of relatively the same standing in some other large cities. And large sums of money are necessary in order to build up these schools according to the high standards they have set for their work. Since its affiliation with the University of Chicago, the career of Rush Medical College has been followed with great interest. By the introduction of the quarterly system and of elective methods of study it became a pioneer in revolution of the medical curriculum. An increasing application for admission in view of the increase in requirements on the student both before and after admission would seem to show that the methods are popular and successful. Dr. Senn's gift will enable the college to meet one of the most crying needs at the present time, namely, more room and better facilities for clinical instruction.

The gradual development in various parts of the United States of medical schools with high scientific standards, adequate equipment, and proper methods is a better foretoken than anything else of a great future for medicine in this country. The history of the Johns Hopkins Medical School, of which every American may be proud, demonstrates that American soil is favorable for the growth of scientific medicine and not merely

a hotbed for medical commercialism. The influences constantly going out from the medical schools of the large universities in New York, Boston, Philadelphia, Chicago, Ann Arbor, San Francisco, and elsewhere, are powerful factors in the interests of higher medical standards. And there are other well-established institutions with their own hospitals—as in Philadelphia—working toward the same end. But the fact remains, that the present number of medical schools in this country—156 or thereabouts—is excessive and abnormal. And what is abnormal must be subjected to active remedial measures and not, as suggested in a recent presidential address, allowed to drag along until eventually eliminated by a kind of natural selection. One reason for the existence of poor schools is that their graduates as yet have comparatively little difficulty in obtaining the right to practice. The state examinations must be made more searching than now. And the character of the work of schools, graduation from which entitles to come up for state examination, must be accurately controlled. Heretofore such matters have been dealt with in only the most general terms.

The facilities for practical clinical instruction demand careful investigation and specification. Too few medical schools have their own hospitals. This is true of some of our most progressive institutions. A most essential part of the work of the medical school is practical instruction and training in medicine and surgery, and how can this be accomplished properly and in accord with modern pedagogic methods unless the schools have the necessary laboratory and other equipments and also have full and absolute control of adequate hospital facilities? Large endowments are necessary for the establishment of well-equipped institutions and hospitals in which to teach and to study medicine. May not such endowments be expected when it begins to be understood what the good medical school is trying to do? Gifts like Dr. Senn's, therefore, will do much to interest the public in these matters and to open its eyes to the magnitude of the work in hand.

CHRISTIAN FENGER.

The memorable dinner on November 3, at which a loving-cup was presented to Dr. Christian Fenger, was a remarkable and highly interesting event, on a par with the recent ceremonies attending the presentation of testimonial volumes to Dr. A. Jacobi, of New York, and Dr. William H. Welch, of Baltimore. Christian Fenger occupies that same exalted position as these men in the hearts and in the opinion of students, colleagues and the medical profession at large. Former assistants, hospital internes and students of Dr. Fenger for some time felt a desire to bring him some definite token of the high appreciation in which they hold him and his work as a surgeon and a teacher; the idea was taken up officially by the Chicago Medical Society and successfully carried out on a much larger scale than originally contemplated by his most intimate associates.

It speaks volumes for the solidarity of our profession that prominent men in all its branches, from far and near, more or less spontaneously join hands in doing honor in appropriate and dignified manner to acknowledged leaders when suitable occasion presents itself. Dr. Fenger's sixtieth birthday was made the immediate occasion for the jubilant and enthusiastic outpouring last Saturday evening.

Dr. Fenger came to the United States and Chicago nearly twenty-five years ago. Already a trained investigator and pathologist, he brought with him a scientific spirit, which was destined to play an essential part in the development of medical science in the great Northwest. Twenty years ago the conditions for scientific work in Chicago were not so favorable as at the present time. But Fenger set to work bravely, doing the best he could in the circumstances then existing, and in but a short time he had gathered about him a circle of pupils, representing the flower of the student-body of those days. Many of those men are now among our foremost physicians and surgeons, and they date the birth of the inspiration, which has carried them to higher levels, to the day they came under Fenger's influence.

It was by his remarkably thorough and matchless pathologic demonstrations, so full of, at that time, new revelations, that Fenger made his earliest impress on students and physicians. The exhaustive character of his investigations and the acumen and clearness of his analysis are referred to with singular emphasis and delight by those who were fortunate enough to follow his work in the dingy post-mortem room of the Cook County Hospital. In the application of post-mortem observations to practical medicine and surgery he showed the value of pathological anatomy as no one before him had succeeded in doing. New fields for diagnosis and treatment, hitherto unexplored in this part of the country, were made accessible for the practitioner; before long the work of ransacking and revelation was carried into practical diagnosis and surgical treatment, the sphere of his influence rapidly widened, and for years he has been the recognized type of the scientific surgeon and teacher. Modest and simple, free from all trace of mercenary motive, all his work blessed with an altruistic grace, the public honor, shown him in a manner that "passed far beyond any ambition" he ever had, is but well-earned reward.

THE ACTION OF DISEASE TOXINS ON THE LOWER FORMS OF LIFE.

One of the indices of a toxemic condition, or of auto-intoxication, is the toxicity of the blood, and this has been tested hitherto by its action on the lower animals when injected into their tissues. Klingman¹ points out that a common fresh-water alga, *spirogyra*, can also be utilized for this purpose, and forms, in fact, a very delicate test for pathologic variations of blood toxicity.

Naegeli had shown some years ago that this organism reacted pathologically to the toxic action of infinitesimal amounts of certain substances, such as copper, silver, lead, zinc, and mercury. Klingman and Israel² repeated some of his experiments, using mere copper foil immersed in water, and produced cessation of protoplasmic streaming, granulation of the protoplasm, followed by division of the cylinder with nuclear changes, and finally retraction of the outer portion of the tube and destruction of the chlorophyll bands. In a more recent investigation Klingman has found that identical pathologic reactions can be produced by various bacterial toxins and toxic blood-serum. Of one hundred and fifty persons whose blood was subjected to the test, about one-third were in perfect health; the others were suffering from various disorders: epilepsy, neurasthenia, hysteria, insanity, syphilis, tuberculosis, alcoholism, etc. In a number of cases, the toxicity of the blood was first tested on animals, the tests with the *spirogyra* following. These were made with all precautions against any toxic contaminations, chemical as well as bacterial. About 1 c.c. of blood was obtained and thoroughly mixed with water previously tested and found uncontaminated. A few drops of this mixture were placed on a clean glass slide and examined under a No. 3 Leitz objective. With the blood of fifty healthy persons no reaction was observed, and the inoculation of guinea-pigs also gave negative results. In all the diseased conditions, except those of alcoholism, gout and rheumatism, a division of the protoplasm of the *spirogyra* occurred. But in the above-named disorders the reaction was somewhat different; the chlorophyll bands were retracted from the protoplasmic cylinder and changed their general arrangement, and the nucleus changed its position and form. In these peculiarities the reaction somewhat resembled that described by Naegeli as caused by chemical action of a very dilute nitrate of silver solution.

The time in which the change will occur varies directly with the amount of toxin present and the species of *spirogyra* used. In one case it occurred when the blood had been diluted with five liters of water, and in this way it can be determined whether or not the toxicity is increasing or otherwise. Klingman also observed that the time of reaction was greatly prolonged during convalescence, and in one case of diphtheria this was observed after two injections of antitoxin. Another interesting observation was that the blood of patients suffering from functional nervous disorders was quite as effective in producing the reaction as that from those with specific infectious diseases. This indicates an auto-intoxication in these also and, as he says, is suggestive as regards the treatment of these affections. Experiments were also made on the protozoa to determine the effect of toxic blood on animal tissue, certain forms of the rhizopoda being selected on account of the nudity of the protoplasm; the treatment with toxic blood, in the same manner as with the *spirogyra*, had the invari-

¹ Amer. Jour. Med. Sci., November, 1900.

² Virchow's Archiv, 1897, cxlvii.

able result of causing their death. With normal blood the effects were negative; there was no change in structure or activity. Control experiments were made by keeping the organisms in the water used, where they flourished without change, while the addition of the toxic blood caused the reaction in from one to twenty minutes, according to the strength of the toxin used.

In concluding his article, Klingman says: "Considering the uniformity with which the reactions in the above experiment occurred, the small amount of toxin required to cause the change, and the easy application of the method, this may be regarded as a delicate, reliable and practical test for toxic states of the blood." What the poisons are that have the effect is not hinted, but the research, aside from its practical applications and importance already mentioned, is very suggestive of future lines of work. The different behavior of blood in rheumatism, gout and alcoholism from that in other disorders suggests that further researches in the different diseases and on the other bodily fluids and secretions, as regards their action on these lower forms of animal and vegetable life, may possibly be fruitful of some results. Other organisms may also be found to throw special light on certain questions; in any case the subject is well worth being followed up in all its aspects bearing on vital reactions, toxins and disease.

PROLIFERATION AND PHAGOCYTOSIS.

Mallory¹ divides the injurious actions of bacterial toxins into cell necrosis, or degeneration, exudation from the blood, cell proliferation, and phagocytosis, this term being used to mean the inclusion and destruction of certain cells by other cells. The last two effects—proliferation and phagocytosis—have come into prominence more recently. As shown by Mallory, the phenomena of proliferation and cellular phagocytes are especially well marked in the lesions of typhoid fever. Similar changes occur, however, in a number of other infections: in the lymph-nodes in diphtheria; in the lungs in acute lobar pneumonia; in the kidney in scarlet fever, diphtheria, pneumococcus, staphylococcus and streptococcus infections; in the meninges and lymph-nodes in some forms of tuberculosis; and Mallory describes a peculiar, nodular cystitis dependent on the accumulation of phagocytic cells in the submucosa in response to the presence of bacilli, morphologically and functionally, of the colon-typhoid group. It is especially endothelial cells that proliferate and acquire phagocytic powers under these circumstances. The cells included are polymorphonuclear leucocytes, lymphoid and plasma cells, and red blood-corpuscles. The epithelial cells of the lungs also respond to the action of toxins in a similar manner, and the epithelium of the glomeruli in the kidney may proliferate freely, but it does not become phagocytic. Whether ordinary connective-tissue cells undergo similar changes is somewhat doubtful, but certain observations of Mallory point in the direc-

tion that they may. It is especially dilute and weak toxins that have this power. Strong, concentrated toxins cause degeneration and necrosis of cells, and vascular exudation. But the exact mechanisms whereby toxins of certain kinds incite proliferation of cells with phagocytic properties, are as yet wholly unknown.

There are other examples of increased cell-proliferation under the influence of toxic substances in which the new cells are devoid, however, of phagocytic activities with respect to other cells: the polynuclear leucocytosis of some infections, especially the pyogenic, may be mentioned; furthermore, eosinophilia in trichinosis; and the increase of lymphoid and plasma cells in scarlet fever and other diseases is another instance of this sort.

The general tendency of the cells that multiply under these circumstances is to disappear with the disappearance of the agents that called them into existence. This is shown well in the entire resolution of the widely-spread lesions of typhoid fever. At other times the new cells occasion more permanent damage, as in the kidney in the acute interstitial nephritis of Councilman, in which lymphoid and plasma cells migrate from the vessels and accumulate between the tubules, compressing the latter and causing their complete destruction. Proliferation of the glomerular epithelium may also be fraught with serious damage to these important structures.

But phagocytic cells are also capable of doing harm: they may occlude lymphatics; block up capillaries and other vessels, thus causing foci of necrosis in the spleen and liver; by virtue of their phagocytic properties they may destroy useful cells, although the inference is near at hand that the included cells suffer damage before their inclusion, but of this we have no direct evidence. Accustomed as we are to look on phagocytosis as a useful process, the abnormal phagocytosis evidenced by the proliferating cells may seem hard to understand from the teleologic viewpoint, but there are many other ways in which the cell-proliferation here discussed works harm, and there is no essential reason for regarding their phagocytic activity as useful.

THE TREATMENT OF THE COMMONER NEUROSES OF CHILDHOOD.

Kauffmann¹ points out that inasmuch as disorders of digestion and faulty diet are often causative factors in the development during childhood of chorea, enuresis, migraine, tetany, bad dreams, nightmare and epilepsy, correction of dietetic errors is one of the main points of treatment. In the majority of cases in which the feeding is at fault it is advisable to cut down the amount of meat. Meat once a day will nearly always be sufficient, and that should be at dinner in the middle of the day while there are still some hours of muscular activity before the child. It is seldom necessary or advisable to remove meat altogether from the dietary. So long as the meat is good, there is not much difference between beef, mutton, rabbit, fowl, game, etc., but fish may with

¹ Journal of Experimental Medicine, 1900, iv, 1.

¹ Lancet, July 14, 1900, p. 75.

advantage be substituted for meat. Light puddings and green vegetables may be given, and potatoes in moderation. In severe cases of enuresis it is sometimes advisable to stop meat altogether for a period, and then to allow it again in small quantities. Sufficient mastication and moderate rest after meals should be insisted on, and the child should not leave the house after breakfast until the bowels have been opened. If cathartics are required the saline purgatives are invaluable, at all events to begin the treatment with, and they are best administered as a single dose of sodium sulphate and magnesium sulphate an hour before breakfast, or in smaller dose the last thing at night. Calomel, alone or combined with a small quantity of colocyth and rhubarb, is also extremely valuable. Should an excess of indican in the urine continue, in spite of the treatment outlined, intestinal antiseptics, such as sodium sulphocarbolate, salol, phenol, mercurial salts, charcoal, and possibly arsenic, may be employed. Tonics may be of use when the general health is enfeebled from previous disease. In conjunction with these measures, besides seclusion, darkness and quiet, the most effective treatment of chorea consists in the administration of 15 minims of Fowler's solution twice or three times daily. When the symptoms of poisoning arise, especially nausea and vomiting, the dose should be diminished. Nocturnal enuresis may be successfully treated, as a rule, by the administration of potassium bromid, together with either tincture of belladonna or of hyoscyamus, as a nightly dose. It is, moreover, well to administer some alkali, such as potassium citrate, to diminish the acidity of the urine and its irritating effects. Should bacteriuria be present, its cause should be located and be dealt with. Attacks of migraine dependent on autointoxication may be successfully cut short by the administration of a smart emetic. Antipyrin sometimes succeeds, but by no means always. For the spasm of tetany the bromids are the most efficient remedies when employed together with the proper treatment for the catarrh of the respiratory or intestinal tract. Quiet and darkness are strong aids in the successful treatment of this affection. The bromids are also the best drugs to be employed in the treatment of epilepsy. Equal amounts of the salts of potassium and of ammonium may be given, the total dose to be determined by the result on the seizures. Should intestinal worms appear to be the cause of the disorder, the proper anthelmintic remedies should be administered. For oxyuris vermicularis, infusion of quassia should be prescribed internally, together with mild purgatives. For tapeworm, male fern is the most successful drug if given when the intestines are empty through fasting, and if helped by cathartic remedy. In any case, however, the altered condition of the intestinal mucous membrane will require consideration, and this condition will demand careful dieting and possibly saline purgatives to be continued over a considerable period of time.

ABOLITION OF THE USELESS CORONER'S OFFICE.

The recent carelessness of coroner's officials in Chicago in a widely exploited case of fraud against insurance companies has directed attention again to this "relic of barbarism," the coroner's office. It is being urged strongly that the office be abolished and the work the

coroner now pretends to do turned over to the police and the health department. There is no question as to the antiquated and unsatisfactory nature of the inquiries carried on by the coroner's office. The jury system is abused and prostituted, and the entire affairs of the office, both medical and administrative, are handed over completely into the hands of politicians without a trace of training or expertness in medicolegal matters. It is no wonder that justice miscarries under these circumstances; that people have no confidence in the coroner's verdicts, and that stories are afloat of extortion carried on across the bodies of the dead. But the coroner is an elective officer, whose election and whose duties in general are prescribed by state law. On paper his powers are as autocratic as can be conceived. The words of the statute give him power to step in wherever he has reason to believe or suspect that a body lies dead from unnatural or unknown causes. To change the present law so as to provide for a more modern, a more intelligent and a more economic method of inquiry into the nature of the causes of death under these circumstances, would require legislative action and submittal of the proposed change to the people at large—a cumbersome and difficult procedure sure to be met by obstacles of diverse nature. The abuses and shortcomings of the present system are especially felt in the large cities. In the country, where most individuals die peacefully and naturally, the people are not discontented with the coroner and they have no occasion to make close acquaintance with the workings of his office. In a large city like Chicago, however, the present coroner's system has outlived its usefulness long ago. Inasmuch as the essential part of the coroner's work is of a medical nature, namely, the determination of the cause of death in a variety of cases, it follows that physicians are interested, especially in the proper administration of this duty. The medical profession must take an active and leading part in the attempt at securing improvement in the present methods, which are inadequate. Local and state societies should bring up matters of this sort for study and discussion in order that the most serviceable plan may be evolved. This phase of medicolegal affairs certainly merits careful investigation.

THE PERMEABILITY OF THE INTESTINAL WALL TO BACTERIA.

It would be expected a priori that both the cutaneous integument and its visceral analogue, the mucous membrane, are under conditions of health impassable by micro-organisms, and that they thus act as protective coverings against infection. This assumption does not, of course, preclude the possibility of invasion of the ducts of glandular structures opening on the surface, as the sweat-glands, the sebaceous glands, the hair-follicles, etc. It seems probable, however, that a portal for the entrance of bacteria may be afforded by lesions so insignificant as readily to escape detection, and from which the tissues under consideration are scarcely ever wholly free. This would perhaps explain the frequency with which the bacterium coli commune, the most constant parasite of the bowel, is found in the lesions of many abdominal morbid processes. Some experimental observations have been made which go to show that

mechanical obstruction of the bowel will be followed by invasion of the blood and the adjacent viscera, under ordinary conditions principally by the bacterium coli commune, but also by other bacteria that may previously have been injected into the bowel. These results have been confirmed by a number of observers, although their validity has not escaped attack at the hands of others, who attribute the permeability of the intestinal wall to bacteria under the conditions of the experiment to the traumatism inflicted. With the object of controlling his earlier observations in this connection, made in conjunction with Lewin, Posner, in association with Cohn,¹ repeated his experiments, observing special precautions to prevent injury of the bowel, and obtained the same positive results as before, artificial occlusion of the anus being followed in from eighteen to twenty-four hours by infection of the peritoneum, the bladder, the blood, the spleen, the liver, the kidneys, and death sometimes ensuing. Dissemination of the bacteria is believed to take place through the bloodstream. It is not denied that the condition is the result of some change in the mucous membrane, which may, however, not be discoverable even on close scrutiny, and it is thought that in this way infection may arise for which other explanation is wanting.

INTEMPERANCE AMONG WOMEN.

A London gynecologist of reputation, Dr. Heywood Smith, has recently indulged in some public utterances that indicate an unfortunate state of affairs in English society. There is, he says, an epidemic of female drunkenness in the upper classes in England, perhaps we should say the upper middle classes, for he says the evil has not yet reached the aristocracy. Another speaker, apparently a clerical one, claimed that more homes were wrecked in London through drunkenness of wives and mothers than through the excesses of intemperate men. If drunken habits are the fashion abroad there is always a danger that they will be imitated here, at least by a certain limited class, and according to the opinion of some American physicians who have allowed themselves to be interviewed, this danger has to some extent been realized. Among the "smart set," it is said, there is much more drinking than is at all desirable, and the habit seems to be growing. Still, no one claims that the condition is as bad as it is represented to be in England, and the social conditions are such as we hope will prevent it even reaching that point, at least in the same class of society. There always has been a certain amount of private drinking among women, but it may be doubted whether it is much worse now than it has been in the past. The special fraction of society that is likely to indulge in excesses of the kind in this country is probably not a very large one, and there has long been a more pronounced sentiment against female drinking-habits here than seems to exist in Great Britain, if one can judge by the more evident signs. Still, it is well to be forewarned and forearmed against any evil possibilities of the future, as well as prepared to combat any actually existing evil conditions. The ancient Romans in their best estate recognized this fact when they made it

punishable with death for women to drink wine. The least, as well as the most, we can do in our days is to make generally known the social, physical and moral penalties that female drunkenness itself will bring, and arouse a public sentiment against it. The more effectively this can be done the better. Intemperance is one of the most serious evils in the male sex; in women it would be even more disastrous.

WOODEN PHELGMONS.

Reclus and others have described a peculiar form of chronic inflammation of the skin and subcutaneous tissue characterized by a slow clinical course and by a wooden consistency, *phlegmon ligneux*, *Holzphlegmon*. Most frequently involving the neck and developing even for months without fever or pain, they so simulate malignant neoplasm that the termination in recovery may be the first means of reaching a correct diagnosis. In one case described by Reclus death resulted from a suddenly developing edema of the glottis. Various organisms, but especially streptococci and staphylococci, have been found in the exudate. Krause has described an instance involving the hypogastrium. Quite recently Chiari,¹ of Prague, has added still another instance, which is quite remarkable because of the extent of the disease, the long duration, the absence of suppuration, and the final general infection with streptococci. The patient was a woman of 50 years. The inflammation probably originated in a dental periostitis, caused by carious teeth. From this point there gradually developed a chronic, painless, afebrile process marked by much production of new connective tissue. In the course of some five or six months the hard, dense swelling had extended to the neck, the tissues of the chest wall, including the mammæ, and of the mediastinum; the cervical and axillary lymph-glands were also swollen, and the left upper extremity showed some involvement. Death resulted from a bilateral acute pleuritis, caused by streptococci, which were found in various parts of the subcutaneous and mediastinal fibrous tissue, whence the pleuræ probably became infected by way of the lymphatics. Streptococci were also present in the blood. During life two attempts at culture experiments proved negative, indicating, it is thought, a change in the biologic characteristics of the coccus. No cultures were made at the autopsy. The disease is an interesting one, which merits further study before the etiologic relations can be fully understood.

TUBERCULOSIS AND MILK.

That tubercle bacilli may be conveyed by milk is generally conceded. Even in the beginning of bovine tuberculosis the milk may be infectious. Bacilli have been demonstrated by animal inoculations in milk of cows giving the tuberculin reaction, but without local lesions. Milk as such is not the only carrier of tubercle bacilli. They are being demonstrated in the various products of milk, such as butter and cheese. Recently Rabinovitch discovered tubercle bacilli in a German patented preparation, made from beef fat and other ingredients, and placed on the market as an artificial butter. They have been found by Morgenroth in margarin. It is suggested by both these investigators that the beef fat used in these

¹ Berlin Klin. Woch., 1900, No. 36, p. 798.

¹ Beitr. z. Dermat. u. Syph., Festschrift f. I. Neumann, 1900, 64, 76.

preparations may have contained minute tuberculous lymph-glands. Certainly bovine tuberculosis seems to constitute one of the important problems in the present struggle against human tuberculosis. Bovine tuberculosis, in all its ramifications, should be subjected to the fullest study, regardless of the immediate economic interests that may be compromised by the results, which are sure to be startling wherever such study is pursued. Anything short of extermination of infected cattle and absolute control of the sources of public milk-supply will probably not suffice in the end.

TAXING PHYSICIANS IN VIRGINIA.

As noted elsewhere in THE JOURNAL, the medical profession in Virginia is up in arms against the unrighteous license law of that state. Why physicians should have to submit to such a tax is incomprehensible, according to any rules of justice and decency. The state might as well specially tax clergymen—we are not sure that it does not, for a legislature that would do one thing would not be above doing the other. Any intelligent individual can see that the utility of the average practitioner of medicine to the state is enough to warrant giving him special consideration instead of adding to his burdens, but the Virginia legislators seem to have been too obtuse even for this. If the medical men of the state use the influence they possess, it would seem that the repeal of the law would be a certainty, and if there is the least difficulty it will have to be credited to that invincible quality against which even the gods strive in vain.

• Medical News.

CALIFORNIA.

THE PRESIDIO HOSPITAL will soon be full to overflowing. It has a capacity of 880 beds, has now nearly 600 patients and the transport *Medeo* is bringing about 275 sick and wounded soldiers.

DR. R. BEVERLY COLE, ex-president of the American Medical Association, San Francisco, was tendered a banquet, October 26, to celebrate the semi-centenary of his entry into the practice of medicine. He was presented with a silver plate suitably engraved with a preamble and resolutions signed by the president and faculty of the University of California.

A SANATORIUM is projected which will utilize the Hotel Mentone property. The Los Angeles physicians interested in the enterprise are William Brill, Charles W. Bryson, Barton Dozier, Paul Broese, William H. Dukeman, David W. Edelman, Joseph A. LeDoux, H. B. Bascom Montgomery, Claire W. Murphy, Francis A. Seymour, James H. Seymour and Charles F. Taggart.

CONNECTICUT.

NEW APPOINTEES to the staff of the New Britain Hospital are Drs. Joseph B. Brocksieper and Charles A. Gillen.

THE NEW HAVEN MEDICAL SOCIETY has petitioned the New Haven Hospital to rescind the rule which prohibits any physician not a member of the staff from attending a patient in the hospital, even if sent there by him.

YALE MEDICAL SCHOOL, New Haven, began its eighty-eighth year, October 4. Prof. Russell H. Chittenden will be head of the department of physiology in place of Prof. Benjamin Moore, resigned, and Dr. Yandell Henderson will be assistant in the same department.

THE LITCHFIELD COUNTY HOSPITAL at Winsted, which is now almost completed, will have conveyed to it \$40,000 by one of the families interested in it. During the life of the donors they will receive a portion of the interest of the fund, but on the death of the devisors, all will go to the hospital.

GEORGIA.

DR. HAROLD L. WARWICK, formerly of Lamar Hospital, Augusta, has located in Savannah.

DR. E. L. OSBORNE has been appointed city physician of Savannah, to fill the place made vacant by the resignation of Dr. M. H. Levi.

THE MEDICAL DEPARTMENT of the University of Georgia, at Augusta, began its 1900-1901 session October 2. Dr. Eugene Foster delivered the opening address.

DR. THOMAS D. LONGINO, councilman of Atlanta, has formulated a plan for organization of the city ward physicians, which necessitates a complete change in the present plans of the health department. Under this plan a health officer will be appointed, to whom the city ward physicians will be subordinate. His duties will not in any way conflict with those of the chief sanitary inspector.

ILLINOIS.

THE CORNER STONE of the new Deaconess' Home and Hospital, Lincoln, was laid, November 4. The building is to cost \$25,000.

THE SOUTH CHICAGO HOSPITAL was opened to the public October 26. It has male and female wards, six private rooms, and an operating room, all properly furnished and equipped.

THE BOARD OF HEALTH of Morris has declined to accept the resignation of City Physician H. Milton Ferguson, has promised to support him in his views in future, has eulogized his service during the recent epidemic and has finally succeeded in inducing him to continue in office.

AN INJUNCTION against the new Deaconess' hospital at Peoria has been applied for by a neighbor, on the ground that her "residence is but thirty-five feet from the hospital, and the groans, shrieks and yells of the suffering patients, coupled with the frequent visits of the ambulances and hearse make the hospital an unbearable nuisance."

STATE ORGANIZATION.

THE COMMITTEE of the Illinois State Medical Society, appointed for such purpose, is proposing to present and recommend to the society at its annual meeting next May a plan by which it is hoped a complete organization of the profession may result. While this committee is at work some of the local societies are also active. The District Medical Association of Central Illinois, the Morgan County Medical Society, the Brainard District Medical Society, the Pike County Medical Society, and the Medical Club of Jacksonville, have adopted the following resolutions: Resolved, That it is the opinion of the members of the _____ that the medical societies of the State of Illinois should be reorganized on some comprehensive plan which would constitute the profession a complete and harmonious organization that would include each county, district and state society. That we believe the success which has attended fraternal organizations is, in part at least, due to their plan of organization; and, further, that the time has come when medical societies besides being bodies for the presentation of scientific topics must take a more active and practical interest in the material welfare of the profession as well as an active participation in all measures which are calculated to preserve the good health of the various communities in the state. Therefore, we would respectfully ask our neighboring county and district societies, as well as the state society, to consider some practical plan of reorganization and take steps to carry it into effect.

Chicago.

DR. FRANK T. ANDREWS has filed suit against the Great Northern Theater and Hotel Company for injuries sustained in an elevator accident two years ago. He claims \$10,000 damages.

A POLISH HOSPITAL, to cost \$250,000, is to be erected by the Sisters of the Holy Family of Nazareth, at the corner of Leavitt and Thomas streets. It will occupy an entire block, will be constructed of cut stone and pressed brick, will be equipped with all modern appliances and will be ready for occupancy in October next.

DR. NICHOLAS SENN'S gift of \$50,000 to Rush Medical College, together with \$30,000 now in hand, will suffice for the total cost of a clinical building for the college. It will be known as "Nicholas Senn Hall," and will be six stories in height, 40 by 90 feet. It will contain numerous small clinic rooms, a dispensary, laboratory and two amphitheatres.

THE PHYSICIANS' CLUB officially approved of medical inspection in the public schools, at its October 29 meeting, when the following resolution was adopted: Resolved, That it is the judgment of the Physicians' Club of Chicago that the result obtained by the medical inspection of the schools of Chicago demonstrates the high sanitary value of the system. As a life-saving measure it is of the greatest importance to the City of Chicago.

KENTUCKY.

DR. JOHN MASON WILLIAMS, formerly of Louisville, and late of the volunteer service in Cuba and the Philippines, was

Republican candidate for congress at his home, Mount Vernon.

DR. JOSEPH B. MARVIN, professor of medicine in the medical department of Kentucky University, is temporarily filling the chair of practice in the Louisville Medical College, made vacant by the resignation of Dr. John G. Cecil.

THE ANNUAL MEETING of the medical staff of the Masonic Widows' and Orphans' Home was held October 31, for the purpose of reorganization made necessary by the death of Dr. Preston B. Scott, formerly physician-in-chief. Dr. Ap Morgan Vance was elected president of the staff and Dr. I. N. Bloom, secretary. The following physicians compose the staff: Dr. Ap Morgan Vance, visiting surgeon; Dr. Henry E. Tuley, visiting physician; Drs. John G. Cecil and Frank C. Simpson, consulting physicians; Dr. I. N. Bloom, dermatologist; Dr. William Cheatham, ophthalmologist; Dr. C. Moir, assistant surgeon; Dr. L. Baltzer, assistant ophthalmologist; Dr. Vernon Robins, assistant dermatologist.

LOUISIANA.

NEW HEALTH BOARDS to the number of 25, have been established since the passage of the bill providing for the establishment of parish boards of health.

THE SCHOOL DIRECTORS of New Orleans have rejected the proposition of the city board of health to inaugurate a system of inspection of school-children for the purpose of detecting communicable diseases.

THE STATE BOARD OF HEALTH adopted resolutions at its recent meeting in New Orleans, providing that fruit vessels with passengers from non-infected ports be detained only long enough to disinfect baggage of passengers, and that vessels, other than fruiters, be required to deliver to the president of the board lists of their passengers with destinations.

MARYLAND.

THE PENINSULA GENERAL HOSPITAL at Salisbury, which will be erected within the next year, will be of brick, well equipped with all modern improvements and will have a capacity of 80 patients.

TYPHOID FEVER prevails to an alarming extent in Elktion, Cecil County. More than 26 cases have been reported to the health department there, and new cases are reported continually. Samples of milk and water have been forwarded to the state authorities for examination.

Baltimore.

DR. WILLIAM B. PERRY, while riding in Druid Hill Park, October 29, fell from his horse and had his left arm broken and his left shoulder dislocated.

DR. FLORA A. BREWSTER, charged with violating the state lunacy law by treating an insane patient at her private sanitarium, was acquitted in the criminal court, October 30.

THE ROHÉ MEMORIAL COMMITTEE, of which Dr. Louise Erich is chairman, appointed over a year ago to collect funds for a memorial tablet in the hall of the Medical and Chirurgical faculty, has engaged Sculptor Ephraim Keyser, recently returned from Europe, to make a bronze portrait tablet of Dr. Rohé. The funds are now in hand. The committee proposes also to establish in the library a Rohé alcove, consisting mainly of works on hygiene.

MASSACHUSETTS.

A CHAIR OF HYGIENE is to be established at Harvard, \$156,000 having been donated for this purpose.

DR. ELIZABETH A. RILEY, Boston, has the distinction of being the first woman lecturer in Tufts Medical School.

PRACTICE without registration has caused the arrest of three doctors in Massachusetts, two of whom found bail, but the third was fined \$100.

HARVARD UNIVERSITY has adopted a system of medical inspection which is eminently satisfactory. Dr. Marshall H. Bailey, the medical inspector, sends to each student at the beginning of term a card with the notification that every case of illness must be reported; all janitors are similarly instructed. As a result, Dr. Bailey has a double check on the health of the University.

MISSOURI.

A TESTIMONIAL TO DR. I. N. LOVE.

At the banquet tendered Dr. Love, at St. Louis, on his leaving for New York, referred to in our columns Oct. 27, Dr. Louis E. Newman, chairman of the executive committee of the St. Louis Medical Society, made the following response to the toast, "Our Guest": "We are here to-night to say au revoir to one who has been a wheel horse in the medical ranks for a quarter of a century; one, who, though still in life's meridian, has made for himself an honorable and enviable reputation not only in the community in which he has lived since boyhood and

which he now leaves for a wider field of labor, but throughout this broad land. At the century's close he goes to another city, the metropolis of the Western Continent, to follow his professional labors, which I am sure will be crowned with greater success even than in the past. I am sure that you are all with me in wishing him all that he deserves and that from the beginning of his new career until the time comes when his work shall have been done, success will crown his labors. It has been my pleasure and good fortune to know Dr. Love since I began the practice of medicine. My office adjoined his, and he was one of the first to bid me welcome, to extend the hand of fellowship to me. Beginning as his neighbor I frequently met him and loved and honored him for his straightforward honorable bearing, as a gentleman and a physician. Later I became associated with him in committee work of the St. Louis Medical Society, and now when I look back on the pleasant and profitable evenings when with good old, true Gulman, we met and discussed matters social, political and medical, I can not but feel how much I shall miss the genial, entertaining Love. Our loss is New York's gain, and yet let us hope that our friend will always consider St. Louis his home, where we shall always be ready to welcome him, not as the returning prodigal, although we shall always be glad to kill the fatted calf for him, but as a visiting brother who must needs from time to time make a visit to his family."

MONTANA.

AS A RESULT of the recent examinations held by the State Board of Medical Examiners, sixteen physicians have been granted certificates to practice.

FREE VACCINATION is announced at Butte and a physician has been employed at a salary of \$150 per month to vaccinate all who apply to him. On the first day 47 appeared. The compulsory vaccination ordinance is in force and those who fail to comply with it will be liable to a fine of \$5.

AN EFFORT is being made to induce Governor Smith to appoint an ad interim or emergency state board of health to act until the legislature can enact the necessary laws. The prevalence and increase of smallpox has rendered the necessity of a central authority and a general plan of campaign for suppressing the disease imperative.

NEBRASKA.

DR. LUTHER M. BOWMAN will open his new hospital in Alliance in a short time. Dr. Vaughan will be associated with him in its management.

DR. H. WINNETT ORR, Lincoln, one of the editors of the *Western Medical Review*, was recently operated on for appendicitis. He was in a serious condition for a time, but is now rapidly recovering.

THE HOSPITAL at South Omaha is in a fair way to be erected. Various money-making schemes are on foot, one being the sale of lapel-buttons. The promoters expect liberal subscriptions from the corporations and the railroads from whom employees the majority of the patients will come.

NEW YORK.

DR. JOHN F. MYERS, Sodus, has opened his new hospital at that village, with a capacity of 40 beds.

WE HAVE RECEIVED from Dr. Louis F. Bishop, secretary of the New York Academy of Medicine, the following minute: The President and Fellows of the New York Academy of Medicine hereby express their high estimate of the character of the late Dr. Samuel S. Purple, as a citizen and a physician; their earnest appreciation of his valuable services as a Fellow and an officer of the Academy, and their grateful acknowledgement for rare books and pamphlets presented by him in large numbers to the library of which he was the founder. They earnestly desire to extend to the members of his bereaved family their profoundest sympathy in this, the hour of their sad affliction.

OHIO.

DR. S. A. HUTT, Waverly, suffered a cerebral hemorrhage. October 25.

A MEMORIAL LABORATORY is to be built and endowed by the friends of the late Dr. W. J. Scott, of Cleveland, in his memory.

DR. ROBERT H. TIMPANY, Toledo, has been lying seriously ill with nervous prostration at St. Vincent's Hospital for the past two weeks.

DR. CHAUNCEY D. PALMER, Cineinnati, has resigned from his position as gynecologist and obstetrician to the city hospital. He will be succeeded by Dr. John M. Withrow.

PENNSYLVANIA.

FRANCIS SCHLATTER, the "divine healer," while on a recent visit to McKeesport, asked permission of the mayor to permit

him to hold outdoor meetings in the public square to preach divine emre, but was refused.

DR. JOHN ELLER, Lancaster, on October 30, celebrated his eightieth birthday. He has been practicing medicine for fifty-seven years, and recently attended a meeting of the State Medical Association of Pennsylvania, which he aided in organizing in 1848.

Philadelphia.

THE BOARD OF MANAGERS of the Pennsylvania Hospital have elected Dr. Alfred Stengel visiting surgeon to the hospital, to succeed Dr. Jacob C. DaCosta, deceased.

STATISTICS compiled in the medical department of the University of Pennsylvania show that 71 per cent. of the students have attended a college or university.

PLANS are being perfected for the erection of a new insane asylum. The name of the new institution will be "The Ogontz Hospital for the Insane." Work on the new building will commence early next year. It will cost about \$50,000.

A COMMUNICATION from the Women's Sanitary League has been forwarded to the board of health, asking for a further appropriation of \$5000 to the Municipal Hospital to build private rooms in the diphtheria pavilion and not less than \$10,000 for the construction of a scarlet-fever ward.

AS A RESULT of an inquiry made among the leading druggists, it has been ascertained that quantities of potassium chlorate are stored in many of these houses, some of which have as many as 25 to 100 kegs. A lesson has been learned in the case of the disaster in New York by which many were killed by an explosion probably of this substance. In the latter instance only 30 kegs of potassium chlorate are said to have been carried in stock.

GENERAL.

A WARNING.—A smooth, well-dressed individual has been collecting money and in other ways defrauding the physicians of Detroit and elsewhere, claiming to represent THE JOURNAL and another periodical. His name is B. F. Kenneth. If any of our readers know the whereabouts of this individual they will confer a favor by telegraphing this office. None of our agents are authorized to collect money, and this is specified on all order blanks carried by them.

A FATAL malady said to resemble typhoid fever complicated by pneumonia now prevails over the valley of the Yukon region; 150 Indians have already died.

THE LADIES of Sitka, Alaska, and others interested in the maternity hospital in the native village, met on October 1 to devise means for the supervision and maintenance of the charity.

COMMANDER SEATON SCHROEDER, GOVERNOR of the Island of Guam, has issued an order opening all hospitals in the island to the civilian patients free. The health of the island is fairly good. There are no typhoid cases and only a few of intestinal troubles.

MRS. LELAND STANFORD, of California, is said to be negotiating for the purchase of certain buildings now used at the Paris Exposition. These are to be taken down and the material used for the erection of an American hospital in the suburbs of Paris.

EDMUND DANTEs, while at work in a drug store in Paterson, N. J., stole the diploma of his employer, John Hall, and sub-stituted his own name. He then went to New York City and obtained a position in a drug store on Second Avenue. He was arrested, and October 31 was sentenced to one year's imprisonment in Sing Sing.

SPIRITUAL MEDICINE.—The "spiritualists" held an annual convention in Cleveland, October 16 to 20. They adopted numberless resolutions, two of which are of some little interest to our profession. They are as follows: "Resolved, That while we are opposed to the existing medical laws, and to all efforts being made to enact so-called medical laws, we would advise all who attempt to treat the sick to become thoroughly acquainted with anatomy, physiology, hygiene, and the general laws of health. Resolved, That compulsory vaccination is not only unwise, unconstitutional, and un-American, but dangerous to health, causing eczema, erysipelas, cancer, tumors, syphilis and often death." It is certainly very kind of them, while declaring their opposition to all medical laws, to advise all those who attempt to heal the sick to become thoroughly acquainted "with anatomy, physiology, hygiene, and the general laws of health." A spiritualist then, not having studied surgery, would probably treat a broken leg by means of "the general laws of health." The second resolution that is quoted above is most startling, or as the newspapers say, it is "important if true." The ills, which we are there told follow in the wake of vaccination, are quite calculated to sear away

"spirits" of ordinary caliber, but as all persons whose mental processes are governed by common sense know the statement to be plainly untrue it is not likely that this resolution will cause much of a stir in this world of hard facts.

CANADA.

OUR LEADING medical societies are now contemplating the publication of their annual transactions in full for the first time, thus giving the members thereof something more tangible than a mere annual membership certificate. It is likewise thought that those members will contribute more cheerfully to a medical defense fund.

AT THE PRESENT time there is more diphtheria in the city of Toronto than in other cities and towns in the province of Ontario; in fact, in some of the northern districts of the city it has almost approached to the status of an epidemic. The records for the present year so far indicate that the number of cases will be more than the average.

ADVERTISING NOXIOUS DRUGS IN THE LAY PRESS.

The death in Toronto this past week of a married woman, in convulsions, brought about through having taken an advertised drug to procure miscarriage; and the recommendation of a coroner's jury that the advertisements of these self-same drugs be listed as an offense against the criminal code, has been the text of a seathing article appearing in a society paper, against the leading daily and weekly papers of the country who profit by the insertion of these obnoxious and dangerous advertisements in their columns. That the lay press are great sinners in this respect has been before pointed out in these columns. It may prove an enlightenment to the public that newspapers are doing nothing more than lending themselves and their columns to criminals first and their victims last. The daily press is reeking with these filthy advertisements, and that of Toronto is indeed a sinner in a great degree.

NOVA SCOTIA BRANCH BRITISH MEDICAL ASSOCIATION.

The annual meeting of this branch of the British Medical Association was held at Halifax October 17. President Dr. E. A. Kirkpatrick, in the chair. The efforts of the association in the direction of securing legislation re tuberculosis have proved successful, as the government of Nova Scotia has provided through special legislation, for the construction and maintenance of a sanatorium. Five new members were elected to the branch during the past year. The election of officers resulted as follows: President, Dr. G. C. Jones; vice-president, Dr. Thomas Walsh; treasurer, Dr. M. A. B. Smith; secretary, Dr. C. D. Murray; counsellor, Drs. Ross, Kirkpatrick, Murphy, Walsh, Trenaman, Major Peeke and Dr. G. M. Campbell. Representatives on General Council, Surgeon-General O'Dwyer.

TORONTO UNIVERSITY FORGING AHEAD.

For many years it has been thought that McGill was supreme as regards educational matters in Canada; but for the past few years there have not been lacking signs that her rival in the West is now outstripping her in the race. As has been pointed out in these columns, the number of students enrolled in the department of medicine has been gradually increasing year by year until this year Toronto has enrolled no less than 110 freshmen. In the department of applied science, where McGill used to be ranked as the first, Toronto is making marked strides as evidenced by the large increase in the past few years in the numbers of her students. In the arts course, Toronto has always been supreme; and evidently in the departments of medicine and applied science McGill must look to her laurels or Toronto if it has not already done so, will snatch them from her brow. When Trinity and Toronto become consolidated into one institution, with their seven hundred students in medicine, Toronto will be the great university of Canada.

FOREIGN.

THE authorities at Paris have confiscated the issue for August 26 of the *Journal de Médecine de Paris* and certain back numbers during the year, on account of articles "outraging morality."

IN SWITZERLAND the new regulations make medical examinations much stricter than heretofore, and the minimum period of study is prolonged to five years.

THE DEATH of Dr. L. Villar is reported from Lima, Peru, professor of anatomy and legal medicine, president of the Academia de Medicina, editor of the *Gaceta Médica*, and senator.

THE MEDICO-SURGICAL SOCIETY of Sao Paulo, Brazil, is organizing a medical college at that place on a large scale, planning for eighteen chairs and fourteen clinical professorships.

THE NEW hospital for the Vienna Allgemeine Poliklinik has been completed. It has rooms for isolation and living apartments for a physician on each floor.

DR. ROBERT TIGERSTEDT, of Stockholm, has returned to his native land, in response to a call to the chair of physiology at Helsingfors.

DR. JAVAL, the eminent director of the Sorbonne Ophthalmological Laboratory, Paris, has been made officer of the French Legion of Honor. He has become completely blind, although only 60 years old.

OCTOBER 13 was observed in London as Hospital Saturday, for the twenty-seventh successive year, and special collections were made in many thousands of business houses and workshops on behalf of the hospitals and dispensaries.

A SCHEDULE of precautionary measures against the spread of plague, with special reference to railways and travelers, has been drawn up by the German Imperial Board of Health.

It is announced that the Copenhagen Academy of Medicine has proposed Professor Finsen as a competitor for the Nobel prize in medicine. Our exchanges state that this prize of 200,000 marks, or about \$48,000, is to be an annual institution.

THE *Scmana Medica*, of Buenos Ayres, has inaugurated the protest against lodge practice in the Argentine Republic, which it seems is assuming large proportions.

A TAPE-WORM charlatana has been imprisoned at Munich, owing to the death of a five-months infant to whom he administered a large dose of extract of male fern. The child died in less than an hour.

PROF. SIEGENBEEK VAN HEUKELOM and his pupils recently published a large work, the "Reconeil de Travaux Anatomopathologiques du Laboratoire de Boerhaave," which has attracted much attention. The death of the promising scientist in his fiftieth year is now announced from Leyden. Dr. H. Abegg, one of the leaders of the profession in Danzig, died recently at Wiesbaden.

BELGIUM has lost in Dr. E. Janssens one of the pioneers in hygiene and public health statistics. It is chiefly by his efforts that Brussels has taken such a high stand in hygiene and sanitation. Every physician in Belgium received from him a weekly bulletin containing the vital statistics of all the principal cities in the world. The death of Dr. A. P. Ferrari is also reported from Buenos Ayres, and of Dr. R. Hirsch from Hanover.

NOR one of the 104 persons connected with the Italian railroads who have submitted to prophylactic measures against mosquito infection of malaria, has contracted the disease during the entire season. On the other hand only 7 or 8 out of 359 persons in similar conditions, whose houses were not screened, have escaped malarial infection. The screens allowed the passage of the culex pipiens and kept out merely the anopheles.

THE BERLIN UNIVERSITY has opened two official courses not before included in the curriculum. One is for "Heilgymnastik," in charge of Dr. G. Schuetz, and the other is for massage, to be given by Prof. J. Zabudowsky at the new university institute—six months for students, and a one-month's post-graduate course.

PROPHYLAXIS AGAINST THE PLAGUE.

Yersin has been interviewed by the correspondent of the *British Medical Journal* in regard to the prophylaxis of the plague. He states that the only effective measure to stamp out the plague is to evacuate the houses and not return to them for six months. Disinfection and even burning down the buildings are ineffectual. By evacuating a village or small community the disease will die out in a week, and by this means he has succeeded in breaking up many epidemics. The ideal plan would be to have two villages, one for the cold weather and one for the summer. In Europe where such measures are impracticable, the chief reliance must be antiplague serum and inoculations, with as thorough disinfection as possible.

THE ORGANIZED EFFORT IN GERMANY.

Krecke endorses the new German society to protect the material interests of members of the profession in their struggle with the *Krankenkassen* or sick-benefit associations. He urges the necessity of an immediate fund for a "defense fund," and suggests that those physicians able to do so will buy a life membership in the society, paying 500 marks at once and for all, instead of the proposed mark a week. He will head the list. He also urges the appointment of reliable officers for the society, who will be able to devote their whole time to it if necessary, and plan to influence the lay press in favor of the medical corps. He concludes his communication in the *Muench. Med. Woch.* of October 16, with the plea that the social interests of physicians should have some attention paid to them in the medical curriculum. Students should be trained to take an interest in general matters affecting the

profession as a whole, and no one should be qualified to lecture until he has spent at least a year in active practice.

PROPHYLAXIS AGAINST TUBERCULOSIS IN NORWAY.

Claus Hansen and Holmboe have drawn up a bill for the state prophylaxis of tuberculosis, which has been adopted by the legislature of Norway and will become a law January 1, 1901. It requires the physician to report all cases of affections of a tuberculous character whenever accompanied by secretions liable to propagate the disease. The attending physician is held responsible for the supervision of the execution of thorough prophylactic measures. If necessary he can call on the local board of health for aid. This board is empowered to send the patient to a hospital or sanatorium if it deems that appropriate hygienic measures are not being enforced. It can also exclude persons known to be affected with tuberculosis from having anything to do with the preparation of food for sale, also with the sale of articles for food, or employment in the dairy business, or as children's nurses. The government is authorized to take the measures considered necessary to prevent the spread of the disease in much-frequented places, hotels, theaters, etc. The traveling expenses necessitated by the application of the law will be borne by the state, but the hospitalization of the poor and disinfection of their dwellings must be paid for by the community. The *Progress Medical* of October 20 agrees with Vallin that the notification of tuberculosis should not be compulsory, but left to the discretion of the attending physician until the day when the public is trained from childhood to sound and judicious conceptions of contagious diseases and their prophylaxis.

CO-EDUCATION IN AUSTRIA.

The new regulations whereby women are admitted as ordinary students to the universities and colleges in Austria, according to the *British Medical Journal*, have already been the cause of some disturbance of academic calm. Prof. Hermann Nothnagel, who holds the chair of special pathology, therapeutics and clinical medicine, in the University of Vienna, when he found a row of young ladies on the front bench of his class-room, refused to proceed with his lecture on the ground that it had not been prepared for students of the feminine persuasion. The girl undergraduates were then requested to depart, which they declined to do, and as the chronicle relates, they had to be led out of the University, but whether from its rooms merely or from its precincts he does not state. At Graz, too, the lady medical students were ungallantly received by their fraternal colleagues on making their first appearance in the medical class-room. On this occasion the girl undergraduates took up a less firm attitude than their Vienna sisters, and left the room with sobers.

LONDON LETTER.

THE PLAGUE IN GLASGOW.

Thanks to the energetic precautions of the authorities, the outbreak of plague in Glasgow has been completely arrested. There are now only 14 cases in hospital and 6 patients have been dismissed cured. Prof. Zabolotny, of the Imperial Institute of Experimental Medicine, St. Petersburg, who has spent several weeks in Glasgow on behalf of his government, has made an important report on the outbreak. His conclusions are as follows: 1. The outbreak, when compared with that of India, China and Africa, with those of Europe of recent years, is of the mildest description. 2. The extension of the epidemic is not great and the mortality insignificant, which may be attributed to the energetic sanitary measures. 3. For the most part the cases are bubonic, which are less dangerous than the pneumonic. The latter are excessively contagious because the sputum teems with plague bacilli. 4. As in the bubonic form the disease spreads only by contact with the skin, isolation and cleansing of linen and clothing are most important. 5. For persons in contact with the sick the best protection is an injection of the serum, 10 to 20 c.c., as here practised. 6. The treatment of patients is most effective when the serum is injected intravenously in large doses, 60 to 120 c.c.

THE FATAL CASE OF PLAGUE AT CARDIFF.

It is now beyond doubt that a fatal case of plague has occurred at Cardiff. The subject was a sailor on board a steamer, which came from Rosario in the River Platte to South Shields on the Tyne. When he landed he felt unwell and proceeded by train to Newcastle and thence to his home in Cardiff, which he reached on September 27. The physician who first saw him diagnosed typhoid fever. But he became suspicious and communicated with the medical officer of health. Plague was feared, and samples of the blood and the serum from an inguinal bubo were sent to the bacteriological laboratory. The bacteriological examination showed that the patient was suffer-

ing from plague. He died on October 4. Most elaborate precautions were taken against the spread of the disease. The patient's clothes and the bedding at his house were burned. His body was cremated. Over 700 rats were destroyed at Cardiff, of which 134 were caught on one ship. All danger of an outbreak of plague seems to be now passed.

FRACTURED SKULL MISTAKEN FOR DRUNKENNESS.

Another of those unfortunate cases in which a fatal head injury is regarded by the police as a case of drunkenness, has just occurred. A Londoner, aged 34, was traveling on business at some neighboring seaside resort. He did not return home until later than when he was expected. On his arrival he complained of his head and seemed in a dazed condition. He said that he had been locked up, charged with drunkenness and fined. He was a man of sober habits, and really had been taken ill and fallen while running to catch a train. Three days later he died. At the inquest it was proved that on the day of his arrest he was sober at 1:45 p. m. A policeman said that about 2 p. m. he saw the deceased staggering toward the railway station. He fell three times. A physician was called, who expressed the opinion that he was drunk, and he was taken to the police station. The police inspector insisted that he must have been drunk, as he could not stand. He admitted that blood was oozing from one ear. Death was found to be due to fracture of the skull, and it was thought that the deceased had an apoplectic seizure before he fell.

THE HOSPITALS COMMISSION.

At Cape Town the commission received evidence of the good management of the Rondebosch Hospital at Sterkstrom, but at the Matland Hospital the patients suffered considerable neglect and three were said to have died in consequence. One of the hospital ships was described as filthy, and the milk and food supply as bad. The civil surgeon at the Tuli Hospital complained that the authorities would do nothing. Horses were allowed to die and rot near the tents, and it was impossible to procure the necessary medicine. Three patients, including one Boer prisoner, died in consequence. The food supplied was unsuitable. At Simons Town the commission concluded taking evidence. The treatment of the Boer sick was found to be most satisfactory. The commission left for England on October 10, where further evidence will be taken.

Correspondence.

Druggists and Prescriptions.

October 31, 1900.

To the Editor:—A patient applied to me recently with gonorrhoea, for whom I prescribed methylene blue in a formula taken from THE JOURNAL of June 2, 1900. Of late years it has been my custom to supply these cases with medicine, otherwise I see them no more. Having seen an advertisement of a Philadelphia pharmaceutical house, offering capsules to the profession, made up, practically of the same formula which appeared in THE JOURNAL, but with a less amount of ol. santal and oil of cinnamon instead of oil of nutmeg, with the addition of one drop of copaiba in each capsule, I wrote to the firm explaining how I prescribed for above patient and I probably would not see him again, as he would most likely have the prescription refilled and supply himself and friends, which conjecture I found correct. I asked the firm whether they could supply me with capsules containing the ingredients in any proportion desired—I have no faith in the minute doses of ol. santal and ol. copaiba, and ascribe the whole benefit to the methylene blue. The firm referred to sent me a sample of the capsule, and their price list and in a letter received subsequently they evaded my latter request and instead suggested that I should have my druggist keep a small stock on hand to meet my prescription demand. This very thing I especially told them I wished to avoid. The fact is that I have been almost driven out of practice by the refilling of prescriptions. The practice of physicians in this section has almost been destroyed. My wife overheard one woman telling another in the street that there could be no better doctor than I, but that I always gave prescriptions and that their druggist bills amounted to more than the doctor's; she did not grudge the latter his fee but was robbed by the druggist. A physician who had been trained in a "surgery" in England, in which they

dispensed their own medicines, as an unqualified assistant I presume, settled here a few years ago, and by supplying his medicine drew patients from the other physicians. I feel that I can employ my time more usefully than in the mechanical occupation of putting up drugs and have consequently gone to the wall.

The manufacturing pharmacists to whom I wrote graciously condescended to inform me of the modus operandi of some of the ingredients of their capsules. Is it come to this that a trading firm dares presume to instruct us in therapeutics. No wonder they grow fat while we starve. It has been my practice to write prescriptions. The druggists we had here formerly, when asked to prescribe, referred the person to a physician. Those we have now charge exorbitant prices for prescriptions and tell them they have something better, and even dress wounds. One druggist, I am told, goes from house to house recommending Bland's pills at so much a dozen. Another put up one of my prescriptions in fancy bottles, tagged on his own name and peddled it around the country in a gorgeous wagon. A druggist in a neighboring town got one of my prescriptions which my druggist put up in powders as prescribed at 75 cents, made them up in quantity and sold them to all comers at 25 cents a dozen. From the operation of which causes I subscribe myself,

SLAIN VICTIM.

The Hall of Fame and the Discoverer of Modern Anesthesia.

HARTFORD, CONN., Oct. 30, 1900.

To the Editor:—In your brief editorial in the issue of October 27, on "Physicians and the Hall of Fame," you say it has been suggested that an expression of opinion through THE AMERICAN MEDICAL ASSOCIATION might have some influence and weight even with the laymen of the jury of award.

You say the suggestion is practical and worthy of consideration. With an ordinary jury this is probably true, but the present jury ranks as an extraordinary one, and the outlook for recognition by them of a physician or surgeon seems almost hopeless. Chancellor MacCracken, of the New York University, who appears to have had something to do with the selection of the judges, is reported in the New York *Sunday Herald* of October 14, under the heading "Prejudice of Class and Pride of Locality Influenced the Votes of the Judges," as follows: "The failure of any physician or surgeon to qualify is to me far more interesting, and again it is the chief justices' light vote that caused it. They must all be in pretty good health. I think, and remember the dentist only when their teeth ache. It is extraordinary though that a large class of men regard physicians merely as a necessity."

There are few probably that will care to disagree with the Chancellor in his estimate of the judges, for he says: "The whole matter has been absorbingly interesting and I am finding new things in it all the time." Chicago's distinguished and well-known physician, Dr. N. S. Davis, will remember the action taken by THE AMERICAN MEDICAL ASSOCIATION at its regular session in Washington, D. C., in May, 1870, the New York Medical Society in 1860, the American Dental Association in 1864, the Connecticut Medical and State Dental Association, the Gynecological Society of Boston, Oct. 20, 1870, and other societies of the country in giving expression of their belief from accurate knowledge of facts regarding the discovery of anesthesia, Dec. 11, 1814, by Dr. Horace Wells, of Hartford, Conn.

Dr. Henry P. Stearns, for the Connecticut State and Hartford County Medical Societies, and Dr. James McManus, for the Connecticut State and Hartford City Dental Societies, had circulars printed giving evidence which was sent to the judiciously enough for them to give to the subject careful, judicial consideration. It has been given out that only twelve of the judges voted for Dr. Wells. It would look as though the others either "willfully or even ignorantly" failed to recognize or appreciate the one great event of the century, when they spurned the name of the American who, as Lecky in his "History of European Morals," said, "has done more for the real happiness of mankind than all the philosophers from Socrates to Mill."

JAMES McMANUS, D.D.S.

American Diplomas in Australia.

SYDNEY, AUSTRALIA, Oct. 4, 1900.

To the Editor:—I enclose a clipping from one of our daily papers; such clippings and those who come out with diplomas from such schools (?) give our country rather a poor name here. The Medical Board of Queensland declines to register American diplomas unless certified to by an examination in Sydney or Melbourne University, and gives as reason of such requirements, that there is great uncertainty as to the value of an American diploma and great difficulty in obtaining reliable information from the United States.

Again I would wish that THE JOURNAL was in exchange with the *Australasian Medical Gazette*, the journal of the Colonial Branch of the British Medical Association.

Yours truly, P. M. K., Jefferson Med. College.

The following clipping accompanied the above, and is taken from the Sidney (Australia) *Telegraph* of October 3:

VALUE OF AN AMERICAN DEGREE.—The University of Delaware, which has recently been offering the degree of doctor of philosophy to all and sundry in Europe and the United States, would seem to be a decidedly curious institution, judging by its incorporators. They are a dentist, a saloon keeper or publican, and the wife of a carpenter. It is said that the University has no office or recognized home, but under its charter, which is perpetual and enables it to operate in any part of the world, the so-called University can teach dentistry, surgery and the science of philosophy, and can confer degrees of these as well as honorary degrees. What the worth of the degree is can not be stated, except in dollars.

Adirondack Cottage Sanitarium.

SARANAC LAKE, N. Y., Oct. 25, 1900.

To the Editor:—I notice an article in your issue of Oct. 20, 1900, by Dr. E. S. Oliver, which for three months connected with the Adirondack Cottage Sanitarium, but who has no connection whatever with the institution at present. I would like to state that the article in question was written entirely without my knowledge, and I hope it is unnecessary to say that many features of it have not my approval. Yours truly,

E. L. TRUDEAU, M.D.

Physicians and the Hall of Fame.

CHARLESTON, S. C., Oct. 29, 1900.

To the Editor:—Your editorial in issue of October 27, "Physicians and the Hall of Fame," should meet the hearty endorsement of the entire profession, and I trust you will push the matter further. The name of Dr. Marion Sims should in my opinion be foremost in the minds of all. Yours truly,

EDWARD F. PARKER, M.D.

Association News.

The following names were omitted from the complete list of members as published in THE JOURNAL, September 29:

- Pratt, E. L., Winsted, Conn.
- Guthrie, H. R., Sparta, Ill.
- Salmon, W. T., Oklahoma City, O. T.
- Williamson, N., New Brunswick, N. J.
- Rarbour, Philip F., Loutaville, Ky.
- Kesalnger, E. M., Sandborn, Ind.
- Watson, G. H., Bridgewater, Mass.
- Schwab, Leslie W., Chicago, Ill.
- Langdon, F. W., Cincinnati, Ohio.
- Reilly, Thomas F., New York City.
- Carr, A. P., St. Clair, Pa.
- Watson, G. H., Bridgewater, Mass.

The following corrections should also be noted:

- L. D. Mason, Greenwich, Conn., should be Brooklyn, N. Y.
- G. W. Piske, Carlisle, Ind., should be G. W. Pirle.
- R. H. Burkel, Manistique, Mich., should be Omaha, Neb.
- J. M. Jackson, Kansas City, Mo., should be Jabez N. Jackson.
- H. E. Pearce, Kansas City, Mo., should be H. E. Pearce.
- W. P. Sexton, Kansas City, Mo., should be M. P. Sexton.
- Wm. E. Guthrie, Sparta, Ill., should be Bloomington, Ill.
- M. A. Rogie, St. Louis, Mo., should be Kansas City, Mo.

Book Notices.

A TREATISE ON MENTAL DISEASES. Based upon the Lecture course at the Johns Hopkins University, 1899, and Designed for the Use of Practitioners and Students of Medicine. By Henry J. Berkley, M.D., Clinical Professor of Psychiatry, Johns Hopkins University. With Frontispiece, Lithographic Plates and Illustrations in the Text. Cloth. Pp. 601. Price, \$5.00. New York: D. Appleton & Co. 1900.

The production of a work on mental diseases, especially a comprehensive and elaborate one, is one of the most difficult tasks that any author can take upon himself, and yet there are quite a number who are ready to attempt it. The present volume is the latest addition to the literature in this country on this subject, and is a very worthy one. Dr. Berkley has attempted to give an account of insanity in its various phases, largely in the light of modern neuro-psychology. He, therefore, commences with a rather elaborate, though not too extended, account of the cortical histology and modern views in regard to its mechanism. The special pathology of the nerve elements and other cerebral organs are also duly considered. The clinical section of the work, however, is more developed than is sometimes the case with those who have attempted to discuss the subject of insanity in this way, and, in the main, the author's method is a useful and satisfactory one. His classification of mental diseases, a matter which he does not altogether slight, is a very simple one, including only four general groups: 1. Mental diseases without appreciable pathologic alteration of the brain substance, or psychoneuroses. 2. Mental diseases sequential to ascertainable alterations, comprising particularly the intoxications, including antioxiations. 3. Those due to inherited or acquired mental instability, or the degenerative insanities. 4. States of complete or incomplete retardation of psychic and physical development. This classification has the advantage of simplicity and in many respects meets the demands. The specific forms are those generally recognized and enumerated in textbooks. The author's idea of neurasthenic insanities is a comprehensive one, as he includes nearly the whole condition in his treatment of the subject, but this is the principal criticism, if it is really a valid one, that we should offer. Each subject is followed by a more or less complete bibliography of literature, while foot notes are generally omitted. The book is a valuable addition to the literature of insanity, and should be in every alienist's hands. It is very handsomely printed and illustrated, and will undoubtedly meet with favor.

TWENTIETH CENTURY PRACTICE. An International Encyclopedia of Modern Medical Science by Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M.D., New York City. In Twenty Volumes. Volume XX. Tuberculosis, Yellow Fever, and Miscellaneous, General Index. Cloth, Pp. 906. Price, \$5.00. New York: William Wood & Co. 1900.

About half of this volume is taken up with a discussion of tuberculosis in its various aspects, the principal contributors being D. Lartigau, who discusses its bacteriology, pathology and etiology, and Dr. Knopf, who treats of its diagnosis, prognosis, prophylaxis, and treatment. The symptomatology is handled by Dr. H. W. Berg, of New York, and tuberculosis of the skin forms the subject of a chapter by John T. Bowen, of Boston. All of these articles are, as might be expected, up to date, and convey the current, accepted views of the disease. The subject of yellow fever occupies over 100 pages, considerable attention being given to the geographic distribution and

the origin of the disorder, prophylactic measures, quarantine, disinfection, etc., as well as to the pathology, symptomatology and treatment of the disease itself. Other subjects in the volume are snake-bites and mushroom poisoning, diseases of the uvula and soft palate, and the neural and mental defects in children, the latter by Francis Warner, of London, the only non-American contributor. The general index for the whole series takes up about one-third of the book—a total of a little over 300 pages. The series thus completed forms a very valuable manual of general medicine which will probably hold its own for some time to come, and as a monographic work, or rather a series of monographs, will be a work of reference for all times.

THE CARE OF THE CHILD IN HEALTH. By Nathan Oppenheim, A.B. (Harv.), M.D. (Col. of P. & S., N.Y.). Attending Physician to the Children's Department of Mt. Sinai Hospital Dispensary. Cloth. Pp. 300. Price, \$1.25. New York: The MacMillan Co. 1900.

This little volume, from such examination as we have been able to give it, appears to be in every way an excellent manual on its subject. The author's views are clearly expressed, and are in accord with the best thought on the subjects of training and care of children, their education, disorders and defects. For its compass too, it is very full and complete, and we notice little that could be made much fuller without unduly enlarging the book. The book should be in the hands of not only physicians, but of educators and parents as well, and we bespeak it a wide circulation among all these classes.

THE MENTAL AFFECTIONS OF CHILDREN; IDIOCY, IMBECILITY AND INSANITY. By William W. Ireland, M.D., Corresponding Member of the Psychiatric Society, of St. Petersburg. Second Edition. Cloth. Pp. 450. Price, \$5.00. Philadelphia: P. Blakiston's Son & Co. 1900.

This is a recent edition of the work published by Dr. Ireland two years ago, which has already found its place in medical literature, and which was itself really a second edition of an earlier, though smaller volume. No very extensive addition has been made to the present work, though it has been revised and brought up to date. Dr. Ireland is thoroughly acquainted with American work in this line, as indeed every one should be, and his references to American authors are numerous and appreciative. The work will maintain its well-earned place as a standard on the subjects of defective and idiotic conditions in children.

STUDIES IN THE PSYCHOLOGY OF SEX. The Evolution of Modesty, the Phenomena of Sexual Periodicity, Auto-Erotism. By Havelock Ellis. Cloth. Pp. 275. Price, \$2.00. Philadelphia, New York and Chicago: F. A. Davis Co. 1900.

This volume has the distinction of not being permitted to be published in the English language in Great Britain, hence it appears in the German, and its first English edition comes to light in this country. It is a scientific treatise, and as such we do not see exactly how it could be ruled out, though undoubtedly the English authorities recognized the fact that it would be sought for by those who were not scientifically minded, and thus come under the condemnation which we recently gave Kraft-Ebing's work on a somewhat allied subject. The present volume seems much less objectionable in its management of its theme than does that of Kraft-Ebing.

ATLAS AND EPILOGUE OF DISEASES CAUSED BY ACCIDENTS. By Dr. Ed. Golebiewski, of Berlin. Authorized Translation from the German. With Editorial Notes and Additions by Pearce Bailey, M.D. Pages, 549; 40 Colored Plates; 143 Illustrations in black. Price, \$4.00 net. Philadelphia: W. B. Saunders & Co. 1900.

The intention in publishing this book is, as stated in the preface, "to present a systematic description of the sequelae of injuries caused by accidents." "The book is expected to be of interest not only to medical practitioners, but also to students" and "to laymen whose interests are connected with accident-insurance."

According to the German law, all workmen, with few exceptions, are insured against accidents received while at their work. This has been the means of stimulating greatly the study of such accidents and their sequelae, and the author's

experience in this line has been particularly large. There is shown a tendency, at times, to extend the effects of injuries beyond what can legitimately be proved. As, for instance, to associate a carcinoma of the kidney with an accident that occurred seventeen years before; to ascribe arteriosclerosis, dementia paralytica and pulmonary emphysema to accidents.

The previous condition of the patient is sometimes not sufficiently considered, as in the case in which locomotor ataxia is said to have resulted from a simple sprained ankle. The patient was a syphilitic, the sprain due to a mis-step and the ataxia was well marked when he got up four weeks after the injury. It is more than probable that the tabs long antedated the sprained ankle.

The indemnity, or "rente" as it is called, is estimated in percentage of earning power during the time of disablement, and little is said of the time necessary to recover. It would have added to the value of the work to American readers had the time element been more fully discussed. These few points, however, are more than counterbalanced by the general excellence of the work. It is quite unique in its kind, and contains much valuable information. The colored plates are all works of art and the skiagraphs illustrate many obscure points in injuries of the bones, and particularly in injuries of the foot.

The work can be recommended to all who have to deal with accidents and accident insurance.

DISEASES OF THE TONGUE. By Henry T. Butlin, F.R.S., D.C.L., Surgeon to St. Bartholomew's Hospital; formerly Erasmus Wilson Professor of Pathology and Hunterian Professor of Surgery at the Royal College of Surgeons; and Walter G. Spencer, M.S., M.B. (Lond.), F. R. C. S., Surgeon to the Westminster Hospital, and in charge of Department for Diseases of Nose and Throat; formerly Erasmus Wilson, Professor of Pathology at the Royal College of Surgeons. Illustrated with 8 chromolithographs and 36 engravings. Cloth, pp. 475. Price \$3.25. London, Paris, New York, Melbourne: Cassell & Company (Limited), 1900.

The first few chapters on the minor diseases of the tongue and semeiology are poorly written. The English is so badly distorted that it is necessary to re-read many sentences in order to grasp their meaning. We find such expressions as "the cutis vera of the mucous membrane," "either of the three," and such sentences as: "The patient finally died exhausted." "A Prussian soldier had his teeth driven into his mouth by a bullet." "In Green's case the cyst was the size of a small bird's egg at ten years of age." (Just think of an egg ten years old!) "The patient swallowed the next day." "The treatment is such treatment as is good for the cure of the eruption on the skin." These are but a few of the many. Such loose expressions as "the size of an ordinary nut" (peanut or cocoa-nut?), should not be used in a scientific work, nor should a thing be measured in inches and weighed in grams. Some uniformity should exist. However, when we reach the chapters on malignant diseases it seems as if another mind was guiding the pen. The sentences are clear and the words well chosen. A complete mastery of the subject is shown. The author's views on early diagnosis and early treatment of malignant growths are so sound and so forcibly expressed that they should be read by all who are likely to come in contact with these cases. The excellence of the part of the work more than counterbalances the defects of the other chapters, and makes the work a valuable one. A number of good colored plates illustrate well the various conditions described.

A TREATISE ON APPENDICITIS. By John B. Deaver, M. D., Surgeon-in-Chief to the German Hospital, Philadelphia. Second Edition, Thoroughly Revised and Considerably Enlarged. Illustrated with Twenty-two Full Plates. Cloth. Pp. 300. Price, \$3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

The first edition of this book was so well received and is so well known that it is necessary to mention only such changes and additions as appear in this, the second edition. The most noteworthy addition is the chapter on the pathology of appendicitis, written by Dr. A. O. J. Kelly. This covers 120 pages, and is based on a careful and systematic study of the large amount of material placed at his disposal by the author.

The various pathologico-histologic changes are well described and excellently illustrated by numerous plates in color, and black and white, and the work of others in the same line receives due consideration.

The author's views on treatment are forcibly and positively expressed, in a manner born of honest convictions based on a very large experience. His advice to operate immediately in all cases in which an early diagnosis has been made—within the first forty-eight hours—and in which no contraindication exists to operation, will, perhaps, when carried out by the experienced surgeon and with ideal surroundings offer the greatest chance of recovery to the greatest number and is the position toward which most surgeons of large experience lean today. In case operation for any reason is not undertaken, the use of cathartics as a routine treatment is strongly recommended. While it is certainly advisable to have the stomach and intestines thoroughly emptied in acute appendicitis, the indiscriminate and persistent use of cathartics may as unquestionably do harm by keeping up a disturbance of these organs at a time when rest is most desirable. Discrimination and judgment should certainly be exercised.

It would have added much value and interest to the work had the unusually large material been worked up statistically, particularly as regards results and sequelae, such as ventral hernie, post-operative adhesions, etc. The difficulties associated with the task, however, are recognized. The work as it stands is an excellent one and should be read as well by physicians and surgeons. The author's style is clear and forcible, and can not fail to carry conviction.

A TREATISE ON NASAL SUPPURATION; or Suppurative Diseases of the Nose and Its Accessory Sinuses. By Dr. Ludwig Grünwald, of Munich. Translated from the Second German Edition by William Lamb, M.D., M.C. Edin., M.R.C.P. Lond., of Birmingham. With Eight Illustrations in the Text, Two Plates, and One Table. Cloth. Pp. 335. Price, \$3.00. New York: William Wood & Co. 1900.

As the translator says in his preface, this is the only book in our language which deals with its subject in any detail, hence the reason for its translation and its introduction to English-speaking readers. Dr. Lamb has attempted to convey the author's meaning as concisely and clearly as possible and the work will be appreciated by the general practitioner as well as the specialist, for nasal disorders do not always occur within the immediate reach of practitioners devoted to this particular class of disease. The book should, therefore, have rather a wide circulation.

ATLAS AND EPITOME OF SPECIAL PATHOLOGIC HISTOLOGY. By Docent Dr. Hermann Duerek, Assistant in the Pathologic Institute; Prosecutor to the Municipal Hospital, L.J., in Munich. Authorized Translation from the German. Edited by Ludwig Hektoen, M.D., Professor of Pathology in Rush Medical College, Chicago. Circulatory Organs; Respiratory Organs; Gastrointestinal Tract. With 62 Colored Plates. Cloth. Pp. 158. Price, \$3.00. Philadelphia: W. B. Saunders, 1900.

In the present volume, which is one of a series, the circulatory organs, respiratory organs and gastrointestinal tract are considered.

The pathologico-histologic changes which take place in the typical diseases of the various organs mentioned are briefly but clearly described, and most excellently illustrated by the numerous colored plates.

The work will find a valuable place, not only with the student in the laboratory, but with the physician who desires to keep himself informed of the progress made in pathology.

THE MEDICAL DISEASES OF CHILDHOOD. By Nathan Oppenheim, A.B., M.D., Attending Physician to the Children's Department of Mt. Sinai Hospital Dispensary, with 101 Original Illustrations in Half-tone and 19 Charts. Price \$5. New York: The MacMillan Company, 1900.

Dr. Oppenheim's former work, "Development of the Child," is an extraordinary book. No one interested in children can afford to overlook it. That work created somewhat of a furor among educators, and it is but natural that physicians who were acquainted with it should be eager to examine his new work on pediatrics. While this one is not so remarkable from

the medical standpoint as the other was from an educational point of view, still it is a valuable work. It is up to date in every respect, except in treatment, which does not receive sufficient attention. The descriptions of lesions and symptoms are strong. The book is a good one and deserves a wide popularity. We can cordially recommend it to the profession.

Marriages.

HENRY HALPERT, M.D., to Miss Evelyn Morris, both of Scranton, Pa., October 25.

THOMAS W. COOPER, M.D., Brownsville, Tenn., to Mrs. Sarah Dinsdale, De Vall's Bluff, Ark., October 25.

JOSEPH A. HALLANAN, M.D., Logansport, Ind., to Miss Nora Mowers, Fayetteville, Pa., October 21.

ARCHIBALD M. WILKINS, M.D., Delta, Ohio, to Miss Bertha E. Morris, of Hillsdale, Mich., October 23.

H. SOMERVILLE, M.D., Chest Springs, Pa., to Miss Catherine Burgoon, of Ashville, Pa., October 25.

ALAN W. SMITH, M.D., Baltimore, Md., to Miss Alvira Adele Bennett, of Portland, Ore., October 31.

CHARLES S. MANGUM, M.D., Chapel Hill, N.C., to Miss Laura Rollins Payne, of Washington, D.C., October 25.

Deaths and Obituaries.

LOUIS W. READ, M.D., University of Pennsylvania, 1859, a surgeon in the Crimean and Civil Wars, and for 25 years surgeon-general of the National Guard of Pennsylvania, from heart failure, at Norristown, November 1, aged 72.

JOHN G. DAVIS, M.D., major and surgeon, U. S. V., formerly of Chicago, at Manila, Philippine Islands, from Bright's disease, superinduced by exposure in line of duty, November 1, aged 52.

JOHN WINSLOW, M.D., Bellevue Hospital Medical College, 1866, the oldest physician of Ithaca, N. Y., suddenly from heart disease, October 28, aged 65.

WILLIAM T. JONES, M.D., Bellevue Hospital Medical College, 1866, of Pine Bush, N. Y., from neuralgia of the heart, at San Antonio, Texas, September 26.

WILLIAM H. TURNER, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1856, at his home near Keokuk, October 29, aged 66.

DAVID NEWCOMER, M.D., Jefferson Medical College, 1859, at Mount Morris, Ill., after an illness of several months, October 19, aged 70.

AUGUSTUS MUMFORD, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1882, at Kimball, Minn., from typhoid fever, October 27.

WALLACE A. SIBLEY, M.D., University of Buffalo, 1875, at Rochester, N. Y., from organic heart disease, October 28, aged 54.

NATHAN A. DALRYMPLE, M.D., University of Wooster, O., 1877, from angina pectoris, at Pasadena, Cal., October 26, aged 45.

MICHAEL W. KELLHER, M.D., New York University, 1886, suddenly, from poison, at Pawtucket, R. I., November 1.

SAMUEL L. MONTGOMERY, M.D., New York University, 1880, of Concord, N. C., at Apex, N. C., October 26, aged 45.

MATTHEW J. GRIER, M.D., University of Pennsylvania, 1863, at his office in Philadelphia, October 28, aged 63.

JAMES MCNUTT, M.D., University of Iowa, 1874, of Columbia, Mo., at Bowling Green, Mo., aged 71.

JOHN C. MORGAN, M.D., Rush Medical College, 1869, recently at Sioux Falls, S.D.

Light from Bacteria.—The *Lancet* states that pure cultures of the photo-bacterium—which is the cause of the phosphorescence of the sea—can be obtained by placing a fresh haddock or herring in a 2 per cent. salt solution and keeping it at about 7 degrees above freezing. In a few days the fish and all the fluid give off a pale greenish light, made more brilliant by adding a little sugar. The cultures can even be photographed by their own light.

Societies.

Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.

The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.

Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.

Indian Territory Medical Association, Muskogee, Dec. 4-5.

Pan-American Medical Congress, Havana, Cuba, Dec. 26-28.

Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

THE CEDAR VALLEY (IOWA) MEDICAL SOCIETY, at its annual meeting at Waterloo, October 4, elected Dr. Frank H. Cutler, Cedar Falls, president.

THE DALLAS-GUTHRIE (IOWA) MEDICAL ASSOCIATION held its annual meeting at Panora, October 25, and elected Dr. Calvin O. Sones, Panora, president; Dr. Samuel J. Brown, Panora, corresponding secretary, and Dr. William J. Williams, Adel, treasurer.

THE BROOKFIELD (Mass.) MEDICAL CLUB held its annual meeting October 24, at Ware, and was entertained by Dr. Maurice W. Pearson. The following officers were elected: Dr. Charles A. Blake, West Brookfield, president; Dr. Albert H. Prouty, North Brookfield, vice-president; and Dr. James C. Austin, Spencer, secretary and treasurer.

THE MEDICAL SOCIETY OF THE WOMAN'S MEDICAL COLLEGE (Baltimore) held its first meeting of the season on October 23. Officers for the year were elected as follows: Dr. E. F. Cordell, president; Dr. W. Milton, Lewis, vice-president; Dr. Mary N. Browne, recording secretary; Dr. Annie C. Shipley, corresponding secretary; Dr. Jennie N. Browne, treasurer. The President's Address was on "The Lameness of Sir Walter Scott."

THE CORSICANA DISTRICT (TEXAS) MEDICAL ASSOCIATION met at Corsicana, October 23, for its annual meeting. Dr. Benjamin F. Houston, Corsicana, was elected president; Drs. J. W. Price, King Willow and John A. McGee, Rice, vice-presidents; Dr. John B. Clark, Corsicana, secretary, and Dr. William T. Shell, Corsicana, treasurer.

THE MASON COUNTY (KY.) MEDICAL SOCIETY met at Maysville, October 31. Papers were read by Drs. Amos G. Browning, on "Certain Forms of Heart Disease as Conducive to Fatal Toxicemia," and by Dr. A. N. Ellis on "Color Blindness." The society appointed a committee to draft resolutions of respect to the memory of the late Dr. Samuel Pangburn.

THE HARTFORD COUNTY (Conn.) MEDICAL SOCIETY held its semi-annual meeting October 17, at which papers were presented by Dr. Fredrick T. Simpson on "Mental and Physical Culture in High Schools"; Dr. Hermann Strosser, New Britain, on "Anesthesia and Anesthetics"; Dr. Oliver C. Smith, on "Pneumonia"; Dr. George R. Shepherd, on "Intra-Spinal Injections of Cocain"; and Dr. William T. Bacon, on "Ophthalmia Neonatorum."

THE CUYAHOGA COUNTY (Ohio) MEDICAL SOCIETY held an "Appendicitis Symposium" at Cleveland, October 7, at which papers bearing on various phases of the subject were presented by Drs. Guy H. Fitzgerald, Charles B. Parker, Charles G. Foote, Louis B. Tuckerman, and Joseph V. Kofron. The usual contest between the medical and surgical treatment of the disease was waged, and with the usual negative result.

THE PHYSICIANS' CLUB (Chicago) devoted its session of October 29 to matters educational. Superintendent of Schools Cooley spoke on "Manual Training"; Miss Laura W. Sanborn, director of physical training in the Chicago Normal School, read a paper on "Physical Training"; Dr. H. B. Favill, one on "Stages of Development in Relation to School Work"; Dr. Arthur R. Reynolds, one on "Medical Inspection of Schools," and Col. Francis W. Parker, of the Chicago Institute, closed with an address on "Education as a Factor in Pathogenesis." A resolution was passed commending the work of the department of medical inspection of schools.

THE UNION DISTRICT MEDICAL SOCIETY met at Hamilton, Ohio, October 25. Dr. Mark Milliken, Hamilton, was elected president, and Dr. Everett R. Brad, Liberty, Ind., secretary. Papers were read by Dr. John C. Sexton, Rushville, Ind., on "Lumbar Cocainization"; Dr. Harry W. Hawley, College Corner, Ohio, on "Gall-Stones"; Dr. James G. Graff, Trenton, Ohio, on "Amputations in Children"; and Dr. David W. Stevenson, Richmond, Ind., on "The Physician's Success from a Business and Intellectual Standpoint." The address of the president, Dr. Garrett Pigman, Liberty, Ind., embodied a brief history of the Society.

THE VIRGINIA MEDICAL SOCIETY held its thirty-first annual session at Charlottesville, October 23, 24 and 25. After the addresses of welcome, Dr. John N. Upshur, Richmond, delivered an address on "The Mutual Relations of the Public and Profession." The address of the president, Dr. Hugh T. Nelson, Charlottesville, was on "The Functions of Medical Societies in General and the Medical Society of Virginia in Particular." In closing he paid an eloquent tribute to the memory of "Virginia's great surgeon, Hunter McGuire." A portion of the session was devoted to clinical reports, after which the general subject of "Malaria," was opened for discussion by Dr. H. Stuart MacLean, Richmond. Dr. Joseph H. White, Richmond, presented a letter from Dr. William H. Taylor, Richmond, protesting vigorously against the present treatment and payment of medical experts in Virginia, and asking the society to take steps for their relief. He cited several cases in which he had been compelled to go great distances as an expert, and when he had rendered the service required and presented his bill, he was confronted with the statement that "there is no law authorizing the payment of medical experts." The court before which he had testified, the state auditor, and the attorney-general of the state had all assured him of this painful and serious fact. After a protracted discussion, the matter was finally referred to the legislative committee, with instructions to place it before the next legislature and endeavor to secure fairer laws on the subject. The subject of the special-license tax excited considerable debate, but all one side—that it be removed. Dr. J. Beverley De Shazo, Ridgeway, introduced the following preamble and resolution: "Whereas, the physicians of Virginia look after the public sanitation, make self-supporting citizens of diseased paupers, fight down deadly epidemics and do more charity work than all other professions combined; and, Whereas nearly every other state in the United States has repealed special-license tax laws on physicians; be it Resolved, That the medical profession of the state, through its State Medical Society, declares this an unjust law and begs the legislature of Virginia for a repeal of this measure at its next session." The matter was referred to a special committee. Dr. R. Sumter Griffith, Basic City, offered a resolution "that the judge of each county be requested by the secretary of the State Board of Health to appoint as members of the county board, physicians who are members of the county medical society. If no such society exists, then to appoint from members of the State Medical Society," which was adopted. Many papers were read and discussed, after which the following officers were elected: Dr. J. R. Gilder-loeve, Tazewell, president; Dr. John H. Neff, Harrisonburg, first vice-president; Dr. James E. Copeland, Round Hill, second vice-president; Dr. Charles W. Pritchett, Danville, third vice-president; Dr. Landon B. Edwards, Richmond, recording secretary for the thirty-sixth time; Dr. John F. Winn, Richmond, corresponding secretary, and Dr. Richard T. Styll, Newport News, treasurer. The next meeting will be held in Lynchburg, Va., during the fall of 1901, the exact date being determined by the local committee of arrangements.

Vermont State Medical Society.

Annual Meeting, Rutland, Oct. 11 and 12, 1900.

President Dr. M. R. Crain, Rutland, in the chair.

REPORT OF COMMITTEE ON REORGANIZATION.

The special committee appointed last year to report a plan for the reorganization of the society, on a basis of representation from county or district medical societies, presented their report. The plan proposed is essentially that of the Connecticut Medical Society, with modifications similar to those recently embodied in the plan of reorganization of the New York Medical Association.

The committee recommends: the establishment in each county of a county medical society, which shall be a branch of the State Society; membership in the State Society—excepting the present members—to be obtained only through the county societies; the county societies to be composed primarily of the members of this Society resident in the county; in case there is at present a county society in any county, the same may become a branch of this Society; the formation of a county society to be obligatory in all cases where there are ten or more physicians who are members of the State Society; the officers of the State Society and the chairman of the regular committees—and if deemed advisable, the presidents of the county societies—to be designated "The Council": The Council to

manage the affairs of the Society when not in session; each county society to elect annually one "Fellow" for every ten members, and for every additional fraction of more than half that number to represent it in the parent society; "The Council" and the "Fellows" to constitute "The Governing Board," which shall conduct the business of the annual meeting; the officers to be elected annually by the Governing Board, or by the Society, as deemed best; the "Fellows" elected each year, to be the delegates to THE AMERICAN MEDICAL ASSOCIATION; each county society to elect its own officers and enact its own laws, provided the latter are not at variance with the laws of the parent society; one fee—payable to the county society—to cover membership in both the county and the State Society and entitle the member to the "Transactions of the State Society"; the State Society to take on itself the duty of defending all suits for malpractice and all suits in any way affecting the professional status of any of its members, when unjustly brought, and to take cognizance of and prosecute violations of the Medical Practice Act, or of the laws of public health. The report further suggested the advisability of the society creating a fund for the care of the aged among its members, when necessary.

The report was discussed by a large number and much enthusiasm was manifested in the remarks of many of the members. The Society as a whole seemed awakened to the necessity of a better and more thorough organization of the medical profession in the state. The report was accepted, and a special committee, consisting of Drs. D. C. Hawley, of Burlington, George H. Gorham, of Bellows Falls, J. N. Jeune, of St. Albans, W. H. Vincent, of Orwell, and H. D. Holton, of Brattleboro was appointed to perfect the plan, frame new by-laws, etc., and report at a special meeting or at the next annual meeting.

LOCALIZATION OF THE LESION IN PARALYSIS.

DR. M. R. CRAIN, of Rutland, delivered the president's annual address on the above topic, in which he said there are two general divisions of paralysis: atrophic and non-atrophic. In the former there is rapid wasting of the muscles, for the reason that the lesion is situated at the atrophic center, or at some part of the tract between the trophic center and the paralyzed muscles, which being cut off from the center that controls nutrition, waste rapidly. The lesion may be in the brain, the spinal cord, the peripheral nerves, or their nerve roots. The non-atrophic form is caused by a lesion of the primitive motor centers or some part of the tract between the motor and the trophic center, causing paralysis without wasting of the muscles, except from disuse. In all cases of paralysis there occurs secondary degeneration of the nervous tract affected, and the degeneration occurs in the direction that the impulses travel. The diagnosis between the two general forms of paralysis is in most cases easy, unless the lesion is so recent that there has not been time for wasting of the muscles to occur. In most cases of atrophic paralysis, the muscular wasting is so great that a diagnosis can be made by inspection. Where this is not possible on account of the recent date of lesion, or on account of the muscles being small, or deeply covered with fat we can bring to our aid electro-diagnosis. All cases of atrophic paralysis, excepting muscles supplied by the cranial nerves, are caused by lesion of the peripheral nerves, their nerve roots, or the anterior horns of gray matter of the spinal cord. If the lesion is in the peripheral nerves there is sensory as well as motor paralysis, but if the paralysis is not complete, sensation is less impaired than motion. If the lesion is confined to the anterior horns, there is motor paralysis without impairment of sensation.

Atrophic paralysis of muscles supplied by the cranial nerves may be produced by lesion of the trophic centers at the base of the brain, the medulla, and the upper part of the cord, also by lesion of the cranial nerves themselves, or by pressure, from swelling of their sheaths as they pass through their bony foramina. As some of these nerves are nerves of motion only, we may have motor paralysis without impairment of sensation. The non-atrophic paralyzes are always central, and are caused by lesion of the primitive centers of motion in the cerebrum or in the path between them and the traffic centers situated at the base of the brain, the medulla oblongata, or the spinal cord,

Impairment of sensation may or may not be present, according to the location and extent of the lesion.

TREATMENT OF THE EYE BY THE GENERAL PRACTITIONER.

DR. GEORGE H. GORMAN, Bellows Falls, presented the vice-president's address with the above title. The general practitioner should be able to diagnose and correctly treat the common diseases of the eye. There are in the United States, according to the census of 1890, over 50,000 persons who are totally blind, and Vermont has the largest relative number of any state in the Union. Great responsibility rests on the general practitioner to properly care for patients with diseases of the eye, as they are in the majority of cases the first to see them. At the time Credé originated his method of treating ophthalmia neonatorum with strong solutions of nitrate of silver, 10 per cent. of all cases in his lying-in-hospital were afflicted with the disease. At present only .02 per cent. are so afflicted. It is not necessary in general practice to follow this method in all cases, but the silver solution should be used in all suspicious cases. A 1 per cent. solution is generally strong enough. The use of a 1 to 5000 bichlorid solution is also good treatment. One-fourth of all the cases of blindness in the civilized world are due to this disease. All children whose distant vision does not reach a certain standard, or whose near point is abnormal, and all with inflamed eyes or lids should receive attention. Asthenopia or eye-strain is exceedingly common in school children, and its treatment is almost imperative. Hygienic surroundings should receive attention, and all errors of refraction should be corrected. Many functional disturbances of the nervous system are due to strain on the ciliary muscle of the eye, or to an unbalanced condition of the extrinsic muscles of the eyeball, and the correction of these conditions will go far in relieving many cases of neurasthenia, epilepsy or hysteria. Chronic or subacute inflammations of the conjunctiva are too often mistaken for trachoma, which is comparatively rare, here in this part of the country. For these cases strong tannic-acid solution, nitrate of silver solution, and subconjunctival injections of bichlorid of mercury 1 to 1000 are proper. Never use pontics. Hot boracic-acid solutions are nearly always permissible, except in cases of injury and acute purulent ophthalmia, when ice-bags or other cold applications are better.

HEMANIOPIA.

DR. A. S. M. CHISHOLM, Bennington, read a paper with the above title. Nettleship wrongly regards every case of hemianopia as symptomatic of cerebral disease, and does not recognize the functional form. The condition is by no means rare, but its onset is so unexpected, its continuance so brief and its most interesting symptoms so fugacious, that the patient fails to note and the physician to discover one of the most suggestive of morbid phenomena, while brief allusions in the text-books, and scanty notices in the medical journals are all that the most painstaking industry can unearth from the written record. REPORT OF THE RECENT EPIDEMIC OF SMALLPOX IN HARDWICK, VT.

DR. S. E. DARLING, Hardwick, said the recent epidemic was started in the person of a lawyer just returned from Arizona, where the disease was prevailing. He arrived May 25, and went about through the streets and places of business until the evening of May 27. A diagnosis of smallpox was made. He was quarantined until May 30, when a consultation resulted in a diagnosis of varicella by a majority present, and the quarantine was raised. June 8, two cases broke out, and between June 26 and July 1, eight cases more. A modified quarantine was instituted, and on July 31 the State Board of Health officially pronounced the disease smallpox. Much difference of opinion prevailing among physicians and others, Dr. George Henry Fox, of New York City, was sent for. He came, saw all the cases, and pronounced the disease smallpox. A detention hospital was established one mile from the village, and all cases able to be moved were taken there. From July 25 till 31 no new cases appeared. From July 31 till August 16 there were twelve new cases, making thirty four in all, thirty-three of the discrete and one of the confluent form. All cases recovered.

(To be continued.)

New York Academy of Medicine.

Stated Meeting, Oct. 25, 1900.

Dr. J. Riddle Goffe in the chair.

ANALGESIA PRODUCED BY MEDULLARY INJECTIONS OF COCAIN IN OBSTETRICS.

DR. S. MARX read this paper. He said that, in obstetrics, he had yet to record a failure with this method of inducing anesthesia. The only two dangers are sepsis and cocain poisoning. None of his cases had shown any true evidence of cocain poisoning. They had, it is true, exhibited certain symptoms which might have been taken as an indication of its toxic action, but that they were not been proved by the fact that the same symptoms had been noted in control tests in which no cocain had been used; hence, they were due to spinal shock. As the symptoms of cocain poisoning are those of cerebral anemia, and as there is likely to be cerebral congestion during parturition, it is not reasonable to suppose that parturient women would prove specially susceptible to the toxic action of cocain. Many patients suffer from intense headache after medullary analgesia. This can be avoided in many instances by giving the patient 30 or 40 grains of bromid about two hours before the operation. When the parturient woman has become completely anesthetized there is no longer any spontaneous bearing down, but if she is instructed to bring her abdominal muscles into play in order to assist the expulsion of the child, she does so as vigorously as when not anesthetized. He has done versions and forceps extractions in women so anesthetized. The method is effective and safe for both mother and child, though failures will sometimes occur most unexpectedly.

SOME OBSERVATIONS ON MEDULLARY ANALGESIA.

DR. S. ORMOND GOLDAN presented in this paper a report of his observations in 20 cases of general surgery. He recommends the use of an attenuated needle of 14-karat gold. It should have a short bevel. The puncture should be made between the fourth and fifth lumbar vertebrae, and not more than one centimeter to the outside. Vomiting had occurred in about half of the cases, and usually more or less profuse perspiration. About half of the patients had suffered from headache, and two had exhibited more or less persistent rigidity of the muscles of the back and head. In one obstetrical case there had been toxic symptoms. The individual susceptibility of the patient to cocain must be determined just as with morphia. He believes intraspinal cocainization will take its place in surgery, but will be restricted to those cases in which general anesthetics can not, or should not, be administered.

MEDULLARY INJECTION IN GYNECOLOGY.

DR. J. RIDDLE GOFFE read a paper on this subject which will be published later.

DR. A. PALMER DUDLEY said that from an experience with this form of anesthesia in six cases he is far from enthusiastic about it. Two very disagreeable features in his cases had been the involuntary evacuations of the bowels and retching and vomiting. The headache which most of these patients experience seems to be worse than the distress after ether or chloroform. Moreover, the period of anesthesia had been of very variable duration, ranging all the way from 32 minutes to 2 hours and 39 minutes. There was almost always a rise of temperature within an hour. The method seemed to him better adapted to obstetrics than to general surgery.

DR. HENRY C. COE described a typically successful case. The woman, a hospital patient "without nerves," had been subjected to an abdominal section, and had chatted glibly during the whole time. Her condition had been so bad that he felt etherization would have been very dangerous.

DR. EGBERT H. GRANDIN described his unfortunate experience with the method in two cases. They were both absolute failures, though the injections had been given by Dr. Marx. He thought the less we exploited this method the better. The danger of sepsis was an ever-present one. It was well to bear in mind that there was reason to believe that the method was not only uncertain, but that it had already claimed some victims. Two gentlemen who had been at the International Medical Con-

gress had separately and independently assured him of the correctness of the following remarkable statistics, namely: One hundred cases of lumbar puncture with 5 deaths, and anesthesia secured in only 17 per cent.

DR. J. BLOX BOGART described his experience with this new form of anesthesia in 25 cases, covering fairly well the field of general surgery. Since he had made it a rule always to get a fluid tap, and to make the puncture between the third and fourth lumbar vertebrae, and had boiled the cocaine for only two minutes, he had had no failures.

DR. MARX expressed regret that Dr. Grandin should have placed on record those remarkable figures, vouched for only by two unknown persons. What was wanted now was information concerning failures and complications. He thought Dr. Goldman used too large doses of cocaine.

DR. GOLDAN said that he had tried to make his observations uniform by using always 20 minims of a 2 per cent. solution of cocaine. In one case he had made the puncture between the fourth and fifth, and again between the third and fourth lumbar vertebrae, but had failed to induce anesthesia. A few days later, a secondary operation being required, he had had no difficulty in securing complete anesthesia. He had tried to report his cases just as they had occurred, giving failures as well as successes.

Chicago Pathological Society.

Regular Meeting, Oct. 8, 1900.

President Ludvig Hektoen in the chair.

MILK-SUPPLY.

DR. S. E. MUNSON, Springfield, Ill., read this paper, discussing in particular the relation between milk-supply and tuberculosis. The recent literature bearing on the subject was discussed, and the use of tuberculin and the slaughter of cows giving a reaction were advocated.

DR. EVANS spoke of the various measures advocated for the elimination of tuberculosis from herds of cows, and concluded by advising the killing of all tuberculous cows, as has been urged by Virchow.

DR. GEHRMANN referred to the measures taken by the Chicago Health Department relative to the detection of tubercle bacilli in milk. The examination of a general milk-supply for the bacilli has been discontinued, and only the milk from individual cows is tested. The use of tuberculin is always recommended in any case where suspicion is aroused, in preference to the examination of the milk. The detection of pns in milk is considered sufficient evidence on which to condemn it, even in the absence of tubercle bacilli.

GLIOMA OF RETINA.

DR. BROWN PUSEY demonstrated specimens of a glioma retinae. The present agitation of the subject of glioma of the retina undoubtedly is due to the article of Flexner, published in August, 1891, and to the book of Wintersteiner, *Das Neuro-epithelioma der Netzhaut*, published in 1897. In these publications particular attention is paid to the "rosettes" found in such tumors. Wintersteiner described the rosette as composed of cells derived from the neuro-epithelial layer of the retina; the wall of the central cavity of the rosette, he considered corresponded to the external limiting membrane of the retina, with rudimentary rods and cones projecting into the central cavity. Flexner and Wintersteiner, working independently came to similar conclusions, and from these studies suggested the name neuro-epithelioma retinae to replace the term glioma retinae. These conclusions have been accepted by many authorities; others have opposed them.

DR. M. HEIZOG agreed that the tumor consisted of glia cells, and that if blood could be demonstrated in some of the spaces, the picture would correspond to a glioma of the central nervous system.

CASTRATION TUMORS IN SWINE.

DR. H. DUNCAN stated that there is a disease of swine characterized by a tumor or growth, which as a rule appears after castration, occupying the position of the testicle. Similar growths occur, however, in other situations and in the female,

usually on the breast. A trauma of some kind invariably occurs previous to the appearance of the growth. The clinical history of the disease is briefly as follows: About two weeks after castration, at the seat of the castration wound, a swelling appears. The tumor as a rule grows rapidly and in from three to five weeks one or more ulcers appear in the cicatrix. Close inspection shows the ulcers to be the external openings of fistulous tracts from which there is a constant discharge of purulent material; the discharge may be intermittent. Not infrequently the growth acquires enormous proportions as compared with the weight of the animal, and in such cases may drag upon the ground. During the early stages the animal thrives, later it becomes cachectic, loses flesh and dies about twelve months after the inception of the growth.

The histology of the growth is uniform and corresponds to the macroscopic appearance, namely a structureless, necrotic center with an enclosing zone of scar tissue. In sections stained for bacteria the necrotic border is seen to contain numerous organisms, sometimes in enormous numbers. There may be bacilli of varying lengths, threads and cocci. The threads stain uniformly or appear as strings of deeply staining spores or cocci. Some of the threads branch. The disease is not infrequent among the swine herds of Iowa, Kansas and Missouri.

Cleveland Medical Society.

Regular Meeting, September, 28, 1900.

President Dr. Henry S. Upson in the chair.

SMALLPOX OF THE PRESENT EPIDEMIC.

DR. MARTIN FRIEDRICHIS noted that while many cases are very mild, and some of them difficult to recognize, yet that others occur which answer perfectly to the old classic description of the disease. A century of vaccination has established a partial immunity by inheritance, even in those who have not themselves been vaccinated. Another potent cause for the mildness of the disease is the use of the antiseptic method, whereby secondary infection of the skin lesions is usually avoided. While the disease is contagious, he did not think that it was highly so, as he had never seen it spread from house to house unless the people visited back and forth. In one apartment house with four families on one floor, three who had visited each other frequently contracted the disease from one case, while the fourth, which did not associate with the other three, entirely escaped. He had noticed that children who play about the floor seem to contract the disease more readily than adults, and the same is true of the women who scrub the floors in infected rooms. The sudden rise of temperature with headache and backache, followed by the eruption, along with which the temperature falls, make the diagnosis clear. He had seen a number of cases that began with severe initial symptoms in which the disease was afterward very mild, only four or five poeks appearing. In the time of an epidemic every pimple should be looked on as suspicious, if its appearance has been heralded by fever. He gave clear directions for differentiating smallpox from measles, chicken-pox and other eruptive diseases.

DR. O. T. MAYNARD, Elyria, reported a case of long duration, with moderate fever, some disturbance of the general health and successive crops of vesicular eruptions, which had been very difficult to diagnose.

DR. G. SEELEY SMITH asked what the essayist thought of red light in the treatment of smallpox. He had seen a report of 17 cases treated with marked success in Stockholm by this method.

DR. H. W. ROGERS said that the point he relied on chiefly in diagnosing smallpox from chicken-pox was that, in the former, eruption appeared at once all over the body, while in the latter it appears in groups. Speaking of the case reported by Dr. Maynard, he said that the pulse was not characteristic of typhoid, being too rapid, and also that the eruption was too late. He thought the case was one of auto-infection from the intestines.

DR. JOHN L. HESS said that during two years, while serving

as health officer, he had seen some 275 cases of smallpox, and that in a very large proportion of them it was impossible to make a diagnosis in the early stages. Many cases at the onset resemble la grippe. He thought that mistakes were almost certain to arise.

DR. C. L. WEBSTER said that, particularly in children, he had noticed early in cases of smallpox a bright-scarlet rash over the lower abdomen and inside of the thigh.

DR. J. T. SMITH said that the smallpox of to-day must be very different from that of forty years ago, if there is any difficulty in making a diagnosis. While in charge of a small-pox hospital during the Civil War he had not seen cases in which there was any question of diagnosis. The confluent cases that he had seen at that time were very severe, although the mortality was low.

DR. N. C. YARIAN said that he had had a case of undoubted smallpox without the typical eruption. In this case the papules developed a week after the disease began and came in successive crops. They were first vesicular and then pustular. The diagnosis was doubtful until other members of the faculty contracted the disease.

DR. W. E. HART, Elyria, in speaking of Dr. Maynard's case, said that while the pustules looked like smallpox, although they were very small, yet the fact that the fever continued after their appearance led him to exclude smallpox. The case was not isolated and no cases of smallpox arose from it.

DR. CHARLES J. ALDRICH said that it was reported that for the last few years there has been an epidemic of smallpox among the negro cotton-pickers in the South, so mild that many of them have not been confined to the house for a single day. In connection with these cases of smallpox, persons who subsequently handled the bales of cotton coming from the same district contracted the disease. He had seen one case, a boy of 8, recovering from mild scarlet fever, in which there suddenly occurred convulsions and high fever, accompanied shortly by smallpox eruption. This child was completely aphasic for three months, but has recovered.

DR. FRIEDRICHS, in closing, said that the diagnosis was absolutely certain and there should be no doubt in any case. He said we did not have to wait until pustules appear.

DR. WILLIAM H. HUMISTON reported a case of left tubero-ovarian abscess containing a diplococcus closely resembling the gonococcus, and also the colon bacillus. He also reported a case of right pyosalpinx.

SUPPURATIVE CHOLELITHIASIS.

DR. GEORGE W. CRILE reported this case. The patient for two or three weeks had had attacks of pain, both in the right and left sides, and later the right side became perceptibly tender. There was marked leucocytosis and a diagnosis of gall-stones was made. At operation the gall-bladder was found to be so elongated that it extended down to McBurney's point, and was very slender. The tip of the gall-bladder was much distended, and a gall-stone was found therein. It was wedged so tightly as to require crushing before it could be removed. One physician who had seen the case had been misled by the fact that early in the case the pain had been chiefly on the left side. This case showed that there might occasionally be considerable difficulty in diagnosing a case of appendicitis from disease of an elongated gall-bladder, and that pain on the left side does not exclude disease of the gall-bladder.

American Public Health Association.

*Twenty-eighth Annual Meeting, held at Indianapolis,
Oct. 22-26, 1900.*

(Concluded from p. 1171.)

TEACHING OF HYGIENE AND GRANTING OF DEGREES OF DOCTOR OF PUBLIC HEALTH.

DR. WYATT JOHNSTON, Montreal, compared methods of hygienic instruction in vogue in the United States and in foreign countries, with the result that the showing was decidedly favorable to the foreign countries. He inveighed strongly against the looseness of methods in this country by which men are able to secure positions as health officers or as

members of boards of health without having the necessary qualification. Dr. Johnston urged the Association to consider this matter and endeavor to arrive at some standard for a purely hygienic education.

DR. L. P. JONES, Greenwich, Conn., outlined the following scheme for preventive medicine: 1. The endowment of a chair of preventive medicine in each of the leading medical colleges of the country. 2. The establishment of an institute, the members of which should be the incumbents of these chairs. 3. An award of prizes by this institute for essays and discoveries of special merit in sanitary science. 4. Establishment of fellowships for a limited number of advanced students.

DR. JUAN BRENA, Zacatecas, Mexico, dealt with the vice of smoking among youths and offered suggestions as to the means of overcoming it.

REPORT OF THE COMMITTEE ON DISINFECTATION.

PROF. F. C. ROBINSON, Brunswick, Me., presented the following conclusions: 1. Household disinfection after infectious diseases should combine the use of formaldehyde with other means. It can be safely relied on for all exposed surfaces, and these only. 2. Formaldehyde requires moisture enough in the air to nearly saturate it for its most efficient working. 3. There is much disagreement among experimenters as to the disinfection of tuberculous matter. One says a 2 per cent. solution of formaldehyde disinfects it; another, that even a 10 per cent. solution does not. Several say that formaldehyde gas applied as above destroys it; others deny this. Further experiments are needed. 4. Soap is a poor disinfectant, but 1 per cent. caustic alkali, or 20 per cent. carbonate of alkali is efficient. 5. Carbolic acid, less than a 5 per cent. solution, has little scientific value. 6. The cresolates, as used in creolin, lysol and solutol, are safe disinfectants. 7. Alcohol at from 50 to 75 per cent. has considerable disinfecting power, but not at other strengths. 8. Most metallic salts, except those of mercury, have little disinfecting action. 9. Bichlorid of mercury should be used in strength at least 5 to 1000 if tuberculous matter is to be disinfected. A fresh solution is more active than one which has stood for some weeks. The addition of salts does not increase the strength of a fresh solution, but prevents it from losing its strength as rapidly. 10. Bright sunlight kills the tubercle bacillus in a few hours, and, as a rule, pathogenic bacteria keep their greatest virulence only when kept in the dark.

DR. JESUS CHICO, Guanajuato, Mexico, gave some hints about malaria from personal observations, in which he did not think the mosquito was as important a causative factor as had been attributed to it in distributing malaria, but in Mexico he thought the injudicious use of tropical fruits played an important rôle.

REPORT OF THE COMMITTEE TO DEFINE WHAT CONSTITUTES AN EPIDEMIC.

DR. BENJAMIN LEE, Philadelphia, read this report. In the minds of the public at large, and of many of the profession, the word epidemic still conveys an idea of universal atmospheric contamination. This is to be deplored, because, while on the one hand its use inspires an indefinable horror and creates panic, on the other hand it leads to the disregard of the very precautions which are of essential use in restricting the spread of the contagion, namely, those which should be taken in regard to the person and the excreta of the patient, his effects and his immediate environment.

In view of changed views as to the propagation of communicable diseases, the word epidemic has outgrown its usefulness. It has become the means of perpetuating false conceptions, and its official use may be misleading and mischievous. Without attempting any stricter, more comprehensive or more lucid definition of this word, the committee recommended that, as opportunity occurs in all laws and regulations in which certain executive action is made contingent on the declaration by health authorities of the existence of an epidemic, the phraseology shall be altered by omitting the word epidemic, and in place thereof inserting a brief statement of the condition calling for such action, as, for example, "whenever a communicable disease prevails to such an extent, or is

spreading with such rapidity as in the opinion of the board to make it its duty to notify either the general public or the authorities of neighboring towns of the fact that such and such action shall be taken." The report of the committee was adopted, and the committee discharged.

REPORT OF THE COMMITTEE ON NATIONAL LEPROY HOME.

DR. H. M. BRACKEN, Minneapolis, chairman, presented this report. The committee dealt with the desirability of establishing national leprosy in the United States. The records of Dr. Bracken, for certain states, were compared with those of Dr. Hyde. He presumes that Dr. Hyde's figures for Iowa and Wisconsin, 20 each, are estimated. Probably they are not too high. He has taken only those cases of which a history could be given. It is probable that the 120 cases credited to Minnesota are taken from Dr. Hansen's report. It seems to him that this, too, must be an estimate. If there were 120 cases in Minnesota, the speaker can not understand why they are not on his records of 61. If there were that many cases in 1888, the number for Minnesota is much higher than he has given, for many of the cases in the official list can not have possibly belonged to Dr. Hansen's 120. It might appear from the report of cases in the Northwest that leprosy was far more common in Minnesota than in the neighboring state. He can see no reason for this belief, for the lepers in this district are among the immigrants from Norway, Sweden, Iceland and China. These people have quite a representation in all this group of states. He can only attribute the more complete returns for Minnesota to the fact, 1, that there has been less agitation against leprosy in this than in some of the neighboring states; 2, that with this lack of agitation against leprosy physicians report their cases more willingly to the state board of health, which has endeavored during the last twenty years to palliate the sufferings of this unfortunate class; 3, that Minnesota is fortunate in having among its physicians men who are familiar with leprosy, and who are interested in philanthropic work, and these physicians have given material aid to the state authorities engaged in securing a list of all lepers in Minnesota. Several lepers in the Minnesota list give the history of a previous residence in Wisconsin, but their names in not a single instance appear on the Wisconsin records. Of the 37 living lepers known to be resident in the Northwest, 17 only are in Minnesota, and there is a strong possibility of 2 of these being dead, but he has no positive knowledge of the fact. He does not dwell on these facts as an alarmist, but simply reminds the Association that leprosy has existed, does exist, and will continue to exist for years to come in all three countries represented in the Association.

A leprosarium should afford a comfortable home for lepers. This means, not only good buildings, but extensive grounds comprising many acres, where the lepers may have liberties and still be in exclusion. The buildings connected with the leprosarium must combine the privileges of a home and of a hospital. Those who have the disease in mild form may need little if any medical care. They need comfortable clothing and good food. With those in whom the disease is more advanced, the care should be that of a hospital patient, with medicines to lessen their suffering and dressings that would commend themselves to any surgeon. A leprosarium should resemble modern colonies for epileptics. It should furnish employment for those who are able to work, and amusement of various kinds for all. Two of the strongest medical societies in Minnesota have placed themselves on record as favoring the establishment of a national leprosarium, also the American Dermatological Association has appointed a committee to determine the best methods to be used in the care of lepers.

By resolutions the Association placed itself on record as favorable to the establishment of national leprosy.

DR. JOHN H. S. FULTON, Baltimore, described a suitable dress for defense against infectious diseases.

REPORT OF THE COMMITTEE ON ANIMAL DISEASES AND ANIMAL FOOD.

DR. D. E. SALMON, Washington, D. C., chairman, urged the importance of careful observations being made of glanders, in

view of the fact that serum for use in the treatment of many human ailments is obtained from horses. Army horses are peculiarly liable to contract the disease in time of war, on account of the extra exertion and frequent lack of full rations during such periods. He criticized the government for not providing skilled and trained veterinarians in the army. He discussed the subject of hydrophobia, and emphasized the importance of active measures looking to the extermination of this disease. He cited statistics of many outbreaks of rabies, and showed the disease to be peculiarly virulent and almost invariably fatal to human beings. Misguided people, who declare there is no such thing as hydrophobia communicated to man from animals, were sternly rebuked. Dr. Salmon declares that their obstructive tactics have wrought incalculable harm in the way of deceiving people into a careless attitude toward this malevolent disease. The Pasteur treatment was highly commended by the committee, which also recommended that the Association take steps to enlighten the public on the disease and its treatment, as well as means for its prevention.

TUBERCULOSIS.

The committee made strong recommendations on the subject of tuberculosis, asserting its belief in the theory that the disease can be and is communicated from infected cows through their milk. Here also the committee encountered learned men who controverted the theory, asserting that the difference in appearance of the bacillus of human tuberculosis and that of bovine indicates that the latter can not communicate the disease to human beings. Bovine tuberculosis is undoubtedly communicable. He inveighed against loose methods prevailing in many creameries by which the milk received from an infected herd is mixed with the general supply of milk on hand; and further, the practice of distributing, without previous sterilization, the waste milk and cream to be used as food for swine was condemned.

President Bryce added a few vigorous utterances on the subject of the care which ought to be employed in dairies to guard against the distribution of milk infected with tubercle bacilli.

DR. R. M. WOODWARD, Washington, D. C., gave a résumé of the recent foreign work of the Marine-Hospital Service.

DR. F. F. WESBROOK, Minneapolis, reported, on behalf of the Committee on Transportation of Diseased Tissue by Mail, recommending that nose and throat specimens be included in one package.

DR. CRESSY L. WILBUR, Lansing, Mich., presented the report of the Committee on Demography and Statistics in Their Sanitary Relations. He mentioned the progress that has been made in matters relating to vital statistics concerning which the Association had acted in the past. He urged the Association to stand for united and determined action in elevating the standard of registration laws in this country, and in insuring the practical success of new laws when enacted.

The following resolutions were introduced, discussed and adopted:

1. RESOLVED, That the Association, recognizing the benefits of medical school inspection, heartily approves the efforts of boards of health and of education directed toward the establishment of systems of inspection. (Offered by Dr. Adolph Gehrmann.)

2. RESOLVED, That the Association approves of and encourages all efforts made by governments, whether national, state or municipal, for the limitation of pollution of streams. (Offered by Mr. C. Monjeau.)

3. RESOLVED, That a committee of three be appointed, to be known as the Committee on Uniform Municipal Statistics, to take such steps as may seem practicable toward securing greater uniformity in all branches of municipal accounts, reports and statistics, and particularly those branches relating to vital and sanitary statistics; said committee to have power to confer with similar committees from other societies already or hereafter appointed to the same general end, and to report at the next meeting of the Association. (Offered by Dr. Leal, of Paterson, N. J.)

SECTION ON BACTERIOLOGY.

The Section on Bacteriology and Chemistry met at the Pathological Laboratory of the Central Hospital for the Insane, Dr. Theobald Smith, Boston, in the chair.

TUBERCLE BACILLUS IN MILK.

DR. H. L. RUSSELL, Madison, Wis., showed the degree of heat which is necessary to destroy the tubercle bacillus in milk without injuring, commercially, the value of the milk. He also read the report of the committee on the bacteriology of milk in its sanitary relations. As illustrating the peculiar way by which such germs find their way into milk, an incident occurring in an hospital at Leeds, England, was related. The nurses in that institution were in the habit of taking glasses of milk from the pantry up into the sick wards several hours before the milk was drunk. An outbreak of typhoid fever occurred among the nurses. Investigation disclosed the practice to which they had been resorting, and when it was ordered discontinued, the epidemic subsided.

DIPHThERIA DUE TO MILK.

DR. V. A. MOORE, Ithaca, N. Y., related a diphtheria epidemic started in that city from milk delivered by a dairyman whose family had suffered from acute tonsillitis. The eldest son, who attended to the milking of the cows, has been pronounced well and resumed his regular work, but scientific investigation demonstrated that he still had germs of the disease in his system.

The following officers were selected for the ensuing year: President, Dr. Benjamin Lee, Philadelphia, Pa.; first vice-president, Mr. Rudolph Hering, New York City; second vice-president, Dr. J. N. Hurty, Indianapolis; secretary, Dr. Charles O. Probst, Columbus, Ohio; treasurer, Dr. Henry D. Holton, Brattleboro, Vt.

Buffalo was selected as the place for holding the next annual meeting. The executive committee recommended that the time be fixed during the third week in September, 1901.

Whites of two eggs	
Sodii chloridigr. xxiv	15

M. Sig. Irrigate the rectum thoroughly with a warm normal salt solution, then give the enema by means of rectal tube or rubber syringe.

—Hunter Robb.

The *American Therapist* contains the following therapeutic measures other than medicaments as given by Johnson in the *Therapeutic Gazette*:

1. Instead of pilocarpin, which is dangerous, use the hot pack, steam or vapor bath, or hot-air bath, in beginning influenza or threatened eclampsia.
2. Instead of atropin and camphor or belladonna ointment to "dry up" the secretion of milk, bandage the breast and massage.
3. Instead of giving opium in acute pleurisy, strap the affected side.
4. Instead of giving ergot for hemoptysis, try intermittent cold applications, sucking of ice, dry cups to the chest and absolute rest and morphin.
5. Instead of rectal injection of chloral and the giving of bromids for convulsions in infants, try cold to the head, the warm—not hot—bath, the mustard pack or mustard foot-bath, flushing of the bowels or enema. Of course remove the cause if possible. Pressure on the carotid and absolute rest.
6. In threatened abortion plug the vagina.
7. In postpartum hemorrhage pack the vagina with plain sterilized gauze.

Rest in many diseases greatly aids in the restoration of health, absolute if possible, but even comparative rest will do very much.

Marfan, in *Jour. de Méd. de Paris*, considers lactation a contraindication to the following drugs: Opiates, atropin, hyoscyamus, colchicum, arsenic, cocaine, chloral, lead salts which are precipitated by milk, digitalis, ergot, antipyrin, the last three only relatively.

Medicolegal.

Disclaiming to be an Expert Not a Disqualification.—Where the testimony of a witness shows him to be an expert in the matter concerning which he gives his opinion, his testimony, the Court of Appeals of Kansas holds, in the case of Walker vs. Scott, is properly received as that of an expert, although he, for some unexplained reason, disclaims being such.

Compelling Excessive Intercourse Warrants Divorce.—The specifications, in the suit of Gardner vs. Gardner for a divorce on the ground of cruel and inhuman treatment on the part of the defendant, were that he was a man of inordinate lust, to which by threats he compelled submission, which had seriously impaired her health. The chancellor, however, refused to permit her to testify to the treatment of her husband in forcing her to submit on the ground that such an inquiry would be against public policy. He also refused to permit another witness to prove conversations had with the defendant husband on the subject. The Supreme Court of Tennessee holds that both of these rulings were erroneous.

Mental Incapacity to Set Aside Deed.—The first appellate division of the Supreme Court of New York says, in the case of Hoey vs. Hoey, that a person who seeks to have a deed set aside on the ground of mental incapacity in the grantor when he executed it has the burden of showing that, at the time the act sought to be avoided was executed, the disease had reached such a stage as to so seriously impair the mind that the capacity to make a valid disposition of property did not exist. The law, the court goes on to say, recognizes that persons suffering from mental disease may make valid contracts or deeds or wills. If, at the time of the execution of the instrument sought to be avoided, the mental condition was such that the act was the intelligent act of the individual, based on his intelligence and rational judgment, with sufficient mental power to understand the nature of his property and his relations to those who would be the subjects of his bounty, and without prompting to arrive at a determination as to what disposition he wished to make of it, the court is not justified in declaring such disposition invalid. Much more is required than merely to show that the grantor or testator was suffering from a mental disease. There must, the court holds, be satisfactory evidence that the disease had progressed to such an extent that his capacity to contract was impaired.

Province of Boards of Insanity.—The Supreme Court of Oklahoma holds, in the case of Maass vs. Phillips, that an order of a board of insanity adjudging one to be insane has no bearing on his legal mental status. The effect of such an order, it says, is to admit one to the territorial asylum for treatment; and it is not entitled to the faith and credit of a judgment of a court, as the members of such board do not act as judicial officers, but as a special board, clothed with special power only. Again, the court says that such an order amounts to no more than the expression of an opinion by any other person or persons out of court as to the mental condition of a defendant's mind, except where the right of the officers of the asylum to confine and treat such person is called in question, or in other cases of a kindred character which fall within the spirit of the law authorizing such finding by the board of insanity. The boards of insanity are special boards created by law for a special purpose. It was only intended to clothe them with the power to determine who should be confined in the territorial asylum for treatment, and they have not the power to fix one's legal status (that is, to declare one to be, in law, sane or insane), and the fact that probate judges are made members of these respective boards changes not the rule. When a probate judge acts in this capacity, he acts as another member of the board, and not as a probate judge or as a probate court. It is the kind of an order adjudging one to be insane which the Oklahoma statutes vest authority in the judge of the probate court to make in certain cases, after a full hearing, sitting as a probate court, the supreme court adds, that the authorities refer to as being entitled to faith and credit, and not to the orders of ordinary boards of insanity.

Communications to Physician in Bastardy Case.—The prosecuting witness and the accused in a bastardy case disagreed as to the date that the first intercourse took place, whether July 15, or August 3. Finally, the latter proposed that witness be examined by a competent physician, and, if the examination disclosed that her pregnancy was of not more than four months' duration, he would regard himself as the author of her trouble and the father of her unborn illegitimate child, and would marry her. This offer was finally accepted, and a reputable physician was agreed on to make the examination. The examination was made, and, in the judgment of the examining physician, it disclosed that the pregnancy was more than six months advanced. To this result of the examination the physician was permitted to testify on the trial. But he was not allowed to testify that during the examination the complaining witness stated to him that the first connection with accused took place, as stated by the accused, on August 3. And this, the Court of Appeals of Kansas holds, case of Clark vs. State, was error. The evidence was excluded on the theory that it was a confidential communication, and therefore incompetent. But a statute making a physician or surgeon incompetent to testify concerning any communication made to him by this patient with reference to any physical disease, or any knowledge obtained by a personal examination of such patient, the court holds, can not be construed to cover such facts as disclosed in this case. The court emphasizes that the physician was not present as the physician of the complaining witness. She was not his patient. The examination was not made for the purpose of treating her for any physical, or supposed physical, disease. She agreed and submitted to the examination for the sole purpose of satisfying the accused as to whether he was the father of the child. She knew that the result of the examination was to be made known to her parents and to the accused before she submitted to it. Under such circumstances, the court holds, statements made by her to the physician during the examination, as to when the first connection took place, could not be regarded as confidential.

Insurantee Not Vitiated by Prescribed Use of Drugs.—One of the provisions in a policy of life insurance, which the Supreme Court of Tennessee had to pass upon in the case of the Endowment Rank, Knights of Pythias vs. Allen, was that if the assured's death was caused or superinduced by the use of intoxicating liquors, narcotics or opiates, then only a pro rata payment should be made on the policy. Under this, the trial judge charged the jury, in effect, that, if they found from the evidence that the death of the assured was caused or superinduced by the use of narcotics, opiates, or intoxicating liquors, and should further find that at the beginning of his illness his attending physician had prescribed such narcotics, opiates, or liquors in moderate doses, and that he continued to use the same in moderate doses, under the advice and prescription, but not beyond the directions, of his physicians, such moderate and prescribed use would not be a violation of the rules, regulations, and by-laws of the insurer. He also charged the jury that the insurer was liable on its policy even if it did show by a preponderance of the evidence that the death of the assured was caused by the use of intoxicating liquors, narcotics, or opiates, if the jury likewise believed from the evidence that he took the intoxicants, opiates, or narcotics under the advice of his physician, and in the manner and amounts prescribed by his physician. It was argued that the advice of a physician in the case would be no protection, and that the contract was plain that, if death was caused by the use of narcotics, there could be no recovery. But the view expressed in the instructions stated, the supreme court holds correct, and says is supported by authority. It also holds that witnesses who were not physicians or experts were not competent to give opinions such as that the assured was a wreck "from the use of morphin and liquor," and "that he seemed to be unable to resist the habit longer," or that "he seemed to be a slave to morphin," and that his physical condition was the result of his taking morphin. Moreover, a physician having stated that he prescribed morphin and whisky for the assured, and, in

answer to the question whether he took more than was prescribed, said that he did not know, the court holds that it was incompetent for the witness to add that he "thought he did," this last being a mere conjecture on the part of the witness, and not an opinion based on facts or appearances.

Distinguishes Between Medical and Legal Insanity.—A California statute requires a suspension of the proceedings in a criminal case whenever it is found pending same that the defendant is insane: that he be committed to the state insane asylum, and that the superintendent of the asylum shall send him back as soon as he becomes sane, in order that the court may proceed to trial or judgment in his case. These provisions, the Supreme Court of California says, in re Buchanan, establish nothing new in criminal procedure. They merely put in statutory form a well-known regulation of the common law—a regulation applicable to lunatics or madmen. But here was a man whose trial for murder had been suspended in compliance with these provisions, who was seeking, by habeas corpus proceedings, to be sent back to have his trial proceeded with, when the officers of the asylum strongly insisted that he was not sane, and never could become so. This leads the supreme court to say not only that there is difference, but that it is notorious that there is a difference, between the medical view of insanity and the view on which the statute is founded. And it holds that the question of sanity or insanity in such a case as this is to be determined with reference to the latter, as contradistinguished from the former, view. Continuing, it says that when the rule became a part of the common law, modern views of insanity were unknown. No sort of insanity was recognized except that which manifested itself in mental deficiency or in mental derangement. A congenital idiot or a raving lunatic was understood to be insane, but in the absence of any sensible loss of memory or material impairment of the intellectual faculties a man was counted sane. If he could remember events and could reason logically, he was not within the letter or the reason of the rule which suspended proceedings against a madman or a lunatic because he was disabled by the act of God to make a just defense, if he had one. And, if he was not within the common-law rule, neither is he, the court holds, within the rule of the statute, which merely re-enacts the common law, and has no other purpose than to suspend proceedings against a defendant who is by reason of mental infirmity incapable of making his defense. So, here, it orders the man in question returned to the custody of the sheriff, that his trial may be proceeded with on the criminal charge, the evidence all showing him to be in possession of every faculty requisite to the defense of the accusation against him, his insanity being of a character which does not manifest itself in any apparent weakness of intellect or failure of memory, but may be best described as a sort of chronic and latent disease of the brain, which, under the excitement of intoxicating drink, to which he is predisposed, will lead him to the commission of criminal acts. The court adds that, if, being found not guilty and discharged from custody, it is thought he should be put under restraint as a person dangerous to be at large, the law affords the means of having that fact adjudicated in a proper proceeding.

AMERICAN.

2. Massage of Seminal Vesicles.—Eastman notices the difficulties of stripping the seminal vesicles, a practice which has come to be regarded by many as a valuable method in the treatment of chronic vesiculitis. The average finger is unable to reach more than a portion of this organ and he, therefore, has invented a thimble, imitating in its form the bent finger,

by which all portions can be reached and pressed. He has used these instruments for several months in a considerable number of cases and has had good results. Of course, they will be serviceable only in chronic cases, and should not be used until a careful examination has been made with the finger alone to ascertain the state of affairs.

3. **Fracture of the Nose.**—De Blois describes conditions met with in fracture of the nasal bones, showing how frequent the accident may be and how it may be remedied. There is more apt to be dislocation than fracture; the nasal bones become separated at their internal borders from the nasal processes of the superior maxillaries and take false positions. The most important treatment is reduction of the dislocation, and if injury is recent this is easy. Sometimes, if the patient is frequently seen and is ordinarily quiet, apparatus can be dispensed with after the fracture has been reduced, but otherwise, if the septum bulges or one side of the nasal bone shows a tendency to slip inward, an internal splint should be introduced on that side. External splints, well padded, will be found useful when the bone border has a tendency to slip outward, and also to protect the reduced dislocation or hinder second displacement. He gives an account of several cases showing how this accident occurs and how it has been remedied.

6.—See abstract in THE JOURNAL of October 27, p. 1104.

7. **Alum Baking Powder.**—Smith has experimented on two healthy young men with bread made with alum baking powder and control-bread without it, using a test meal in each case and examining for total acidity, total hydrochloric acid, free hydrochloric acid, combined hydrochloric acid, and the pepsin test. The results in the two cases have been only such as would be likely to occur under any circumstances between the tests and varied alike after using the alum baking powder bread and the control-bread. The amount of bread used each time was 60 grams, which has been found to be most beneficial for stimulating gastric secretions; he considers it a fair amount. A more elaborate experiment was undertaken to determine whether the baking-powder bread was absorbed from the alimentary tract to the same extent as the control-bread and whether in the process of digestion and absorption there was evidence of any disturbing influence. The procedure was based on the method for determining the coefficient of availability of the constituents of the dietary. An individual was given a definite diet for a certain period of time—in his experiment, three days—and from the amount and composition of the food eaten and the stools separated it was determined how much the body had gained from the diet. By comparison with a control period under precisely the same conditions it was possible to conclude from his experiment whether or not the baking-powder bread was utilized by the body to the same extent as the control bread. The inquiry further included a study of the urine during each period to determine the nitrogenous waste and the relative amount of the products of putrefaction absorbed from the intestine. The subject was a healthy man, who had slight dyspepsia sometimes, but under ordinary circumstances had normal digestion. The diet during the experiment consisted exclusively of bread, meat, milk and butter. He gives the details of the experiment. It was found that the availabilities of the diets in the two periods are practically identical, agreeing as closely as can be expected from duplicate experiments on precisely the same diet. The conclusion reached by the author from these experiments is that food prepared by the use of a so-called alum baking powder does not interfere with secretion in the stomach, and that, even when it makes up the major part of the diet, it is utilized by the body in the same way and to the same extent as an acceptable control diet. The investigation does not reveal any reason for believing such food at all injurious or unwholesome.

8.—See editorial in last week's issue and also p. 1170.

9. **Transplantation of the Patella.**—Senn reports and illustrates a case of extensive osteomyelitic defect of the tibia in which restitution of the bony structure was made by transplantation of the patella. The limb appears to be in a useful

position and the patient is able to go about with the use of a cane, though it is hoped that this can soon be dispensed with. The case also shows that we can not rely on transplantation of bone from the lower animals, as this method failed.

10.—See also §129.

13.—See abstract in THE JOURNAL of October 27, p. 1104.

14. **Foreign Bodies in the Esophagus.**—King reports the case of a penny whistle impacted in the esophagus which required esophagotomy for its relief. He describes the anatomical structures and conditions and reviews the possibilities in such cases. Of course the operation of election would be removal through the mouth, but there are cases in which esophagotomy is called in; forcing the object down into the stomach is permissible when the object is known to be smooth and straight and not liable to lacerate the tissues.

15.—See abstract in THE JOURNAL of November 3, p. 1172.

16. **Electric Light in Tuberculosis.**—The value of light always has been recognized and Freudenthal gives special attention to the effect of electric light in laryngeal tuberculosis, reporting cases. He was induced to try this method by a patient who claimed great benefit from transillumination of the larynx made for diagnostic purposes, and while his expectations have not been entirely fulfilled in this kind of treatment, he believes that it is valuable and will be perfected. For the last twelve months he has been trying to have a more perfect apparatus made for light treatment of lung tuberculosis, but has not as yet succeeded. At present, however, he is able to say that we have in the chemical rays of electric light a healing power which promises to be of the greatest value in the near future. Although his attempts at treating tuberculosis of the lungs by this method are encouraging, he is not yet prepared to report upon them.

17. **Preliminary Treatment for Intra-Nasal Operations.**—The importance of preliminary treatment before operating on the nose is emphasized by Seiler, who describes the methods. What he calls the natural method, or as some patients have described it, drinking through the nose, is easily taught, easily learned and is efficient without being harmful. It consists in placing two ounces of blood-warm Seiler's solution in a small tumbler or cup, and placing the end of the nose within the rim of the tilted vessel until the liquid enters the nostrils, closing the mouth, and then, by a moderate inspiratory effort, drawing the solution into the nose and nasopharynx, thus bringing it in contact with all the parts of the nasal mucosa. The vessel should then be quickly removed and the liquid within the nasal cavity blown out through the nostrils at once and the process repeated until the vessel is emptied. The solution which he uses is that of his antiseptic pastil, which he says at present is not made accurately by manufacturers according to his formula, and he has therefore requested them not to use his name with it, as has been done. The cleansing process thus applied should be continued by the patient, while local applications of mild astringents and alteratives to the mucous membrane of the anterior and posterior nasal cavities are made by the surgeon at intervals of a day or two. The solution which he prefers is the iodine solution in glycerin (iod. met., gr. viii; glycerin, ℥ss; potass. iodid., gr. xxiv). This is best applied by pledgets of cotton on the end of a delicate armed applicator, which should be carried through the nostrils along the lower meatus, which manipulation should be executed as gently as possible. Cocain in any shape or strength of solution should never be used within the nasal cavities except as a local anesthetic for minor operations. The habitual use of the drug has a relaxing effect, inducing slow repair of the injuries. He takes up the preliminary treatment in cases for operation for several weeks until the mucous membrane becomes comparatively healthy. In cases where on one side there is atony, or cartilaginous projection occludes one of the anterior nasal chambers, while the other is the seat of atrophic changes, stimulating astringents such as zinc sulphate, etc., should be employed until a reaction from the atrophic condition has taken place.

18. **Diagnosis of Appendicitis.**—The point made by Robin is the blood-count in which the leucocytes will show an addition, sometimes within twenty-four hours. He asks what other means we have for diagnosing suppurative appendicitis, and answers, "Unfortunately, none." What we are able to diagnose is purulent peritonitis, but that does the patient very little good. We may occasionally detect a walled-off abscess, if it points externally, but this is rare. It is rational, therefore, to use a frequent blood-count in cases of appendicitis, and he maintains that this is almost imperative. It is true that sometimes fatal toxemia comes on so rapidly that no increase of leucocytes foretells it, but this is not the rule.

20. **The Consumptive Poor.**—Meyer makes a plea for the erection of state institutions for the care and treatment of the consumptive poor. He reviews the objections, mentioning that expense is a bugaboo and ought not to be considered. The saving would be in the wrong direction if it was made at the expense of human life. The claim that it will not eradicate the disease is not reasonable, and he asks why we should stop trying to eliminate or prevent it for this reason? He gives statistics showing the inadequacy of present provisions and holds that since the disease is a menace to public health, the state should take a hand in attempting its suppression.

21. **Ventral Hernia.**—The operation described by Beck suggests the one reported by Ferguson and abstracted in our last number. However, instead of using the rectus-muscle sheath, he takes a section of the muscle itself. His illustrations are intelligible and fairly explain the operation.

22. **Excision of the Ovaries.**—Harris pleads for conservatism in sparing the ovaries in operations for diseased tubes, and divides the operation for abolition or removal of the tubes into two general classes: One in which more or less of the tube is removed by cutting it off, which he calls amputation of the tube, and the other embraces the performance of complete removal of the tube, which can be effected only by an encircling or elliptical dissection around the tube and into the uterine mucosa. The incision in the wall of the uterus is then sutured. This he calls excision of the tube. Amputation alone does not, he thinks, destroy the function, and pregnancy may follow. It is probable in many cases that the short tubal stump forms a new ostium. He is satisfied that it would be better in the majority of cases to dissect away the diseased tissues around the ovaries and save these organs, or at least part of them. He himself has abandoned the practice of removing the ovaries with diseased tubes.

23. **Rest in Pulmonary Tuberculosis.**—The advantage of rest in pulmonary tuberculosis is insisted on by Edson, who points out the dangers of bringing about inflammatory action by exercise. The most important physiologic reason for insisting on rest in pulmonary tuberculosis is, he says, the influence of bodily exercise in increasing the temperature. Not only our physiologic knowledge, but clinical experience shows that the surest way of reducing the fever of pulmonary tuberculosis is by prolonged rest in the open air, that is, as nearly complete bodily quiet in the recumbent position as can be had. The additional tax on the circulation and respiration, especially in thinner air or higher altitudes, is all the work it is well to ask of the consumptive at first. If the patient adds to this a further call for muscular exertion the task is over-great. He gives as an illustration one case out of many showing the contrasted action of rest and muscular exertion under these circumstances. The objections offered to the treatment are the irksomeness, which he thinks is fallacious, and the possible interference with digestion and elimination, which he also considers ungrounded. Any signs of intestinal stasis are more easily remedied than the harm from extension of tuberculous disease induced by over-exertion.

25. **Congenital Dislocation of the Hip.**—Bradford advocates opening the joint and spreading the capsule in such a way as to free the acetabulum, inserting the head of the femur, stretching the capsule over and sewing it to the tissues around the neck. He advises osteotomy in cases in which there is a

twist in the neck of the femur or an anterior obliquity of the plane of the acetabulum, as it remedies the condition. The cases operated on in the last year or so are encouragingly successful.

26. **The Coroner System.**—Abbott is in favor of the abolition of the coroner system, which, he thinks, is a hindrance to medical progress. He reviews the conditions existing in different parts of the country, in the main accurately, as we suppose, though he errs in regard to Illinois when he says that coroners are there appointed by the governor.

27. **Autopsies and Physical Examinations.**—This paper is written by a lawyer. The point on which he insists is the necessity of thorough examinations, instead of mere satisfaction as to the immediate cause of death. The autopsies, at least the correct and careful ones, can be made but once, and it is only by careful observation that all theories can be met and all questions answered, and this may be of the greatest importance to the state and to accused parties. In conclusion he makes some remarks in regard to physical examination of the living and the partisanship of experts.

30. **Congenital Tumors of Childhood.**—Riley reports the case of an extensive tumor of the abdominal wall which, she thinks, may be called a lipoma telangiecticum, and reviews the general subject of congenital growths.

37. **Compound Fractures.**—Senn's address treats exhaustively of the subject of compound fractures, reviewing the old and the more recent methods and statistics, the etiology, diagnosis, pathology, prognosis and treatment of these accidents. The treatment of the wound is far more important, he says, than that of the fracture, and especially during the first two weeks. The utmost care should be taken to render it aseptic in these cases. The dressing should be changed as little as possible. In case the wound should become infected, as shown by the rise of temperature after the first twenty-four hours, every stitch must be removed and drainage established wherever it appears necessary. Moist antiseptic compresses must take the place of dry dressings and frequent antiseptic flushings are indispensable. Antiseptic irrigation should be preceded by hydrogen peroxid and, if suppuration does not yield promptly to this treatment, continuous irrigation with mild antiseptics, such as Thiersch's, should be employed, which may save life. For further details the reader is referred to the article itself.

38.—See abstract in THE JOURNAL of October 3, p. 975.

39.—Ibid.

40. **Renal Calculi.**—Harris' article is largely historical, reviewing the facts and literature, also giving the symptoms, diagnosis and treatment. He holds that almost all renal calculi are microbial in their origin; the division into bacterial and non-bacterial will not stand the test. He describes the operation of nephrolithotomy. Other treatment is practically useless. There is no medical treatment unless it be symptomatic.

44. **Hearing After Operations.**—Wagner discusses the possibility of damage to hearing before and after radical operations, its tone-limits, hearing-duration, tone-education, etc., and concludes that when diseases in the ear have progressed to such an extent that all symptoms indicate the necessity of operation, the hearing power is reduced so that it will be affected to only a very small degree by the operation. The state of hearing occupies only a second place in the indications for operation, though in doubtful cases it may be that the expectant treatment will be desirable and useful.

56. **Diet in Acute Pneumonia.**—The theme of this paper is the special indications as regards feeding in acute pneumonia and a protest against over-feeding. The author thinks that pushing the nourishment has become with many the leading indication and the fact that adynamia is a result of systemic poisoning and not of exhaustion has been lost sight of. The full stomach aids in embarrassing the already labored breathing and also may produce flatulence as a result of fer-

mentation, making a very serious complication. We should restrict the diet in pneumonia, according to Smith, to the amount that can be easily digested and assimilated under the unfavorable conditions present. The food should be of such a nature that it will not readily ferment. The occurrence of atulence should be met promptly by such medication as to the quantity and quality of food as will reduce the production of gas to a minimum. If other forms of food are not properly digested and assimilated, the substitution of a larger proportion of alcohol is indicated.

57. Treatment of Pneumonia in Hospitals.—Salinger, after remarking on the diet, which should be nutritious and easily assimilated, mentions the symptoms that often require attention. Pain is about the first of these, and can be relieved by local applications, though in some cases opium may be desirable. The early use of blisters is unnecessary, and enesection, while generally abandoned, may be life-saving in some cases, especially in young robust subjects with marked cyanosis, greatly distended right ventricle, feeble pulse and labored breathing. Here the withdrawal of 8 or 10 ounces of blood often materially helps the case. The second symptom is cough, which may be troublesome, but is readily relieved by small doses of opium. The temperature rarely requires treatment; antipyretic drugs are dangerous. If aetnal dyspnea is present the hypodermic use of strychnin is valuable and oxygen inhalations may be useful, but they must be continued for at least fifteen minutes at a time and repeated every two or three hours. Among the cardiac tonics strychnin is perhaps the best and may be given either hypodermically or by the mouth. Alcohol as a routine treatment is not necessary. It has its value in asthenic and alcoholic cases, but may be harmful in others. Heart failure is best controlled by strychnin, digitalis and the nitrates. When there is evidence of contraction of the peripheral circulation, nitroglycerin pushed to its physiologic effects often reverses the fatal issue, sulphonal and trional are the best drugs for insomnia; hyosine hydrobromate is of use in some cases. The salts of ammonia are useful in the stage of resolution and normal salt solution under the skin is indicated when the tendency to collapse is marked. Tonics are often required during convalescence, but recovery is usually rapid. In drunkards, active stimulation is necessary; alcohol, strychnin and oxygen are chiefly to be relied upon.

58. Hydratic Measures in Pneumonia.—Barach mentions the advantages of the tub-bath, with a temperature of 5 F., reduced in five to eight minutes to 85, in children. Baths of this kind repeated every four to six hours at the bedside calm the respiration, reduce the temperature, promote sleep, slow and strengthen the pulse and refresh the nervous system. In the interval between the baths he is in the habit of raising the temperature and pulse are high, of using a compress wrung out of water at 65 around the upper portion of the trunk, renewed every hour if necessary. This may keep up the effects of the bath and diminish the need of its frequent repetition. In adult patients the tub-bath is less convenient, but wet compresses wrung out of water at 60, repeated every hour or oftener, if hot when removed usually fill all the therapeutic indications, and together with this he gives frequent draughts of water at 45. He finds this fortifies the patient's resisting power. The frequency of application, temperature, etc., are matters of judgment in each individual case.

76. Arthritis and Tuberculosis.—Tuberculosis and arthritis are rarely combined and Croftan has found in 100 consecutive cases of the latter, i. e., functional manifestations of the uratic diathesis, typical and atypical gout, only one case tubercular infection, while in 300 selected cases of advanced almonary tuberculosis, only 3 showed coincident arthritic manifestations. He recalls his former articles showing that the arthritic taint consists in a tendency on the part of the organism to disintegrate a quantity of nuclein in excess of the normal and that the poisons circulating in the blood of the arthritic subject are the alloxuric bases. He argues that there is, consequently, a tendency to deposit the mineral constituents of the blood in the infected area of devitalized tissue and

to aid in cutting them off from the rest of the body. In this way insufficient pabulum is offered the imprisoned bacilli, their vitality becomes impaired and they are ultimately destroyed. The necrotic tissues are absorbed and of the whole process nothing may remain but a fibrous cicatrix of chalky nodule. When leucocytic activity, a tendency to form concretions and nuclein-katabolism are at a maximum, the probability of invasion by the tubercle bacilli would be reduced to a minimum; therefore, arthritis forms a considerable immunity against tuberculosis. Diagnostically, when we find an increase of the excretion of the sum of alloxuric bases and of uric acid in cases at all clinically suspicious, we may consider it corroborative evidence toward the diagnosis of arthritis. The prognosis is in a measure favorable as regards tuberculosis, but if these are entirely absent in urine, and a low figure for the sum of uric acid and alloxuric bases is found, together with absence of perinuclear basophile granulations from the blood, it may be taken as corroborative evidence in the early diagnosis of tuberculosis.

83. Chromoscope.—Kries describes the chromoscope, an instrument devised by him for detecting color-defects, consisting of a box lined with black velvet in which one side can be turned down nearly to a horizontal. On the opposite side above is a small projection on which is a mounted flint-glass prism with an angle of 60 degrees. A strip of white paper 5 to 10 millimeters broad, is viewed through the prism, one margin of it being brought into the field, and the patient is instructed to select a skein of yarn similar to the color seen, without calling it by name. With this instrument he has detected a new form of congenital violet-blindness previously unrecognized, which he thinks is not rare. In ordinary life such persons are regarded as having normal color perception; it can hardly be noticed that they call violet blue or purple red. He sums up the chief points of his paper as follows: 1. Besides the well-known anomaly in which only two colors are seen, there is another still more frequent anomaly—violet-blindness—in which the remainder of the spectrum is seen correctly, and at least three fundamental color-perceptions must exist. 2. This color-anomaly accords neither with the Helmholtz nor with the Hering theory. 3. The chromoscope is a very convenient instrument for determining the color sense of the macula. 4. The four colors seen in the chromoscope are the fundamental colors for that particular individual. These may differ at different times in the same person if there is disease of the optic nerves. 5. According to their number and location in the spectrum, the congenital color-anomalies with normal anatomical and ophthalmoscopic conditions may be differentiated into two forms, each with two fundamental colors, the most fitting designations for which are: yellow-blue seeing and orange-blue seeing (the red-blindness and green-blindness of Helmholtz, protanopes and deuteranopes of v. Kries, and red-green blindness of Hering), or a form with as many fundamental colors as the normal-sighted possess, which is best designated as violet-blindness, since this is its prominent characteristic, although there is a shortening of the long-waved end of the spectrum, which measured in wave lengths is almost as great as the shortening of the short-waved end—perception of four colors with contraction of both ends of the spectrum. 6. All three of these forms of congenital color anomaly are to be regarded as states of a less advanced development of the color-perception. The latter develops in extruterine life in a way contrary to that in which it is lost in disease of the optic nerve. The three congenital anomalies of color are the three principal stages in the development of the color-sense. Intermediate stages may at times come under observation, but these are very rare.

93. Acute Infections in Infancy.—Abbott notices the infrequency of septic infections in early infancy and accounts for it on the theory that the mother affords the child immunity through milk, protecting it temporarily from the same disease from which she had herself suffered, and that with the cessation of nursing this protection is withdrawn.

95. Lateral Sinus Thrombosis.—The improved prognosis of operations for this condition is noticed by Randall, and he

remarks in regard to the operations that there are three things in regard to which much yet has to be learned, one of which is diagnosis. The clinical symptoms may be strongly indicative in some cases or there may be complications masking their import. The prognosis in virulent infective cases is invariably fatal, as also in the less severe cases occurring in the weak and cachectic. The possibility that infection may dislodge septic particles or admit air-emboli must not be disregarded. In technique rapidity should be of the utmost importance. Jugular ligation is not invariably needful. He advises the thorough removal of all possible infection, hence curetting is probably, on the whole, better than irrigation. Shock should be sedulously avoided by preventing loss of blood, by the use of hot saline solution to maintain the temperature and by rapid and smooth use of the chisel, spoon or rongeur, avoiding as much as possible the mallet. Metastases already formed, even in the lungs, are not always contraindications for the operation, since the secondary foci are generally less virulent and may heal. Brain abscesses should be watched for, especially in the cerebellum. Meningitis alone seems to preclude recovery, and in some cases its symptoms disappear, showing it to have been a purely irritative affection.

96-97. **Glandular Fever.**—Several cases are reported by Griffith which simulated glandular fever and showed the difficulties of positively identifying such a condition. In the cases reported it would seem that influenza was really itself present. Hand reports several cases and concludes that the trouble is of various etiology and obscure as yet as to its pathology, and while the generally existing view is that it is one of the manifestations of influenza, there are cases where this complication and other causes are undoubtedly absent. The designation acute cervical lymphadenitis is, on the whole, better than that of glandular fever.

105. **Treatment of Uterine Retro-Dislocations.**—West recognizes three classes of cases of retro-dislocations: The first class, comprising about 6 to 8 per cent. of the cases, includes those of recent origin, that have existed less than one year. They are without adhesions and can be cured by palliative means such as restoration by bi-manual palpation and injections of bichlorid of mercury and water, and tampons and pessaries. The second class includes those with slight adhesions, which may be easily broken with the finger or may be dissipated by massage when more persistent treatment is required; there is also some promise to the patient from treatment with pessaries. The third class includes the old chronic dislocations without adhesions; these can not be cured by the use of the pessary, nor can they be remedied by plastic operations from below. The great majority of cases, with or without adhesions, form over one-half of all cases which present themselves for treatment, and he reviews the different operations. If there are firm adhesions in Douglas' cul-de-sac, with or without adhesions of the appendages, laparotomy in the median line, followed by uterine suspension, or Alexander's operation modified by anterior or posterior colpotomy, median laparotomy or incision through the internal rings may be required. If it is certain that adhesions to the fundus and tubes exist without other pathologic conditions, it is possible to safely separate these adhesions per vaginam and perform Alexander's operation. In cases of doubtful separation and doubtful condition of the appendages laparotomy in the median line should be performed. The advice to incise through the internal inguinal ring in order to deal with adherent tubes and ovaries does not recommend itself. It is a double operation, more open to the dangers of infection, and the danger from hernia is much greater. The objections to uterine suspension are not valid; they are only so as opposed to uterine fixation. He formulates his conclusions as follows: 1. There is a certain percentage of curable cases of retro-dislocation by palliative means alone. 2. Plastic operations alone will not cure chronic retro-dislocations. 3. Vaginal operations, except as adjuvants, are, as a rule, a failure. 4. The Alexander operation is indicated in all uncomplicated cases of retro-dislocation requiring operative treatment. It is indicated in cases of retroverted, ante-

flected uterus without adhesions. It is indicated in cases of retro-dislocation with adhesions, when normal appendages exist, the adhesions in these cases first to be separated by anterior or posterior vaginal incision.

106. **Pain in Appendicitis.**—Lee finds that in appendicitis, as well as in other abdominal lesions, the pain in the early stages of the disease is of a colicky nature and due to an acute distention of the organ affected; that the greater the distention, the greater the pain. 2. That as soon as the acute constriction or distention has subsided or the obstruction has been relieved, these reflex colicky pains and nausea and vomiting cease, and the pains after this time are of a steady character. They should be described more as a tenderness in the right iliac fossa and are due to the circumscribed peritonitis. 3. That this last-mentioned pain subsides as the disease progresses toward its favorable termination, either by a perforation of the abscess into the bowel or possibly by the absorption of the circumscribed inflammatory process.

114. **Accidents of Syphilis.**—The accidents of syphilis noticed by Pudor include mistakes of diagnosis, non-recognition of syphilis and false diagnosis of its existence. Both of these may be disastrous, as he shows by case histories. The second series of accidents are those of treatment. He says that, with the exception of a few misguided individuals, the profession is uniform in the belief that in the mercurials we have a veritable specific against the virus. The form of mercury and the method of its administration, however, are disputed points. He mentions two ways of administering it, inunction and the internal use of the drug. The former is the one on which he depends as the only proper and satisfactory treatment. The so-called abortive treatment he condemns absolutely because it destroys the possibility of diagnosis at the time. Another accident of treatment is that of not giving the patient severe and explicit directions how to protect his neighbor, and he reports cases illustrating this fact. Nothing should be left for the patient to think out for himself in these cases.

117. **Gynecologic Hot Douche.**—The successful use of the hot douche in pelvic inflammation depends: 1, upon the degree of heat in which it is used. The water should have a temperature of 115 to 125 degrees; 2, the length of time in which it is employed. If it is discontinued before the secondary effect is secured, the parts are left in a worse state than they were before the douche was begun. It should not be discontinued under fifteen or twenty minutes. The longer the operation the better. The posture of the patient is of great importance and he recommends Sim's position, in which the vagina is ballooned out and its folds are obliterated. This is rather inconvenient, but the better efficiency of the position amply repays for all extra trouble. The head of water is important, and he thinks that this is overdone. It should not be over five or six inches above the pelvis. This gives a slow, steady flow of the current without much force, but carries as much heat to the part as two or three times that amount of water. He has invented a fountain syringe for irrigation. It has a double bag with a Y-piece and connected to a common discharge pipe. Each bag, however, is regulated by a faucet and the temperature can be increased or decreased at will.

129. **Cardiac and Renal Disease.**—The relation between cardiovascular disease and renal troubles is discussed by Kelly, who calls attention to the hypertrophy of the heart, the cardiac complication characteristic of chronic intestinal nephritis. This affects the left ventricle and with it we find increased arterial tension and other degenerative changes, showing evidences of embarrassed circulation. The clinical picture, in cases where compensation fails, is that of primary cardiac disorder and it may be important to know whether this is actually the case or whether the kidney disease is the real cause. If, however, we find, in addition to hyaline epithelial casts that albumin continues in the urine in spite of reduction of congestion in other parts of the body, it is probable that there is nephritis, but whether this is of long standing or not is to be determined by the past history. In the early stages of the condition, when the cardiac and renal dis-

orders are discovered before clinical evidences of their existence appear, the prognosis is not bad as regards life-expectancy. The patient should be advised to lead a hygienic, moral and abstemious life. When, however, the circulation becomes embarrassed, the prognosis becomes bad. The dangers to be apprehended are cardiac failure, arterial rupture and remia. The patient should be put under hygienic conditions, should avoid excessive exercise, keep the bowels regulated, favor the action of the skin by using hot baths judiciously, and the diet should be regulated. Large quantities of proteids are certainly injurious. Meat once a day is sufficient, tea and coffee in moderation, but alcohol should be prohibited. If, with the above methods and an occasional saline purge, the symptoms are ameliorated, no medicine should be given, but when the heart begins to flag, Kelly knows of no better remedies than nitroglycerin and caffeine. Only enough should be given to produce amelioration. The amount he suggests is nitroglycerin in 1/100 gr., and caffeine in 3 gr. doses, but more may be required in individual cases. If there is an attack of remia, as shown by headache, nervousness, etc., it is well to restrict the diet to milk and to give large quantities of water, as well as to add saline cathartics and alkaline diuretics. When there is no marked cardiac debility, there are several drugs that should not be given, among these digitalis and stramonium. The latter is valuable in all stages of parenchymatous nephritis, but is not so useful in renal cirrhosis. When marked dilatation is present and compensation fails, digitalis is indicated; but if it is not found of use after three or four days, it should be discontinued and strophanthus substituted. The alternative use of these remedies may also be useful. tryphmin is also another valuable remedy. Other remedies mentioned are the iodids, and mercuric chlorid, but the author does not specially favor their use. See also ¶10.

130. Incipient Tuberculosis.—The early symptoms of pulmonary tuberculosis, with sputum tests, are: First, a dry, hacking cough of the unobtrusive or throat-clearing variety, growing worse as the disease progresses. Next, the temperature. Normal or practically normal temperature after 5 or 6 a.m. is of great diagnostic import. The next is the pulse-frequency and arterial tension, beginning with almost constant acceleration of 10 to 20 beats, with diminished pulse-tension, the pulse not being influenced by the recumbent position. Hemoptysis and the gastric symptoms are also important. The patient has had no experience with the X-ray in diagnosis, but thinks it would be of value only when used by an expert. He has been afraid to use the tuberculin test. Too much consideration must not be given to any one physical sign or symptom; every point that can be brought out must be considered. In the treatment of incipient tuberculosis he lays special emphasis on out-door life and fresh air. As far as the diet is concerned, he would give nitrogenous foods first place in importance. Pulmonary gymnastics are of value, should be frequently indulged in and to the point of respiratory fatigue, he thinks that forced expiration is as important as prolonged inspiration. The wisdom of this, however, is doubted in slightly advanced cases on account of the danger of spreading the foci in forced inspiration. Pulmonary gymnastics with intrapulmonary medical treatment by nebulization under high pressure is a plausible method of treatment. Of the external remedies, eucosote has probably stood the test of time best, but lately he has used ichthyol in its place with better results as regards the stomach. The serum treatment, he thinks, offers more promise for the future than any other, though at present it is not perfected. In no disease is a specific and methodic attention to details more essential. This is the reason why sanatoria have such success.

131. Antipneumonia Serum.—Rosenthal has employed antipneumonic serum apparently with advantage, using it hypodermically in the side of the chest. When the temperature is 103 F. or over, the pulse 140, and the respiration 48 or over he begins with 20 c.c. of the serum, or where the type is more severe, with double this amount, followed every four hours by double the initial injection until the disease is under control, as shown by lowered temperature, slowing of respira-

tion and disappearance of pain and improvement of the pulse and general condition. He thinks that it does not interfere with any other treatment and is itself harmless. It is important to get a fresh and reliable preparation and none of the foreign preparations possess these qualities.

FOREIGN.

British Medical Journal, October 20.

Prevention of Valvular Disease of the Heart in Cases of Acute Rheumatism. RICHARD CATON.—To prevent heart complications in rheumatism stop the disease as rapidly as possible and prevent all aggravation of it by chills. For this purpose rest in bed is of the first importance; salicylates to be given in full dose, often with alkalies, and cholagogues in such measure as to cause free evacuation but no diarrhæa. The diet should be confined to milk and light farinaceous food; no red meat should be allowed for a considerable length of time. If there should be cardiac trouble or a bruit has developed which can be heard in the axilla and the second pulmonary sound becomes accentuated, rest is still more important and should last for five or six weeks at least. He advocates blisters near to or above the joint, and also in the region of the first four dorsal intercostal nerves, to directly stimulate the trophic and vasomotor nerves of the heart. For the removal and absorption of exudates he uses the iodids, usually sodium iodid and sometimes with caution a mercurial. His results in 85 cases during the last fifteen years, have been on the whole very satisfactory; of 54 already having had signs of cardiac trouble 34 of the diseased hearts apparently completely recovered, and only 3 of these in which it did not exist on reception developed it. He sums up the principles of treatment in acute endocarditis into prolonged rest and avoidance of active or violent exertion for several months after the attack and other precautions against another attack of rheumatism.

On the Resting Position of Anopheles. L. W. SAMBON and G. C. LOW.—The authors' remark on the statement which is going around that the anopheles at rest has its body nearly perpendicular to the surface on which it is fixed, and state that the anopheles claviger as observed by them in the Roman Campagna this year, had its body only at a partial angle, and by no means perpendicular. Some other species, however, agree with the common description. The resting attitude of the mosquito has lost this important diagnostic character between the culicx and the anopheles genera.

Oophorectomy in Cancer of the Breast.—Boyd has investigated the subject of the effect of oophorectomy in cancer of the breast and tabulates the cases which he has obtained notes of in the literature. He thinks that the atrophy of cancerous masses after oophorectomy can not be an accident, and it is not due to laparotomy, nor to the use of thyroid. He divides his tabulated cases into two classes: 1, those where it seems to produce a clear or considerable result, and 2, those where it had little or no effect or the effect was dubious. Comparing these two groups he thinks that the average age of group 1 is considerably more than that of group 2, that is to say oophorectomy appears to do the most good in elderly women, contrary to what would be naturally supposed. The cases in group 1 are of more chronic type than those in group 2, and with one exception all the patients certainly past the menopause are included among the failures. As regards the amount of disease present the cases in group 2 are rather worse than those in group 1, though the quantity of superficial disease does not make the difference between failure and success. Wherever it has been evident that viscera and bones have been infected no improvement has taken place in them. On the other hand a very slight amount of disease may be little affected by the operation. The evidences of success appear early. Amenorrhœa, atrophy of the uterus and more slowly of the breasts, are constant phenomena. Unpleasant effects, such as premature aging, grayness, mental changes, etc., seem to be rare. Sexual feelings are usually unaffected. He concludes that oophorectomy should be offered in cases other than the very acute in women over 40, with no visceral or bony lesions, in fair condition and before the menopause. The subject is still in the experimental stage.

Surgical Treatment of Exstrophy of the Urinary Bladder. JOHN BERG.—The conclusions of Berg's paper are as follows: "1. There is yet no method of treatment suitable for every case of exstrophy of the bladder. In selecting a method we must take into consideration the local changes as well as the patient's age, general state and especially the functioning of the heart and the kidneys. In so doing I think we shall meet a certain number of cases where all the circumstances are so extremely favorable for the less dangerous treatment—I mean the direct union—that no other method ought to be thought of, at least not until this has been tried in vain. 2. We are able in a number of cases to create such favorable circumstances—which could not be affected by means of orthopedic measures—by a sychondrosectomy after Trendelenburg or an osteotomy after Berg. The last named operation may have the advantage of a quite reliable osseous healing and of a more easily corrected position of the two halves of the basin. It can be performed on older patients. Trendelenburg puts as the highest age for the operation 8 years. I have successfully osteomised a patient of 15 years. With both these operations the direct danger of the treatment no doubt becomes greater, and thus we are left to make our choice between the autoplasic method and the transplantation of the ureters. 3. I suppose that many surgeons yet prefer the autoplasic method, as probably less dangerous. Personally I prefer, for reasons before named, to recommend the above-described method with single skin flap, covered by Thiersch's plan on its deep surface. 4. Considering the improved technique and the diminished danger which the operation of John Simon in our time has achieved, especially through Professor Magell in Vienna, it seems probable that this operation will be found to supersede other methods in a number of cases. For my own part, I should not hesitate to make use of it in old cases where the bladder is deeply destroyed or the other methods have failed. Though I fully join in Professor Bergmann's opinion expressed two years ago, that our present treatment of this deplorable deformity is far from ideal, I shall believe that the work of the past century even in this field has given us sufficiently firm ground for further labor, and that it would be unwise to make any wide departures from that which has already been gained."

The Lancet, October 30.

The Clinical Study of Heart Disease. NORMAN MOORE.—Moore advises full notes in every case of heart disease, giving what is actually heard or seen without any mixture of hypothesis as to the cause. The habit of determining accurately what we hear should be cultivated and all doubtful or doubting expressions avoided, so far as the evidence of the senses is concerned. Another point is to observe the pulse and compare its results with that of auscultation. In examining a case of valvular disease it is not too much to feel the pulse with close attention throughout three complete minutes, giving the number of beats in a minute in which any inequality or other peculiarity is observed. Another point in examining, is to determine if hypertrophy of the heart exists: it has almost always a morbid explanation. If it is a hypertrophy of the left side it means that valvular disease, chronic interstitial nephritis or adherent pericardium is present. When it is determined, it is to be decided which of these three conditions has produced it. As to the amount of hypertrophy his own experience does not entitle him to go farther than to say that when the apex-beat is in the nipple line and sixth interspace it may be double its natural weight. Dilatation, as distinct from hypertrophy, may be inferred from symptoms, but is rarely capable of being accurately demonstrated by physical signs alone. It may be rapid; he has seen extreme dilatation in six weeks. In most cases of long-standing chlorosis he believes some dilatation of the heart exists. In undoubted valvular disease the cardiac impulse is sometimes accompanied with a thrill. The question is whether this is due to mitral stenosis, to rigidity of the aortic valves, or to aortic aneurysm. The thrill produced from mitral stenosis is never felt except at the apex, but the thrill of rigid aortic valves may be felt there as well at the base and sometimes alone at the apex. The character of the pulse will in such cases prevent error. The systolic murmur of aortic obstruction, and the diastolic murmur of aortic regurgitation,

and the double murmur caused when both defects are present, are occasionally distinct at the apex and more rarely inaudible at the base. The murmur of mitral stenosis is never audible at the right base. The murmur of aortic stenosis is probably the loudest of all; it is the only one he has ever heard at a distance of six inches without contact with the patient's chest. Any systolic murmur which is distinct at the apex may also be heard at the angle of the left scapula, and the great majority of these will prove to be cases of mitral regurgitation. The diastolic or presystolic murmur of mitral stenosis is never heard at the back. Careful auscultation of the back is important, especially in relation to the separation of a group of murmurs in the same heart. If the patient has mitral regurgitation and aortic stenosis, the systolic murmur produced at the mitral and aortic orifices may thus be distinguished in many cases. On the back the mitral murmur will be loudest at the angle of the left scapula; the aortic murmur will often be well marked in right supraspinous fossa. If this systolic murmur is traced down toward the angle of the left scapula it will be found to grow fainter, and then when the angle is reached to be again loud. The aortic stenosis murmur is generally audible in the right supraspinous fossa, where the diastolic murmur of aortic regurgitation may sometimes though less frequently be also heard. It may not be always possible to be sure that both mitral stenosis and aortic regurgitation are present. A distinct thrill confined to the apex will in many cases prove that the presystolic sound is due to mitral stenosis, while an accompanying diastolic murmur at the right base is never due to this and is proof of the presence of aortic regurgitation. Disease of the valves of the right heart are rare. Moore has seen postmortem one case of tricuspid stenosis in which stenosis of the mitral valve was not present. He has seen three cases of stenosis of the pulmonary valves without any congenital malformation or any valvular disease. The characteristic feature of such cases are the congenital murmur, loudest at the left base, and the fact that the pulse is normal and has none of the characters of the disease of the aortic valves or of the inequality common in mitral disease. It may be difficult in early childhood to distinguish the disease of the mitral valve from pulmonary obstruction with a small opening at the upper part of the septum between the ventricles. Careful and repeated examination of the pulse often is the best guide. One of the most difficult things to determine is whether or not there is an adherent pericardium, and Moore thinks the diagnosis can be made with actual certainty only when the mitral stenosis without other valvular disease is present. It is never on its own account, associated with hypertrophy of the left ventricle, and if we have this without signs of chronic interstitial nephritis the hypertrophy is certain to be due to adherent pericardium. The commonest valvular disease in the young is mitral regurgitation, and it is the most hopeful as regards prognosis. In a general way Moore thinks we ought to believe that every case of rheumatic fever is a case of endocarditis, and take the child's temperature four times a day if possible and treat every slight rise in temperature as a fresh attack. When angina pectoris is present, disease of the aortic valves is almost always present. Now and then a severe cardiac pain toward the apex occurs in mitral disease, but lasts longer than true angina pectoris. Aside from angina pectoris, mitral stenosis is of all forms of cardiac disease the most distressing to the patient, and absence of such distress will make it clear that aortic regurgitation and not mitral stenosis is the cause of a thrill and diastolic murmur. In mitral stenosis engorgement of the liver takes place early and often causes much pain. Bleeding from the arm, before a painful degree of hepatic engorgement has taken place, often relieves the heart, and after considerable engorgement of the liver has set in some relief may be obtained by leeches applied over this region.

Bulletin de l'Académie de Médecine (Paris), October 9.

Restoration of Palate, Nose and Lachrymal Ducts. GOLDENSTEIN.—The entire palate process, upper teeth and nose had been destroyed in the patient presented. Goldenstein's prosthesis consists of a part supplying the missing roof of the mouth, gum and teeth, with a second portion applied over the

cavity of the nose, applying an artificial nose and screwing to the portion inserted from below. The average weight of the parts to be supplied is about 66 gm. and this prosthesis weighs 6 gm. less. By an ingenious contrivance of springs the latter is supported by the floor of the nasal fossa, on which spring clamps hold it immovable.

Journal de Médecine de Paris, October 7.

What Fractures are Amenable to Immediate Massage?

LUCAS-CHAMPIONNIÈRE.—The term *gluco-kinesis* has been coined by Championnière to express his method of gentle massage without causing pain, applied as soon as possible after the injury that caused the fracture, with no attempt at immobilization. The repair of the bone and absorption of fluids is much more rapid and complete than with other methods of treatment. The vitality of the parts, suppleness and nutrition are maintained while the pain and contraction rapidly disappear. The fractures that always benefit by this treatment are those of the upper portion of the humerus to the insertion of the deltoid, and of the lower portion to four finger widths from the joint; all fractures of the malleoli with no tendency to displacement sideward or backward; all fractures of the elbow and especially of the olecranon, all fractures of the radius at the wrist without too much retrodisplacement; nearly all of the clavicle; all of the lower portion of the fibula without a tendency to deviation from the axis of the foot; all fractures of the femur or tibia at the knee without displacement, and also all fractures of the scapula. Other fractures which exceptionally justify this method of treatment are those of the middle portion of the humerus and of the two bones of the leg without displacement, and fractures of the two bones of the forearm. In certain other cases massage and immediate mobilization can be combined with the use of an apparatus, but the results are less complete and remarkable than when no apparatus is used. In children mobilization is sufficient without massage, and the latter is also omitted in the aged if the veins are dubious.

Presse Médicale (Paris), September 26 and October 17.

Remote Results of Operative Treatment of Hypertrophied Prostate.

F. LEGUEU.—Hypertrophy of the prostate is taking its place as a primary affection, the bladder involvement secondary to the mechanical interference, with consequent retention of urine. The most rational treatment is the removal of the obstacle. The benefits will be more apparent the earlier the intervention, before the bladder has lost its contractility and before infectious complications have appeared. The excision must be ample, removing all the portions of the gland that are hypertrophied or liable to become so. Suprapubic prostatectomy is sufficient for a limited obstruction, but the lateral lobes can be effectively reached only by way of the perineum, although it is impossible to remove the extravascular protuberances by this route. Legueu suggests that a combination of both routes might be useful, removing the middle lobe by a hypogastric incision and the lateral lobes by the perineal route. He anticipates in the near future the advent of total prostatectomy. Cystostomy is a last resource and merely palliative. Castration is only beneficial when bilateral and done in the first phase of acute retention. Later it proves merely a palliative resource to prevent recurring orchitis and attacks of congestion with hemorrhage, although it occasionally improves the vesico-prostatic conditions. The only benefit derived from vasectomy and its only indication is the suppression of recurring orchitis. These operations on the testes will soon join Battey's method of ovarian castration as a treatment for uterine fibromata, and only survive in history.

Revue de Chirurgie (Paris), October.

Suturing Wounds of the Heart. F. TERRIER.—Two years ago Terrier reviewed the experiences and indications for suture of the heart and pericardium in the treatment of stab wounds. He has since collected twelve new cases, and after carefully studying the methods of incising and suturing and the results of the intervention, pronounces the evidence in favor of Fontan's method of reaching the heart. This is by means of a large flap opening outward, comprising the fourth, fifth and sixth ribs, the nipple in the center, the inner edge just inside the chondrocostal articulations, the lower edge extending

through the center of the space below the sixth rib. The upper edge of the flap follows a horizontal line from the center of the space on the left to the chondrocostal articulation of the fourth rib. This flap, turned outward, can be enlarged at will. The soft parts and cartilages left on the right can be turned back over the sternum. The upper and lower ribs are cut on the axillary line; the middle rib is broken with the hand. This flap can be rapidly cut and enlarged at will. Hemostasis is simple and it is easy to keep from injuring the pleura, but the chief advantage is that it allows the latter to be detached and pushed out of the way. Fontan and Maliszewski seized the bleeding portion of the lung with forceps and left it until after they had attended to the heart wound. This terminated, they returned to the lung, resecting or suturing with catgut, and then attending to the pleura. In suturing the heart a continuous suture seems to be preferable to separate stitches. The pleura, and especially the pericardium, should not be drained, but closed completely whenever possible. Three of the 12 patients recovered. The deaths occurred between the first and twentieth day. Infection was evident in 5 cases, in 2 death was due to extreme loss of blood. Narcosis was induced in 2 of the 3 successfully operated cases. The left ventricle was the seat of the injury in 7, the right in 2, the apex 2, and the left auricle in 1. In each case the pleura had been traversed by the stab and blood was found in it, once as much as 3 liters.

Subpyloric Gastroduodenostomy. E. VILLARD.—In three cases of cicatricial stenosis of the pylorus Villard isolated it and produced an ample outlet for the stomach with none of the disadvantages of the usual gastroenterostomies, by suturing together the stomach and the duodenum where they parallel each other below the pylorus. He first made a continuous suture of the two juxtaposed sides, stopping an inch or so below the arch of the pylorus. Then both stomach and duodenum were incised for the proper distance, the incisions brought face to face and the suture continued around them, thus making a lateral anastomosis. Fine silk was used for the sutures. The incision into the stomach was made on the posterior margin of the greater curvature, not on the front. The benefits were apparent at once in the three cases described. Vomiting ceased and with it the oppression and pain. One patient gained two kilograms in six days, and more than twenty-three in four months. The chemistry of the stomach has become normal even in one case in which suspected cancer and pulmonary tuberculosis are progressing. One case dates from 1897. The indications are cicatricial stenosis of the pylorus, or stenosis of biliary origin in which the mere liberation of an adhesion will not re-establish the lumen of the intestine. He has found the operation very successful in relieving an ulcer of the stomach with hematemesis and uncontrollable vomiting. Thorough lavage and emptying of the stomach is an indispensable preliminary.

Berliner Klinische Wochenschrift, September 24 and October 8.

Treatment of Bronchial Affections by Reclining with the Head Lower Than the Feet.

O. JACONSON.—The benefits of reclining flat and then having the foot of the bed raised are most pronounced in chronic bronchial affections. Jacobson explains the mechanism of the process as the shifting of the secretions by their own gravity from the spot where they have been accumulating to spots where the mucous lining has not become desiccated by long contact with them. When they touch new, sensitive points, reflex coughing is induced and the entire accumulation is coughed up. This method prevents stagnation and putrefaction of the secretions and is particularly valuable in curing fetal bronchitis, relieving the patient for all day. It also renders good service in certain cases of abscess of the lungs, and especially in chronic "cylindrical" bronchogonorrhoea. It is contraindicated in acute bronchial affections in which the mucosa is always hypersensitive, and coughing is incessant. The patients recline for an hour morning and evening, and later only in the morning.

Centralblatt f. Bakteriologie (Jena), September 20.

To Fix Blood Specimens. A glass bell, like a large bottle without a bottom, is placed over the thin specimens of blood on cover-glasses. One drop of formalin is then placed on a

cover-glass fastened to the bottom of the stopper of the bottle, which is then replaced and the specimens left for fifteen to thirty minutes in the fumes that develop. The bell is about 135 mm. in diameter by 150 high.

Dermatologisches Centralblatt (Berlin), October.

Prevention of Syphilis and Sycois in Barber Shops. S. BEHRMANN.—There is little hope that barbers will conscientiously sterilize their instruments and towels to prevent contagion, even if police regulations require it. Behrmann thinks that the better way is for the customer to require him to rub a little mercurial ointment or soap on every spot that bleeds after shaving. Extensive bleeding can be controlled with salicylated gauze or cotton. He recommends carrying some of this salve and gauze to the barber shop for the purpose. Bay rum will destroy the parasite of sycois or herpes tonsurans, and a little gray ointment rubbed into and left on a cut or scratch will destroy any syphilitic infection. This can be done after the return home.

Muenchener Med. Wochenschrift, October 9 and 16.

Commencement of Idiopathic Dilatation of the Heart. E. WOLFFHEGEL.—All the injuries which lead to acute dilatation of the heart have in common an increased pressure in the arterial vascular system and an increase in the heart's action to overcome it. The most frequent cause is an infectious disease, in the largest majority of cases influenza or articular rheumatism. The obesity that follows excessive beer drinking is another cause. Most of the cases of idiopathic dilatation have long been preceded by abnormal heart action, although not sufficient to arouse attention. Marching in uniform, with constricting collars and belts, is an important factor, interfering with respiration and secondarily with the heart action. Under other circumstances the coat is thrown open, the burdens laid down on the first symptoms of oppression, but the soldier is ambitious to keep up and in his place. Excessive exertion is not necessary to tax too far a heart with a congenital or acquired weakness of the muscle. Auscultation and percussion determine, in case of valvular insufficiency, whether it is a regulating process or due to weakness of the muscle. Radioscopy is also an important aid in diagnosing. In general it is best to refrain from taxing soldiers who present evidences of a dilating weakness of the heart muscle during the second year of service, while on the other hand, during the first year it is reasonable to expect that judicious training will strengthen the muscle. If the weakness persists after the first year it is practically irremediable.

Acute Formalin Intoxication. J. KLUEBER.—A healthy man drank a little diluted formalin by mistake. His symptoms resembled those of acute alcohol intoxication, stupor for several hours, anuria for nineteen and congestion of the conjunctivæ and throat, with complete recovery by the third day.

October 16.

Typhoid Cystitis. H. CURSCHMANN.—About fourteen writers have mentioned the occurrence of typhoid bacteriuria in their experience, ranging from 2 to 100 per cent. of all cases of typhoid fever, or an average of 15 to 30 per cent. None mention the occurrence of secondary bladder infection, but Curschmann has recently had occasion to observe three cases of suppurative cystitis with the typhoid bacillus pure in the lesion. The affection seemed milder in its course than cystitis due to the streptococcus or staphylococcus, and yielded readily to the ordinary measures. Houston's is the only similar case to be found in literature and his was distinguished by the duration of the cystitis—three years. The urine was acid in each of these cases.

Disinfection With Carboformal Incandescent Bricks. DICHPONNE.—A very simple and effective method of disinfection of rooms, etc., is provided by the bricks, containing 59 gm. of paraformaldehyde in the center, which have recently been put on the market. Lighted with a match, the bricks smoulder and the paraformaldehyde generates gas without actually igniting. For country practice they will be found invaluable. To produce the necessary preliminary moisture two liters of boiling water will fill an ordinary room with steam. Tests with 2.5 gm. formaldehyde to the cubic meter in these carboformal

bricks destroyed all the bacteria and almost all the anthrax spores. Even as small a quantity as 1.6 gm. destroyed 60 per cent. of the germs.

Significance of the Crystals in the Feces. SCHILLING.—Numerous examinations of the sediment of softened feces have convinced Schilling that the variety and amount of crystals to be found in the stools has been far underestimated. He states that every plant, berry, fruit, blossom, leaf and root contains crystals, mostly oxalates and calcium carbonates. These are found in the feces in great numbers and also the triple phosphates. The glittering of the crystals can be seen with the naked eye in the sediment of the feces. These crystals probably serve some useful purpose in the alimentary canal, possibly stimulating peristalsis and the innervation by the mechanical irritation of the thousands of tiny insoluble particles. If this assumption prove correct vegetable diet acquires new significance in the treatment of habitual constipation.

Brazil Medico (Rio Janeiro), September 23.

The Operated Xiphopagus. I. DA ROCHA.—In all scientific literature there were only three cases recorded of the separation of a xiphopagus, until Chapot-Prevost operated on Rosalina-Maria. One of the three cases is extremely doubtful: it was recorded in 1689, and is mentioned as dubious by contemporaries. The second was only a superficial connecting band between two twins, the wound measuring 5½ cm. The patients in this case were operated on by the father, Dr. Boehm, of Bex, Switzerland, in 1866. The third case was a true xiphopagus, the first ever operated on, and was reported by Blandet and Bugnion in 1881. The liver was continuous, and both children died in six hours afterward from hemorrhage of this organ. Chapot-Prevost's operation is thus the first successful one of the kind in history, and although Maria died from pleuro-pericarditis five days later, the autopsy showed that the wound in the liver was normally cicatrized. The connecting band was 14 cm. wide by 7 thick; the area of the cut surface of the liver, 4 to 6 sq. cm. Such an extensive hepato-tomy has never been done before. The operation was performed at the urgent request of the parents. The heart in the surviving Rosalina is on the right side.

Revista Medica del Uruguay (Montevideo), August.

Syphilitic Contagion from Nurslings. L. MORQUIO.—The outside service of the Foundling and Orphan Asylum at Montevideo had charge of 819 children in 1899, with a mortality of 8.9 per cent. In spite of the most rigid care, there were a few cases of syphilitic contagion of the wet nurses to whom the foundlings are confided at their homes. To prevent this calamity Morquio is urging the regulation that every infant less than 3 months old, whose parents are unknown, shall be considered possibly syphilitic, and not given out to breast-nursing. Besides avoiding the danger of contagion, this enlarges the choice of nurses. He always gives the preference to those in good circumstances rather than to the very poor.

 B. W. Yielding, Starrucca, to Forest City, Pa.

usual plate on the door of the office, and the pension card in the window.

UNTOWARD ACTION OF DRUGS.

CHATTANOOGA, TENN., Oct. 25, 1900.

To the Editor:—Will you kindly state in THE JOURNAL if there is any work on the unusual, peculiar or strange action of drugs, similar to but more satisfactory than Lewin's "Untoward Action of Medicine?"
 Yrs. sincerely,
 U. S. McGHEE.

Ans.—We know of no recent work. Some years ago Morrow published a work on drug eruptions (Wm. Wood & Co.), but this does not cover the whole field and we believe there has been no recent edition of either it or Lewin's work. There have been numerous articles in the medical journals on special by-effects of various drugs, but no collective summary of them in book form so far as known to us.

OWNERSHIP OF PRESCRIPTION.

ESSEX, ONT., Oct. 29, 1900.

To the Editor:—Would you kindly inform me to whom a prescription belongs, druggist or physician, after being once dispensed? If druggist removes from one store to another can he legally take the prescription with him for the purpose of again being dispensed at request of patient, supposing, of course, that the physician objects. It appears to me the physician has a property-right in his prescription. Please answer in the next issue of your valuable journal.
 J. B.

Ans.—This question is one in regard to which there has been as yet no legal decision. In THE JOURNAL, June 24, 1899, p. 1463, there appeared a notice of a Texas decision, in the case of Stuart vs. Hirsch, in which the Court of Civil Appeals held that a druggist has a right of property in prescriptions filed with him, and such rights are transferable in Texas. The rights here spoken of, however, are considered particularly as existing between the druggist and third persons, the rights of the persons depositing the prescriptions being only incidentally referred to. The court did not consider a prescription merchandise in the usual and understood sense of the term, so as to be covered by a mortgage of stock, fixtures, etc. This does not seem to touch especially on the property-right of the physician. The subject has been considerably discussed, and the view held by the druggists and physicians appears to be that whatever may be the case as between them, the patient has no property-right in a prescription.

The Public Service.

Army Changes.

Movements of Army Medical officers under orders from the Adjutant General's Office, Washington, D. C. Oct. 17 till 24, 1900, inclusive:

William J. Boyd, first lieutenant and asst.-surgeon, U. S. V. (recently appointed), is assigned to the 40th Infantry, with rank from Sept. 6, 1900.

Henry H. Bradley, acting asst.-surgeon, from Camp William H. Osborne, Idaho, to Buffalo, N. Y., for annulment of contract.

Carroll D. Buck, acting asst.-surgeon, to proceed from Fort Yellowstone, Wyo., to San Francisco, Cal., for transportation to Manila, P. I., where he will report for assignment in the Division of the Philippines.

James Carroll, acting asst.-surgeon, sick leave of absence extended.

William D. Crosby, captain and asst.-surgeon, U. S. A., member of a board in New York City to examine officers of the quartermaster's department for promotion.

Charles Fitzpatrick, first lieutenant and asst.-surgeon, U. S. V. (recently appointed), is assigned to the 45th infantry, with rank from Aug. 9, 1900.

Joseph C. Garlington, acting asst.-surgeon, from Washington, D. C., to duty at Fort Mott, N. J.

James H. Hysell, major and surgeon, U. S. V., leave of absence granted.

Thomas D. Ingram, acting asst.-surgeon, from Fort Mott, N. J., to Washington, D. C., for annulment of contract.

David J. Johnson, acting asst.-surgeon, from Plattsburg Barracks, N. Y., to Roxbury, Mass., for annulment of contract.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board in New York City, to examine officers of the quartermaster's department for promotion.

Paul H. Ludington, acting asst.-surgeon, from Omaha, Neb., to New York City, for assignment to the transport *Kilpatrick*.

Edward L. Munson, captain and asst.-surgeon, U. S. A., sick leave of absence extended.

Herman J. Schlapeter, acting asst.-surgeon, from temporary duty at Vancouver Barracks, Wash., to report to the commanding general, Department of California, for assignment.

Milton Vaughan, acting asst.-surgeon, relieved from duty in the Department of Eastern Cuba, to proceed to San Francisco, Cal., for assignment to duty with troops going to the Division of the Philippines.

Richard Wilson, acting asst.-surgeon, from duty in the Department of Eastern Cuba, to report to the Surgeon-General at Washington, D. C., for instructions.

Queries and Minor Notes.

MEDICAL PRACTICE LAWS.

RIDGEFARM, ILL., Oct. 31, 1900.

To the Editor:—What states require an examination before state Board for practice? It is the states of Iowa, Indiana and Wisconsin of which I wish to know. I may say that I am a graduate of Bellevue Hospital Medical College of New York City. If you can give me any information relative to the subject you will greatly oblige.
 Yours respectfully,
 J. B. M.

Ans.—License is given on registration of a satisfactory diploma a Wisconsin. If diploma is not satisfactory examination is required. The State Board of Medical Examiners meets on the second Tuesdays in July at the Park Hotel, in Madison; in October, at the Athearn Hotel, in Oshkosh, and in January and April, at the Hotel Pfister, in Milwaukee. Circulars of instruction can be obtained from Dr. H. M. Ludwig, secretary, Richard Center, in Iowa a satisfactory diploma and examination is required. The secretary is Dr. J. F. Kennedy, of De Moines. The conditions of practice in Indiana were given in THE JOURNAL, Sept. 8, p. 656.

PENSION BOARD SIGN.

CHICKASAW, I. T., Oct. 20, 1900.

To the Editor:—In the following instance what is your opinion? A Pension Examining Board selects the office of secretary of the said board as its regular place of meeting for the transaction of its official business and designates such place to the public by affixing the words "Pension Board" on the window facing a public thoroughfare, said window is contiguous to a window on which the secretary's name is lettered, together with the word "doctor." Is this office legal and unethical?
 C. P. B.

Ans.—Applied for pensions would be put to some inconvenience to find the examiner's office if it were not designated by some sign. The putting of the Doctor's sign in an adjoining window is a matter of taste, but is not unethical or objectionable, because it does not advertise himself any more than a doctor's would do. As a matter of taste it would be better to have the

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ended Oct. 27, 1900.

P. A. Surgeon D. H. Morgan, commissioned passed asst.-surgeon from Nov. 27, 1899.

Asst.-Surgeon R. E. Ledbetter, appointed asst.-surgeon from Oct. 19, 1900.

Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Oct. 25, 1900.

Surgeon Preston H. Ballhache, to proceed to the purveying depot, New York City, as inspector.

Surgeon J. M. Gassaway, two days' leave from October 19, 1900, under paragraph 179, Regulations.

Surgeon G. W. Stoner, three days' leave of absence Oct. 16, amended so that said leave shall be for two days only.

Asst.-Surgeon L. E. Cofer to proceed to Philadelphia and report to the medical officer in command for temporary duty.

Asst.-Surgeon Carroll Fox to proceed to Portland, Ore., and assume command of the service.

Asst.-Surgeon J. C. Bean granted leave of absence for two days.

Asst.-Surgeon G. A. Gregory granted leave of absence for seven days.

Hospital Steward and Chemist H. Gahn granted leave of absence for twenty days from November 12.

Temporary Hospital Steward and Assistant Chemist A. M. Roehrig relieved from duty at San Francisco, Cal., and directed to proceed to the Immigration Depot, New York City, reporting to Surgeon L. L. Williams for duty.

Hospital Steward W. P. Schlaar, upon being relieved by Temporary Hospital Steward and Assistant Chemist A. M. Roehrig, to proceed to Washington, D. C., and report at bureau for duty.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 27, 1900:

SMALLPOX—UNITED STATES.

Colorado: Arapahoe County, Sept. 17-Oct. 10, 9 cases; Rio Grande County, Sept. 25-Oct. 5, 4 cases; Custer County, Oct. 5, 1 case.

Kansas: Cherokee County, Sept. 1-30, 3 cases; Crawford County, Sept. 1-30, 4 cases; Douglas County, Sept. 1-30, 1 case; Rawlins County, Sept. 1-30, 4 cases; Shawnee County, Sept. 1-30, 2 cases.

Louisiana: New Orleans, Oct. 13-20, 1 case.
Minnesota: Minneapolis, Oct. 13-20, 1 case.
New Hampshire: Manchester, Oct. 13-20, 1 case.
Ohio: Cleveland, Oct. 13-20, 7 cases.
Pennsylvania: Philadelphia, Oct. 13-20, 3 cases.
Utah: Salt Lake City, Oct. 13-20, 6 cases.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Aug. 1-31, 10 cases, 4 deaths.
Austria: Prague, Sept. 22-29, 1 case.
Belgium: Antwerp, Sept. 22-29, 1 case.
Canada: Yukon Territory, Dawson, Sept. 24, 4 cases.
Egypt: Cairo, Sept. 23-30, 1 death.
England: Liverpool, Sept. 30-Oct. 6, 4 cases; London, Sept. 22-Oct. 6, 3 cases; Southampton, Sept. 30-Oct. 6, 4 cases; West Hartlepool, Sept. 30-Oct. 6, 3 cases.
France: Paris, Sept. 23-30, 7 deaths.
Gibraltar, Oct. 1-7, 1 case.
Greece: Athens, Sept. 30-Oct. 6, 2 cases.
India: Bombay, Sept. 18-25, 1 death; Calcutta, Sept. 15-22, 1 death; Madras, Sept. 15-21, 2 deaths.
Italy: Sorrento, Oct. 10, generally prevalent.
Japan: Formosa, Aug. 1-31, 1 case.
Mexico: Vera Cruz, Oct. 6-20, 2 deaths.
Russia: Moscow, Sept. 22-29, 2 cases, 1 death; Odessa, Sept. 30-Oct. 6, 10 cases, 1 death; St. Petersburg, Sept. 22-29, 7 cases; Warsaw, Sept. 15-20, 22 deaths.
Scotland: Glasgow, Oct. 5-22, 25 cases, 1 death.

YELLOW FEVER.

Columbia: Boens del Toro, Oct. 22, 1 case.
Cuba: Havana, Oct. 6-13, 18 deaths.
Mexico: Tampico, Oct. 7-14, 3 cases, 1 death; Vera Cruz, Oct. 6-20, 13 deaths.

CHOLERA.

India: Bombay, Sept. 18-25, 61 deaths; Calcutta, Sept. 15-22, 7 deaths; Madras, Sept. 15-22, 51 deaths.
Japan: Nagasaki, Sept. 11-20, 1 case.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 5-10, 2 cases bacteriologically confirmed.

PLAGUE—FOREIGN AND INSULAR.

China: Hong Kong, Aug. 18-Sept. 1, 13 cases.
Egypt: Alexandria, Sept. 17-21, 2 cases, 1 death.
India: Bombay, Sept. 18-25, 89 deaths; Calcutta, Sept. 15-22, 24 deaths.
Japan: Formosa, Aug. 1-31, 4 cases, 3 deaths; Kobe, Oct. 23, present.
Scotland: Glasgow, Sept. 30-Oct. 6, 1 death.
Wales: Llandoff, Oct. 11, 1 case on steamship *South Garth* from the River Platte.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from their subscription to the membership list should send certificates of above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION. . . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medicinal nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have the contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proof. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Mail checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

MEDULLARY ANESTHESIA IN GYNECOLOGY.*

J. RIDDLE GOFFE, M.D.

Professor of Gynecology at the New York Polyclinic Hospital;
Visiting Gynecologist to the New York City Hospital;
Assistant to the Skin and Cancer Hospital, etc.
NEW YORK CITY.

It is now about one year and a half since Bier, of Kiel, Germany, announced to the profession that he had found a new method of anesthesia, consisting of injections of cocain into the subarachnoid space of the spinal cord¹. His methods were promptly put to the test by various obstetricians, gynecologists and surgeons, and to-day the whole surgical world is agog to learn the indications for the use of this method, its limitations and its special field. The original supposition was that it was applicable to cases demanding a limited field of work and the practice of the early operators was to confine it to operations upon the lower extremities. This was gradually extended to include operations within the pelvis, the line of analgesic demarcation being drawn at the umbilicus. This naturally led to the conclusion that the special field for its application was embraced in the three departments of obstetric, gynecologic and genito-urinary surgery, together with the general surgery of the lower extremities. Further experience with the method and with the use of larger doses has extended to the regions of the body in which surgical work can be done under this method of anesthesia until it includes all parts, both superficial and deep, from the tip of the toes up to and including the breasts. The head, neck and upper extremities are outside its sphere, and probably will always remain so.

It would seem, therefore, to be a matter of special pleading to insist that gynecology has any special claim on the method for its particular use, and yet there are reasons for insisting that it has in this department a special indication. We know that after an injection of the cocain, the analgesic effect begins in the toes and gradually extends up the lower extremities, the extent of its complete analgesic influence depending on the amount of the drug used. It has been thoroughly established, however, that the dosage necessary to produce anesthesia as high as the umbilicus is perfectly safe; its action is prompt and the unpleasant effects are not severe.

Tuffier began his extension of the work from the lower extremities to the trunk of the body by operations, first on the perineum, then on the rectum, extending it

gradually to the bladder, ureter, to vaginal hysterectomies, appendectomies, hernias, and finally gastroenterostomies. Encouraged by his success in these regions, he has extended the field of operation to the kidneys and even to operations on the breast. To secure surgical anesthesia in these latter regions it is not necessary to make the injection any higher than the fourth space in the lumbar region, but it is necessary to use larger doses.

On Sept. 27 last, I had the privilege of seeing Dr. Neven, one of Tuffier's assistants, remove a small fibroid tumor from the right breast, the patient showing no signs of pain, either during the incision or the sewing up of the wound. In this instance three cubic centimeters of a 2 per cent. solution of cocain were used. Seven minutes after the injection the incision was made and the entire operation completed in about twenty minutes. There was no vomiting in this case, but the respirations were excited and sighing in character. Profuse perspiration came on during the operation, and when the woman was raised up on the table for the purpose of applying the dressing and bandage, she became extremely faint and limp, and asked for water. The faintness was not, however, greater than under similar circumstances after the use of ether or chloroform. Hot black coffee was used in this case as a stimulant.

In addition to the increased dosage, it is possible that the line of anesthesia can be carried higher up the body by a forcible injection of the cocain. In my own experience, the first case in which I used it was subjected to this method; that is, the piston was shoved home quickly and the fluid was suddenly and forcibly injected. In that case, although the operation was a vaginal hysterectomy, the tests that were applied showed that the line of analgesia extended above the breast line; and it was remarked at the time that undoubtedly an operation in that case could have been performed on the breast as painlessly as on the uterus.

At the Lariboisière Hospital it is the custom of both Dr. Tuffier and his assistants to inject the cocain slowly and steadily. Whether there was headache following the large dose of cocain in the breast case just mentioned I was unable to learn, but the other phenomena—nausea, vomiting, sweating, chilly sensations and general depression—were not so pronounced as in a case of vaginal hysterectomy for epithelioma of the cervix done on the same day by Dr. Lyot, another of Tuffier's assistants, with only 1/6 grain of cocain. It has doubtless been the observation of all of us that in many instances a small dose of morphin administered hypodermically will be followed by serious nausea, vomiting and headache, while a larger dose in the same patient will not be attended by any of these distressing symptoms. It is quite possible that the same rule will apply to the dosage of cocain in these spinal injections. Indeed, in conversation with Tuffier in the early part of this month, he expressed himself as inclined to think that the rule

* Read in a general discussion of Anesthesia by Lumbar Puncture before the Section on Obstetrics and Gynecology of the New York Academy of Medicine, Oct. 25, 1900.

1. Bier performed his first operation under medullary analgesia Aug. 16, 1898, and published a report of his first six cases in April, 1899. We now know that J. Leonard Corning, of New York, devised this method and put it on a practical basis in 1885.

would hold, and that the dosage would be rather enlarged than diminished as further experience was gained. In one case in which I saw him operate, the operation being an abdominal hysterectomy for bilateral hydrosalpinx, 1/3 grain of cocain was used. The anesthetic effect was more promptly produced, the vomiting consisted in one slight eructation about three minutes after the injection was made and before the operation was begun. There were very extensive and firm adhesions in the pelvis, but during the entire operation, even to the passing of the final stitch, the patient gave no evidence of the slightest pain or discomfort from the manipulations.

The various phenomena, the vomiting, sweating, the hurried respiration and excited pulse, are aggravated in nervous patients; the apprehension of pain and the fear that something terrible is going to happen is much more common with women than with men, and it is permissible, therefore, to attribute the exaggeration of these symptoms to nervous excitement rather than to any untoward effects of the drug. Tuffier illustrated this fact in an operation which I saw him perform on a young man of 23 years for an omental inguinal hernia, with adhesions. In this case 2/3 of a grain of cocain was injected and the patient lay as quiet and indifferent as to what was going on as he would had he been reclining in a barber's chair.

The temperature present in a large proportion of cases is undoubtedly due to a mild form of sepsis, the infection being carried in by the needle as it passes through the skin. If this explanation is correct, the needle devised by Dr. Leonard Corning, in which he passes a smaller needle through a trocar thrust into the skin, would tend to avoid, if it did not completely obviate, the possibility of infection. The same object could be accomplished by the little procedure suggested by Dr. Bodine, of first incising the skin with a bistoury and passing the needle in at the bottom of the incision.

The practical question suggests itself: When is this method to be used in preference to general anesthesia by ether or chloroform? Accepting Tuffier's dictum that the method is absolutely safe, is it as well for the patient? Many men as well as women suffer profound shock even from the sight of blood; in many the constant apprehension lest they might suddenly suffer great pain is a serious element of depression; and the conversation of the surgeons, the consciousness of some unforeseen accident in the midst of an operation, are the unfortunate factors in a surgical case. It is true that occasionally, perhaps frequently, conditions arise in the course of an operation in which it is important to know the desire of the patient in reference to extending the originally contemplated operation, and of course the spinal anesthesia affords an opportunity for this.

Whether or not it will prove a safe method of anesthesia in cases suffering from heart complications, or kidney involvement, can only be determined by more extended experience. Tuffier has had one death in a series of over two hundred cases in which this method had been used, but autopsy confirmed the previous conviction that any other form of anesthesia was contra-indicated.

From my experience with the method, and from what I saw and heard from Tuffier and his assistants at the Lariboisière Hospital, I believe that the method can be relied on to produce anesthesia in all cases demanding gynecologic or abdominal operations. The

failures may be accounted for in various ways: escape of the solution through the puncture, too long level of the needle point, or to using stale solutions of cocain, or to boiling the solution for the purpose of sterilization. It is an accepted fact that boiling a solution of cocain destroys its potency to a greater or less degree. Tuffier uses a solution of cocain prepared in the laboratory. The cocain is first dissolved in sterile or distilled water, then sealed in glass bulbs and subjected for one hour on two successive days to a temperature of 175 F. This solution may be drawn from the bulb directly into the syringe or poured into a sterile glass and drawn into the syringe from it. Van Horn & Co., at my instigation, have had some bulbs made and have placed on the market a solution of cocain sterile and ready for use. Tuffier declares in his latest article on the subject, that he regards the method as absolutely safe. He does not hesitate to declare, however, that its safety depends on the most rigid asepsis in every detail. This, I think, we are all ready to accept. The great danger is that in carelessness in some of the many details unfortunate consequences may follow and the method be brought into disrepute.

Dr. W. W. Keen, of Philadelphia, has successfully substituted, in at least one case, beta-eucain for the cocain solution in his use of the method, on the ground that this drug can be boiled when in solution without impairing its efficacy, and that it is less toxic than cocain, and therefore safer.

It may be said that in gynecology there are both psychologic and esthetic considerations why the method should not be used, but in appropriate cases it offers a means of anesthesia when general anesthesia may be positively contra-indicated. I shall continue to use it in my clinical work and thereby contribute my experience, as far as it may go, to determine the actual and relative value of the procedure.

PURPURA HEMORRHAGICA OR SCORBUTUS?

A CLINICAL SKETCH.*

HENRY E. TULEY, A.B., M.D.

Professor of Obstetrics, Medical Department Kentucky University;
Visiting Physician Masonic Widows' and Orphans' Home,
Home for Friendless Women, Louisville City Hospital, etc.
LOUISVILLE, KY.

Since encountering the case shortly to be detailed the writer has been inclined to the belief that the condition known as purpura hemorrhagica is not a distinct morbid entity. Buck¹ describes it as a disease of the skin, characterized by the development of variously sized, smooth, reddish or purplish hemorrhages which do not disappear under pressure. Quain² calls it a diseased condition in which circumscribed effusions of blood take place into the upper layers of the cutis and beneath the epidermis, occurring with or without certain constitutional symptoms or in the course of various diseases, and attended by hemorrhages under and from the mucous membranes as well as into various serous cavities. Oliver³ states that purpura resembles scurvy, differing from it in that it is not specially associated with deprivation of any particular kind of food. Struempell³ points out the only difference between scurvy and purpura is that in the latter there is no hemorrhage from the gums.

The cause of purpura as an independent condition is not clear. It is generally believed, however, to be

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

the result of an acute infection, most likely from the gastrointestinal tract. Efforts to discover bacteria in the ecchymotic spots have been unsuccessful. It has not been attributed, so far as the writer can ascertain, to errors or deficiencies in diet. By some it is considered as entirely symptomatic, by others, notably Oliver,³ as a distinct morbid entity, due to toxic, mechanical or vascular causes.

Among the vascular causes of purpura, mentioned by Fruitnight,⁴ are specific blood diseases, anemia, leucocytosis and jaundice; and the mechanical causes given are hepatic and cardiac diseases. These would rather have reference to the symptomatic forms than to the idiopathic.

Those who are the warmest advocates of the belief that purpura hemorrhagica is a distinct pathologic condition claim but little is known in regard to its pathology. Steffen⁵ quotes Casel and Leloir as having found in scorbutus and morbus maculosus an extensive endarteritis, hyaline and fatty degeneration of structure, narrowing of lumen, hypertrophy of the endothelium and secondary thrombi.

It is also true that in an altered blood state, with normal vessel walls, there will be a passage of blood through them, or as Oliver⁵ states, there may be an altered blood state and a disturbed nervous mechanism whereby nutrition of the walls of the arterio-capillaries are deranged and a hemorrhage results.

A purpura simplex is described clinically as appearing in the form simply of petechial spots everywhere, without much prodroma, beyond perhaps a slight indisposition, the first symptom of consequence being the appearance of the hemorrhages. Generally there is a quick recovery. Purpura hemorrhagica has been described as a severe purpura simplex. Steffen records 128 cases, of which 32 were personally seen. Of these 128 cases there were 40 deaths.

Scorbutus has perhaps been more closely studied than any other disease, especially since Northrup first called the attention of the profession of this country to it. Since then a great number of cases have been reported, and the collective investigation of the American Pediatric Society has greatly added to our knowledge of it.

It was early described as a condition of malnutrition which affects the capillaries, allowing the blood to escape from the vessels, producing gingivitis or spongy gums, hemorrhages and collections of blood.⁶

The classical symptoms presented are the following:⁷ spongy bleeding gums, swellings and ecchymoses about the joints, hemorrhages from the nose and occasionally from other mucous membranes, extreme hyperesthesia and often pseudo-paralysis of the lower extremities. In addition there is generally a cachexia with marked anemia.

The cause is essentially dietetic, generally one of the proprietary foods being used exclusively, or the continuation of one article of diet to the exclusion of all others, which is deficient in some element necessary to the child's nutrition. The improvement under an "antiscorbutic" diet is almost magical and is universally seen in all cases.

CASE—W., aged 2 years and 7 months, was the second of three children; was breast fed until about one year of age, after which time he was fed at the table and given a general diet. He was subject to frequent attacks of vomiting and diarrhea, as often as every two or three months, from which he generally recovered quickly and apparently perfectly. He had no trouble with his teeth, which appeared at about the usual

time. There is no history of a "bleeder" in the family, either in near or remote connections.

On Nov. 21, 1899, he was first seen by Dr. C. H. Stine, the attending physician, through whose courtesy I was later called to see the child, and to whom I am indebted for the details of the child's early history. At the time of this visit by Dr. Stine the child had a diarrhea, with mucous stools containing some blood. This irritation of the bowel was found to be due to a quantity of canned corn which had been eaten the day before. This was removed by free catharsis and by irrigation of the bowel. On light diet, irrigations, and a mild astringent he was discharged cured on the 26th.

He was not seen again until December 11, when Dr. Stine was again summoned and found much the same state of affairs as before, the digestive disturbance this time being due to oatmeal which had been freely eaten and which was evidently undercooked, it being passed undigested. Castor-oil was administered as before, the stools then containing some mucus. The child was cross and peevish, but had no temperature. On the fourteenth he was seen again; there was considerable diarrhea, stools frequent, which were thin, green and contained mucus and blood.

About this time there appeared a few petechial spots on the legs and thighs; co-incidentally there appeared a tenderness of the ankles and a slight fusiform swelling. This was followed in a day or so by pain in the knees and an inability to walk. The gums were spongy and bled upon the slightest irritation, the lips and teeth were covered with dried blood. Very soon the thighs, buttocks and back were thickly covered with purpuric spots varying in size from a five-cent piece to areas larger than a silver dollar. There were a few scattered spots on other parts of the body. The stools continued to contain blood and mucus; there was considerable prostration and restlessness with some fever, reaching 101 to 103 at times.

He was seen first on December 22 by the writer in consultation with Dr. Stine. There had been but little fever for several days previously, the prostration increased, and there was great restlessness, with anorexia. There was considerable irritation in the bowel with frequent small movements accompanied with a good deal of straining. The child was markedly cachectic, the pallor being somewhat intensified by his auburn hair.

The diagnosis was made of scorbutus. He was given calomel, followed by bismuth and tannalbin, with orange juice and broths. The orange juice was taken greedily, the broth only after considerable persuasion. His condition improved for twenty-four hours very materially, the diarrhea and tenesmus ceased and he seemed much more comfortable. On December 24 the temperature rose to 104.5 F., the breathing became much more rapid and there was some cough. Auscultation revealed very high pitched breathing over the bases of both lungs posteriorly, which gradually increased in intensity, approaching bronchial. He died in the early morning of the 27th.

Milk was not given at this time, because of the great bowel irritation, but it was our intention to begin its administration as soon as the bowel irritation had subsided.

Bearing in mind the points as detailed above, we have, clinically, a typical case of scorbutus, presenting the cardinal symptoms as detailed by all authorities; spongy, bleeding gums; fusiform swellings at ankle-joints; hyperesthesia; pain and inability to walk; hemorrhage from the bowels; petechial spots and ecchymoses all over the body, especially the lower extremities and lower portion of the trunk; diarrhea and considerable temperature.

The symptoms presented were also those of purpura hemorrhagica, as mentioned in the beginning of this paper. As the child had been fed at the table upon a more or less general diet, the case could hardly have been scurvy, as Crandall and others state that children who are allowed to eat at the table and have a very general diet never develop scurvy. Bearing in mind also the findings of Casel and Leloir, the similar path-

ologic findings in scorbutus and morbus maculosus, we are more at sea than ever as to the proper classification of this case.

As the child had not been fed upon an exclusive diet for a long time, though presenting the symptoms of scorbutus, taking the view of the authorities above quoted, it could hardly be classed as scorbutus. The joint symptoms being much more pronounced than generally described as being present in purpura hemorrhagica, and there being bleeding gums, which, according to Struempell, is not common to purpura, leaves it out of that class.

The occurrence of pneumonia, with the rapid dissolution, prevented the complete response to the "anti-scorbutic" diet, which we believe would have occurred, because of the temporary improvement for twenty-four hours before the onset of the pneumonia.

From a study of these subjects, then, it is the belief of the writer that purpura simplex, an occurrence of petechial and ecchymotic hemorrhages in the skin, is never an idiopathic disease; that purpura hemorrhagica, the disease in which there are hemorrhages into the skin, from the mucous membranes, subperiosteal and into the serous cavities, is not an independent condition, but is a modified form of scorbutus. It is due to, perhaps, a one-article diet, or to an ill-directed general diet, with a consequent development of a malnutrition, atrophisa or marasmus as a forerunner to scorbutus.

DISCUSSION.

DR. J. P. C. GRIFFITH, Philadelphia—It has been my conviction for a good many years, and it has been my constant habit of teaching that many of the diseases in which we have purpuric eruptions and certain other cutaneous manifestations, shade into each other. I do not mean to say that they are all forms of one disease, for I do not know that; only that I have noticed this curious way in which they shade into one another. For instance, take that disease ordinarily called purpura rheumatica, in which we have with the purpuric eruption a swelling of the joints. In many of the cases there is rather a decidedly urticarial eruption. Certainly the name purpura is here a misnomer, for purpura is by no means always the most marked symptom. Another affection which is closely allied to urticaria on the one hand, and more remotely to purpura on the other, is that curious affection, angioneurotic edema. We note, too, the form in which the purpuric eruption is very well marked, but in which there are also curious visceral complications. I refer to Henoch's purpura. I have sometimes thought certain of the varieties of purpura might be allied to scurvy, but I tried treatment by dietetic measures with no result whatever.

After all, "purpura" is just such a word as jaundice, and jaundice is only a symptom. The causes of the purpuric eruptions we do not know as yet. We must remember that we can have a purely symptomatic purpura eruption, as in cases of profound sepsis, and in cases of advanced marasmus, and is then an indication of impending death. Further study may perhaps teach us what these various causes of purpura are, but the relationship of the different purpura affections is certainly not much understood at present.

DR. J. LOVETT MORSE, Boston—I think we must admit at present that our knowledge of so-called purpura is very limited. What we do know is that purpura is a symptom, and not a disease. This symptom is due to some change in the blood-vessels, and this change may be the result of various causes. These causes may be bacterial invasion, or the pres-

ence in the circulation of bacterial substances, probably toxins, or of other chemical substances, probably not toxins, or malnutrition. That is about all we know. As to scurvy being due to a single cause—food—it seems to me to have been disproved; it is much more probable that it is due to many causes. Food, however, is undoubtedly the most important.

DR. A. C. COTTON, Chicago—I think we should not overlook the fact that sponginess of the gums does not necessarily indicate scorbutus, though it is one of the conditions obtaining in scorbutus. Purpura does not specially indicate scorbutus. I believe sponginess of the gums in this relationship is partly an accident, for it obtains when there are no other evidences of scorbutus. That it is a dietetic disorder, or due to that, may be true enough, but that we should insist on calling a case scorbutus because of the sponginess of the gums seems to be no more necessary than that we should call it scorbutus because of the purpura. Hemie conditions have been generally held to be responsible for purpura. As Dr. Griffith has well said, purpura is an accident of certain conditions of the circulation found on the approach of death. The old term "necremia" may still be used to explain one of the etiological factors of purpura, that is a condition of the blood giving rise to purpuric spots.

DR. BURNS—I wish to speak of the case of an adult who had had in childhood two attacks of purpura hemorrhagica with bleeding from the mucous surfaces. The first attack followed a fall from a horizontal bar when he was a boy of 9 or 10 years. At the time I saw him he was about 26 years of age, and had had malarial chills. He insisted on going about in spite of having chills on alternate days. The blood destruction was very great, and there were very free hemorrhages from the mucous surfaces. He did not have very much fever or distress. The purpuric eruption was of a bluish cast. I do not recall at present the condition of the gums. I mention the case because malaria, as a great blood-destroyer, may be one of the etiological factors. We have a good deal of gingivitis without the purpura and hemorrhages from the mucous surfaces, except from the gums.

DR. HENRY E. TULEY, closing discussion—My principal reason for reporting this case, was that the discussion might bring out the present difficulties of differentiating scorbutus and purpura. I believe, as stated in my paper, that the term "purpura hemorrhagica" should not be used, and that the conditions ordinarily described under that name should be classed as scorbutus. I am in accord with Dr. Griffith when he says that ordinary purpura, like jaundice, is merely a symptom, and that the name should not be used in the classification of disease. That purpura may occur without any alteration of the blood-vessels I believe is true, also that purpura may occur as the result of an alteration of a blood state, and not necessarily of a change in the blood-vessel wall. The sooner we recognize that purpura is a symptom, and not a disease, and that cases of so-called purpura hemorrhagica should be classed as scurvy, the more quickly will we arrive at a better understanding of this subject.

DIABETES MELLITUS IN CHILDREN.

A REPORT OF TWO CASES.*

LEOPOLD F. W. HAAS, M.D.

NEW YORK CITY.

The etiology of this disease in children, due to its rarity, is obscure. A few years ago Stern had collected 117 cases which had been reported in medical literature. Between 30 and 50 years of age, the proportion of males to females affected is about 3 to 2, but at the extremes of life this difference tends to disappear. Heredity plays an important part in its causation, while a family history of insanity, phthisis or gout is frequently obtainable. The patients generally belong to the wealthier classes; the Jews are often the sufferers.

* Address to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The immediate causes are variously stated to be: Injuries of the nervous system, especially of the floor of the fourth ventricle; lesions of the pancreas, of the liver, and of the kidney. Its occurrence as a sequel to some infectious diseases, such as rheumatism, typhoid fever, diphtheria, malaria, and syphilis, has given origin to the microbial theory of diabetes.

Normal blood contains .05 per cent. of sugar, and the urine of a healthy person contains traces. Ten times as much sugar is found in the blood of diabetics, while their urine contains from 2 to 15 per cent.

In 1819 Bernard proved that the liver contains sugar after death, and he inferred that the liver was a sugar-producing organ, an inference which has since been substantiated. Carbohydrates are absorbed as sugar, stored as glycogen in the liver, and reconverted into sugar to meet the demands of the system. Pavy showed that sugar can be artificially produced from proteids, and assumed that the body can also do this. The sugar which is put into circulation by the liver is stored as glycogen in the muscles and used up when the muscle is in action. This is proved by the loss of glycogen in a muscle which has been exhausted by tetanic contraction, e. g., after strychnin poisoning. Whether in diabetes the increase of sugar in the blood is due to an over-production by the liver, or to a diminished consumption in the muscles, is still a debatable question. If the elimination of carbon dioxide in diabetes were below the normal, we would have a convincing proof that less sugar was consumed than in a healthy person, and that our efforts must be directed to increase the consumption. But repeated experiments have failed to show this.

Efforts have been made to prove the so-called nervous origin of diabetes. This theory is based on the fact that glycosuria often follows injuries to the nervous system; for example, to the cardiac and solar plexuses, to the nerves of the liver, and to the various parts of the brain and spinal cord. Diabetes has been caused experimentally, by puncturing the floor of the fourth ventricle—diabetic puncture—but diseases of this locality, although met occasionally, are not very common. Other experimental lesions have been followed by glycosuria, the glycogenic power of the liver being abnormally stimulated for the time being; but as a rule these effects are only transitory.

In 1857 Lancereaux advanced the theory that the pancreas was affected in all cases of diabetes. Latterly, extirpation of the pancreas in dogs, with resulting glycosuria, has helped to support this view. Still more convincing is the fact that no diabetes follows when a small portion of the pancreas is left, or is grafted into the muscles of the abdomen. But why should the pancreas have such an influence on the excretion of sugar? Lepine suggested that the pancreas secretes a sugar-destroying ferment, but the exhibition of pancreatic extracts has had no action in controlling the disease. Two months ago MM. Lepine and Boulu¹ reported that the urine of diabetics contains a diabetogenous substance which produced an intense glycosuria when injected subcutaneously in dogs and guinea-pigs. Further experiments on this subject ought to prove interesting.

Robert Saundby, in speaking of the duration and prognosis of diabetes in children, says: "In children and young persons diabetes is an acute and rapidly fatal disease, lasting only weeks or months, or at most one or two years, but even in children cases have been known to extend over five, six, or more years." Other

authors agree with him in this hopeless outlook. A very few cases have been reported cured, but these are generally regarded with suspicion.

The following are the histories of two children in one family who have been under my care:

On Feb. 23, 1900, I was called to see the first patient, who complained of pain in the joints, fever, and palpitation of the heart. She had been sick for two days. The family history was as follows: The father had had an attack of articular rheumatism some ten years ago, but had recovered without sequelae. The paternal grandfather and an aunt on the father's side had died of tuberculosis, and the paternal grandmother of cancer. The patient's mother has had several severe attacks of asthma, and probably has tuberculosis, but refuses to be examined. The maternal grandmother died of tuberculosis, but the rest of the mother's family are healthy. There is no history of insanity or nervous diseases on either side, and none were ever known to have diabetes. There are four children in the family, and all have adenoids and large tonsils. The urine of every member of the family was examined, but no sugar was found except in the two children whose histories are given.

CASE 1.—M. F., female, aged 9. Patient is a pale, thin child, fairly well developed and nourished, rather small for her age, but seemed to be bright and intelligent. She complained of pain in the left shoulder, arm, and hip. The joints were not swollen, but slightly reddened, and the limbs could not be moved freely on account of pain. There was a rash on the body and legs, dark-red in color, looking like purpura around the painful joints, and like measles at some distance from the joints and on the right leg. The eruption was burning in character and not itching. Her temperature was 100.5 F., respiration 32, and pulse 132, full and strong. The apex-beat could be seen distinctly, even at a distance. The heart sounds were clear. The bowels were regular, no vomiting, and no pains in the stomach. Lungs, spleen, and liver were normal. The tonsils were enlarged and the patient breathed with her mouth open. Urination was frequent, and the child wets the bed at night. There was marked thirst. The case thus far appeared to be one of peliosis rheumatica. Salicylate of soda was prescribed, and cold compresses were ordered to quiet the heart's action. The urine passed that morning was of a pale straw-color, with a specific gravity of 1040; it contained no albumin, but 5.1 per cent. sugar. At first this was thought to be a temporary glycosuria, but on telling the mother at my next visit that the child had sugar in the urine, she informed me that another one of her children, a boy of 5 (Case 2), also had sugar in the urine, according to the statement of a physician three or four months before. On February 24 the patient was again seen, and the rash had disappeared from the legs and body, but the neck and arms were now covered. The pain had entirely disappeared and the joints appeared to be perfectly normal. The temperature had fallen to 99 and the respiration was normal, but the pulse was still 132. Cold applications to the heart were continued. She passed 64 ounces of urine during the 24 hours; specific gravity 1040. On February 25, rash was present on forearms and face, but was of a lighter shade; pulse was 114 and heart's action less tumultuous. No adventitious heart sounds heard. On February 26 the rash was still present on the face and head, but the rest of the body was free. Pulse was 110; temperature and respiration normal; specific gravity of urine 1042; su-

gar 4.9 per cent. On February 27 the rash had disappeared entirely and there were no signs of any constitutional disturbance. Pulse was 96 and specific gravity of urine 1044. The appetite, which had remained fairly good, now increased, while urination was not so frequent, but still copious. During the last three days no carbohydrates had been allowed; nothing but milk, beef tea, and soft-boiled eggs had been given.

On February 28, pulse had fallen to 72, and specific gravity of urine 1036; general condition good. On March 2, patient felt very well and showed no signs of any trouble, except that her appetite and thirst were abnormally developed. She had a craving for bread, which, however, was not allowed to be satisfied. Codein and bicarbonate of soda were substituted for the sodium salicylate, and the patient allowed to go out into the open air. No desquamation had occurred. Her weight was 55 pounds; specific gravity of urine had increased to 1044, and still showed 5 per cent of sugar. The diet had been increased, and she was allowed small pieces of toast in addition to other nourishing food. From this day, however, she was put on a strict anti-diabetic diet, and all carbohydrates were interdicted. The effect of this was to reduce the specific gravity from 1044 to 1038 on March 6, and the sugar to 2.8 per cent. on March 15. Carbohydrates were now allowed in small quantities. On April 1 she voided only 48 ounces of urine, and did not wet the bed at night as she had done previously. Urine was 1040 and contained 4 per cent. of sugar. On April 17, her weight was still 55 pounds, and the amount of urine voided was 332 ounces; since then she has been passing the same quantity daily. On May 7 her weight was 54 pounds, and her urine contained 5.2 per cent. of sugar.

At present her condition is as follows: Her weight has fallen to 53½ pounds, but her condition otherwise is excellent. She is bright and runs about a great deal. Her complexion is clear but sunburned; her hair is rather coarse, a family trait, which, however, is said to be a frequent condition in diabetes. Her tongue is clear and healthy looking; some of her teeth are in bad condition. The lungs are absolutely normal, but the heart's action is slightly irregular. Her bowels are regular; her appetite is good, but not as voracious as it was. She voids on the average 32 ounces of urine daily, which has a specific gravity of 1040 and contains generally about 5 per cent. of sugar. Her general condition being so good, all medication was discontinued, while a moderately strict anti-diabetic diet was continued.

CASE 2.—F. F., male, aged 5; a bright child, well developed and well nourished. He had been troubled with large tonsils, which had been removed three years ago. He still breathes with his mouth open, but does not have the choking spells which had been so common before the operation. There are some adenoid vegetations in the pharynx at present. About eighteen months ago he was run over by a bicycle and severely hurt, although I could not ascertain the exact nature of the injury, except that he was hurt internally. In November, 1899, he suffered from general malaise and pains in the back. Kidney trouble was suspected and his urine examined. Neither albumin nor casts were found, but quite a large amount of sugar. On February 23 I saw him for the first time, and nothing appeared to be wrong with him. His urine was examined the next day; it had a specific gravity of 1044 and contained 5.6 per cent. of sugar. His weight was 47 pounds, and he passed about 32 ounces of urine daily. The

bowels were regular. He was put on a moderately strict diet. In March he had an attack of measles, with quite a severe bronchitis, but made a good recovery. Since then he has been doing very well. On May 7 his weight had fallen to 46 pounds, and he passed 24 ounces of urine, which had a specific gravity of 1040 and contained 4.8 per cent. of sugar. At present he weighs 45 pounds, looks well, and he voids on the average 24 ounces of urine daily, which has a specific gravity varying between 1036 and 1034, and contains between 4 and 6 per cent. of sugar.

These two cases are interesting for several reasons. The well-marked family history of tuberculosis on both the maternal and the paternal side bears out the view that tuberculosis predisposes to diabetes. In neither of the cases do we know how long sugar has been present in the urine, a fact which is to be regretted. In the boy's case we have the history of an injury sustained a year before sugar was first noticed in the urine. Whether this injury has any etiologic significance or not is, of course, uncertain. It is unfortunate, also, that the physician who treated the boy after the bicycle accident is now dead, for he would have been able to supply several important details as to the nature of the injury.

From the coincidence of the eruption, the joint pains, the fever, and the tumultuous heart action there is no doubt that the first patient had peliosis rheumatica in addition to diabetes. It is a question whether these two conditions came on simultaneously or whether the diabetes existed before the rheumatic attack.

CONCLUSIONS.

1. Diabetes occurs more frequently in children than is generally supposed.
2. Urinalysis is just as important an element in the scientific diagnosis of disease in children as it is in adults. It is to be regretted that the general practitioner rarely realizes this fact.

3. There is a possible etiologic connection between peliosis rheumatica and diabetes. The pathogenesis of both conditions is so obscure, however, that speculation on this question can only point out a direction for further research.

773 Forest Avenue.

DISCUSSION.

DR. HEINRICH STERN, New York City.—As to the frequency of diabetes mellitus in children, according to the statistics of the New York City Board of Health, which I have collected and carefully gone over from 1889 till 1899, there occurred: 4 deaths under 1 year old, 1 death at one year, 2 deaths at 2 years, 2 deaths at 3 years, 4 deaths at 4 years, 11 deaths between 5 and 9 years, 17 deaths between 10 and 14 years, 38 deaths between 15 and 19 years.

Out of a grand total of 1867 deaths from diabetes mellitus for the period of eleven years, the mortality from this affection in childhood and early adolescence, when it almost always terminates fatally, being 79, forms about 4.25 per cent. of all the deaths from the disease during the period in question. The period of puberty seems to exert no specific influence on the causation of diabetes mellitus nor on its lethal termination. Of the 13 instances of death which took place under 5 years of age, 3 were in females. The 66 other deaths were divided equally over both sexes; 33 occurred in males and the same number in females.

The pathogenesis of diabetes in children, it seems to me, is not obscure in the measure as is commonly supposed. In my opinion, the glycosuric condition of children, in most cases, has nothing whatsoever to do with the true diabetic state in the adult. The glycosuria, I opine, is rather due to some developmental anomaly, especially of the medulla oblongata and other portions of the nervous system. Death in these instances

rather supervenes on account of the developmental structural inefficiency than on account of "diabetes," though the symptom-complex may point to a fatal termination by the latter. The disease in childhood, in most cases, does not seem to be caused by any metabolic disorder as such, and I do not hesitate to predict that in the near future the life of many children affected with "diabetes mellitus" so-called, will be saved by simple operative procedures within the skull.

DR. LOUIS J. LAUTENBACH, Philadelphia—In connection with this paper, there is a subject which seems to me to have come up in every Section I have attended this year. It may be a fashionable complaint, or it may be a common disease which has not been generally recognized. I notice the author referred to adenoids as a possible factor in the causation of his cases. I was surprised that no mention was made of whether or not he removes them. These adenoids in the vault of the pharynx seem to be an expression of some deep general condition, probably tubercular, syphilitic or scrofulous, the exact nature of which is not apparently known as yet. In all of the cases of phlyctenular conjunctivitis I have seen there have been adenoids in 40 per cent, or more of the cases. This may give us a clue to the nature of the disorder. We specialists take the ground that whenever we know adenoids are present it is our duty to remove them promptly. Whether adenoids are a part of a strumous condition or not I do not know, but I do know that their presence does induce a series of other phenomena which should be avoided whenever possible, and the only thing to do is to remove the postnasal obstruction at once.

DR. LOUIS FISCHER, New York City—I had the pleasure of seeing at my clinic several months ago the cases reported in the paper. I examined the urine and found a large percentage of sugar. A very important point, it seems to me, and one brought out in the paper, is the fact that those cases which are tuberculous or of a type formerly called scrofulous, are the ones in which we look for these abnormal conditions. It was only two or three weeks ago that I undertook to examine a series of urines from children in private practice, and in the urine of 61 children I found one case that showed a transitory glycosuria. Sugar was found in the urine from this child on three different occasions, though the child presented no symptoms whatever pointing to either diabetes mellitus or insipidus. The child has a little atrophesia and general malaise, yet the urine contained 1 per cent. of sugar. It would be well, I think, for us to make it a rule to examine the throat and the urine of every child coming to us for examination.

DR. HEINRICH STERN—May I ask by what method the uranalysis was performed?

DR. FISCHER—By Fehling's test and the fermentation test.

DR. EDWIN ROSENTHAL, Philadelphia—I have only seen two cases of diabetes mellitus, and the impression that I gained was that it was the first beginnings of life that started diabetes. In one of these children, 5 years of age, having a good family history, the diet had been an artificial food. The child died at the age of 5 years. The second case was the grandchild of a professor of obstetrics in Philadelphia. The child was a girl. The prognosis in these cases is invariably bad. The question of consumption, syphilis and similar disorders does not enter at all into these cases. I myself thought the diabetes in these cases was the result of the method of bringing up the children. One of the children had never been nursed, having been entirely fed artificially.

DR. J. C. DE VENNEY, Harrisburg, Pa.—I wish to state that I have seen a case similar to the one mentioned by the last speaker. It had been fed on malted milk and an artificial food until 4 years old. It was a well-marked case of diabetes.

Pathogenesis of Acute Deafness.—Baginsky relates in the *Arch. f. Kindh.* xxviii, that a girl of 13 presented the clinical picture of cerebrospinal meningitis with complete deafness in two days. The latter persisted after recovery. She succumbed three months afterward to sepsis from a malignant carbuncle on the lip. At the autopsy no traces of the supposed meningitis could be discovered, but indications of a bilateral lesion of the labyrinth were unmistakable. The organ of hearing had been completely destroyed by endostitis ossificans, which had manifested itself clinically as cerebrospinal meningitis.

MALARIAL HEMOGLOBINURIA.*

WILLIAM BRITT. BURNS, M.D.

BECKERVILLE, ARK.

We are accustomed to using this term—the principal symptom of the disease—because it overshadows all others. Under ordinary circumstances it makes the diagnosis, and the layman knows its import.

The synonyms are, black-water fever (Das Schwarzwasser Fieber), hematuria, hemoglobinuric fever, swamp fever, ieterohematuric fever; fièvre bilieuse hématurique, first described by French naval surgeons stationed at Nosibé, a French settlement off the northwest coast of Madagascar.

The pathology and pathologic anatomy of malarial hemoglobinuria is in all essential particulars the same as—and in fact is—that of a malignant malaria, with the addition of hemoglobin in the urine and rapidly increasing jaundice. There is always a history of one or more paroxysms—chills and fever—with insufficient or no treatment.

A cachectic may have had no active manifestations of malaria for months, and after undue exposure or fatigue, have a violent hemoglobinuria and die in twenty-four hours. Usually, however, there are two, three or four, or even more paroxysms, immediately prior to the hemoglobinuric symptoms. There may or may not be a cold stage; my cases have all shown a short mild cold stage with distressing prolonged fever, sometimes very high temperature, more often not to exceed 103-4 F. When the fevers have been of short duration the urine has cleared up rapidly; this has been no assurance though that at the end of twelve or twenty-four hours longer an exacerbation of all symptoms would not come on in an aggravated form.

The general appearance of the patient, if seen early after the coloration of the urine, is one of more or less excitement; the face is blanched as if in extreme shock; the eyes follow every movement; the speech is catchy and respiration sighing; he may be fairly quiet, more often there is restlessness, at times tossing over the bed, seeking a comfortable place; yet he seldom complains of pain. Indeed, the rule seems to be that there is very little pain, and if asked will answer that there is no suffering; but he goes on sighing and groaning. I have seen persons with a notably clear skin and sclera pass black water with a first or second paroxysm and in twelve hours present the color of saffron. The spleen and liver are nearly always palpable below the costal margins and are extremely tender; some tenderness exists over the kidneys, sometimes extreme backache. Nausea and vomiting are usually present, but it is only rarely that it is so prominent that the stomach has to be abandoned in treatment altogether. These symptoms obtain far more often in acute malaria than in hemoglobinuria. The vomited matter may be at first a straw color, but it soon becomes green, dark-green, brown, almost black, blue-black and grumous, sometimes offensive. After icterus comes on, the saliva, perspiration and lachrymal fluids are loaded with bile pigment, which responds to bile tests. The urine is from a poke-berry juice to a black-coffee color. All of these fluids, and the feces when diluted, show a saffron stain and deposit of bile salts on linen. Consequent upon repeated and accumulating infection we have the destruction of red corpuscles by the malarial parasites, the liberation of hem-

* Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

oglobin along with the malaria toxins into the blood plasma.

Under ordinary circumstances the liver cares for the hemoglobin by converting it into bile pigment, and the remnant corpuscles by elaboration into young corpuscles, or the complete destruction of same. But there are metes and bounds beyond which the liver will not stand. Besides its metabolic functions, constructive and destructive, its other functions must be safeguarded, and it must also protect itself from a flank movement from the intestinal tract, from which source come our intestinal toxemias. One-sixth, or even one-third, of all the red corpuscles may be destroyed by one pernicious paroxysm, this coming when the hemopoietic function is overthrown; the liver now fails to care for the free hemoglobin here liberated, and a hemoglobinemia obtains. It must not be understood that each parasite-destroyed cell contributes its normal quota of hemoglobin to the existing hemoglobinemia; it is considered that the greater percentage is consumed and converted into proper tissue and pigment by the parasites.

It is suggested that there is set free at sporulation a certain hemoglobin-dissolving substance, which hitherto has acted as a digestive agent in the assimilation of the coloring matter of the red cells and which retains after liberation its digestive function, continues to act as a hemoglobin solvent, and so dissolves out hemoglobin from healthy cells, or at least, probably, unstable young, and vulnerable red corpuscles. May it not be possible to recover some of the hemoglobin from the malarial pigment thus set free by the same agent?

We know that there is a distinct poikilocytosis; at times there does not appear to be a sound corpuscle in the patient's body. The erythrocytes are terribly misshapen, crenated, spiculated, tailed and buckled, shriveled and otherwise deformed; there are microcytes, megalocytes and shadows, and after the second or third hemoglobinuric paroxysm, the vessels are empty and relaxed, and the blood so deteriorated that it is a difficult matter to get a smear. The blood does not exude, even after large punctures. The adhesive quality is lacking to the extent that the ordinary adhesion of the lens through immersion oil drags the cover-glass from the slide. Here the field is practically colorless, save the debris and a few ghost-like corpuscles; the wonder is that there should ever exist a hemopoietic power sufficient to restore such a blood to normal. There is now added to the destruction wrought by the plasmodia *per se*, their toxins. Moreover, the presence of bile salts and bile acids induces a cholemia, which latter condition, says Oliver, comes on before the appearance of pigment or icterus in all forms of jaundice.

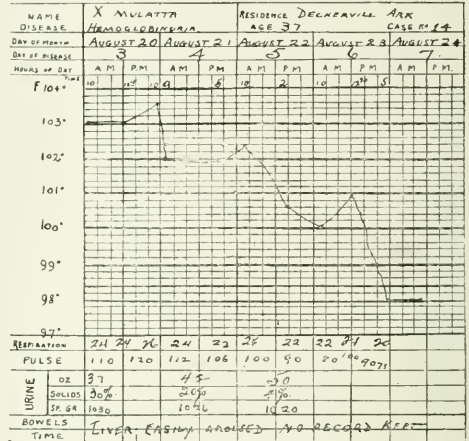

If we now reflect upon the toxicity of the bile salts, we may be able to explain in part the appearance of such a quantity of hemoglobin in the urine, which is not satisfactorily accounted for by parasitic destruction *per se*. We find that even in aqueous solution of 2 per cent. bile salts kill one kilogram of body-weight; the chlorate of sodium in dose of 54 eg. and chlorate of potassium in dose of 46 eg. Bouchard says that during twenty-four hours a man makes by the activity of his liver alone, enough poison to kill three men of his own weight.

Indeed, a cholemia alone may produce a hemoglobinuria; injection of bile salts into the circulation has produced hemoglobinuria in animals. Moreover, there are various solvents which find their way into the blood-current and which will take from the erythrocytes their hemoglobin, or a part at least, without accomplishing the

destruction of the protoplasmic body. The extreme pallor of the uninfected red cells is a striking evidence that there are hemoglobin solvents in the circulation which do not otherwise injure these bodies.

Maraghano explains paroxysmal hemoglobinuria on the idea of a lessened resistance to the ordinary environments, and especially to the toxic plasma.

The effect on the liver of this great hemolysis may be polycholia—filling of the gall-bladder; injection of the bile capillaries, even to their finest rootlets. The liver cells are thinned, capillaries are dilated and in places

This mulatto had been passing claret-colored urine for over forty-eight hours before I was summoned. He was very weak, his skin saffron-colored, and his eyes injected with bile. Fever and hemoglobinuria were continuous. I at once gave calomel gr. xvi, turpentin, gr. xx, to be repeated gr. ii and grt. ii, respectively, every two hours until the urine should clear up. I also gave quinin dihydrochlorate, gr. xv, hypodermically at 10 a. m. and 2 p. m. on the 20th.

Urine.—Claret-colored; containing blood and granular casts, amorphous granular matter and hematin crystals.

Blood.—Very pale; red cells almost devoid of color. Spiculated, tailed and buckled pigmented leucocytes, crescents and ovoids. There was seen one presegmenting form.

At 10 a. m. on the 21st the urine was clearing up slowly. Calomel was replaced by sodium hyposulphite and quinin sulphate was given in 7-gr. capsules every three hours, while the turpentin was continued. Raw eggs were also given.

At 2 p. m. the urine was clear, and the blood showed pigment and pigmented leucocytes. The urine remained clear, and the temperature gradually decreased. He was dismissed on the 23d.

This is the first case I have ever seen before frost. Cases 11, 12 and 13 have been reported, all very much the same as this. (See Trans. Section on Materia Medica, Pharmacy and Therapeutics, Columbus meeting; *Louisville Med. and Surg. Jour.*, Aug. 1899.)

are replaced by fat drops. Necrobiotic change occupying rather extensive areas, are seen. The vessels are filled with pigmented leucocytes, dead parasites, remnants and debris, and blocks of yellowish-black pigment; Kupffer's cells and certain endothelial cells undergo multiplication by karyokinesis. Thus we have the hepatic tumor; this has a blackish, leaden appearance and is soft on section.

The splenic tumor may be merely palpable below the costal margins or it may reach below the navel and to the anterior superior spinous process of the ilium. Ord-

narily, however, the enlargement does not assume the great proportions seen in malarial cachexia. Post-mortem, the surface of the spleen is dark, sometimes black; on section the gland tissue is also found to be dark; the parenchyma of the organ is much softened; the tarry pulp may be washed away with quite a gentle stream of water. The pigment of malaria is here found within the endothelium of the arterioles and capillaries in minute grains, often in actual blocks; we find aggregations of pigmented leucocytes, dead and breaking-down parasites forming actual thrombi and actually

abundance of pigment and pigmented leucocytes. Quinin dihydrochlorate, gr. xv, was given in solution. This was vomited and repeated immediately and retained. At midnight the fever was subsiding rapidly, and the urine clearing up slightly. Turpentin, gr. xv, was given at 10 p.m. and repeated in 2-drop doses every two hours until urine cleared.

Dec. 21: At 8 a.m. the urine was clear, and there was no fever. The blood contained free pigment, pigmented leucocytes and debris, also two old crescents. Quinin bisulph., gr. v, and strychnin nitrate, gr. 1/200, in solution was ordered. Sodium hyposulphite and beef-juice to be given every two hours and a bath and normal salt solution every four hours.

Dec. 22: At 8 a.m. patient was put on tonic and light diet.

It will be noted that at 5 p.m., Dec. 20, quinin, gr. viiss, was given hypodermatically, yet the paroxysm came on at 10 p.m., at which time quinin, gr. xv, in solution by the mouth was administered and vomited, repeated at once and retained, and emeticism was profound. This may be evidence of precipitation of the alkaloid by the alkaline tissues.

occluding the vessels. The spleen and bone-marrow have the distinction over all other organs of containing pigment in the cells of the parenchyma outside and away from the blood-vessels. In these latter organs pigment is contained in ordinary leucocytes, but in the splenic vein this substance is included not only in leucocytes but also in certain large white cells identical with those occurring in the spleen and evidently of splenic origin. The rôle of the spleen in infectious diseases has lately been gone over by Courmont and Duffau, Blumreich, Jacoby and Kurloff. Their deductions appear to be, that it makes no particular difference whether the spleen is present or not. Splenectomy seems to contribute to an increase in the bactericidal powers of the blood, while its antitoxin properties are unimproved. Ligation of the splenic vessels, the spleen being allowed to remain, appears to subserve the same end as does splenectomy on experimental infections. One of the striking changes in the blood after splenectomy is an increase in the number of leucocytes, especially the lymphocytes. This lymphocytosis is said to produce the protective powers of the blood seen in the cutting out of the circulation the spleen. It is explained again, that the spleen during health retains the disintegrated leucocytes and other cells. This detritus is regarded as being closely related to the alexins, and after splenectomy it accumulates in the blood and thus increases its bactericidal powers. Have we not occlusion of the splenic vessels in a hemoglobinuric spleen sufficient to act in a like manner, or in a considerable degree at least, as would a ligation of those vessels? May not this account in part for the lymphocytosis in hemoglobinuria?

The decrease in the bile pigments and the increase of the amount of bile secreted, as demonstrated by A. Pugliese, and the experiments of Fedeschi showing that the livers and bone-marrow in animals deprived of the spleen are richer in iron than the livers of normal animals, would show the close chemical relation of the two organs, and further the hypothesis of a grave occlusion of the splenic vessels in hemoglobinuria, as suggested. The condition would also contribute to the existing polycholia. The kidneys in an early stage of the disease are enlarged and congested; the tubules are blocked with hemoglobin infarcts; the cells are loaded with yellow pigment grains, and the capillaries with black malarial pigment. If the patient survives three or four weeks he is said to die of uremia. The appearances are then those of the large white kidney. The severest cases of nephritis of malarial origin are found in hemoglobinuria. The urine between the attacks may be per-

This patient had a chill, December 17. Quinin in No. 2 capsules was administered every four hours until hemoglobinuria came on.

Dec. 19: At 11:30 a. m., the patient was comparatively comfortable and slightly drowsy. The urine was dark. A smear of blood was taken and while examining it, I was hurriedly summoned. I found the urine the color of coffee. Both this and the first specimen responded to the guaiac-turpentin test.

The first blood showed plasmodia. A second smear taken after the urine colored up showed: plasmodia, estivo-autumnal parasites in all stages of development, moderate poikilocytosis, a number of lymphocytes, leucocytes greatly increased, polymorphonuclear and mononuclear phagocytosis.

The lips and gums were pale, also the tongue, which is large and flabby, with a thick, white coat and a tinge of brown over the back part. Icterus notably mild.

At 1:30 p.m., calomel gr. x and turpentin grt. xx—turpentin in a beaten egg—were administered, to be repeated every two hours in doses of gr. i and grt. ii, respectively, until the urine cleared up. Quinin dihydrochlorate, gr. viiss, hypodermically, was given at 1:30, 5 and 10 p.m., adding strychnin, gr. 1/220 to each injection. At 10 p.m. the urine was still black.

Dec. 20: At 8 a.m. the urine was clearing up nicely. Calomel was replaced by sodium hyposulphite solution, gr. xx, every two hours. Beef juice was ordered—a half teaspoonful every two hours. Quinin bisulphate in hot solution was ordered—gr. x every four hours.

At 5 p.m. the dihydrochlorate, gr. viiss, was given hypodermically to avoid paroxysm. A tepid bath, containing a little sodium bicarbonate for a cleanser, followed by hot whisky and quinin, was given. Sponge and normal salt enema every four hours.

At 11:30 a.m. the urine was clear; turpentin was discontinued and at 5 p.m. the condition was practically normal.

At 10 p.m. the urine was quite dark.

The blood contained numerous hyalin bodies, crescents and round bodies; leucocytosis was marked. There were a few lymphocytes; phagocytosis was marked, and there was an

fectly or practically normal, but with the attack it becomes, as before mentioned, from a poke-berry juice to a black-coffee color, somewhat turbid and smoky in appearance, and when allowed to stand precipitates an abundant chocolate-like sediment. This sediment is chiefly amorphous granular matter, disorganized corpuscles, with minute hematin crystals. Urea is generally increased; albumin is in abundance and globulin may be seen on close testing. The specific gravity ranges between 1015 and 1030, is usually acid in reaction, but oftentimes faintly alkaline, and the volume

oldest being 38 and the youngest 5 years of age. Dr. McElroy, of Stovall, Miss., shows a record of 40 cases, of these there were 30 males and 10 females.

Hemoglobinuria is extremely rare in infants. Fish reports one case in a child of 14 months; McElroy, one at 12 months. It is said that the full-blooded negro is immune to the disease. Easman, Eyles and Quartey-Papafio have recorded hemoglobinuric attacks in native Africans; Krause, of Memphis, reports one case in a "pure negro." Of my 16 cases, 3 were very light mulattoes; of Dr. McElroy's 40 cases 13 were negroes, 2 of which he writes to me were full-blooded negroes. There are, however, observers of decided repute who maintain very stoutly that the disease does not obtain in negroes of full blood.

The parasitology of hemoglobinuria, so far as my observations go, is estivo-autumnal pure and simple; and I believe this is the consensus of opinion; there are those, on the other hand, who hold to a special parasite, and others appear to have observed a special bacillus in the blood and urine.

Paroxysmal and toxic hemoglobinemias aside from the parasitic agent are accounted for in the same manner as that of malarial origin, i. e., any agent that will set free more hemoglobin in the circulation than the liver can care for will set up a hemoglobinemia—this in turn is thrown off at the most convenient outlet by the renal epithelium—a hemoglobinuria. Paroxysmal hemoglobinuria is precipitated by exposure to cold, or to the application of cold to the hands, etc.

Toxic hemoglobinuria is said to be produced by certain drugs, among which are cited: chlorate of potassium, carbolic acid, naphthol, carbonic oxid and quinin. To all of these, save quinin, I objected in my paper on hemoglobinuria, read before the Section on Materia Medica and Therapeutics, of this Association, at Columbus, Ohio. Chlorate of potassium is being used in large doses by my confrères and myself for pytalism, as recommended by the elder Gross; hemoglobinuria does not follow, nor does any other toxic effect. Carbolic acid, because a poisonous dose produces a coagulation of albumin and such a rapid and violent inflammation of the mucous lining of the stomach, that absorption is prevented to any great extent, and death is so sudden that hemoglobinuria could hardly obtain. Naphthol: Bouchard says it would require a half-pound to produce death in a healthy man weighing 150 pounds. Carbonic oxid combines with the hemoglobin of the red cells and renders them unfit for conveying oxygen, but does not disturb the continuity of the cell—no hemoglobinemia, no hemoglobinuria.

TREATMENT.

Of my first 6 cases, 2 died, 1 of these latter never having had a movement from the bowels, despite large doses of calomel and frequent enemas. Whether this was a paresis of the bowels, due, as Dr. Jones, of Memphis, thinks, to malarial toxemia, I am not prepared to say. Calomel, turpentin, eliminants, hot applications and supportives formed the treatment. I am persuaded that this gave a good percentage of recoveries. No. 7 bade fair to recover; urine was clear for 72 hours; but the patient relapsed after gormandizing; collapse followed with suppression of urine and passing of feces; yet his kidneys partially recovered, and he became strong enough to start on a journey home, but died on the way. No. 8 got on nicely without quinin. Nos. 9 and 10 died. No. 11, a little girl of 5, had no chill in two or three months; then she had a chill at 3 a.m. I was

TIME	LIVER ACTED WELL						

Patient was a cigarette smoker since 10 years of age. He had had bronchitis for several days, together with some pain in the chest. There were no other signs of pneumonia, and hot applications to the chest relieved the pains. Quinin, gr. v, every hour did not control the fever, but a purgative acted well.

On the morning of the 8th the urine was of a pokeberry-juice color, and responded fully to the guaiac-turpentin test for hemoglobin. The blood showed poikilocytosis, leucocyte-increased, estivo-autumnal parasites in all stages of development. The red cells crenated, tailed and buckled; phagocytosis. The urine showed a large quantity of granular and blood casts; amorphous granular matter, hematin crystals, squamous and columnar epithelium. Icterus was intense. Quinin dihydrochlorate, gr. xv, and strychnin, gr. 1/40, were given hypodermically at 8:30 a.m., and the same was ordered by the mouth at 4 and 10 p.m.

At 9 a.m. on the 9th the urine was clear and the fever rapidly abating. Quinin, gr. v, in solution was ordered for 10 a.m. and gr. x for 10 p.m. At 2 p.m. fever had disappeared.

Here quinin internally failed to control fever, which responded at once to it hypodermically. Icterus disappeared rapidly. The patient was up on the morning of the 10th for breakfast, smoked several cigarettes and went to bed at noon with pain in the chest. I was called and found what developed in a few hours into a violent pneumonia, from which he died on the 15th. There was no return of the hemoglobinuria.

may be increased. There are casts, principally dark granular ones, though hyaline casts may be found. Many of the casts are made up of hemoglobin. Rarely a few scattering blood-corpuscles are noted.

Hemoglobinuria occurs in the old residents, usually after the second or third year, rarely in new-comers, more often in males than in females. This is probably on account of the greater exposure of the male. Out of 16 cases seen by me, 13 were males and 3 females, the

not called until 8 a. m., at which time she passed the first black water. Calomel, strychnin, hot applications and mustard bath were employed. Urine cleared up perceptibly and symptoms subsided, but at midnight urine darkened again, and remained so the following day, though voided in large quantities. Icterus became marked. Vomiting was distressing, and restlessness pitiable; delirium came on at 5 p. m.; another chill occurred and urine became black; there were plasmodia present. I finally gave quinin, also normal salt solution by hypodermoclysis. It was too late to be of benefit. Nos. 12, 13, 14, 15 and 16 were given the same treatment plus quinin. All recovered nicely. Nos. 12 and 13 were the same person in two separate attacks. I now depend more on quinin. Nos. 12, 13, 15 and 16 took quinin in large doses before the hemoglobinuria came on. Larger and better cinchonism, however, proved to me that quinin is not such a destroyer of red cells, and the decided phagocytosis would appear as tolerable evidence that the movement of the white cells is not very unfavorably interfered with, but that it does rapidly destroy and banish from the circulation the malarial parasite, and thus closing out the hemoglobinemia and necessarily the hemoglobinuria. Of course the eliminants throw off the toxic environment, which contribute very considerably to the hemoglobinemia. Other agents are methylene blue, nutmeg and tannic acid. The first I have used in one case, but very little of it was retained; vomiting was excited every time it was given. I regard, though, methylene blue quite favorably in cachexia.

DISCUSSION ON PAPERS OF DRs. LAZEAR, WOLDERT, CRAIG, JONES AND BURNS.*

DR. WILLIAM KRAUSS, Memphis, Tenn.—I must say that the five-minute limit cripples me completely and it is impossible to say much or do justice to the discussion of all these papers. I had desired to discuss some of the earlier papers, but since they are mostly in line with my own findings, I will leave them to take issue with my friend Dr. Burns. I feel a sense of humiliation for the writers of my adopted country, except the Johns Hopkins School, when I read the allusions, and incorrect allusions at that, to this syndrome of malarial origin—I object to its being called a symptom. It is sincerely to be hoped that they will revise that part of their books in future editions. The fatal dictum "malaria ergo quinin" has sent countless hundreds to their graves. I have attempted to harmonize existing views, not having one of my own to defend, and think I have constructed a working hypothesis of the origin of the "disease," if you please. There is not the faintest analogy between this and the hemoglobinurias due to the ingestion of drugs in non-malarial subjects. Dr. Burns has given us its symptomatology. What are the principal known facts in regard to malarial methemoglobinuria? 1. Hemolysis can not be caused by adding quinin to the blood of a hemoglobinuric, *in vitro*. 2. Hemolysis never occurs in acute malaria. 3. Active infection by malarial organisms bears an indifferent ratio to the severity of the attacks; indeed, it may be absent in fatal cases. 4. Quinin may, in some cases, produce hemolysis in an individual to-day and not to-morrow; while in others the hemolysis is permanent, and if quinin is persisted in it will destroy the patient. 5. Hemolysis may be present in rare cases in the absence of a quinin history. 6. We know, as a positive fact, that in all cases where the plasmodia existed early in the attack, they rapidly disappear from the peripheral circulation under the influence of the hemoglobinuria; post-mortem, the parasites are always entirely absent. 7. Occasionally we find mild cases in which the plasmodia survive the attack. 8. The constant evidence

of the estivo as the only parasite. 9. The entire absence of any evidence of a specific malarial toxin.

Now, what do we find as the determining factors in hemoglobinuria? 1, persistent neglect of an old infection; 2, superimposition of an added acute infection; 3, some gross indigestion; 4, constipation and biliary stasis resulting in the resorption of bile; 5, change to a better climate, better location, better surroundings; 6, anti-malarial treatment. Here, then, we have two opposing factors producing similar results. Noeggerath's dipping experiments with Texas fever cattle had to be abandoned because a large percentage of these developed murrain with destruction of the animals. This is quite a parallel case. We must suppose then, that, after a while, in persons living in malarial climate a symbiosis is established, which is an exact balancing of two opposing factors to the extent of producing apparent health, a disturbance of which precipitates a paroxysm; if the potential is high, quinin or some other agent will produce a grave paroxysm; if low, it may not do much or any harm.

Bignami tries to make the point that probably hemoglobinuria is produced by the precipitation of the pigment in the epithelium of the convoluted tubules, the epithelium breaking down and causing a retention of hemolytic substances in the circulation. I have here some photo-micrographs apparently refuting this idea. They show absolutely no pigment in the epithelium of the convoluted tubules; it is in a state of cloudy swelling or even further degenerated; there is stasis in the vasa recta, the glomeruli and Bellini tubules are the seat of the pigment, which is in coarse particles; there is obstruction of the loops of Henle. In none of my preparations is there anything which can be regarded as even resembling a plasmodium.

Hemoglobinuria is probably an exaggeration of the tissue reaction which ordinarily is conservative and salutary. Proof is shown in the destruction of the parasites. All this is in accord with the clinical proof. I have seen 13 consecutive recoveries under the "eliminative" treatment; no such record can be shown under the quinin therapy. (Three more cases and no deaths at time of revision of this proof.)

Active malaria is not an essential factor. The plasmoidal effect of the hemolysis is greater than that of any amount of quinin. No death from the "disease" can be ascribed to the malaria *per se*. There is no logical indication for quinin except in the rare cases in which the parasites survive the attack. Quinin is dangerous during the attack, though it is the best prophylactic.

DR. T. J. HAPPEL, Trenton, Tenn.—I could not, even if I desired to, review the ground so thoroughly gone over; others are more competent to do so than I. As a general practitioner, living in a malarial section, I desire to state that we deal with malaria nine months out of each year. I shall not attempt to discuss any of the special papers, but I do want to emphasize what was pointed out by Dr. Jones, that too little attention is paid to the clinical history of the disease and we are attempting to learn too much from discussions on theory. We are gradually turning the study of disease over to the laboratories. We will soon have no real practitioners. Soon we will have men carrying away blood to the laboratory to ask the question: "What have we got?" I think we are going to extremes. We certainly have been able during the past years to diagnose malarial fever, typhoid fever, etc., and we are able to do so to-day without the microscope. There are far abler men in the profession than I who are prepared to state that the results of treatment were as good then as under the present advanced knowledge of the disease. If the gentlemen will come South at the invitation of Dr. Jones they will find a different type of mosquito, which does not convey the disease. In the South the poison hangs on every bush. Our children do not get malaria from mosquitoes, which bite them through almost the entire year.

DR. W. S. THAYER, Baltimore—Perhaps the most important point in Dr. Lazear's communication is the fact that he has brought before us easy, practical methods of making and applying Romanovsky's stain. This is a valuable clinical advance. All who use the microscope know how hard it often is

* The papers covered by this discussion, other than that of Dr. Burns, are that of Dr. Lazear, October 13, p. 917; Dr. Woldert, October 13, p. 933; Dr. Craig, November 3, p. 1139, and Dr. Jones, November 3, p. 1148.

to find small hyaline malarial parasites when but few are present. Proper investigation of the fresh blood specimen may, under these circumstances, require a great deal of time and patience, much more than is possible for the active practitioner to give. By these methods, however, it is not difficult to make a few dried cover-glass specimens at the time of the visit, and to stain them later. The results are so clear and sharply defined that one can readily detect parasites when only few are present.

I must confess that I am not satisfied with the existence of a distinct quotidian malarial parasite. It may be possible that in some instances the cycle of our estivo-autumnal parasite may be barely as short as twenty-four hours, but I do not believe that there is a distinct quotidian species. The view which we first held, based entirely on temperature charts, that paroxysms due to quotidian parasites were common with us, I have been compelled to abandon some years ago, and I am inclined to agree with Gautier and Ziemann that the estivo-autumnal parasite is one whose cycle lasts ordinarily about forty hours. In the recent publications of the Italian observers, they speak with considerable precaution with regard to the possibility of the existence of a distinct species of quotidian estivo-autumnal parasite. It seems to me that on careful analysis of these charts one observes that the paroxysms every third day begin at approximately the same hour, while those on alternate days vary slightly more. This is extremely suggestive as indicating a double infection with parasites, the cycle of which is of about forty-eight hours.

Our observations in Baltimore have led us to agree entirely with the views of Dr. Jones concerning the frequency of malarial nephritis in the negro. The vulnerability of the negro's kidneys, as well as of his lungs, appears to be especially marked. The frequency and high mortality of pneumonia in the colored race, as well as of nephritis, as compared with the white, is striking.

With regard to hemoglobinuria, I can not speak from experience. In Baltimore malarial hemoglobinuria does not occur. From a study of the literature there can be little doubt, however, that in those cases of hemoglobinuria where active malarial parasites are present, quinin does good. There is apparently also no doubt that in certain instances where the parasites are present at the onset, the mere occurrence of the paroxysm is sufficient to destroy nearly all, if not all, the organisms present. This is in all probability due to the fact that the infected corpuscles are especially vulnerable and thus prove subject to dissolution in an attack, the parasites, which are set free, being immediately destroyed. It has further been definitely shown that some attacks of hemoglobinuria occur after an acute malarial infection has entirely passed by, when no parasites are to be found in the blood.

There is no doubt that true quinin hemoglobinuria does occur, though the direct causal action of quinin is probably rarely observed. There is also some reason to believe that in individuals who have taken quinin for very long periods of time there develops sometimes a predisposition toward this manifestation. I should give quinin in any case of hemoglobinuria where active parasites were in the blood. I should abstain from giving it if they were not present.

DR. HENRY D. DIDAMA, SYRACUSE, N. Y.—In 1852 we had a swampy region in the neighborhood of a salt plant, and there was a good deal of ague; there were about 200 cases in one year. The treatment, at that time, was in giving calomel and jalap to get the liver in good order. I was a younger practitioner then than now, and I thought the complaint was the result of some poison. There was a quantity of mosquitoes, but I did not blame them. The ague is not there now, but the mosquitoes are there just the same.

DR. ALEX. A. WESTLEY, Chicago—In reference to the excellent paper given us by Dr. Jones, of Tennessee, in which he makes the positive statement that the negro does not have chronic malaria, I beg to disagree. It was my privilege, while in Cuba, to see over 1000 cases of malaria among the negro soldiers, and I have seen chronic malaria among them. There are now in Chicago some of these soldiers who have returned from Cuba and who are suffering with malarial

cachexia. Shortly before I left Chicago for this convention a former soldier came to me presenting a coated tongue and a cold, clammy skin, which had a peculiar ashen hue. He also complained of having had dysentery and an aching throughout his body and chilly sensations, which were sometimes followed by fever. I put him upon quinin and mineral acid and he improved. Further, I wish to state that while serving as surgeon in Cuba, not having any microscopic appliances in the hospital, I sent to the United States for cover-glasses, on which I made a number of blood smears, using every care in sterilization. These specimens were sent to Dr. A. J. Coey, of Chicago, who has made an especial study, both in Vienna and at Johns Hopkins, of the parasite of malaria. His report showed that the blood in many of these specimens contained crescent bodies, and evidences of malignant and chronic malaria. Thus it will be seen from the clinical picture given, and the scientific data here presented, that it is a mistake to say the negro does not have chronic malaria.

It seems to me that all subjects coming before this body should be considered of sufficient import to demand the most careful consideration of every phase thereof and to require the careful collection of all scientific data pertaining thereto before any generalizations are made, especially when those generalizations effect a whole people. I wish to enter my protest against medical men making positive statements without any, or at most, very little scientific data on which to base the same. In regard to the negro's susceptibility to kidney disease, I have only to say that in our command of over 2100 negroes we had over 1500 cases of malaria, which predisposes to kidney disease, but we had only one death directly traceable to the kidneys.

DR. N. S. DAVIS, JR., Chicago—I should like to ask Dr. Howard whether he has information about the migration of anopheles. The disease often disappears from localities and reappears in them many years later. For instance, in my boyhood days malaria was not uncommon in and about Chicago. During the first ten years of my practice there a case of ague was rarely seen, unless it was brought to the city from a considerable distance. However, when the lagoons were made in Jackson Park and the grounds were prepared for the World's Fair, and when excavation began and was in progress for the Chicago drainage canal, malaria appeared among the laborers in these localities and gradually spread, and still clings to neighboring sections of the city. The drainage of the land about Chicago undoubtedly caused the disease to disappear. What has caused it to reappear? Was it because the anopheles were given a suitable place in which to breed, or was it due to their migration, and if the latter, what laws govern their migration?

DR. L. O. HOWARD, U. S. Dept. of Agriculture—There are no evidences to show any migration to a distance.

DR. W. R. TAYLOR, Wheeling, W. Va.—There is nothing that will live eternally but truth. Upon this rock let us build. I should like to call attention to the fact that if malaria is due entirely to the bites of mosquitoes every man who goes to the Klondike would be killed in a month. There is no region on the earth where these pestiferous insects are more numerous nor their bites more venomous. Yet, malaria does not exist there. In our city of Wheeling, during the months of August and September, we sometimes have countless hosts of these insects, and plenty of the anopheles or dapple-winged variety. A large part of the city is built on an island, surrounded by the waters of the Ohio River. The island ground is low, and part of it swampy, yet malaria *de novo* is never seen here at the present time. After the war with Spain many soldiers came back from the South and from Cuba literally saturated with malaria, but they did not prove to be sources of infection for our citizens, although the mosquitoes were here busily engaged in carrying the infection to our unsuspecting and uninfected citizens. Wheeling Creek runs through the central part of that portion of the city which lies east of the Ohio River. In the summer months this creek is little more than an open, stinking sewer; a perfect paradise for mosquitoes, but we have absolutely no malaria. These facts may be multiplied and elaborated *ad infinitum*.

What inferences must we draw from these facts. Mosquitoes may carry the plasmodium malarie from the blood of a patient afflicted with malaria to one who is not, as flies may carry the tubercle bacilli from the sputum of a tuberculous patient to other persons and deposit it on or about them; they will not all become infected, only a very small percentage of them. Mosquitoes can not develop malaria de novo. Persons who are perfectly well may go into a malarial district in the early spring—before mosquitoes are hatched and developed—and work in the ground and contract malaria without ever seeing a mosquito. Foster defines malaria as "air tainted by deleterious emanations from animal or vegetable matter, especially noxious exhalations of marshy districts, capable of causing fever or other disease." This definition is in strict accord with all of our exact knowledge of malaria.

DR. O. T. OSBORNE, New Haven, Conn.—I should like to emphasize Dr. Davis' point. I have had somewhat the same experience in New Haven that he has had in Chicago. Fifteen years ago there were a great many cases of intermittent fever. From that time until five years ago we had very little. In the center of the city there was almost none. Then they began to put up a number of large buildings, dug cellars, put in electric cars, which went all over the city; the streets were much dug up. From that time typical intermittent fever reappeared. New Haven is accustomed to a few mosquitoes; we have very little trouble with them and seldom do we find it necessary to screen against them.

DR. R. C. NEWTON, Montclair, N. J.—I should like to ask if it is true, as has been frequently asserted, that malaria does not originate in localities which are over 700 feet above the sea-level. And if this popular belief is well founded, what shall we say about the presence of the anopheles? Is it found at an altitude of 700 feet or over above the sea-level?

DR. W. S. THAYER, Baltimore—With regard to the effect of the mosquito bite one should remember that it is not the number of mosquitoes which bite one, but the kind of mosquito, and the result depends entirely on whether or not it is infected. The great mass of mosquitoes all over the country are perfectly harmless, as far as malaria goes. There is only one genus of mosquito which is capable of transferring the disease and this genus inhabits those regions which we know as malarious. Members of this genus are, however, present in other regions which may not generally be known as malarious but which may be shown to be potentially so, as was the case in the epidemic which has recently been referred to, following the advent of Italian laborers. And in such districts when one looks carefully into the history of the region he will probably find that malaria has, at one time or another, existed. There is really no evidence to show that malaria can be acquired through the gastro-intestinal tract. There is simply no positive evidence that any epidemic of malaria is due to an infected water-supply.

DR. L. O. HOWARD, U. S. Department of Agriculture—In answer to the question asked regarding the occurrence of malarial mosquitoes at an altitude above 700 feet I would state that they have been observed at an elevation of 1000 feet and over.

DR. ALBERT WOLDERT, closing the discussion—Experiments have shown that the length of time the anopheles remains infected after it has bitten a case of malarial fever is about three weeks. After this length of time has elapsed it is believed the insect can not inoculate man with malarial fever.

Referring to the subject of malarial hemoglobinuria, in my opinion the etiology is not definitely known. Many cases of hematuria of doubtful origin have been spoken of as malarial hemoglobinuria. A distinction should be made between hemoglobinuria and hematuria by the use of the microscope. At one hospital I know of, over 2000 ounces of quinin had been given to patients in which the clinical diagnosis of malarial fever had been made, without producing hemoglobinuria. Of five cases of supposed malarial hemoglobinuria all took quinin and all recovered.

DR. WILLIAM BRITT, BURNS, Deckerville, Ark.—I came to this meeting to especially make a plea for harmony in the treat-

ment of hemoglobinuria. As my reports show—of course, 16 cases does not show a large clinical report—more than one-half the cases died under the treatment, without quinin. It is the custom for many physicians in the southern states to use no quinin in the treatment of hemoglobinuria. One year I was losing all my cases and I determined to try one case, and see if he would live if I used quinin. This patient had considerable jaundice and an enlarged spleen, a typical case, in short, wherein those, who fear quinin, would have withheld that agent. He had been given quinin sulphate in large doses by the mouth, and on the third day developed hemoglobinuria. How easy it would have been to have arrived at a quinin-hemoglobinuria. Quinin saved that man's life, I believe; I began at once, not to withdraw, but to get quinin into the circulation, giving 7½ grain doses every four hours of the hydrochlorate, intra-gluteally, and to my surprise he got well; moreover this same person was treated successfully with quinin in a second attack some months later. Ever since, I have treated every case with calomel, turpentin, hot applications and beef-juice I have also been using the normal salt solution, per rectum, which I find replenishes the blood and allays thirst. This mode of treatment, with quinin applied, in the past five cases has proved successful. I object to the term post-malaria in any form; I know of no post-malarial condition, except convalescence and sound health. I find estivo-autumnal parasites in all cases of hemoglobinuria, and knowing the great hemolysis wrought by these agents, I would doubt the wisdom of withholding the one agent which would eliminate the plasmodium from the blood. I no longer fear quinin in hemoglobinuria.

MASSAGE OF THE EYEBALL.

PRESENT STATUS AND VALUE, WITH THE CONSIDERATION OF WHAT DISEASES OF THE EYEBALL MAY BE FAVORABLY INFLUENCED BY THIS THERAPEUTIC MEASURE AND WHAT ARE THE BEST MEANS OF ITS APPLICATION.*

CASEY A. WOOD, M.D.
CHICAGO.

Massage is one of the oldest remedies known to ophthalmic surgery, and it may well be believed that a method of treatment not only in vogue thousands of years ago, but also adopted and retained by almost every school of medicine, must have special virtue.

Having used ocular massage extensively for many years, I gladly avail myself of this opportunity of exchanging with my colleagues opinions as to its efficacy.

First, I wish to speak particularly of the simple and not of the instrumental variety, such as the direct rubbing with pieces of cotton wool or some fabric mounted on a convenient shaft, the *tapotement* (or tetanization) of Maklakow, the use of sounds, with or without buttonheads, and other devices. In the main, indirect massage (Pagenstecher, Michel) with the pulp of the finger placed on the skin of the lids is to be preferred. Costomiris, formerly of Athens, who speaks enthusiastically of massage, believes that the best results are obtained by the direct rubbing of the finger tip or tips on the exposed cornea and conjunctiva. So far as the latter membrane is concerned, I believe direct massage is valuable, and in some instances decidedly preferable to the indirect method, but the stroking movements, with slight pressure on the exterior of the eyelids, are usually sufficiently efficacious, are certainly less difficult to carry out in practice, and are more readily borne by the majority of American patients.

It is necessary to say that the amount of force used, the length of each sitting, the frequency of the appli-

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

cations, the strength and character of the remedial agent—if any—used with the rubbing, and the susceptibility of the patient, are prime factors in the successful employment of massage, and are quite as important as the selection of cases appropriate for this remedy. Let us consider these in the order stated.

In indirect massage the act should never of itself produce pain, and rarely more than a passing discomfort. I think little is to be gained by the employment of much force. If the lids are the parts to be treated, the patient should be told to look down in massaging the upper lid, and up in the case of the lower lid. In each instance, the other lid should be drawn away from the one undergoing massage. If the cornea is to receive attention, the patient should look straight forward. The duration of the séance must be varied according to circumstances; it should rarely exceed three or four minutes. The tip of the second finger I have found the best instrument for the application, as it can readily be used for all the movements of palpebral massage, circular, centrifugal, and centripetal. It is also well adapted to the to-and-fro pressure required to reach the conjunctival areas about the inner and outer canthi. Once daily to twice a week constitutes the range of frequency of these applications. It is better in most cases to perform a gentle, non-irritating massage of even ten minutes' duration daily than a rough, painful rubbing twice a week.

As to the strength and character of remedial adjuncts, and without discussing the action of massage, which forms no part of this paper, I have come to rely on variations of some half dozen remedies. When I desire to use massage for its own sake, as I usually do, I instill a drop or two of cod-liver or pure castor-oil, telling the patient to wink and move the globe about so as to thoroughly distribute the oil throughout the conjunctival sac before beginning massage. For the rest I greatly prefer oily solutions or mixtures to powders or collyria. When these oleaginous compounds are made perfectly smooth and of a consistency that permits of their ready distribution over the eyeball, it is surprising how little pain or discomfort is set up even by strong doses of such irritants as mercuric chlorid, silver nitrate, etc. This is probably due to the fact that massage has an anesthetic action, probably due to emptying the capillaries and lymph-vessels of their contents and to the continued pressure on the nerve endings.

Most observers find in mercurials of various strengths, combined with all sorts of oleaginous excipients, the most useful massage agents, and my experience coincides with theirs. I pass around for your inspection a brown ointment of this character that I have found very effective, and one that combines qualities of great value in ocular massage. It is nothing but the old citrine ointment—the ointment of the nitrate of mercury—made with brown cod-liver oil instead of lard-oil. This, after standing exposed, to get rid of irritating nitrous fumes, for a week or ten days to the air, but not to dust, may be further diluted with from 25 to 50 per cent. of cod-liver oil. It should be dropped from the end of a glass rod or silver probe into the lower sac. If the massage movements are begun at once, the smarting is very slight and transient, even when the stronger mixtures are employed. The subsequent action of the remedy can be modified as desired by the length of time, usually an hour, before it is washed off the eyelashes with warm water.

At the end of, or during the act, combinations of the remedy with the ocular secretions—especially mucus—

should be coaxed out of the sac by small "dabs" of damp cotton, or, if watery or glycerin mixtures or solutions be employed, by the irrigating stream, and the stroking movements resumed until nothing further comes away.

I wish to emphasize the contention that one rarely gains anything by inducing a marked hyperemia of the scleral or ciliary vessels by using force or by the employment of very irritating adjuncts in massage. A little smarting, that passes off in five minutes; a temporary congestion of the already visible vessels, and, perhaps, some foreign body sensations are all that are justifiable. I might generalize by saying that the patient, half an hour after the lid friction, should not experience any added discomfort. It is evidently impossible for me to even enumerate the various diseases of the lid proper, conjunctiva, lachrymal apparatus, cornea, and of the interior of the eye, in whose treatment massage has many warm friends. In a general way its most satisfactory employment will be found in chronic diseases of the eye borders and substance, in almost all those subacute and chronic infections of the conjunctivæ that one commonly includes in the title "conjunctivitis"—with or without an adjectival affix or prefix—in the second stage of acute inflammation of the conjunctiva, in most forms of ulcer of and deposit in the cornea, and it may be employed for the temporary relief of glaucoma and in some forms of retinal embolism. It is not indicated in the early stages of "acute conjunctivitis" and of "keratitis," in all forms of true trachoma, in spring catarrh—although Costomiris and others dissent from this opinion—in diseases of the iris, ciliary body, lens, choroid, vitreous, or optic nerve. Finally, while I am very skeptical of its efficacy in the absorption of the connective tissue that composes the mass of a true cicatrix, I am convinced that, in young subjects, especially, it does lessen the opacity following ulcer of the cornea. If applied early it promotes the removal of the surrounding infiltrate that would otherwise remain. In the same way it is valuable in the treatment of interstitial keratitis.

USE AND ABUSE OF POTASSIUM IODID IN OPHTHALMIC PRACTICE.*

ALBERT RUFUS BAKER, M.D.

Professor of Diseases of the Eye, Ear and Throat in the Cleveland College of Physicians and Surgeons; Oculist in the Cleveland General, City, and Saint Alexis Hospitals.
CLEVELAND, OHIO.

Iodid of potash was first used medicinally by veterinary surgeons for the removal of splints from horses. Its efficacy in removing these osseous growths suggested its use for the removal of tumors and exudates from man. Its value in the cure of many tertiary syphilitic lesions soon became apparent, and it is slowly but surely forcing the medical profession to acknowledge that its use is not restricted to syphilitic diseases.

Many years ago I became convinced of its value in the removal of goiter. I recall a case many years since that forcibly impressed on my mind the efficacy of iodid of potash in cases other than syphilitic ones. I was in attendance on a little girl with pneumonia, but resolution failed to become established. The lung remained solid several weeks. The child was slowly but surely dying. The father, a physician, as well as myself felt helpless, and we called in council an old prac-

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

itioner, who prescribed immense doses, as we thought, of iodid of potassium. The rapid improvement was most marvelous. It was such observations as this that led me to gain greater confidence in the use of the drug in the removal of exudates than my previous studies had led me to believe possible. It was while the above case was still fresh in my mind that two patients came at the same time, each having received a blow on the eye, the anterior chamber filled with blood. I determined to try the use of iodid of potassium to absorb the blood-clot in one, and let the other go without specific treatment. The blood-clot disappeared in five days from the case in which the iodid was used. In the other, remains of the clot could still be seen at the end of two weeks. While it is true that a single observation of this kind can not have much scientific value, yet my experience covering a wide variety of similar cases has confirmed me in the opinion that iodid of potash is of value in removing not only hemorrhages, but exudates of almost every kind as well.

I seldom meet patients who can not take the iodid. Sometimes I have discovered that they could not take small doses of the drug without discomfort, but could take large ones quite well. That there may be no misunderstanding, I shall detail at some length the manner in which I usually prescribe the drug. In the vast majority of cases I combine it with bichlorid of mercury as in the following prescription:

R. Hg. chlor. cor.	gr. i
Potassium iodid	ʒi
Tr. cinch. comp.	ʒii
Aque, q. s. ad.	ʒiv

M. Sig. Teaspoonful three times daily in water after meals.

I use this as a menstruum for the administration of the larger doses, and give this prescription:

R. Potassium iodid	ʒi
Aque, q. s. ad.	ʒi

with instructions to add 5 drops to each spoonful of the first prescription, increasing 5 drops additional to every dose, thus giving 45 grains the first day, 60 grains the second, 75 grains the third, and thus rapidly increasing the dose up to 500 grains daily. I urge the patient to drink an abundance of water, to eat all the appetite craves, and make no restrictions as to the kind of food. I also insist on frequent hot baths, which I deem most important. I caution the patient not to take the medicine if a full meal has not been eaten, and on the first indication of intestinal disturbance stop the drug entirely for a day or two, or if needs be, until the appetite returns. Administered in this manner, it is rare indeed that I meet a patient who can not take from 100 to 300 grains daily. It is surprising sometimes what enormous doses can be taken without any apparent deleterious effects. I have notes of a patient in the City Hospital who had been there some months with a diagnosis of diabetes. When I entered on my service I examined his eyes and found he had a choked disc, and made a diagnosis of brain tumor, and expressed the opinion that the sugar in the urine was due to the irritation of the tumor, probably near the floor of the fourth ventricle. Iodid of potassium was administered until the dose was increased to 900 grains daily, with complete disappearance of the sugar in the urine, and although this was nearly ten years ago, the patient is still living and enjoying good health. These large doses can not be taken for a long time, but should be pushed to the point of tolerance and then stopped entirely for a few days or weeks, if not an urgent case; in the meantime I administer mercury, iron, arsenic, strychnia, or

other drugs, alone or in combination, as indicated, and then, if necessary, repeat the large doses of iodid as before. This way of administering iodid of potassium has proved most satisfactory in my practice, not only in syphilitic cases, but in many that were not diagnosed as such. In cases in which the patients object to the taste of the drug, I have been in the habit recently of prescribing it in carbonated water, which covers the taste completely and apparently relieves much of the tendency to irritation of the digestive apparatus. I do not wish to be understood as saying that I never give small doses of iodid; indeed, I believe there are cases in which most excellent results may be best secured by small doses continued for a longer time. But I wish to make a plea for larger doses in many non-syphilitic cases, and express the opinion that as a routine practice less harm may be done by large doses given for a brief period than by smaller ones for a longer time.

Of course, the most brilliant results will be attained in cases of choked disc due to syphilitic brain disease, but I have resorted to this treatment in cases of optic neuritis of almost every variety. The urine should be examined, and in the presence of albumin the drug should be used with great caution. I also learned from sad experience many years ago that, in degenerative disease of the optic nerve such as we have in posterior spinal sclerosis, the use of the iodids will do great harm and often hasten blindness. I do not hesitate to give large doses in cases of optic neuritis in meningitis, tubercular as well as other forms of the disease.

I have also had good results in neuritis following injuries of the head, either due to pressure from blood-clots or exostoses following fractures, or effusion from localized meningitis. I have also found the iodid useful in relieving the headaches in cases of brain tumor other than specific ones. Some years ago we had a boy in the Cleveland General Hospital who suffered most intensely from headaches. Opiates always aggravated the pain; almost the entire materia medica was exhausted without avail. It was found that 50 or 100 grains of potassium iodid, followed by a hot bath, would give him relief for a week or two, and sometimes longer. He died suddenly after a hypodermic of morphia given by a physician called in in an emergency. The autopsy revealed a large tubercular tumor of the cerebellum pressing up into the floor of the fourth ventricle, which was enormously dilated, holding a pint or more of fluid. The iodid undoubtedly relieved the pressure, while the opiates increased it, and thus aggravated the headache.

I am tempted to report at length exceedingly interesting cases in which the drug has proved of unusual value, like one I reported recently to a local medical society, of a patient who became totally blind subsequently to cauterization of the turbinated bodies for hypertrophic rhinitis. Rapidly increasing doses of iodid were prescribed until 450 grains were given daily. Perfect vision was quickly restored.

It was not the purpose of this paper to discuss such cases, but rather the ordinary ones that come to our consulting rooms frequently. I have already intimated that I believe the drug to have a specific influence in absorbing blood from the anterior chamber, and I also have faith in its efficacy in removing clots of blood as well as exudates from the vitreous, where, as we are well aware, absorption is a much slower process. In all cases of choroiditis with exudation into the vitreous, I give a relatively favorable prognosis, at least I have no hesitation in encouraging my patient to believe that

with vigorous medication we can clear up opacities of the vitreous, thereby improving vision. This improvement is not alone in syphilitic cases. In cases of progressive myopia in which there is not the slightest suspicion of syphilis, I have witnessed the most marked improvement. Indeed, there is no case of choroiditis in which I would not give the remedy a trial with the expectation of benefit. I have notes of an interesting case of a school teacher with a large subhyaloid hemorrhage, presenting a beautiful picture of a thin layer of bright-red blood covering a large portion of the fundus. Notwithstanding the presence of albumin in the urine, large doses of the iodid were given, with the gradual clearing up of the hemorrhage and restoration of perfect vision. This was five years ago, and the teacher is still at work and apparently in good health.

I have not found the iodids of benefit in secondary syphilitic iritis. These cases are best treated with mercurials. On the other hand, I have found the iodids of great service in the treatment of idiopathic or rheumatic iritis—those cases in which we have great pain running a chronic course, often relapsing; in which the impairment of vision is out of proportion to the cloudiness of the aqueous; in which the pupillary area may be quite free from exudates; in which the eye is tender to the touch; in other words, a cyclitis rather than an iritis, or at least in which the ciliary region is quite seriously involved, with exudation into the anterior part of the vitreous. These are the cases that try our skill, but which often yield to large doses of iodid of potash and hot water used as taught by our ex-chairman, Dr. L. Connor.

Serous iritis, the punctated keratitis of the older authors, is always benefited by the iodids. In these cases, however, I have been contented to use smaller doses. Interstitial keratitis is peculiarly a children's disease, and always runs a chronic course, which can be greatly shortened by the judicious use of iodid of potash. The latter can be much more safely and much more conveniently given in relatively large doses for a short time, alternating with mercury and general tonics, repeating the iodid from time to time as the general health of the child permits. Interstitial keratitis in adults in my experience always runs a much shorter course than in children. due, I believe, to the fact that we can safely give the iodid much more vigorously.

There are a large variety of cases of extraocular paralysis involving the third, fourth, sixth, and fifth nerves, undoubtedly many of them syphilitic, but often due to other causes. It has been my custom to prescribe iodid of potash in large doses without spending too much time in making inquiries as to the etiology, as I believe that prompt and heroic treatment at the beginning is essential to success in the management of these cases.

I must confess that the use of large doses of iodid of potash has been disappointing in the removal of post-operative exudates; for some reason I have not had the courage of my convictions, and in very few cases of this kind have I ventured to give large doses. So many of these patients are old, or feeble, or illy nourished, or have already run a painful debilitating course, I have not been inclined to push the iodid to the extent that I have done in other cases. I can not say the results in such cases have been encouraging.

CONCLUSIONS.

1. Iodid of potash should generally be administered in rapidly increasing doses until from 1 to 500 grains are given daily.

2. The drug should always be given after eating, and well diluted with water.

3. Frequent hot baths are essential to the best results in the use of the remedy.

4. Not infrequently large doses will be tolerated when smaller ones can not be well taken.

5. The use of the large dose is not limited to syphilitic cases.

6. Large doses are indicated in: optic neuritis; ocular paralysis; choroiditis; serous iritis and in relapsing iritis; cylitis and interstitial keratitis.

7. It is contraindicated in gray atrophy of optic nerve and in most cases of postneuritic atrophy.

8. Albumin in the urine, generally speaking, is a contraindication for large doses of iodid.

9. Young children do not take the iodid kindly and it should be administered cautiously.

10. The remedy is of doubtful value in early syphilitic iritis.

11. Large doses are of doubtful utility in the removal of post-operative exudates, but should be given further trial.

DISCUSSION ON PAPERS OF DRs. WOOD AND BAKER.

DR. J. L. THOMPSON, Indianapolis—I fully agree with Dr. Baker, though it is true I have not given the very large doses he uses, being rather afraid, but in the future I shall certainly try it. Occasionally we meet with cases in which more than four or five grains will produce the most terrible symptoms, in other words, there is an occasional idiosyncrasy. I recall a case of brain tumor in a little girl seen some fifteen years ago, with impaired vision, headache and choked disc, who after treatment by potassium iodid was able to attend school for two years subsequently. An autopsy made later showed sarcomatous tumor of the cerebellum.

Concerning the ointment which Dr. Wood recommends for use with massage I want to say that I accidentally stumbled on that mixture many years ago, in fact, before I went into the Civil War. Later, returning home, I found my friend, Dr. Williams, prescribing the same ointment, which he called the "brown citron ointment." The only objection to it is that ladies complain of its horrible odor. Concerning the use of massage in glaucoma, I have had several cases of hemorrhagic glaucoma in which I have used it, together with eserin and other remedies, of course. I think it would be well to give some of our patients an instrument like that suggested by Dr. Woods, because it gives them something that rattles. I wish I could give many of my patients some instrument that rattles or makes a noise while it is working.

DR. C. F. CLARK, Columbus—Since the Doctor calls for something that rattles, I have one to show him—presenting instrument. I have under my care a patient who consulted Dr. Ayres ten years ago and who has been a high myope since childhood. She has detachment of the retina, with complete loss of sight in one eye and partial detachment in the other. Her condition has improved greatly under potassium iodid. I only learned from her a few days ago that, before going to Dr. Ayres, she had presented to her this circular, which probably the older members of the profession are familiar with, concerning an instrument for reducing myopia. She had systematically produced massage with this rattling instrument for many years, and whenever she had to do some particular work she felt that she helped her eyes by pressing this on the lids. I have no doubt that with this instrument she succeeded in producing the detachment. I have tried it on my own eye and in one or two applications succeeded in making the eye ache for about two hours; I am myself myopic.

I believe in massage thoroughly for many diseases of the eye if properly applied, but it must be always guarded by the physician, and it would be a bad thing for the public to get the idea that by rubbing the eyes as the osteopaths do they could rub away disease.

DR. LEARTUS CONNOR, Detroit—There are two points I would like to speak of. I quite accept Dr. Wood's presenta-

tion on the subject of massage and I have found it extremely useful. The case related by Dr. Clark recalls to my mind the case of an old soldier who had lost one eye from myopia when the other was progressively failing. He went to Cincinnati to attend a grand army encampment, and while there a friend persuaded him to have one of these cups applied. It was applied once and he never saw afterward; from being a useful member of society he was converted into a blind man.

Respecting potassium iodid, I also favor large doses of it, but use it without bichlorid, and suspect that some of Dr. Baker's good results have been due to this attendant drug, which, however, is a different proposition. My method of using it is different from his, in that I usually prescribe it to be taken after meals in milk. I give it in drop solutions so that it may be increased by drop doses, each drop representing a grain. I was quite surprised to hear Dr. Baker say he found it intolerable to children, for in our Children's Hospital I have used it with great satisfaction, and they seem to take it better than adults.

I wish to say a word also in regard to subconjunctival injections to which Dr. Troncoso referred. In a number of these exudates the injections do assist materially in clearing of the cornea, but in other cases, no matter how many injections we have used, there has been only little benefit. As to the selection of cases in which subconjunctival injections would or would not be of benefit we have been unable to determine beforehand. It is necessary to try them, and if benefit results, very good; if not, we discontinue them. I would like to emphasize the remarkably quick relief from pain given in cases of iritis and cyclitis by these injections. I have seen many cases of these diseases in which the pain was excessive and in which no relief was obtained from other remedies, but they were promptly relieved by one or two injections of a few minims of normal saline solution.

DR. C. A. VEASEY, Philadelphia—I am quite sure that most of us who have had any experience with massage of the eye-ball will agree with almost all Dr. Wood has said in his excellent paper. It is perhaps a question not so much of the employment of massage but of the manner in which it shall be employed that raises points of difference. In the service of Dr. De Schweinitz, at the Jefferson Hospital, it has been our custom for years to use it to assist in the removal of exudates found in the layers of the cornea and especially in interstitial keratitis. Formerly it was our custom to apply the massage ourselves, but in a large clinic that proves to be impracticable. We then tried to teach the patients to use it, but quite recently we adopted something of an innovation by employing a trained masseuse. Certainly in the few opportunities we have had to make observations since starting this we have every reason to believe the results are better than those obtained by previous methods. The substance which we have mostly used has been the yellow oxid ointment. A small portion is placed in the conjunctival cul-de-sac, and the lids being closed a number of circular movements are made with the tip of a finger on the upper lid, and after a short time this is followed by radiating movements from the center toward the periphery, and the sitting ended with a few tappings.

DR. FRANK C. TODD, Minneapolis—I believe in the use of potassium iodid for eye diseases and in strong doses, but I have not been able to use it internally as strong as Dr. Baker recommends. I believe I have been able, however, to get it into the system in as great amount in another way. I have been in the habit of using inunctions of potassium iodid, just as it is customary to use mercury, and with very good results.

DR. G. C. SAVAGE, Nashville—There is one practical point I would like to mention concerning the administration of potassium iodid. I do not know where I got the idea, but, somewhere and somehow, I learned that jaborandi, in promoting the absorption of watery effusions in acute inflammatory processes, aids the potassium iodid in effecting this absorption of plastic effusion. I give the fluid extract of jaborandi in 15 to 25 drop doses at 9, 3 and 9 o'clock, and the iodid in increasing doses after each meal.

DR. J. A. LIPPINCOTT, Pittsburg—I have had some experience with subconjunctival injections of bichlorid and normal

salt solutions, and in some cases it is a method of treatment of undoubted value. The writer of the paper mentioned that Darier used acoin to obviate the pain. My patients complained very little if the eye was thoroughly cocaineated and if a small quantity of cocaine was added to the solution before injecting.

I have been using massage for many years in some affections of the eye, but recently more especially in glaucoma. There is no doubt in my mind that in massage of the eye-ball we have another means of prolonging vision in glaucoma, especially in the chronic inflammatory form where there is gradual tendency for the visual field to contract and blindness to ensue ultimately. I think massage in those cases does tend to relieve the pain, keep the eye-ball soft, and in conjunction with other measures to preserve the vision.

As to large doses of potassium iodid, I have used them, but not with as much enthusiasm as our friend Dr. Baker. I have seen others, however, use it in that way with benefit.

DR. G. A. ASCHMAN, Wheeling—There is one disease of the many that Dr. Baker mentioned in which I have had some particularly good results with potassium iodid, that is detachment of the retina. This is a disease so difficult to treat and so many things have been tried for it that I think potassium iodid, which does so much good in removing exudates, should be tried. I have given it after the method recommended by Dr. Connor. I have under my care at present a young girl of 18, whom I think Dr. Lippincott has seen, on these increasing doses. When first seen her vision was only the counting of fingers and the detachment covered one-fourth of the inferior quadrant of the eye, but it has now diminished two-thirds and her vision is 15/70. I would like to ask Dr. Baker whether he has tried the large doses of potassium iodid for this affection.

DR. URIBE TRONCOSO, Mexico—Dr. Veasey certainly stated the truth when he said that subconjunctival injections are of no great value in certain cases of interstitial keratitis, but there are some conditions in which the clearing of the cornea is marvelously assisted by this means. When I find that three or four injections do not bring success I think their use must be stopped. In regard to the pain produced by them I have not been so happy as Dr. Lippincott, for my injections have always been very painful, notwithstanding that care was taken that the needle should not penetrate Tenon's capsule, but only the conjunctiva. Darier proposed acoin, but, as I said in my paper, unfortunately I do not succeed in relieving the pain with it. Cocain can be added only to the cyanid of mercury because when added to the bichlorid it is decomposed and loses entirely its anesthetic properties. (Darier.) The action of the cocain is only temporary and a quarter or half an hour after the injection the pain begins, and lasts about two hours.

DR. CASEY A. WOOD, closing discussion—I would say that so far as my knowledge goes, I believe we are indebted to Dr. Moyer, professor of therapeutics in the University of Chicago, for the explanation of the different action of potassium iodid in large and small doses. When given in small doses and without a great deal of water it forms organic combinations in the stomach that produce irritation, but when given in large doses its action is mainly that of a diuretic, especially if given with a quantity of water. It is then carried off by the kidneys, as well as by the skin and mucous membrane. If this be true it explains why in large doses we get the benefits of the drug without its deleterious effects. I heard Professor Moyer recently say that he was in the habit of giving as much water as the patient could possibly drink and the larger the quantity taken the less frequently the disagreeable symptoms of iodism are present. In my experience that is true and I frequently give 400 or 500 grains a day.

I was very much interested in what Dr. Thompson said about the "brown" ointment. I have never laid any claim to originality in this matter, but I have not as yet discovered the inventor of what I consider a valuable addition to the ophthalmic armamentarium. I never advise patients to use massage at home, for I think it is possible for them to do harm with this and other agents employed with the massage.

Dr. A. R. BAKER, closing discussion—It was with a great deal of hesitation that I presented this paper, because I have been criticised by some of my medical friends at home for giving such large doses, and the sanction that has been given to the use of large doses of potassium iodid is very gratifying indeed. Such an excellent authority as Jonathan Hutchinson, I believe, says it is never necessary to give over 15 grains at a dose. I am very glad to hear Dr. Connor's favorable experience with young children. In the early part of my practice I thought I had injured some infants by the use of large doses, and though I was surprised recently in looking over my notes to see that I was giving such large doses to children with good results I felt that it was necessary to apologize for it in my paper.

In regard to Dr. Aschman's question concerning detachment of the retina, I would say that I have used it in a number of cases with doubtful benefit. In some cases where there was doubt of the diagnosis I have had improvements; it is certainly worthy of further trial in these cases.

ELECTRIC RECORDING PERIMETER.*

WILLIAM M. SWEET, M.D.

PHILADELPHIA

Of the many perimeters which have been devised for recording the field of vision, the instrument devised by Dr. Malcolm M. McHardy, of London, has met with the most favor. It is an excellent instrument, and whatever its defects, they are to be found in all similar forms of apparatus in which the test object is moved by a flexible cord. The instrument here shown was devised with a view of correcting the faults which experience shows exist in the ordinary form of perimeter. Apart from the use of small electric lamps for the fixation spot and for the test object, it differs in important details of construction from the usual form of perimeter. The arc which ordinarily carries the movable test object is replaced by a steel tube, at the end of which are cog-wheels for rotating a metal arm carrying a small electric lamp. Motion is transmitted to this arm by a shaft running through the center of the tube; the rotation of this shaft is communicated by suitable gearing to a slide carrying a steel point, as in the present form of perimeter, for making the record on the chart.

The electric lamp at the extremity of the rotating arm is designed for the test-object, two discs being provided in front of the lamp, one containing openings of various sizes, and the other holding circles of differently colored glass.

The usual form of chin-rest is employed, adjustable to various heights. The fixing point consists of a small mirror, which reflects the light from an electric lamp placed above. This permits the fixing point to be made of small size, so that the illuminated test-object may pass behind it, a matter of importance in the plotting of scotomata near the center of the field.

The record of the field is made in the usual manner by pressing the chart against a steel point. On the upright support of the perimeter is a steel pin, fitting into an opening in the arm of the chart-carrier. By this means the errors which often occur from sagging of the chart-carrier are avoided. The steel pin is adjustable to permit a heavy or light puncture on the recording chart.

The instrument is designed for a chart about six inches in diameter, experience proving that the small

form of chart tends to confuse the details of the field, especially when it is desired to record the form and color-fields on the same sheet.

Since the illuminated object passes behind the fixing point, each meridian of the field may be measured through an arc of 180 degrees without rotating the main portion of the instrument.

An important feature of the instrument is the button on the base of the stand for extinguishing the light of the test-object. When the patient first recognizes the light as it enters the range of vision, the pressure of the finger on this button puts out the light of the test-object, and determines the correctness of the patient's first answer.

The electric lamp may be operated with small storage cells, or, if desired, by the ordinary direct or alternating commercial circuits. The three-cell dry battery employed for small electric lamps gives satisfactory illumination, and may be replaced at moderate cost.

The advantage of beveled gearing, with absence of lost motion, over flexible cords for operating the est-

Electric Recording Perimeter.

object, will be apparent, while the substitution of a noiseless moving light, of constant intensity of illumination, for the present traveler, carrying colored discs, whose brightness varies with the character of the daylight, insures visual fields which are uniform for purposes of comparison.

The perimeter is made by Queen & Co., of Philadelphia, who have admirably worked out the mechanical details necessary to assure an accurate instrument.

1205 Spruce Street.

DISCUSSION.

Dr. H. F. HANSELL, Philadelphia—The advantages that this perimeter has over those in use are its noiselessness, and facility for the accurate measurement of the limits of the field by eliminating the possibility of deception and imperfect observation on the part of the patient. Its single disadvantage is its expense.

Water Treatment of Catarrh of the Upper Air Passages.—According to Linkenheld's description of his hydropneumatic treatment of catarrh, published in the *Deu. Med. Ztg.* 45, the temperature and force of the stream are the chief factors in the cure and not the chemical composition of the fluid used. He irrigates the upper air passages with plain water at 28 C. in acute catarrh. In the hypertrophic variety he rinses alternately with water at 27 and 32 C. In atrophic catarrh he uses large amounts, 5 to 2 liters of water under considerable pressure, alternating 27 and 32 C. with 18 C.

GLIOMA OF THE RETINA.*

G. A. SULZER, M.D.
PORTSMOUTH, OHIO.

As glioma of the retina is not commonly met with, particularly in private practice, I venture to report the following case. More than a year ago, through the courtesy of Dr. P. J. Kline, of Portsmouth, Ohio, a 14-months-old girl was brought to me for treatment of the right eye. The parents stated that the eye did not seem natural in appearance at birth, though marked signs of disease did not present themselves until the fourth month, when a whitish reflex was visible through the pupil, and later the eye increased in size, became inflamed and painful. On examination, it was found to be considerably larger than its fellow, and the ocular and palpebral conjunctivæ were congested; a well-marked pericorneal zone was evident. The cornea was clear and measured 12 mm. in the vertical meridian, and 13 mm. in the horizontal. The pupil was 5 mm. in diameter, and fixed. The anterior chamber was very shallow and the iris a dark green, in decided contrast to the bright blue of the iris of the left eye. A whitish reflex could be seen through the pupil. The tension was very high, the eye almost stony hard and tender to the touch. With the ophthalmoscope a large, whitish mass was seen almost filling the vitreous chamber, the fundus reflex being invisible. The left eye was normal in appearance and vision good. Glioma retinae was diagnosed; enucleation was advised and adopted. The operation and convalescence were without incident. The ball was hardened in 1 to 8 formaldehyde solution, and at the end of a week was removed. An incision at the equator gave escape to a greenish viscid fluid; the anterior and posterior chambers emptying through an incision into the cornea, caused the iris to return to its natural blue color. The large, whitish tumor mass almost filled the vitreous cavity, apparently growing from the optic papilla, pressing forward the lens and iris and was slightly attached to the lens capsule. Section of tumor showed small spots of fatty degeneration and calcareous infiltration. The retrobulbar portion of the optic nerve appeared to be normal. The choroid and retina seemed disorganized, and the lens was peculiar in having a yellowish opaque nucleus about 3 mm. in diameter. The cortex was clear, but yellow.

Dr. David Riesman, of Philadelphia, to whom the specimen was sent for a pathologic report, stated that, because of fatty degeneration of the tumor mass, it was difficult to interpret it, finally concluding that it was a glioma. Further he says: "The glia cells are large, chiefly round, but occasionally slightly oval with deeply stained nuclei, which apparently have no protoplasmic ring. The cells are without processes. The tumor seems to have lifted the retina and lies between it and the choroid, separated in places from the latter by cells having spindle-shaped and oval nuclei and considerable intercellular substance, and placed angularly toward the choroid. Where the tumor nodules are very compact, the cells are distorted by mutual pressure and here and there among them are found large peculiar bodies, probably degenerated cells, which stain a pale blue. Much detached pigment lies near the choroid coat. The vitreous chamber is largely occupied by the new growth, the cells of which occur in small, scattered groups and vary considerably in

size. An extensive hemorrhage has filled the tumor with red blood-corpuscles, which are fairly preserved, and scattered among them are peculiar dumb-bell-shaped bodies of a brownish-black color, somewhat resembling diplococci, but representing probably some form of blood crystal. The retina is detached in places and thrown in folds."

Schob¹ in his excellent chapter on glioma, in the "System" of Norris and Oliver, defines glioma as a malignancy; intraocular growth. "Histologically a more or less circumscribed hyperplasia of the retinal neuroglia, most frequently arising from the inner granular layer, though it may spring from any of the layers having supporting fibers, except the layer of rods and cones." There are two forms, circumscribed and diffused, and according to the direction of growth, glioma endophytum, that form growing into the vitreous, and glioma exophytum, growing backward into the sub-retinal space. The etiology of glioma is as obscure as that of tumors generally. Fuchs⁴ refers to a "congenital morbid disposition." Schob¹ mentions the same feature and says: "No predisposition or other etiological factors are known, although a connection between trauma and glioma has often been maintained but never proved." As regards pathology, Schob¹ in quoting Greef, says: "From these investigations it would appear that gliomata practically consist of hyperplastic glia cells, the offshoots of which form a dense network of fibers, ganglion cells and nerve-fibers." For this he proposes the name of "neuroglioma ganglionare."

Fuchs⁵ quotes Virchow, thus: "Glioma develops ordinarily from the two granular layers of the retina, principally from the inner granular layer, and is composed of small cells and a very soft basement substance. The cells consist of a nucleus surrounded by a very scanty amount of protoplasm, which in many spots possesses minute processes. According to the varying character of these processes, the cells are classed partly as glia cells, partly as ganglion cells. Usually the tumor cells are aggregated in peculiar dense masses along wide blood-vessels, which thus get to have cloak-like envelopes, and the entire tumor consequently exhibits a tubular structure. In many cases there are also found long, cylindrical cells, which are undoubtedly to be regarded as constituent parts of the external layer of the retina or the neuro-epithelium of Schwabe. (Flexner, Wintersteiner.) These are arranged in groups, usually in such a way as to enclose a free cavity into which their extremities, representing outer members of the rods and cones, project. Hence, if we take these structures into account, it would seem more correct to give glioma the name of neuro-epithelioma of the retina."

Histologic sections of the tumor have been made, and I take pleasure in presenting them for your inspection. In this case two points are of especial interest: 1, there has been no return of the disease, though fourteen months have passed since the enucleation; 2, the family history is negative, the patient being the third of a family of three girls. Discussion of the case and on glioma retinae is solicited with the hope of refreshing our knowledge of the subject.

DISCUSSION.

DR. G. E. DE SCHWEINITZ, Philadelphia—Dr. Sulzer's complete presentation of his case leaves little room for discussion, and I will therefore content myself with the exhibition of a drawing illustrating the structure of that type of glioma which receives the name *neuro-epithelioma*—a name which Wintersteiner believes should always be used in place of glioma. You observe the tubular structure and how the cells send processes through the walls of the tubules into their lumina. The elements here involved are analogous to the cone-nucleus, the *membrana limitans externa*, and the cone-body of the normal retina. The first paper calling attention to this conception of the ultimate structure of gliomas was written by Dr. Simon Flexner, now of the University of Pennsylvania.

DR. J. L. THOMPSON, Indianapolis—I simply want to speak of the results of these cases. A great many have stated that true glioma of the retina is always fatal. If you recall it, I reported some 17 cases three years ago and 4 out of those 17 are still living. In all of these cases the tumor was examined by Dr. Knapp, or Dr. Weeks or Dr. Wynn, all expert microscopists.

DR. J. M. BALL, St. Louis—I am under the impression that some cases have been reported as glioma of the retina where a careful microscopical examination would have shown the pseudo-glioma. I might report a case which a number of ophthalmologists considered to be true glioma, but which on examination proved to be a pseudo-glioma. A period of three years has now elapsed since the operation, but if that specimen had been badly treated or mislaid, or no microscopic examination made, it would have been considered a true glioma, the operation for which had been followed by no recurrence.

DR. SULZER—I have only to add that both Dr. Shumway and Dr. Flexner saw this specimen and agreed on the diagnosis.

A DOUBLE HOOK FOR USE IN ADVANCEMENT OPERATIONS.*

C. F. CLARK, M.D.

COLUMBUS, OHIO.

This instrument is intended to simplify the operation for advancement of the recti muscles and to make it

A and B is a strip of tape drawn up into a fold by the hook at C D, showing the points for the insertion of sutures at XXX.

possible to regulate with certainty the amount of shortening obtained. It consists of a small hook, the shank of which is embedded in the anterior surface of a larger one, and the arm of which passes between the blades of the forked arm of the larger one. By means of a milled screw and a ratchet the single hook may be projected beyond and between the blades of the double one, so as to take up a fold of the tendon and draw it up

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

between the blades to the desired height, when the sutures may be introduced and the superfluous fold cut off, if so desired. The instrument is made with a detachable handle, so that during the suturing the aid of an assistant may be dispensed with. I have found it operate most satisfactorily when the capsule of Tenon is included with the tendon of the muscle, as this gives greater holding power to the sutures.

I think the accompanying illustrations will make clear the character of the instrument.

AIDS IN THE MEASUREMENT OF REFRACTION.*

EDWARD JACKSON, A.M., M.D.

DENVER, COL.

The two instruments that I herewith present have proved of sufficient value, in facilitating the testing of the refraction of the eye, to justify me in calling the attention of the members of the Section to them. The first is

A TRIAL-FRAME FOR SKIASCOPY.

It is simply a light trial-frame, in each cell of which is fixed a metal disc, with a central opening large enough to allow the application of the shadow-test through it.

Upon the disc are enameled bands of black and white, each occupying an angle of 30 degrees of the disc. In the center of each band is marked a point, white in the black bands, and black in the white bands. This constitutes a graduation to 15 degrees spaces. The center of a white band marks 90 degrees, and the center of a black band, 180 degrees, of the usual graduation of the trial-frame. This arrangement affords a kind of graduation that can readily be seen with the light thrown on the eye while applying the test. It furnishes something with which one can easily compare the band of light in the pupil that indicates the directions of principal meridians of astigmatism. This frame has been made by H. C. Boden & Co., of Philadelphia.

CROSSED CYLINDERS.

The recent publication by Dr. T. B. Schneideman, of an article urging the value of the crossed cylinder in testing refraction,¹ seems to have stimulated renewed interest in the subject; and two different opticians

have brought me these convenient arrangements for the use of the test. Each has the axis of the convex cylinder indicated in the usual way for showing the cylinder axis. The lens is mounted in a frame having a handle set at 45 degrees from the cylinder axis. Holding the lens before the eye, with this handle between the thumb and fingers, one can, by a very slight movement of rotation, instantly change the direction of the cylinder axis 90 degrees, thus reversing the cylindrical effect! The lens is used as a supplementary

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

lens, held in front of the lenses already chosen, which are placed in the trial frame. By this reversal of the axis we alternately increase and diminish the cylindrical effect of the combination before the eye. The lens with the round handle is made by Messrs. Bousclur & Holmes, and the lens with the flat handle is made by Messrs. Wall & Ochs, all of Philadelphia. The one with the round handle (see illustration) is the more easily turned; while the one with the flat handle can be more

readily kept exactly perpendicular to the visual axis. Either will be found of great practical value in refraction work.

DISCUSSION.

DR. W. F. SOUTHARD, San Francisco—Five years ago I devised a method of transillumination for the ophthalmometer, which I believe was the first effort in this direction. I first used ground glass, and gave that up because there was not a good distribution of light, and then I began to use porcelain [exhibiting the instrument]; a 16-candle power, 110-volt lamp is used. I did not think that it was obligatory to have it patented, but that any instrument-maker could be privileged to make it without danger of prosecution and such difficulties as I have experienced. I have testimonials from several manufacturers to show that this instrument was the first of the kind that they saw. One of the gentlemen spoke yesterday of the blurred edges of the mires as they approach each other. That is true and always will be, because it is due to an optical defect. I pay no attention to that myself, knowing that it is an optical illusion, and when at the point of contact there will be a little whitening more than we see here. I have demonstrated this instrument before a number of medical societies, and I desire the privilege of having my claim of priority published now in the transactions.

DR. A. EDWARD DAVIS, New York City—I may say that there was a transilluminated mire in use several years ago. Javal himself had one, but it was not so perfect an illumination as this.

DR. MILES STANDISH, Boston—I want to illustrate a little scheme I have adopted on my ophthalmometer, which aids me greatly in judging the point of contact. I have painted in the center of the solid white portion of the first step a little spot 1 mm. square, so that when the mires approach you have a point still beyond the light diffusion, and by watching this point you can judge the point of contact very accurately. It can be very easily accomplished by pasting a little black square on the mire, and once having placed it there you will never take it off again.

SYMPTOMS AND DIAGNOSIS OF HYPERTROPHY OF THE PHARYNGEAL TONSIL.*

GEORGE MORGENTHAU, M. D.
CHICAGO.

Symptoms.—Hypertrophy of the pharyngeal tonsil is, in many cases, combined with enlargement of one or more other parts of Waldeyer's so-called lymphatic ring of the pharynx, and of the adenoid or lymphatic tissue found in all the mucous membranes. The symptoms produced by these abnormal conditions, while mainly traceable to the pharyngeal tonsil, may not be ascribed to it entirely, but must be considered in reference to a possible constitutional anomaly of which the adenoid vegetations are but a local manifestation. The most common of these is the excessive discharge which flows either into the nasopharynx or into the nose. It is of thick consistency, sometimes with a slight odor, and comes from Luschka's tonsil itself or from the nose. The tonsillar secretion in conjunction with the venous stasis, especially of the posterior ends of the lower turbinates, and the mechanical interference with drainage of the nasal chambers, by the enlarged tonsil, result in chronic rhinitis. This, in turn, is favored by various malformations found so often in patients with adenoid growths, be the relation causal or accidental. The growths being situated behind the choanae, inspiration may be performed, while in expiration the growths fall against the nose, acting as valves. "Blowing the nose," is, therefore, quite inefficient. They are but seldom large enough to obstruct more than the upper part of the choanae, so that the children can, although with some effort, breathe through the remaining lower part of the canal. But when this, too—as is most apt to be the case when the children are in a horizontal position—is either obstructed by the accumulating mucus or by the swelling of the posterior ends of the turbinates or even by the action of the erectile tissue in the tonsil, then they are forced to breathe through the mouth. Infants are sometimes unable to nurse at the breast. Bosworth states that acute rhinitis is comparatively rarely met with in a child. In most cases, when it has an apparent cold in the head, it is really suffering from a subacute inflammation of the pharyngeal tonsil. The nose is rendered still more inadequate for breathing by a condition to which Ingals drew attention, abnormal narrowness of the choanae—a factor which accounts for some disappointing results after the growths have been removed as thoroughly as possible. Nosebleed sets in often, from small capillaries in the anterior lower angle of the septum or in the tonsil. If the blood can not escape, small petechiae are to be seen in the submucous tissue, especially of the soft palate and the uvula, or in the tonsil itself. The discharge from the nose is apt to excite eczema at the introitus, thickening and roughness of the upper lip, etc., symptoms often attributed to scrofulosis. The chronic inflammatory condition of the nose is, in many cases, followed by impairment of smell and taste; frequently by conjunctivitis, occasionally by blepharitis, and even by keratitis. Or, as discharge gathers in the nasopharynx during the night, it may trickle into the stomach or be unconsciously swallowed, causing vomiting and gastric mischief, thus adding to the malnutrition of our little patients. The laryngeal and bronchial

*Read in a Symposium on Hypertrophy of the Pharyngeal Tonsil, before the Chicago Climatological and Laryngological Association, July 5, 1900.

symptoms, again, are either brought on by the descending mucus or by mouth-breathing. The most common symptoms are cough, hoarseness and false croup, and bronchitis and bronchopneumonia. While Bosworth states that, in laryngismus stridulus, there is acute swelling of the lymphoid tissue in the larynx proper, it does not seem unlikely that the mechanical irritation of the mucus might excite such attacks. Adenoid growths are often accompanied by nervous disorders. Caution is therefore necessary in drawing deductions from a comparison of the state of the patient before and after operation. The psychical effects of the operation itself might prove corrective of some of the nervous disturbances, or the greatly improved general condition of the patient after operation might be responsible for the beneficial change. In a word, the association of nervous predisposition and of lymphatic growths might be accidental, as the latter are of such common occurrence, especially in children. However, cures of asthma, chorea, even of epilepsy have been reported. Stammering and stuttering, not uncommonly met with in such cases, have been greatly benefited by the operation. Major ascribes enuresis nocturna to carbonic-acid gas poisoning from insufficient ventilation of the blood, the breathing being too superficial because of the stenosis. Of this, interrupted sleep and snoring are a further result. The best explanation is advanced by Fraenkel, that the base of the tongue falls backward on the epiglottis, thereby obstructing the larynx. The deformities of the chest are, according to some authors, caused by the necessity of breathing through the mouth, the respiration being superficial, with limited expansion of the chest. Fraenkel finds that in the chest, as in all stenoses of the upper air tract, the upper parts are emphysematous, the lower atelectatic. Trautmann and others speak of a paralytic form, predisposing the patient to tuberculosis. Talbot, however, considers the deformities of the chest—and of the face—not the result of adenoid growths, but, with them, signs of a general degeneration of the body combined with degeneracy of the mind. The children appear stunted in their physical growth, but it is common enough to see them increase in size and weight very soon after the operation. The peculiar facial appearance is produced by the broadening and flattening of the bridge and root of the nose, the narrowness of that organ, while the nasolabial folds are not well defined, the mouth is open, the eyes seem veiled. The dull expression is enhanced by the impairment of hearing so often present.

In marked cases, the jaw seems compressed from side to side; the hard palate is not flat but forms a high arch; the alveolar border is not rounded but comes to a point in front, is V-shaped; the teeth override each other; the upper incisors protrude from the mouth and beyond the lower incisors, which are usually normal; the teeth are more liable to diseases. Koerner distinguishes two forms according to the presence of adenoid growths before or after second dentition. In the first case, the palate is higher; in the second, the V-shape is characteristic, occurring only when there is nasal obstruction by adenoid growths. While the patient may appear to be stupid, he is not necessarily so. It is certain that such patients are often enough the brightest of children. They do, however, often complain of headaches and inability to concentrate the mind. Gaye has termed the latter aprosexia. Whatever theory may be based on the anatomical connection between the nasopharynx and the brain, the symptoms are greatly alleviated by the removal of the pharyngeal tonsil.

Scanes describes a distinct transverse vein across the root of the nose. Schmidt relates that, in two children with continued elevation of temperature, the removal of adenoid growths did away with the fever. The importance of such an observation must be acknowledged in its bearing on a doubtful case of tuberculosis, etc. Most characteristic is the "adenoid" speech. The whole nasal cavity being excluded as a resonator, the voice sounds dead, different from that state when the nose is closed in front, or when enunciation becomes indistinct from enlargement of the faucial tonsil. Certain consonants are mispronounced; m becomes b, and n becomes d, etc. Lately, it has been shown by actual count that the blood of children with adenoid growths is impoverished and that, soon after their removal, it quickly approaches the standard averaged from examinations in normal children.

Thost asserts that symmetrical swelling of the numerous small glands of the superficial cervical plexus, in the lower triangle of the neck, behind the sternocleidomastoid, is characteristic of Lusehka's tonsil.

Last, but not least, in this brief summary, are to be mentioned the effects of hypertrophy of the pharyngeal tonsil on the organ of hearing. While not as obvious and manifest as, for instance, the evils of mouth-breathing, there is hardly any condition which calls more imperatively for removal of the offending growths than the various affections of the ear whose cure is otherwise often impossible. Adenoid growths are the most prolific cause of certain diseases of the ear in childhood, excepting, perhaps, the infectious diseases. And these themselves seem to be less of a menace to that organ when the children are relieved of the growths. Simple, so-called, catarrhal otitis media, tubal stenosis, purulent otitis media, with its many sequelæ and complications, eczema of the external canal, etc., often owe their origin to inflammations which either start from the hypertrophied tonsil or are due to conditions dependent on its presence. Otology dates one of its greatest advances from the recognition of the supreme influence of nasopharyngeal and nasal diseases and abnormalities on the anatomically and physiologically intimately related hearing apparatus.

Diagnosis.—The combination of the characteristic facial appearance, of the manifold signs of nasal stenosis, of the voice—which, to be sure, is very similar in paralysis of the soft palate—combined with the aural symptoms, make the diagnosis possible almost at a glance. Sometimes the growths are abundant enough to hang below the soft palate and to become visible as soon as the tongue is depressed. The posterior wall of the pharynx may be studded with lymphoid follicles enlarged from the irritation of the secretion flowing from above. If the children be not too nervous or unwilling, they can be examined by posterior rhinoscopy. The growths can be divided into, practically, two varieties: Either there appears in the mirror a whitish, firm, semispherical cushion, resembling an enlarged faucial tonsil, lying between the openings of the Eustachian tubes, encroaching on the upper part of the septum; or real vegetations are seen, resembling stalactites, berries, etc., and filling the whole or parts of the nasopharynx, spreading from the choane into the tubes and far over the vault, the posterior wall of the pharynx, and sometimes the pharyngeal wall of the soft palate.

With anterior rhinoscopy, the growths may be distinguished as they are lifted by the soft palate in phonation, the light reflexes moving with them. They can also be felt with a probe introduced through the nose.

Oil sprayed with an atomizer into one nostril returns with almost undiminished volume through the other if it does not meet with an obstruction. Bosworth advises this method for confirming the diagnosis of adenoid growths. Palpation with the index finger introduced gently behind the soft palate is a quick and valuable way to examine the nasopharynx, even if it is not pleasant nor elegant.

The question when lymphatic glands are pathologically enlarged is usually answered without hesitation. As even the most superficial ones can not be felt through the skin when they are in normal condition, it seems reasonable to pronounce tonsillar tissue pathological when it is plainly visible on macroscopic examination.

The differential diagnosis should be quite clear in the vast majority of cases; as retropharyngeal neoplasms and nasal growths extending into the nasopharynx are exceedingly rare in patients between the ages of 5 and 15, when adenoid growths are most prevalent and troublesome. Palpation would, generally, when the patient is well anesthetized, enable one to decide between uncomplicated adenoid vegetations, on the one hand, and nasopharyngeal sarcoma, or fibrosarcoma, or unusual prominence of one of the retropharyngeal lymphatic glands, on the other. An appeal to the microscope might, however, be necessary if the tonsil should be invaded by malignant or tuberculous disease.

IODIN USED HYPODERMICALLY IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

ALFRED CARENO CROFTAN, A.M., M.D.

Formerly Assistant Professor of General Diagnosis and Clinical Instructor of Diseases of the Chest, College of Physicians and Surgeons, Chicago.

PASADENA, CAL.

The action of iodine on the healthy body has been exhaustively studied; ideal conditions, we may say, were naturally created for such investigation. It seems that the water, soil and air, and consequently the flora of Geneva, Switzerland, are singularly free from iodine; the inhabitants of that region, therefore, constitute a virgin soil for the drug and display a remarkable susceptibility to its action.

Coindet, of Geneva, first described the physiologic effects of the drug; he was led to his studies on iodine while investigating the curative effects of sponge-preparations on goiter—bronchocoele—which occurs with such frequency in Geneva; he suspected that iodine was the active remedial principle in the sponge and the other marine products that had for generations been successfully employed for the cure of this affliction. Rilliet, also of Geneva, continued these investigations and in a remarkable "Memoir" presented to the French Academy of Medicine, in 1860, first described iodism and introduced the drug into practice. Trousseau reports on this "Memoir" in the 25th Bulletin of the French Academy. From the reports of these two investigators, that have since been repeatedly corroborated and amplified by reliable authorities—Binz, Niemeyer, Kaemmerer, Séé, Stillé—we glean the following information in regard to the pathogenesis of iodine.

Iodine is peculiarly a drug against which different subjects show marked idiosyncrasies; some people can take large doses with impunity, others are speedily and violently affected by almost incredibly small doses. Thus Trousseau reports that the Geneva goiters are cured with doses of iodide of potash of less than a

milligram, the sponge preparations necessarily contain most minute quantities; in certain sensitive subjects, Rilliet reports "grave accidents" from using quantities of table-salt that contained one part of iodine to 10,000 parts of the salt. He even saw iodism develop in these people from a sojourn at the seashore where, it is estimated, they inhaled from a fiftieth to a tenth of a milligram a day. Cod-liver oil contains about one part of iodine to 40,000 parts of oil, and it is not impossible that the curative effects that this marine product exercises on certain "strumous" diseases and the benefits that are claimed for it in tuberculosis may be attributed to the presence of even so minute a quantity of iodine.

The chief symptoms observed are emaciation, usually accompanied by profuse sweats, some pyrexia and an accelerated pulse; a peculiar psychical depression develops a form of hypochondriasis, "anxietas."

A large field of action is the mucous lining of the respiratory tract; when the system becomes saturated with iodine, almost any of the manifestations of inflammation of these tissues may supervene, coryza, angina, laryngitis "with hoarseness, aphonia and chronic inflammation, even simulating laryngeal phthisis;" the lungs show "congestive oppression, and hemoptysis may occur;" Zeiss¹ reports an "abundant serosity" in the lungs of dogs that had been subjected to subcutaneous injections of iodine and an iodide in solution. The serous membranes, too, become affected and pleuritis has been observed. These effects on the respiratory passages, it must clearly be understood, are remote effects of the drug and follow the administration of iodine wherever in the body it may have been introduced; they must not be confounded with its local irritative action following inhalation or topical application.

The lacteals and the lymphatic system are probably the main sphere of action; iodine acts as an irritant, and possibly this explains the emaciation, inasmuch as the chyle is absorbed more slowly, is insufficiently elaborated by the mesenteric glands, and the absorption of fats is, as a consequence, reduced. Hence, probably, too, the profound remedial action of iodine on bronchocoele, lymphatitis—scrofulosis, strumous diathesis—and tabes mesenterica, in all of which afflictions the lymphatic and lacteal systems are inclined to hyperplasia, with resulting sluggish function, etc.

If we study the symptomatology of incipient tuberculosis we find that essentially the same tissues are stimulated to a reactive display of energy by the tubercle virus as by iodine. Again, we must carefully exclude the local, mechanical, and destructive action of the living parasite, and try to draw into the circle of our considerations only the remote effects that are exercised by the products of microbial life near the focus of infection and in distant parts of the body.

Locally, we have that "liquefaction of tissue" that is so commonly attributed to the action of iodine; remotely, the specific selective affinity for the respiratory mucosa, the serous membranes, the lympho-lacteal system; we have the emaciation accompanied by pyrexia, tachycardia and sweats; probably the initial psychosis so often observed is the same.

In the light of our theoretic beliefs the administration of iodine should act curatively in pulmonary tuberculosis; the virus of tuberculosis, entering the blood at first in minute quantities, produces certain slight reactive phenomena from the

1. La Clinique, Feb., 1900.

cells that it is selectively attracted to; this reaction may or may not become subjectively and objectively perceptible; that will depend on its intensity, the character of the reactive symptoms and our facilities for recognizing these symptoms with the rather crude clinical means at our disposal and the uncertain evidence of our senses. If the stimulation and the resulting reaction are strong enough, then the *vis medicatrix* can protect the organism unaided; if it is not sufficiently powerful then the organism is in danger, and it is here that a substance that is capable of irritating the same cells that are reacting to the tubercle virus can produce an increased reaction and aid nature.

Finally, if a carefully graded and sufficiently small dose of iodine will exercise a curative effect in tuberculosis, then a large dose should aggravate by overstimulating and consequently exhausting the very cells that are by their reaction counteracting the toxin invasion. Clinical experience bears this out. Knopf speaks of the "congestive and softening" action of the drug in incipient and latent tuberculosis, and condemns the practice of administering iodids for diagnostic purposes in such cases: it increases bronchial secretion and generally accentuates the physical signs. Hughes speaks of "the occasional development of phthisis pulmonalis in iodized patients in whom apparently no previous tendency thereto had existed."

Accurate dosage is essential to the success of the plan of treatment that is being advocated; too large doses of iodine will certainly aggravate, too small doses will be inefficient. A variety of plans were tried to secure accurate dosage of iodine. At first, the administration of iodid of potash by mouth was considered; it was expected that, according to the researches of Binz, the alkaline iodid, when it reached the tissues, would in the presence of protoplasm and CO_2 be decomposed and free iodine be liberated; this actually occurs, but only a small portion of the iodid of potassium is dissociated in this way and a large proportion is voided in the urine and wasted. On the other hand, Sée calls attention to the fact that iodine, when given by mouth, necessarily unites with the sodium in the stomach contents and is consequently absorbed as alkaline iodid; this entering the tissues is again partly decomposed and partly wasted: accurate dosage of iodine by mouth, either as iodine or in the form of its alkaline salts, is, therefore, impossible.

Administration by inunction in an oily menstruum was considered; euprophen and the other non-irritating iodine compounds recently brought before the profession lend themselves very readily to such use, but accurate or even approximately accurate dosage is, of course, impractical. Hypodermic administration of iodine seemed the only reliable plan, and here the irritative properties of the drug seemed to prohibit its use; at this juncture our attention was called to a paper by Klingmueller,² in which he reports the results of his investigations with an iodine preparation called iodipin, which is an iodine addition product of sesame oil, a yellow fluid of oleaginous taste, 10 per cent. iodine. Klingmueller reports as follows: "It was first found by experiments on animals that the drug employed hypodermically was not toxic; thirty-six patients were treated and received 220 injections of a 10 per cent. preparation. No unpleasant effects were observed even when 20 c.c., the equivalent of 30 grains of iodine, were injected daily. . . . Subsequently additional injections of a 25 per cent. preparation were made with

equally satisfactory results. Not only was the iodine deposited in the subcutaneous tissues slowly absorbed and distributed, but all of it was necessarily taken up and rendered active. Iodine appeared in the urine in from three to five days after the treatment was begun and its excretion continued for several weeks, while in the other preparations the iodine appears earlier and the period of elimination is much shorter. . . . The subcutaneous method of injection of iodipin has the further advantage of being painless, convenient and cheap. . . . The specific action of iodine was manifested after subcutaneous injections of iodine in the same degree as when other iodine preparations, and especially iodipin, were injected by mouth."

Before attempting the hypodermic administration of iodipin in human subjects, the advisability of preliminary animal experiments was considered; however, it is well-nigh impossible to experimentally simulate tubercular invasion as it actually occurs; instead of gradually gaining a foothold in some weakened spot of a bronchus or bronchiolus, the bacillus in laboratory tuberculosis is injected in enormous quantities directly into vulnerable tissues; its virulence is great; the animal's natural means of defense are speedily overcome and it succumbs in every instance. Furthermore, we know that iodipin injected into a non-tubercular subject can do no harm and that, if the dose be carefully regulated, only beneficial effects can be expected in a tubercular case. Animal experiments were, therefore, waived as unnecessary and the administration of iodipin tried directly on patients in whom the diagnosis of tuberculosis of the lungs had been positively made.

Iodipin was employed in the form of the 10 per cent. preparation. The injections were made into the subcutaneous tissues between the skin and the muscle, and preferably in the gluteal and interseapular regions. No discomfort of any kind was ever caused, no inflammatory reaction observed at the site of the injections, though some patients received daily injections for a period of three or four months.

Beginning with one drop of iodipin, which, to give the necessary bulk for hypodermic administration, was dissolved in half a dram or so of sterilized oil, the injections were gradually increased, one drop being added to the dose each day. The dosage was regulated by the symptoms; as soon as an improvement became apparent, the dose exhibited at the time was continued for a period of thirty to sixty days. Much will depend on the individual idiosyncrasies of the patient and the stage of the disease. In some cases the quantity that acted beneficially for a time seemed to grow insufficient and the dose was again increased drop by drop: more than 60 minims a day have so far never been given. Bad effects from this mode of administration were never observed. As 100 drops of the 10 per cent. iodipin weigh 2.5 gr., and consequently represent 0.25 gr. of iodine, each drop of iodipin administered represents only 0.0025 gr. of iodine, or about 0.04 grains.

The object of giving the drug in gradually increasing doses is apparent from our theoretic postulates; it is twofold: 1, to avoid the exhibition of too large a dose, the aggravating effects of which are recognized; 2, in order to create a full artificial immunity against the drug; by employing this plan much larger doses can be administered finally with impunity and more decided reactive effects produced in the end.

The results obtained so far by this plan of treatment have been uniformly good; in a few cases amelioration of symptoms was marked from the beginning: appe-

tite improved, the cough, the night sweats grew less severe, the patients gained in weight and improved in spirits. The physical signs were modified and seemed to show that the process was at least being held in check and rendered latent; in 2 out of my 27 cases a recurrence of symptoms occurred at the expiration of three and five months, respectively; these patients underwent a second course of treatment with good result. It is altogether too early to make any statements in regard to a cure.

Iodipin injections were tried only on carefully selected cases. Where great destruction of lung tissue had occurred, when the patients were devitalized by long-lasting mixed infection, in other words, in the so-called tertiary stage of the disease, the treatment was not instituted.

Twenty-seven cases have so far been treated with good results; 19 were cases of incipient tuberculosis with only circumscribed areas of infection in one or the other of both apices; in the other 8, larger areas in one or both lungs were involved; in 7 of the 27 cases, streptococcus infection co-existed; the remaining 20 were simple infections. Detailed reports of my cases are reserved for future publication, when more clinical material shall have been adduced and the evidence in support of our theories and our practice shall have grown more numerous and more positive.

The results obtained so far are not conclusive; they are only suggestive, and final judgment on the efficacy of this method of treatment must be suspended. The results, it is true, appear to be sufficiently striking to warrant an optimistic view. The number of cases treated, however, is small and the subjects were carefully selected; in addition to the iodipin injections the patients enjoyed the benefits of all the hygienic and dietetic measures suitable to each case and the numerous advantages incident to outdoor life in the warm and equable climate of Southern California.

Notwithstanding all this, it seems more than coincidence that of the 27 cases on record all improved under iodipin injections; if nothing else, these findings should encourage to further investigation and the collation of further clinical evidence.

In conclusion, we make an earnest plea for the early recognition of pulmonary tuberculosis; the sooner the disease is recognized and treatment begun, the better the prognosis. Our clinical experience in the past leads us to join the ranks of those who consider pulmonary tuberculosis, in its incipiency and before it has become a mixed infection, one of the most easily curable of bacterial diseases.

HERNIA OR DIVERTICULUM OF THE CHORION.

L. H. LAIDLLEY, M.D.

ST. LOUIS.

Cysts of the placenta have been reported by Millet and others, supposed to have developed from the exudation of blood forming a clot separating the chorion, usually of small size, and in some cases more than one is noted. Ercolani reported two cases; in one the entire fetal surface of the placenta was sown with round tumors covered by chorion—the largest being about the size of a cherry. Some have been opened and the chorionic wall torn, showing a solid material filling the depth of the cyst; others were more solid, and were filled with coagulated fibrin, in which rounded masses of granular hematoin could be seen.

Ercolani proved that the interior wall was formed by the chorion, which covered the whole bloody mass, of which half projected above the placental surface, while half dipped into the placental tissue, and lay in immediate contact with the effused blood. The term cyst is therefore inexact. At the placental depth of the tumors, the villosities, more fibrinous than usual, formed a compact layer, certain spots in which turned out to be cells of the serotina. Small irregular calcareous concretions were scattered through the mass.

Bustamente describes a kind of cyst which is sometimes found on the fetal surface of the placenta, of a regularly rounded or elongated shape and varying in size from $\frac{2}{5}$ of an inch to 2 or $2\frac{2}{5}$ inches. They are placed below the chorion and amnion, which form their superficial fetal boundary, being limited below by

Schematic diagram of Hernia or Diverticulum of the Chorion.

the placental tissue itself. The contents of these cysts were solid and liquid.

A. Daugan reports a case of an oval tumor $4\frac{2}{5}$ inches long by $3\frac{1}{5}$ inches broad and covered by the membranes, which are partly detached from its surface. Several large venous and arterial branches of the umbilical vessels run over its surface and penetrate its substance to the center. Divided longitudinally, the tumor appears to be composed of intimately adherent lobes, some being of a dead-white and others of a pale or deep-rose tint. Its tissue is homogeneous.

The case which I present has the following history: Mrs. I., age 32, was confined at the seventh month, being her second pregnancy, on August 5. She was in labor about six hours. All that time the os was fully dilated, without any pain, until a few minutes before her delivery, which was normal; twenty minutes afterward a tumor-like body 7 inches in diameter was expelled, proving to be a sac containing an amniotic fluid, with coagulated blood. It was attached to the placental covering, 1 inch to the left of the funis, making a pedicle $\frac{1}{2}$ inch in diameter, made up of chorionic

blood-vessels and connective tissue. The placenta was detached forcibly, in order to preserve the sac and its contents. A microscopic examination of the cyst-wall shows it to contain the same anatomical structures as the chorion, fed by the same blood-vessels, producing a diverticulum, or hernia of the chorion; the fetal side presenting the chorion, the inside the amnion.

The literature does not present a similar instance of this form of tumor. As to the cause of its development, I offer the following theory: Early in the pregnancy there was, because of a relaxed state of the wall of the chorion, a portion of it so twisted as to form a new chamber, receiving its blood from the usual source; its cavity was supplied by the normal amniotic fluid, and because of the partial interference of the blood-vessels an effusion into the sac.

TUBERCULOSIS OF THE TESTICLE.

WITH SPECIAL CONSIDERATION OF ITS CONSERVATIVE TREATMENT.

JOHN B. MURPHY, M.D.
CHICAGO.

(Continued from p. 1191.)

Association of Tuberculosis of the Testicle with Tubercular Lesions Elsewhere in the Body.—As stated above, in from 73 to 75 per cent. of persons dying from all causes, mediastinal glandular tuberculosis is present, and this in the majority of cases is probably the atrium of infection in the cases of testicular disease. The latter is not usually associated with pulmonary tuberculosis, though Reclus observed that 50 per cent. presented lung findings, and 2.5 per cent. of the pulmonary cases over 15 years of age suffered also from localization in the testicle. In his analysis of 500 cases of phthisis, 64 had involvement of the genito-urinary tract, 45 of the genital tract, and in 19 the testicles alone were affected. Simonds, from his post-mortem experience, found the genital organs involved in 2 per cent. of all tubercular children.

Tuberculosis of the lymphatic glands and bones is not often accompanied by disease of the genital organs.

In children, tuberculosis of the peritoneum sometimes coexists with disease in the testicles. Reclus thinks there is, in these cases, a communication between the cavity of the tunica vaginalis and the peritoneal cavity, the processus vaginalis.

Tillmans states that tuberculosis of the testicle almost always develops in persons already tuberculous, but this is not borne out by the experience of most surgeons.

In the majority of our cases the disease, so far as could be determined by physical examination and clinical history, was primary in the epididymis.

As a Part of a General Miliary Tuberculosis.—This is of but little interest to us in the consideration of this subject, because when it is present, it is overshadowed by the manifestations of the disease in other parts. Koenig states that the testicles are rarely affected in general miliary tuberculosis. When the involvement does occur, both testicles and both epididymi are affected simultaneously. Hutinell and Deschamps state that tuberculosis of the testes in children is seldom primary, but usually a part of a general infection.

Occurrence of the Disease in Misplaced and Inverted Testicles.—No authentic case of tubercular disease affecting an undescended testicle is on record, although several cases supposed to be such have been reported, one by G. Fischer, in 1861, and another by F. Roberts.

The details of the cases in these reports are indefinite, so that it is very doubtful if they were really cases of tuberculosis. No satisfactory explanation of the apparent immunity possessed by these misplaced organs has been offered. In a case reported by Rushton Parker, of general tuberculosis, the left testicle was absent, and the left seminal vesicle free from disease, while the right testicle was present and the right vesicle involved.

Inversio-testis was noted by Koenig five times in his cases, and it is thought by him to be a predisposing cause. Case No. 13 of our series presents this anomaly in the testicle first attacked.

The right testicle is attacked first in the majority of cases. Rintelen (quoted by Senn) observed in 15 cases that the right organ was affected first in 10, and the left in 5. In 10 of our cases, in which an accurate history of the onset could be obtained, the right was involved first in 8, and the left in 2. Whichever organ is primarily attacked, it is usually only a question of time before the other becomes similarly diseased, this extension being due, in all probability, to transmission of the infectious material along the vas of the affected side to the prostatic urethra and down the opposite vas to the epididymis on the other side. Jullien states that in children the left testis is commonly affected first.

Pathology.—There has been and still is a marked diversity of opinion as to the location of the primary focus in the testis, and its method of extension subsequently, and a still greater divergence as to the relation which the testicular disease bears to tuberculosis of other portions of the genito-urinary tract, or of more distant portions of the body.

The epididymis is, in a very large percentage of the cases, first attacked. Cases have been reported (Reclus) in which the disease began in the testicle proper, but they are so very rare that practically they may be excluded. Gilbert Barling, M.B., reports a case of acute tubercular disease of the bodies of both testicles. In this case castration was performed, and caseous areas and tubercle bacilli were found in the bodies of the testicles, the epididymi not being involved. There was, however, a suspicion of phthisis in the right apex.

Most authors hold that in the majority of cases the globus major is first attacked, the infection spreading from there to the body and globus minor, and finally to the testicle proper. From our own observations, however, we would say that in adult cases the globus minor is most frequently primarily attacked, the body, globus major, and mediastinum testis becoming affected secondarily by continuity of tissue, or by extension along the surfaces of the seminal ducts. In children the primary nodule has usually been in the globus major.

The morbid anatomy of a testicle, the seat of tubercular disease, varies greatly, depending on the stage to which the process has advanced, the anatomical distribution of the lesion, and the presence or absence of secondary infection. We will not consider here the testicular affection which is a part of a general miliary tuberculosis. In the majority of the cases the epididymis is alone involved, and presents in the early stages one or more small nodules, situated in the globus minor or major. Later other nodules form in different parts, which enlarge and coalesce, converting the epididymis into a hard, irregularly shaped mass, which, at a still later period, after caseation and softening have taken place, may be soft and fluctuating. Section of the epididymis in the early stage shows the nodules to be composed of a homogeneous material, which has

largely taken the place of normal tissue, the latter being compressed and infiltrated with inflammatory products. The capsule of the epididymis is greatly thickened, and the vas, near its attachment to the globus minor, may be thickened and nodular, due to the infiltration of the tissues surrounding it, or to an involvement of its walls proper. Later the small nodules have fused with one another to form larger ones, the homogeneous material may be liquefied so as to resemble pus. Fibrous tissue may have been formed around some of the softened areas, and between them islands of normal or altered tubular tissue may be seen. The capsule now presents caseating areas, and the cellular tissues of the serotum in its neighborhood may be edematous, infiltrated and adherent to it and the skin. When secondary infection has taken place, and frequently without it, the pus may have burrowed toward the skin, the abscess cavity ruptured, and a discharging sinus surrounded by thick fibrous walls formed. The fibrous capsule which surrounds the caseous areas may become infiltrated with lime salts, and in this way a thick shell of calcareous material, surrounding it or perhaps the entire epididymis, is formed. This was

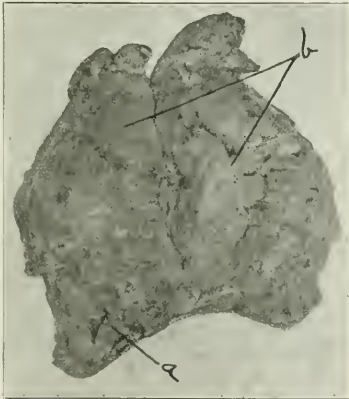

Fig. 5.—Showing involvement of testicle proper and epididymis, the former by extension from latter. a. Globus Major. b. Testicle proper.

beautifully illustrated in a case recently reported by Dr. H. G. Wells. In other cases the disease is not limited to the epididymis, but has also involved the testicle proper by continuity of tissue. (See Fig. No. 5) In these the epididymis presents the appearances described above, and scattered through the testicle proper are numerous small tubercular nodules in all stages of development. These nodules are most abundant at the periphery of the organ, where they are very small, and on section present the homogeneous appearance characteristic of young tubercles. In the mediastinum testis they are apt to be larger and caseous, showing that this was the part first affected by extension from the epididymis. The distributions of the lesions in the testicle proper indicate that the extension took place along the seminiferous tubules. Later, in the course of the disease, the nodules here, as in the epididymis, coalesce to form larger ones, these caseating, becoming encapsulated, or frequently breaking externally. Calcareous deposit may take place either in the fibrous capsule or throughout the broken-down nodules. The

glandular portion is wholly or in part destroyed. The tunica vaginalis usually presents evidences of chronic inflammation, thickening and adhesions between the visceral and parietal layers, or, in some cases tubercular lesions. This involvement of the tunica vaginalis by the tubercular process is well illustrated in Fig. 6, which is a photograph of a testicle removed by Dr. Oswald. In this case the entire testicle had to be removed on account of the extensive involvement. An effusion into the cavity of the tunica vaginalis is present in most cases, but is usually small in amount.

Fig. 6.—Tuberculosis of Tunica Vaginalis. a. Tubercular areas. b. Epididymis. c. Healthy Tunica Vaginalis.

Spermatic Cord.—This is affected in a considerable proportion of the cases, but usually not throughout its entire length. The parts most apt to be involved are either or both of the extremities, the intermediate portion remaining free. In some cases, however, the entire vas is thickened and nodular (Scnn).

The tubercular deposits in the cord are usually situated in the neighborhood of the vas, the infection having taken place by extension along the surface of its mucous membrane from the infected epididymis. All stages of development of the tubercular lesions are found here as in the epididymis, but in most cases have not advanced to the same stage. The mucous lining of the vas is greatly thickened, the outer layers of the wall being affected to a lesser degree. The connective tissue surrounding it may also present nodules and caseous areas, but much of the thickening is due to edema and inflammatory exudate.

Vesiculae Seminales.—The vesiculae seminales come next to the vas, as regards their frequency of secondary involvement. While usually these organs are involved

only after the vas has become more or less extensively diseased, this is not always the case. The process in them may be far advanced without the vas being affected at all, or the latter may present lesions which have evidently developed at a later period than those in the vesicles. Later abscess may form and the pus be discharged through the bladder or rectum, or externally through the perineum.

The Prostate.—This organ follows the vesiculæ seminales in order of frequency of involvement, though some observers (Koehler) state that it is affected much oftener than is commonly supposed, the disease in it being overlooked on account of the absence of symptoms and physical signs in the early stages. The process here is the same as in other parts, the deposits going on to caseation and supuration, and later rupturing into the rectum, urethra or externally. In most cases the prostatic lesions are in an earlier stage of development than those in the epididymis. The prostate and seminal vesicles may be affected unilaterally, and when this is the case, the side presenting the lesion usually corresponds to that of the diseased epididymis. It is more common, however, for the entire prostate or both vesicles to be affected.

Fig. 7.—a. Cross sections of tube of epididymis. b. Tubercle with giant cell. c. Old fibrous tissue. From Case 11.

Microscopic Appearances.—The series of pathologic changes which follow the lodgement of the bacilli in the tissues is the same as in tuberculous lesions elsewhere in the body, modified somewhat by the anatomical structure of the organ. The bacilli, having gained access to the circulation by one of the channels mentioned above, lodge in the walls of the smaller blood-vessels of the epididymis and there produce their characteristic reaction. (Nepveau.) As to the exact situation of the starting-point of the process, there is great difference of opinion, Malassez and Reclus locating it in the walls of the seminal tubules; Virchow, Tizzoni, and Gaule, in the intertubular connective tissue; while Langhans, Curling, Koehler, and others believe it to be in the interior of the tubules themselves. Hutinel and Deschamps found the primary focus in the perivascular spaces in the cases examined by them. As in the majority of cases, the infection probably takes place through the blood-current, it seems reasonable to suppose that the primary lodgment of the bacilli is in the intertubular connective tissue of the epididymis, and this view is certainly supported by studies of tuberculosis in other organs.

The specific irritation set up by the bacilli and their products causes, first, an increased vascularity of the part, and then proliferation of the fixed-tissue cells, and emigration of leucocytes from the capillaries. In this way nodules of the so-called tubercle tissue are produced between the coils of the tube of the epididymis (Fig. 7), widely separating them from each other and encroaching upon their lumina. This tubercle tissue consists essentially of: 1, epithelioid cells, derived from the fixed tissue cells, connective tissue and endothelium of the blood-vessels and lymph-spaces; 2, the reticulum, in the meshes of which the epithelioid cells lie. This reticulum may be derived from the newly proliferated endothelial cells, or it may be the remains of the tissues which previously existed. Later, in addition to the tubercle tissue, the leucocytes, which at first were present in small numbers, become more numerous, especially at the periphery of the nodule. (Fig. 8.) It is in this so-called round-celled infiltration that we find the plasma cells, sometimes in great numbers and usually arranged in groups. These, according to different authors, may be derived either from the lymphocytes of the blood, or from the connective-tissue cells. Their function at present is doubt-

Fig. 8.—Showing young tubercle between coils of tube of epididymis. a. Tube of epididymis. b. Tubercle. From Case 11.

ful, some claiming that they possess phagocytic properties; others that they have no such function, and are destined to become converted into fibrous connective tissue. Scattered through the tissue, usually occurring singly rather than in groups, are found the mast cells of Ehrlich, which are also of doubtful origin and function. The epithelioid cells may be mononuclear or polynuclear, giant cells (Fig. 9), which latter are formed by the proliferation of the nucleus of the cell without division of the cell body, and are usually found in the center of the tubercle, surrounded by the mononuclear epithelioid cells.

When the individual tubercles have attained a certain size, caseous degeneration sets in, due both to the action of the toxin and to the gradual shutting off of the blood-supply, and it is at this point that the process may be arrested by encapsulation, or that secondary infection, with destruction of a part or whole of the organ, may occur. If encapsulation takes place, the connective-tissue cells which have proliferated at the periphery of the tubercle, or tubercles, gradually contract and become converted into a dense fibrous tissue, in this way causing

an arrest of the process, the nodules remaining for an indefinite period of time.

During the progress of the changes described above, the coils of the tube of the epididymis are encroached upon and present a variety of changes. The epithelium may have entirely desquamated at the site of involvement, the cells lying loose in the lumen, which may be greatly dilated and contain pus-cells and granular debris, the remains of degenerated cells and spermatozoa. In other sections the lumen is filled with caseous material, which has probably come from the tubercles in the walls, rather than from the interior of the tube primarily. The duct may present in certain parts great dilatation and be filled with purulent material and spermatozoa. In these latter the epithelium may be intact or desquamated in parts.

Tubercle bacilli can usually be demonstrated in the sections, especially where the process is in the early stages. Later, after caseation has taken place, they may be so few in number as to escape observation, even on careful examination.

Reclus has described a rare pathologic condition in tuberculosis of the testicle, in which, instead of the

Fig. 9.—Giant cell in center of Tubercle. From Case 11.

changes described above, the epididymis presents a reticular arrangement, the alveoli of which are filled with pus.

Symptoms.—These differ materially, as in tuberculosis of other organs, varying with the rapidity of advancement of the process, the presence or absence of mixed infection, and again as the disease is primary or secondary in the testicle.

The symptoms of onset vary greatly at the different periods of life. In infants and young children the parents' attention is usually first called to the presence of a small nodule in the epididymis, the child having manifested no other symptoms, except perhaps slight tenderness in this region.

In adults the initial symptoms may be sudden or gradual in their onset, the latter being much the more common of the two. When associated with mixed infection, the onset is stormy, and there are all the manifestations of an acute epididymitis, resembling the gonorrhoeal form. (Case 10.) Abscess formation may be rapid, and the pus find its way to the surface in a short time, leaving a sinus that heals slowly. Instead of breaking externally, the burrowing may be in the direction of the testis proper, and a portion or all of this organ be destroyed. Rupture into the cavity of

the tunica vaginalis must be extremely rare, if it ever occurs.

When unassociated with mixed infection, the onset is slower, and many of the patients come to the physician for the first time because of the nodule which they have accidentally discovered in the epididymis. They are usually unable to say how long it has been there, but in some instances date its development from a slight injury or a gonorrhoeal epididymitis. The nodule or nodules are at first painless and only slightly tender on compression; but usually after a short time the patient experiences a dull, aching pain in the testicle, brought on or aggravated by exercise. This pain may be referred to the testicle or upward along the spermatic cord, sometimes even extending into the ilio-lumbar region of the same side. It is rarely severe, and may be entirely absent when the patient is at rest.

A urethral discharge, usually whitish and mucoid in character, has been noted in a considerable proportion of the cases, usually quite early in the course of the disease. Instead of being white, it may be purulent or

Fig. 10.—Globus Minor and body of epididymis dissected from testicle proper. a. Globus Minor and body. b. Globus Major. c. Reflected tunica Vaginalis. d. Testicle proper.

even bloody. Various theories have been advanced as to the origin of this discharge, some claiming that it is due to tuberculosis of the prostate, vesiculæ seminales, or the prostatic urethra, while others believe it is caused by a catarrhal condition of the posterior urethra and seminal vesicles. The latter is probably the true explanation, as it disappears after castration or epididymectomy. Symptoms of vesical irritation are present in the great majority of cases without mixed infection, and in some they are the first to attract the patient's attention. At first, there may be slightly increased frequency of urination, with perhaps a little burning during the act, referred to the base of the bladder. As the case progresses, the irritability becomes more marked until the patient is unable to retain his urine more than fifteen or twenty minutes at a time, involuntary passage taking place if he attempts to do so. Later, also, tenesmus develops, and may become very severe. The fact that vesical symptoms are usually absent in the cases with secondary infection is to be explained, in all probability, by the edema and swelling of the vas, which does not permit the irritating material to pass through it to the vesiculæ seminales.

(To be continued.)

BUBONIC PLAGUE IN SAN FRANCISCO.

FURTHER CASE REPORTS.

CASE 19.—Moon Li Chee Yung, age 30, mongolian female, resided at 802 Dupont, died October 31. A bubo was found in the left femoral region. An incision showed a necrotic lymph-node about the size of a walnut, the surrounding tissue being infiltrated with a bloody fluid. Smears from the gland substance showed plague bacillus. The diagnosis was confirmed by inoculating a guinea-pig, from which pure cultures of the germ were obtained. Pure cultures were also obtained direct from the gland.

A Chinese school-teacher died in these same rooms on September 12, of this year, supposedly of pneumonia. She was taken sick suddenly, had a severe chill, high fever, and died in four or five days.

CASE 20.—Yung Wah Noui, a mongolian female, age 9, resided and died at 802 Dupont, a daughter of the preceding case, and died twenty-four hours after her mother, after displaying similar symptoms. The autopsy was held twenty-four hours after death. Decomposition was well advanced; there was no enlargement of the superficial lymph-nodes. Smears of sputum stained showed the presence of a bipolar staining bacillus. The entire left and the lower lobe of the right lung involved in a bronchopneumonia. The pericardium contained a bloody fluid, the heart muscle was soft and the ventricles filled with blood-clots. The spleen was enlarged, very soft, and its structure partially broken down. The peritoneum over the small intestines was congested. There were submucous hemorrhages throughout the small intestines. The vessels of the mesentery were injected. The mesenteric lymph-nodes were soft and very dark in color. No ulceration in the intestines. Smears of the spleen, lung, and mesenteric glands show the plague bacillus. A guinea-pig was inoculated and died four days after displaying typical plague lesions.

CASE 21.—A female nurse, 28 years of age, entered a hospital in this city on October 31, 1900, with a history of exposure to diphtheria, having nursed a case from 7 p. m. October 21 till 1 a. m. October 22. This case, Samuel Fluth, aged 19, said to have come from San Jose, had been treated for typhoid fever by his physician for about a week, when, after a consultation with another physician a diagnosis of nasal diphtheria was made, and a death certificate to that effect sent to the health office on the death of the man, which occurred six hours later. The girl complained of severe pains all over the body, especially in the abdomen. Temperature 40 C., pulse 104, respirations 33. There were no throat symptoms at any time. An injection, supposedly diphtheria antitoxin, had been administered in the left forearm by Dr. E. R. Wisner. The patient refused to say where she had been in the interval after leaving her last patient before entering the hospital.

The case was immediately placed in the contagious building. The following day, the pain continued, accompanied by tympanites, and turpentin stupes were applied. Toward evening the condition was improved, the temperature falling to 37.4, and abdominal pain and tympanites lessening. A cellulitis was now seen developing on the inner side of the left arm near the axilla, but no swelling of the axillary glands. The following day, November 2, the arm became very painful and the temperature rose to 38.5 at 7 p. m. At 2 a. m. November 3, there was some weakening of the pulse, and stimulants were given, and the condition improved. At 3.30 a. m. she passed urine containing blood, and spat blood-tinged mucus. Hemorrhagic petechiæ appeared around elbows and ankles, temperature dropped to 36.6, pulse grew weaker, and death occurred at 4 a. m.

Autopsy Report: External appearance: Subject a well-developed young female. Rigor mortis marked. Cadaveric lividity on dependent aspect, especially marked about head and neck. Purplish red spots, not raised from the surface, about both ankles, both knees and both elbows. Inguinal glands slightly, but not markedly enlarged. Axillary and cervical glands not enlarged. No noticeable change in left forearm where antitoxin was injected.

Abdominal inspection: Muscles and subcutaneous tissues firm, well developed. Peritoneum markedly injected over on

tire extent, especially about cecum. About three ounces of free, non-clotted blood at bottom of pelvis. Stomach considerably dilated and displaced downward, lower border $2\frac{1}{2}$ inches below umbilicus. Other organs in normal positions. A few enlarged glands in mesentery, size of a bean. Appendix free from adhesions.

Thorax Inspection: Pericardium filled with straw-colored fluid. Lungs free. No fluid in pleural cavities.

Examination of organs: Spleen was enlarged, deep purple color, extremely soft and friable; on section minute glistening points, size of pin-points, scattered throughout—cultures and cover slips taken. Stomach was dilated and displaced downward; contained yellowish curdy fluid; mucosa covered with purplish spots size of a pea. Left kidney was about normal size; capsules strip readily; on section considerable fluid-blood oozes from surface; cortex injected; substance soft—cultures and covers taken. Right kidney was similar. Liver was normal size, fatty. Gall-bladder's peritoneal surface covered with purplish blotches, irregular in shape—subperitoneal hemorrhages. Small intestine had scattered throughout its length, small whitish-gray elevations similar to tubercles; here and there are purple spots—submucous hemorrhages—most marked and in greater number in the lymphoid follicles. Large intestine: The caecum is thickened, grayish color; its surface covered with innumerable whitish-gray elevations similar to those in small intestines, but more numerous; besides these are submucous ecchymotic spots. Appendix was free from adhesions; vessels injected; submucous coat infiltrated with blood. Mesenteric glands showed a chain of five enlarged to size of a bean, soft; no hemorrhages inside—cultures taken. Fallopian tubes were congested and purplish in color; these extend over posterior surface of uterus. Left ovary contains a Graafian follicle on point of rupture. Uterus, normal size. Either cornu contains a soft reddish material—cultures taken. Heart enlarged, muscle rather soft; right auricle greatly dilated, filled with clotted blood; all the cavities are filled with soft red clots; mitral valve thickened; aorta contracted; aortic valve slightly thickened and opaque; tricuspid and pulmonary valves normal; the endocardium of right auricle is dull, lusterless, and has a pinkish-red color, looks as if covered with a red scum, this appearance noted in all the cavities, not so marked as in right auricle—cultures and slides taken. At root of left lung about a half-dozen whitish spots size of grain of sand, look similar to tubercles; lungs otherwise normal.

Pathological Diagnosis: Septicemia, with tendency toward minute hemorrhages in tissues; cause probably *B. pestis*. Septic spleen, fatty liver, gastroptosis and submucous hemorrhages in stomach, septic enteritis and colitis, acute septic nephritis, hypertrophy of heart, chronic mitral—thickening—regurgitation, hemorrhagic necrosis of endocardium.

Bacteriologic Examination: The blood was found full of plague bacilli. There were enormous numbers of them in the spleen; they were obtained in pure culture from the spleen. Guinea-pigs inoculated with spleen tissue died within thirty-six hours of typical plague septicemia. The spleen and peritoneal cavity contained an exudate full of the bacilli. The body of Samuel Fluth, the young man attended by this nurse, was exhumed and examined by the city bacteriologist, Dr. Kellogg. The body was found very much swollen, indicating rapid decomposition; pieces of tissue were taken for examination.

Post Operative Irrigation of the Bladder.—By continuous irrigation after suprapubic cystotomy, danger of infection and infiltration of urine is obviated. The wound heals by first intention and if the bladder is painful, the hypersensitiveness is diminished. Dandoy related at the International Medical Congress that the recovery was surprisingly rapid in the two cases he described. The wound was sutured except where a Guyon-Perries tube was inserted, bringing the water from a reservoir above, the flow regulated by stopcocks. A Nelaton with irrigator was introduced into the bladder through the urethra, and the irrigation continued for four to six days.

MEDICAL LIBRARIES IN SMALLER CITIES.

Excellent public libraries are springing up in our thriving smaller cities of 20,000 to 50,000 and more inhabitants. These libraries are partly the result of endowment by wealthy and public-spirited persons, partly of wise appropriations by the municipality. And smaller libraries are being established quite generally in cities of less size as well as in villages. While the larger centers are rapidly acquiring good medical libraries, thanks largely to concerted action by interested persons in the medical profession, little or nothing has been done as yet toward securing library facilities of a medical character for smaller cities and the territory naturally tributary to them. There is unquestionably good room here for undertakings of this kind. There is no need for argument in favor of the value of medical libraries within the convenient reach of physicians, whether in the city or in the country. One of the reasons for the reluctance of the young physician to leave the larger cities is the absence elsewhere of medical libraries.

The renewed activity of the smaller local societies and the tendency to make them the basis of larger associations, all modeled according to a more or less common plan, speak well for the truly professional spirit of our medical men. Medical libraries would strengthen the solidarity of the profession wherever they may be established. By a system of loaning out books and journals they could be made of great service to the country practitioner and the physician in the smaller cities and villages. Local societies might well canvass this matter. The local situation may determine different modes of action. By means of a small annual income, judiciously expended, a few years would lead to useful collections of medical literature, sure to receive substantial accretions from private libraries from time to time and from exchanges with other libraries.

Perhaps the question of housing, in a proper manner, libraries of this kind may be a difficult one to meet. When larger public libraries already exist, it may be that these could be induced to set aside the necessary space for the books and journals. These public libraries not infrequently occupy pretentious buildings. In other cases local hospitals might furnish the necessary rooms; and then again, suitable space may be rented at a comparatively insignificant figure. The matter is largely one of enterprise. Energetic action on the

part of a few men in a district would surely carry the matter to a successful issue. It should always be borne in mind that a library to be successful must be more than a collection of old and discarded text-books. These have their place, but it is not an important one. A successful library must contain indexes, dictionaries, encyclopedias, and, especially, living medical literature, that is, journals and current publications. Private libraries, in the great majority of cases even, only partly fill the needs of the owner, and the expense and difficulties of maintenance absolutely preclude their ever supplanting the need of public libraries. The right use of medical literature is acquired slowly. Its preservation in accessible form is a prerequisite for its proper appreciation and the unfolding of greatest usefulness. Local medical libraries tend to broaden the views and to increase the scholarship of their supporters.

THE DIAGNOSTIC SIGNIFICANCE OF BENGE-JONES
ALBUMOSURIA.

In the middle of the present century, Bence-Jones described a peculiar reaction of the urine, namely, the occurrence of turbidity on heating, or of a precipitate on addition of nitric acid, but clearing up on further heating and recurring on cooling. The substance on which this reaction depends was further found to be precipitable by alcohol, the precipitate being soluble in water. The body was recognized to be an albuminoid substance, but only many years later was it shown by Kühne to be an albumose, differing in its relations, however, from other albumoses. Since then not many cases have been placed on record in which the urine is reported to have this reaction present. The first two were considered to be instances of osteomalacia, and almost all of the others have been attended with disease of the bone-marrow for which the designation "multiple myelomata" has been proposed. The symptoms present in these cases were in part referable to the osseous system and in part anemic in character. The former include severe pain in the nape of the neck, the shoulder, the chest and the back, rarely in the upper extremities, usually occurring in paroxysms without appreciable cause, but aggravated by movement. The cervical or dorsal spine, as well as one or more of the ribs, were at the same time tender, and in some instances the seat of circumscribed prominences. In most cases, deformities of the cervical and dorsal spine and of the thorax developed in the course of time, resulting in marked kyphosis, and protrusion of the sternum, in consequence of angulation of the ribs, as a result of spontaneous fracture. Sometimes profound nervous disturbances occurred—radiating neuralgiform pain, visceral pain, bulbar symptoms, and typical symptoms of compression of the spinal cord. Death resulted from these complications or from progressive cachexia or intercurrent disease. Although multiple myelomata have been present in almost all of the cases in which

albumosuria has been observed, all cases of multiple myelomata have not been attended with albumosuria.

That other diseases of the bone-marrow, however, may be associated with albumosuria is demonstrated by a case of lymphatic leukemia reported by Askanazy.¹ The patient was a man 51 years old, who, a year before coming under observation, began to complain of undue readiness of fatigue. In the course of six months progressive enlargement of the cervical lymph-glands took place. Following convalescence from an attack of pneumonia at a later date the legs became swollen and an abdominal tumor made its appearance. The patient was pallid and cyanotic. The cervical and axillary lymphatic glands were moderately enlarged, and the chest was the seat of numerous small, subcutaneous enlargements. The abdomen contained a glandular tumor as large as a man's head, and smaller nodules were palpable in the rectovesical space. The bones exhibited no alteration. The blood presented changes characteristic of lymphatic leukemia. The urine contained albumose in abundance. Deaths resulted from pulmonary edema, and post-mortem examination confirmed the clinical diagnosis. A study was made to determine whether the substance found in the urine was present also in the bone-marrow, the tumor-masses, the blood, the pericardial fluid and the pleuritic exudate, with the result that albumose was detected only in the bone-marrow.

Examination of the urine in another case of lymphatic leukemia failed to disclose the presence of albumose. The opinion is expressed that Bence-Jones albumosuria is a manifestation of disease of the bone-marrow and generally multiple myelomata, although exceptionally it may result from the presence of other diffuse, lymphoid alterations in the bone-marrow, such as are observed in cases of lymphemia.

CEREBRAL ABSCESS FOLLOWING TYPHOID FEVER.

Pyogenic micro-organisms may gain access to the brain and give rise to the formation of an abscess through direct injury or through metastasis from a primary focus of suppuration, contiguous or remote. The most common single etiologic factor is disease of the middle ear, while the disorder is rarely a complication of the infectious diseases. A case in which an abscess of the brain developed in the sequence of an attack of typhoid fever, and giving rise to symptoms of focal epilepsy, with successful operation and discovery of staphylococci in the pus, is reported by A. C. Brown.¹ The nervous symptoms made their appearance during convalescence from the fever, and infection is thought to have taken place from the intestinal tract through the medium of the ulceration of the bowel. There was no history of injury and no evidence of middle-ear disease, or of any other suppurative process. The patient was a girl 19 years old, and the first manifestation consisted

in twitching of the left side of the face, the left arm, and the left leg, followed by paresis. Later, headache and vomiting set in. On one occasion the patient became conscious of noises in the right ear, numbness of the left hand and a sensation as if the left hand and arm were being gripped, passing gradually up the arm to the left side of the face and head. The left hand then began to shake. The painful gripping sensation in the hand and arm gradually passed off, but the left leg began to shake violently and the shaking in the left leg passed up the arm. In a short while the left leg was found heavy and powerless. Loss of consciousness supervened and persisted for ten minutes. When consciousness returned the head was drawn to one side and the eyes rolled. For a few minutes the patient was unable to speak. There was a mist before her eyes and her head ached badly. For two hours she felt unable to move, as the left arm and leg were still heavy and powerless. On getting up there was a tendency to fall to the left, and a limp that had been present in the left leg since the attack of typhoid fever, was distinctly more pronounced. The patient grew gradually worse and at a later date an early stage of optic neuritis was discovered. Headache persisted and the twitching and weakness of the muscles of the left side of the body increased. The knee-jerk, elbow-jerk and the supinator-jerk on the left became exaggerated, and ankle-clonus could occasionally be elicited.

In the diagnosis, hysteria, tuberculosis and syphilis were excluded, and the conditions were thought to be due to a rapidly growing glioma, though the possibility of abscess was considered. Operation was undertaken, with the result of finding an abscess in the right motor region, involving the ascending parietal and ascending frontal convolutions. The pus, in which bacteriologic examination disclosed the presence of the staphylococcus pyogenes aureus, was evacuated and drainage provided for. The further course of the case was noteworthy only for the marked improvement that took place, the patient recovering entirely the use of her leg and to a great degree also that of her arm.

Suppuration is not an uncommon complication of typhoid fever, the typhoid bacillus being sometimes found in the lesions; but abscess of the brain is rare. Indeed, Brown believed that his case is the first that has been reported in the sequence of an attack of typhoid fever, but Keen² refers to three cases recorded in the literature, without bacteriological findings, however.

THE VITA PROPRIA OF HUMAN CELLS.

The vitality which is characteristic of and belongs to the individual cell—the vita propria of the cell of Virchow—has received comparatively little study. Grawitz claims to have observed that the corneal corpuscles withstand drying as long as eleven days, but the correctness of his observations has been questioned.

1. Deutsches Archiv f. Klin. Med., lxxviii, 1 u. 2, 11, p. 34.
1. Edin. Med. Jour., September, 1900, p. 228.

2. "Surgical Complications and Sequels of Typhoid Fever," Phila., 1898, W. B. Saunders.

Busse states that ciliated epithelium in the covering of nasal polypi may maintain the motion of their cilia for eighteen days after separation from the matrix. Spermatozoa are said by Schade to manifest evidences of vitality for a considerable time after the death of the body as a whole and after having been expelled from the living organism. This persistence of the life of spermatozoa is of medicolegal interest. Living spermatozoa have been demonstrated in the rectum of a boy eight days after death at the hands of a pervert, the body lying in water at a temperature of about 0 C. Ljunggren's study of the power of epithelial cells to live outside the body are of great interest, and recently Grohe¹ has studied the *vita propria* of the cells of the periosteum of rabbits. The pieces taken from the tibia and the radius were kept at a temperature between zero and 4 C., because at low temperature the vitality of various cells has been found to persist longer. At various intervals the pieces were transplanted into the muscles of the arm and thigh of animals of the same species. Without going into details, suffice it to say that the cells in the inner layer of the periosteum in numerous instances were found to retain their osteoblastic powers for from forty-eight to one hundred hours after removal from the body, producing, when implanted, osteoblasts which formed islands of cartilage and osteoid tissue. In twelve days, a piece of periosteum, kept one hundred hours, formed a mass as large as a hazel-nut composed of hyaline cartilage and osteoid tissue.

Morpurgo² calls attention to the almost forgotten observations of Mantegazza on the survival of periosteum and of human and of frog spermatozoa, and of those of Bizzozero on the *vita propria* of ciliated epithelium, bone-marrow cells and smooth-muscle fibers. Morpurgo himself demonstrated that the cells of the periosteum of chickens may retain their vitality outside of the body for one hundred and ninety-two hours, when kept at 3 to 6 C., and for one hundred hours when kept at 40 to 41 C.; at the end of these periods bone was produced by implantation. The favorable action of cold is ascribed to its restraining influence on vital processes in consequence of which the reserve food lasts longer.

Wentscher³ shows that the epithelial cells of the skin possess a greater surviving power than indicated by Ljunggren's experiments, in which an attempt was made to nourish the cells by preserving them in serum. Wentscher employed Thiersch grafts, taken from the outer aspect of the thigh and kept in sterile salt solution or in cotton in an empty bottle; the latter method gave best results. He obtained positive evidences of life, in the form of mitoses in the cells of pieces thus preserved and grafted on erural ulcers, in the case of the wet specimens after ten days, and in the case of the dry, after twenty-two days. The pieces kept dry became

hard and it was necessary to soften them before grafting; on softening, the epidermis was permeated by fluid and expanded again. In the successful experiments—twenty-one in sixty—there was a permanent return, or revivescence, of all vital characteristics, and the subsequent events were the same as in transplantation of fresh pieces.

Cardile found that leucocytes kept in bouillon under favorable circumstances remained alive for seven days outside the body.

These illustrations of the *vita propria* of the cells indicate that Grawitz is not so far from the truth when he says: "Perhaps weeks may pass before the life in the last cell ceases."

THE MOSQUITO AND YELLOW FEVER.

The evidence adduced by Drs. Reed, Carroll, and Agramonte that the mosquito is the carrier of the infection of yellow fever, has called out other evidence or suggestions. The freedom of the Southern piney woods region from yellow fever has been noticed before. It is said that the disease never spreads there, and the fact was generally attributed to some peculiar influence of the pines. Now it is claimed that the absence of the mosquitoes in the pine woods may account for the freedom from the disease, previously credited to some medical virtue of the trees. Another thing noticed in the South as corroborative of the mosquito theory, is that, while the yellow-fever infection seems sometimes to survive a cold winter, it disappears after a slight frost, which also makes an end of the mosquito. These are not yet scientifically demonstrated facts, but they may be worth looking into and verifying if possible. There is ample room for further study as to the nature and etiology of yellow fever, and every little helps.

LAY USE OF THE CLINICAL THERMOMETER.

An enterprising firm which manufactures clinical thermometers, is advertising its instruments to the general public in some of the magazines. There does not seem to be any reason for an objection from the medical profession to this procedure. On the contrary, it is probable that the intelligent use of the clinical thermometer by the laity may be the means of enabling the family physician to see many cases of illness at an earlier period than would otherwise be the case; and it would often obviate the necessity of responding in person to a night call, as the record of the clinical thermometer transmitted by telephone would usually enable the physician to properly estimate the immediate gravity of the case. The advertisement referred to advises people to regularly take the temperature of themselves and children, which is neither advisable nor practicable. A reading taken when there is any feeling of malaise, might be of assistance to the physician in enabling him to see the case in the primary stages of disease and in aiding him to arrive at an early diagnosis. On the whole, it would seem to be advisable for physicians to encourage the intelligent use of the clinical thermometer.

THE ACTION OF COLD AND HEAT ON THE INTESTINES.

Observant individuals have long noted that, after having taken a purgative, exposure of the surface of the abdomen to cold, as a draught of cold air, is very likely to produce a colicky pain. Conversely, many people, who on slight cause suffer from acute diarrhea and cramps, have found that protecting the abdomen very carefully from damp and cold is effective in reducing the frequency of attacks. People living in the tropics, where diarrhea and dysentery are always at hand, have learned to wear a woolen binder about the abdomen, as it has been found to very materially reduce the danger of contracting these diseases. No true has this been found that the British army furnishes its troops serving in the tropics with flannel binders, and our own troops when going to Cuba were in part so supplied, but had not the necessary experience to ensure their intelligent use. There seems to be a definite relationship between exposure of the surface of the abdomen to cold and damp, and the production of diarrhea, either mild or severe. The relief afforded by the application of external heat in intestinal colic is well known.

ORIGIN OF LEPROSY IN HAWAII.

The introduction of leprosy in Hawaii, from recent statements, seems to have been under the special protection of the native royalty and aristocracy. It first appeared in the person of a chief Kakaunohi, who had been to China, and from him was transmitted to another Naea, who was closely related to the reigning family. From the latter it quickly spread to his tenants and retainers, and for a considerable time was known among the natives as the "ma'i alli," or the chief's, or royal, disease. The missionary physicians soon learned to recognize it and one of them, Dr. Dwight Baldwin, it is said, made a report on it, stating the facts of its origin, etc., and filed it with the minister of the interior, but it was held from publication, doubtless on account of the connection of royalty with the introduction of the disease. So long as the Hawaiian monarchy existed, segregation of lepers, though legally demanded, was very imperfectly carried out, owing, it is said, to the interference in high places. Since the overthrow of the monarchy, however, the measures have been more effective and the seeing of lepers on the streets, which was formerly an occasional event, is no longer possible. The isolation law is an unpopular one with the native Hawaiians, who possibly regret the passing of the old régime on that account as much as on many others. These data are obtained from the Honolulu *Commercial Advertiser*, whose authority for the main facts is the Rev. Sereno Bishop, who was one of the earliest to recognize the affection on the islands. We have not seen this bit of medical history narrated elsewhere.

SCHOOL INSPECTION IN CITIES.

The advantages of the Chicago school inspection were set forth in a communication made October 30 to the Board of Education by Dr. A. R. Reynolds, health commissioner. Since the beginning of the year over 75,000 children have been detained by school principals for medical inspection, and of these 4539 were temporarily excluded from school on account of danger

of contagion, and in 711 a bacteriologic examination was made to confirm the inspector's diagnosis. The results of this care are a very notable decrease in the mortality from those disorders that are especially fatal to children, such as diphtheria and scarlet fever. The average mortality from diphtheria for the ten years, 1890 till 1899 inclusive, during the month of September has been 85.5, or about 4.5 per cent. of the total deaths. For October the like figures are 127.9 and nearly 7 per cent. Prior to 1890 the figures are still higher for years in which accurate statements are available. During the past two months, September and October, 1900, there were 42 and 77 deaths respectively from this cause, certainly a notable reduction. Similar results could be cited as regards scarlet fever, and for other months. It is hardly necessary, however, to demonstrate the value of school inspection by object-lessons such as these, though they are impressive to the laity. The dangers of contagious disorders in schools are sufficiently obvious, however much they have been ignored in times past. One of the advantages of the inspection will be the impression it makes on the teachers themselves, and the reinforcing their feelings of responsibility in regard to these matters. Too many of them have heretofore had no idea whatever of the risks to health and life that a little inattention on their part may involve. The mere fact of arousing them to observe morbid symptoms must be one of the greatest value as regards the health of the school children and the community, and, with an intelligent inspection added, goes far to insure against serious results from school epidemics of contagious diseases. The value of the human life saved, to say nothing of the suffering, bereavements, and disease prevented, infinitely outweighs the comparatively trifling cost. Municipal authorities who wilfully neglect this precautionary measure on economic grounds may have human lives charged up against their account.

A NORTH-AMERICAN MEDICAL ASSOCIATION.

The *Dominion Medical Monthly* editorially comments on the suggestion of the *New York Medical Journal*¹ that Canadian physicians be admitted to membership in the AMERICAN MEDICAL ASSOCIATION. The proposition appears to strike our Canadian confrère favorably. It enumerates some of the advantages that would thus ensue to Canadian practitioners; the closer associations with the great body of medical men on this continent and the advantages of THE JOURNAL to Canadian physicians are specially noticed. There is no question that there are many reasons why it would be advantageous to both Canadians and Americans to come together on common ground in medical matters, and membership in the AMERICAN MEDICAL ASSOCIATION would be the most available means to this end. There is only one possible objection, and that would not affect the scientific side of the question. The AMERICAN MEDICAL ASSOCIATION has often to deal with matters exclusively American, questions of legislation, etc., and it would be manifestly improper to have those not directly interested have a voice in the decision. This, however, would not affect general, non-

1. See THE JOURNAL, July 21, p. 181.

voting membership, with all the scientific and social privileges, provided there was a way by which this could be legalized. At present, Canadian physicians can become members only through membership in an affiliated organization. If there could be a rule adopted whereby membership in the Canadian Medical Association, or affiliated bodies, would qualify for non-voting associate membership or something of the kind, in the AMERICAN MEDICAL ASSOCIATION, and vice versa, it might work to the mutual advantage of both bodies. From the scientific viewpoint, Canadian physicians should be more nearly affiliated with their fellow members of their profession in this country than with any others, and scarcely anything would be more effective in bringing them together than such an arrangement as proposed above. The suggestion is, in any case, deserving of thought.

PARESIS AMONG THE JEWS.

In the London *Lancet* of October 27, there is an interesting editorial analysis of an article by Beadles, of Colney Hatch Asylum,¹ on insanity among the Jews. One of the most interesting observations made by this author is that of the great preponderance of parietic dementia in this race. Thus he found that 21 per cent. of all male Jews admitted in the London County asylums were parietics, while the proportion in the average asylum population of England is, according to the most recent report of the Commission in Lunacy (1899), only 13 per cent. In female Jews the ratio is not above that of insane females generally, and we find, therefore, that paresis is 60 per cent. more frequent among Jewish men than among other male patients of English asylums. The predominant cause, or at least antecedent, of paresis is syphilis, and this fact is therefore of the most interest, since it is often claimed that specific disease is rare among Israelites. It is a well-known and, we believe, generally admitted fact that the Jewish race is neurotic to a greater degree than others, but their greater liability to paresis has not been before brought prominently into the light. It is possible that the reason is not so far to seek as might at first appear. Syphilis by itself is not necessarily a cause of paresis, the added factors of excesses, and especially of mental stress, are probably required. The dominating idea in the average city Jew, even more than the non-Jew, is business, and they are particularly liable to this chief exciting cause. Many of them are speculators and therefore especially under the strain of mental anxiety in the vicissitudes of business. Syphilis may be rarer in Jews than in others, but they are nevertheless its victims to a certain extent, and Beadles finds sexual excesses playing a large part in the alleged causes of insanity among them. Many of the Jews of this country, and Great Britain also, come from parts of Europe where syphilis is far more common than here, in certain parts of Russia, for example, where it is said to be endemic in the lower grades of the population. All these considerations are to be taken into account and may serve to render more intelligible the fact announced by Beadles. It would be of interest to have results of similar studies in the asylum population of other sections, the metropolitan asylums of this country for example.

THE PLAGUE IN SAN FRANCISCO.

In the latest "Public Health Notes," of the Marine-Hospital Department, Surgeon Kinyoun reports three cases of the plague occurring among the Chinese in San Francisco during the month of October, and expresses his opinion that the area of infection is growing wider and that conditions favor its further outbreak. His report is dated October 29, and, as will be seen elsewhere in this issue, our correspondent has sent in details of three more deaths which occurred October 31 and November 1; one of them was a white woman, a professional nurse, who had been attending a fatal case reported as "nasal diphtheria." This case is being investigated and may possibly furnish further revelations. There does appear, therefore, to be some ground for apprehension of further trouble and need of more energetic measures on the part of the local authorities than have been attempted heretofore. The existence of the Chinese quarter in the business center of San Francisco is a peril to health at any time, and all the more when it includes active plague-foci, which there is too much reason to fear is now the case. There is no city in Europe or America that has met the peril of the plague in the way San Francisco has done, and this is not said in commendation of her course. It may be, as some French alarmists have said, that there have been concealed outbreaks in some southern European ports, but there is no place where the press and public have so persistently fought the necessary sanitary measures in their desire to prove that the plague did not exist among them. It would be a business misfortune to be quarantined against, but it is taking serious chances to ignore a possible danger in the hope that it may pass off without actually developing to any great extent. If the plague should become a little more an undeniable reality than it is at present, the residents and business men of San Francisco, and possibly others, may have ample reason to regret the course that has been thus far followed. The methods of the ostrich are not always the best; and certainly not the most courageous in meeting such a danger as the bubonic plague.

THE SLEEPING SICKNESS.

This disease is confined to the tropical part of West Africa. Within the last few years three cases have been brought to England for the purpose of study, the results of which have been made public recently by Manson, Mott, and Mackenzie.¹ It is a chronic disease, which when introduced into a village may persist for years and cause serious loss of life. The leading clinical characteristic of sleeping sickness is physical and mental lethargy, which begins almost imperceptibly. In the fully-developed disease the patient is almost always asleep; muscular tremor and an itching papular eruption are quite constant. The deepening lethargy and muscular weakness finally render the patient bed-ridden; death occurs after much wasting, either in an epileptiform seizure or from some intercurrent disease-infection, bedsores, diarrhea, etc. Post-mortem examinations so far recorded have not shown any characteristic naked-eye abnormality. In the blood, Man-

¹ Jour. Ment. Sci., October.

¹ Trans. London Path. Soc., 1900, II, 99-124.

son has found, in several cases, sometimes in great abundance, a peculiar worm, named by him "Filaria perstans." The geographic distinction of this worm and of sleeping sickness corresponds fairly well; but it has also been found in the blood of healthy persons. Perhaps additional factors come into operation which are not now understood, if *F. perstans* is the cause of the disease. The mode of action of the parasite would then become a most interesting subject for study. Mott describes the changes in the central nervous system in two cases of African lethargy. The principal lesion was a meningo-encephalo-myelitis, which may be readily construed as produced by a poison that affects especially the lymphatic system of the central nervous organs. As indicated, the pathology of these lesions, which may be regarded as the proximate lesions, awaits full explanation until the true cause of the sleeping sickness has been established. The case of sleeping sickness exhibited by Mackenzie,² in 1890, showed the same meningo-encephalitis as in Mott's two cases.

Medical News.

ALABAMA.

THE BANDAGE-ROLLER MANUFACTURING COMPANY has been organized in Selma, with the object of manufacturing a mechanical appliance for rolling bandages of all kinds and sizes.

DR. WILLIAM H. SANDERS, state health officer, will make an effort to induce the coming legislature to provide adequate compensation for county health officers. He says that under the existing system, one county pays the county physician only \$5 a year, and many others pay only \$25.

THE STATE INSANE ASYLUM at Tuscaloosa, with a capacity of 1000, has now about 1500 patients and is refusing applications for admission by the hundred. Dr. J. T. Searcy, the superintendent, has addressed a letter to each member of the legislature, calling attention to the overcrowding of the institution, recalling the fact that the state has the 1600 acres of land and the buildings of Mt. Vernon barracks and reservation donated to it by the United States, and begging the legislature to pass measures to relieve the overcrowding.

COLORADO.

DIPHTHERIA is prevalent in Globeville, and the schools have been closed in consequence. On October 20, there were four deaths and three days later 20 cases had been reported.

Denver.

THE NATIONAL JEWISH HOSPITAL FOR CONSUMPTIVES was incorporated in Denver, October 31, not for pecuniary profit, by Henry Frankle, Sol. L. Holzman and David May.

THE HOSPITAL CORPS of the First Infantry, N. G. Colo., has been reorganized and now contains eighteen enlisted men, officered by Major Carey K. Fleming, M.D., Captain Aubrey H. Williams, M.D., and Lieutenant David D. Thornton.

AFTER JAN. 1, 1901, every school in the city will have assigned to it a medical inspector, provided the city council will authorize the necessary expenditure. The health commissioner, Dr. Thomas J. Carlin, urges that a daily inspection of every school be made.

ILLINOIS.

BLESSING HOSPITAL, Quincy, will have the following staff for the next six months: Dr. Charles D. Center, physician-in-charge; Drs. Leonard L. Gill and Edmund B. Montgomery, consulting physicians; Dr. Robert J. Christie, Jr., surgeon; Drs. Joseph Robbins and Robert J. Christie, consulting surgeons; Dr. Sarah Vasey, obstetrician and gynecologist; Dr. Charles W. Root, consulting obstetrician and gynecologist; Dr. Frank E. Tull, oculist and aurist, and Dr. Frederic M. Pendleton, consulting oculist and aurist.

Chicago.

DR. J. CHARLES STAMM has been sued for \$20,000 for injuries alleged to have been received by a woman while under his professional care.

THE CHICAGO COLLEGE FOR NURSES has been founded, with the intention of giving "women training in all duties of skilled nurses without requiring two years of bondage in hospitals and training schools."

DR. W. S. CHRISTOPHER, of the board of education, in view of the excellent results of medical inspection of schools last year, wants the inspection of both public and parochial schools intrusted to the health department.

A MOTION was made on November 8, to quash the indictments against the officials of the Metropolitan Medical College on the ground that the indictments are faulty because the charges do not come within six calendar months.

HEALTH DEPARTMENT.

The mortality of Chicago for the first ten days of this month was 18 per cent. lower than for any previous like period. At this rate the annual death-proportion of Chicago per 1000 would be only 10.56. For the week ended November 10, only 361 deaths was reported, or 79 less than for the corresponding week of 1899. Of the deaths only 5 were from typhoid fever, which compares favorably with 12, the figures of a year ago; 56 were from consumption; 31 from pneumonia; 26 from heart diseases; 23 from acute intestinal diseases; 29 from violence; 9 from diphtheria and 1 from scarlet fever.

INDIANA.

DRS. A. G. BRETZ AND R. R. THOMPSON, Indianapolis, now internes of the City Dispensary, have been appointed to the staff of the City Hospital.

THE STATE BOARD OF HEALTH has sent out circulars to all health officers and school officials warning them against expected outbreaks of diphtheria. The disease exists in every county in the state, and the State Board advises systematic inspection of school-children and quarantining of suspected cases.

DUNKIRK PHYSICIANS have organized a Physicians' Protective Union, officered by Dr. J. S. Lytle, president; Dr. W. H. Benson, vice-president, and Dr. Donn P. Murray, secretary and treasurer. The object of the union is to force collections of accounts due physicians and to blacklist the recalcitrant debtors.

IOWA.

DR. H. LANDIS GETZ, Marshalltown, has resigned as chief surgeon of the Iowa Central Railway.

MISS MIRA HIRSHLEY, Muscatine, has purchased ground on which to erect a hospital which she will donate to the city when completed.

THE TOTAL COST of the one case of smallpox that occurred last winter in Independence, was \$1500, including the cost of the suit brought by Dr. Joseph H. McGready, for \$800, due for his services, but which the board of supervisors attempted without success, to cut down.

A DONATION of \$50,000 has been offered by A. Slimmer, of Waverly for the erection of a hospital in Fort Dodge, provided that the city shall furnish an equal amount of money as a maintenance fund and that the hospital shall be free to persons of all colors and creeds.

MAINE.

ON NOVEMBER 3, Dr. and Mrs. S. F. Conant, Skowhegan, celebrated their golden wedding.

THE BUILDING at Presque Isle, formerly occupied by St. John's Diocesan Hospital, has been offered by Bishop Codman, to the Northern Aroostook Medical and Surgical Society for a hospital, which is urgently needed for that locality.

THE BIENNIAL REPORT of Dr. Albion G. Young, Augusta, secretary of the State Board of Health, is an unusually valuable document. He discusses tuberculosis in Maine, vaccination and vaccin lymph, and summarizes the reports of the local boards of health of the state.

MARYLAND.

SEVERAL CASES of smallpox have broken out among negroes at Hyattsville, and the State Board of Health is taking active measures to prevent an epidemic.

THE WOMEN of Govanstown, Baltimore County, have organized an improvement association and have brought pressure to bear to induce the County Board of Health to establish systematic collections of garbage and night soil under the supervision of the local medical officer of health.

THE LADIES HOSPITAL CORPS of the B. & O. R. R. at Brunswick, Frederick County, have opened a hospital at that place. Quarters were secured in the bunk-house and fitted up with all modern conveniences. It was rendered necessary by the frequency of accidents in the railroad yards.

Baltimore.

THE CITY WATER DEPARTMENT is exercising a close scrutiny over the streams from which the water-supply is derived, seek-

ing out the cases of typhoid fever and observing the disposition of the excreta from infected houses.

THE UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE has lately received a bequest of \$3500 from the estate of Dr. Charles M. Hitchcock, who graduated at the university in 1835, moved to California, and died in San Francisco about twenty-five years ago.

THERE WERE 190 deaths for the week ended November 10, a death-rate of 18.26 per 1000 per annum. There were 11 deaths from typhoid fever, 30 from tuberculosis, 7 from cancer, and 8 from pneumonia. Of new cases reported there were: Diphtheria, 43; scarlet fever, 12; typhoid fever, 33; measles, 4; whooping-cough and mumps, each 2.

MASSACHUSETTS.

DR. RUPERT W. PARKER, Boston, was knocked down on November 4, his left arm broken and his wrist badly sprained. His assailants numbered four, one of whom he managed to hold and give into custody.

THE HOUSE OF MERCY, Pittsfield, cared for 1147 patients during the fiscal year just closed, and still reported a balance in the treasury. The managers are making great efforts to raise the \$50,000 required to build the new hospital, and as they have succeeded hitherto in their endeavors, the new building may be considered a fact on the extreme verge of accomplishment.

THE HEALTH REPORT of the state for October shows a general increase in infectious diseases, and especially in diphtheria. Greater vigilance is urged on school inspectors, and a temporary hospital has just been opened in Cambridge, for contagious diseases. During 1900 there have been in Boston 3715 cases of diphtheria, 1463 of scarlet fever, 586 of typhoid fever, and since May 1, 650 cases of consumption have been reported.

TFT'S MEDICAL SCHOOL, Boston, has increased its faculty by the appointment of Dr. George W. Kaan as assistant professor of clinical bacteriology; Dr. Timothy Leary, as professor of pathology and bacteriology; Dr. E. Channing Stowell, as assistant professor of children's diseases; Dr. Horace D. Arnold, as professor of clinical medicine, and Dr. Herbert W. White, as assistant professor of theory and practice of medicine. The new building for the school will be ready about May 1 next.

MICHIGAN.

THE WOMEN in the medical department of the University of Michigan number 49.

DR. R. JOHNSTON PALMER, Battle Creek, was severely injured in a runaway November 4.

DR. B. D. HARRISON, secretary of the State Board of Medical Examiners, will institute legal action to prevent A. G. Retz, of Muskegon, practicing as a physician without having the necessary qualifications.

MINNESOTA.

DR. HALDOR SNEVE, St. Paul, has been appointed surgeon to the St. Paul Union Stockyards Company.

THE CITY HOSPITAL, Minneapolis, with its 100 patients, nurses and staff, is in quarantine on account of a recrudescence of smallpox.

MISSISSIPPI.

DR. JOHN J. STEVENS, Hattiesburg, has been appointed health officer of Perry County.

A NEW CASE of yellow fever with death was reported from Natchez, November 8. The United States Marine-Hospital surgeon is endeavoring to trace the source of infection.

CANDIDATES for medical licenses to the number of 28 appeared for examination in the House of Representatives, Jackson, on October 10. Six were colored, including one woman.

IN DEFAULT of funds to carry out measures for the limitation of scarlet fever and smallpox in the state, the State Board of Health has formally reported to the governor that these diseases prevail in certain portions of the state.

NEW YORK.

THE MEDICAL BOARD of the Watertown City Hospital has re-elected Dr. James D. Spencer, president, and Dr. Frederick B. Smith, secretary.

THE HEALTH BULLETIN for October, issued by the State Board of Health, shows 10251 deaths, representing 16.5 per 1000 per annum. Of this number 245 died from typhoid fever and 980 from consumption.

GUY E. WHITE, a senior student in Syracuse Medical College, who served in the 202d New York Infantry, U. S. V., and afterward in the hospital corps of the army, died from heart disease, October 23, aged 22.

TYPHOID FEVER is unusually prevalent in Syracuse, and investigation as to its cause is being made by the city health authorities. During October, 24 new cases of the disease were

reported and, on November 6, 29 cases were under treatment in hospitals.

CONY ISLAND is assured that it will have a hospital before the opening of summer. The building on West Eighth street, near Surf avenue, formerly occupied as a police station, will be leased and transformed into a hospital. The district contiguous has a population of about 50,000 and the nearest hospital is five miles away.

Buffalo.

THE CRADLE-BANK receipts for the maintenance fund of the Children's Summer Hospital at Athol Springs amounted to \$5444.29 for the season.

AN INTERNATIONAL CONGRESS OF NURSES is expected to be held during the Pan-American Exposition in commemoration of the rise and progress of nursing.

THE BUFFALO GENERAL HOSPITAL will soon build an addition costing \$50,000. It will be 38 feet wide and 96 feet long, and will be used for ward purposes.

THE EMERGENCY HOSPITAL at the Exposition grounds, begun about two weeks ago, is now nearly completed. It is a T-shaped structure, with wards for men and women, operating room and an ambulance barn in which four automobile ambulances will be kept ready to answer emergency calls.

OHIO.

DR. MERRILL RICKETS, Cincinnati, gave a dinner in honor of Dr. Thomas H. Allen, of New York, November 8.

DR. AND MRS. ALEXANDER J. ERVIN, Mansfield, sail for Europe on the *First Bismarck* to-day, and will winter on the Nile and the Mediterranean.

THE CITY HOSPITAL of Cincinnati has elected Dr. John M. Withrow, gynecologist, Dr. John E. Griewe, clinical director, and Dr. David J. Wolfstein, neuropathologist.

DR. ORLANDO B. LONGENECKER, Dayton, has been found guilty of advertising a medicine through the mails for an illegal purpose, and has been sentenced by the United States Court to jail for six months and to pay a fine of \$50 and costs.

DURING the 24 hours from November 5 till November 6, 11 cases of diphtheria, 10 of scarlet fever, 3 of smallpox, 1 of typhoid fever and 3 of membranous croup were reported in Cleveland, yet the health officer says he sees "no reason for alarm."

THE ATTORNEY-GENERAL of the state has decided that "any person found guilty of wilfully refusing to comply with any lawful order of the local board of health may be fined not exceeding \$100 for the first offense and can not be legally imprisoned, and for subsequent offense of like nature he may be fined and imprisoned for not more than ninety days."

DR. J. C. CULBERTSON, editor of the *Cincinnati Lancet-Clinic*, gave an "evening of authors" at the Hotel Sterling to meet Rev. and Mrs. Henry C. Culbertson, at which the leading literary lights of the Ohio Valley were present, including Dr. Charles Frederick Goss, author of "The Redemption of David Corson"; Dr. John Uri Lloyd, author of "Stringtown on the Pike"; Coates Kinney, author of "Rain on the Roof"; John J. Piatt, Dr. W. H. Venable and some forty others. A unique feature was the dining table set in the form of a hollow square, in the center of which was another table piled with copies of the books written by the guests of the evening.

OREGON.

THE North Pacific Sanatorium has recently been opened in Portland.

DR. L. T. BROCK, Sumpter, has been appointed assistant surgeon to the Sumpter Valley Railroad.

THE UNIVERSITY OF OREGON Medical Department began its fourteenth annual session at Portland, October 1. The dean, Dr. Simeon E. Joseph, made the opening address.

THE GOOD SAMARITAN HOSPITAL, Portland, received the entire gate receipts of the street fair for one day. In addition to this amount, \$553 has been donated toward the building fund of the hospital.

PENNSYLVANIA.

AN EPIDEMIC of typhoid fever is now prevailing in the town of Cementon, and several deaths have occurred. Up to November 8, 42 cases had been reported.

THE POLICE of Lancaster, a few days ago, found a man suffering from smallpox, and he was at once taken to the county hospital. He recently came from Baltimore.

THE STATE HOSPITAL at Norristown has asked for an appropriation from the state amounting to \$85,000, to be used for a new buildings for male consumptives to cost about \$5000; two buildings for nurses, \$50,000; pathological laboratory, \$3000, and a chapel, \$10,000.

THE CARBONDALE HOSPITAL has reorganized its staff, which now consists of Dr. Alexander F. Gillis, chief of general surgical staff; Dr. John S. Niles, chief of special surgical staff; Dr. David L. Bailey, chief of medical staff, and Dr. William W. Fletcher, in charge of eye, ear and throat department.

Philadelphia.

FIVE of the ten filters for the public schools have been installed at a cost of \$1269. The water from these filters has been tested and approved by the chief inspector of the bureau of health.

DR. LAURENCE TURNBULL left an estate of \$79,000.

A BEQUEST was left by the will of Mary Ann McCumney to St. Mary's Hospital, and the amount—\$800—has been paid to this charity.

FOR THE WEEK ended November 10, the deaths numbered 369, or 7 less than the previous week. Tuberculosis caused 40 deaths; pneumonia, 37, and bronchitis, 7. Of diphtheria, 153 cases were reported, with 21 deaths.

THE FUNDS accumulated by the relief association maintained by Shoneman Bros., on the retirement of the firm from business, were divided between the Free Hospital for Poor Consumptives and the Children's Country Week Association.

THE MEDICAL INSPECTORS OF SCHOOLS, who have served a year without pay, have organized and will ask the council for an appropriation for the coming year. Failing this, the system of medical inspection in the public schools will be likely to fall to the ground.

RHODE ISLAND.

THE EMERGENCY HOSPITAL at Providence was opened on September 3. The building is being rapidly furnished and equipped.

DR. EDWARD P. STIMSON, Tiverton, has been appointed medical examiner of District No. 1, County of Newport, vice Dr. A. S. MacKnight, Little Compton, resigned.

TYPHOID FEVER is said to be epidemic in Newport. Fifty cases have been reported, the local hospital is full, and endeavors are being made to secure an emergency hospital. Incidentally the board of aldermen has directed that the city water be examined.

THE STATE BOARD OF HEALTH is investigating the case of Dr. Joseph Roy, Harrisville, who is charged with grossly unprofessional conduct in that the diploma presented by him to the board was originally issued to another person; that he has not had a sufficient education to practice medicine with safety, and that he obtained his certificate to practice by misrepresentation.

TENNESSEE.

THE MEMPHIS HOSPITAL MEDICAL COLLEGE opened for its twenty-first annual session November 1.

THE QUARANTINE over Maury County was suspended November 4 on account of improved smallpox conditions there.

DR. CHARLES S. BUTLER, Bristol, has successfully passed the examination and has been commissioned as assistant-surgeon in the United States navy with the rank of lieutenant.

DR. WILLIAM D. HAGGARD, JR., Nashville, has been elected to fill the chair of gynecology and diseases of children in the medical department of the University of Tennessee, formerly occupied by his father for many years.

THE SUPREME COURT of Tennessee has decided, in the case of Dr. Henry P. Colle, who sued the city of Knoxville for \$1000 extra compensation for attending smallpox cases during an epidemic, that he could not recover in the absence of a specific contract.

TEXAS.

THE MEDICAL UNIVERSITY of DALLAS held its opening ceremonies October 30 and installed its faculty.

THE MEDICAL COLLEGE of the State University, Galveston, reopened on November 15, and will continue its session until June 29.

"DR." L. W. JONES, Cleburne, was arrested at Buel October 27, charged with the forgery of a doctor's certificate. He was released on bond.

STATE HEALTH OFFICER DR. WALTER F. BLUNT, Austin, has visited Smithville and Hondo to investigate the smallpox situation in those places.

VIRGINIA.

DR. WILLIAM M. SMITH, Alexandria, was elected major and surgeon of the 17th Virginia regiment, on October 10.

DR. JOHN G. TRIVILIAN, in charge of the Richmond City Ambulance and Hospital, has asked the city council for a third ambulance physician.

THE WILL of Dr. Hunter McGuire was probated September 30. The estate is valued at \$150,000 and is devised to his wife,

and his library and instruments are to be divided equally between his sons, Drs. Stuart and Hugh McGuire.

THE VIRGINIA HOSPITAL, Richmond, between October, 1899, and July, 1900, cared for 399 patients, and the dispensary treated 5516 patients. The hospital was closed from July 20 to October 1, when it was opened for charity cases, and private patients were admitted November 1.

GENERAL.

BILLS OF HEALTH to vessels engaged in foreign trade will hereafter be issued at Manila by the officials of the United States Marine-Hospital Service.

THE ASHES of eighteen cremated plague victims, each in its own sealed receptacle, are reposing in the offices of the Honolulu board of health, awaiting instructions from the friends of the deceased.

THE REPORT comes from Cape Nome, in October, of the nine hospitals open at the end of July, one only was in operation. This hospital is about to close, as it has not enough patients to warrant its continuance.

DR. FRANCISCO DEL VALLE, formerly mayor of San Juan, Porto Rico, is the first Porto Rican to vote without going through the formality of naturalization. He was "naturalized by annexation," and voted at the recent election at Baltimore.

DR. MANUEL S. YGLESIAS, health officer of Vera Cruz, Mexico, has been visiting Philadelphia, and recently paid a visit to the quarantine station at Marcus Hook. He was chosen a delegate from Mexico to the American Public Health Association at Indianapolis, and since that time has been making a study of the quarantine stations in various parts of the country.

SMALLPOX has broken out at several of the Indian reservations in the West. Reports show that the disease has appeared and is epidemic on the Wichita, Apache, Kiowa and Comanche, and Cœur d'Alene reservations, and that it is increasing at Fort Hall Agency, Blackfoot and Pocatello, Idaho, and at Valentine, Neb., shipping point for the Rosebud Agency.

PROFESSOR TILMANN, of Griefswald, Germany, professor of surgery at that place, and well known to the profession of this country by reason of his contributions to surgical literature, the latest of which is his experimental research on the results of wounds from the modern small-caliber, steel-jacketed bullet, forming a part of Professor Von Coler's work on that subject, has recently visited Chicago in the course of a vacation trip through North America.

MAIL FROM MOLOKAI, the leper settlement of Hawaii, is disinfected with sulphur dioxide at the settlement, transferred to the steamer and received in clean and disinfected sacks. On its arrival in Honolulu, the mail in sacks is disinfected with formaldehyde. All letters are perforated and the corners clipped before disinfection. Although non-disinfected mail from Molokai has been handled for many years, no case of leprosy has ever been discovered among post-office employees.

PROF. WILLIAM W. KEEN, Philadelphia, was entertained November 2, by his old students of Jefferson Medical College resident in and near Indianapolis, and in the evening was tendered a banquet at the Bates' House, in which 60 participated. Dr. Thomas C. Hood officiated at toastmaster. Dr. Alembert W. Brayton made the address of welcome; Dr. G. W. McCaskey spoke on behalf of the medical profession of Indiana; Dr. Frank C. Ferguson, for the Marion County Medical Society, and Dr. Frank B. Wynn contended that "Indiana is no mean State."

PAN-AMERICAN MEDICAL CONGRESS.—This congress will be held at Havana, Cuba, Dec. 26-29. Dr. Henry P. Newman, 100 Washington street, Chicago, American secretary of the Section on Abdominal Surgery and Gynecology, desires to hear at once from those who wish to take part in the scientific work of his section. Also he would be glad to hear from any from the West who are thinking of attending the congress, as arrangements are being made for low railroad rates from Chicago. Dr. Charles H. Hughes, of St. Louis, Mo., who has been appointed Secretary of the Section on Nervous and Mental Diseases, requests alienists and neurologists especially, and all medical men who appreciate the importance of, and who desire to advance, neurology and psychiatry in clinical and legal medicine, to ally themselves with this section and to prepare contributions on proper subjects. He requests that titles and summaries of papers be sent to him at once at 3857 Olive Street, St. Louis, Mo.

DR. FREDERICK PETERSON, president of the board of managers of the Craig Colony for Epileptics, at Sonoma, N. Y., offers a prize of \$200 for the best original unpublished contribution to the pathology and treatment of epilepsy. All manuscripts should be submitted in English. The prize

is open to universal competition. Each essay must be accompanied by a sealed envelope, containing the name and address of the author and bearing on the outside a motto or device, which is to be inscribed also on the essay. All papers received will be submitted to a committee of three members of the New York Neurological Society, and the award will be made on its recommendation, on October 8, 1901. Manuscripts should be sent to Dr. Frederick Peterson, 4 West 50th street, New York City, on or before Sept. 30, 1901.

A NEW EMERGENCY RATION.—Officers of the War Department are endeavoring to determine the value of a new emergency ration, fitted to meet the requirements of troops in the field. The test is being made upon 25 men of Troop A, Eighth U. S. Cavalry, stationed at Fort Reno, Okla. Two different emergency rations are being experimented with. The first consists of two cakes of pure chocolate, three cakes of a combination of meat and bread-stuff, in compressed form, with salt and pepper. The second consists of tea instead of chocolate, and a combination of meat and bread-stuff in a compact form. The experiment will begin by having the expedition to leave Fort Reno under hurried orders. Five regular, and emergency rations will be issued at the start. The men will live for two days on the regular ration and then will subsist for five days on the new ration. The temperature and weight of each man will be taken twice daily. The investigation is being made by a board consisting of Capt. S. W. Fountain, Eighth Cavalry, S. W. Foster, Fifth Cavalry, and Capt. and Asst.-Surg. J. D. Poindexter, of the medical department of the army.

CANADA.

POLITICS AND THE PROFESSION.

A notable feature of the recent general elections was the personal defeat of Sir Charles Tupper and his subsequent retirement from the leadership of the Conservative party in the Dominion. Sir Charles was at one time a prominent and successful practitioner in the County of Cumberland, N. S., but forsook medicine for politics at the age of 34. He is a graduate of the Royal College of Surgeons, Edinburgh, was instrumental in founding the Canadian Medical Association, and was thrice elected to its presidency. Dr. Roddiek was a candidate for political honors in the City of Montreal, and it is very gratifying to the medical profession that he has again secured the confidence of his constituents.

THIRD ANNUAL REPORT—NATIONAL SANITARIUM ASSOCIATION.

The annual meeting of the National Sanitarium Association was held in Toronto on the afternoon of the third inst., Chief Justice Sir William Meredith, president, in the chair. The third annual report was presented, which showed that the work in the Muskoka Cottage Sanitarium was of the most gratifying character. This institution was opened only three years ago, and already 371 patients have been received, of whom 47 are still under treatment. The number discharged apparently cured has been 57; with disease arrested, 95; with marked improvement, 78. In most cases, the patients have not remained long enough to reap the benefits of the institution, but the average stay has increased each year, and this year amounted to 129 days. On Oct. 1, 1899, the beginning of the hospital year, 48 patients were present, and during the year, 141 more have been admitted, making a total on the books of 189. Of these 43 were from the City of Toronto, 130 from other points of Ontario, 4 from other provinces of Canada and 12 from the United States. Out of the total, 122 patients remained in the institution over three months, and of these 109 gained in weight, 6 lost in weight, and 7 neither gained nor lost. The total receipts for the year were \$19,020. The expenditure amounted to over \$20,000; \$3148 was expended in butcher's meat and \$1263 in milk. A letter was read from the medical superintendent, Dr. J. H. Elliott, at Nordrach, who has been spending a year in Europe studying the methods pursued there.

LAY PRESS DEFENDS PATENT MEDICINES.

A measure has been introduced into the Ontario legislature at its last session in regard to regulating the manufacture and sale of patent remedies, as well as limiting also their advertisement in the press of the province. Considerable opposition to the measure is arising amongst the manufacturers and the retail druggists, probably more particularly now amongst the latter, as the requirements of the bill are such, that if they wish to prepare and sell a preparation of their own, they will have to pay into the treasury of the province \$1000, to license them to manufacture any article which they might wish to expose for sale in their shop windows; and if they desired to sell different receipts or "non secrets," they would be required

to put up \$10,000. It has been pointed out on behalf of the druggists—and a very ingenious point it is—that the newspapers of Ontario would stand to suffer to a greater extent than the retail druggists, as a very large percentage of the revenue of the press comes from the advertisement of "trade-mark" articles; and of course the newspaper owners are up in arms against the proposed legislation and are hand and foot with the patent-medicine vendors, with the single exception of one society journal, which has given its contemporaries of the press some pretty severe raps on their advertisements and their opposition to this bill. Commenting further on the relation of the manufacturers of patents, the press and the public, this writer goes so far as to say: "In the interests of the patent-medicine houses the newspapers should not entirely forget the interests of the public, nor for the sake of temporary profit impair their permanent interests." It is certainly refreshing to see at least one paper in Ontario taking such a firm stand for the good of the community; and while all the provisions of the bill may not be considered perfect, it contains elements which ought to count as its essential principles, and which ought to commend it to right-thinking legislators.

FOREIGN.

YELLOW FEVER is declared to be epidemic at Leone, Nicaragua.

DR. CAVALLI, who accompanied the Duke di Abruzzi on his arctic trip, has been made a Commander of the Order of the Italian Crown.

MR. WILLIAM ANDERSON, surgeon to St. Thomas' Hospital, London, and professor of anatomy at the Royal Academy, died October 27.

DR. POZZI, in a recent lecture in Paris, paid a glowing tribute to American surgeons, whom he characterized as "scientifically audacious and brilliantly cool."

THE ASSOCIATION of Physicians of the Seine recently offered a banquet to its president, Dr. R. Jaumin, on the occasion of his decoration with the button of the Legion of Honor.

THE LANCET announces the dedication of a new and permanent building for the Free Home for the Dying. The building is said to be well adapted for its purpose, containing 25 beds, 12 in the woman's ward, 8 in the men's and the rest in single rooms.

SINCE THE DEATH of the plague-stricken sailor from the steamer *Marienburg* at Bremen, several new cases of the disease have been discovered. The outbreak is causing a panic on a small scale, and is affecting seriously the shipping interests of the port.

EIGHT SEAMEN suffering with beri-beri, and the body of one who had died of the disease, were landed at Palmouth, Eng., October 17, from the Norwegian bark *Brilliant*, from Newcastle, N. B., for Grimsby. All had been taken off the waterlogged Norwegian bark *Homewood*, which sailed from Ship Island for Havre, August 3.

AT THE LAST meeting of the British Medical Association, a Committee on Reorganization of the British Medical Association was appointed. This committee, of which Mr. Edmund Owen is chairman, is now holding meetings in order that it may have its report ready to present to the branches by Feb. 1, 1901. We understand that the committee is instructed to consider the advisability of adopting the delegate system. This would be a reform in the right direction, and, if adopted, will likely result in taking away from the council a large part of the power as a legislative body which it enjoys at present.

THE VITAL STATISTICS of New South Wales in 1899, as given in the *British Medical Journal*, show a decreasing birth-rate and a slightly decreasing death-rate. The number of children to a family have dropped from 5.26 to 4.34, and the birth-rate is only 27.10 to the 1000 of population, the lowest recorded. The mean annual increase of population by excess of births over deaths is 1.67 per cent. for 1890 to 1899, as against 2.30 in the period of 1880-81. Illegitimate births are increasing, amounting to 7.16 per cent. of the total, and having increased from 4.09 per cent. to 6.84 per 1000 in 1896-99. Phtisis showed a decrease from 14 per cent. in 1889 to 11 per cent. in 1899, while cancer is on the increase.

Treatment of Dysentery with Methylene Blue.—Berthier administers methylene blue in dysentery in two to four injections of 1 to 2 cc. in a liter of warm water. It rapidly arrests the pains, and diminishes the number of the stools, by its parasitocidal, analgesic and cholagogue action. It is also a mild disinfectant and powerful antitoxin. The patient recovers and retains as much of the injection as possible. The bile reappears in the feces by the second day at latest.—*Int. Med. Congress.*

Correspondence.

Medical Study in Helsingfors, Finland.

VIENNA, Oct. 25, 1900.

To the Editor—The University at Helsingfors is very well equipped, having over 2000 students, and a teaching staff of about 100 professors and docents; a fair proportion of the students belong to the medical faculty, which is justly celebrated throughout Europe.

In the medical clinic I saw some excellent work carried on by Professor Rüneberg, son of the national poet of Finland, and his assistant, T. W. Tallquist. As is well known, these investigators have made admirable studies of the different anemias, especially of that form of secondary anemia which is due to the presence of the bothrioccephalus latus. I saw many of the latter class of cases in the University Hospital, as well as several cases of pernicious anemia, a malady very similar in its clinical history. It is a matter of routine in that clinic to examine microscopically the feces of every patient suffering from any form of anemia, in the hope of finding the eggs of the above parasite. The detection of these eggs is marvelously easy; a very large number of these cases yearly is at the disposal of this clinic. The Helsingfors observers have quite definitely proved by experiments on dogs the manner of action of this parasite. Formerly it was supposed that the worm produced anemia either by its effect on the nervous system, or by the actual absorption of fluid; the real mode, however, is by the generation of some poison which enters the general circulation, and produces destruction of the red corpuscles. Clinically, these patients, besides suffering from a profound anemia, are distinguished by a deep icterus of the conjunctivæ and a dark color of the urine. A curious fact in connection with patients carrying this worm, is that only a very small percentage, hardly 1 per cent., develop a condition of anemia.

An examination of the blood shows regularly a diminution of the leucocytes; the ratio of multinuclear white corpuscles to the uninuclear varies greatly; in this regard this form of anemia varies from the pernicious variety, which shows only an abnormal increase of the uninuclears. Often the number of the red corpuscles in a cubic millimeter sinks down to 500,000; in spite of this great oligocythemia most of these cases recover after the expulsion of the worm. In most of the cases are found nuclear red corpuscles, some of which are normoblasts, but a few are megaloblasts.

Tallquist has constructed a handy method of determining the percentage of hemoglobin; it is by means of comparing a drop of blood sucked up by white filtering paper and comparing it with a colored scale; the filtering paper and the colored scale are bound together in a book, making a clinical determination of hemoglobin a very easy matter.

The surgical clinic at Helsingfors, whose head was formerly the lamented Eslander, during the year 1898, had 1358 in-patients and 9804 out-patients. Their methods were the ordinary ones in use in well-appointed hospitals, and need not be given in extenso.

Among the hard-working peasants of Finland hernias are very common and a very large number of them have been radically treated at this clinic; a careful investigation as to the final result of the different operations for rupture is now being conducted by the surgical staff. This is not yet completed, but through the kindness of Dr. E. Sandelin, I was able to get some preliminary figures. For inguinal hernia the years 1889 till 1898 inclusive there were performed 1039 radical operations, mostly by Bassini's method. Of these cases 5 died; of crural hernia in these years there were 51 operations with one death. For umbilical hernia there were 19 operations with no death, and for hernia in the linea alba there were 31 operations with no death. Relapses after operations for external inguinal hernia took place in about 7 per cent., for internal inguinal hernia in about 12 per cent., in all cases.

It was my privilege to spend two days at the gynecological clinic of Professor Otto Engström, and to witness that skilled operator perform several difficult operations. Professor Eng-

ström's new clinic has only 26 beds; in connection with these is a polyclinic where 1600 to 1700 patients are yearly treated; from Jan. 1, 1900, till Sept. 8, 1900, there were 1472. Moreover, to these should be added the patients belonging to his very large private practice, many of whom go to his clinic for operation. For example during 1899 he performed 56 ovariectomies, 37 ovariectomies with removal of the tubes, 6 ventrofixations for ordinary prolapse, 90 ventrofixations for retroflexion, 23 cauterizations of the ovaries, and so forth. Engström as an operator is very conservative; that is to say, wherever it is possible he endeavors to save an important organ. Uterine myomata he always strives to enucleate. At the congress of gynecologists in Amsterdam, September, 1899, he reported 180 cases of enucleation of intramural myomata of the uterus by the abdominal route with a mortality of hardly 3 per cent. Of these women 9 have since become pregnant. This is certainly not a small result, for more than half of those operated on were unmarried, and among those who were married, were many over 40 years of age, and others suffering from the effects of old inflammations in the pelvis. Since September, 1899, he has had many more cases of enucleation, and many more of his patients have become pregnant. Even in cases of total prolapse of the uterus, he never does an extirpation unless the patient is in, or has passed, the climacteric, or there is reason to suspect cancer. In bad cases of prolapse, as plastic operations on the vagina, and of uteri rarely suffice, Engström makes regularly a ventrofixation of the body of the uterus by a sort of peritoneal suture, to wit: the serosa of the fundus is scraped off, the peritoneum is shoved somewhat to one side, the fundus is then united with strong catgut sutures to the freshened recti muscles just over the symphysis. In this way he gains a very firm union.

So far as the ovaries are concerned, Engström is very careful. In cases of supravaginal amputation on account of myomata as well as extirpation of the uterus for cancer, or prolapse, or in cases of removal of the tubes, he makes the attempt to save them. If the whole ovary can not be saved, he yet tries to preserve a bit of the normal ovarian tissue.

It is surprising how little importance Engström attaches to certain conditions that other gynecologists make much of. According to his experience a retroflected uterus per se is very rarely the cause of the symptoms of disease. The latter are almost invariably occasioned by inflammatory processes, communicated to the uterus or tubes. This view Engström advanced at the Amsterdam Congress, as well as on other occasions. It is needless to say that he rarely uses pessaries. In those retroflexions that are bound down with adhesions he always proceeds in the following manner: After thoroughly breaking up the adhesions the anterior part of the fundus is united by its serous surface to the serous surface of the abdominal wound; a strong silk suture is then passed through all the layers of the abdomen and through the uterus; this suture remains two weeks.

The peasantry and neighboring classes of Finland frequently are found to have floating kidneys; in the year 1899 in Engström's clinic 600 cases were diagnosed; of these only 2 were treated by nephrorrhaphy. Engström usually examines these patients in the upright position, and is heretic enough to believe that this condition per se does not give rise, as a rule, to serious symptoms.

In all the above-mentioned operations the strictest antiseptic precautions are invariably observed, even to the bathing of the patient, operator, and assistants just before the operation. In all plastic operations about the vulva, as a preliminary procedure, the anus is sewn up by a puckering string suture, which naturally is removed directly after the operation. The scientific results of Engström's work are of a very high order, and are published at intervals in the German language, although his teaching is naturally given in the Swedish tongue. Many of the studies are from his own pen, but a large proportion is the work of his pupils. The scientific activity of his school is shown by the fact that a volume appears every three months. The last number, xxxi, is entitled: "Ueber Schwanghaft in unvollkommen entwickeltem Horne eines Uterus bicornis unicollis." ALLEN STAPLES, M.D.

The Individual Communion Cup.

PHILADELPHIA, Nov. 9, 1900.

To the Editor:—In THE JOURNAL for November 3, a brief reference is made (p. 1150) to a "Sanitary Substitute for the Individual Communion Cup," which the *Lancet* suggests, namely, "intinction," or "the ancient custom of dipping the bread in the wine." With regard to the ecclesiastical or sanitary reasons for the revival of this method of celebrating the Lord's supper I have nothing to say here, pro or con. But the reason for advocating the change that the *Lancet* gives, namely, that individual communion cups are not practicable, is valid or not, according to the point of view: that is, whether from the dogmatic and ecclesiastical, or from the purely sanitary.

If the *Lancet* means that according to the doctrine and ritual of the Church of England (presumably, because the state church), individual communion cups are impracticable, then I have nothing to say; the advocates of this sanitary reform do not urge any body of the Christian church to relinquish any beliefs that it considers vital and dear to its spiritual serenity and moral conduct, and holding which, it believes would be jeopardized by substituting individual for commonly-used communion cups. But if the *Lancet* means that individual communion cups are not practicable from a sanitary standpoint, then it is either ignorantly or wilfully, certainly wofully, mistaken. Of course, there are very few churches in England that use individual communion cups; and these are "dissenting" churches. Perhaps the *Lancet* thinks that sanitary progress among dissenters is unknowable, or unworthy of notice. Yet, surely that great journal can hardly be so stupidly agnostic of American literature on the subject, not to know that in these United States there are hundreds of churches and hundreds of thousands of communicants demonstrating that individual cups are not only practicable, but practical; clean, safe, convenient, satisfactory.

The "dissenters" here outnumber the sister denomination of the Church of England by so many millions that the *Lancet* could hardly have failed to know, even with a manifest sectarian bias, that sanitary advancement in this matter is ahead here, even if the editor of that journal believes that in England the state church ought to live up to its traditions as a sanitary leader, and adopt intinction instead of having many mouths of questionable cleanness and health using a single chalice. Sincerely yours,
HOWARD S. ANDERS, M.D.

Marriages.

THOMAS J. TALEBOTT, M.D., to Miss Bessie Olivia Fisher, both of Baltimore, October 31.

JAMES L. PHILLIPS, M.D., New York City, to Miss Marion Ewing Hamilton, Baltimore, Md., October 30.

LOUIS H. BIRMINGHAM, M.D., Boston, to Miss Jennie R. Marsh, at Sutton, Mass., November 1.

MARTIN L. DALTON, M.D., Willis, Va., to Miss Lula M. Lester, Floyd, Va., October 30.

JOHN W. COFFIN, M.D., Beaver Falls, Pa., to Miss Gertrude M. Jolly at Coraopolis, Pa., October 31.

S. WHITFIELD HARTT, M.D., Port Angeles, Wash., to Miss Bertha Dayton, Lisbon, O., October 31.

W. KEELING WOOD, M.D., Centreville, Va., to Miss Elda Belle Vanderlip, of Indian Lake, Mich.

O. WELLINGTON ARCHIBALD, M.D., St. Paul, Minn., to Miss Emily Kennedy, of Jamestown, N. D., at St. Paul, Minn., October 30.

PAUL WILLIAMSON HOWLE, M.D., Mt. Carbon, W. Va., to Miss Adeline Green, Richmond, Va., November 1.

ALBERT F. MILLER, M.D., Auburn, N. Y., to Miss Alice L. Lovell, of Syracuse, N. Y., November 1.

Deaths and Obituaries.

JOHN BERRYMAX, M.D., Edinburgh, 1861, at St. John, N. B., November 4, aged 72. After a trip to Australia he studied in

Edinburgh, and was assistant to, and lived with, Sir James Y. Simpson. On the outbreak of the Civil War he was put in charge of a hospital in West Philadelphia. Soon after the close of the war he moved to New Brunswick and settled in St. John. In 1886 he was returned to the House of Assembly from St. John.

AUGUSTUS D. MERROW, M.D., Bowdoin College, 1854, for thirty-three years a practitioner on Freedom, N. H., twice state representative and twice state senator, at his home, October 16, aged 73.

STANLEY MAC C. STUART, M.D., first lieutenant and assistant surgeon, assigned to 11th Cavalry, U. S. V., at Santa Cruz, Luzon, November 6, from fracture of the skull, caused by a fall from his horse.

REMUS ROBINSON, M.D., College of Physicians and Surgeons, Baltimore, 1881, from paralysis after several years, at his residence in North Windham, October 29.

M. LAFAYETTE GORDON, M.D., College of Physicians and Surgeons, for twenty-eight years a missionary in Japan, at Auburndale, Mass., November 4, aged 57.

CLINTON W. SIEGER, M.D., University of Pennsylvania, 1875, from dropsy, after an illness of several years, at his home, Siegfrieds, Pa., October 27, aged 47.

WILLIAM A. CLAPP, M.D., Jefferson Medical College, 1847, who had practiced medicine more than half a century in New Albany, Ind., November 7, aged 73.

GEORGE M. DEWEY, M.D., Jefferson Medical College, 1883, at Keytesville, Mo., where he had resided for fifty-four years, November 5, aged 81.

JOSHUA N. SPEED, M.D., College of Physicians and Surgeons, Keokuk, Ia., 1860, the oldest practitioner in Rushville, Ill., November 6, aged 66.

EDWARD V. NEWTON, M.D., New York University, 1875, coroner of Norfolk, Va., at that place, November 3, after a lingering illness.

STANHOPE C. SMITH, M.D., Tulane University, 1850, was found dead in his house, Lacey's Springs, Ala., October 30, aged 80.

C. W. RILEY, M.D., Fort Wayne College of Medicine, 1896, from concussion of the brain, in a runaway accident, November 1.

VINCENT SULLIVAN, M.R.C.S., England, of Kingston, Ontario, at Las Vegas, N. M., November 4, from tuberculosis, aged 32.

A. T. ROBINSON, M.D., Albany Medical College, 1895, from apoplexy, at his home, Mansfield, Mass., November 4, aged 34.

THOMAS WHEELER, M.D., Medical College of Evansville, Ind., 1854, at Bloomfield, Ind., October 31, aged 79.

HIRAM GREENTREE, M.D., University of Maryland, 1855, from dysentery in Baltimore, October 28, aged 78.

JAMES P. CLEAVER, M.D., University of Pennsylvania, 1894, at Lakewood, N. J., November 8, of tuberculosis.

CHARLES NORMAN HAMPER, M.D., Edinburgh, at Meeker, Colo. October 29, of heart disease, aged 32.

JAMES H. LOWE, M.D., Tulane University, 1858, at his home, Knight's Ferry, Cal., October 16, aged 64.

T. E. STAPLES, M.D., Missouri Medical College, 1848, at his home, Nelson, Mo., October 27, aged 70.

LEVIN W. MAGRUDER, M.D., Tulane University, 1867, at his home, Woodville, Miss., October 30.

FRANK H. WILY, M.D., Jefferson Medical College, 1887, at Centrepot, Pa., aged 37.

New Instruments.

Grooved Director for Vaginal Hysterectomy. Uterine Elevating Forceps.*

E. D. FERGUSON, M.D.

TROY, N.Y.

Though simplicity and fineness of instruments in operative work is the pride of many surgeons, there can be no question concerning the help that most operators find in special devices to meet special indications. The two instruments which I

* Read at the Meeting of the New York County Medical Association, October 15, 1900.

present have been tested in actual work and have been found helpful.

The first which I show is a director intended to be passed behind the broad ligament in vaginal hysterectomy, thereby bringing at once into the operative field, and in full view of the operator, the lateral tissues to be incised.

Having opened freely into the pouch of Douglas and having freed the bladder from the uterus, the left index finger of the operator is passed behind the broad ligament and made to appear above that structure at the side of the uterus, the peritoneum having been incised previously at the corresponding vesical fold, or the opening being made on the end of the finger which shows above the broad ligament.

Having made sure that no tissue aside from that belonging to the broad ligament is included by the finger and having sufficiently separated the parts, the director is passed along the palmar surface of the finger until its tip appears well below the broad ligament, when the finger can be withdrawn. The instrument is curved so as to allow of its use when the broad ligament will not permit free descent of the uterus, though in most cases in actual use the director can be advanced until the broad ligament lies on the convex portion.

Having thus brought the broad ligament well into view, the groove in the director enables the operator to ligate securely in sections the uterine connections on the selected side,

that side being the one more readily secured by the finger. The method of ligation will be that in which the operator is most facile, the writer preferring the cobbler's stitch made with a strong kangaroo tendon. The separation of the uterus can go hand in hand with the ligation, which when completed allows the uterus, now freed on one side, to be turned out of the vagina, thus affording opportunity for the ligation of the opposite broad ligament and excision of the uterus. Of course, it is understood that at the lower portion of each broad ligament care is taken to avoid the ureter, but it seems to the writer that if the director emerges close to the uterus at its cervical portion, and the sewing is done along the line of the groove, the ureter will necessarily lie to the outside and remain unharmed.

The reintroduction of forcible and moderately protracted compression as a means to control hemorrhage, notably in the use of the angiotribe, would seem to lessen materially the occasion for the device which I present, and the convenience and even utility of the angiotribe is freely conceded by the writer.

There is one condition for the safe use of the angiotribe which should be kept in view, and that is that the stump should have no rude handling after the incision, otherwise the vessels may be re-opened. Should we be unable to include all the parts we wish to excise in the grasp of the angiotribe, the traction and manipulation necessary to bring other and higher parts into view may result in embarrassing or even serious hemorrhage. At present it is believed that most operators will feel a sense of security in interrupted but locked suturing of the broad ligament, and in particular where the condition of the organs is such as to render it desirable to attack the ovaries after the removal of the uterus.

The other instrument is intended to aid in bringing the uterus into the operation field in ventral suspension of the uterus.

It is only occasionally that the operator will feel the urgent need of such a device, though in many cases he will find it a convenience.

In cases where the uterus is somewhat rigid in its retroflected form, and the pelvic tissues do not allow it to return forward

with slight support, this device will be found a convenience. If added to these obstacles to easy operating, we have to deal with a thick layer of abdominal fat in a patient subject to ether retching, the difficulties of the operation become great without some device like the uterine elevating forceps.

The method of application is simple, one blade being applied behind the uterus on the palmar surface of the requisite number of fingers, the other blade being placed in front of the uterus, when on locking and compressing the uterus, that organ is completely under the control of the operator, who proceeds to place the anterior stitch, passing it through the fundus of the uterus between the blades of the forceps. As soon as this stitch is made to include both lateral walls and the uterus, the forceps can be removed, as the uterus is now under control.

It is possible that the shape of the blades would have been modified if the author could have been at the side of the instrument-maker, for the shape is not entirely satisfactory to him, though Tiemann & Co. have done exceedingly well from the rather poor drawings which were furnished. In actual work, however, the instrument has never failed to fill all requirements and that without any detectable abrasion on the uterus.

Epiglottis Retractor.

SETH SCOTT BISHOP, M.D.
CHICAGO.

The accompanying figure illustrates an epiglottis retractor designed for use in cases in which it is impossible to obtain a good view of the interior of the larynx without holding the epiglottis upward and forward. The spade-like blade which rests on the posterior or under surface of the epiglottis is sufficiently wide to produce a certain degree of a flattening

BISHOP'S EPIGLOTTIS RETRACTOR.

effect on an omega-shaped epiglottis, thus facilitating laryngoscopy in two ways. A firm control over the retractor is given by the employment of the double-ring handle, such as is used in the biting forceps.

Books and Pamphlets.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

BOOKS.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, and the Kindred Branches with their Pronunciation, Derivation, and Definition, Including Much Collateral Information of an Encyclopedic Character. By W. A. Newman Dorland, A.M., M.D., Assistant Obstetrician in the University of Pennsylvania Hospital. Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Diplococci, Micrococci, Streptococci, Ptomains and Leuko-mains, Weights and Measures; Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. With Numerous Illustrations and 24 Colored Plates. Leather. Pp. 770. Price, \$4.50. Plain, \$5.00. Index. Philadelphia and London: W. B. Saunders & Co., 1900.

PATHOLOGY AND MORBID ANATOMY. By T. Henry Green, M.D., F.R.C.P., Physician and Special Lecturer on Clinical Medicine at Charing Cross Hospital. Revised and Enlarged by H. Montague Murray, M.D., F.R.C.P., Physician to Out Patients, and Lecturer on Pathology and Morbid Anatomy at Charing Cross Hospital. Ninth American Revised from the Ninth English Edition by Walton Martin, Ph.D., M.D., Assistant Demonstrator of Anatomy,

College of Physicians and Surgeons, Columbia University. With 4 Colored Plates and 339 Illustrations. Cloth. Pp. 585. Price, \$3.25. Philadelphia and New York: Lea Bros. & Co. 1900.

SAUNDERS' POCKET FORMULARY. With an Appendix Containing Posological Table; Formule and Doses for Hypodermic Medication; List of Poisons and their Antidotes; Diarrhetes of the Female Pelvis and Fetal Head; Obstetrical Table; Diet List for Nervous Diseases; Materials and Drugs Used in Antiseptic Surgery; Treatment of Asphyxia from Drowning; Surgical Remembrance; Tables of Incompatibilities; Eruptive Fevers; Weights and Measures, etc. By William M. Powell, M.D., Author of "Essentials of Diseases of Children." Sixth Edition. Thoroughly Revised. Leather. Pp. 207. Price, \$2.00. Philadelphia: W. B. Saunders & Co. 1900.

EYE, EAR, NOSE AND THROAT. A Manual for Students and Practitioners. By William Lincoln Balleger, M.D., Assistant Professor of Otolaryngology and Laryngology in the College of Medicine of the University of Illinois, and A. G. Wippert, M. D., Professor of Ophthalmology and Otolaryngology, Chicago Eye, Ear, Nose and Throat College. Series edited by Bern B. Gallouet, M.D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University, New York. Illustrated with 150 Engravings and 6 Colored Plates. Cloth. Pp. 511. Price, \$2.50. Philadelphia and New York: Lea Brothers & Co.

LABORATORY DIRECTIONS FOR BEGINNERS IN BACTERIOLOGY. An Introduction to Practical Bacteriology for Students and Practitioners of Comparative and of Human Medicine. By Veranus A. Moore, B.S., M.D., Professor of Comparative Pathology and Bacteriology, New York State Veterinary College, Second Edition, Revised and Enlarged. Cloth. Pp. 142. Price, \$1.05. Boston: Ginn & Co. 1900.

A PRACTICAL TREATISE ON GENITO-URINARY AND VENEREAL DISEASES AND SYPHILIS. By Robert W. Taylor, A.M., M.D., Clinical Professor of Venereal Diseases at the College of Physicians and Surgeons, New York. Second Edition, Thoroughly Revised. With 138 Illustrations and 27 Plates in Colors and Monochrome. Cloth. Pp. 722. Price, \$5.00. New York and Philadelphia: Lea Brothers & Co. 1900.

THE THEORY AND PRACTICE OF HYGIENE. (Notter and Firth.) By J. Lane Notter, M.A., M.D., (Dub.), Fellow of the Chemical Society, and W. H. Horrocks, M.D., B. Sc. (Lond.), Assistant Examiner in Hygiene, Science and Art Department; Assistant Professor of Hygiene in the Army Medical School, Netley. Second Edition. Cloth. Pp. 1085. Price, \$7.00. Philadelphia: P. Blakiston's Son & Co. 1900.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES. Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume I. Illustrated by Numerous Chromolithographs and 498 fine Half-Tone and Wood Engravings. Cloth. Pp. 739. Price, \$7.50. New York: Wm. Wood & Co. 1900.

MODERN MEDICINE. By Julius E. Salinger, M.D., Demonstrator of Clinical Medicine, Jefferson Medical College, and Frederick J. Katelyer, M.D., Assistant Demonstrator of Clinical Medicine, Jefferson Medical College. Illustrated. Cloth. Pp. 801. Price, \$4.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

MODERN SURGERY, GENERAL AND OPERATIVE. By John Chalmers Da Costa, M.D., Professor of Principles of Surgery and of Clinical Surgery, Jefferson Medical College. With 493 Illustrations. Third Edition, Revised and Enlarged. Cloth. Pp. 1117. Price, \$5.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By Lewis A. Stimson, B.A., M.D., LL.D., (Yalen.), Professor of Surgery in Cornell University Medical College, New York. Third Edition Revised and Enlarged. With 336 Illustrations and 32 Plates in Monochrome. Cloth. Pp. 842. Price, \$5.00. New York and Philadelphia: Lea Bros. & Co. 1900.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. By James M. Anders, M.D., Ph.D., LL.D., Professor of Practice of Medicine and Clinical Medicine in the Medico-Chirurgical College, Philadelphia. Illustrated. Fourth Edition, Thoroughly Revised. Cloth. Pp. 1292. Price, \$5.50 net. Philadelphia and London: W. B. Saunders & Co. 1900.

SAUNDERS' QUESTION COMPENDS—"ESSENTIALS OF HISTOLOGY" by Louis Letoy, B.S., M.D., Professor of Histology and Pathology in Vanderbilt University. Arranged with Questions Following Each Chapter. 72 Illustrations. Cloth. Pp. 231. Price, \$1.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

NINETEENTH REPORT OF THE STATE BOARD OF HEALTH OF NEW YORK. Transmitted to the Legislature February 13, 1899. Cloth. Pp. 771. (With Accompanying Maps for 1898, in separate volume.) New York and Albany: Wykoop, Hallenbeck, Crawford Co. 1899.

A TEXT-BOOK OF PATHOLOGY. By Alfred Stoenel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. With 372 Illustrations. Third Edition, Revised. Cloth. Pp. 873. Price, \$5.00 net. Philadelphia and London: W. B. Saunders & Co. 1900.

MEDICO-CHIRURGICAL TRANSACTIONS. Published by The Royal Medical and Chirurgical Society of London. Volume lxxviii. (Second Series, Volume lxxv.) Cloth. Pp. 349. London: Longmans, Green & Co. 1900.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Authors and Subjects. Second Series. Vol. v. Enamel-Flyner. Cloth. Pp. 1127. Washington, D. C.; Government Printing Office. 1900.

TRANSACTIONS OF THE INDIANA STATE MEDICAL SOCIETY, 1900. Fifty-first Annual Session Held at Anderson, Indiana, Thursday and Friday, May 24 and 25, 1900. Cloth. Pp. 478. Indianapolis, Ind.: Wm. B. Burford. 1900.

PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST. By Richard C. Cabot, M.D., Physician to Out-Patients, Massachusetts General

Hospital. With 142 Illustrations. Cloth. Pp. 310. Price, \$2.50. New York: Wm. Wood & Co. 1900.

PAMPHLETS.

ADDRESS BEFORE THE AMERICAN DERMATOLOGICAL ASSOCIATION. By the President, Henry W. Stelwag, M.D., at the Twenty-fourth annual meeting held in Washington, May 1, 2 and 3, 1900, in connection with the Fifth Triennial Session of Congress of American Physicians and Surgeons. 1900. Paper. Pp. 12.

Miscellany.

GENERAL REMARKS ON THE GUNSHOT WOUNDS OF 1898 AND 1899.

[Extract from Annual Report, now in press, of the Surgeon-General of the Army.]

Of the 4919 men injured by gunshot during the years 1898 and 1899, 586 were killed and 4333 were wounded and received into the field and other hospitals. The killed constituted 11.9 per cent. of those struck; the wounded 88.1 per cent. In other words, 1 man was killed for every 7.4 wounded. The Mauser bullet must therefore be regarded as less deadly than the larger missile used during the Civil War. The "Medical and Surgical History" of the Civil War shows the following casualties:

	Killed.	Wounded.
United States troops.....	59,580	280,040
Confederate troops.....	31,425	227,871
Total.....	111,285	507,911

In percentages the casualties were: killed 17.97; wounded 82.03, or 1 man killed to every 4.56 wounded. The relative proportion of killed was therefore considerably larger during the Civil War than during our recent experiences. It is to be noted also that many of the wounds of the past two years were made by missiles of large caliber. Of those reported in 1899, 471 were specially stated as having been caused by the Remington bullet of caliber .45. It is safe to say that had the whole number of wounds received been inflicted by the

smaller Mauser or Krag-Jørgensen bullet the percentage of immediately fatal wounds would have been materially lessened.

The less deadly character of the injuries inflicted by the modern bullet is manifested also when we exclude the killed and regard only those wounds which came under the care of the surgeons. Of these, during the two years, there were 4333, and 259 of the patients, or 6 per cent. of the whole number, died. The corresponding percentage from the records of the Civil War was 14.3. Table C in Part I of the medical volume of the "Medical and Surgical History of the War of the Rebellion," shows that among the white troops of the army there were borne on the reports of sick and wounded 230,018 gunshot wounds, of which 32,907 or 14.3 per cent. proved fatal. The marked reduction of the ratio of killed to wounded may be placed to the credit of the small-caliber bullet; but the lessened mortality among the cases which came into hospital may not wholly be attributed to the humane character of the wounds inflicted by this missile. Due credit must be given to the improved surgical methods of the present day. Wounds of any region of the body may be taken in comparison and the result will always be found to show a decided lessening in the percentage of cases ending fatally among those of the past two years as compared with those of the Civil War. Take, for instance, gunshot wounds of the femur. During the Civil War surgeons in the field hospitals regarded a fractured femur as a serious menace to life, the danger from which was believed to be materially lessened by an immediate amputation. The field-hospital surgical work after a battle consisted in great part of amputations, excisions and resections. Of 6576 fractures of the femur 2923 cases were treated by primary amputation, 186 by resection and the remaining 3467 by conservative or expectant measures; this conservative action being due in many cases to a want of favorable conditions for the performance of primary operations. The limb was promptly amputated in 44.4 per cent. of these gunshot fractures. On the other hand during the past two years 82 cases of gunshot fracture of the femur were reported, 6 of which were treated by primary amputation and 2 by resection, the remaining 74 cases being treated by conservative methods, not because the conditions were not favorable for the performance of primary operations, but because of a conviction that under present methods of treatment the limb could be preserved without adding materially to the danger of life. The limb was lost through surgical intervention in only 7.3 per cent. of the cases.

Not only limbs but lives were saved by the surgical practice of the past two years. In the 82 gunshot fractures of the femur the upper third was involved in 32, of which 5 were fatal, the middle third in 27, of which 3 were fatal, and the lower third in 23, of which 1 was fatal. The mortality varied from 4.3 per cent. of the cases in which the lower third was fractured to 15.6 per cent. of the cases in which the upper third was the site of the injury, whereas the corresponding percentages of fatal cases during the Civil War were respectively 42.8 and 49.7. The whole of the lessened mortality in these serious fractures may be credited to the protection given to the wound by the first-aid dressing and to the care exercised in the subsequent aseptic treatment of the fractured limb.

In penetrating wounds of the thorax the rate of mortality fell from 62.6 per cent. during the Civil War to 27.8 per cent. during the years 1898 and 1899. The Civil War reports show 8403 cases in which the results were determined; 6260 deaths occurred among the number. The reports for the later years, as already stated, show 198 cases, of which 55 were fatal.

There were during the Civil War 3475 penetrating wounds of the abdomen in which the ultimate results were determined; 3031 of these, or 87.2 per cent. of the total, proved fatal. During the years 1898 and 1899 116 cases, 81 fatal, were recorded, the fatal cases constituting 70 per cent. of the total. Of 10 cases in which laparotomy was performed 9 were fatal.

The alteration in the percentages of mortality in fractures of the cranium is less marked than in wounds of other parts of the body. Of 4243 cases of cranial fracture during the Civil War, 2514, or 59.2 per cent. were fatal. In 1898 and 1899 68 cases were recorded, with 37 deaths, the latter forming 54.4 per cent. of the whole number.

Societies.

Indian Territory Medical Association, Muscogee, Dec. 4-5.
Pan-American Medical Congress, Havana, Cuba, Dec. 26-28.
Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

THE OHIO COUNTY (W. Va.) MEDICAL SOCIETY at its recent meeting at Wheeling elected the following officers: Dr. William R. Taylor, president; Dr. Charles A. Wingerter, vice-president; Dr. Henri P. Linsz, secretary, and Dr. Robert J. Reed, treasurer.

THE PEORIA (Ill.) CITY MEDICAL SOCIETY, at its annual meeting, October 30, elected Dr. Emerson M. Sutton, president; Dr. William T. Sloan, vice-president; Dr. Emma J. Lucas, treasurer; Dr. Elmer M. Eckard, secretary; Dr. Albert L. Corcoran, censor, and Dr. Aloysius J. Kanne, pathologist.

THE MEDICAL CLUB, composed of women physicians of New Jersey, was organized November 2 at Newark. The officers elected were Dr. Katherine D. Porter, Orange, president; Dr. Mary D. Hussey, East Orange, recording secretary; Dr. Isabel M. Geddes, Newark, corresponding secretary, and Dr. Augusta M. Madison, Newark, treasurer.

THE CENTRAL DISTRICT MEDICAL SOCIETY, at its session, November 2, at Sedalia, Mo., elected Dr. Joseph B. Norman, Pilot Grove, president; Drs. Squire H. Redmon, Tipton, Ethan F. Statts, Beaman, and A. E. Monroe, New Lebanon, vice-presidents; Dr. William O. Dunlap, Sedalia, treasurer, and Dr. Horace B. Cole, Sedalia, secretary.

LUCAS COUNTY (Ohio) MEDICAL SOCIETY met in Toledo, November 2. Dr. Park L. Myers read a paper on "Some Thoughts on the Alleged Deterioration of the Human Female as a Factor in Reproduction," and Dr. Orville W. Kimball a paper on "Diphtheria." "Prophylaxis and Treatment of Incipient Tuberculosis" was the subject for general discussion, opened by Drs. J. T. Jacobson and William A. Dickey.

THE MEDICAL SOCIETY OF THE COUNTY OF KINGS held a special meeting in Brooklyn, November 4, when eulogies were delivered on the following members who had died during the year; Drs. John Cargill Shaw, Charles Edward West, John Cooper, Aaron Edgerton Peck, Robert Francis Cunnion, Henry Dwight Bliss, Landon Carter Gray, Alexander Johnston Chalmers Skene, Julius Charles Rappold, Frank Stephen Milbury and William Webb Browning.

THE AESCULAPIAN SOCIETY OF THE WABASH VALLEY held its fifty-fourth annual meeting at Paris, Ill., October 26, and elected Dr. John A. Baughman, Neoga, president; Dr. Francis D. Lydick, Paris, vice-president; and Dr. Harry McKenna, Paris, secretary and treasurer. A resolution was passed by the society prohibiting its members from advertising special methods of treatment, on pain of expulsion. Among the papers read were those by Dr. W. J. Fernald, Rantoul, on "Strychnia as a Therapeutic Agent"; Dr. E. L. Birch, Robinson, on "Puerperal Hemorrhage"; Dr. J. L. Firebaugh, Robinson, on "Shock," and President Charles B. Johnson, of the State Board of Health, Champaign, on "Some Medical Discoveries of the Nineteenth Century."

San Francisco County Medical Society.

Regular Meeting, Oct. 9, 1900.

SOME ACCIDENTS IN THE USE OF OBSTETRIC FORCEPS.

DR. HENRY GIBBONS, JR., presented this paper. He bases his experience with forceps on 1200 obstetric cases in private practice, and 150 in consultation. In 190 of these cases forceps had been used. With ordinary care, he thinks serious injury to the mother from forceps used was not likely to occur. He has never known a death to take place, or anything more than laceration of the soft parts. In these days of aseptic methods death should not occur, but the injury to the soft parts may leave important disabilities. Extensive lacerations of the perineum are more likely to occur in occipito-posterior positions, when rotation anteriorly has failed to take place. Lacerations of the neck of the uterus not infrequently occur from the use of the instruments by attempting to extract the head before full dilatation of the cervix takes place; and if the patient's strength is good, and there are no other contra-indications, the forceps should never be applied until dilatation is complete. He called attention to the liability of bruising the tissues covering the inner surface of the pubic arch by

the jamming of the head and forceps against it. This occurs when the head is still in the oblique diameter, and pretty well up, so that the handles of the ordinary forceps can not be depressed sufficiently to insure traction in the direction of the axis; and in these cases axis-traction forceps should be used, preferably those of Tarnier.

The danger to the child is far more serious than to the mother. Aside from minor injuries, which are not infrequent, but are usually of little importance, fracture of the bones of the head, rupture of vessels in the brain, or lacerations of the brain itself, may occur. The conditions of election for the forceps are complete dilatation of the cervix, sufficient time for molding of head, that it may more easily pass through the pelvis, completion of the long rotation in occiput or chin posterior positions, and rotation of the head into the conjugate diameter of the pelvis. When these conspire, the forceps, in competent hands, have almost no danger to the child, and the danger should not be much, even with the tyro, if he has some experience in the use of tools and is a man of good judgment. But as we recede from these conditions the risk to the child becomes greater. When the head is still in the oblique diameter, and not high up, the risk is not greatly increased, provided the instruments are applied to the sides of the head and in its occipital diameter with the occiput to the heel of the blades. The difficulties of application have, however, increased, and not even an expert can always get them in exact position. If not exactly applied they grasp the head more or less obliquely, and if much force is required to effect delivery any of the accidents named above may occur. He thinks there was no excuse for the accidents which occur from forceps slipping. Such an accident has never occurred in his practice. If the index finger of the hand that clasps the lock be extended to touch the presenting part the operator at once appreciates when slipping begins and can avoid it. All the risks to the child are increased the higher the head is in the pelvis, with the added danger resulting from the impossibility, with the ordinary forceps, of making traction in the direction of the axis of that part of the pelvis in which the head rests, and of being required to apply extra force, since much is lost by the necessary dragging of the head against the pubic arch instead of under it. The Tarnier forceps are far better suited to such cases. When the head is at the brim the dangers are supreme. None but an axis traction forceps should be used in such cases.

He urged more conservatism in the use of instruments in labor, bearing in mind the fact that the duration of normal labor in primipara averages twenty hours, and often extends into the second, or even the third, day without serious inconvenience or harm; and in the absence of those emergencies which imperatively call for the application of forceps the case should be left to nature.

Dr. JAMES F. McCONE considered episiotomy useful for preventing deep perineal tears, and thought Eichelberg's high incisions the best method of performing episiotomy. The necessity of waiting for the molding of the child's head, particularly in women of rachitic pelvis, should be emphasized. He had seen spoon-like depressions that allowed heads to pass through contracted straits. Had forceps been applied too early injuries high up in the pelvis would have resulted.

TREATMENT OF LARYNGEAL TUBERCULOSIS.

Dr. ROBERT D. COIN, in this paper, divided the disease, as regards its therapeutics, into three stages. In the first stage, with the exception of a circumscribed infiltration, or ulceration, the larynx is healthy. In this stage, the only one in which a permanent cure can be hoped for, the treatment consists in curettement in case an infiltration be present; in eauterization with lactic acid in case an ulcer be present. If the general condition, especially that of the lungs, be good these procedures are imperative and should be repeated at intervals of from one to three weeks until the diseased condition is completely removed.

In the second stage the larynx presents extensive infiltrations or ulcerations. Here complete elimination of the morbid tissue can no longer be hoped for, but antiseptic treatment comes to the front, the author preferring antiseptic inhalations

of carbolic or boracic acid or lysol. If the epiglottis permit an inspection of the interior of the larynx, the antiseptic swab can be used to advantage. By these methods secondary infection, and the terrible dyspnea and dysphagia of the last stage is prevented.

Finally, if the case is first seen in its last pitiful stage, all that can be done is to treat it symptomatically, to administer a morphia powder before each meal, or, better still, to apply a 10 or 20 per cent. solution of cocaine to the pharynx. In impending suffocation, tracheotomy must of course be performed.

TECHNIC OF THE NEW BASSINI OPERATION.

Dr. CAMPBELL FORD presented a short paper describing the technic from his own observations.

Dr. HENRY J. KREUTZMANN presented two pathological specimens, namely, a uterine fibroid and a multilocular cyst of the ovary.

Omaha Medical Society.

Meeting of Oct. 9, 1900.

FRACTURES OF THE NECK OF THE FEMUR.

Dr. J. P. LORD stated that most works give a very antiquated treatment for these fractures. They usually advise the use of Buck's extension and sand-bags. Senn's method of securing better apposition of the fragments is much used and approved. All authorities advise reduction and the best possible apposition. The ideal treatment is difficult to carry out. Improper immobilization and fixation are the chief causes of non-union. The old methods of the weight and pulley fail; eversion occurs; poor results follow. To best show his method, he gave the details of a case of fracture of the narrow part of the neck of the femur in a man of 37, weighing 190 pounds. He had leaped across the "horse" in a gymnasium and landed beyond the mat on the floor, falling on his hip; there was immediate eversion and $\frac{3}{4}$ inch shortening. These two things led to the diagnosis of fracture at the narrow part of the neck rather than at the base. General anesthesia was given; 4-inch adhesive strap, with block at the end, was run from the perineum down; the malleoli were protected by cotton around them, not over them, as is too common. The limb was covered with cotton and bandaged; plaster-of-paris bandage was then placed from the toes to mid-thigh; traction was made from a pulley in the ceiling behind the patient to a band pulling against the perineum. The extension block was pulled to over-correction of the shortening. A padded board $2\frac{1}{2}$ feet long was then incorporated into the outer and posterior aspect of the thigh and carried up and behind the greater trochanter. The pelvis was well padded and the plaster bandage was then carried up on to the trunk to the cartilage of the eighth rib. The mattress was reinforced with boards beneath to prevent sinking down in the bed. Fifteen pounds were placed on the extension and it was believed that apposition and fixation were well done. In eight weeks the dressing was reapplied and in four more it was removed. There was no eversion and only $\frac{1}{4}$ inch of shortening. There was no limp. The old methods give about 2 or $2\frac{1}{2}$ inches of shortening and many cases of non-union. Serious trouble often results in the knee or ankle from improper extension.

Dr. A. F. JONAS, in discussion, said that Senn devoted much time to the subject of impacted fractures; he reached the conclusion that impaction was often desirable; when there was no shortening no disturbance was to be made. The aged often die from these fractures and great care must be taken. Dr. Jonas was of the opinion that the method outlined by Dr. Lord was a good one, but not the only one. Buck's extension and the sand-bags are not good; they move or are moved. He has had most excellent results from the Volkman splint; it is a tin trough in which the thigh and leg rest; lateral arms of iron project from the sides so that turning of the splint is impossible. Extension is made in the ordinary manner; eversion is impossible. An advantage of this splint is that it lies clear of the bed.

Dr. HAMILTON said that he had more annoyance from such fractures than from any other troubles. When the periosteum

was torn away from the proximal end of the bone, non-union was certain, no matter what apparatus was used.

DR. J. CAMERON ANDERSON said that the old classification of intra- and extra-capsular was not a good one; he preferred to class them as at the small part or at the base of the neck. Senn's apparatus was by no means approved by the best surgeons. In sleety times injury of the soft parts forbids any fixed dressing. Fractures of the neck in children are often overlooked or called hip-joint disease.

DR. A. F. JOXAS related his experiences and thoughts on the International Medical Congress, in extenso.

Vermont State Medical Society.

Annual Meeting, Rutland, Oct. 11 and 12, 1900.

(Continued from p. 1232.)

President Dr. M. R. Crain, Rutland, in the chair.

LOBAR PNEUMONIA.

DR. W. L. HEATH, Richmond, presented a paper on lobar pneumonia. He defined it as an acute disease in which a specific parasite invades the air cells of one or more pulmonary lobes, where it grows in the fibrinous medium exuded from the capillaries and generates a toxin that affects the system at large with constitutional disturbances. In the treatment of pneumonia he recommended the inhalation of chloroform in connection with oxygen, by adding one or two drams to the water in the wash bottle; calomel for its effect on the bowels as well as its absorptive effects, and blood-letting in robust patients. Aconite is a safe drug for relaxing the arterial system. It withdraws the blood from the venous system and stores it in the arterial. Alcohol is valuable and should be given early; guaiacol with hypophosphites in convalescence. For the cough, codein or heroin, with muriate or carbonate of ammonium. Steam inhalations are useful and comforting to the patient. The application of cold to reduce temperature is valuable. The diet should be liquid and the free administration of water is recommended.

VAGINAL HYSTERECTOMY.

DR. C. W. STROBELL, Rutland, said the operation of vaginal hysterectomy is more difficult of performance than its progenitor, which enters the abdomen along the linea alba. The operation has met with violent opposition. The objections urged against it are the alleged impracticability of rendering the birth canal sterile, danger of hemorrhage, narrowness of working space, and danger of pelvic hernia and injuring the intestine. Improved technique, and the combined lithotomy and Trendelenburg posture have proved the fallacy of most of these and experience has shown pelvic hernia to be rare. The writer noted that nausea and surgical shock were markedly less when the lower route was taken, and that intestinal obstruction and intestinal paralysis were rare.

Vaginal hysterectomy is performed by three methods, namely, the American, the German and the French. Of these, the American is the most surgical, and the French is the safest in the hands of most operators.

PUERPERAL SEPTICEMIA.

DR. E. M. POIN, Rutland, read a paper with the above title. Puerperal septicemia is a preventable disease; it is a wound infection, and arises from septic material being carried into raw surfaces at the time of confinement. As a rule the poison is introduced into the wound by the physician or attendants, or by instruments or dressings. There are cases, however, in which the disease arises from pus tubes, pelvic abscesses, etc. A confinement case should be conducted as aseptically as an abdominal section. Post-partum douches should never be used excepting as symptoms demand them, for the reason that the uterine cavity is supposedly aseptic, while the vagina is not, and by reversing the flow secretions may be carried within the uterus, thus favoring infection. Lacerations and contusions should be treated on surgical principles, and aseptic dressings always used after confinement. Sepsis generally arises from retained membranes or clots, and is promptly relieved by intrauterine irrigation.

RUPTURE OF THE UTERUS DURING CHILD-BIRTH.

DR. L. H. HEMENWAY, Manchester, reported a case of rup-

ture of the uterus during confinement, with recovery of the patient. The symptoms were sudden and extreme exhaustion of the patient, with rapid and feeble pulse, great pallor, and an anxious countenance. An examination showed the head presenting, and a shoulder and arm could be plainly felt just beneath the abdominal wall. An attempt to put on the forceps failed, and the child was turned and delivered. The woman made a slow but perfect recovery.

ABDOMINAL PALPATION IN OBSTETRICS.

DR. F. E. CLARR, Burlington, advocated the employment of abdominal palpation in all obstetrical cases. He said that the presentation and position could be made out in nearly all cases, by this means, and he deprecated frequent vaginal examinations. If practiced early, malpositions could be corrected. The special point urged was that vaginal examinations increased the danger of sepsis, and should therefore be practiced as infrequently as possible. The writer explained in detail the technique of abdominal palpation, and urged all physicians to become as expert as possible in the method.

(To be Continued.)

Toronto Clinical Society.

First Regular Meeting of Season, October 3, 1900.

President DR. W. H. B. Aikins in the chair.

PRESIDENT'S ADDRESS.

DR. AIKINS referred to the honor conferred on the Society through Mr. I. H. Cameron, one of their number, being elected an honorary F. R. C. S. The Society now has three members who hold this degree. The better consideration of suggestive therapeutics was insisted on. He thought this branch of medicine was now being put on a scientific basis.

THE MEDICAL SIDE OF THE SOUTH AFRICAN WAR.

DR. GEORGE STIRLING RYERSON delivered an address on the above subject. It dealt particularly with typhoid fever, dysentery and veldt fever. He especially eulogised the splendid work of the hospital orderlies. Their work was indeed trying. He had not seen any typhus fever. A noteworthy fact was the total absence of smallpox in an army of 200,000 men, which proved most emphatically the importance and the power of vaccination. He thought statistics would prove later that typhoid inoculation was a valuable means of preventing this scourge of armies. No Canadians had been inoculated, and there had resulted no mortality from the process.

RETROPHARYNGEAL ABSCESS.

DR. G. SILVERTHORN presented a child less than a year old with a retropharyngeal abscess following an attack of measles. Symptoms occurring were dyspnea and convulsions. Operation was performed externally through the sternomastoid muscle of the right side. Recovery took place within a week from that date. There was no history of syphilis or tuberculosis, and it was not carious in origin.

DISPLACEMENT OF THE LIVER.

DR. H. B. ANDERSON presented a patient and described the history of the case. The subject was a young man aged 25 years, who for the past ten years had repeated attacks of asthma. He had also had pleurisy on the right side three times. The lower border of the liver was below the umbilicus, and percussion over the normal position of the organ elicited a tympanitic note. Rest in bed in this case always resulted in beneficial results. The interesting point in the case is that it is associated with definite attacks of spasmodic asthma.

PECULIAR BULLET COURSE.

DR. SILVERTHORN presented this paper and specimens. They were from the body of a father who had been shot by his son. On the left side, commencing 1½ inches outside the nipple line, and on a line with the nipple itself, was the wound of entrance, ¾ inch wide. On following this wound backward, the bullet was found to have fractured the left fifth rib and torn up a portion of its upper edge 2¾ inches from its junction with its cartilage. It then passed through the pleura and through the anterior angle of the upper lobe of the lung, and then through the pericardium; then along the left border of

the heart, which it grooved up, and passed on backward, tunneling the fat in the auriculo-ventricular groove; it then passed out again from the pericardium and backward through the anterior portion of the lower lobe, and still backward into the aorta, and just through the aorta opposite the ninth dorsal vertebra, causing considerable amount of hemorrhage into the posterior mediastinum; but the bullet could not be found. It could not be found where it was apparently lost, so an examination of the arteries was made; it was found in the left femoral artery, just below where the profunda femoris is given off. The size of the bullet was 1/4 inch in diameter, and in impinging the posterior wall of the aorta had perforated that wall supported behind by the vertebral column, had fallen back into the blood-stream, and, either through the force of gravity or the force of the blood-current, or both combined, had been swept on to the position in which it was ultimately located. The specimen of the artery was also shown with the bullet in situ.

Therapeutics.

Chronic Rheumatism.

R. Potassii iodidi	3ii	8
Vini colchici rad	3iiss	10
Aque menth. pip., q. s. ad.	3iii	96

M. Sig. One teaspoonful every four hours.

Sweating Feet.

R. Sodii salicylatis	gr. xxx	2
Potassii permanganatis	3i	4
Bi-smuthi subnitratris	3iiss	48
Acidi borici, q. s.	3iii	96

M. Sig. Dust on the feet and into the stockings and shoes every morning.

First Stage of Pleurisy.

R. Tinet. aconiti	m. vii	45
Spts. etheris nitrosi	3vi	24
Syrupi simplicis, q. s. ad.	3iv	128

M. Sig. One dessertspoonful every hour until eight doses are taken, then every two or three hours.

Furuncles.

R. Acidi carbol.	gr. v	33
Ext. ergotæ flu.	3i	4
Pulv. amyli		
Zinci oxidii, aa.	3ii	8
Ung. aque rosæ	3viii	32

M. Ft. unguentum. Sig. Spread the ointment on a thick layer of absorbent cotton and hold in place by means of adhesive plaster.

—L. D. Bulkley.

Myalgia.

R. Linimenti chloroformi		
Tinet. aconiti		
Tinet. opii		
Spiritus camphoræ, aa.	3i	32

M. Ft. linimentum. Sig. Apply locally two or three times a day.

Mucous Patches in the Mouth.

R. Acidi borici	3ii	8
Glycerin	3ii	64
Tinet. myrrhæ	3i	32
Aque rosæ, q. s. ad.	3viii	256

M. Sig. To be used locally to the patches in the mouth.

Mucomembranous Colitis.

R. Bi-smuthi subnitratris		
Bi-smuthi salicylatis, aa.	3iiss	10
Mucilaginis eydonii (quincee)	O i	512

M. Sig. Use as rectal injection.

Aortic Insufficiency in Acute Articular Rheumatism.

R. Sparteine sulphatis	gr. iss	09
Infusi digitalis		
Syrupi aurantii amari, aa.	3i	32
Aque—gum	3ii	64

M. Sig. A tablespoonful every four hours.

—*Reforma Medicæ.*

Eczema of the Scalp in Children.

R. Resoreini	gr. vii	15
Sulphuris	gr. xli	2 66
Lanolini	3ii	8
Adipis, q. s. ad.	3iii	96

Sodii boratisgr.	xl	2 66
Aque, q. s. ad.3viii	256	

M. Sig. Two tablespoonfuls every two hours. —Sajous.

Styes on the Eye.

Keiper states that styes are usually due to eye-strain. He recommends the following as a wash:

R. Acidi borici3i	4
Aque destil.3iv	16

M. Sig. Bathe the eyelids every hour.

Hypodermoclysis.

R. C. Kemp, in *Med. News*, states that the administration of normal salt solution hypodermically will prevent the development of certain symptoms sometimes produced by the administration of large doses of antistreptococic serum, and that congestion of the kidneys, which sometimes occurs after the administration of antitoxic serum will not take place if twice the amount of normal saline solution be injected immediately after the administration of the antitoxin. The most suitable place for introducing the normal salt solution is in the lateral lumbar region, as there is no interference with respiration, nor pain on moving the limbs.

Medicolegal.

Right of City as to Location of Smallpox Hospital.—The case of Frazer and others vs. the City of Chicago was brought to recover damages for the menace to the health of the inhabitants in the vicinity of a smallpox hospital, or, rather, to those inhabitants who in the intended future use of the plaintiffs' property might become residents in the vicinity thereof, and who, by reason of its location, would be deterred from purchasing the plaintiffs' property, and the consequent loss in the speculative value thereof. But the Supreme Court of Illinois holds that no such cause of action could be maintained. It points out that power is expressly given, in the village act, "to erect and establish hospitals and medical dispensaries, and control and regulate the same." Consequently, the establishing of the smallpox hospital referred to was clearly within the police power of the city, and, the court holds, in the absence of carelessness or negligence, or of an abuse of that power in any way, the hospital could not be a public nuisance. Nor, it goes on to say, could it be a private nuisance unless it should become such in its subsequent use or unwarranted operation, having in view the peculiar conditions under which it was established and maintained. The law is well settled, it declares, that where a thing not malum in se, or a wrong in itself, is authorized to be done by a valid act of the legislature, and it is performed with due care and skill, in strict conformity with the provisions of the act, its performance cannot, by the common law, be made the ground of an action, however much one may be injured by it. But it was contended that it is an unreasonable, unusual, and extraordinary use of property to utilize it for the segregation of diseases. However, the court says that, under the express delegation of power by the legislature, it cannot hold that the application of property for the use of a smallpox or other hospital is such an unusual or unreasonable use of property as would take it out of the police power of the city, so as to render it liable for such application, when, as here, it is conceded that the pesthouse is rightfully located and well conducted. To this it adds that it can

see no difference, in principle, between the right of a city to establish and maintain a smallpox hospital, and to erect and use jails, fire-engine houses, calabosoes, and the like. Greater care might be required in the maintenance of one than the other, and different considerations would undoubtedly enter into the selection of a site of a pest-house than of the fire-engine house or jail; but the city would be liable only for an abuse of authority or an unwarranted exercise of discretion in locating or maintaining the same, having reference to the present necessities, the crowded condition of the locality in which they are placed or maintained, and other pertinent facts and circumstances.

On Self-Treatment and Proof by Physical Acts.—Arkansas River Packet Company vs. Hobbs, is the title of a personal injury case brought by the latter-named party, and appealed to the Supreme Court of Tennessee, by the former. At the trial, the jury was instructed that it was the duty of the plaintiff—Hobbs—upon being injured to do all reasonably within his power to have his knee cured and restored to its original condition. It was also instructed that if he selected and used all reasonably accessible means for that purpose, and for a time, on his own judgment and without medical advice, adopted and pursued such treatment as a physician of ordinary care, prudence, and skill would have used in treating an injury, the law would accept that action on his part as full discharge of his duty in that behalf, even though it might appear from the evidence at large that a more skillful treatment might have produced a more favorable result. These propositions the supreme court pronounces entirely sound and unobjectionable. The first, it says, announces the generally accepted doctrine that he who is injured in his person or in his property by the wrongful act of another should take reasonable precautions to repair the injury, and prevent the enhancement of ultimate damage; and the second, rightly applies that doctrine. The exercise of reasonable and ordinary care and prudence, according to the circumstances of the case, the court declares, is all that the law demands, and in no event will the wrong-doer be heard to say that the person injured was bound, at his peril to secure the services of the most skillful physician in the community, or to adopt the treatment which in the end would prove to be the most efficacious. The court also holds that the grounds on which the privilege of voluntarily exhibiting an injured limb to the jury is practically unanimously accorded to a plaintiff, to show the nature and extent of his injuries, by the authorities, which are greatly divided in opinion as to the court's power to compel such exhibition, justifies with like force the voluntary performance of physical acts which are in themselves fit and appropriate as illustrations of the same fact. Indeed, it thinks that allowing such physical demonstrations, with the privilege of all legitimate cross-examination to the adverse party, affords a superior method of getting at the truth, and produces a higher order of evidence than is usually attainable, in that it adds physical illustration to oral statement, and impresses the court and jury through the sense of sight as well as through that of hearing. It may be true, it says, that a designing witness can exaggerate the true condition of an injured limb by false and constrained movements, and yet that can not render the performance of physical acts inadmissible as evidence, any more than the equally obvious fact that he may give undue and false coloring to his oral statements renders him incompetent to testify by word of mouth. That objection goes only to the question of weight or credibility, and does not reach that of competency or admissibility.

Illegal Quarantine of Race and District.—The remedy by injunction the United States Circuit Court, Northern District of California, holds is the proper one for such a case as that of *Wong Wai vs. Williamson* and others. In other words, it, in this case, holds illegal and void, and to be kept by injunction from being enforced, such quarantine restrictions and regulations as the acting board of health and acting federal quarantine officer in San Francisco imposed upon the Chinese when they made their inoculation with Haffkine prophylactic a condition to their being allowed to leave the city for other parts of the state. To begin with, it finds that, while suitable

provision was made in the city charter for the necessary legislation providing rules and regulations to secure the proper sanitary conditions in the city and for the protection of the public health, the board of health was without legislative authority to deal with the bubonic plague situation, through apparent lack of action on the part of the board of supervisors. And it says that when the municipal authority has neglected to provide suitable rules and regulations upon the subject, and the officers are left to adopt such methods as they may deem proper for the occasion, their acts are open to judicial review, and may be examined in every detail to determine whether individual rights have been respected in accordance with constitutional requirements. Then, too, it holds that the quarantine officer in the marine-hospital service of the United States at that port had no jurisdiction to impose quarantine regulations or restrictions upon any class of persons traveling from place to place within the state. But of perhaps still more importance, it holds that any quarantine regulation or restriction imposed upon any particular class of persons, as Chinese or Japanese, and not imposed upon others similarly situated, is an arbitrary and unreasonable interference with, and discrimination against, the individual liberty of the persons regulated and restrained, contrary to the provisions of the fourteenth amendment to the constitution of the United States, and therefore void. In *Jew Ho vs. Williamson*, where the evidence was such that the court says that, if it were within its province to determine the issue, it would be compelled to hold that the plague did not exist and had not existed in San Francisco, it holds unreasonable, unjust and oppressive, and therefore contrary to the laws limiting the police powers of the state and municipality in such matters, a quarantine of a district comprising 12 blocks containing 10,000 persons, with free intercommunication within the district. At the same time, it accords to the board of health the right to maintain special quarantines in places suspected of having disease, and the right to enforce such regulations as it may deem proper in order to secure an absolute exclusion of such places from the remainder of the community. And where suspicious cases are found and a quarantine is imposed upon the proper locality or house or building, the physician who has been attending the person afflicted, the court holds, should be permitted to continue to attend. In case of a death among the Chinese, a physician selected by the Chinese association interested, it also thinks, should be allowed to attend any autopsy that might be made. But this privilege, the court adds, should not be abused, and there should not be an effort on the part of everybody, out of curiosity and otherwise, to attend upon such autopsies, and there should be no unreasonable interference with the authority of the board of health in matters of this kind.

AMERICAN.

1. Local and Regional Anesthesia.—Matas' paper is a valuable historical and critical review of the methods of regional anesthesia as employed in surgical practice, including the subarachnoid method. He gives full credit to Corning, Halsted and others as pioneers in the local use of cocain. He describes the methods at length, illustrating the different operations for regional infiltration, etc., and reports cases in his

own practice, which has been extensive with these methods. He considers anesthesia with cocain or its allies most often impracticable and unsatisfactory in the following conditions: 1. All operations or manipulations in which complete muscular relaxation is required to accomplish the object of the intervention; as in the reduction of fractures and dislocations of the larger bones and joints—the hip, the shoulder, the elbow, and the knee—in relaxing ankylosed joints, spastic muscular contractures; stretching sphincters—of the rectum and bladder—etc. 2. In all extensive atypical operations on the head and trunk in which the neuro-regional method is inapplicable and the field of the operation can not be well defined or circumscribed, as in the radical extirpation of mammary cancer by Halsted's and Meyer's methods; in the extirpation of bilateral and multiple chains of adherent lymphatics in tuberculosis of the neck, etc. 3. In all atypical operations involving prolonged and complicated maneuvers in the splanchnic cavities, especially when the organs operated upon are adherent and inflamed. 4. In all operations upon patients whose emotions are beyond the control of reason or the will, as in the violently insane, in delirious patients, in children, in hysterical and extremely timorous patients, and in all those in whom the mere consciousness of the operative act—without physical pain—is sufficient to produce great mental excitement and distress. In spite of these he says the number and character of the cases in which the most rebellious conditions can be brought under the domain of the new technic by a patient, tactful and skilled operator is astonishing. Spinal cocaineization is considered at length, and its advantages and disadvantages discussed. The author's personal experience, begun in 1899, has been limited to nine cases and shows very little objection to this method. Judging from this, he would limit its indications for application for the present: 1. To adults, and to reasonable persons who have good self-control, thereby excluding children, hysterical patients, and the insane. 2. To patients in whom the methods of local or regional anesthesia are inapplicable. 3. To patients suffering from emphysema, advanced asthma, chronic bronchitis, and other respiratory affections in whom a general inhalation anesthetic is absolutely contraindicated; in advanced cardiac cases with degenerative lesions, he would fear the possible depressing effects of the injection and excitement on the circulation. 4. In the majority of cases in which the painful part of the operation is not likely to be prolonged beyond one hour and a half, as he would be averse, in the present state of our knowledge, to repeat a second cocaineization or to increase the total dose of the cocain to more than 2 cgm., especially in exhausted subjects. The danger of repeating the intradural injections to prolong the anesthesia is also one of the objections to the use of the method in ordinary labor. But its advantages in instrumental cases, as shown by the successful experiences of Dupaigne, of Louviciennes, France—who, according to Tuffier, first applied the subarachnoid method in labor, January, 1900—and of Bumm and Kreis, of Basle; of Doleris and Malartic, of Paris; and Marx, of New York, can not be doubted, especially in nephritic patients.

2. Cocain Analgesia.—Fowler reports forty-four cases of which he gives a brief résumé and one case in which antipyrin was injected. The analgesia in this case did not seem to have been quite complete according to the author's belief and there was nausea, vomiting, headache, acceleration of pulse and rise of temperature quite up to the average of this operation in connection with spinal cocaineization. In certain cases Fowler employed also ether or chloroform anesthesia where the analgesic effect was not sufficiently prolonged and in special disturbances no bad effects were noticed and, rather less of the anesthetic than usual was required.

3.—See abstract in THE JOURNAL of November 3, p. 1172.

4. Analgesia in Obstetrics.—The report by Marx is a general one of his experience with medullary injections of cocain in obstetric practice. He thinks the usual precautions for sepsis are the same as in abdominal operations, and remarks that he has seen the analgesia from the ears down, but in most cases it extends only to the umbilicus. The analgesia from one injection lasts from one to five hours, and

he has never met with any serious symptoms in labor such as are actually seen in surgical work. There was no fainting pulse and cyanosis. The use of certain drugs has given such excellent results that, barring a very short vomiting and headache, he never sees any of the distress he was formerly accustomed to. The drugs which he relies on are the bromids, hyoscin hydrobromate and nitroglycerin, and he thinks it well to have the stomach of the patient emptied some time prior to the expected puncture. His best success has been in those cases where 30 to 40 grains of sodium bromid were given one to two hours before. Only when this fails does he allow the use of hyoscin hydrobromate in 1/100 to 1/200 of a grain, given in the anesthetic areas. Nitroglycerin he usually reserves until slight cyanosis becomes apparent and the pulse fails. He gives it also hypodermically in 1/25 to 1/100 of a grain doses. Uterine contractions are not interfered with. He does not hesitate to use repeated injections. He says he has carried a woman through a labor of eight hours by repeated injections, with practically no pain. A special point noticed is the ease with which the cervix can be dilated when the patient is cocaineized. He is careful to avoid any psychic exhaustion, and therefore insists on quiet, blindfolding of the eyes and plugging the ears of the patient.

5. **Anesthesia in Adenoids.**—The following are the conclusions of Halsted's article: 1. Children with adenoids present two distinct conditions, viz., the lymphatic diathesis, manifesting itself locally in the nasopharynx, and the constitutional and local effects of mouth-breathing. 2. Mouth-breathing children and those of the lymphatic diathesis are in depressed general health and possess a lowered general tone of all the cells and organs of the body and so resist badly all heart depressants, such as chloroform, shock, fright, etc. 3. Instead of being regarded as comparatively safe during the period of childhood because of the existence, among so many children, of the lymphatic diathesis; the presence of this diathesis is a positive contraindication to the use of chloroform in any operation. 4. The adenoid operation in children under 12 years of age without general anesthesia must as a rule be condemned because it does not permit of a thorough removal of the growths, is exceedingly painful, and because the pain and loss of blood produce such shock that irreparable injury is often done to the nervous system of a sensitive child. 5. For the removal of adenoids, ether properly administered is incomparably safer than chloroform, and in skilled hands is but little more disagreeable to the patient, and in the great majority of cases is the best anesthetic in this operation.

11. **Subarachnoid Injections of Cocain.**—Phelps notices the enthusiasm in regard to medullary anesthesia and gives special caution not to progress too fast.

12. **Nitrous Oxid and Ether.**—Brown and Kelly mention the advantages of the combined method of using nitrous oxid with the Bennett inhaler, followed by ether, and have been using it in all cases operated on during the last eight months in Dr. Kelly's private hospital. It seems to possess so many advantages to the patient, operator and anesthetizer and so few disadvantages that it has become a distinct part of the operative technique.

13. **Ethyl Bromid.**—The uses of ethyl bromid are detailed briefly by Krusen, who specially mentions the need of thorough examination of the patient before anesthetizing and the employment of a pure drug. The advantages which are claimed for this agent are: 1, the short space of time required to render the patient unconscious; 2, the small quantity of the drug employed and the rapidity of its elimination from the system; 3, the simplicity of its administration, no cumbersome apparatus or inhaler being required, and 4, the comparative freedom from unpleasant sequels, such as headache, nausea, vomiting, etc., which characterize the other more popular anesthetics.

15.—See abstract in THE JOURNAL of October 20, p. 1049.

16. **Cesarean Section.**—Dudley pleads for Cesarean section in placenta previa as being a comparatively harmless and

efficient method of saving two lives instead of risking one or both. He claims that it is practically free from danger if properly performed. By the latter condition he means that an ante-partum diagnosis justifying the operation shall have been made, proper asepsis employed and the operation done before the patient has become in any way exhausted.

21.—See abstract in THE JOURNAL of November 3, p. 1170.

22. **Incineration vs. Earth Sinks.**—The disposal of camp refuse, especially the excreta, is an important matter, as shown by experience in the late Spanish-American war with typhoid fever. Bissell describes and illustrates an incinerator used by the National Guard of New York in their encampment in 1899 and the excellent results obtained. He gives the testimony of those who have observed its action and advocates its more extensive use.

23. **Acute Appendicitis.**—Johnson reports forty cases of appendicitis operated on during a period of a little more than a year and calls attention to certain special points, especially the value of abundant saline irrigation of the peritoneal cavity through a moderate incision and without evisceration, in cases of purulent peritonitis.

24. **Military Gunshot Wounds.**—This article of La Garde's reports the results of observations on the wounds received in the Santiago campaign. He thinks that the Mauser bullet apparently has sufficient stopping power for the purpose of war, as the men who were hit almost invariably fell back at once. The terrific explosive effects were not observed, but he accounts for it by the fact that the fighting was done in a country covered with bushes and the bullets necessarily lost much of the velocity through obstructions. This also accounts for the large number of lodged bullets—10 per cent. The flesh wounds were comparatively slight and the experience in the Santiago campaign does not confirm the apprehensions as to hemorrhage produced by small jacketed bullets. The gunshot injuries of the diaphyses of the bones, as a rule, were not attended with much comminution, and in the joints perforations were usually clear-cut. More than one-half of the injuries to the head ended fatally; about one-fourth of those of the thorax recovered—a favorable showing. After-effects, however, have been noted, and this must be considered. Gunshot wounds of the abdomen were very fatal and laparotomies invariably so. He gives a tabulated comparison of the effects of the new arm as compared with the conclusions based on the results of many deaths with the old weapons, showing the larger percentage of wounds of the extremities in modern war.

25. **Purpura Hemorrhagica.**—This disorder is discussed by Burt, who describes the symptoms and notices its frequent fatality and gives histories of cases. He considers it a bacterial disease. It is especially liable to affect young children and pregnant women and is rather less frequent in the male than in the female. It is treacherous in its course; it may commence mildly and be converted very suddenly into a really dangerous disorder. The results of medical treatment are not especially favorable, and certainly not in the virulent forms. In conclusion he gives extracts from Pflügge's "Die Mikroorganismen," showing the bacteriologic findings.

26. **Rectal Feeding in Peptic Ulcer.**—Two cases are reported by Sears which seem to show that nutrient injection of peptonized food is a valuable method in gastric ulcer. The tube is inserted beyond the sigmoid flexure if possible, at least eight or twelve inches inside the rectum, and the fluid injected slowly. Efforts at expulsion are prevented by a pad and the enemata are repeated every six hours. He does not claim that all the necessary nourishment can be furnished this way, but in his cases the improvement of the patient by this method was encouraging.

27. **Climatic Treatment of Phthisis.**—Swan points out the factors acting to produce the many failures to receive benefit from the Colorado climate. They are, the advanced stage of the disease at which many patients seek this change, the poverty which requires them to work, and often at damaging occupations, when they should rest, and their neglect of

the proper methods of living. He urges three points: 1, do not send patients with far-advanced phthisis to Colorado, unless they are able to make the change without serious fatigue, and unless they can live there in the manner they should and for a prolonged period; 2, do not send early cases, unless there are assured means for proper hygienic living for a period sufficiently long to get the patient well enough to earn, in part at least, his living, and to find employment. How long will depend on the individual case and his progress, but, roughly speaking, three or four months at least. There are many openings for employment, but more people looking for the desirable ones, and 3, most important of all, instruct the invalid to rest and keep quiet after his arrival until some one competent to advise him considers it safe to begin to exercise; and then have his manner of life and hygiene directed from time to time, according to his progress and condition.

28. **Puerperal Eclampsia.**—After first noticing the cause and assuming that eclampsia is due to an accumulation of toxins in the system, produced in the body, Killebrew concludes that one of the best methods of treatment is to dilute the toxins as much as possible and at the same time to increase the activity of the excretory organs by the use of normal salt solution. The pregnant woman, he says, should be under constant observation by her physician, at least after the sixth month. If there are any premonitory symptoms of toxemia such as disturbance of vision, epigastric pain, nausea, mental irritability, etc., it is a strong indication that toxemia is present. She should be kept quiet, put on a liquid diet, largely of milk, and the bowels looked after carefully; she should also have a daily warm bath with an hour or more of rest in bed and hot enemata of one to three pints of normal salt solution once or twice in every twenty-four hours. If, in spite of this, the symptoms progress, or if convulsions have occurred when the patient is seen active measures must be taken; excepting in very anemic cases, he advises bleeding. While the dark toxin-laden blood flows from the distal end of the divided vein, normal salt solution at a temperature of about 100 F. is injected into the proximal end. Intravenous injection is preferable to other methods as being more certain and rapid and not more dangerous. If the patient is edematous and the circulation is sluggish, salt solution under the skin is probably never taken up by the lymphatics. The uterus should be emptied immediately. After these measures have been taken the colon should be thoroughly irrigated, and if convulsions recur they should be controlled with chloral given in an enema, and if they again become severe another infusion of normal salt solution should be given, but this rarely will be necessary. During convalescence the patient should be kept in bed and the bowels and other excretory organs kept active. The diet should be restricted to liquids for a week and then gradually increased as deemed best. Hot saline enemata should be given twice daily. All excitement, worry, depression and callers should be avoided. Other drugs than chloral are not especially favored by the author.

29. **The Malarial Parasite.**—Craig describes the staining reactions of the different forms of tertian, quartan and estivo-autumnal parasites in malaria. For staining he uses either Romanovsky's or Chenzinsky's method, preferably the latter. The former is a mixture of equal parts of saturated methylene-blue and 1 per cent. aqueous eosin solutions. The latter is somewhat similar, but in different proportions; a concentrated watery methylene-blue solution, diluted one-half with water, is added to an equal amount of a .5 per cent. solution of eosin in 60 per cent. alcohol.

30. **Animal Tissue and Poisoning.**—Meltzer and Langmann report experimental studies of the effects of animal tissues on certain poisons, such as snake venom and strychnin. Their results can be briefly summarized as follows: Constriction of an extremity of an animal, even after removal of the constriction, markedly retards the fatal outcome of snake-poisoning and transforms an effective minimum dose of strychnin into an ineffective subminimum dose. This effect is apparently due to some impairment of the power of absorption within the constricted leg. It seems quite certain that

no part of either poison becomes fixed or neutralized by the tissues of the animals experimented on. The claim of v. Czylharz and Donath to that effect could not be sustained.

31. **Eye-Work in General Practice.**—Toms calls attention to the ocular conditions producing reflex symptoms, such as anorexia, vomiting, vertigo, gastro-intestinal disturbances, etc., and cites cases illustrating his views. He says in conclusion that it is apparent that there are many cases presenting nondescript ailments due to some latent irritation to susceptible nervous centers, capable of reflecting impressions to organs easily deranged, that are indirectly dependent on abnormal conditions of congenital eye defects in refraction or muscular unbalance. He does not assume that general practitioners can become experts in the detection of the obscure etiology of these conditions, but they should be able to do more than is sometimes done at the present.

32. **Interstate Reciprocity.**—Amberg continues his paper, giving the statements of the officials in various states of their desires and standing in regard to medical reciprocity, and suggests that all local medical societies appoint committees to settle the question, and that the various state and territorial medical societies appoint a certain committee which should be in touch with the committees of the local societies, and also a committee to be appointed by the AMERICAN MEDICAL ASSOCIATION or its Section on State Medicine. The latter should be in constant touch with the committee of the National Confederation of the State Medical Examining and Licensing Boards. He also thinks it would be advisable that the certificates of the medically strong states be accepted by the weaker states and territories without the stronger accepting the certificates of the weaker. The medical profession will not cease in its efforts until the point is reached when the title of M.D. in any place in the United States gives a guarantee that the bearer has complied with the requirements of the present state of medical science.

33. **Subcutaneous Injection of Alcohol.**—Eastman suggests the use of a small amount of alcohol in normal saline solution in certain cases where a direct cardiac stimulant is required. He has found the salt solution containing whisky more prompt and certain in its results than the plain physiologic salt solution. The pulse was distinctly reduced in rate and increased in force by the use of the combination in a case of serious toxemic and fulminating appendicitis, and he suggests it as worthy of a further trial.

34. **Constipation.**—The general subject of constipation is reviewed by Monroe, who considers it less an actual than a relative disease. While normally there should be a passage of the bowels once in twenty-four hours, there are exceptions to this rule. He mentions one of a man who lived to the age of 77 in good health up to within two years of his death and yet who defecated only about twice a month. The causes are noticed: sedentary habits, bad air, strictures, tight-lacing, etc. He thinks the continued use of oatmeal, especially in those of sedentary habits and in the aged, will produce this condition, and another cause is the use of large enemata, the frequent repetition of which paralyzes the muscles of the rectum. The various symptoms of the condition are also noticed—mental depression, headache, intestinal obstruction, nervousness, hemorrhoids, etc.

40.—See abstract in THE JOURNAL, xxxiv, p. 1334.

44. **Meningococcus Intracellularis.**—The special point of Fischer's article is the comparatively more favorable prognosis with the meningococcus than with other forms of infection in the meninges and the value of lumbar puncture as a diagnostic method of determining its presence. His own experience with this procedure as a therapeutic measure has been rather favorable, as it also enables him to give a better prognosis when the meningococcus has been found.

51. **Syngomyelia.**—Mink argues for the impossibility of an absolute diagnosis of syngomyelia during life, claiming that many cases have been wrongly diagnosed, as shown by post-mortem and that in others the reports have been with-

held for this reason. In enumerating the different troubles that may be confounded with it, he mentions hysteria, leprosy, tabes, bulbar palsy, etc., and concludes that the diagnosis is impossible during life with reasonable certainty, for the following reasons: 1. It has no definite symptomatology. 2. In some cases it has no symptomatology at all. 3. The so-called syringomyelic dissociation of sensation upon which so many diagnoses have been based is not characteristic of syringomyelia, as it occurs in many central nervous diseases and is lacking in quite a few cases of syringomyelia. 4. Dissociation of sensation is, to a certain degree, a normal condition. 5. There are no special symptoms or groups of symptoms characteristic of syringomyelia alone. Comparatively few cases diagnosed during life have been confirmed by post-mortem examination, e. g., cases by Raymond, in France, and Dereum, in this country, but they are so few in number compared with cases unverified or contradicted by post-mortem examination or unsuspected until then that they appear to be of the nature of "lucky strikes."

52. **Railroads and Overwork.**—Hughes protests against the policy of railroads in demanding long hours of specially trying work, including in those thus overtaxed not only the subordinates and train dispatchers, but also higher officials. The human brain is a limited machine, its limitations should be recognized as much as those of the machines of the shop and road.

54. See abstract in THE JOURNAL of October 20, p. 1049.

58. **Hemostasis in Abdominal Surgery.**—The difficulties of the various methods of hemostasis in abdominal surgery are noticed by Montgomery, who concludes that the angiotribe supplemented by the ligature is probably the best method. In catgut properly prepared we have a ligature which is capable of absorption and yet may remain sufficiently long to insure the patient against hemorrhage. The angiotribe prepares a groove in which the ligatures may be placed. He prefers the catgut prepared by his own methods for safety.

62. **Curette.**—Stahl emphasizes the advantages which the finger has over the curette in locating foreign bodies and its superior facility in shelling out intact the secundines instead of the usual morselling by the curette and forceps. He claims that he has never yet met a uterus whose fundus he can not reach and whose cavity he has been compelled to curette a second time for retention. The index finger can not be used so well, but the middle finger can, and he illustrates his method.

67. **Postpartum Hemorrhage.**—After first noticing the pathology, etc., of postpartum hemorrhage Byers insists on two measures which should be adopted in every case for its prophylaxis: 1. The proper management of the third stage of labor. 2. The important principle never to deliver in the absence of pains. He advises waiting patiently for the separating of the placenta, avoiding all efforts to massage or stimulate the uterus. As regards the second point, he insists on that no matter how tired the physician may be or how tedious the labor, he must avoid doing anything when pains are absent. The proper method is to give a dose of opium, when the patient will fall asleep, and after sufficient rest the pains will reappear and she will probably be able to complete the birth without the forceps. As regards the treatment postpartum, he thinks the best method is the external uterine massage. The introduction of the hand into the uterus is a very dangerous procedure, and should be done only when it can not possibly be avoided. He would use hot water in cases where uterine massage fails. In case both of these fail, bimanual compression should be made, though he thinks this very fatiguing and trying. He describes the technique of gauze plugging, and where in spite of such packing, hemorrhage continues, he would recommend drawing the uterus down as far as possible, which he thinks acts by kinking and compressing the uterine arteries. Injection of iron has not been used by him for the past five years; it is not without danger and interferes with subsequent measures. The sources of hemorrhage are mentioned, especially lacerations and their treatment.

68. **Spina Bifida.**—Wilson's article is an elaborate treatise on the whole subject of spina bifida and its operative treatment. Palliative measures he thinks may be successful, but the possibility of spontaneous cure must not be forgotten. The special technique of removal of the tumor and closure is described, and he mentions the risks of the proceeding.

71. **Symphiseotomy.**—The dangers of symphiseotomy, according to Carr are: 1. Dangers from anesthesia and from shock, which are unavoidable. 2. Danger from infection, which is unnecessary but real. 3. Danger of attempting it in unfavorable cases where the pelvis is too small. He goes at some length into the discussion of this subject. 4. Danger of lacerating the bladder or uterus or the sacro-iliac ligaments. This can be avoided by insuring not over two and a half inches separation in all cases, and there will then be no laceration of tissues excepting some peeling off of the periosteum. 5. Danger of hemorrhage from rupture of the anterior vesical veins or those of the elitoris. Usually this may be checked by gauze packing, but may be entirely obviated by separating the tissues carefully all around the symphysis and for three-quarters of an inch to one inch on each side of the median line. 6. Danger of sepsis, and he insists on special antiseptic precautions, using 1-2000 bichlorid solution freely. 7. Discomforts and dangers that may follow from the imperfect methods of coating the bones which he thinks can be obviated by wiring the joints. This should be done in every case. The two cases he reports are not enough to base an opinion upon, but they show that wiring the bones does not necessarily produce any bad results. The contrast between the cure where wiring was used and that where it was not is most marked, and until this becomes part of the operation, symphiseotomy will not meet with general favor.

74. **Compression of the Ureters by Myomata Uteri.**—The conclusions of Knox' article are given as follows: 1. Some compression of the ureters is produced by a large proportion of all large myomatous uteri. 2. The resulting hydroureter and hydronephrosis may continue for years and give rise to no discomfort to the patient. 3. The presence of a dilatation of the ureter and renal pelvis, however slight, lowers the resistance of these organs to toxic and infectious agents, and hence inflammatory conditions of the ureter and kidneys not infrequently follow ureteral compression. 4. In all instances of uterine myomata, the possibility of urethral involvement must be considered. When such a condition is suspected, every effort should be made by means of direct examination, urethral catheter, etc., to arrive at an accurate diagnosis. 5. Exploratory incision is occasionally justified to establish a diagnosis. 6. The ureters should be inspected whenever the abdomen is opened for the removal of a tumor. 7. A myomatous mass found to be existing under pressure upon one or both ureters should be removed, if possible, unless operative interference is contraindicated. Such serious sequelae of ureteral compression as extreme hydronephrosis, pyelonephrosis, etc., should receive appropriate treatment.

81. **Immunity in Tuberculosis.**—From a study of the cases in a special locality and among the tribe of Indians of the Cattaraugus Reservation, Lake finds a very large mortality from tuberculosis, but he has come to the conclusion from his studies here and elsewhere that early tuberculosis in the form of serofulous engorgements, etc., seems to confer a certain degree of immunity to later pulmonary infection. The same protection seems to be conferred in tuberculosis of the bones and joints. He observes that the development of phthisis at puberty is a common occurrence in the special population where it has been here studied, but those who have undergone extensive glandular tuberculosis with suppuration appear to escape. He thinks that with very few exceptions the whole population of the reservation may be divided into two classes: 1. Those who manifest existing tuberculosis. 2. Those who have suffered from the affection as shown by scars, deformities, etc., and have become the most vigorous men and women of the tribe. Recoveries from this, like other contagious diseases, appear to protect against a second invasion.

82. **Autochthonous Malaria in Buffalo.**—Lyon and Wright have endeavored to ascertain whether there is any such thing as locally-originating malaria in Buffalo. They have investigated the mosquito forms, finding no specimen here of the anopheles genus. Neither have they found any evidence that malaria originates in that particular locality. They do not pretend to have settled the question absolutely, but simply to have collected some facts and statistics and believe that only by such study as they have made can the true state of facts be ascertained.

95. **A Study of Cases of Inebriety.**—Partridge reports about twenty histories of drunkenness and calls special attention to the mental element in the cure of the habit. He finds that the craving is not for drink itself but for something it produces. There is a possibility of inebriety being self-limited, the tendency dying out at certain periods, generally in the climacteric period of life. Very few succeed in going right early, the average cure seems to come on between the age of 30 and 50, as he finds by reference to authorities and his own observations. If the physiologic basis for drinking is the change of protoplasm due to the continued assaults of alcohol, as many maintain, it will be difficult to account for the fact that young men are as a rule less easily cured than older ones. The social feeling is the most common cause of drinking.

99. **Mental Studies in Morphinomania.**—Green reports two cases of prisoners in the Georgia penitentiary, one who had been in the habit of taking over 400 grains and the other 350 grains of morphin daily. Both were treated by gradually diminishing the doses, keeping up the impression that they were taking the full amount by giving them quinin instead. The remarkable features of the cases were the reduction of 400 grains in the first case and 350 grains in the second case in about 70 days. At the same time a nutritive diet was insured, and no bad effects were observed excepting the rapid, nervous heart and pains in the limbs which disappeared like magic under the combination of digitalis, iron, quinin and suggestion.

101. **Delirium Tremens in Moderate Drinkers.**—Referring to a paper by Dr. Elmergreen, of Milwaukee, in the *Medical Times* in which he reports cases of delirium tremens in moderate consumers of alcohol, Pritchard concludes that the symptoms of delirium tremens, etc., are due in these cases to uremia coming from kidney disorders. His conclusions are stated as follows: 1. A renal disturbance is a constant accompaniment of uncomplicated delirium tremens. 2. The relation of time between the renal disturbance is an acute nephritis, which, as a rule, probably develops without any preceding chronic nephritis. 3. The course of the renal disturbance follows so closely, step by step, with the delirium that there is good ground for assuming that there is a genetic connection between the two phenomena. 4. There are so many similar points in the two states which are notoriously brought about by an insufficiency of the renal functions—uremia—and delirium tremens, that there is reason to assume that the delirium is an acute auto-intoxication psychosis as a consequence of the insufficient kidney function, which is due to the acute nephritis. 5. The peculiar form that this psychosis takes on is dependent upon its developing in chronic alcoholics. 6. There is a probability that delirium tremens in pneumonia is dependent not on the pneumotoxins directly, but on the always present renal lesion. He says finally that he has examined the urine of quite a number of beer and whisky drinkers, and finds that when in average health their kidneys are not quite normal, the urine being thin with a slight trace of albumin, a little renal epithelium and occasionally casts if they are a little under the normal. If they take cold the condition is aggravated. He doubts whether the cases in delirium tremens were normal before the attack and whether the real insufficiency actually developed on such virgin soil as assumed by Hertz, who has studied the subject, in *Hospitals Tidende*, (1898, Nos. 8, 9, and 10).

105. **Dyspepsia.**—McLeod's paper is largely a recommendation of caroid as the most valuable single agent we have for

the treatment of dyspepsia and since he has begun to use it, he has not been obliged to make elaborate examinations of the stomach-contents preliminary to treatment, reserving this for certain rare cases in which there are special reasons for knowing the exact chemical and other conditions existing in the stomach. Treatment by caroid without this procedure has been exceedingly satisfactory. Of course, the diet must be attended to as usual, especially the foods which produce troublesome symptoms. He seldom bars tea and coffee unless their use has been excessive. Excepting when special symptoms are particularly accentuated, these cases may be satisfactorily treated with a combination of caroid with charcoal and boric acid or sodium bicarbonate, which, in the form of tablets, is beneficial. If fermentation and excessive acidity are especially pronounced creosote in 3-gr. doses may be judiciously combined with caroid or thymol, or bismuth or larger doses of sodium bicarbonate according to individual needs. In atonic dyspepsia characterized by loss of appetite and in inability to digest foods, a combination of caroid with the usually employed bitter-tonics affords quick relief and in most cases permanent cure. He offers this paper not as a systematic study of dyspepsia but simply to emphasize the fact that this condition under ordinary rules can be satisfactorily treated without necessarily studying the exact chemical and pathological conditions existing in the stomach.

109.—This article has appeared elsewhere. See *THE JOURNAL*, October 27, 1900, p. 1115.

111. **Torticollis.**—Eight different etiologic varieties of torticollis are enumerated here by Wood: 1. Torticollis of infancy due to the shortening of the sternomastoid muscles. He considers this torticollis usually due to hematoma, while some cases may be due to muscle rupture without a tumor. Some of these cases disappear without contraction following. He advises general massage with passive motion, with care to prevent tension of the contracted side. He would not hesitate to use a retention collar at night in a stubborn case. 2. Contractured cases in children, where in addition to the sternomastoid, the deep muscles, the scaleni and posterior group, have not developed their full length. These cases are amenable to surgical, mechanical and calisthenic measures, and a cure depends upon a correct appreciation of the amount of attention to be bestowed on each plan of treatment. He thinks all three are required, and advises to confine surgical interference to the sternomastoid, the platysma and the underlying fascia. The deeper structures should be thoroughly stretched until they cease to exert a force to pull the head back, but this should be done very carefully and slowly to avoid danger. After the manipulation he has used a slightly over-corrected position kept up by a plaster-of-Paris cast. 3. Muscular torticollis due to cervical muscular rheumatism, and if treated by the salicylates, Turkish baths and massage, easily cured in a short time. 4. Glandular torticollis due to inflamed cervical glands, the head being kept in position to relieve this. There are usually signs of infection. 5. Osseous torticollis with spasmodic contraction of the posterior groups of muscles due to reflex irritation from vertebral caries. These are generally treated for some months on a frame cot in the recumbent position, with head-extension applied by weight. Only after pain has ceased should any collar, brace, mask, or chin-cup be applied. 6. Cases due to ocular defects brought on by change of position to assist accommodation. The cause, of course, must be corrected. 7. Cases due to occupation. They may come on suddenly. These cases can generally be improved and cured by rest in bed combined with sedative and later tonic medication. Lastly he mentions the severe spastic cases, the cause of which he is inclined to think is cortical though the evidence as yet is meager. The only reasonable procedure is the division of the posterior branches of the upper cervical nerve-ends in addition to the older procedure by Gardner and Keen. There is some evidence that section of the muscle alone, if sufficiently radical, may cure these cases, and it seems to be proved by experiments and indicated by partial operations that paralysis of the head will not follow even if both posterior groups and both sternomastoid muscles are removed. The risks of the operation are

relatively not great; there has been only one death and that was due to erysipelas. As to cure, the statistics are not sufficiently positive as regards the final results.

112. Tubercular Peritonitis.—Besides the discussion of tubercular peritonitis, McNaughton reports a very interesting observation of heredity. A child apparently healthy at birth became ill a few days later and died aged twenty-one days. Autopsy disclosed abundant tubercular deposits in the lungs, and numerous cavities.

131. Hay-Fever.—Referring first to an article by E. B. Gleason on the treatment of hay-fever with hydrobromic acid and nitro-muriatic acid, Bishop calls attention to the fact that, while in his earlier papers, he had pronounced the acid treatment as effective, he has repeatedly emphasized the greater value of the eliminative treatment. He quotes a paragraph from his work on "Diseases of the Ear, Nose and Throat" to this effect. It is desirable, he says, to have a uranalysis made in all cases of hay-fever to determine whether there is an excess of uric acid as compared to urica and whether a sufficient amount is being excreted or not. While he repeats all he has said for the value of acid treatment for temporary relief during the paroxysm, the most gratifying results have been obtained from the use of lithia. The effervescing tablets, 3 or 5 grains, should be taken every morning and night until from 15 to 25 grains a day is taken in divided doses. He cautions against too much indulgence of the appetite and over-feeding and emphasizes the importance of taking an abundance of pure water.

132. Common Diseases of the Throat and Pharynx.—The points in this paper to which Murray wishes specially to call attention are: 1. Teeth should receive attention from infancy, in order that caries may not invite forty-two different kinds of micro-organisms. 2. The mouth is the primary cause of many throat troubles, and ought to receive treatment simultaneously with the throat. 3. There is a quality of mildly offensive breath, which arises from micro-organisms present in the mouth, throat, naso- and oro-pharynx. 4. A bad taste in the mouth, particularly before meals, suggests infection of the tonsils, naso- and oro-pharynx. 5. Diseased tonsils, not necessarily enlarged and often hidden, no longer act as a barrier to disease, but rather as a germ incubator, and the diseased outer surface ought to be removed. 6. The term "rheumatic sore throat" should be used with less freedom. 7. The vicious habit of the mother tasting the child's food before giving it to the child should be preached against. 8. For the same reasons all instruments, drinking utensils, should be carefully cleansed before use. 9. Coating of the tongue, which is often local in origin, should be removed as systematically as the tartar from the teeth.

139. Care of the Nose.—Russell insists on the importance of proper care of the nose in catarrh to prevent chronic disorder. He thinks that salt water in the strength commonly used is irritating and dangerous and advises baking soda in 2 per cent. solution, 5i to a tumbler of warm water, as the best for this purpose. He gives, also, the formula of Dobell's solution as a valuable therapeutic agent and would substitute, if carbolic acid is objectionable, menthol, thymol and salicylate of soda 2 grains each to the pint. He says this treatment should be carried out night and morning in all cases of cold in the head and describes the method of douching the nose.

FOREIGN.

British Medical Journal, October 27.

Signs and Symptoms of Bubonic, Pneumonic, and Septicemic Plague. JAMES CANTLE.—The three types of plague, bubonic, pneumonic and septicemic are here described. The former compose about 70 per cent. of all the cases met with. The history is best considered under the headings of exposure, incubation, invasion, defervescence and convalescence.

Contact is the most potent agent in its spread. It appears that the disease spreads through abrasions, wounds of the skin, scratches, etc. Infection by the alimentary canal would seem feasible and is supported by the fact of the abundance of plague bacilli in the feces and that animals seem to contract the disease in that way. Infection by the breath is unlikely, but impact of the sputum in pneumonic cases is believed to have spread the infection. The rat is credited with the largest share of animal transmission and some consider the vermin of the animal as the real agent. The body parasites of man, such as fleas, lice, bugs and also flies and ants, may absorb the plague bacilli and possibly convey them by their bites. The average incubation is five days, but it is believed that it may have a shorter or a longer one, extending to even ten or fourteen days. The maximum and minimum periods are undetermined. There are no special symptoms peculiar to incubation; general discomfort is sometimes experienced, but is not characteristic. The onset of plague is generally sudden; a splitting headache, prostration, pains in the limbs and back, etc., may usher in the disease. There is nothing characteristic, however, beyond marked prostration and early appearance of cerebral disorder, until the glands become tender or buboes appear. Abrasions of the skin should be sought for especially in the lower extremities, if buboes appear in the groin. The fluid drawn from the gland or periglandular swelling is usually found to be of the sero-sanguinolent character but later becomes sero-purulent, and finally pus. The plague bacillus will be found in numbers, unless the buboes are of several days' standing, when none may be found. The lips become cracked early and the teeth covered with sordes. Nausea and vomiting frequently usher in the disease. Diarrhea may occur early, but it is seldom frequent or profuse. The liver may be tender and somewhat swollen. The urine is slightly albuminous as a rule. The pulse is frequent from the onset and throughout the illness, becoming later soft and dierotic and toward the end irregular and running. The lungs rarely show any change in bubonic plague, though they are attacked in the pneumonic form. Delirium is common and sleeplessness one of the most distressing symptoms. The rise of temperature is gradual up to 104 or 105 F. on the third or fourth day, falling at the end of that period sometimes below the normal. It may again increase but generally subsides after the opening and discharging of the buboes. In some cases, however, it may be high from the beginning. Apyrexia is not common in true bubonic plague, but in such conditions as *pestis ambulans* and fulminant plague it is the rule. The pneumonic form appears like septic pneumonia, it is discovered only by the presence of plague bacilli. The pulse is short and compressible from the first and there is much cardiac distress. Delirium, frequently followed by coma, prevails and the patient usually dies on the third or fourth day. In septicemic plague the patient seems struck down as if by active poison and the prostration from the first is extreme. There may be no buboes detectable during life, though a swelling is found in post-mortems. Hemorrhages are frequent. Apyrexia is not uncommon, delirium of the typhoid type is frequent. The disease usually ends in two or three days. The pathologic anatomy is described, the enlarged glands, congested viscera, heart and pericardial changes, hemorrhages in the peritoneum and bowels, congested kidneys, meningeal congestion. In the pneumonic type are to be found the engorged lungs with typical pneumonic consolidation.

The Bacteriology of Plague. DAVID C. REES.—Virchow, in 1879, reasoning from analogy, predicted that plague was microbial, but the discovery of the organism was made within a short period, and independently of each other by Yersin and Kitasato in 1894. The micro-organism resembles closely the chicken-cholera bacillus. It is a small bacillus measuring from one to two microns in length and from .3 to .5 micron in width, though larger forms are sometimes met with. Its ends are rounded, giving it an oval appearance and it is usually described as non-motile, though Kitasato has described it as actively motile in a temperature of 37 C. It is frequently seen arranged in pairs and in the broth-cultures seems to form streptococcus-like chains. Involution forms are

frequently met with; these occur generally under unfavorable circumstances. It does not form spores and has no true capsule. It is a facultative anaerobe. It stains readily with the ordinary anilin dyes, but is decolorized by Gram's method. In cover-glass preparations it stains more intensely at the ends, giving rise to a bipolar appearance. Laboratory cultures may exhibit this feature, but they do not always. It can be brought out best by overstaining with a strong carbol fuchsin for four or five minutes and then carefully decolorizing with absolute alcohol. The plague bacillus shows a great affinity for the thionin group of stains. It grows well in ordinary media and at a temperature of 25 to 30 C., so that in a hot climate an incubator may often be dispensed with. Haffkine's stalaetite growth is also noticed as characteristic. Apes and rodents are especially susceptible to inoculation, sheep, goats, cows and horses to a less degree, and dogs and cats very slightly. Birds and also swine are refractory to repeated inoculations. Rats or guinea-pigs usually show evidence of intoxication on the first day. There is no dispute as to the bacillus being the cause of the disease. It does not, as a rule, possess high powers of resistance outside its vertebrate hosts. It is readily killed by direct sunlight, disinfectants, or rapid drying at a high temperature; with slow drying it has more resistance. It is, therefore, more readily killed in a hot, dry than in a damp temperate climate. Pure cultures which are protected from light and drying may retain their vitality for months. It is extremely resistant to cold. Laboratory cultures soon lose their virulence, but may regain it by passing through susceptible animals. Inoculation is usually through the skin. The Australian commission states that it has succeeded in infecting a rat by rubbing a virulent culture into the intact skin. It is possible that in densely-crowded dwellings it may be contracted by aerial infection. It is not likely that it is usually contracted through the intestinal tract, though this may sometimes occur. The Australian commission is inclined to believe that infection takes place sometimes through the tonsils. With sporadic cases at the onset of an epidemic, the bacteriologic examination should be careful and systematic. During the epidemic, however, a provisional diagnosis can often be made by simple examination of the cover-glass preparations made from the glands, sputum or blood; it is good practice to examine the blood in all cases of plague. The bacilli are usually present in very small numbers in peripheral blood; Rees finds it best to make the preparations on slides for this reason. In mixed infections, endeavor should be made to isolate the bacillus from plate colonies or by the employment of Haffkine's salt medium. It may sometimes be necessary to make sections of organs and glands in suspected cases. The diluted blood-serum obtained from a case of plague is said to cause clumping with plague bacilli, but this has not been proved of practicable value, as it can be obtained only late in the disease, and then not always. Rees regards the bacillus as belonging to the septicemic group of pathogenic micro-organisms, that is, one that may be present in the blood and cause toxemia or death without local manifestations. It is parallel in some respects with the anthrax bacillus, though its action on the lymphatic glands is different. It does not itself produce pus, but can cause necrosis of tissue.

On the Methods of Making Antitoxic and Preventive Fluids. C. BALFOUR STEWART.—The method of making antitoxic and preventive fluids from plague are described by Stewart, who notices the serums of Haffkine, Yersin, Lustig and others. Haffkine's method is to take the broth in which the microbe was grown after sterilizing it. It is really not a serum, but a vaccin, and the misuse of the former term is to be regretted. A small definite quantity of plague poison is injected, which is easily dealt with by the body, and which can not increase, there is the same distinction as between a case of mild septic intoxication and a case of septicaemia. The antitoxic serum of Yersin is used as a curative agent for plague, and also acts as a prophylactic measure, but the immunity conferred is very short, only about fifteen days. The principle of this serum is the same as that of the antidiphtheritic serum and others. An animal, preferably a horse, is immunized by inoculation at intervals with dead or living cultures of the

specific microbes, and after the first or second inoculation the quantities are increased and the intervals between inoculation shortened. The animal, which takes the place of a human being who has been inoculated with a vaccin, acquires an active immunity, and if the serum of such an immunized horse be inoculated in considerable quantities into a human being suffering from the specific disease, the latter is ameliorated or cured. The serum may act in one of two ways; it may be bactericidal by killing the microbe in the body or preventing its growth, or it may be antitoxic. Roux says that antitoxic plague serum, however it is made, is always antitoxic, but that this property is more marked in some cases than in others. Those made by injecting living cultures are more antitoxic than those made by injecting dead cultures. This fact, according to Metchnikoff, explains the difference in the results obtained with the Yersin serum. Lustig's method of prepared vaccin is based on the observations that the nucleo-proteid which he separated from the bodies of plague microbes, is a substance which induces immunizing properties when injected; neither the metabolic products of growth nor toxins are used. The plague microbe is cultivated on an agar plate and the growth is scraped off and dissolved in a 1 per cent. sterilized solution of caustic potash. This solution is then rendered slightly acid with hydrochloric or acetic acid, and the resulting precipitate collected on filter paper; after washing it is dried in vacuo. It gives the chemical tests of a nucleo-proteid and is easily soluble in a weak solution of carbonate of soda. He proposes to use this solution as a prophylactic, but no report of its trial for this purpose has been made. The results of the curative serum were not at first very satisfactory, but lately better results seem to have been obtained. Neither Yersin's nor Lustig's serum appears to come up to what might be expected of a specific treatment, and the latter does not appear to be so efficacious as the former. This is possibly accounted for in a way similar to that of Metchnikoff's explanation of the difference in Yersin's sera referred to above. Haffkine's prophylactic is the greatest success as a scientific preparation.

The Lancet, October 27.

The Role Played by the Spleen in Pancreatic Digestion of Proteids. HENRY F. BELLAMY.—First noticing the experiments of Schiff, which seem to indicate that the splenic function is essential to the formation of trypsin in the pancreas, and the apparent contradiction to this from Heidenhain's discovery of the zymogens, together with the later investigations of Herzen, which confirm in a measure the ideas of Schiff and seem to indicate that the spleen furnishes the product of internal secretion causing in the pancreas the transformation of inert zymogens into active trypsin, Bellamy next proceeds to notice the criticisms of Lussana and others of Herzen's views, and especially those of Popelski, and points out their weakness. Extirpation of the spleen apparently produces in animals no serious disadvantage, but the actual loss according to Herzen's results is that there is almost complete cessation of proteid digestion by the pancreas, this function being in such cases almost entirely performed by the stomach. The question as to the destiny of the zymogen which the pancreas continues to elaborate, is answered by the suggestion that it becomes gradually transformed into trypsin by oxidation and other agencies along the intestinal tract. It has been noticed that the spleenless animals require more food, which can be explained not only by the loss of direct proteid substances in the alimentary tract, but also in that the parapeptones normally going on to the duodenum to be converted into true pancreatic juice are, owing to the breakdown of the pancreas, no longer capable of being absorbed and assimilated by the organism. The stomach and pancreas, therefore, so far as the digestion of proteids is concerned, would appear not only to be in direct harmony with each other in the intact organism, but also if from any cause one or the other is thrown out of action, its work is assumed and efficiently carried on by the survivor.

Bulletin Medical (Paris), October 20.

The Operation on the Xiphopagus.—The entire issue of the *Bulletin* is devoted to the description of Chapot-Prevost's famous operation, with numerous photographs and skiagrams.

(See cut in THE JOURNAL, xxxiii, p. 746.) The surviving twin is illustrated as a bright, pretty girl of 12, with nothing to betray her previous condition except a straight linear scar, 15½ cm. in length, on the front of the trunk. After the separation some time elapsed before she learned to balance herself without support. The hour-glass shape of the continuous liver is illustrated. The pericardium in each was connected by a fibrous band, as was also the pleura. The latter was inadvertently opened in one during the operation; possibly this was responsible for the fatal pleuropneumonia in her case. Separate anesthesia was required for each of the twins, but methylene blue injected in one was eliminated by both. During the operation Maria made an effort to vomit, which resulted in hernia of a large portion of the intestines in each through the wound. Replacing the intestines in the two abdomens was a perplexing task, much facilitated by the aid of an assistant who had taken his position under the table, and who was able, by raising from beneath the still unincised rear portion of the connecting band, to distinguish between and separate the intestines belonging to each. Chapot-Prevost never speaks of the case as twins, but always as "the monstrosity." The singleness of the monstrosity was decided by the majority of members of the profession who examined the case, and this conception legally justified intervention, which was besides urgently demanded by the parents.

Gazette Hebdomadaire (Paris), October 18.

Cure of Hemorrhages from a Dysenteric Ulcer by Injection of Gelatin. A. PUGNAT.—The hemorrhages occurred during defecation and had been noted for five years at intervals and daily during the last year. A tumor could be palpated in the cecum. After a subcutaneous injection of gelatin the hemorrhage recurred the following day as usual, but never appeared after this.

Presse Medicale (Paris), October 13 and 27.

Uremic Origin of Angina Pectoris. A. GILBERT.—Angina pectoris is caused by a neuralgia or a neuritis of the cardiac plexus, usually of toxic origin and, in case of arteriosclerosis, connected with the uremic intoxication. This conception entails an important therapeutic indication, i. e., that a patient with angina pectoris should have every cause of intoxication from food or drugs carefully eliminated. Among the arguments Gilbert advances in support of this theory are that obliteration of the arteries and ossification of the costal cartilages are unable to induce the syndrome of angina pectoris, while neuralgia or neuritis of the cardiac plexus satisfactorily explains all the symptoms. The prompt relief that follows local anesthesia of the precordial region with methyl chlorid is another argument. Coincidence of interstitial nephritis with the angina is the rule in severe cases. The curative action of a strict milk diet is also remarkable. The milk does not cure the angina any more than it cures uremic asthma, but it enables the patient to live comfortably with his renal lesion until some new indiscretion in eating or some other cause inaugurates the toxic symptoms once more, although they may appear this time as a nervous, respiratory or gastrointestinal disturbance. Drugs, especially morphin, soothe for a moment, but then hasten instead of retarding the attacks. The iodids alone seem to act favorably on the renal process and attenuate the toxins. When the toxic angina is transient, as when it is due to tobacco, tea, coffee, etc., the cure follows removal of the cause, but when caused by an irremediable lesion of the kidneys, the syndrome is liable to recur again and again. With an exclusive milk diet the life of the patient may be prolonged, while injudicious medication may prove rapidly fatal.

October 27.

Medullary Anesthesia. F. LEGUEU.—From experience with fifty-seven patients, Legueu concludes that this method is not destined to supplant general anesthesia, but that it is an excellent method of analgesia for brief, simple subumbilical operations, and for those on the perineum, lower urinary apparatus and legs if the muscular contraction—which is not suppressed by the cocain—does not prove a hindrance to operating. The dose should average 2 gm. The symptoms that followed the injection were all slight and transient. Vomiting

occurred in 13 cases after return to bed and in 11 during operation, but it was always slight and lasted less than five minutes. Cephalalgia was experienced 29 times, usually slight, but in 2 cases it was severe, and in another persisted for thirty-six hours in an extremely severe form. The temperature rose in 12 out of 55 cases. The pupils were dilated in the cases followed by vomiting and cephalalgia, and possibly this sign can be utilized to determine the tolerance. The anal sphincter became relaxed in 7 patients, with consequent incontinence. Paresis of the legs was noted in one patient for three days, but then vanished. In one case there was retention of urine for a week, in a young man operated on for a hydrocele. Incontinence of urine, persisting for three days, occurred in another. The patient is returned to his bed smiling and tranquil, free from the vomiting that follows chloroform. He can eat before and after the operation, and the best proof of the advantage of this method of analgesia is the eagerness with which it is demanded by other patients, witnesses of the first. Those who have previously had experience with chloroform are loudest in their praise of the new method.

Berliner Klinische Wochenschrift, October 22.

Trigger-Finger. TILMANN.—In the majority of cases of trigger-finger the phenomenon is due to a thickening of the flexor tendon, caused by repeated compression of the tendon against the volar side of the head of the bones of the palm by grasping a hard object by an unaccustomed hand. The thickened tendon is unable to pass the central sharp edge of the tendon sheath at the joint and waits until this edge is lowered, when, with a snap, it slips over it, and once past, acts normally. The thickening sometimes retrogresses when cause is removed. In fresh cases this may occur in four to six weeks, but in older cases three to six months are required, and in a very old case no improvement can be anticipated without an operation, which should consist in resection of the thickened center of the tendon, leaving the surface intact as much as possible.

Fracture of the Greater Tuberosity of the Humerus.—H. WOHLGEMUTH.—The greater tuberosity of the humerus is more frequently torn off in case of fracture or luxation of the upper portion of the arm than is generally appreciated. Failure to recognize and treat it, however, may entail serious functional disturbances. Suture is not necessary, merely the application of a bandage, with the arm raised and in abduction. A Middeldorf "triangle" is of great assistance in holding the supine forearm for the purpose.

Hemorrhagic Erosions of the Mucous Membrane of the Stomach. C. PARISER.—Hemorrhagic erosions of the mucous membrane are merely a complication of chronic gastritis in its early stages, or a special variety which may be called chronic, exfoliative gastritis. Pariser has found the best measure to relieve pain and cure the lesion to be lavages of silver nitrate applied after rinsing out the fasting stomach with half a liter of tepid water, twice in succession, carefully measuring the siphoned fluid to ensure that all has been removed, then introducing half a liter of .5 to 1 per 1000 solution of silver nitrate, allowed to remain one minute in the stomach and then removed, repeating this lavage twice. The stomach is then rinsed with a liter of tepid salt solution in two portions. This treatment is repeated every other day and continued for ten to twelve days after all scraps of mucosa have disappeared from the stomach contents. The diet is equally important in treatment. The measures applicable to an ulcer sometimes succeed when the silver nitrate fails, or may be allowed when lavage is refused by the patient.

Centralblatt f. Inn. Medicin (Leipzig), October 20.

Pathology of Alcohol. G. ROSENFIELD.—Twenty dogs were given alcohol on an empty stomach in doses from 12 to 27 c.c., continued for a long time. In every case in which more than four doses had been administered the liver was found in fatty degeneration, the fat constituting 17 to 36 per cent. of the organ. In a parallel series of tests, 60 gm. of sugar were administered with 35 to 30 c.c. of alcohol and there was no fatty degeneration nor other symptoms of intoxication. The fat in the liver was even less than normal in this case.

Mitteilungen a. d. Grenzgebieten (Jena), vii, 1.

Traumatic Stricture of the Intestines. H. SCHLOFFER.—Nine cases of traumatic stricture are known to date and Schloffer adds a tenth. Five patients died. In order to determine the mechanism of stricture, he experimented with sixty-three dogs and several swine. He finds that contusion injuries of the intestines in dogs, that did not entail the death of the animal, terminated always in complete *restitutio ad integrum*, but in pigs an annular stricture could be produced. The conclusions are that traumatic stricture may occur in consequence of incipient invagination, the rigidity of the muscular wall having been compromised by the trauma. Annular strictures are probably favored by injury of the submucosa and of the mesentery, with resulting disturbance in the circulation, and necrosis. Partial or complete laceration may also entail a stricture as it heals with adhesions. One case is recorded in which a traumatic stricture was consecutive to an invagination which healed spontaneously with expulsion of the invaginated portion per anum. Traumatic adhesions between loops of intestines may produce stenosis sooner or later, with symptoms appearing suddenly.

Therapeutische Monatsheft (Berlin), October.

Diet in Typhoid Fever. H. EICHHORST.—There have been only 64 relapses out of the 1154 cases of typhoid fever treated at the Zurich clinic. Eichhorst attributes this success to his use of milk; 50 to 100 c.c. are given every half hour during the febrile period, the milk boiled and cooled and administered alone or in milk-soup, coffee or tea; no alcohol is given except in case of great prostration, and then always warm. This strict milk diet is continued for three days after the fever has disappeared, commencing with meat the seventh day. At the slightest indication of recurrence of fever the exclusive milk diet is resumed. He gives a tepid bath twice a day during the febrile period and then once a day. The last week before dismissal a gram of salol is administered three times a day.

Therapie der Gegenwart (Berlin), October.

Extrabuccal Feeding. C. A. EWALD.—The mixture preferred by Ewald for rectal feeding is made by stirring two tablespoonfuls or 40 gm. of flour in 150 c.c. tepid water, adding one or two eggs and about 3 gm. of salt and 50 to 100 c.c. of a 15 to 20 per cent. solution of grape sugar and possibly a glass of red wine. This represents about 450 calories, but not all of it is utilized. Subcutaneous injections of oil are painful and fail to supply the moisture needed by the system. In feeding through a gastric fistula, the opening should be made as close to the pylorus as possible in case of a malignant neoplasm, and predigested food preferred. But in case of a benign cicatricial stenosis the digestive function is not materially disturbed and these precautions are unnecessary.

Influence of Oophorin on the Transformation of Albumin. L. THUMM.—The experiences and research described in this communication demonstrate that larger doses of oophorin can be administered with impunity than hitherto have been considered advisable. The albumin metabolism was at its highest point during the administration of oophorin in the tests and it is asserted that it does not produce the slightest destruction of the nitrogenized elements of the tissues.

Janus (Amsterdam), October 15.

Heat-Melancholia. A. DAVIDSON.—Among other varieties of heat-diseases Davidson thinks that we are entitled to include a heat-melancholia which often leads to suicide. This form appears to be peculiar to temperate climates and is most common when a high temperature suddenly sets in. It is doubtful if sunstroke in tropical countries is more destructive to life than this heat-melancholia. There were sixty suicides in London during the two weeks of unusually high temperature last June succeeding a cold May.

Gazzetta Degli Ospedali (Milan), October 21.

Present Status of Our Knowledge of Tuberculosis. E. MARAGLIANO.—This recapitulation of what is known in regard to the etiology, pathogenesis and cure of tuberculosis, states

that the variations in the gravity of tuberculous infection are in direct proportion to the number and amount of the means of defense possessed by the organism, as can be demonstrated by investigation of the blood; also that to combat and neutralize the infection it is as necessary to annihilate or neutralize the toxins which result from the vital action of the tubercle bacilli as it is to destroy the latter. He concludes with the statements that tuberculosis can be cured, but phthisis never. Physicians must not wait for physical symptoms and bacilli in the sputa. The process is then too far advanced. The diagnosis should be based on the tuberculin test, on the demonstration of tuberculous toxins in the urine and in the blood, on the agglutinating power of the serum, and on the demonstration of the typical disturbances in the metabolism of nitrogen. In respect to the physical signs, it should be borne in mind that any anomaly detected at, and restricted to, the apices is an indication of pulmonary tuberculosis.

Revista de Medicina Tropical (Havana), September.

Gangrene Consecutive to Yellow Fever. E. MARTINEZ.—One case of gangrene of the scrotum consecutive to yellow fever is entered in the records of the Havana Hospital Mercedes, and one of the leg, terminating in recovery, has occurred in Bango's long experience there. With these exceptions, Martinez can find no record for many years of gangrene after yellow fever. In 1896 he attended a young woman with the disease. The tenth day a patch of gangrene appeared on the thigh, which rapidly spread until the entire limb was involved and death ensued the twelfth day. The symptoms indicated thrombosis of a branch of the femoral artery, later involving the main trunk. The older writers—Rush, Moultrie, Devèze and Lefort—mention a few cases of this complication. Martinez suggests that the custom of blood-letting, so common in those days, may have contributed to the greater frequency of embolism and gangrene in earlier practice.

Vratch (St. Petersburg), September 28.

Remarkable Success in the Treatment of Eclampsia. V. V. STROGANOFF.—Out of ninety-two cases of eclampsia which Stroganoff has had occasion to treat during the last three years, only five patients have died, and two of these were moribund when received. The third died from sepsis twenty-seven days after termination of the eclampsia, the fourth from pneumonia and the fifth from atonic hemorrhage four days after the eclampsia was over, the delivery being complicated in this case by a ventrofixation done four years previously. Seventy-nine out of the ninety-eight infants were saved. He considers eclampsia a self-limited, infectious disease, the contagion air-borne, but so slightly virulent that no one except a woman in the puerperium is affected by it. His views have already been mentioned in THE JOURNAL, xxiv, pp. 735 and 1257. He treats it with a combination of morphin and chloral, the former for its influence on the sensory centers and the latter to control the convulsions. By this means he arrests the attacks in twenty-four to forty-eight hours: the urine increases in quantity and the secretion of mucus diminishes. He has evolved the following system, which he urgently advocates: First, a subcutaneous injection of .015 gm. morphin hydrochlorate during the first attack, or when first seen, repeated in one hour. The third hour a rectal injection of 2 or 3 gm. of chloral hydrate is administered and repeated the seventh hour. The thirteenth hour a similar rectal injection of 1.5 to 2.5 gm. chloral is given and repeated the twenty-first hour. The twenty-ninth hour another rectal injection of 1 to 2 gm. of chloral is administered and repeated the thirty-seventh and forty-fifth hours. If the comatose condition still continues, with headache, especially if delivery is not terminated, the patient is still kept narcotized with small doses, .015 to .03 gm. of morphin and 4 gm. chloral for the following twenty-four hours. Systematically proceeding in this manner, the recurrence of the attacks is prevented and delivery occurs normally or can be hastened without danger to mother or child. His tabulated statistics show that the number of attacks in all his cases averaged only 2.4 to 3.3 per patient, while in other institutions they ranged from 6.9 to 9.5 during the same periods. He lays great stress on the importance of relief

ing the heart and lungs of every source of irritation, mechanical, physical or mental. The heart-action becomes very much depressed during an attack. Continuous reclining on the left side should not be allowed, nor even the pressure of the hand or arm on the heart or lung region. The clothing, blankets, nor pillows should not be allowed to bind or weigh on the thorax in any way to impede the action of the heart or lungs. The mouth and nose must be kept free from obstruction from mucus. Fluids should be supplied by subcutaneous injection of 150 to 200 c.c. of salt solution or rectal injection of a liter in four or six parts during the day. Warm milk can be substituted for the salt solution in case of protracted eclampsia. Digitalis, inhalation of oxygen and other measures as indicated will also be found beneficial. The patient should be turned from the right to the left side and back again every hour or hour and a half, and other measures should be applied to loosen and favor the expulsion of mucus. If the lung symptoms become alarming and edema is threatened, great benefit can be derived from dry cupping. These minor points are all of great importance, but the chief aim in treatment is the suppression of the convulsions which can surely be accomplished by the system of administering morphin and chloral outlined above.

New Patents.

Patents of interest to physicians, Oct. 16 to 20:

660,042. Powder insufflator. Wm. F. Barry, Woonsocket, R. I.
659,640. Disinfecting composition. Henry S. Blackmore, Mount Vernon, N. Y.
659,642. Clinical thermometer case. Albert F. Blagdon-Richards, Swansea, England.
659,846. Truss. Decatur D. Dennis, Chicago.
660,014. Ice bag. Daniel Hogan, New York City.
659,574. Massage apparatus. Benjamin F. Hutches, Jr., Chicago.
659,978. Antiseptic broom. Oscar S. Kulman, Savannah, Ga.
659,820. Making persulfate of sodium. Auguste and L. Lumiere, Lyons, France.
659,685. Truss. Wm. S. Miller, Maryville, Mo.
659,755. Invalid-bedstead. Austin Moulton, Montpelier, Vt.
65,842. Design, pessary. Richard H. Vesey, Denver, Colo.
660,568. Hermal truss. James D. Day, London, England.
660,212. Syringe. Emanuel E. Ertsmann, Chicago.
660,388. Catamenial appliance. Charles A. Moberg and J. E. Brady, Portland, Me.
660,233. Apparatus for treating diseases of the ear. Robert Watson, Washington, D. C.
33,447. Design, surgical stocking. Charles J. Sadler, St. Louis, Mo.
660,885. Ankle-brace. Arthur J. and R. T. Brauer, St. Louis, Mo.
660,895. Truss. Joseph Pandey, Los Angeles, Cal.
660,859. Making soluble compounds of quinin and caffeine. Aisik Kraidmann, Altona, Germany.
660,994. Sterilizing-case, James G. Mastin, Chicago.
660,781. Pessary. Horace M. Paine, Newton, Mass.
660,972. Diagnosing belt. Fortune R. Ryan, Memphis, Tenn.
660,739. Saife-box. Augustus C. Taylor, Washington, D. C.
660,874. Bandage. George Voellner, Elizabeth, N. J.
33,456. Design, catheter. Wm. W. Harris, New York City.

Change of Address.

L. Anderson, Biloxi, to Port Gibson, Miss.
Earl V. Adams, Topeka, to Birmingham, Kan.
L. E. Blattner, 1219 Washington Ave., to 418 S. Jefferson St., St. Louis, Mo.
G. S. Heardsley, Washington, D. C., to The Holmhurst, Atlantic City, N. J.
R. H. Born, Washington, D. C., to Montoursville, Pa.
F. A. Butterfield, Chicago, Ill., to Lawrence, Mich.
E. Birney, Greene, to Nora Springs, Ia.
S. J. Coyne, Aberdeen, S. D., to Dayton, Minn.
F. R. Dwyer, 358 Lincoln Ave., to 3035 Michigan Ave., Chicago.
J. C. Dodds, Tolono, to Champaign, Ill.

F. J. Shook, 291 Ogden Ave., Chicago, to 9 Calwell Bldg., Ottawa, Ill.
H. J. Tillotson, 5039 Grand Boul., to 84 Dearborn St., Chicago.
J. S. Wallingford, Newport, to Paris, Ky.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the navy for the week ending Nov. 3, 1900:

Surgeon A. M. D. McCormick, commissioned surgeon from Nov. 11, 1899.
Asst.-Surgeon R. E. Ledbetter, ordered to the *Constellation*.
Surgeon C. Biddle, detached from the *Texas*, when put out of commission, and ordered home to wait orders.
Medical Director C. M. White, detached from the naval museum of hygiene, Washington, on reporting of relief and ordered home to wait orders.
Medical Inspector G. P. Bradley, ordered to duty in charge of the naval museum of hygiene, Washington, Nov. 15.
Surgeon H. E. Ames, detached from the *Kearsarge* and ordered to the *Massachusetts*.

Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital service for the seven days ended Nov. 1, 1900:

Asst.-Surgeon J. A. Nydegger, relieved from duty in the Philippine Islands, and directed to return to the United States at once.
Asst.-Surgeon L. E. Cofer, relieved from temporary duty at Philadelphia, and directed to proceed to Washington, D. C., for examination for promotion.
Asst.-Surgeon G. M. Corput, to proceed to Cairo, Ill., and assume temporary charge during absence of medical officer.
Asst.-Surgeon W. W. King, to proceed to San Juan, P. R., on special temporary duty.
Asst.-Surgeon J. M. Holt, granted leave of absence for seven days.
Asst.-Surgeon J. S. Rogges, relieved from duty at Chicago, and directed to proceed to Philadelphia, Pa., and report to medical officer in command for duty.
A. A. Surgeon B. W. Goldsborough, granted leave of absence for four days.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 2, 1900:

SMALLPOX—UNITED STATES.

Colorado: Arapahoe County, Oct. 10-13, 2 cases; Costilla County, Oct. 15, 1 case; Ouray County, Oct. 9-16, 10 cases; Wild County, Sept. 1-30, 2 cases.
Indiana: Indianapolis, Oct. 20, 1 case.
Kentucky: Lexington, Oct. 27, 2 cases.
Michigan: Detroit, Oct. 20-27, 1 case; Delta County, Oct. 14-20, 1 case; Maple River Township, Oct. 14-20, 21 cases.
New Hampshire: Manchester, Oct. 27, 1 case.
Ohio: Cleveland, Oct. 20-27, 27 cases.
Utah: Salt Lake City, Oct. 20-27, 9 cases.

SMALLPOX—FOREIGN.

Austria: Trieste, Oct. 6-13, 1 case.
Bohemia: Prague, Oct. 6-13, 5 cases.
England: Liverpool, Oct. 6-13, 3 cases; London, Oct. 6-13, 1 case.
France: Paris, Oct. 6-13, 6 deaths.
Germany: Solingen, Oct. 1-7, 1 case.
India: Karachi, Sept. 23-30, 1 case.
Mexico: Mexico, Oct. 7-14, 2 cases, 1 death.
Russia: Moscow, Sept. 29-Oct. 6, 3 cases; Odessa, Oct. 6-13, 17 cases, 1 death; St. Petersburg, Sept. 23-Oct. 13, 18 cases, 4 deaths; Warsaw, Sept. 29-Oct. 6, 13 deaths.

YELLOW FEVER.

Cuba: Havana, Oct. 1-27, 274 cases, 67 deaths.
Mexico: Oct. 7-21, 4 cases, 2 deaths.

CHOLERA.

India: Bombay, Sept. 26-Oct. 2, 54 deaths; Karachi, Sept. 17-23, 4 cases, 3 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 14, 1 death.

PLAGUE—FOREIGN AND INSULAR.

China: Hongkong, Sept. 1-8, 4 cases, 4 deaths.
India: Bombay, Sept. 26-Oct. 2, 86 deaths.
Japan: Osaka, Sept. 11-29, 26 cases.
Madagascar: Tamatave, Oct. 16, reported present.
Philippine Islands: Manila, Sept. 7-15, 1 case.
Scotland: Glasgow, Oct. 13-19, 14 cases, 1 death.
West Australia: Perth, April 7-Aug. 11, 6 cases, 3 deaths.

APPENDICITIS.*

JOSEPH PRICE, M.D.

PHILADELPHIA.

For a number of years my experience differed from that of many operators in the fact that the trouble occurred 16 in the male to 1 in the female. An operation on a female, young or old, was uncommon; in boys and young men, very common. In the work of Hunter McGuire the proportion was precisely the same.

In the last three years my experience has wonderfully changed—the proportion now is about the same.

Coincident with increasing numbers of young females, I had a group of old women—some five or six, 60 to 72 years old—with severe attacks of appendicitis, most of them gangrenous.

In young women and children it has occurred in working girls and in young women fond of field sports. This has also been so in young men, about all of them have followed trades or some professional sport. It is simply surprising the great number of athletes—ball players and professional swimmers—requiring the removal of the appendix.

Young surgeons seem more prone to the disease than any other class of medical men. Three-fourths of the surgical staff of one of the prominent hospitals in our city have had their appendices removed.

The disease has been very common in Pennsylvania throughout the last grip epidemic, and has also been more common in females than ever before in my experience. In some villages and towns it has occurred in two and three female members of the same family. In the practice of a prominent western New York physician he saw three girls, aged 13, on the same day, and from all he promptly removed the gangrenous appendix; one of the three was his granddaughter.

I am satisfied the error of treating appendicitis for typhoid fever is more common in the female than in the male; the pain and tenderness is at a lower level in the female than in the male. The suppurations in the male are higher and quite commonly extend to the kidney—in a good number of cases recently in my own experience I found large quantities of pus and filth from the head of the cecum to the kidney, disorganization of the ascending colon with perforation or multiple perforations. Some few of these cases have occurred in the post-puerperal period, in a few during gestation. The pelvic complications in the female are sufficiently common in suppurative forms of tubal and ovarian disease to influence us in the adoption of the suprapubic route in all cases. In about

9 per cent. the appendix and the head of the cecum are involved, and require removal with the diseased tube and ovary.

You all remember, while students, how common psoas abscesses were in clinics and in the hospital wards; such cases at present are scarcely ever found in the hospitals. I have questioned large numbers of hospital residents and ex-residents as to whether they had had any of those cases during their term of service, and they have all answered, "None."

Perinephritic abscesses quite commonly have their origin in appendicitis. None of the cases in females have been mild and the original attacks have been severe, and but few of the patients have waited for subsidence or recurrence. In all that have waited for subsidence, the recurring attacks have resulted in sloughing, perforations, extensive adhesions and large abscesses.

Fortunately for patients, the general practitioner has not as much confidence in therapeutics and delay as he had a few years ago. It seems impossible to educate the profession up to the importance of prompt, early interference. Occasionally, we see a patient the seventh, eighth, or tenth day of his illness, distended and vomiting, and the consultants holding out for another day for the trial of croton-oil. Localities seem to have something of a causal nature in them. The disease is very common in Norristown, Pa.; also in West Chester, and in a broad district between there and Philadelphia, in both children and young people.

The diagnosis in girls or females is more difficult or doubtful than in males. The mortality is also higher; this, I am satisfied, is due to the delay and the delay to a doubtful diagnosis. The mortality in little children is also increased by the delay and dread the laity and profession have to operate on children.

The results from early operative interference are always favorable. If we made it a practice to operate when the trouble is first recognized, without the delay of a day or more for consultations and for therapeutical treatment, the deaths would be very few. The fashionable and popular practitioner in small cities and towns is commonly a so-called very conservative man and claims that about all these cases can be cured by remedies, and gives us the ugly abscess class of cases and the virulent, perforative cases at the eleventh hour.

A great number of teachers are undecided as to when and how these cases should be treated. But few have decided there is only one treatment and that it can not be applied too early—the diagnosis being made.

Deaths are numerous all about us in good subjects that could and ought to be saved. Surgical interference, early, and never late, would save them all.

Recently a good and safe operator saw four patients two or three hours before dissolution—recognizing that they would die in a few hours without adding a feather to depress the beam.

Nothing can be sadder in our experience than the

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

last hours of many patients dying of appendicitis, the result of an error or a late diagnosis and prolonged medication, with the final suggestion that surgery is all that will avail.

DISCUSSION.

DR. WILLIAM R. PRYOR, New York City—The remarks I have to make bear on the relation of adnexal disease on the right side, to appendicitis. I have performed 173 vaginal hysterectomies for pelvic inflammatory lesions, and in only one case have I seen the appendix slough off, the patient being saved by operation thirty-six hours after vaginal hysterectomy. So much for the influence of removal of the diseased adnexa on the vitality of the appendix which may be adherent to it. In only two other cases have I had to do a laparotomy for the removal of an inflamed appendix some time after I had performed a vaginal hysterectomy. So much for the relation between chronic appendicitis and removal of inflamed adnexa through the vagina. These observations are somewhat important because it has gone out from a great many sources that if we find the appendix adherent to the diseased adnexa we may know that appendicitis exists. What I have seen convinces me that such is not the case, but that the perfectly normal appendix may become united to the diseased adnexa just as the intestines, etc., may be. Dr. Price is entirely right; the new athletic craze among young girls is responsible for the increase in appendicitis in them. Many of my cases were in golfers. The exercise is exceedingly violent and is generally sharply taken up by a girl who has never had much exercise before.

DR. G. T. HARRISON, New York City—I am on record as having operated on the youngest person for appendicitis. I operated the other night at the New York Infant's Asylum on a baby 17 days old. I found the intestines tied down in the neighborhood of the appendix and there was some suppuration. I do not believe that it was a case of appendicitis at all. It probably was an infection through the umbilical cord, which may be the cause of a good many of our cases of appendicitis in infancy.

DR. F. WARNER, Columbus—I would like to ask Dr. Price a question, one which is prompted not only by the title of the paper, but by a case which presented itself to me recently. The young lady had pains for twenty-four hours, and along with this pain there was rigidity of the muscles, vomiting, colic and tenderness over the region of the appendix. I operated and found a perforated appendix, together with much pus. In another case I operated on the second day, found no pus, but a decidedly inflamed appendix. The question at once presents itself: "When should we operate." Having seen a number of cases in my own practice as well as in that of others, I have been forced to the conclusion, irrespective of the opinion of many men, that if we are going to operate for appendicitis we must do it early. There are no reliable symptoms which will enable you to judge when it is safe to let a case run on for a while. I want to ask Dr. Price how are you going to know that there is a sloughing appendix or one undergoing gangrene. Oftentimes the symptoms will subside and suddenly a peritonitis sets in, due to the condition of the appendix. I believe that we will get much better results if we do our operations early rather than to temporize, hoping to get along without an operation. When people do not agree to an operation it is another matter, but when they do I am in favor of an immediate operation.

DR. EDWIN RICKETTS, Cincinnati—I saw a patient recently who had an attack of appendicitis five weeks before I saw her. I was called in great haste, and when I reached the house she was gasping; her lips and finger-nails were blue. She had been blistered over the region of the appendix. Finding dullness at the base of the right lung, I plunged in an aspirator, and drew out nearly a pint of fluid. The abdomen was hard and firm, and after a few days we opened it over the appendix, and took out two quarts of pus, showing that the pus in the pleura had perforated from the abdomen. This patient eventually recovered, but I had a difficult case on my hands. I have a record of 8 deaths out of 88 cases. The earliest possible diagnosis followed by the earliest possible operation, is the only thing to do.

DR. I. S. STONE, Washington, D. C.—The symptoms of appendicitis in young people are not often directed to McBurney's point. I remember one case very distinctly where there was no pain in the region of the appendix. I saw two cases where the pain was in the epigastrium, due to intestinal distension probably. In another case the symptoms were all on the left side, and I found the appendix nearly in the center of the abdomen. In regard to what Dr. Pryor said, a vaginal operation would surely have resulted in the death of the patient. The appendix was found torn off when I took out the pus sac. In late years I have made it a habit to look at every appendix before I close an abdomen. The last hysterectomy death I had was from a long adherent appendix.

DR. A. H. CORDIER, Kansas City—There is a remarkable mortality in cases occurring in young children, which I think is due to this reason. The great majority of cases of appendicitis in young girls are of a variety known as appendicitis gangrenosa, in which the symptoms come on very suddenly and on operating fifteen hours afterward the appendix is gangrenous. I think that in these young girls the ovarian artery has not developed fully and the blood-supply is deficient. Later in life the appendiculo-ovarian artery becomes better developed and we have fewer cases of appendicitis. In nine cases out of ten the first symptom these cases will present is a pain in the epigastrium, in the region of the solar plexus, which is due to the irritation of the sympathetic fibers. While the pain is located over the solar plexus the tenderness in the great majority of these cases is in the region of the appendix. The appendix early in life is not at McBurney's point. The cecum is high up in the abdomen and does not descend until later, hence we expect to find the appendix high up in the abdomen early in life. The least blocking of the single little vessel running up into the appendix cuts off the blood-supply and causes the death of the appendix and that variety of disease so fatal in early childhood.

DR. F. F. LAWRENCE, Columbus—I wish to emphasize the necessity of prompt and positive interference. I was called to see a young man who had been ill fifty hours. His bowels had moved and he was apparently all right. I was not inclined to operate, but stated to the father of the boy that it was only a matter of time as to whether we operated then or in interval. The father agreed to have the operation performed at once. I removed the appendix, which was so foul that two physicians who were in the room became sick and had to go out. Another case in which every danger seemed to be past, I operated on because the patient lived a distance from surgical relief. The appendix was removed, and in handling it to a by-stander it dropped into a basin of water and immediately ruptured. I do not believe that any human being is safe after having had an attack of appendicitis unless that appendix is removed.

DR. ROBERT MORRIS, New York City—I did not hear all of the paper, but there is one point connected with the question of appendicitis being dependent on athletic exercises which I wish to discuss. Place a patient on his back, then ask him to flex the leg so as to contract the psoas muscle, it will be readily seen that it rises in a hard firm ridge, hard enough to produce a traumatism if applied suddenly to any vulnerable appendix. A bicyclist riding a wheel up a hill contracts the psoas muscle so firmly and in such a hard ridge that the appendix is rolled over the edge of the hard psoas muscle with every stroke of the leg. This may no doubt be continued many times without producing any injury, but there is a definite cause for traumatism readily discoverable and one which I am sure causes a break in the mucosa of the appendix, and an infection atrium that produces the disease. A number of my cases have given the history of violent exercise, which included the firm constant contraction of the right psoas muscle. The young women of to-day are engaging in athletic exercises more than in years gone by, and this fact is certainly worthy of consideration. We can easily palpate the psoas muscle and satisfy ourselves that the appendix must be injured by it, producing a break in the mucosa and you have the best kind of an infection atrium.

DR. JOSEPH PRICE, closing the discussion—I am very thankful to you for your kind discussion. It has been a more scien-

tific one than we are accustomed to have on this subject. Deaths from appendicitis are much more common than they have been in the past. Even medical men seem to be especially afflicted with it. All through the country people are dying from appendicitis. A young lady, who had gone to Virginia Beach for the benefit of her health, developed appendicitis, and her physician recognizing it, gave her a note to me. I examined her carefully and told her to have her appendix out. She wanted to see her mother in New York first, and while there Dr. Boldt operated, and she made a beautiful recovery.

Tubercular appendicitis is common. About 2 per cent. is my own experience. You will find that where you have a tubercular appendix you have a localized patch of tubercular bowel, which you may have to remove. I find that a tubercular peritoneum is very much like a fine baby, the rougher you are with him the better he enjoys it, and the better he thrives. Separate the bowels, split the mesentery on both sides, expose it to the air, look at the right side, then at the left of the mesentery. The dry treatment is the most successful. If you can free all the adhesions without injury to the bowel they all get well. Injuries to the bowel rarely heal and the cases end fatally.

Dr. Pryor gives us a series of 173 operations and recoveries for diseased viscera, in which it was necessary to remove the appendix two or three days later. I found the appendix involved and primarily affected in 69 per cent. of cases of disease of the pelvic viscera. I remove the appendix at the time of operation because there is very little additional inconvenience to the patient. Some years ago, I removed the appendix of a nursing infant. It was a midnight operation, and the resulting peritonitis was general and fatal.

A man was admitted recently to some hospital for a stab wound. He also had appendicitis. The surgeon on opening the abdomen found the appendix perforated and removed it. I allude to this to show you how common it is. Some few surgeons, and I am satisfied the few I allude to ought to play with their grandchildren, always stand on two stools. On opening the abdomen before his class he will always say "gentlemen, this is a case of no appendix"; when he can not find it.

When to operate depends wholly on the diagnosis. I think it should be, and it can be made early. The methods of operating are too numerous. A simple, rapid and safe procedure is that of cutting the appendix from the head of the cecum as you would a rotten apple. You can simply cut it out after introducing three or four ligatures and then close up the wound. Transfixion or circular ligation, the canterly and carbolic acid are unsurgical. I have noticed that it is very easy indeed to recognize the condition after anesthesia; much better than before. If you are in doubt about the operation etherize the patient and inform the family that additional efforts of the therapeutic sort are wrong and dangerous. I would rather operate 99 doubtful cases than to lose one that should be saved. None of your appendicitis cases should die.

POST-OPERATIVE TREATMENT OF ABDOMINAL SECTION IN WOMEN.*

WALTER B. CHASE, M.D.

Consulting Gynecologist and Obstetrician, Long Island Medical College Hospital; Consulting Gynecologist to the Nassau Hospital, Hempstead; Attending Surgeon and Gynecologist, Central Hospital and Polyclinic; Attending Gynecologist, Bushwick Hospital.
NEW YORK CITY.

The closing of the abdominal incision is worthy of careful consideration, first as to the material, second as to the method of its use. As to material, choice may be had between silkworm-gut, silk and silver wire, for through-and-through suturing, any of which fulfill the needful requirement of a good suture. They should be introduced from within outward, thereby lessening

in some degree the liability of infection and resulting stitch-hole abscesses.

If layer suturing is followed, catgut or kangaroo tendon should be employed. The cost of the latter practically excludes its use in general practice, but as to its tensile strength and slow absorption there can be no question.

Now that we have improved methods in the preparation of catgut from the standpoint of sterility, chromicized catgut for such use is practically an ideal suture. If this method is adopted its introduction should be dexterous and rapid, as the element of time is too important to be disregarded. Nicety of coaptation should mark every step in the procedure, and special care should be exercised that this apply in particular to two structures, the peritoneum and the transversalis fascia, as the latter gives most important support to the abdominal wall.

If through-and-through interrupted sutures are employed, they should be sufficiently near to carefully approximate the structures. Too often they are tied too tightly. This undue constriction of tissue tends to ulceration and cutting through of the suture. Even though layer suturing is followed, it is better to give it support by silkworm-gut sutures at intervals of three-quarters of an inch running down to the peritoneum.

Buried unabsorbable sutures ought never to be employed, first for the reason they are not required, and second they are foreign bodies, and as such contrary to good surgery from every standpoint. The line of incision can be dusted with iodoform or boric-acid gauze applied and secured in position by strips of adhesive plaster placed transversely. Unless the dressing is moistened by exudation it should remain a week or ten days. The stitches can well be left for ten to twenty days. In the through-and-through suturing case I usually remove the alternate sutures first, allowing the others to remain a few days longer for support.

Position.—Unless for reason I fear hemorrhage or undue traction on sutured intraperitoneal structures, I give my patients as much latitude of position (after abdominal section) as is conducive to their comfort. The rigid rules which many operators enforce, that the patient must remain on the back for days, and even keep the legs extended, is not only unnecessary, but harmful. Especially does change of position facilitate peristalsis and help relieve flatulence.

Treatment of Shock.—It is well just before the close of an abdominal section to give a high enema of a pint of hot normal-salt solution, containing an ounce of whisky, if evidences of shock are present. Should this be inadequate, intravenous or interstitial injections of warm (105 F.) salt solution may be administered with positive advantage, associated or followed by strychnin, spartein, caffeine, nitroglycerin or atropin, according to the indications. Care should be exercised to maintain the bodily temperature by application of dry heat to the cutaneous surface, which is often diminished from wetting the patient during the operation, and by lowering the head and trunk sufficiently that the arterial current to the brain be aided by gravity.

Treatment of Hemorrhage.—Hemorrhage after laparotomy is a most unfortunate and perplexing occurrence. The differential diagnosis between the symptoms from hemorrhage and shock are of the highest importance, but time will not permit a discussion of the points of difference to any length. Shock and hemorrhage are both attended with rapid pulse. In hemorrhage the

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

face is blanched. It may be to a less extent in shock. The symptoms of hemorrhage are usually sudden in their appearance, and progressive in their development, while the tendency in shock is likely to be toward improvement. Hemorrhage is usually attended with restlessness, while absence of this symptom is usual in shock. The efficiency of filling the blood-vessels with saline solution in the relief of hemorrhage covers one of the most brilliant chapters in conservative surgical procedure. While the adage remains true "that blood is thicker than water," the fact remains that water is better than no blood. Doubtless the depletion of the circulation is responsible for the intensity of thirst following laparotomy; at all events the leaving of a pint or quart of hot salt solution in the peritoneal cavity at the time of closing the abdomen diminishes this distressing symptom, and unless reason exists for leaving the peritoneal cavity dry it is good practice. Occasionally hemorrhage ceases spontaneously and nature seals the leak, but if serious, and the state of the patient threatening, no waiting is permissible. Nothing remains but to secure the bleeding vessel. Occasionally if space has been left for abdominal drainage the removal of the gauze may reveal the source of the bleeding, and the vessels may be secured either by ligature or compression. If the abdomen had been closed it must be opened. Under conditions like this when a few moments may determine the result, there is no time for delay or elaborate preparation; even the moving of the patient to the operating-table might imperil the results. Under such conditions when possible—which is usually practicable in hospital cases—do the work in bed, as suggested by Ricketts. By so doing you will save valuable time and perhaps your patient.

Drainage.—To drain or not to drain, is the question. This is a feature in pelvic surgery which constantly confronts the operator, in which only general rules can be formulated. Every surgeon deprecates the necessity of drainage, but recognizes its necessity in certain cases. It is a common statement now-a-days, that drainage after laparotomy means imperfect surgery. I desire to take issue with this theory as illogical and dangerous, and I do not hesitate to affirm that only the surgeon who is capable of discriminating when drainage is indicated, is to be trusted. True, the improved technique of these later days makes the necessity for drainage far less frequent, but every case must be judged by its own merits.

The truth of the saying that "he who hesitates is lost," finds no more ample field for demonstration, than in the faulty reasoning and reckless uncertainty which characterizes the vacillating and timid operator in deciding his course under conditions like these. If drainage is decided on, care must be exercised that neither too little nor too much material be used, and that it be dispensed with at the earliest possible moment. It is equally needful that it be so arranged that it shall not be incarcerated in the peritoneal viscera. Failure in this particular has led to awkward and disastrous consequences. If an area of some extent require drainage the gauze may be included in a Mikuliez bag, so that it can be removed at pleasure, and in such amount and from such portion of the bag as seems needful. Usually gauze with a coarse mesh, iodoform or plain, or the two in combination meet every indication. In some cases where considerable areas have to close in by granulation, or sinus remains, rubber tubing can be used later on to advantage. Occasionally, through-

and-through drainage is to be recommended with manifest advantage. This is applicable in septic conditions, when a drain can pass from above into the pelvic cavity and down into the vagina or out through the flank from the pelvic cavity. The position and its bearing on the results in septic peritonitis has of late received attention. Fowler claims if the upper portion of the pelvic cavity be on a higher plane than the more dependent portion, the drainage is thereby greatly facilitated and recovery follows in what would appear to be otherwise hopeless cases. The further results of such procedures will be watched with interest, and the profession will not be slow to utilize any advantage such procedure confers.

Flatulence, Nausea and Vomiting.—In my individual experience the most common annoyance after laparotomy is flatulence, and that in spite of the most thorough preparation of the patient. In nausea, if occasioned by the anesthetic, that will disappear as the system eliminates the drug. If due to reversed peristalsis, and associated with bilious vomiting and diminished peristalsis, the use of salines is indicated.

Nutrition.—From twelve to twenty-four hours after the operation, according to the condition of the patient, teaspoonful quantities of hot mutton or chicken broth are given, at intervals of an hour or two. If acceptable, the quantity may be increased. If the stomach tolerates these, give beef-juice expressed from cooked beefsteak, milk with equal quantity of lime-water—if it is known that milk is well digested by the patient—at longer intervals of two or three hours. Nothing in my experience gives more discomfort to the patient than imperfect digestion of milk, extending to the whole length of the alimentary canal. Early feeding as is consistent with the patient's condition is advocated.

Urinary Secretion.—Unless some contraindication is present, allow the patient to micturate if she can. If she can not, have a catheter used four or six hours after the operation. This will give some suggestion whether the urinary tract has suffered injury during the operation and assist in determining the status of the renal secretion and the amount voided, which should be made a matter of exact clinical record; any marked decrease in the elimination of urea or other toxic agent should receive immediate attention. If there is a marked deficiency or suppression of the urinary secretion no time should be lost in re-establishing it. The agents to be employed are persistent dry cupping over the kidneys, the administration of salines by the mouth or by high rectal enema until brisk catharsis is established, assisted by calomel; copious drafts of pure water if admissible; the establishment of diaphoresis; and if the blood-pressure is diminished, the use of digitalis, together with the application of hot poultices to the back alternated with dry cupping. Under such management the secretion is usually restored.

The Pulse.—As a guide to diagnosis, prognosis and treatment in pelvo-abdominal surgery, the condition of the pulse is of great value. As an indicator of change and complications it serves as a barometer. As is the pulse so is the patient, is especially applicable in these conditions. In all cases the pre-operative pulse must be taken as the standard for comparison. If there is vital depression, the pulse becomes accelerated. Shock, hemorrhage, sepsis, all manifest their influence to modify its rhythm and power, and as a rule its rapidity and volume determine the status of the patient. To this rule there is one exception which should always be noted, that of over-stimulation of the inhibitory

cardiac nerves, in which case atropin is the remedy par excellence.

Usually in cases which do well, the pulse falls in frequency during the first twenty-four hours after operation, while rapid rise suggests the presence of some complication.

Temperature.—Closely allied with the causes which induce rapid pulse are those which manifest themselves in connection with rise in temperature. It may be safely assumed that a proper appreciation of the causes which lead to a variation of pulse and temperature will be the key to their management. Subnormal temperature means vital depression, and occurring soon after an operation indicates the presence of shock or hemorrhage. With the appearance of these symptoms there is usually absence of a hot face. Sudden rise of temperature during the first two days is regarded with suspicion. If due to nervous disturbances it will not be long maintained, but if persistent it is ominous of grave conditions. It may mark the advent of sepsis, either intra-abdominal suppuration or that arising from stitch-hole abscesses. If the latter, there will be localized pain; so also pulmonary complication, from either. Peritonitis and abdominal effusion produce fever, though the last condition usually occurs during the second week. A persistent temperature of 100 to 101 F., extending over a week, is occasionally present without assignable cause. Another form of fever which occurs in certain patients has, in my opinion, not received the consideration which its importance demands. I refer to malaria. This fact was profoundly impressed on my mind within the past few months, after operating on a lady from the south for the extirpation of an axillary growth, from a malarial development attended with high temperature and alarming weakness which nearly resulted fatally. A recent experience of a temperature of 106 F., complicating an operative case of appendicitis, from malaria tended to emphasize the necessity of discriminating it from other causes of hyperpyrexia. I have, therefore, made it a rule in all selected operative cases to ascertain whether the patient has ever suffered from malarial attacks, to the end that antimalarial treatment could be instituted prior to operation. If doubt exists as to the malarial origin of the attack, blood examination will reveal or exclude the presence of the plasmodium.

The treatment of stitch-hole abscesses consists in removal of the stitches, evacuating the pus, and providing for drainage. Abdominal distension—by causing pain and spasm—is sufficient to cause elevation of temperature. The presence of septic processes, whether local or systemic, or both—one being a sequence of the other—are the severest complications which confront the operator. If they are due to local pus accumulation the indications are plain and unmistakable; if to local or systemic infection which are not amenable to surgical interference a clear discernment as to indications for treatment must be formulated.

The rapid pulse and feeble cardiac movement, associated with low fever or subnormal temperature, resulting from overpowering septic peritonitis, must be differentiated from depression and slow exhaustion. The symptom of intestinal perforation or evacuation of pus into the peritoneal cavity is so grave a matter as to demand immediate attention. If any surgical aid is to be rendered there can be no delay.

Hyperpyrexia due to intraperitoneal infection usually requires the prompt exhibition of salines. As to the hyperpyrexia itself, the extraction of bodily heat by the

application of cold promises most for the patient. Cutaneous sponging and the head and abdominal coil offer the most efficient measures for its relief. Under such conditions the use of the coal-tar derivatives to reduce temperature is never admissible. In profound systemic poisoning the heroic use of alcoholic stimulants, with supporting doses of quinin and appropriate heart tonics offer the best hope for the patient.

Pain.—The pain following laparotomy clamors for relief, and from whatever causes can not be altogether ignored. It is not to be assumed that all pain demands the use of anodynes; in fact their administration is a choice of evils. If due to intestinal distension by gaseous accumulation, the remedy should be found in the escape of the gas and the arrest of its formation. That the results of a laparotomy should be attended by pain is to be expected, but that often abates within the first twenty-four or thirty-six hours.

The nervous perturbation, from prolonged pain, is not only a source of irritation but may be sufficient to cause fever. The wise surgeon will so interpret the causes which lead to pain and the injury associated with it, that his remedies shall not only be timely in their exhibition but those which shall not unduly perturb the patient by their after-effect.

In most cases after laparotomy I find no need for giving anodynes, and for some years I have almost never resorted to morphia or opium.

When necessity makes needful some anodyne I give codein from $\frac{1}{4}$ grain up as is required. Most patients are tolerant of it, both as regards unpleasant after-effect on the nervous system and its comparative innocence in checking secretion and diminishing peristalsis, two very important considerations. Compound spirits of ether exercise some influence in the control of pain, while bromid of quinia acts both as a support and sedative.

Exhaustion.—Among the many unmentioned complications following laparotomy, the only other I shall refer to is exhaustion. In serious cases its degree and persistence mark the limitations of possible convalescence and its appropriate preventive treatment will antedate its positive development. Prudent but well-sustained feeding, stimulation and appropriate nursing will not be overlooked. When for any reason stomach digestion is impossible, early resort will be had to rectal alimentation and stimulation.

Tonics, like quinin, strychnin, and iron will find their appropriate field of usefulness, while the individual professional attention, untiring and persistent, will conserve to the fullest extent the strength of the patient and her chances of recovery.

263 Hancock Street.

DISCUSSION.

Dr. I. S. STONE, Washington, D.C.—Dr. Chase has given us a most valuable paper. I want to congratulate him that he has written something which is reliable. I often find that papers read before this body advocate a variety of treatment which if applied would be followed by disastrous results. Many of us have come to the conclusion that these cases get well without a great deal of after-treatment if the operation has been properly performed. When we close the abdomen it is about all we can do in many cases as far as saving the life of the patient is concerned. In regard to the use of morphia, we all agree that it is rarely necessary. I have heard many men say that it should never be given, never should be in reach for fear it might be used. I have rarely used morphia in my private hospital, but there are some cases where patients' lives have apparently been saved by it. The other day a lady was brought to my hospital, and although she was

a morphin fiend her physician did not mention it to me. This is decidedly wrong, as we should always be informed of it. The lady was operated on, and suddenly grew very pale, with cold, clammy skin, although there was little hemorrhage. Salt solution seemed to have no effect, other than slightly increasing the volume of the pulse. This condition continued for some hours. Finally we gave $\frac{1}{2}$ grain of morphin with 1,200 grain of atropin, and that patient's condition changed for the better in the twinkling of an eye.

In closing an incision I used for years the serial, or layer, suture, but I now condemn it because the through-and-through sutures closely approximate the entire length of the incision in every direction, while the layer sutures leave spaces between the different layers which can not be approximated. After using the through-and-through suture, we put fine catgut suture in the fascia, and it is a rare thing to have a case of suppuration after that method.

With regard to preliminary stimulation, my experience has shown me that it is best to leave your patient alone for some days prior to the operation. Do not use digitalis or nitroglycerin or any other thing which young hospital physicians and family physicians do. The family will bring much pressure to bear on you to do something, but you will get better results if you will carefully avoid excessive stimulation and medication.

DR. REED, West Virginia—Dr. Stone has covered the point I was just about to make. We can not get along without through-and-through sutures, as we must perfectly approximate the different layers of the wound. After the suture has been placed we can use in addition some fine catgut, and you will rarely ever have a case trouble you because of suppuration. Suppuration will only occur when the catgut has not been sterile, and there is no way of being absolutely sure of that fact. The introduction of a stitch into the fascia, which can be removed at the same time that the through-and-through sutures are removed, seems to me desirable. That can be done by using silkworm gut and drawing the fascia together by a running stitch. By introducing a silkworm-gut from one end of the wound down through the skin, through the fascia, picking up the fascia on one side and on the other side one-half inch in advance, and so on, you have a continuous suture. When you draw on either end you bring the fascia together and the ends can be anchored by shot. It is re-enforced by through-and-through sutures so that there is no possibility of any yielding. If the fascia is in perfect apposition the silkworm-gut can be removed at the end of two weeks with perfect ease. There is no suture material left in the wound and consequently no possibility of infection.

DR. W. E. B. DAVIS, Birmingham, Ala.—I wish to say a few words in regard to the closure of the abdominal incision. I referred to this subject in my address. The tier suture with absorbable material has a just and high place in surgery and is practiced by many of the best surgeons, but the majority close the wound by the interrupted through-and-through suture of non-absorbable material. The method which I practice combines some of the advantages of both, and obviates some of their objectionable features. I use interrupted sutures of silkworm-gut, uniting the aponeurosis, recti muscles and peritoneum, and secure the sutures by means of very small silver tubes, corresponding in length to the thickness of the skin and subcutaneous fat, through which the ends of each suture are passed, and then through a perforated shot. After the aponeurosis has been well approximated, each tube is pressed well down and secured by the compression of the shot at the distal end of the tube. After all sutures have been secured, the skin is brought together with a very small size suture of silk or catgut. The sutures should be very superficial or subcuticular. The little tubes with shot project just beyond the wound. Compresses of gauze are placed on the sides of the incision to approximate the subcutaneous fat. The silkworm-gut sutures should remain from two to three weeks, and can be removed by clipping the ends of the suture between the tube and shot, and after the tube is removed the suture comes without difficulty. By this method the wound is freed of all

foreign material before the patient is discharged, there being nothing left to cause subsequent trouble.

DR. A. H. GOELET, New York City—I agree with many of the points brought out by Dr. Chase, whose paper I have listened to with much interest, but I think the after-treatment of laparotomy should begin before the operation. I think it is of the greatest importance to prepare the patient thoroughly for operation. We must understand that patients who require these operations are not usually in good physical condition. The whole system is out of order. The digestive apparatus and the liver are not working properly, and I think that when we come to spend a few weeks in the preparation of our patient for operation we will have less trouble with the after-treatment. My experience has taught me this. The only cases where I have had trouble have been those where I left the preparation of the patient to the man who sent me the case. Where I have prepared the patient myself I have had no trouble.

Pain is one of the principal things we have to contend with in the after-treatment of laparotomy, and intestinal distension is responsible for the pain to a great extent. That can be, and should be, gotten rid of by thorough preparation of the patient before the operation. This is particularly important whenever an anesthetic is given, and when the abdomen is to be opened.

I was glad to hear Dr. Stone speak in favor of some anodyne after operation when the patient is suffering from pain. I think it is our duty to give morphin when the pain is excessive, and I have never seen any bad results from it when combined with atropin. It does not interfere with convalescence when judiciously used.

In regard to closing the abdominal wound, I think the objection raised to the buried suture comes not so much from the spaces left, because a good operator would not leave such spaces. It is because knots are left buried in the tissue and they act as foreign bodies. When I use a layer suture I never make a knot. I start with a slip-knot and make one continuous suture close all the different layers without tying at the end, and I avoid taking sutures through the skin, using the subcuticular suture. Where I have used deep interrupted silkworm-gut sutures I avoid the pain produced by the cutting of these sutures by putting a layer of several thicknesses of gauze below the knot on top of the line of incision, tying the sutures over the gauze. I have often relieved intestinal distention and pain satisfactorily by using asafetida, sometimes in the form of a suppository and sometimes in the form of a high enema of the milk of asafetida.

DR. EDWIN RICKETTS, Cincinnati—The after-treatment of many of these cases depends greatly on the ante-operative method. I wish to call your attention to the fact that if you will look into the history and life-work of Mott, of New York, and Blackman, of Cincinnati, and take into consideration that they were rapid operators, I am sure that many valuable lessons can be learned from these men. Blackman amputated the hip-joint in 28 seconds. I want to say to you that recently I saw a patient under an anesthetic 20 minutes while the operator was washing his hands. I object to this because it has a most damaging effect on the after-treatment of these cases. In regard to the closure of the abdominal incision, my friend Stone had been taught the lesson of the through-and-through suture and he departed from it only to come back to it again. I have never departed from it because you can not improve on the through-and-through suture. Put your sutures in alcohol instead of hot water and you will have very few stitch abscesses. Over-training is over-doing. Over-doing in the after-treatment of these cases means to lessen your patient's chance. Do your work well while you are doing it. The best men we have are the rapid operators. The men who give their time to this special work and do nothing else are the rapid operators. Any man who takes up 30 minutes of time for an ovariectomy is not worthy of the name of specialist. Ten minutes is long enough when there are no adhesions. Many operations are done in 45 minutes when 15 minutes would be amply sufficient.

Digitalis is a much over-estimated remedy, so, too, is nitroglycerin. The old-fashioned remedy, strychnin, can not be improved on.

DR. F. F. LAWRENCE, Columbus—So far as the lives of our patients and the reputation of the men of our section are concerned, this is one of the most important papers we have heard. The remote as well as the immediate results depend more on proper preparation of our patient before operation and judicious after-treatment than on anything else. Many of the renal complications following laparotomy are simply due to the conditions present which compress or irritate the bladder and ureters. We frequently find albumin. This may be relieved if prior to the operative work you fill your patient full of hot water for two or three days. In reference to the length of the operation and the amount of manipulation of the viscera, I wish to say that nausea, vomiting, shock, peritonitis, septic infection and obstruction of the bowels occur exactly in inverse proportion to the rapid manipulation of the operator. Infection will be in relation to the length of the incision. The peritoneum is a lymphatic covering; the upper part has the greater number of stomata and the lower part the lesser number, hence, we have so few cases of infection following tubo-ovarian abscess. Open the abdomen wide, soil your fingers and get them in contact with the upper part of the peritoneum and your patients will surely have sepsis. Short incisions, little manipulation, rapid work, short anesthesia are the keynote to the entire situation. Dr. Ricketts emphasized short anesthesia. The man, who will start his anesthetic before he begins the preparation of himself, is exposing the patient to unnecessary risk. I prepare myself before I have the patient anesthetized, and even prepare the sutures first. Whether we have stitch abscess depends on how the sutures are tied and the sterile condition of the material rather than on whether it is silkworm-gut, catgut or anything else. Stitch abscesses are more frequently due to devitalizing the tissue within the stitch by too tight tying than from infection.

The use of morphin has been emphasized. If pain demands it, give it before your patient comes out from under the anesthetic. The cases in which we will have infection are those brought into the hospital to-day and operated on to-morrow. The greatest question is when and how to operate.

DR. C. L. BONFIELD, Cincinnati—There are two or three points which I wish to refer to. Patients after abdominal section suffer a great deal from thirst, which is very much increased if purgation, preparatory to laparotomy, is done with salts. I think it is a great mistake to do this. This intestinal tract should be thoroughly clean, but other agents than the saline should be used to accomplish this. I favor the compound extract of colocynth for this purpose. I also urge my patients to drink water freely for two or three days prior to the operation. Then they do not suffer so much from thirst and are better able to stand the loss of blood during the operation.

Regarding the use of morphin, we have been taught not to give it under any circumstances. We all realize that this was an exaggerated statement. It is a good thing to impress the fact on us that morphin is dangerous. It has been my custom for two or three years, when patients are suffering, are restless, can not sleep, to give a rectal injection of phosphate of codain and chloral. The combination acts better than either drug alone. Codain relieves pain and chloral quiets the nerves. It may be objected to by some that chloral is a depressant, but I have never found it so in this connection. If the patient is robust I give 3 grains of codain and 30 of chloral. This dose may be repeated in a few hours, but I rarely have to do so. Of course, we are more apt to have pain when the operation includes the removal of appendages that are nearly normal.

As to stimulants, Dr. Stone spoke very wisely on that subject. Because the patient is operated on is no reason for giving stimulants. If the patient requires stimulants, give them, but not otherwise. If you give stimulants when not needed, you have nothing to depend on when you do need them.

As to suture material, I wish to advocate the layer suture. I am surprised to hear it said that we have no catgut at present that we can depend on. I have been using it for a number of years, but do not remember the formula how the hospital prepared it. I have used it in all sorts of cases and have never had any trouble. My experience leads me to believe that the trouble which has caused operators to return to through-and-through suture comes from not using enough sutures and the presence of serum or capillary hemorrhage between the layers. That has led me to adopt two measures to prevent it. The peritoneum itself is particularly apt to be separated from the tissue immediately above it. After closing the peritoneum, I carry the next row of sutures through thin-muscular tissue and in every alternate stitch I take a little bite of the peritoneum, so as to maintain it in contact with overlying structures. I close the fascia and if the subcutaneous fat is thick I put in an extra row of catgut here. The skin is closed with a continuous subcuticular suture of silkworm-gut.

Dr. Ricketts has emphasized the necessity for speed in operating, but the necessity for speed is not so great now as when the illustrious Blackman, the most noted surgeon west of the Alleghenies, performed his operation. We have more perfect asepsis than he had and therefore we do not have to make up for that deficiency by speed, as he had to do. Asepsis should never be sacrificed for the sake of speed in the present state of our knowledge.

DR. P. A. HARRIS, Paterson, N. J.—Much stress has been laid on the condition known as "stitch-hole abscess" by the various gentlemen taking part in this discussion. I would advise not to allow the first dressing to remain more than six or seven days without lifting it up and examining the incision. I not only look at it, but I palpate it to see if there is any place where there might be an accumulation of serum or where an infection may have started up. I have also made it a practice to inspect the wound every second day after the removal of the first dressing, until about the twelfth day, for the purpose of promptly discovering any collection which may be forming. You may find a little accumulation of fluid or pus, and if you do, it is well to take a pointed trocar, probe, or tissue dissector and open the incision at that point and let the fluid out. In a certain number of cases, in which the patient has not complained and where there has as yet been little or no rise in temperature, a small quantity of serum, blood or pus may thus be discovered and evacuated, and the extent of the suppuration limited.

DR. A. H. GOELET, New York City—I would like to say a word in regard to the preparation of silkworm gut; if it is boiled for half an hour in a 1 per cent. solution of lysol it becomes just as pliable as catgut. It is, of course, preserved in the same solution until used.

DR. G. T. HARRISON, New York City—I wish to mention one very important complication that occurs after laparotomy, namely, ileus. The best way to avoid that is to handle the intestines as little as possible. It is one of those things where prevention is a great deal better than cure. Our cures are very few, but we nearly always have it in our power to prevent this complication. I do not know anywhere in the whole domain of surgery where the surgeon's sagacity is put to a more severe test than where this complication occurs. I had such a case not long ago, and the question was what to do? I decided not to open the abdomen, and the patient died. I believe now that I made a mistake, as I think it best to open the abdomen again, as a cure may be effected by ascertaining the cause of the pathological condition.

DR. C. C. THAYER, Clifton Springs, N. Y.—I think it is unfortunate, as well as unphysiological, to give remedies when preparing the patient which have a tendency to reduce the fluids of the body. The compound licorice powder is better than any saline compound. The fluids of the body are needed during the operation and during the convalescence. In regard to sustaining the patient, it has been said that strychnin is one of the most important drugs. I would also mention oxygen when there is a tendency to collapse. We should never operate

on a patient without having a can of oxygen and plenty of strychnin on hand.

In preparing a patient for abdominal surgery the alimentary tract should be not only evacuated, but disinfected, and functional disorders corrected. We should remove a pathological, and secure a physiological, condition by beginning earlier the process of preparation, making it more thorough, and thus avoiding many complications which often arise from their neglect. It is unphysiological to use, just before a surgical operation, evacuatants that tend to reduce the fluids of the body. Compound licorice and castor-oil are among the best intestinal evacuatants, with which some disinfectant or germicide may be happily combined. Any preliminary disturbance, general or local, should be overcome, rather than added to the effects of the operation. The stomach and bowels being set in order and the colon thoroughly washed just previously, best prepares the patient, not only for the operation, but for the convalescence. In regard to restoratives, as whisky is often worse than useless, and digitalis, strophanthus, nitroglycerin, and ammonia are often unreliable, strychnin is the most potent motor and vasomotor stimulant and must stand at the head of drug restoratives in surgery. Oxygen is far superior to all, being the quickest, safest and surest. If used intermittently, with the anesthetic, collapse may be averted. We never think of using anesthetics without a cylinder of oxygen ready at hand.

DR. GEORGE J. ENGELMANN, Boston—I have lately studied the pulse and find a normal variation of from 30 to 40 beats; this teaches us that if we are to understand and appreciate danger-signals we must study the pulse of the individual patient beforehand, and this is too generally neglected. I have been surprised that a normal, thoroughly healthy pulse may drop to 68 or 60 and may rise to 94 after taking food, that it may vary 20 beats in different portions of the body and more with emotion. I want to call your attention to a suture with which I must confess I have had no practical experience. You may be familiar with it. It is advocated by Jonnesco, a brilliant young surgeon of Bucarest, who uses an aluminum or silver wire suture. The suture is not buried, yet it is a tier suture and helps sustain and hold the various layers in position. The lowest suture, including the peritoneum, is placed two centimeters from the edge of the incision and goes entirely through. The suture which takes in the next layer and all above it is a little nearer the incision, and so on. No suture is tied, every wire is laid out until all are in place so that the tissues are not distorted and the field is a normal one. When all are in place they are tied, beginning at the highest and nearest one. Dr. Davis' idea of using a little silver tube is a good one and worthy of consideration.

DR. F. F. LAWRENCE, Columbus—Sutures should be taken out on the seventh day. I never leave sutures in longer than one week, as there is absolutely no use of their being there after that time.

DR. CHASE, closing the discussion—I am confident that our individual experience should to a large extent control us in our work, although we should not be entirely oblivious to the experience of other men, nor underrate what they do. We must be guided largely by our convictions and individual opinion. By so doing we shall retain all that is best in our own method. We all deprecate rapid changes, jumping from one extreme to another in the work we do. Unless it is an emergency case, there is no excuse for operating until we are ready, no matter whether it takes one week or six weeks. There should be no hesitancy on our part to apply honest criticism, as it tends to good results and we also by so doing, affirm the reasons for our belief.

Experience has taught us that there are patients who are extraordinarily susceptible to morphin. A single dose producing nausea, etc. I can admit that anodynes must be given in some cases, but not as a routine practice. We get just as much benefit from codein given hypodermically in most cases as from morphin. If we increase the dose of codein we get the same good results as from morphin, minus the bad effects. I think when it comes to giving stimulants, a great deal of care should be exercised. Much depends on circum-

stances and we should thoroughly understand the physiological effect of drugs. No two of them act alike and the therapeutic result, to a great extent, depends on the condition of the patient. It is my practice to fortify my patients by strychnin, but not unless they need it. If there is great nervous depression, there is nothing that will compare with strychnin, but I am sure that Dr. Ricketts and others of my friends here, have given so much strychnin in an individual case that no more could be given. Then spartein or caffein can be given, but they are evanescent in their effect. The conditions under which digitalis should be given are those in which there is diminished arterial pressure attended with vital depression.

THE VALUE OF BLOOD EXAMINATION FOR DIAGNOSTIC PURPOSES.*

JULIAN WALTER BRANDEIS, M.D.

NEW YORK CITY.

If we pause for a moment to consider what a valuable aid to diagnosis, differential diagnosis and prognosis is afforded by the microscopical examination of the blood—in itself a comparatively simple procedure—we can not fail to wonder at the indefiniteness of information to which most medical men must confess in regard to the subject. The cause of this shortcoming, however, need not be far sought, and lies in the fact that it is only within a short period that the medical institutions of this country have provided instruction and laboratories for study in this important branch. Indeed, the entire subject is still in its infancy of investigation.

There are many important and practical instances in which this method lends a valuable aid in the establishment of accurate and scientific diagnosis, as well as assists in determining prognosis. Little is required in the way of apparatus, and only a moderate degree of skill is necessary to master the technique.

DISEASES IN WHICH BLOOD EXAMINATION IS ESSENTIAL TO DIAGNOSIS.

1. Chlorosis. In this disease, by numerical count, there is found to be an oligocythemia; the number of red cells average, however, as high as 4,000,000 per cubic millimeter, although in many cases the count is much lower. There is also an oligohemoglobinemia wherein the cells look paler and smaller than normal. The presence of poikilocytes, microcytes and macrocytes is detected, and in very severe cases a few nucleated erythrocytes of the normoblast variety are found; in such cases degenerative changes also occur in the red cells, such as a tendency to accept more than one stain, the appearance of hyaline spaces in the cells, the loss of the entire hemoglobin and the absence of the tendency to form rouleaux. The blood plaques are increased. There is no leucocytosis, but a lymphocytosis occurs at the expense of the polymorphonuclear forms. In the average case, by test, the hemoglobin is found to be about 40 per cent. of the normal, thus causing the color-index to be considerably less than normal.

2. Secondary anemia. Here we find a decrease in the number of red cells and in the percentage of hemoglobin, which diminish more in proportion to each other than in chlorosis, though the hemoglobin always suffers more severely; the number of erythrocytes sometimes remains approximately normal, while the hemoglobin is often sufficiently affected to cause the color-index to descend as low as that of chlorosis. According to the severity of the disease occur microcytes, macrocytes, poikilocytes

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

and other degenerative changes in the red cells, normoblasts and megaloblasts. A leucocytosis is usually present.

The following two points, characteristic of the blood of children, should be borne in mind.

A leucocytosis, polycythemia and increased percentage of hemoglobin are characteristic of the blood of the new-born, but gradually disappear, the last in fact reaching below the normal within a very few weeks, where it remains during the rest of childhood. Any influence which retards the development of the child—e. g., rickets—has a like effect on the blood, thus causing a leucocytosis, of which a large percentage are lymphocytes, and the appearance of nucleated erythrocytes without necessarily the coexistence of an anemia.

Again, in the anemias of infants and children the red cells are destroyed to a greater extent, and degenerative changes are more marked than in like cases in adults. Nucleated erythrocytes, especially normoblasts, are more frequent, and often show mitotic figures and fragmentations of their nuclei, and, finally, myelocytes are more common than in anemias of corresponding severity in adults. In very severe infantile anemias a condition is encountered in which the white cells present all stages of degeneration, no two looking alike.

3. Pernicious anemia. In this there is a marked oligocythemia, the number of red cells averaging about 1,000,000, or slightly over, per cubic millimeter. The hemoglobin is reduced to an average of about 25 per cent., thus causing each erythrocyte to contain an increased amount of hemoglobin, or, in other words, the hemoglobin-index to be greater than one. The existence of microcytes, macrocytes, degenerative changes of the erythrocytes and of nucleated erythrocytes of both normoblast and megaloblast type, is observed; and the presence of the giant nucleated cell in greater numbers than that of normal size is a characteristic of this disease. The number of blood plaques is diminished. Finally, there is no leucocytosis, or even a hypoleucocytosis, the proportion of lymphocytes, however, being increased. Not all cases of pernicious anemia observed in infants have shown a color-index increased above the normal, some have shown a slight leucocytosis.

4. Leukemia—myelogenous. The characteristic feature of the blood in this disease is an enormous leucocytosis, amounting to an average of 400,000 white cells per cubic millimeter, of which myelocytes constitute one-third or more. The lymphocytes are increased in absolute number, but decreased in percentage in proportion to the normal, and the same is true of the multinuclear type, which show signs of degeneration such as loss of neutrophile granules, paleness, irregular shape and hydropic swelling of the nuclei, etc. The percentage of eosinophiles is slightly increased. The large mononuclear leucocytes are characterized by the absence of ameboid movements, and Flemming and others have called attention to karyokinesis occurring in the leucocytes, especially in the form just mentioned, namely, myelocytes. The changes of a secondary anemia, of a severe type, always occur, including diminution of the hemoglobin, oligocythemia, microcytes, macrocytes, degenerative changes, normoblasts and megaloblasts; the normal-sized nucleated erythrocyte is especially numerous in this disease, and frequently shows fragmentation of the nucleus.

5. Leukemia—lymphatic. Here, again, the characteristic of the blood is a considerable leucocytosis, averaging about 150,000 white cells per cubic millimeter, of which 90 per cent. are lymphocytes, the polymorpho-

nuclear form being diminished in proportion and myelocytes very scarce. A secondary anemia, with all of its changes, co-exists, though nucleated erythrocytes are rare excepting in children. In diagnosing this disease from the blood examination it must be remembered that an extensive lymphocytosis may be the result of various causes in children.

6. Hodgkin's disease. This presents early only normal blood, and later the alterations of secondary anemia.

7. Anemia infantum pseudoleukemia. In this interesting affection the number of erythrocytes always falls below 3,000,000 per cubic millimeter, and sometimes as low as 820,000. Microcytes, macrocytes, poikilocytes and other marks of degeneration characteristic of severe anemia are in evidence. Nucleated erythrocytes are numerous, and many of the normoblasts show karyokinesis, which is a feature considered by Luzet to be characteristic of the disease. The hemoglobin suffers, as it does in any severe anemia. A leucocytosis invariably occurs, and is stated as varying between 40,000 and 114,000 cells per cubic millimeter. Some observers report the multinuclear variety as being particularly increased, while others state it to be the uninuclear forms which are principally multiplied. Von Jaksch found the number of eosinophiles decreased, while Luzet and Zappert report them increased.

8. Malaria. The important point here is the discovery of pigment, flagella and the plasmodium malariae in the blood. A secondary anemia is regularly present, ordinarily marked by a reduction of the red cells, which is proportional to the diminution in the hemoglobin, causing the color-index to be about one. No leucocytosis occurs.

9. Relapsing fever. A microscopic examination during the course of the fever will reveal the presence of the spirocheta obermeieri, which is the pathognomonic sign here. An oligocythemia and an oligochromemia occurs during the paroxysm, but return to the normal in the apyretic period, and a leucocytosis follows the same rule. Large protoplasmic bodies resembling leucocytes, but of larger size, many of them containing fatty granules, are discoverable in the blood during the existence of pyrexia; finally, there must be mentioned the occurrence of free, dull-colored granules, and of fatty, degenerated endothelium, the latter from the blood-vessels.

10. Filaria sanguinis hominis. The finding of the parasite in the blood is the diagnostic point in this affection. An eosinophilia offers confirmatory evidence in suspected cases. A secondary anemia is an ordinary accompaniment.

And lastly, under this heading, let me call attention to the fact that, in certain cases, the finding of the causative germ in the blood has rendered the diagnosis of the following diseases positive: typhoid, tuberculosis, tetanus, ulcerative endocarditis, anthrax, grippe, glanders, septicemia, pyemia, pneumonia, and undoubtedly others which I have neglected to mention.

DISEASES IN WHICH BLOOD EXAMINATIONS ARE AN IMPORTANT AID TO DIFFERENTIAL DIAGNOSIS.

1. Chlorosis from secondary anemia. The differential diagnosis, by means of an examination of the blood, often presents great difficulty in these two diseases; for, while we are more likely to find normal erythrocytes among the small, paler ones of secondary anemia, and although the hemoglobin-index is apt not to be as low as it is in chlorosis, still the only feature that we can depend on is the occurrence of a leucocytosis, which is

pretty regular in symptomatic anemia, but absent in chlorosis.

2. Chlorosis from pernicious anemia. The reduction of red cells and hemoglobin is rarely as great in the former as in the latter, and the degeneration of the erythrocytes is more severe in pernicious anemia. The color-index is less than one in chlorosis and greater than one in pernicious anemia. Myelocytes and megablasts are regular features in pernicious anemia, but their occurrence in chlorosis is extremely rare.

2. Pernicious anemia from the anemia of malignant disease. From the anemia of malignant disease, as well as those that follow syphilis, typhoid fever and malaria of severe type, the following points serve to distinguish pernicious anemia: the large number of megablasts; the greater size of the erythrocytes, and the color-index greater than one; the absence of leucocytosis.

4. Leukemia from Hodgkin's disease. In the latter disease the blood shows, at most, a secondary anemia, which is easily distinguished from the blood of leukemia.

5. Leukemia from tumors of the spleen or kidneys.

6. Leukemia from tubercular, syphilitic or malignant adenitis. In 5 and 6, the blood examinations of the affections contrasted with leukemia do not show the changes of the blood of that disease.

7. Syphilitic from tubercular or malignant disease. As stated by Cabot, in adults a leucocytosis, marked by an increased percentage of young leucocytes and eosinophiles, points to a diagnosis of syphilis as against tubercular or malignant disease.

8. Typhoid fever from malaria. 9. Paroxysmal hemoglobinuria from malaria. 10. Pneumonia from malaria. In 8, 9 and 10, the finding of the plasmodium malariae settles the diagnosis.

11. Malignant liver disease from other liver disease. 12. Puerperal sepsis from puerperal mania. 13. Renal or cardiac from bronchial asthma. In regard to 11, 12 and 13, according to the teachings of Neusser and his followers, an eosinophilia would point to the presence of the second as opposed to the first of the diseases in each couplet.

14. Hysteria and neurasthenia from many of the diseases which they simulate. The finding of normal blood where we could expect to encounter certain pathological changes serves readily to make the distinction here.

15. Gastric ulcer from gastric cancer. The occurrence of a digestive leucocytosis points to the former.

It is obvious what an aid may be rendered by blood examination in obscure abdominal cases, for the presence of a leucocytosis would point to: 16. Appendicitis as against typhoid. 17. Appendicitis as against intestinal, biliary or renal colic, or floating kidney. 18. Peritonitis as against tubercular peritonitis. 19. Malignant disease of the liver as against catarrhal jaundice. 20. Perinephritic abscess as against cyst of the kidney.

In doubtful pelvic cases the absence of leucocytosis excludes the presence of pus or hemorrhage, and, in general, the mere existence of a leucocytosis would suggest the first as opposed to the second of each of the following couplets: 21. Pneumonia and typhoid. 22. Pyemia or septicemia and typhoid. 23. Meningitis and typhoid. 24. Meningitis and brain tumor, lead encephalopathy, diabetic coma, sunstroke, narcotic or alcoholic intoxication. (Cabot.) 25. Pneumonia and uncomplicated grippe. 26. Scarlatina and measles. 27. Empyema or pneumonia and serous pleurisy.

In the last disease, however, there is usually a mild leucocytosis during the febrile period, but it is not as great as that of the contrasted affections. An important point is an increase in the leucocytosis as indicating a change from serous pleurisy to empyema. It must be kept in mind that serous pleurisy, as well as all other serous inflammations in children, causes such a high leucocytosis that this point can not be depended on as a mark of differentiation between serous and purulent inflammations in them.

To continue, the same sign serves to differentiate: 28. Serous pericarditis from cardiac dilatation or hypertrophy. 29. Osteomyelitis from neuralgia or "growing pains." 30. Malignant from benign tumors. 31. Purulent from catarrhal otitis media; as well as all suppurative from non-suppurative processes. 32. Suppurative processes from tubercular processes.

PROGNOSIS AS DETERMINED BY BLOOD EXAMINATION.

1. Pneumonia. In this disease the absence of leucocytosis in any but the mildest cases is a bad sign, and points toward a fatal issue; while its presence merely assures us that the system is reacting, but does not suggest the outcome.

2. Diphtheria. Here, again, the absence of leucocytosis in any but the mildest cases is a bad sign, and the degree of leucocytosis keeps pace roughly with the severity of the infection. Engel considers the presence of large percentages of myelocytes as characteristic of fatal cases, and Ewing finds the staining reaction of the leucocytes proportional to the severity of the disease.

3. Chlorosis. The prognosis, of course, is regularly good, but the chances of rapid recovery or the reverse depend on the severity of the blood-changes existent at the time treatment is begun. For instance, we can expect an early return to the normal, where the only change is a loss of hemoglobin, while the course would be proportionately slower where oligocythemia, changes in the shape and size of the red cells, degenerative changes, etc., are added. Neusser finds eosinophilia a favorable sign in chlorosis, as it shows an active regeneration of the blood, and, for the same reason, he considers it a good prognostic sign in the:

4. Anemia following hemorrhage. 5. Pernicious anemia. In this disease, too, Neusser states that the occurrence of an increased percentage of eosinophiles is a good sign. The prognosis, however, is always bad, and it can only be said that cases are not so rapidly fatal in which remissions occur, and in which the blood-changes enumerated above are not so severe.

6. Scarlatina and scarlatinal nephritis. Here, again, is eosinophilia a good sign, according to Neusser, while its absence is bad. The leucocytosis is proportional in degree to the severity of the disease in scarlet fever.

7. Appendicitis. In this inflammation, as in pneumonia and diphtheria, mild and very severe cases may show no leucocytosis. As Cabot states, an increasing leucocytosis may be the only thing to suggest an extension of the process.

8. Septicemia and pyemia. The occurrence of leucocytosis in these diseases follows the same rule as in several of the diseases already mentioned, that is, marked leucocytosis in most cases, and no increase in the leucocytes only in the mildest or in those cases in which the outcome is sure to be fatal.

9. Malignant disease. The recurrence of a leucocytosis which has disappeared with the removal of a malignant neoplasm indicates a return of the tumor.

10. Phthisis. Neusser points out that, in certain cases of this disease, some of the large uninuclear and multinuclear leucocytes contain perinuclear basophilic granules which, as the mark of a uric-acid diathesis—a tendency which is antagonistic to the development or spread of tuberculosis—suggest a favorable prognosis.

And, lastly, Neusser is also responsible for the statement that in deciding whether a case of hysteria, neurosis or psychosis would be benefited by castration, the presence of an eosinophilia suggests the affirmative.

DIFFERENTIAL DIAGNOSIS BETWEEN
ABDOMINAL TYPHOID AND APPENDI-
CITIS BY MEANS OF IODIN REAC-
TION. REPORT OF A CASE.*

DR SIEGFRIED WEISS.

SECUNDAR PHYSICIAN OF THE CAROLINEN-CHILDREN'S HOSPITAL,
VIENNA, AUSTRIA.

The clinical value of the iodine reaction of the blood has an established place among the clinical methods of examination since the investigations of Czerny, Livierato, Weiss and Goldberger. The following case will illustrate its value in the differential diagnosis between purulent perityphlitis and abdominal typhoid:

The patient, H. N., is 9¾ years old. The mother died of pulmonary tuberculosis. A younger brother died of scarlet fever. Two other sisters and the father of the patient are in good health. The child has had, until now, nothing but rubella; the present illness began the last week in November, 1899. On the 25th of that month the child was troubled with cough, and on the 28th had a temperature of 38.3 C. She also complained of abdominal pains, which appeared spontaneously, like colic, and pressure on the abdomen did not seem to intensify the same. Along with it watery stools occurred, alternating with constipation, and no vomiting.

Status presentis: The child is well-developed; its bones show slight rachitic thickening; the cutaneous surface shows a marked pallor; moist, mucous membranes appear slightly injected. The pharynx shows nothing abnormal; the tongue is reddened, and has a slight whitish coating; the ears are clean. On the left submaxillary region a glandular swelling, of the size of a pigeon's egg, and not sensitive, is found. In the region of the submaxillary joint a deep shining atrophic scar is found. The sensorium is clear. The temperature 38.3 C.; the lungs have a dry catarrh, with harsh breathing, and numerous dry rhonchi. Heart dulness is not increased; the sounds are clear and regular. Arteria radialis is soft, well filled, with normal tension and frequency of 130. The abdomen in the neighborhood of the thorax is soft, not tense, and somewhat tympanitic; at the navel it is sensitive on pressure. Constipation exists; the liver is not enlarged. Dulness of spleen begins in the eighth intercostal space, in the middle axillary line, and extends backward to the scapular line, and forward to the border of the ribs; it is not palpable. The urine is free from abnormalities.

Calomel was given in doses of .1 gram. The diet consisted of milk and soft moist food. On November 29 her temperature was 38.7 C., and pulse 130. The abdominal pains were increasing; three liquid stools occurred. Tannalbin, .3 gram, was prescribed. On the 31st, no change was noticed.

On December 1, severe subjective symptoms of illness are apparent. Temperature is 37.8, pulse 120; sordes appear on lips; the tongue has a white coating; the diffuse catarrh over the lungs continues. The splenic tumor is enlarged and extends over the border of the ribs, and can be palpated. Constipated condition remains unchanged from the 2d to the 5th.

December 6, the temperature is 38, and pulse 120. The splenic tumor becomes plainer; in the left hypochondrium five to seven rose-spots are visible. Abdominal pains continue; one stool daily, slightly bile-stained. The urine gives a positive diazo-reaction. Blood examination shows a positive Widal reaction, in the dilution of 1 to 50 in one-half hour. A specimen stained with the iodine gum solution does not show an increased leucocytosis; one-half of the leucocytes show a positive and diffuse reddish brown stain, and an iodine sensitive deposit, which is oak-shaped. Extracellular they are single and in masses of reddish brown granules.

December 7, no change. On the 8th, in the ileocecal region there is a diffuse resistance, hard to palpate, and slight meteorism; three liquid stools; roseola getting paler.

On December 9, the border of the tongue is cleaner, but a distinct fur in the center of the tongue; there is a resistance in the ileocecal region, pointing backward and downward. The pains are described as being in the umbilical region. The iodine reaction in the blood is positive; the same also of the Widal test 1 to 40. Treatment is tinct. opii, 15 drops; ice bag applied.

December 11, pain decreasing; temperature 37.2; no resistance on palpation; slight gurgling; one slimy stool; large doses of opium continued.

December 12, appetite and general condition good. Pain is in the ileocecal region on pressure; no fever.

December 14 to 20, general condition improved on a strict milk diet. Blood shows no iodine reaction, and no agglutination.

In this case there seemed to be at first a type of influenza with a form of bronchitis, and intestinal symptoms—constipation, diarrhea and colicky pains. When, however, typhoid symptoms, such as splenic tumor, roseola, typhoid tongue and lips, besides the Widal reaction 1 to 40, and also the diazo-reaction in the urine appeared, then the diagnosis of abdominal typhoid was made. The fever showed a remitting, subfebrile character, but it is well known that typhoid symptoms in children are either atypical or irregular. The diagnosis was questionable when the iodine reaction was found in the blood, and this latter showed the presence of pus. The existence of the tumor spoke against the existence of typhoid, and the disappearance of the same was certainly peculiar. Thus, it seemed that we were dealing with a suppurative local perityphlitic inflammatory condition, with adjacent peritonitis, which subsided in the course of a few days. With the disappearance of this tumor, the iodine reaction also disappeared. The rapid convalescence following the disappearance of the swelling, and the negative appearance of the Widal reaction speak against typhoid, so that the iodine reaction was the determining factor in establishing the diagnosis of suppurative perityphlitis as against abdominal typhoid.

The staining solution used was:

R. Iodin sublim.	5
Kal. iodati	15
Aqua destil.	50
Muc. acacia ad consist. syruposam.	

Misce.

DISCUSSION ON PAPERS OF DRs. BRANDEIS AND WEISS.

DR. JOHN LOVETT MORSE, Boston—The attitude of the profession at large seems to me to be rather different from that stated by Dr. Brandeis. A few years ago we knew little or nothing about the blood; now, too much is expected from blood-examinations. The paper of Dr. Brandeis is a very able contribution to the blood diseases of the adult, but what he said applies very little, it seems to me, to blood-examination in children. The blood diseases in children are decidedly dif-

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

ferent from those in adults, and the classification of the blood diseases of adults does not apply in the differentiation of the blood diseases of children. For example, it is only in older children that we have chlorosis, although the chlorotic type of blood is very commonly observed in all the anemias of children. In children, the hemoglobin is almost invariably lower than the red blood-corpuscles. I am extremely doubtful about pernicious anemia occurring in children. I am inclined to think that many of the cases called pernicious anemia in children are really examples of severe secondary anemia. The blood of secondary anemia in children is not the same as in adults. It may show any and all forms of anemia, mild and severe, with and without leucocytosis, and any or all of them may or may not be associated with enlargement of the spleen. This blood condition is not paralleled in adults. As to the importance assigned to different forms of corpuscles in childhood, I should say that the nucleated red cells, and others, do not have the same significance as in adult life. The tendency in children's blood is to revert to the fetal type with a preponderance of megaloblasts, and this reversion does not have the serious significance in children that it does in adults. We are not justified in making the diagnosis of pernicious anemia on the excessive proportion of megaloblasts in children.

The number of leucocytes and their proportions are very different. The increase in the number of leucocytes is very much greater in children than in adults, under similar conditions and is not of the same significance.

As to the count of the white cells, I think that it is one of the most important parts of blood diagnosis. To be of use however, it should be used intelligently on broad general principles. It is not the absolute count that is of value. It is the fact that some diseases have a leucocytosis, while others do not, that makes it useful. In making the diagnosis between two conditions, if one of those conditions has a leucocytosis, and the other does not, the blood count helps; if both conditions have, or do not have, leucocytosis, the blood count does not help.

Dr. Brandeis stated that there was slight leucocytosis in serous pleurisy. For the last two years I have had counts made of the white blood-cells in every case of pleurisy in my wards every day, and there has not been any leucocytosis in any case. The blood count in these cases appears to be of no use whatever as to the amount of fluid or as to whether it is increasing or diminishing. A possible explanation is that the great proportion of serous pleurisy is tuberculous, and, as is well known, pure tuberculosis does not show a leucocytosis.

DR. LOUIS FISCHER, New York City—I thoroughly agree with Dr. Morse regarding the care that should be bestowed in making the diagnosis, but I think he will agree that if we have a case showing a series of symptoms of typhoid fever, and the spots are not defined and the spleen is not enlarged, and other important signs and symptoms are absent, it is well to resort to other diagnostic tests, such as the Widal and the Ehrlich reaction. I am very sorry that the paper of Dr. Weiss has not brought out a larger discussion, for the paper is the result of a very large amount of labor and consideration, and has been very much quoted abroad. Dr. Weiss certainly does not wish it understood that the diagnosis of perityphlitic abscess should be made by the examination of a drop of blood solely and singly, but, given a child showing a series of symptoms corresponding with an appendicitis, and added to this there is a glyco-genic reaction of the blood, this last reaction would strengthen the opinion that there was present a suppurative process. I have been greatly impressed with the remarks made by Dr. Morse regarding the great number of leucocytes existing in children. I believe the paper of Dr. Brandeis has been presented with a view to bringing out the opinions of those present concerning the necessity for more frequent resort to blood-examinations. I know that in hardly one case in ten of those seen by me in New York City has a blood-examination been made, although there are decided reasons for utilizing this aid as a valuable diagnostic adjunct.

DR. EDWIN ROSENTHAL, Philadelphia—I should like to ask Dr. Morse if, in the examination of blood for leucocytosis in

typhoid fever, the differential diagnosis could be established when other suppurative conditions besides the Peyer's patches, as for example, of the bile duct, were present, and what influence such examinations would have on the treatment.

DR. MORSE—Pure typhoid does not have an increase in the number of leucocytes, and the presence of leucocytosis would point to some complication. The same is true of pure influenza. I do not wish to be understood as saying that I do not believe in the serum reaction or in examination of the blood for malaria, nor do I wish to be understood as wishing to diminish the value of blood examinations, but I do wish to insist on the point that the examinations of the blood should be made systematically and with a definite object in view, and not in a haphazard manner.

MODES OF INFECTION OF THE MAXILLARY SINUS.*

M. H. CRYER, M.D., D.D.S.
PHILADELPHIA.

There are various modes by which the maxillary sinus is infected, among them being diseased teeth, diseases of the ethmoid cells, of the frontal sinuses, of the sphenoidal sinus, syphilitic necroses, etc.

Figure 1.

The general impression in both the medical and dental professions is that the maxillary sinus is infected through diseased teeth more than from any other source. Some claim that three-fifths of the diseases of the antrum are brought about in that way. From study of the anatomical relations and from my clinical experience, I conclude this is a mistake. In order to demonstrate this more clearly, it is necessary that the anatomical relations of the maxillary sinus with the teeth and internal structures of the face should be thoroughly understood. The development of the teeth and face, with their great variations, should also be considered.

The development of the sinus begins about the fourth month of gestation by an invagination of the lining membrane of the nose, from the hiatus semilunaris into the body of the maxilla. From the time of the invagination until the eruption of the permanent teeth, the greater portion of the maxilla is occupied by the dental organs. As the invagination progresses the cancellated portion of the bone undergoes resorption. This absorption of the internal portion of

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

the maxilla is continued, in a variable degree throughout life, until in old age the walls usually become exceedingly thin.

As this process goes on the roots of the premolar and molar teeth are encroached upon by the walls of the sinus, until in many cases the points of the roots are covered only by a thin lamina of bone. Even this, in rare cases, may be lost, leaving only the muco-periosteum as a root covering. By the resorption of the bone and the enlargement of the sinus, it may occasionally be extended into the malar bone. The frontal and sphenoidal sinuses, the ethmoidal and other air-cells of the face are developed in a similar manner; i. e., from an invagination of the mucous membrane of the nose into various bony structures, through which the cells and sinuses derive their names. Therefore, these sinuses and cells are associated with the nasal chamber

chamber, the middle ethmoid cells, and the developing maxillary sinus also show to what extent the maxillary bones are taken up by the developing tooth organs.

In Fig. 6 of the same article, a good illustration is given showing how the floor of the antrum descends between the roots of the molar teeth, a condition much more common among the white race than among the negroes. I also said in that paper, that it is a generally admitted fact that pus or infected matter will pass in the direction of the least resistance; we might suppose by the close approximation of the apical foramina of the roots of the molar teeth that when an abscess is formed at their points, the infected matter would pass into the antrum instead of through the alveolar

Figure 2a.

Figure 2b.

and consequently are closely related to each other. As one is affected by disease, the other is liable to become so affected in proportion to the relative position of the sinuses or cells to each other.

The teeth are developed by an infolding of the mucous membrane of the mouth. Diseases of the teeth have influence within the mouth, and diseases of the mouth affect the teeth, the causes of these diseases being more or less common to both.

In a paper entitled "Anatomical Variations of the Nasal Chambers and Associated Parts," read before this Section last year, and published in *THE JOURNAL*, Oct. 14, 1899, I gave some illustrations to which I here refer.¹ Fig. 5 showed a transverse section of both jaws from a skull of a seven months' fetus. The nasal

Figure 3.

Figure 4.

process into the mouth. My clinical experience teaches otherwise, i. e., an abscess from an infected tooth usually makes its fistula opening into the mouth. The only reason I can give for this is, that nature usually protects apparently weak, though important points, in various ways. In this case I believe the muco-periosteum lining of the sinus takes up its defense, and through its osteoblastic layer builds and protects its walls against absorption and perforation.

In another paper, read before the Section in 1897, published in *THE JOURNAL* of April 2, 1898, I gave an illustration (Fig. 5 of that article) of the left superior maxilla, where, through the death and decomposition of a pulp of a molar tooth, there has been first irritation and constructive periostitis on the floor of the antrum, which has caused a thickening of the bone over the apex of the root. At a later period, suppurative inflammation has occurred, and an abscess has perforated the floor of the antrum.

The following illustrations are from new sections. The first few demonstrate the manner in which impacted or diseased teeth have or may have been a source of infection to the maxillary sinus, and through the sinus being infected, the other spaces belonging to the nose are also liable to become diseased.

Fig. 1 is a transverse vertical section of a face, made in the region of the first molar teeth. Besides the other interesting points, it will be noticed that the crown of the canine tooth has penetrated the palatine surface of the mouth and that the root is within the anterior

Figure 5a.

Figure 5b.

portion of the antrum. Before the dissection was made, the root was covered by a thin lamina of bone. Similar conditions are often found, not only with the canine tooth, but also with the third molars, and occasionally with other teeth, which often remain in such positions for years without giving any trouble whatever, until after middle life, when by natural resorption of the bone the crown and root become exposed within the antrum or nasal chamber. At such times these teeth are liable to cause irritation in the antrum. Occasionally impacted roots of various kinds are found in the floor or walls of the nasal cavity.

Fig. 2 is a sagittal section made through the middle of the orbit, the antrum and the roots of the molar teeth. The retarded development of the third molars has caused an irritation of the floor of the antrum, in the region of the palatine root of the first molar the

lining membrane of the sinus has been elevated, which is due to the first molar tooth being abscessed.

Fig. 3 is a view of the floor of the left antrum and nasal chamber. It will be noticed in the middle of the antrum that there is a conical elevation with an opening in the center exposing the apex of a tooth.

Figure 6.

Fig. 4 is a transverse section of the sinuses and nasal chamber. In the floor of the right antrum it will be noticed that the conical portion of bone covering an infected tooth has been cut through its center, exposing the end of the root in the infected region.

In these cases the muco-periosteum has endeavored to protect the invasion of the antrum, but at some sub-

Figure 7a.

Figure 7b.

sequent time the bone has broken down and the antrum has become infected. From the foregoing illustration it is evident that the impacted and diseased teeth can and sometimes do cause infection of the antrum. Nevertheless, the writer believes that they are exceptional and not the general cause of the diseases of the maxillary sinus. The relation of the maxillary sinus with the nose and its various ramifications, with their com-

mon variations and malformations, more often cause infected antrums, and by these infections the teeth are subject to interference through their nerve and blood-supply being disturbed as they pass along the floor and wall of the sinus.

In the two papers the writer read before this Section in 1897-99, he demonstrated the great variations of the sinus, and of the cells and sinuses associated with the nose. He also demonstrated how the hiatus semilunaris could be closed by the enlargement of the bulla ethmoidalis, this enlargement being posterior to the osteum maxillæ, thus the fluids from the frontal sinus will be forced directly into the maxillary

much smaller sinuses than the shorter-faced picture below. The septum is deflected and has a spur extending outward until it comes in contact with the inferior turbinal. The sinuses pass well down below the level of the center of the orbits. There is also a marked cell in the crista galli which opens anteriorly into the frontal sinus. The existence of a cell in the crista galli was demonstrated last year.

Fig. 6 was made in the same manner as Fig. 5, representing sections in two different skulls cut in about the same position. There is again a great difference in the depth of the face. The maxillary sinuses in the right picture are small and high up,

Figure 8.

Figure 10.

Figure 9.

Figure 11.

sinus, causing disturbance within this cavity until the fluids would pass out through the wall where the least resistance could be found. He likewise showed how fluids could pass directly from the frontal sinuses and ethmoidal cells into the antrum, even if the hiatus semilunaris were not obstructive. Variations were given in the individual skulls. Since writing those two papers, sections have been made, further demonstrating other variations not spoken of heretofore.

Fig. 5 is from two transverse vertical sections made from different skulls. They show great variations as to the depth of the face, the size, shape and position of the maxillary sinuses; the one above having

allowing the lower portion of the nasal chamber to extend outward over the alveolar process. In the left picture the sinuses are large and their floors extend downward below the floor of the nasal chamber, and pass over the roof of the mouth, leaving but a small nasal chamber. The one above gives a good illustration of the four meatuses and a partial fifth.

Fig. 7 is made from two sagittal sections taken from different skulls, showing variations in the depth of the nasal chambers. The one above gives a good illustration of the four meatuses and a partial fifth.

Fig. 8 is a transverse vertical section. The anterior cut is made in the region of the premolar teeth. It

will be noticed that the septum of the nose is deflected and the spur comes in contact with the right turbinal. The frontal sinuses are large, extending outward over the orbits. They also extend down below the middle of the orbit. Between the two frontal sinuses there is an interfrontal cell extending backward into the crista galli, which is shown in Fig. 9. It will be noticed that a wire passes from the right frontal sinus downward and is again seen in the antrum.

Fig. 9 is a posterior view of the same section as Fig. 8. It shows where the section has been cut vertically in the region of the second molar tooth. The frontal sinuses will be observed passing well over the orbits, and the cell in the crista galli is clearly shown. The inner surfaces of the anterior walls of the bulla ethmoidalis will be observed extending inward toward the middle turbinate bones, the wire marking the infundibulum, the hiatus semilunaris, and the ostium maxillæ into the maxillary sinus, the last named being small in proportion to the size of the skull.

Fig. 10 shows a section cut anteriorly to the second molar teeth. In this case the maxillary sinuses are almost cuboidal in shape and extend down below the level of the nose, and upward into the region of the middle ethmoidal cells. The inner walls are not straight,

Figure 12.

as they are in a typical skull. Beginning at the floor of the antrum, almost over the center of the dome of the mouth, the inner wall extends upward in a convex manner to the point at which the inferior turbinal projects into the nasal cavity. There is a direct communication with the anterior ethmoidal cells and the frontal sinuses.

Fig. 11 affords a good view of the skull of an aged person. The floor of the maxillary sinus, the nasal fossæ, and the lower border of the alveolar process are almost on a horizontal line. The left maxillary sinus extends upward until it passes into the frontal sinus. In the crista galli is shown a small sinus which extends forward into the frontal sinus, as shown in other figures.

Fig. 12 is an anterior view of a section cut in the region of the molar teeth. Between the orbits are the anterior ethmoidal cells, and also a sinus in the crista galli. It will be noticed that both antra extend upward and become common with the ethmoidal cells and the frontal sinuses.

These illustrations, as well as those shown in previous papers, demonstrate how great the variations may be in the nasal chamber, the maxillary, frontal and

sphenoidal sinuses, as well as in the cells of the orbital process of the palate bone and the ethmoidal cells.

The treatment and surgical manipulation of disease in these regions will vary, of course, to as great an extent as the variations in the anatomy.

The writer believes that it is through the common communication between the frontal sinuses, the ethmoidal cells, and the maxillary sinus, that infection is generally conveyed to the antrum from the cells and sinuses above it, recognizing, at the same time, that the posterior ethmoidal and sphenoidal cells and the cells of the orbital process of the palate bone, can also infect the antrum by the resorption of the partition between these cavities. The writer also believes that there are more cases in which teeth are lost through diseases of the antrum, than cases in which the teeth are primarily diseased, causing infection of the antrum and associated cells.

DISCUSSION.

DR. E. S. TALEOT, Chicago.—The members of the Section on Stomatology are quite familiar with the work of Dr. Cryer. The illustrations shown this afternoon are very interesting. From original research of the last twenty-four years, I can confirm the work here presented. Dr. Cryer, owing to his connection with the University of Pennsylvania, has a better opportunity for studying recent specimens than I have. My investigations have been made principally on the skulls. I have made an examination of about 20,000 skulls, and have seen just such conditions as the Doctor explains. I do not see how it is possible for any specialist to practice on the nose, throat and sinuses without a thorough understanding of the anatomy of the parts. The anatomy as laid down in the textbooks is worthless so far as diseases of the nose and maxillary sinuses are concerned. Owing to the limited time, I will confine my remarks to etiology. The early races, such as the Indian and the Eskimo, rarely have these diseases. They are common with the higher races. To understand the causes of these diseases embryology and evolution must be studied by two different methods. The early races have protrusion of the face and jaws. A line dropped perpendicularly from the superciliary ridge demonstrates that the jaw extends beyond; the lower in evolution, the farther the forehead recedes from this line. With the advance of evolution the forehead protrudes, the jaws recede. A few years ago I made a special study of the evolution of the face. I visited every country in Europe and studied the people, not only the soldiers, policemen and cab-drivers, but also the individuals in public institutions, insane hospitals, prisons, etc. Most of the Latin races have protrusion of the jaws, but in the Scandinavian and English peoples, etc., the jaws recede and the forehead protrudes. In the examination of 5000 people in Stockholm I found 2 per cent. outside, 14.70 per cent. on the line, and 83.30 per cent. had jaws inside of this line. In the examination of 10,000 people in London I found about 83 per cent. of the jaws were located inside of the perpendicular line. In 3000 school children I found about 93 per cent. had jaws inside of this line, or some 10 per cent. more than grown people. About the same statistics obtain in this country. The rapid evolution of the facial angle is shown in the faces of the American negroes. In New Orleans, among the lowest type, 83.57 per cent. were found to present protrusion, 15.95 per cent. on the line, and 1.13 per cent. recession; in Chicago, 51 per cent. protrusion, 31 per cent. on the line, 16 per cent. recession; in Boston, 45 per cent. protrusion, 39 per cent. on the line, and 15 per cent. recession. There is one factor in this evolution. In the evolution of the face from childhood to manhood arrest of development of the face may take place at any period, since these tissues are transitory. If after the sixth week of fetal life there is malnutrition arrest of development of the face occurs. If at any time after birth a child should have any of the constitutional diseases, marked arrest of development of the face takes place. Among the criminal classes arrest of development of the face is often seen, either a hollowing out of the face or a

protrusion of the jaws, and it is in such cases that we have abnormal development of the jaws, frontal sinus and the maxillary bones. In regard to disease of the antrum from diseased teeth, I agree with Dr. Cryer in every respect, because I have noticed about 367 cases in which the death of the molar pulps has taken place. There is only about 2 per cent. in my practice of disease of the antrum from these conditions of the teeth. In an examination of 3000 skulls, which were broken so I could get into the antrum, making 6000 antra, there were about 21 per cent. with abscessed molar teeth. Of this number 6 per cent. discharged into the antra. The percentage of these diseased antra, therefore, as the result of disease of the teeth, is very small.

DR. GEORGE L. RICHARDS, Fall River Mass.—This is the third time that I personally have had the pleasure of hearing Dr. Cryer before the AMERICAN MEDICAL ASSOCIATION demonstrate the anatomy of the antra and the other accessory sinuses, and I move that a vote of thanks be extended to him this year, as we did at Columbus last year, and at Philadelphia two years before, for the illustrations given us. Those of us who do much nasal work must become more and more alarmed every time he addresses us because of the anomalies he presents. I move that a vote of thanks be extended to Dr. Cryer, and also to Drs. Stout and Talbot.

SYPHILIS OF THE UPPER AIR-TRACT.

SOME REMARKS ON ITS DIAGNOSIS AND TREATMENT.*

GEO. L. RICHARDS, M.D.

Otologist and Laryngologist, Fall River and Emergency Hospitals;
Fellow of American Laryngological, Rhinological and
Otolological Society, Etc.
FALL RIVER, MASS.

The present paper is based on observations of such syphilitic patients as I have had in my private practice during the last four years, some forty in number. No attempt has been made to figure out the percentage to total number of patients treated; the number is too small for such figures to have any value. No case of primary syphilis of the upper air-tract has been met. They must be quite rare, especially so if primary chancre of the lip be excluded from this analysis and we confine ourselves strictly to the upper air-tract. Secondary and tertiary manifestations are common, the areas most frequently involved being the pharynx and tonsillar region, the nose and larynx. The sore throat of the secondary stage is one of the most common of syphilitic lesions, yet in my experience is less often seen by the specialist than the tertiary. This condition is usually seen and treated by the general practitioner who is treating the disease as a whole, since it is one of comparatively slight discomfort and soon passes away. The upper air-tract lesions of the tertiary are sooner or later referred to the specialist, and not infrequently the first correct diagnosis is made by him. Most of my cases have been of the tertiary variety.

The primary chancre is usually found on the tonsil and soft palate. Buckley reports 307 cases of chancre of the tonsil out of 9058 cases of syphilis, and Schadek found 34 cases of chancre of the tonsil out of a total of 68 cases of extragenital chancre. The lesion is an indurate ulcer, and can be so slight as to escape notice. Students of Hajek's clinic in Vienna will recall a case of primary chancre of the nose he was wont to describe. The victim was a physician who had examined a woman per vaginam, not knowing at the time that she was syphilitic; subsequently he picked his nose with the finger and inoculated himself with syphilis, the insufficiently cleaned finger nail carrying the virus. Dr. W.

Freudenthal, of New York, has observed a similar case. The lesson from this is obvious, and the physician in all his relations to syphilis must never forget that it is possible for him to become infected. Primary affections of the soft palate and tonsil are mostly from pipes and drinking cups, but have doubtless also occurred from congress per os.

The secondary manifestations occur in the upper air-tract from three to nine months after the primary lesion, and are at first those of a simple catarrh with no particular diagnostic characteristics apart from the history, except that recovery is much slower than in ordinary simple inflammation of the region. This stage is usually passed unnoticed by the physician unless the patient is under treatment for other syphilitic lesions. Following this, appears the mucous patch; it involves the sides of the mouth, tonsils and faucial pillars, pharynx, nasopharynx, nose and larynx, and base of the tongue. They appear as slight elevations of the mucous membrane, flat, round or oblong in shape, from 3 to 7 mm. in diameter, and grayish-white in appearance, looking as though the surface had been lightly touched with nitrate of silver. If the superficial epithelium is denuded, the covering of the patch will be a thin, yellowish mucopurulent one. When the tonsil is affected it is considerably swollen and has a boggy appearance. Some difficulty in swallowing is complained of, and little pain. In one of my cases one tonsil was greatly swollen, the other slightly, and the patient stated that previously there had been no tonsillar enlargement whatever; he sought relief from a specialist because his sore throat had lasted five weeks without improvement. A history of a "soft" chancre three months previously was obtained and improvement under appropriate treatment was immediate. A sore throat, or laryngeal, or pharyngeal irritation coming on without apparent cause, lasting for weeks without improvement, with the mucous surface of a coppery glazed look, and covered with a thin secretion, is to me very suggestive of a secondary syphilis even in the absence of any confirmative history. It can be premised that an angina lasting longer than four weeks, and in a practically stationary condition, may safely be considered as probably syphilitic, especially so in the absence of any sufficient cause. When the mucous patch is on the surface of the pharynx, buccal surface of the tongue or soft palate, it is less likely to be seen by the specialist than when on the tonsils or palatine arches. When in the nose it will usually be entirely overlooked unless the person seeing the case examines the nose as a routine measure. I have not found enlargement of lymph-glands a very reliable sign by itself alone, though confirmatory. It is more apt to be an accompaniment of the secondary, is occasionally in the tertiary, and may be present in hereditary. More cases of enlarged lymphatic glands are non-syphilitic than syphilitic. Occasionally one will be in doubt between this stage and the tertiary, and some authors, as Schrötter, describe the manifestations of syphilis only and do not divide the upper air-tract lesions into stages. In one of my cases I was much in doubt as to whether I was dealing with an ulcerative mucous patch or with an ulcerative gumma. There was one swollen edematous cord and thickened papillae at the base of the tongue, while the pharynx was as above stated. He improved under mixed treatment, so the exact stage was a point of no special import. The treatment of this stage is the general treatment of the disease. Beyond keeping the surfaces absolutely clean, I do not believe that any local treatment materially in-

*Presented to the Section on Laryngology and Otolary, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

fluences the disease. I apply a weak solution of nitrate of silver, order an alkaline wash and prescribe mercurials, and sometimes iodid of potassium as well. Hydrargyri protoiodid has been my mainstay in doses of $\frac{1}{4}$ grain, but latterly I have been using mercury by inunction. This has always been recommended by European writers, but has not been used as extensively in America owing to the disagreeableness of the treatment. In no other way, however, is the system so rapidly brought under the influence of the mercurial. One dram is rubbed in every other day for two weeks and then a cessation for a week; then begin over again, lengthen the interval as symptoms will allow, watch for salivation and keep the mouth very clean. Omit when salivation demands, though a moderate amount of salivation is readily borne.

The manifestations of the tertiary stage appear from three to fifty years after the primary lesion; in two of my cases, thirty-five years had elapsed without symptoms, during which time healthy children and grandchildren had been born. Owing to the long time which has elapsed since the primary lesion the symptoms are frequently wrongly interpreted or entirely overlooked. The patient himself has frequently forgotten about the original trouble, or at least places no causative relation between the two, and in women they may never have known what the original cause was. Syphilis is a disease whose past or present it is usually desirable to conceal; hence all histories are in the main apt to be unreliable, and a diagnosis should never hang on the presence or absence of a satisfactory history, but should be made on the symptoms as positively as though a clear history were obtainable. Moritz Schmidt says: "It is sufficient when the physician has recognized the affection. The knowledge of how it was obtained does not hasten the healing." Nevertheless, I always try to obtain a history.

In typical cases the diagnosis is clear enough; in others it may be very difficult, due to the lapse of time since the primary sore and to the well-known trait which syphilis has of simulating nearly every one of the more chronic affections of the body, no part being exempt from its ravages. I have elsewhere reported a case of perichondritis of the larynx where a history of syphilis thirty-five years before was obtainable, where rapid improvement took place under large doses of iodid of potassium. The final course and the histologic examination showed the perichondritis to be carcinomatous. It is not at all improbable that both conditions were present. A syphilitic person is as likely to suffer from carcinoma or tuberculosis as any one else, in fact more so, since the syphilitic condition lowers the powers of bodily resistance. The early manifestation of the tertiary is the formation of the gumma, a round-celled infiltration of all grades of severity and affecting the superficial and deep layers of the mucous membrane, elevated above the surrounding tissue and later breaking down in the center from insufficient blood-supply. The periglandular tissues and the vascular tissues are pressed upon, their caliber markedly diminished and an endarteritis obliterans set up. The extent of the gummatous deposit and the rapidity of its destruction are an index of the virulence of the virus. No portion of the upper air-tract is exempt from the gummatous deposit. I have observed it principally in the pharynx and nose, and in nearly every case ulcerative changes have begun before the case has come under observation. In the nose the gumma attacks the septum at the junction of the bony and cartilaginous portion, ulceration

soon follows, and destruction of a greater or less portion of the bony and cartilaginous wall with necrosis of the bone, and accompanied frequently by an abundant formation of foul crusts. This feature is frequently a marked one, and in an early stage may be mistaken for atrophic rhinitis. The resulting destruction may result in saddle-nose, but if the side walls are uninjured, saddle-nose will not take place, as this condition is brought about only when the interstitial tissue that binds the cartilage and skin of the nose to the bone is involved in the syphilitic process.¹ I have a patient now under observation with complete destruction of the anterior one-half of the bony septum and of a large part of the cartilaginous as well, but none of the saddle-nose deformity. Primary infection in this case occurred thirty-five years previously. In addition to the destruction in the nose there was a small gumma on the tip of the tongue. This case was at first supposed by me to be one of atrophic rhinitis, but the removal of a piece of necrosed bone from the septum confirmed the diagnosis of syphilis. It may be stated as practically an absolute rule that necrosis of the bony framework of the septum, in the absence of history pointing to phosphorus or some irritant poison as a cause, is of syphilitic origin. I was once led astray by another case simulating an atrophic rhinitis. A young woman, previously under care of two physicians, was referred to me by one of them for atrophic rhinitis, and told me in answer to inquiries that he was very sure that syphilis was not a factor in the case. I treated it as a case of atrophic rhinitis without making much headway. There was a perforation in the cartilaginous septum and some necrosis of the edge of the bony septum, and many foul crusts. After a while I began to get away bits of necrosed septal and turbinal bone, and a saddle-nose appeared. I sought for a syphilitic history, asked some leading questions and began an antisyphilitic treatment. In the midst of this she became pregnant, was delivered of an apparently healthy baby and disappeared from observation. Later she returned, I continued antisyphilitic treatment and told her what the trouble was. She again disappeared from treatment, but returned one day with a gumma at the margin of each ala and with the process attacking the skin and cartilage between the two. This extension does not agree with the observation of Bosworth that syphilitic disease shows a marked hesitancy to transgress anatomical boundaries. She stated that she had absented herself because she was angry at my telling her she had syphilis, but the conditions becoming so desperate she had again sought me that I might save the external nose if possible. The process rapidly subsided under the mixed treatment in large doses, and the external nose and ala were saved from destruction. In this case valuable time was lost by my allowing an absence of history to stand in the way of a proper diagnosis.

In a young man referred to me for septal operation I found a broken-down gumma and almost complete ulceration through the septum at junction of the cartilage and bone. I easily obtained a history of a syphilis which the patient supposed was cured. Operation was postponed until several weeks of syphilitic treatment could be carried out, and healing was prompt. Operations on these cases during the active stage of a gumma do badly and healing does not take place; instead the fresh wound may be involved in the process. In another case, elsewhere reported in full, I found the tertiary lesion involving the ethmoid cells high up and producing head-

ache of such severity as to simulate a true meningitis, which it probably would have led to had he not been etherized and the offending necrosed bone entirely removed. Perhaps I have been led astray oftener than is the rule. I imagine, however, that we all occasionally go astray on this subject. An elderly man with no syphilitic history, denying, in fact, anything of the kind whatever, was referred to me for difficulty of hearing and an obstruction in the nostril. I started to remove with a saw what was apparently a large cartilaginous spur, only to find it soft and easily cut; on examination I found it to be wholly granulation tissue. I feared it might be sarcomatous, but the bleeding was slight and there was no especial pain or tendency to extend very much. It showed, however, a tendency to recur. At the same time he complained of the throat and of rheumatism. Distinctly rheumatic treatment did not do much good. Under the antisyphilitic treatment all symptoms have cleared up, and he recently told me that he was never better in his life.

In my experience the pharyngeal lesions have been the most troublesome, especially when occurring high enough up on the pharyngeal wall to result in adhesions between the pharynx and the pillars. In that case the cavity of the pharynx may be completely shut off from that of the nose through the resulting contractions. The syphilitic pharyngeal ulcer is quite characteristic, being irregular in shape, of various sizes, with an elevated ulcerated border and a gnawed, mouse-eaten appearance, and with ridges and little hillocks of granulation tissue on its borders. It is covered with a gray exudate, and shows no tendency to heal until antisyphilitic treatment is begun. On the contrary, it is as destructive at times as rodent ulcer. I have several times tried antisyphilitic treatment as a diagnostic measure when it seemed in the individual case as though syphilis could not be present. Local and cleansing treatment was of no avail until this treatment was begun. The tonsils and both sides of the epiglottis are frequently the seat of the gumma. All the laryngeal cartilages may be affected by perichondritis occurring as a late and destructive result of the gumma, and life be endangered, or even destroyed, as a result. One of my patients reported that he had been told by an eminent expert on syphilis that he was cured. I found a broken-down gumma of one tonsil and the adjacent pharyngeal wall. Another patient had an ulceration of the left side of the pharynx, with mouse-tooth excretion, raised borders, a dirty gray mucous deposit and a cup-shaped ulceration of the lingual surface of the right side of the epiglottis. This whole condition had been laid at the door of a dentist who had worked on her teeth, as due to infection from improperly cleaned instruments. Careful questioning revealed that she had been keeping company with a man who had been treated for some constitutional affection, probably syphilis, some three or four years before, but was reported cured. Improvement under proper remedies was rapid. As in the secondary, even more so here I regard the presence or absence of pain as important in the diagnosis. In syphilis there is little pain, whereas in carcinoma and tuberculosis, the diseases most likely to be confounded with syphilis at this stage, there is considerable pain, while the disturbance of nutrition and general constitutional dyscrasia is very marked.

Treatment: While authors usually recommend iodid of potassium only for this stage, I have had much better results with it when mercury was given at the same time. Cases which were not doing well under the iodid prompt-

ly improved when mercury was added. I have not usually given the iodid in large doses—5 to 10 grains three or four times a day, though I have given as high as 70 to 80 grains per dose three times a day. As a mercurial I have mostly used $\frac{1}{4}$ grain of the protoiodid. Both of these are given until the disease is under control and then one is given one week and the other a week, and later the entire treatment is intermitted every other month. Such treatment should be kept up two years. Mercury by inunction can be given if the above fails, and I am now using it in this form in a tertiary where the other seemed insufficient.

Thompson advises inunctions of 1 dram of mercurial ointment per day. Twenty-five to thirty inunctions are given and the treatment then intermitted for six months. At Aix-la-Chapelle daily inunctions are given by an experienced rubber together with sulphur baths, the mercury forming with the sulphur a sulphid of mercury which is easily eliminated. For local treatment of the ulcerated area I apply solid nitrate of silver stick as often as the case is seen and alkaline antiseptic washes.

It remains briefly to consider the hereditary type, the late manifestations of which in the upper air-tract have been variously described as syphilis congenita tarda, latent syphilis or occult syphilis, and occurring about the age of puberty, are substantially of the tertiary variety so far as appearances and symptoms go. The gumma seems usually to appear some time between puberty and 20 years of age, though syphilitic symptoms may appear at any time from birth on. In one case I was unable to determine whether it was a late congenital or a straight tertiary, as absolutely no history fitting either hypothesis was obtainable. When first seen, the characteristic pharyngeal ulcerations and granulations were present and beginning adhesions to the soft palate with accompanying contractions. I found she had been treated by an ophthalmologist for an iritis which he regarded as syphilitic, although as much in the dark as to the cause as I. The most searching questioning of the girl and both parents threw no light on the subject, yet the case was undoubtedly syphilitic. A good example of delayed hereditary syphilis was in a 17-year-old girl who came with her mother. The father's history was uncertain; the mother had a perforated septum and a saddle-nose. The girl had a perforated septum, saddle-nose, and cicatricial contractions and adhesions of the pharyngeal wall and soft palate, there being an opening into the nasopharynx only large enough to admit a probe. The history was that the throat conditions had been growing worse for several years; the condition probably began to develop somewhere around puberty. Improvement was rapid under treatment, but the adhesions and contractures remain. I once had a case of hereditary syphilis in a child referred to me, recovery of which took place promptly on removing a shoe-button from the nose.

What can be done for the relief of the deformities and interferences with bodily functions which result from the cicatrization and contraction following the healing of the ulcerations? When of soft palate and pharynx, the cavity of the mouth may be entirely cut off from that of the nose or its movements so affected as to prevent the natural action of the parts. This causes regurgitation of liquids during the act of swallowing and permanent mouth-breathing. The destructive process may ulcerate through the hard palate into the floor of the nose or vice versa. One of my cases had left as the only evidence of having had the disease a perforation of the hard palate into the floor of the nose; this I tried in

vain to cover over. Operative measures such as dilatation and cutting away the adhesions seem to be of little avail. The tissue is very fibrous and does not stretch, while after cutting operations the contraction may be greater than before. It is my opinion that there is not much we can do that offers much chance of real improvement. The worst adhesions are those between the soft palate and pharynx. In general, syphilis is a disease to be treated with constitutional measures and not with the knife or curette, though I have occasionally cut away with snare or scissors a little of the elevated granulation tissue of the pharyngeal ulcer.

DISCUSSION.

DR. EMIL MAYER, New York City—I am reminded of the injunction of a French writer to think always of syphilis, and when you are through think again of syphilis. We have all ways to bear that disease in mind when we have any one of these cicatricial conditions present. But I must take issue with the writer when he says that every destruction of the septum in the absence of history to the contrary should be considered syphilitic. If that were the statement of the writer I must disagree with him, because we have a number of destructions of the cartilaginous septum that are not syphilitic.

DR. RICHARDS—I referred to the bony septum.

DR. MAYER—Well, then the statement is correct. There is a condition in the pharyngeal wall that is most difficult to describe, but which at once presents the picture to our minds as being due to syphilitic disease. That was shown recently in a case presented by Dr. Quinlan before the Academy of Medicine. The very moment I glanced at the pharynx in that case it gave the picture of syphilis, and shortly after Dr. Quinlan arrived and said it was one of his syphilitic cases. To say that our patients lie to us when they deny a syphilitic history is putting it pretty strong, for we do not know how long syphilis will carry. I myself have seen syphilis in the third generation, being able to trace it back to the grandmother. In one man who came to me the pharynx had that indefinable appearance that led me to suspect syphilis, but in the absence of a specific history I was forced to believe him. His brother had been operated on for genito-urinary trouble, a stricture being cut, and he promptly died, to the astonishment of his physician. The physician was severely blamed by the family, but it would seem to me that he probably also had syphilis, and if that had been known the defense of the operating surgeon would have been strong. My patient progressed nicely. The man's story was true. He never had an initial lesion, but later the father of my patient came to see me regarding the son. I then saw that the father had almost total destruction of the nose. In answer to my inquiries he said that he had had a fall in childhood, and in response to further inquiries said that a sister of his also had a similar deformity. So my patient had inherited a specific taint from his father, who had congenital syphilis and my first suspicions proved to be true and yet the statement of never having had syphilis was true enough as far as my patient knew.

DR. G. F. CORR, Buffalo—Dr. Richards has mentioned the transmissibility through the drinking-cup. How many cases are transmitted in that way it is impossible to tell, but that there are many of them I do not doubt. I know of a young girl who had an attack of tertiary syphilis, which was believed to be diphtheria, by her attending physician. It finally healed without any special treatment, leaving considerable scar tissue about the throat. This girl went from one physician to another for seven years, until finally she drifted into the dispensary and was treated for syphilis. Tracheotomy had to be done to save the girl's life, and finally gastrostomy to permit food to enter the stomach. That case was due to the use of the drinking cup. Too often we have a common public drinking-cup. Dr. Richards spoke of using mercury and potassium iodid, but I do not think that is the best treatment. In the secondary stage no doubt mercury is the best drug to use, but in the tertiary stage potassium iodid is the proper drug. But when mercury has not been used in the secondary stage you must then use it before you can get the best results from the iodid.

Sometimes the patient is very much run down and then he or she will improve under tonic treatment, and afterward you can use the mixed treatment with much better result. The poison to be eliminated in the third stage is quite different from that in the second; the one is innocuous while the other, that of the second stage, is violently contagious, hence the difference in treatment and results.

DR. C. W. RICHARDSON, Washington, D. C.—I consider syphilis one of those diseases in which we should not only be charitable to the patient, but also to our fellows and to ourselves. There is hardly any disease in which one can be so well excused for making errors of diagnosis as in syphilis. We all find at times cases of syphilis in which we can scarcely make out the clinical history of syphilis until the case has been under observation for some time. Almost all the great syphilographers agree that in some cases it is almost impossible for one to make a differential diagnosis between syphilis and other ulcerative lesions in the same situation. The writer has given us a most excellent paper, and it seems impossible to find any point with which we can take issue; of course it is impossible for any writer to consider the subject in its entirety in a meeting of this kind. I shall refer to one or two points that the essayist neglected to touch on and which seem to me quite important. One of these is the frequency of syphilis of the postnasal cavity and the frequency with which it is overlooked, not only by the general practitioner but occasionally by the specialist. I refer to tertiary lesions in this region. This is not an infrequent form of syphilis of the pharynx and I have seen extensive infiltrations and broken-down gummatous areas in the vault, the posterior wall and on the posterior surface of the velum. An ulceration on the posterior surface of the velum is almost the clearest pathognomonic symptom of syphilis that we can find. Syphilitic lesions in this area are the ones that usually give us the greatest difficulty in the after-treatment, on account of adhesions forming and causing attachment between the velum and the posterior surface of the pharynx, resulting in those cicatricial contractions which render the life of the patient almost unbearable. At times formations of syphilitic lesions or infiltrates on the anterior surface of the velum and palatine arch are extremely difficult to differentiate from tubercular infiltrates. Of course such a differentiation is not always difficult. Last year I saw one of this type of ulcerations situated just above the tonsil, covering an area of considerable extent, ragged and presenting all the superficial appearance of a tertiary lesion of syphilis. The only thing which would lead me not to believe it was syphilis was the intense pain on swallowing. In order to clear up the diagnosis I put the patient on antisyphilitic treatment and the lesion healed and cleared up in about ten days. The patient was a splendidly nourished man from the mountainous district of Virginia. He returned in about a month with a freshly involved area just in front and below the area formerly affected, and with the first evidence of tubercular manifestation of the lungs, in the way of cough and expectoration. The diagnosis was then clear. The bacilli were found. Therefore, I say in these cases we should be extremely charitable, not only with ourselves, but with others. We meet also a large class of cases in the female, both in the married and in the single female, in which we have to depend to a large extent on the appearance of the local lesion. We can not scrutinize these cases too closely. We must put them on general treatment if we think they look like syphilis and clear up the history if possible in that way. You all know what I mean by going carefully into the examination of these cases. If we feel around we may elicit evidences of secondary symptoms. Often we will find none. We can not always confront the patient, and sometimes it is better not to go too far into the history. The differentiation of syphilitic conditions is sometimes easy and sometimes attended with considerable difficulty. Syphilitic lesions of the larynx usually involve the epiglottis and they are usually single, while the tubercular lesion is usually situated on the posterior wall of the larynx and the aryepiglottidian fold. But there comes a class of mixed cases in which no signs hold and there again we are thrown back on the effect of treatment. Dr. Richards, in his paper, spoke of the

treatment of adhesions between the palate and the posterior wall of the pharynx and the difficulty of getting good results. Of course they are difficult to manage. But if an eyelet be made on each lateral wall between the attachment of the velum with the posterior pharyngeal wall, by the passing of a ligature through and letting it stay there long enough to form a thorough cicatricial border, then the separation may be gradually made between this eyelet and the centrum and you will usually find the result will be more or less permanent.

DR. C. F. THISEN, Albany.—Dr. Richards' paper has been so exhaustive that it is almost impossible to add anything. There is, however, one condition which has not been considered, the primary tumor which occasionally occurs on the nasal septum of a syphilitic subject. The condition is certainly rare, and when it exists it is almost impossible to make a differential diagnosis clinically. A few years ago a gentleman came to my office who admitted having had syphilis. He could not breathe through one nostril. I found a growth about the size of a strawberry on the septum, left nostril, and I at once jumped to the conclusion, because of the fact that he had had a chancre, that it was simply a syphilitic condition. I gave him potassium iodid, but he got constantly worse. I then removed the tumor with the cold snare, thoroughly curetting the seat of attachment, and later for some time lactic acid was applied. The nose got entirely well, and there has been no recurrence. Later he was again given antisyphilitic treatment. On examination the tumor was found to be a granulation growth, containing thousands of tubercle bacilli and some typical necrotic tubercles. One other point occurs to me with regard to the treatment. Dr. Richards says he used potassium iodid in combination with mercurials. I have not had good results with this method of treatment in tertiary syphilis. I use potassium iodid only, and very large doses if necessary. This has always given me the best results. In the secondary stage, of course, nobody will question the value of mixed treatment.

DR. J. O. ROE, Rochester.—Whenever you are in doubt in regard to the nature of any ulcerative condition of the nose and throat, always suspect syphilis. A lady past middle life came to me with ulceration about the throat and a large growth in the fauces just below and behind the velum. There was also ulceration of the velum. This being a lady from a family above reproach, and having an unquestionable character herself, nobody had suspected syphilis. As soon as I examined her I was satisfied as to the nature of the trouble. In ascertaining the history of the case, I found she had been under the care of an excellent surgeon, who had not suspected syphilis because of her social standing. He regarded the case as one of epithelioma. The outcome of the case was that large doses of potassium iodid cured the "epithelioma," and in less than six weeks it entirely disappeared. This lady had lost her voice, had great difficulty in swallowing and many clinical characteristics which would confirm the opinion that it was an epithelioma. The case illustrates the fact that we should always suspect syphilis even in cases where we might believe the disease to be something else. At the present time I have three other cases of syphilis occurring in persons regarded as above reproach. The patients are females, in families where syphilis would not be suspected. It is not even necessary to seek a history of the infection and especially for one familiar with the manifestations of the disease; and furthermore, the treatment will confirm the diagnosis, if the disease be of specific origin. The presence of syphilis, however, does not necessarily implicate the person, for if not hereditary it is often contracted in a most innocent manner, without even the knowledge of the patient.

DR. F. J. QUINLAN, New York City.—One or two points struck me as the essayist interested us in his recital. One is in reference to the secondary manifestations of this disease, namely, in those erosions which later on appear as condylomata. I have for a long time been at sea for some method which would relieve these conditions that are obstinate, resistant and I may add rebellious. In conversation with an eminent syphilographer he asked why I did not try the ordinary black wash. I can recommend it to you in the cases where

there is breaking down. After thoroughly cleansing the surface, apply the black wash. This gives great activity and stimulation. Now, in regard to the use of mercury, I have given the protiodid of mercury and my patients have not received any benefit from it. I think the form of the medicine often is important. I have resorted to a French pill which I find one of the greatest adjuncts to this treatment. The tablets disintegrate almost in the mouth and the mercury readily gets into the circulation. When a patient appears I question him as to the presence of syphilis and if there is any doubt I put him on antisyphilitic treatment. I do this because several years ago I had a very lamentable experience. I went away from the city, and in a few days a patient from whom I had removed a spur was taken with alarming, and it was feared at the time it would be fatal, hemorrhage. It was controlled. Some wise head suggested potassium iodid, and the trouble entirely disappeared. Where there is the slightest suspicion of syphilis I at once introduce the antisyphilitic treatment before resorting to any surgical measures. This not only aids the tissue to recuperate much better, but it gives an additional reactionary power.

DR. R. C. MYLES, New York City.—Some one has said that syphilis is always surprising us. I do not know that it is necessary to impress this on specialists so much as on semi-specialists and the general practitioners. I have had many patients present themselves with gummatous processes who had been treated previously, apparently without the condition being recognized. Potassium iodid always removes the doubt in the diagnosis. I have seen several patients who had received 15 or 20 grains of the iodid without any effect, when within ten days 80 grains caused complete healing and stopped all the symptoms which before had constantly increased. In the diagnosis of incipient gumma we can not pay much attention to the history. Often there is no history obtainable until you find one for them, possibly dating back, as the Doctor says, from three to thirty-five years. We should try to impress on those in general practice the importance of early recognition of the gummatous manifestations of the upper respiratory tract, and if they can not diagnose the condition, to refer the case to some one who can, even if the case must be referred back to them.

DR. OTTO JOACHIM, New Orleans.—I wish to call attention to two factors. Mixed infection has been called attention to because of its difficulty in diagnosis. I have had recently two cases in which there appeared what seemed to be a mucous patch on the soft palate, in one instance extending to the tonsil. Upon inquiry, primary infection was denied. No evidence to the contrary could be found in the history of the patient after diligent and careful examination, nor from physical examination. I withheld constitutional treatment from the case, as I did not think we were justified in launching such a patient on a course of treatment that extends from two to four years. I do not think, unless we have absolute corroborative symptoms of syphilis of some sort, that we should make a diagnosis from a mucous patch in the throat alone. In these two cases the trouble disappeared in two weeks and no secondary or other symptoms have since appeared. The patients have been and are under continual supervision. In the treatment of syphilis, many cases have come under my care which have been in the hands of excellent practitioners and have received adequate treatment without benefit to the local condition. In these cases I could almost always find some gastro-enteritis or some catarrh of the digestive tract, which to my mind interfered with the absorption of the otherwise proper medication. In these cases I have resorted to theunction treatment, and by giving the stomach a rest these patients have done, usually, excellently well: In some cases the progress of the disease is remarkable. I remember one case in which the gumma broke down, leaving a hole in the soft palate the size of a quill, which increased to one the size of the end of your finger by the next day, and to insure quick action I was induced to use intramuscular injections. I used the salicylate of mercury in oleum petrolati. This is of value when the disintegration is rapid and the treatment must be pushed. Laterly I have added orthoform in 1 per cent. to relieve the pain that usually accompanies these injections.

A PLEA FOR GREATER SIMPLICITY IN THERAPEUTICS.*

LOUIS FAUGERES BISHOP, A.M., M.D.

Attending Physician, Colored Hospital; Assistant Physician, French Hospital; Secretary New York Academy of Medicine, etc.

NEW YORK CITY.

The tendency in development of the physical world is toward complexity. Evolution pictures animal life progressing from the simplest atom to the most complex animal. In the world of science, on the other hand, the greatest steps have been always toward simplicity. The greatest attainments of the intellect have been in the discovery of the principles and laws governing complex nature. So, while the accumulation of knowledge is constantly going forward, we find science, which is an application of mind to matter, always simplifying.

In scientific therapeutics the same process is seen. The accumulation of observations has been great. They must be simplified and brought under straightforward laws and applications. The first step must be the selection of a few drugs that represent the activities of their class. The advantage of such classification to the physician will be that the great amount of labor in the attempt to master an elaborate pharmacopœia will be saved. Such an attempt, as a rule, stifles efforts toward a clear understanding of the principles of therapeutics. The habitual handling of a small number of drugs tends to a clearness of thought and a definiteness of purpose that makes the treatment of disease more scientific, and a delight to the practitioner and to all who take part in its study. Nor are the advantages less to the patient than to the physician.

Single drugs are more easily administered. When it has been decided to use the product of a certain plant it is but a step to the use of its active principle. In this way the number of disagreeable physiologic symptoms is diminished even further than by the use of a single drug. If the patient is more susceptible than is expected, this fact is immediately discovered, and a change of plan can be instituted without delay. When many drugs are given at a time, it frequently happens that a single ingredient of a complicated nature causes injurious effects that are attributed to the course of the disease. How frequently this may happen is easily appreciated by those who have noted the violent symptoms that sometimes accompany a full physiologic dose of a single drug. Such an instance is a patient of my own, who is so susceptible to potassium in any form that she is made violently ill by it. How many ordinary prescriptions containing a small amount of potassium might she have taken, and suffered from the taking, without this idiosyncrasy having been discovered! A patient may not be able to take the smallest quantity of quinin without it producing violent symptoms. There is hardly a drug that has not its person who can not take it in any form or quantity. I do not maintain that every case can be treated by a single drug, or by any particular number, but that drugs should be added to the therapeutic plan one at a time, and that the component parts should be so planned that they can be withdrawn one at a time if necessary.

In this connection the claim for the ready-made mixtures, of which so many hundreds are advertised, must be examined. Medicine has been blessed at long intervals by the discovery of remedies which have a specific power to cure particular diseases. These remedies can

be counted on the fingers of one hand, but so satisfactory are they that an intense desire for more has been awakened. The introduction of mixtures under specific names is founded upon this craving of the profession for specific remedies that can be used as direct antagonists to particular diseases. It is pleasant to forget the fact that most diseases must be treated indirectly, and that it is nearly always necessary to treat the patient and not the specific disease. Most medication is administered with the immediate object of obtaining a physiologic effect of the drug, with the expectation that this effect will have a beneficial influence on the morbid process. In this light it is an absurdity to give a patient a large number of drugs mixed up together, no one of which is in large enough dose to produce a definite result. It is far more philosophic to arrange the plan of medication for each case as indications arise.

It is necessary to speak of proprietary mixtures in this connection, because many younger men, even those who are hospital trained, who have not the technical knowledge to construct complicated prescriptions, fall into the habit of using certain mixtures. Some of these mixtures almost rival, in the number of ingredients, the original formula of Warburg's tincture, and it is impossible often by the most careful examination to analyze the effects, since the proprietors, for their own commercial protection, conceal the quantities of some of the ingredients.

Simple prescribing is much facilitated by the use, as far as possible, of the active principles of drugs, though the fact must be carefully kept in view that not all drugs, even the most important, are satisfactorily represented by a single element that can be isolated. Notably is this the case with digitalis and aconite.

Another great disadvantage of complicated prescriptions is that when used with an intelligent conception of the action of their component parts the chances are few of meeting cases that they exactly fit. This applies particularly to the so-called "favorite prescriptions" that are often spoken of. The use of these ready-contrived mixtures is no less cumbersome than it would be if an artisan had a separate box of tools for every different piece of work. How clumsily would the tools be used, and how inferior this workman to the one who had a small number of tools, each of which he was able to handle with skill. Medicine will gain in accuracy when therapeutics becomes less obscure, by requiring every physician to know, as far as possible, the complete natural history, not only of disease but of the drugs with which disease is to be combated. The old notion, perpetuated in that abominable word "allopathy," whereby each drug or a mixture of drugs was supposed to have the power of meeting and destroying a disease, is not longer held by men of scientific attainments. It is known that there are powers inherent in the body itself which tend to the cure of disease. It is also known, that drugs are sometimes capable of removing the active cause of disease, by destroying the infection and modifying the secretions; that they have the power of assisting the tissues in their mutual reconstruction where the course of disease has been checked, and of modifying physiological processes whereby the body is rendered more able to resist disease. All these things are brought about by the application of suitable remedies to certain conditions and is best accomplished by a few simple and well-known drugs. Our plea is for an open hand-to-hand contest with disease, seconded by the use of well-tried, strong and clearly understood weapons, instead of a contest carried on in

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

obscurity, like ancient battles fought with poor weapons, obscured by the fumes of black powder.

Thus the idea of the prescription as a formula constructed at the time to cure a disease under the precise conditions present must not be lost sight of. The active agent in the prescription may be less conspicuous than the adjuvant, the corrective or the vehicle. The older art of therapeutics needs to be brought into line with modern practice or else dropped altogether. It is painful to see students who have been taught only the use of alkaloids, serums and tablet triturates, attempting, when they begin practice, to prescribe according to the demands of an average family practice. Some fall into the iniquitous habit of ordering in a routine way copyrighted formulæ. Others buy a pocket formulary, which is often a poor conglomeration of prescriptions, and copy such that seem to them suitable for the case. Few are able to construct satisfactory formulæ to suit individual cases. A student should be taught how to prescribe drugs; to know what may be expected from their use, and what other drugs will facilitate their action or render their administration more easy.

A true education in the use of drugs should commence like a training in music, or any other art or science, in the use of a few simple elements and the gradual acquisition of power to combine them and use them in groups. In hospitals and teaching institutions a student is too often taught the treatment of disease by the use of an established formulary. This is a constant menace to therapeutic education. You see the hospital interne experimenting upon the patient of Dr. D.'s "antibilious"—or "anagout"—triturate without any definite comprehension of which of the various elements in the combination are the active ones. I have often seen men, so trained, regarding as different therapeutic agents formulæ differing only in the vehicle. Students taught to build up their therapeutic plan from simple indications would not be subject to any such absurdity.

The plea for a greater simplicity in therapeutics is directed particularly to those men who have reached what might be called the confusional stage of knowledge and whose medical experience has crowded upon them with such a flood of therapeutic suggestion that they are smothered by a sea of vague promises. It often requires a profound knowledge of medicine and much self-confidence to adhere to a simple and straightforward therapy in a case that is not doing as well as one might wish. There is a spirit of the gambler in him who would try an experiment with some complicated or secret remedy because it is backed by the certificates of inaccurate observers, implying that the case in hand is exactly like one that was cured by this wonderful combination. It can not always be said that a combination is no better than one of its active ingredients, but it can be said that there is no mixture that would not be better for having been confined to as few as three or four ingredients. A prescription that contains a dozen or twenty drugs is of use only to the one who wishes to take the gambler's chance that some one ingredient will do more good than will all the rest do harm. Like all gambling, the game is against the player in favor of the house—the house being in this instance the manufacturer of the medicine, who, whether there is success or failure, always gets his profit.

If a young physician, or an older one for that matter, only understands a few drugs thoroughly, it would be

better for him to use them in appropriate cases and rely on hygiene in all others. What we need is a reconstruction of our therapeutics, whereby knowledge and experience will be built up, brick by brick, each one being solidly in place before another is added. The younger men would in all probability become most familiar with the newer drugs and use them to the exclusion of the older ones. This is only natural, and older men must not feel that it is their duty to use every new thing. Their old tools are often better, and it is time enough to adopt new ones when their usefulness is thoroughly proved. Nitre may be a better drug than nitroglycerin in the system of practice of many a good practitioner, still the young hospital graduate knows but little of the former most splendid remedy, but can talk by the hour on the use of the latter.

More definite and simple therapeutics are an advantage to science in that the scientific method of inductive reasoning can be applied. True logical reasoning as to cause and effect are found when either the premises are within the grasp of the intellect or the intellect is large enough to grasp the premises. The premises in therapeutic reasoning comprise exact knowledge of diseased conditions and a comprehensive understanding of the probable action of any treatment under the circumstances present. When a complicated pathology forms a composite picture with the not less complex physiology of even a single drug, how difficult is the analysis! Who is to understand such a picture when confused by twenty active therapeutic elements? What wonder is it that we hear of therapeutic nihilism; that many a strong mind abandons the serious study of therapeutics for the more definite and interesting field of clinical and microscopic pathology, or that the surgical specialties so far occupy public attention? Science demands that there shall be a re-study of each drug by itself and that its place shall be definitely settled. How attractive are even false systems, when their supposed principles are such as are easily grasped by the mind! May we not look forward to a time when scientific medicine shall be so clearly worked out that it will be possible to define its claims by explanations as simple as those of systems constructed for the purpose of deceiving the public? It is utterly impossible to meet by popular argument, based upon therapeutics in their present complicated state, such simple propositions as that all disease is imaginary, or that all disease is to be cured by the restoration of a dislocated ligament. The apostle of any faith who has a simple, definite proposition to present has often more advantage with the masses from its simplicity than disadvantage from its falsity. So not only for the sake of science, but for the dissemination of medical truth, methods must be simplified and results clearly defined.

54 West Fifty-fifth Street.

THERAPEUTIC PROGRESS.*

J. TRACY MELVIN, M.D.

SAGUACHE, COLO.

It seems particularly appropriate at this time, when so much attention is being given to the decennial revision of the National Pharmacopœia, to take special notice of the progress which we have made along therapeutic lines during the past ten years, and try to note some of the lines along which future progress will

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

probably occur, and some of the reasons why our progress has not been more rapid in the past.

We are obliged to confess at the outset that scientific therapeutics is to-day far behind all other branches of medical science. The cause is not far to find. The almost farcical teaching of *materia medica* and therapeutics, even in our best medical schools, gives us every year thousands of men appallingly ignorant of the physical and therapeutic properties of our most common drugs, yet well versed in other branches.

Again, our progress has been retarded because of the great mass of comparatively worthless and poorly-understood drugs which compose a large part of our present Pharmacopœia. Of the thousand titles in that work, not one-tenth are remedies whose action and effects have been definitely worked out and placed on a scientific basis; and if this is so of official medicines, what can we say of the thousands of non-officials which are being so freely prescribed?

Of the thousand official titles not more than one-fifth will be encountered in checking over tens of thousands of prescriptions from every section of the country. Why, then, should we continue to carry this load?

Another serious bar to more rapid progress is the marked credulity which physicians have, in common with ordinary people, toward the most transparent therapeutic humbug, if its virtue be only impressed on them by the repeated iteration of skilful advertisers. The most irrational combinations, the alleged properties of which are weekly impressed on the physician's mind, soon efface the memory of slightly taught official therapeutics.

If we turn to our works of reference, where the leaders of the profession are supposed to point out the way, how frequently do we come upon complicated prescriptions whose ingredients are known to the junior pharmacist to be incompatible, physiologically and chemically! And what a vast majority of the formulæ published in some of our medical journals are simply unutterable abominations, therapeutically and pharmacologically!

Trousseau says: "The practice of medicine is the art of curing, and it is nothing more than that; to cure is its object, and all our plans must culminate in medico-surgical therapeutics." If this be so, and surely the great body of our profession will acknowledge the correctness of the definition, how far have we at times wandered from our true aim! How little space is taken up in our journals by contributions which directly attempt to increase our knowledge of the exact effects of remedies which we prescribe so freely?

Another bar to therapeutic progress is that even our best known and most used remedies, of whose value there can be no shadow of doubt, are of uncertain and indefinite composition, as at present most commonly prescribed. Let us take, for example, *digitalis*. This is officially described as consisting of the second year's leaves of the biennial plant, collected when the flowers are two-thirds opened and from the wild plant grown in England. We are further told that the leaves rapidly deteriorate in strength, and those more than a year old should be destroyed. Now this description may have been a most valuable guide to the druggist of one hundred years ago, but of what practical value is it to the druggist or physician of to-day, who depends wholly on the wholesale houses for his supply, and perforce must accept whatever is sent him? Even the last suggestion for destroying old stocks of the drug is very seldom followed. Far more frequently are they

converted into tinctures and infusions. Yet the sole point of interest to the physician in regard to this drug is simply how much of the active principle does a given dose contain? Yet on this one vital point the Pharmacopœia is as silent as the grave. In passing, permit me to remark in this connection that it is surprising that the seeds of this plant, which are far more uniform in strength and deteriorate very little and yet average ten times the strength of the leaves, are not made official in their place.

The entire discussion in regard to the relative merits of the whole drug, the powdered, the extract, the fluid extract, the infusion and the tincture can easily be dismissed, and should be, if only the physicians of to-day would recognize what it is they really want, to-wit, that minute amount of active principle which alone gives to the drug its value for his purposes. It seems to be one of the most difficult matters for the most careful physician to clearly discriminate in regard to exactly what effect he wishes to produce in giving any drug, and equally hard for him to observe with scientific accuracy the exact effect, if any, which he really produces by administering it.

This element of uncertainty as to just what effect a given dose of any of our galenicals will produce, is, I believe a defect inherent in the form of the drug of itself and in our blind way of administering it. Why? Because it is practically impossible that any two samples of any of our active vegetable drugs will contain exactly the same amount of active medicinal principles, be they alkaloids, glucosids or others.

We too often forget that it is not the sole object of any plant's existence to produce those particular principles which we happen to desire and which constitute their value to us as crude drugs. The amount of these active principles present must depend in any given case on a hundred external circumstances beyond the control of man. Heat and cold, moisture and drouth, the richness of the soil, the length of the season, all these and many more incidentals determine whether a single given plant shall prepare and store up .85 per cent. of aconitin or only .25; and yet in giving the tincture of this most powerful drug, we complain of the lack of uniformity in the effects of a given dose when two specimens prepared from two equally good-appearing plants must vary over 300 per cent.

Gentlemen, is it not sarcasm to speak of the scientific practice of medicine while such anomalies are a part of our system? Yet far wider variations than these are reported by undeniable authority, and by those who handle great quantities of these, our trusted weapons of warfare.

Again, we are often confused in the process of our investigation of drugs at finding that one and the same plant often produces at the same time two or more active principles whose medicinal effects are diametrically opposed to each other along a greater part of their spheres of action.

The ancient and honorable opium is a well-known example of this fact, where the convulsive and exciting narcotin and thebain exist side by side with the sedative and narcotic codein and morphin, yet both would be constantly given together if we had not learned to abandon the crude drug so largely and give only the pure alkaloids for the special indications which we desire to meet. Jaborandi is another marked example of this fact. Of its alkaloids, pilocarpin is relaxant and diaphoretic to a remarkable degree, while jaborin is myotic and convulsant second only to atropin. Now,

in using the crude drug or any of its preparations, what possible means have we of knowing just what proportion of these antagonistic alkaloids are present in any particular specimen? Consequently it is impossible for us to arrive at any exact dosage for exact effect. We know that usually pilocarpin greatly predominates, but both the actual percentage of pilocarpin and its relative proportion to jaborin is extremely valuable. For this reason the profession has of recent years been driven to almost abandon the crude drug and its preparations, and use only the alkaloid pilocarpin to obtain the specific effects desired. What has been done in these instances, I believe, must be done with all.

The widespread interest which is being manifested to-day by the great mass of our profession, outside of the large cities, in the so-called alkaloidal plan of therapeutics, is, I believe, one of the most important steps in scientific therapeutic progress which has ever been made, although perhaps largely influenced at present by commercialism; yet I believe that the next ten years will see it established as the only recognized method of securing galenic drug effects on the human organism.

Along the line of progress must also be noted the universal adoption of synthetic remedies of definite composition and exact therapeutic effect. While it is hardly to be expected that the vision of a few years past will ever be wholly realized, that is, that the chemists will be able to present to us remedies whose properties can be exactly foretold by their chemical composition, and may therefore be prepared to exactly meet any and every desired therapeutic indication; yet they have already done more than in all the years that went before, in giving us remedies which will definitely control suffering in many of its forms.

It would be folly for me to attempt more than an allusion to the crowning achievement in scientific therapeutics, namely, the production of immunizing serums which will definitely combat definite disease processes, thereby approaching closely the ideal of an absolute specific, and the allied products or so-called organic extracts, as for example, suprarenal extract and thyroid extract. The marvelous effects of the latter in cases of cretinism and allied conditions, we believe, have never been paralleled by the discovery of any one therapeutic agent for any pathological condition since the science of medicine began. This one achievement marks an epoch in therapeutic progress.

Let us also acknowledge that the high tide of therapeutic nihilism which threatened for a time to sweep away all reliance on therapeutic drugs, has served a most valuable purpose in stimulating real therapeutic progress. It has roused the profession to demand scientific proof of the efficiency of each and every agent to accomplish the purpose for which it is advised. It has led them to observe more clearly and reason more closely in ascertaining in the first place just what effects it wishes to produce in a given case, and then to discriminate more thoroughly as to just what agent, if any, will in the simplest and most nearly physiological manner accomplish the effect desired. In short, the present tendency of the profession to sweep away the vast mass of accumulated trash from the Pharmacopeia, to adopt simple alkaloid medication where needed, to relieve immediate and unnecessary suffering by definite synthetic compounds, to apply the physiological specific of animal origin whose efficiency is unerringly proved by the clinical laboratory, and to employ no remedy whose beneficial action can not be accurately demon-

strated—all constitute a great stride toward scientific therapeutics which marks the doom of the old-time drug shop, it is true, but at the same time shows that the profession at last is making true therapeutic progress.

DISCUSSION ON PAPERS OF DRs. BISHOP AND MELVIN.

DR. N. S. DAVIS, JR., Chicago.—There is no question of the desirability of using exclusively, or almost exclusively, simple preparations of drugs in place of complex formulae. It is preferable to use alkaloids and active principles of drugs whose composition is known and definite, where it is possible to do so, in preference to combinations of uncertain value. There are some drugs whose effects are known, but whose active principles have not yet been determined. These must be used in their pharmacopoeial preparations, especially in the form of fluid, or solid extracts. As regards standardization, I think that it is not possible, on this account, to standardize all preparations at the present time. Much advance has already been made in this direction, but as it depends on the work of trained investigators, pharmacists and expert chemists, it is necessarily expensive and slow in its progress. I do not feel, as many do, that we should always adopt the rule of prescribing only one drug at a time. We obtain a much better effect, in some cases, from a combination of drugs. For instance, if we wish to utilize only a part of the effect of the drug opium, such as the anodyne action of it, and wish to avoid the constipating effect, we may accomplish this by combining with it a laxative. The fact is well known that most of these crude drugs have more than one effect on the human body and act on different organs. They have several distinct actions and produce a complex effect; we can not get a simple effect from them. By our combinations, however, we can get a more simple effect by concentrating the action on certain organs and diminishing other undesirable effects. He expressed the hope that our profession would act harmoniously with the pharmaceutical profession in this important work of determining the active principles of all remedies and establishing their physiological effects so that prescribing may be rendered more exact, definite and scientific.

DR. FRANK WOODBURY, Philadelphia.—The enterprising manufacturers of pharmaceutical specialties, in their desire to introduce new remedies, not only publish enthusiastic reports of the new agents, but also try, both directly and indirectly, to discredit the older remedies which physicians are using. This deliberate attempt to create dissatisfaction with the materia medica is often successful and is responsible for a great deal of therapeutic skepticism, for when patients see their medical attendants willing to "try" all the new remedies, it breaks down their confidence in the judgment and skill of their physician. The speaker suggested that new remedies should be used exclusively by hospital physicians until their value or worthlessness is fully established by clinical and laboratory investigation, and that, as the rule, the profession at large should stick to the pharmacopeia.

DR. T. B. GREENLEY, Meadow Lawn, Ky.—Patients often think that they can not take certain remedies. A man with malaria, to whom I wanted to give quinin, absolutely refused to take it. I had some blue mass with me and I made up several pills, each containing 2 grains of quinin. The patient took the pills, one every two hours, and did not know that he was taking quinin: the chills did not return. In another case, which was that of a lady, who also said that she could not take quinin, I thought that the symptoms she spoke of might be psychologic, so I prescribed it in some combination and did not let her know that she was taking quinin. The next day, however, I found her broken out with a rash of urticaria, and she requested me to stop the remedy. In a case of typhoid fever that needed quinin, but could not take it by the mouth, I employed the hypodermic method of administration of bisulphate with much better results, and the patient did not know that he was taking quinin. We should not rely too absolutely on the statements of the patient with regard to the effects of a remedy, but if it is required, it should be given in some other form, without the patient's knowledge: at the same time we should watch for any ill results.

DR. O. T. OSBORNE, New Haven—One thing that has caused some delay in the progress of therapeutics is the need of the clinical study of cases while taking little or no medicine, so as to determine the cause of the disease if left to itself. Secondly, therapeutists frequently give drugs which mask the disease. The path of progress lies between these two. Therapy does not mean drugging, but we must know the pathology of the disease and the effect of our remedies, and then make a scientific application of the remedy to the condition. With regard to simplicity in prescribing, he approved of the plan of giving drugs in as simple a form as possible. He did not think it polypharmacy to give several drugs, which work together in the same line, each one assisting the other. Polypharmacy is giving combinations of various remedies with contrary effects, and arises from uncertainty in the prescriber's mind as to what remedy is the best to give; it is unscientific and should be condemned in favor of scientific simplicity in therapeutics.

DR. C. C. FITE, New York City—Something has been said about the recent great increase in the demand for nostrums. I think that it is often due to the fact that the physician does not give the patient the prompt relief that he desires, and he accordingly goes to a drug store and asks for a nostrum which will relieve his symptoms without delay. He thought that there is a tendency toward too much scientific study of the disease and not enough attention is paid to the therapy of the case by many physicians.

DR. WARREN B. HILL, Milwaukee—The reader of the paper advised teaching a few drugs to students at our colleges, and teaching them well. He would say, teach many drugs and teach them all well. The trouble is that not enough attention is given to this important department in our colleges; less money is spent for teaching drugs than for the other branches. One difficulty with the text-books is that they do not systematize the information as they should. It is a fact that it is better to know a few drugs and to know them well than a greater number imperfectly, but it is better to know many well. There should be greater discrimination between remedies with similarity of action. The busy physician falls into routine prescribing and is too apt to say: "This is a case of heart disease, therefore give digitalis." This remedy should be appropriate to the physiology and pathology of the case.

DR. A. B. LYONS (delegate Am. Pharm. Ass'n.)—I appreciate fully the importance of the principles laid down in the papers just read. At the same time, I wish to insist that we are not now in a position to assay a great many of our drugs, such as ergot, aconite and so on; and we really have no scientific data as to their use. We know that one manufacturer will obtain what he calls aconitin and another makes something very different, which he calls aconitin. These vary greatly in their physiological effects. The crude drugs will vary a great deal more than the proportion stated, of 25 and 85 per cent. If standardization, as advocated by the author of the paper, should be carried out at present we should be led into the greatest possible confusion, while apparently making a scientific advance in our therapeutics. The revisers of the pharmacopoeia have given this subject much discussion and still have it under consideration. I think that they have done the best that could be done under existing conditions.

DR. J. N. URSHUR, Richmond, Va.—The student of medicine should be taught at college, and should make it the axiom of his life, not to prescribe any drug unless he has a good reason for prescribing that particular drug, and not to combine drugs unless he could give equally good reason for combining them. The greatest difficulty in the study of medicine is with the materia medica. In teaching this complicated and difficult subject, I advocate commencing with drugs that are comparatively simple in their structure and definite in their action. Following these, should be gradually introduced the drugs that are more complicated. The physician should not close his materia medica when he leaves college and lay it aside, but should make it his daily study. I like the method, generally, of giving single drugs and of simplicity in prescribing. While we are under great obligation to the manufacturing pharmacist for many excellent preparations, I would say that the

greatest menace to our profession to-day is the multitude of proprietary products with which our offices are filled by these enterprising manufacturers. These are often attractive preparations and physicians are urged to prescribe them. The misfortune is that we know nothing about their real composition or about their physiological action. I recall a case of failure of the circulation in a patient with inflammation of the kidneys. Several physicians were in consultation on the case and they had recommended diuretin. I advocated strychnin in preference, as diuretin contains salicylate of soda, which is a heart depressant, and should not be given, but I was overruled and the patient had diuretin and died. I think it full time that an effort should be made to impress on the profession the necessity of paying more attention to this subject.

DR. GEORGE J. LOCHBOEHLER, Washington, D. C.—Why should we allow ourselves to be insulted by these men who leave their samples of drugs at our offices? An agent left a preparation at my office last week; it was a combination of pepsin and pancreatin, and he had the impudence to ask physicians to use it for indigestion, although we all know that pepsin requires an acid solution in order that it may act and pancreatin an alkaline solution. And yet physicians use this preparation or it would not pay the manufacturers to send out their representatives to push it. These men know nothing about therapeutics and they come to our offices to tell physicians how to treat cases of disease. One of these did not know what strychnin is, and when asked, said that "strychnin is the active principle of arsenic." I call attention to the impudence of a firm which sends out men to teach physicians to use drugs; ignorant men, who do not know more than to say that strychnin is the active principle of arsenic.

THE PHYSICIAN AS A SCIENTIST.*

N. SENN, M.D., PH.D., LL.D.

Professor of Surgery, Rush Medical College, Chicago.
CHICAGO.

The sentiment to which I have been invited to respond on this pleasant occasion is a timely and important one. My friend and colleague, Professor Fenger, who is our honored guest this evening, has reached his sixtieth birthday, and we are assembled around this festive board to tender our congratulations and to wish him many years of usefulness in the interests of our profession and humanity.

It is an easy matter to eulogize the dead, it must be a source of great and lasting satisfaction to receive the recognition and encomiums from competing colleagues during the prime of life, as in the case of our guest.

Professor Fenger needs no introduction. His name and fame are known wherever modern surgery is practiced. Although a general surgeon, the sentiment "The Physician as a Scientist," applies to him as he is a physician in the broadest sense of the word, and his scientific researches have for the last forty years graced and enriched medical as well as surgical literature. Science is an exacting and jealous mistress. She detests pretension and illogical, immature conclusions. She loves and honors the truth. She ignores nationality, creed, politics, and social position. She plucks her golden treasures from all available sources. She demands from her devotees earnestness, honesty, perseverance, unselfishness. She is exacting, always ready to criticize, but just in her final decision. She is reserved in the distribution of honors, and when honors are received at her shrine, it always means that they have been dearly bought, not with gold or through outside influence, but by hard and unselfish work. Science has little sympathy with what is regarded by the world as amusement. The span of human life is so short and the field of science so vast

* Response to a toast at the Testimonial Banquet to Professor Christian Fenger, Nov. 3, 1900.

and rich, that those who explore and cultivate it have but little time to spare for their own recreation and amusement.

How I envy the men whose vocation in life consists in the pursuit of science, unobstructed by the hardships and anxieties of a professional career! What a source of pleasure and satisfaction it must be to devote the energies of a lifetime to scientific investigations and research! How different with the physician as a scientist! From morning until night, and from night until morning, he must spend most of his time in the care of his suffering patrons, and there is not an hour he can call his own. And yet what has the physician done for science? The healing art rests on science, and the physician is the one who built the foundation.

SCIENCE THE FOUNDATION OF TRUE PRACTICE.

Without science the practice of medicine and surgery of to-day would be what it was four hundred and fifty years before the birth of Christ, crude and empirical. The light of science began to illuminate the temple of medicine with the classical writings of Hippocrates, and it has shone brighter and brighter until at the present time its effulgent rays are penetrating its remotest nooks and corners. What gems of wisdom and erudite teaching can be found in the writings of the great physicians in the distant past! Who can read the works of Hippocrates, Celsus, Galen, Avicenna, and their contemporaries, without being thrilled by the spirit of scientific investigations which they contain? Then came the dark ages which inhibited scientific progress, followed by a rekindling of the light of medicine by the epoch-making labors of Harvey, Vesalius, Morgagni, Haller, and a host of co-workers who paved the way to make medicine what it is to-day—a science and an art. I need not tell you what medicine owes to the scientific work of John and William Hunter, Schwann, Johannes Mueller, Ludwig, Helmholtz, Virchow, Rokitansky, Rindfleisch, Sir James Paget, Billroth, Thiersch, Pasteur, and a host of earnest investigators of more recent date and of to-day in clearing up the mysteries of life and disease. Their work stands as a living monument of the Physician as a Scientist.

SCIENTIFIC WORK AND THE BUSY PRACTITIONER.

Permit me to cite a few instances which will prove that some of the very best scientific work has been done by the busy practitioner. Virchow, the founder of modern pathology, accomplished what he did untrammelled by the daily routine work of an active practice. Robert Koch, the father of the new science of bacteriology, has immortalized himself by the bacteriologic researches which he made when a general practitioner at Wollheim, a provincial town in Germany. Nothing he has done since in the well-equipped laboratory, as a professor in the University of Berlin, can ever equal what he accomplished during the spare hours as a struggling village doctor. Billroth, for many years the star of the medical faculty of the University of Vienna, did science the greatest service in the preparation of his wonderful book on "Cocci Bacteria Septica," published in 1873. His work on "Surgical Pathology" passed through many editions during his lifetime; was translated into nearly all of the living languages; is familiar to every medical student and practitioner, and has been in use in almost every medical college in the world, is but the shadow of his work on bacteriology which foreshadowed the subsequent revelations of the new science upon which is based the modern progress in medicine and surgery. It is a book that has never received the appreciation it de-

serves, and, I dare say, but very few copies could be found in this country. I have always regarded it as the most important contribution to science by the great surgeon whose name is identical with modern surgery. This book was written soon after he left Zurich for Vienna, a change which brought with it a greatly increased demand on his time by teaching and an enormous private practice.

The success of von Langenbeck as a surgeon and teacher was the outcome of his early scientific training and his own original researches during a long and busy professional career. What made von Volkmann the peer of surgeons was his scientific researches rather than his skill as an operator. The lifework of the late distinguished Professor von Nussbaum was foreshadowed by his graduating thesis. He conceived the idea of restoring sight lost by opacity of the cornea by excising the opacity and inserting a minute glass window. Although his painstaking experiments did not prove of any practical value, the student's work became emblematic of his whole surgical career, which was characterized by the originality of his work and his deep interest and intense enthusiasm in everything pertaining to science. Without a deep knowledge of science Lord Lister would never have discovered the light which has revolutionized surgery.

TWO GREAT SURGEONS OF TO-DAY.

The two greatest surgeons living to-day, von Bergmann and Kocher, are the best examples of how much scientific work the busy practitioner can accomplish, and what it contributes to a successful professional career. Von Bergmann's researches on sepsis and intracranial pressure are contributions to medical literature that would bring luster to the names of men engaged exclusively in the study of pathology. Kocher's experimental work on acute osteomyelitis, and his numerous researches on the relation of micro-organisms to other various surgical diseases have become an important integral part of the new science of bacteriology.

OGSTON, HORSLEY, THIERSCH AND MACEWEN.

Professor Ogston, of Aberdeen, will always be remembered as the discoverer of pus microbes, and Victor Horsley by his experiments on cerebral localization. Thiersch, one of the most profound students of the science of surgery, left behind him as the most important legacy of his scientific work an account of his memorable investigations on the healing of wounds and his classical work on epithelioma. Macewen is best known by his lucid description of intracranial surgical affections.

In our own country the rank and file of original investigators is rapidly increasing. It is with a source of pride that I mention in this connection J. B. Murphy, Jacob Frank, and M. E. Connell and his son Gregory, of our city. Marion Sims made his enviable reputation as a country practitioner and S. D. Gross is best known by his work on intestinal suppuration. The few names that I have mentioned out of hundreds of active practitioners who in recent times have added their good share to the science of medicine should be a sufficient encouragement to the younger members of our profession to combine their practical work with scientific investigations from the very moment they enter upon the practice of medicine. There has been more progress made in the science of medicine during the last two decades than during the thousands of years before, and yet it is just a beginning of what is destined to follow. The harvest has just commenced, and many laborers are needed.

SCIENTIFIC PHYSICIANS WILL ALWAYS REMAIN IN THE FRONT RANK.

Every progressive physician should take a part in unraveling the many mysteries which must be cleared up before medicine can become an exact science. Combined with science, medicine is the noblest of all professions; without science it is the meanest of all trades. A good microscope and a small laboratory have become essential aids in the study of disease, and in the pursuit of original research. The modern physician, then, must be a scientist if it is his ambition to remain in the front rank of the most progressive of all professions.

CHRISTIAN FENGER.

We are paying tribute to-night to an ideal scientific physician. Before our distinguished guest entered on the threshold of his profession, his reputation as a scientist was established. His thesis for the degree of doctor in medicine, on "Carcinoma of the Stomach," indicated the bent of his inquiring mind. He showed by his careful investigations that a direct relation exists between the location of the disease and branches of the pneumogastric nerve; in other words, in explaining one of the clinical phenomena—pain—he demonstrated the involvement of nerves by the carcinomatous process when the disease is at all productive of pain. All of his writings since that time breathe the same spirit of critical inquiry and originality of thought. He has never written anything which has not found a permanent place in medical literature and that is not eagerly sought for by all who respect progress and love science. Much of the time of our guest has been spent in the dead-house. It is there that he became a master in pathology, a distinction unanimously granted him for more than a quarter of a century. To him anatomy is an open book. Every operation he performs is an anatomical demonstration. I believe I am not going too far when I make the statement that if called on inadvertently to describe any of the intricate physiologic processes he would proceed without hesitation and give the desired information with a clearness and thoroughness that would do credit to a professional physiologist. He is so familiar with the functions of every organ in health that any disturbances caused by disease are quickly recognized, a knowledge upon which depends his acumen as a diagnostician. Take him into a chemical laboratory and he will make analyses and experiments that would fascinate the students and astonish the director. The microscope is our guest's most constant and nearest companion. To him its diagnostic and scientific revelations are a source of constant interest and unalloyed pleasure. As a practical surgeon, he stands pre-eminent. There is no operation he has not performed, no region he has not invaded. Twenty years ago he taught us how to explore the brain systematically and safely in search for abscess. To him belongs the credit of having led the way in this country to successful surgery of the lung. His articles on the surgical affections of the biliary ducts have become common property, and can be read in all living languages. He stands next to Simon and James Israel in renal surgery. There is no one who would pretend to know half as much as he does of the surgery of the ureter. If our guest has any speciality in surgery, it is the abdomen and pelvis. He has performed more difficult pelvic operations than any teacher of gynecology in this city. He was the first man in Chicago who performed vaginal hysterectomy for carcinoma of the uterus.

WHY DO WE HONOR HIM.

What has brought so many of Professor Fenger's

friends and admirers together this evening? Is it because he has reached the age of sixty? No! Is it because he has reached the climax of his successful surgical career? No! We are here to tender our congratulations to Fenger, the Scientist. We are here to express our feelings of gratitude to the teacher who taught the young men of our profession in this city how to make a post-mortem, and how to use the microscope. We are here to honor the surgeon who planted the banner of aseptic surgery in Chicago, and who has unselfishly and unceasingly instructed its followers in the technique of aseptic operations. We are here to emphasize the meaning and to show our appreciation of the sentiment, "The Physician as a Scientist." History repeats itself. Sixty-seven years ago the distinguished Dr. Hufeland, then the most famous physician in Berlin, was given an ovation after he had been actively engaged in the practice of medicine for half a century. On that impressive occasion a poem was read, and an album containing the autographs of several thousand of his friends and admirers was presented to him. Strangely this treasure came into my possession through the Baum Library. With few changes this poem expresses our feelings toward our honored guest:

Sie senden Dir, ein Kranz—der Erinnerung,
Den Gruss der Heimat, Grüsse der fernem Flur,
Sie rufen Dir, im Abendstimmer
Ehrerheiterter Tage, Heil! zu.

Heil, edler Mensch, Dir! Der, an dem Geisterquell
Der Wissenschaft, des Lebens Geheimnisse,
Balsames voll, in stiller Stunden
Goldene Schalen geschöpft, und hilfreich,

Ein Göttersohn, der frohen Gesungenen
Willkommen Keich mit tröstender Hand gefüllt,
In heissegequälter Brust des Fiebers
Gluten zu löschen mit kühlem Schlaftrank.

Heil, tapfer Kämpfer! Welchem der Sonnengott
Des Pfeil geschärft, der tief in den Drachenkamm
Des frevlen Irthums siegend eindrang,
Doeh in gerechten Triumph versöhnend.

Erfahrner Meister! Der Du die irdische,
Die kurze Bahn, die über der Sterblichen
Verhültem Gang zum dunkeln Jenseit
Blühend sich wölbt, mit des Sehers Lichtblick

Durchwandeln lehrtest, hier in den Rosenthor,
Hier durch des Weinstocks lachende Traubenpracht,
Hier warnend vor verborgner Natter
Tückischem Biss und des Sumpfes Gifthauch.

Viel sind der Priester, viele dem Opferdienst
Der Kunst geweiht. Des Sehers Begeisterung
Entloekt der Finsterniss den Funken,
Der sich in Flammen vom Staub' emporschwingt.

Und naht Dein Abend? Stralen des Tages nur
Umweben glorreich, Wem die Unsterblichkeit
Den Palmenzweig, von Harfenlauten
Heiter Stimmen umklungen, darbeut.

Die Lehrer leuchten hell, wie des Himmels Glanz,
Und gleich dem Licht urreiziger Sterne geht
Der Heldenname niemals unter,
Welcher die Pfleger der Welt verherbricht.

A SANATORIUM and convalescent home for the soldiers and civilian employes of the government will probably be established at Baguio, 4700 feet above the sea level, five miles south of Trinidad, in the province of Benguet, Philippine Islands. The temperature at this place is low and the climate resembles that of Arizona, Colorado or New Mexico.

THE DANGER OF SPINAL ANESTHESIA.

JOHN V. SHOEMAKER, M.D., LL.D.

Professor of Materia Medica, Therapeutics and Clinical Medicine
in the Medico-Chirurgical College.

PHILADELPHIA, PA.

Shortly after the introduction of cocain as a local anesthetic, Dr. J. Leonard Corning, of New York, demonstrated that it was possible, under its influence, to remove large tumors and perform amputations. Continuing his researches, he developed, in 1885, a method of injecting the drug into the vertebral canal between the spinous processes where it "should become absorbed by the minute plexuses of veins and so carried to the cord." Quite recently, Professor Bier, of Kiel, has advanced one step in this practice and deposited a solution of cocain within the subarachnoid space. His example was speedily followed by Oberst, Seldovitch and other European surgeons, and, above all, by Tuffier.

This practice is now extending to the United States and other countries. Various reports have been published, narrating its successful application in major operations involving the lower extremities, genital organs and abdominal cavity. Anesthesia ensues within five to ten minutes and continues for half to nearly an hour, or has even been prolonged to five hours in cases of parturition.

Mixing with the cerebrospinal fluid the solution of cocain speedily affects the sensibility so profoundly that, although the sense of touch remains unimpaired or at least is not obliterated, the perception of pain is destroyed.

The subarachnoid space should be quite as good an absorbing medium as the subcutaneous cellular tissue. On one side is a delicate serous membrane and on the other a mesh of capillary blood-vessels, the whole being in direct communication with both spine and brain. It is known that the cerebrospinal fluid is both produced and absorbed with great rapidity. There would seem, therefore, to be every reason why the characteristic physiological action of cocain should be quickly manifested and, indeed, with accentuated power, inasmuch as it is injected in such close proximity to important nerve centers. One writer, Dr. S. Marx, of New York, explicitly says that in a case when he had injected 1/6 of a grain into the canal he got dangerous symptoms of morphin poisoning, "showing how strong is the absorbing power of the spinal fluid." What is true of morphin must be equally true of cocain.

The drug is liable, in excessive doses, to disturb seriously the innervation of the heart and lungs, to depress the circulation, cause rapid and weak cardiac action, and render the respiration labored and shallow, while in some instances it produces thrombi and emboli. Severe toxic manifestations are not always fugitive. The phenomena of acute cocainism have been known, from ordinary hypodermic injections of moderate doses, to extend over a considerable period of time and cause severe distress, if not danger to life. Constant headache, habitual insomnia, vertigo, syncope, dejection of spirits and presentiment of approaching death, pricking and numbness, with other serious symptoms, lasted for several months as a consequence of a single injection of 1/8 grain. Death has resulted from the incautious employment of cocain. It must be remembered, moreover, that this is a treacherous drug. In many individuals there is a peculiar sensibility to its influence, and a small dose may be followed by a severe reaction. I recall the case of a young lady to whom a moderate

dose of cocain was given in the form of a suppository. Very pronounced intoxication occurred, with marked intellectual confusion, anxiety and decided depression of the heart's action. If such unexpected results follow the administration by mouth, rectum or hypodermic injection of a quantity far within the limits of supposed safety, I can not but be apprehensive that the successful course of the new operation of spinal anesthesia will be vehemently interrupted by dangerous and even fatal accidents. It is now thrown into the subarachnoid space in a 2 per cent. solution and the quantity usually introduced is equivalent to 1/6 of a grain, although I read of larger amounts—1/5 to 1/4 grain—being employed, or of repeated injections being made.

The operation, indeed, is not always so easy as it has been represented. I have myself been an eye-witness on more than one occasion to prolonged efforts before the vertebral canal and subarachnoid space could be entered, the operators being men of eminence and manipulative ability. Dr. S. Marx, who writes approvingly of the procedure in obstetrics, says: "As a rule the puncture is very easily done, but in some few cases there has been the greatest difficulty in its performance. In one case six distinct punctures were made before the tap revealed fluid. In one case with an antecedent lumbar disease I failed absolutely, and was compelled to make the injection in the dorsal region, and then with good success." When we consider that this author's latest report¹ embraces only 23 cases, the few cases of difficulty will swell into a large proportion. The same writer, furthermore admits that "explorations, versions, extractions, placental removals were readily done, not with quite as great ease as under chloroform, but with greater facility than in a non-narcotized woman." I have seen a single injection give rise to alarming symptoms of respiratory failure. The procedure is likewise productive of marked pain, and in order to avoid this effect, Bier and others have employed Schleich's infiltration anesthesia as a preliminary measure.

A number of writers have made allusion to inconveniences attending the method. In some cases chill and fever have followed the injection. Severe and long-continued headache has been noted in other instances and, in fact, seems to be a common manifestation. Distressing nausea and vomiting have also been excited. In exceptional instances staggering gait and sharp spinal pains were experienced on the day following the injection. In some patients free sweating and in others marked debility have occurred. Numbness and tingling are other accidents which have been mentioned. In some cases anesthesia was not produced by the operation. Writers have generally presumed that this failure indicates that the fluid had not entered the subarachnoid space, but this is scarcely a sufficient explanation. Injections into the subcutaneous tissue cause local anesthesia, and the solution must have been absorbed, although perhaps not so rapidly as if it had penetrated the selected space.

Dr. John B. Murphy, writing in the *Chicago Clinic*, for September, 1900, includes among the advantages of spinal anesthesia, "the avoidance of one of the greatest dangers to surgical procedures at the present time, namely, the primary, intermediate and secondary sequences of the anesthetic, as cardiac phenomena, pulmonary lesions and renal disturbance." Nevertheless, some fatal cases have already occurred from medullary narcosis. Tuffier, reporting to the Thirteenth Inter-

1. Med. Record, Oct. 6, 1900.

national Medical Congress in regard to this operation, stated that death had taken place in five cases. In four of these the fatality could not, in his opinion, be attributed to the operation. The fifth patient had died of asphyxia, due to pulmonary congestion complicating a mitral insufficiency. Gumprecht believes that as a rule the operation is unattended with danger, yet he cites a dozen or more cases in which death had followed. Most of the cases collected by Gumprecht were of intracranial tumor and death was caused almost invariably by respiratory paralysis. Although in any circumstances the patients could not have lived long, yet it is admitted that the puncture was undoubtedly the determining cause of death.

It is conceded by all that the operation should be practiced under the most rigid aseptic precautions. In the present state of surgery, however, the proviso is a matter of course and applies alike to every intervention.

I would not be understood as condemning absolutely the production of spinal anesthesia or as denying that it may have a field of usefulness. It is our duty, however, to be cautious in this matter. One hundred odd cases by one surgeon without a death has a very promising sound, yet experience has been too short and the total number of cases is still too few to warrant positive conclusions. Every operation should be regarded in the light of an experiment. The danger signals should not be underestimated. It is not wise to teach that this procedure is easily performed, painless and free from danger. Such statements do not accurately represent the subject in question. If we reflect on the number of times that a general anesthetic is administered far more often than any statistics exhibit; when we consider, moreover, the number of parturient women who may require more or less anesthesia at different stages of their accouchement and for various reasons, we must acknowledge that a few hundred cases constitute but slender evidence for positive assertions. Gurlt, in his studies of general anesthesia, tabulated 14,506 cases in which ether was used by German surgeons without a death. Julliard collected data relative to several hundred thousand administrations of ether and chloroform. In the presence of such figures we should be extremely circumspect in promulgating advice.

Dr. Corning himself is the latest writer on this subject.² From a paper entitled "Some Conservative Jottings Apropos of Spinal Anesthesia," I select the following passages:

The most recent physiology favors the close reciprocal relations between the cerebrospinal fluid and the circulation of brain and cord. . . . And now a further word or two as to the danger of expecting too much from this discovery and of bringing it once more into the neglect certain to follow in the train of disappointed hopes. First and foremost, it is necessary frankly to look at facts and confess that there is nothing in those till now brought forward remotely to warrant the belief that the days of cerebral or general anesthesia are numbered. Some curtailment in their use there may, ay, doubtless will be, but abdication of their broad dominion—never. Again, it is absolutely necessary to remember that, despite all apparent conformity with the exactions of technique, spinal anesthesia sometimes leaves one in the lurch. To what is this failure to appear ascribable? I do not know, nor have I yet come upon a convincing explanation. Cases are on record, too, in which the anesthesia was not of sufficient duration, and the injections had to be repeated, always a deplorable circumstance. Every one at all conversant with the serious results inevitably following infection of a serous cavity must

be profoundly impressed with the necessity of a rigid asepsis. This point has been insisted upon by most if not all recent writers. Yet I foresee that amid the indiscriminate slitting by irresponsible persons, sure to follow in the wake of the conservative achievements of the judicious and the competent, there is likely to be a neglect of those necessary and elaborate rules of antisepsis so necessary to the safety of the subject. Then a procession of gory tales; and a great and useful principle cast into shadow by the misadventures of a herd of venturesome empirics. There will be fatalities; but let there be a concerted effort by the invocation of every known precaution to keep the percentage of mortality as low as possible. Let there be less rivalry of the knife—less endeavor of one to outslit the other—and more attention to improvement of method.

1519 Walnut Street.

THE TREATMENT OF ADENOID VEGETATIONS OF THE NASOPHARYNX.*

OTTO T. FREER, M.D.

CHICAGO.

Medical treatment usually is ineffective as far as reduction of the growths is concerned, but as there is often an undoubted connection between lymphoid enlargements in childhood and future tuberculosis of the lung, much can be done to prevent this by general means. The surgical treatment of adenoid vegetation is the one to be considered, therefore, and the first subject that presents itself is whether it is better to employ general anesthesia in operations for removal of the hypertrophied pharyngeal tonsil or not.

The advantages of operation without anesthesia avoid the dangers of enforced insensibility, the fact that the operation loses much of its formidable appearance to the child's parents, and the absence of the disagreeable after-effects of anesthesia. The objections to operation without an anesthetic are many. The first is the pain inflicted. It is comfortable for the operator to imagine that the nasopharynx is not especially sensitive, but there is no reason why this should be so. It is well supplied with branches of the plexus pharyngeus of the vagus, glossopharyngeus and spinal accessory nerves. Those who think this region one of blunt sensibility will find that even mildly irritating applications to the nasopharynx will convince them of the contrary, if they apply them to themselves. Not only is the operation decidedly painful, but the nervous and mental shock it inflicts on a child, the terror it must undergo in being held while its mouth is forced open and an instrument is pushed into remote regions, the sight of the streaming blood, a possible reintroduction of the instrument, all these things will leave a child nervous, timid and distrustful for years. The mental shock is a matter of serious moment. Intense fright has often done serious damage to the nervous system. Without an anesthetic the operation becomes an uncertain one. This is obvious to any one who has compared the knowledge of the condition of a child's nasopharynx obtained by palpation when the child is awake and when it is under an anesthetic. The reflex contractions of the muscles of the soft palate, the levator and tensor palati, the salpingopharyngeus and the constrictors of the pharynx, distort the parts so that it is hard to tell lymphoid protuberances from prominent muscles and folds of mucous membrane, and often where the diagnostic touch has made us think that we have but a small

*Read in a Symposium on Hypertrophy of the Pharyngeal Tonsil, before the Chicago Climatological and Laryngological Association, July 5, 1900.

central adenoid mass, examination under anesthesia will show the fossa of Rosenmüller and the region above the Eustachian tube full of adenoid growths. If we can not locate accurately the adenoid masses without anesthesia, how can we operate with enough precision to remove all that is needed, even if the child's head can be held so that it does not move at all, and this can not generally be accomplished? In fact, there is a risk that the child's struggles make us liable to cut parts that we wish to avoid; injury has been done to the septum and posterior parts of the turbinals, and, what is of greater consequence, to the lateral wall of the nasopharynx with the Eustachian orifices. The rich blood-supply of these parts makes serious hemorrhage a possible sequel. The haste with which the operation has to be done adds still more to the chance of its being incomplete and imperfect.

Therefore, it seems logical to conclude that though a proportion of cases with adenoid vegetations of limited extent can be successfully operated on without general anesthesia, nevertheless the operation is apt to be incomplete, haphazard and imperfect, with a large element of lucky chance in its successful performance, and that consequently general anesthesia is necessary to insure the thorough removal of the entire hypertrophy of the pharyngeal tonsil.

Is it important that the operation should be complete and thorough? Will not the remains of lymphoid tissue left behind disappear by atrophy? They will not only not do so in childhood but will often be the source of a regeneration of the adenoid vegetations. In adolescence or adult life this atrophy may be hoped for, but is not sure to occur. The younger the child the more vigorously will the lymphoid tissue reform. A return of the disease produces lack of confidence in the operation on the part of parents. Parents have said to me: "We have been told that the operation is of no use, as the growths come back, so we have put it off until the child's condition became intolerable." Or we may be told that there has been a recurrence of the disease, so that a second trial of the operation seems hopeless. Many cases doubtless do not come to us at all, because the parents think an operation only of temporary benefit, a needless torment and expense. Therefore, the operation without anesthesia is a mode of procedure adapted to discredit our methods and keep children from receiving the benefit of operation at all.

A second reason for the importance of thoroughness is deafness. Deafness is often caused by adenoids that produce none or but little obstruction to breathing. Usually they are small masses situated just above the Eustachian tubes. To locate these requires a delicacy of touch unattainable without anesthesia. Another reason for thoroughness is the fact that some enlarged pharyngeal tonsils contain tubercular foci. One removed by me was honeycombed with cavities filled with soft, cheesy tubercular matter. Brindel found 8 cases of tuberculosis of the pharyngeal tonsil in a total of 64 removals, Gottstein 4 cases in 33, Pluder and Fischer 5 cases in 32, Luzetti 2 cases in 50, L. Lewlin, 9 cases in 150.

Entrance of tubercular infection through the lymphatic structures of the fauces and pharynx is thought by some to be the most frequent source of pulmonary phthisis in later life, a more frequent mode of infection by far than the much described method by direct inhalation of bacilli into the lungs.

Local anesthesia by means of cocaine is practically free from danger, if the cocaine is merely sprayed on the parts.

This can not be said of the method of injecting cocaine solutions directly into the adenoid tissues, as dangerously rapid absorption can take place under these conditions. This latter method would be impossible for children, or would be at least as hard as the operation itself, and neither mode would render insensible a large enough area to make the operation painless. Merely spraying the field of operation with cocaine will make the introduction of the instrument but little felt, but will not blunt the sensibility if the nerve-fibers in the depth to which instruments must penetrate.

Of general anesthetics, nitrous oxid does not give us sufficiently long anesthesia for a thorough operation. It has been used as a preliminary to ether anesthesia by Emil Mayer, who claims that it shortens the stage of excitement and makes a minimum of ether needed. He advocates as best the Schleich mixture, but this can be said to have come decidedly out of vogue, as the ether and petroleum-ether evaporates rapidly and leaves a dangerous amount of chloroform.

Chloroform is an unsafe and unaccountable anesthetic. I have had three bad frights from it in operating for removal of the pharyngeal tonsil; Hinkel reports one death and the record of 7 deaths from other sources during adenoid operations; Leyser states that 1 death occurs in 2606 chloroform narcoses. F. Barnhill reports a case of chloroform death one hour after operation for adenoids; W. T. Holloway, of the Central London Throat and Ear Hospital, reported 11 deaths from chloroform up to 1898, after operations on the pharyngeal or faucial tonsils. Casseberry reports a case in the practice of D. Dunne, death one hour after operation. T. K. Hamilton, of Adelaide, South Australia, had such frights from chloroform that he has ceased its use. In administering chloroform Sir Felix Semon advises to let the anesthesia stop short with the abolition of the corneal reflex, while the pharyngeal and laryngeal reflexes are maintained. It is very difficult to keep the anesthesia at this precise stage and if there is not complete enough narcosis to abolish reflex retching the operation is as difficult nearly as without an anesthetic.

Ether has its objections. It can not be used where we have a pre-existing bronchitis; its stage of excitement is long; the somnolency after its use may lead to concealed bleeding with swallowing of the blood until the patient is faint, but it is the safest of the anesthetics. Personal experience has shown me that in many children a quieter, more rapid narcosis is possible with ether than can be obtained with chloroform, and I have had to turn from the latter to ether to get some children to sleep. Ether narcosis is to be preferred to any other, in my opinion.

In operating under narcosis many prefer the position of the hanging head. A more convenient and as safe a position, as far as the flooding of the larynx and trachea with blood is concerned, is one in which the patient lies on his side and chest, close to the edge of the table, while the left arm is placed behind the back. The face looks partly downward toward the floor. In all the operations that I have performed in this position I have never had any trouble from vomiting food or blood getting into the trachea.

Adenoid vegetations can be removed with the post-nasal forceps, the sharp spoon, the ring-knife, snare, small ring-knife and the finger nail. The sharp spoon is apt to do injury. Trautmann, its originator, admits that it can tear off the posterior lip of the Eustachian orifice. It scrapes deeply but is apt to leave pieces hanging. It causes severe hemorrhage. The snare is only used in

adults for removal of small pendulous pieces. The finger nail is useful to clean up the field after operation, especially the fossa of Rosenmüller. It is quite inefficient for removal of adenoid masses if these are at all fibrous, as they often are, so that their base is too firm to yield to the finger nail. Complete operation with this instrument is seldom even approximately possible. The Gottstein ring-knife is the most popular of all the instruments used. Its modifications are many, too many to describe. The favorite ones are the Gottstein-Beckmann, the Hartmann, and the Moritz Schmidt ring-knives. This instrument is admirably adapted to do a rapid, showy and incomplete operation. If it is so constructed that it will reach the lymphoid masses just back of the posterior nares it will slight the adenoid masses on the posterior wall opposite the foramen ovale magnum of the occipital bone. It is my experience that in most cases adenoid tissue often to a large, sometimes the chief, amount is found low down on the posterior wall of the nasopharynx. If the shank of the knife is so bent, as Lenzmann has bent it, that the ring-knife will readily reach the posterior wall of the nasopharynx, it can not be made to place itself around those adenoid growths that are found back of the septum. D. Bryson Delavan says: "Time and again I have found that in the hands of many operators the Gottstein knife has merely cut through the lower part of the growth, or removed a certain amount on one side, leaving the other full, or has fairly cleaned the vault, leaving abundant deposits on the posterior and lateral pharyngeal walls." Delavan's experience is seconded by that of Dr. George Torrison of this city, who informed me that he has abandoned the operation with the ring-knife, because the results that he obtained with it were imperfect and uncertain. Since he has used the Löwenberg forceps with anesthesia, his success has been perfect in all cases. Where an adenoid mass occupies only the center of the pharyngeal vault it can be removed quite well with the Gottstein knife, even if not to a good depth, but it is obvious that the very important regions just above the Eustachian tubes and the fossa of Rosenmüller can not be cleared by it. A ring-knife that fits into one nasopharynx will not adapt itself to the next perhaps. The operation with the ring-knife is mechanical and depends much on chance for seizing the tissues to be removed, if used as it usually is, without an anesthetic. It can only take growths with a limited base, yet is supposed to do the operation at one sweep. The ring-knife is too large an instrument to apply itself to the nooks and recesses of the unequal surface of the nasopharynx, especially as this differs so greatly as to shape and size. It is a reasonably safe instrument, but might wound the Eustachian prominences. Three cases of prolonged bleeding are reported after the use of the Gottstein knife, by W. A. Martin. The first occurred one and one-half hours after operation, the second twenty-four hours after, the third nine days after. All of the patients lost much blood. There have never been any serious hemorrhages following the numerous operations for adenoid vegetations done with the Löwenberg forceps in the clinics at Rush Medical College; nor have these ever occurred in the private practice of Dr. E. F. Ingals, myself or others using the method. It is probable that the three cases of severe bleeding reported by Martin were due to injury of the lateral wall of the nasopharynx with the ring-knife, as the vessels of the pharyngeal vault are too insignificant to give rise to much hemorrhage, while the lateral walls of the nasopharynx contain large branches of the ascending pharyngeal, the ascending palatine, and

the Vidian arteries. The late occurrence of these hemorrhages can be accounted for by the changes in blood-pressure following operation. The last one, after nine days, was, of course, due to sloughing. As the operation with Gottstein's knife is frequently an incomplete one, recurrences after it are necessarily common. Although I do not use this method, I have seen two cases of recurrence after operation with the ring-knife in which the pharyngeal tonsil was supposed to have been completely removed by distinguished operators, who performed the operation as perfectly and deftly as it can be done. To judge from the literature, about 25 per cent. of the operations with the Gottstein knife are followed by return. Those using that method do not deny that recurrences follow. I state with positiveness that a thorough operation with the Löwenberg and Ingals nasal bone forceps, removes the hypertrophied adenoid tissue for all time. My own experience tells me this, as do our results in the college clinics and the records of the operation in the private practice of Dr. E. F. Ingals, including hundreds of cases, from which no account of a return has come to his knowledge. My knowledge of operation with the Löwenberg forceps has not taught me to "warn any operator that he must not say that his case do not recur," as has been said by Tredell, of Melbourne. Far from it, I can assure him that if he removes the growths completely with the Löwenberg forceps he will positively have no return of the disease, providing he completes the procedure from in front, by removing the adenoid masses commonly found in the posterior nares with nasal cutting forceps. The ring-knife can not possibly reach these pendulous lymphoid excrescences that hang down beside the septum within the nares or fringe the rim of the choanæ. These masses can only be reached from in front, and constitute a very frequent and serious obstruction to breathing. So large are they and so often present that they explain many of the half results obtained with the Gottstein knife.

Adenomatomes need but be mentioned. They are large instruments that operate on the principle of the tonsillotome and can not possibly fit every pharynx, while they can do serious injury on account of their great strength. Their use, and that of the ring-knives, should be confined to operations on adults, and those children where a circumscribed growth can be accurately located. The forceps used for adenoid operations are as numerous as the ring-knives. The Löwenberg forceps is the type of these. It opens laterally, while the Schuetz modification opens from before backward.

A large and a small-bladed pair of forceps are needed for the operation. The mouth is held open with a gag while with a large-bladed forceps the bulk of the growths on the vault is removed with one or two introductions. The small-bladed instrument, following the finger as a guide, clears out the fossa of Rosenmüller and regions above the Eustachian tube, until the finger feels nothing more of the growths. Whatever masses occur on the posterior wall are to be removed thoroughly. Then Ingals' nasal bone forceps are introduced through each nostril, and while the finger in the nasopharynx presses the small masses usually found within the posterior nares against it, these are cut away. Several introductions of the forceps are generally needed. No operation for adenoid vegetations is complete without this last stage of the performance. Though the finger pressed into the choanæ may at first discover no growths whatever, as soon as the bone forceps are pushed through the nostrils against it these polypoid masses are readily felt. They can not be seized from behind without en-

dangering the septum or turbinals. The comparatively roomy and broad nostrils of children, with their small undeveloped turbinals, offer no obstacle to the bone forceps, which must be passed close to the septum and floor of the nose.

The occlusion of the posterior nares is not invariably due to lymphoid growths. The disuse of the nostril is prone to leave the choanæ narrow, the turbinals encroaching on the septum, while partial diaphragms of mucous membrane may be found, especially closing the upper arch of the posterior nares. Where the posterior nares are in this narrowed condition, dilatation with Ingals' nasal bone forceps is needed, with infraction of the turbinals, if necessary, while with the beak of the forceps the occluding edge of mucous membrane can be cut away. It has been claimed that Löwenberg's forceps remove the tissue too deeply, clear to the basilar fibrocartilage. If this were generally true, it would be better than a superficial removal, and could do no great harm, but even a moderately educated sense of touch and sense of the resistance the tissues offer to the forceps will guard against this, as the adenoid masses come away readily, while the fascia offers strong resistance. The septum may be seized or the turbinals be wounded, the posterior lip of the Eustachian tube may be injured, but it takes an unusual degree of awkwardness to do these things, as the operation is done with the sense of touch to guide us, and these structures are constantly being felt by the finger.

The internal carotid artery in the adult is separated from the nasopharynx by intervening dense connective tissue three-quarters of an inch thick, and it is hard to conceive of its being wounded. It is stated that the hemorrhage at the time of operation is greater, as a rule, than with the Gottstein knife, but if so this is only proportionate to the more thorough removal of tissue. We have never had any serious bleeding in any of our cases, showing that the arteries of the lateral pharyngeal wall are safe from anything but unusual clumsiness. The adenoid growths that are found on the posterior wall of the nasopharynx are generally firm and tougher than those in other locations. In removing these, care must be taken not to pull downward, but upward, with the forceps, lest the mucous membrane be stripped from the posterior wall of the oropharynx. After-treatment is not needed. The parts heal best under the protection of an undisturbed blood-clot.

The importance of the subject must excuse the length of this article. It can not be denied that the operation with the ring-knife has displaced all other methods, but it has not done so because of its excellence. The reason for its prevalence is the ease with which it can be done and the fact that its mechanical qualities prevent its demanding especial skill, in fact, many general practitioners are removing Luschka's tonsil with the ring-knife, and the public and they have come to regard the operation for adenoids as a trifling matter. Its proper performance is certainly nothing of the kind, but requires especial skill and an educated touch that only come from frequent digital examinations of the nasopharynx.

It is the placing of an easy, superficial and imperfect operation in the hands of the general operator that tends to bring the operation for adenoid vegetations into disfavor with the public.

DISCUSSION ON PAPERS OF DRs. PIERCE, CORWIN, MORGENTHAU AND FREER.*

DR. E. FLETCHER INGALS—I wish to ask the first speaker

* For papers of Drs. Pierce, Corwin and Morgenthau, see JOURNAL of Nov. 3, 10 and 17, respectively.

(Dr. Pierce), who considered the anatomy, about the location of the pharyngeal tonsil. I believe he stated that it is above the middle of the Eustachian cushion. While I think that in normal subjects this is undoubtedly correct, yet it is very common to find a good deal of adenoid tissue below this plane. I think that there is some hypertrophy of the adenoid tissue below this plane in at least 10 per cent. of the cases. In other words, there are often considerable masses below the plane of the middle of the Eustachian orifice, as in a case that I operated on to-day, where there were large masses on both sides below the plane of the Eustachian orifices.

The importance of the conditions that are often present with hypertrophy of Luschka's tonsils was referred to by the first speaker, and I do not think they can be magnified too much. The question, however, would naturally arise as to whether these conditions caused it, or whether they were caused by it. But, as has been intimated, there are certain conditions, ordinarily known as serofula, etc., or conditions in which children are very miserable, that are immediately relieved as soon as the patients are operated on. We have most of us often seen very great improvement after these operations. It is quite common to see these patients gain from 20 to 30 per cent. in weight and general condition after these operations.

My observations do not correspond with the statement made by the second speaker, that enlargement of the pharyngeal tonsil is not uncommon between the ages of 15 and 20, but perhaps this is only a question as to the exact definition of the word "uncommon;" certainly the percentages of cases between 15 and 20 is small in my experience.

Reference has been made by nearly all of the speakers to the relation between hypertrophy of Luschka's tonsil and tuberculosis, i. e., does tuberculosis cause enlargement of Luschka's tonsil, or does it result from the latter? These are questions of much interest, but upon which we have very little definite information. The fact that in a given number of cases of enlargement of Luschka's tonsil, tubercle bacilli, or other evidences of tuberculosis, are found, does not cut much figure in determining the relation of the one to the other. In 125 autopsies made in the Foundlings' Hospital of New York, tubercle bacilli were found in some of the tissues of the body in every case. In a recent editorial in THE JOURNAL the results are given of 500 autopsies in the Zurich Pathologic Institute by Nägeli, which revealed latent or non-fatal tuberculosis in 97 per cent. of these bodies. If these statements are true—and I see no reason to doubt them—the relationship between an enlarged Luschka's tonsil and tuberculosis is probably merely casual.

I heartily agree with the second speaker about the uselessness of removing all enlarged Luschka's tonsils. I think he said that Bosworth was in favor of removing all enlarged Luschka's tonsils. Some physicians are in favor of removing almost anything that is abnormal. This is artistically correct, but so far as the patient is concerned, I do not think it is the best thing to do unless the abnormality causes some definite inconvenience.

Dr. Corwin spoke of the necessity for a guarded prognosis in cases of deafness, where Luschka's tonsil had been enlarged for a long time. This is correct. It is surprising to see how many such cases of deafness are greatly relieved or absolutely cured within a few weeks by the operation.

The symptomatology of this affection was so thoroughly gone into that I have nothing to add to it.

The last speaker spoke of internal medication, a phase of the subject which is so important that we should give it a little more consideration. There are certain conditions in which I believe it is good policy for the physician to recommend internal treatment. I would not recommend anything from financial policy, but there are many parents who are very much afraid of operations, and who are willing to have almost anything done to avoid them. In such cases, if we recommend immediate operation, the people will be frightened into doing nothing. Such persons should be told that an operation would be the best thing to do, but if we find them strongly opposed to it, it is worth while to give them a chance to try internal medication. While, as a rule, internal medication seems to me mere puttering, yet I have seen a number of cases in which,

after the administration of syrup of hydriodic acid, or chlorid of calcium, there has been a rapid diminution of the glandular tissue to such an extent that an operation did not appear necessary; however, I do not think such treatment would succeed in many cases. If a child is suffering any serious inconvenience from the growth, or if there is much deafness, we are not justified in giving the people any assurance or reason to hope that the affection may be cured by these temporary measures.

Like the last speaker, I have great fear of anesthetics. Although I have never had a death from the use of any anesthetic in these operations, I recall two or three cases in which I have had considerable difficulty in restoring patients to whom anesthetics have been administered. If any anesthetic could be given without danger I should adopt it at once regardless of inconvenience. The plan of giving nitrous oxid gas and following it immediately with ether ought to work well. While in the East recently I saw nitrous oxid gas and ether used in this way. The gas was admitted to the same bag which was afterward filled by ether vapor, so that the inhaler was not removed at any time from the patient's face. The patient came under the influence of the anesthetic rapidly, and it appeared as though the plan was excellent. Dr. Kyle suggested to me the giving of chloroform with oxygen, the oxygen being passed through the chloroform and inhaled with the vapor of chloroform, taken up in the same manner that oxygen which is to be inhaled is passed through water. I have tried this method several times, but the patient's face was so covered during the administration of the anesthetic that I could not feel safe, therefore I am not very favorably impressed with it. I have used chloroform almost exclusively in these operations, although I realize its great danger. Prof. Edmund Andrews, some twenty-eight years ago, read a paper on this subject in which he gave the death-rate from chloroform narcosis at about one in 1000; from ether, about one in 3500, and from nitrous oxid gas, about one in 75,000. Nitrous oxid gas is not a satisfactory anesthetic, for the reason that the patient is very rigid during the period of anesthesia, so that it is difficult to operate satisfactorily. I have not used other anesthetics enough to know about them.

I can not quite agree with the last speaker in the statement that it must require an unusual degree of awkwardness to cut the posterior lip of the Eustachian orifice. With my finger in the nasopharynx, the Eustachian orifice has often felt like an abnormal growth, and I think that physicians with very little experience might deliberately attempt to remove it, even though they were not awkward.

In removing portions of the growth from low down in the pharynx the last speaker said that the biting should be from below upward, to prevent stripping off the mucous membrane. The plan I adopt to prevent this is to hold the mucous membrane with my finger back of the forceps; I rest my finger on the growth immediately before seizing it with the forceps, keeping it there until I catch the growth behind it; I then press firmly with my finger below and back of the forceps in order to prevent any stripping of the mucous membrane as the tissue is cut and pulled away.

DR. J. HOLLINGER.—Dr. Froer said that the operation of adenoids is a difficult one and should be reserved entirely for the specialist. I object to that. This operation is not a difficult one; it is one that the general practitioner should be able to perform. If the Doctor has had much experience in general practice he will know that much more difficult problems confront the general practitioner every day than the removal of the diagnosis of adenoids.

Dr. Morgenthau spoke of high palate and V-shaped maxilla as being connected with adenoids. I would like to call the attention of Dr. Morgenthau to a paper by Dr. Grossheintz, in which he gives measurements of a large number of patients. His statements are not mere speculations or suppositions. He found that high palates and V-shaped maxilla occur in people without adenoids just as often as they do in patients with adenoids.

Although adenoids are very frequent, it is a fact that we know very little about their etiology. Much work has been done to clear up the subject, but few facts have been clearly

demonstrated. Among these facts I would mention that tuberculosis has been repeatedly found in the glands, but not as often as we should think. Hypertrophy of Luschka's tonsil may develop in children who have never had any symptoms of it, after scarlet fever, measles and diphtheria. They are general infections of the organism which have as their first point of invasion the upper air-passages, and may be associated with scarlet fever and measles, and run their entire course in the upper air-passages like diphtheria.

To prove that mouth-breathing alone may lead to adenoids, I will give the following history:

A deaf-mute boy, 11 years of age, had sufficient hearing to lead me to think that he might be educated to talk. He was a mouth-breather. I removed a large hypertrophic Luschka's tonsil. I saw the boy six times during the next ten weeks, and he was always breathing through the mouth. I saw him January 22, and again February 6. At these times he could close his mouth and breathe freely through the nose when ordered to do so. February 20 a good deal of mucus had to be removed before he was able to breathe through the nose freely. Even then the tonsils were not quite free. In the early part of April, four months after operation, I received a letter from the mother stating that the boy had been examined by another throat specialist, who had found a recurrence of the growth. This recurrence took place after a period of perfectly free breathing through the nose of at least twenty-seven days. I believe the persistent mouth-breathing in this case was largely responsible for the recurrence.

A different cause for adenoids was found in the following case: A boy, 10 years of age, was operated on twice during the last two years for adenoids, once in a clinic and another time at the office, by two well-known and capable men of this city. I talked the matter over with the mother for an hour and brought forth these points, which are of interest: The father and mother and two younger children are well and living on California avenue in a seven-roomed flat, second story. In the first story is the saloon of his father. Formerly they lived in the country. The boy always felt well as long as he was in the country, but as soon as he came to the city he started to breathe through his mouth and snore at night. What was the reason for this? The air could not be held responsible because the house of the patient was bordering on the prairie on two sides and there was plenty of space in the flat. Therefore, some other cause had to be looked for. I inquired, besides many other things, into every detail of the diet, as to time of meals, quality and quantity of food, and how it was prepared, and could not find anything abnormal until the boy told me that regularly, when he came home from school, he ate several pieces of hunch which was cut up in the saloon. The otherwise intelligent mother could not see anything wrong in this. But I persuaded her that these sausages are usually made of the poorest kind of meat, and contain an over-abundance of spice. No operation was done. The diet was changed. The boy was placed on syrup of iodid of iron, which I often use in this class of cases as an after-treatment, and in a week a marked improvement was noticed, which kept on. I have seen the boy many times since. I am satisfied that the adenoids had disappeared. He sleeps soundly and now breathes through his nose.

I will mention another case, boy P., upon whom I operated, and during four successive consultations at my office I found him breathing through the mouth, with both nostrils closed up. His sister assured me that he could breathe through his nose in sleeping and in waking. One day I called unexpectedly and found that this was true. At the next consultation in my office I found him breathing again through the mouth. In this case a tight collar was the cause of the suspected recurrence of the adenoids. Leaving it off, the patient was instantaneously cured. A simple compression of the neck by the collar interfered with nose-breathing.

While I do not think I can add anything new to our knowledge of the etiology of this disease, yet every one of these cases has been carefully watched and studied, and I am led to think that we can not attribute the recurrence of adenoids to any one cause, but that every factor has to be considered. The question has been studied quite extensively abroad, as to

the influence of conditions under which people live. Every single case must be considered from a broad standpoint. We may find that the disease is due to trouble in some distant part of the body, and we can only expect to effect complete cures by studying every causal factor. The recurrence of adenoids can not be ascribed to incomplete operation. Of course, if an operation is incomplete and large masses or lumps are left behind, recurrence is almost sure to take place. If, on the other hand, very complete and radical operations are performed, recurrences are not so likely to take place.

DR. EDWIN PYNCHON—As has been granted by one of the essayists, the etiology of adenoids is more or less clouded in obscurity. It has always occurred to me that the condition of moisture in the nasopharynx, and the retention of secretions, have been important factors in exciting the growth of adenoid tissue and causing its recurrence after operation. All of us have observed cases wherein there were undoubtedly present adenoids after a tonsillectomy was done, and yet shortly thereafter shrinkage of the adenoids took place, which simply emphasizes the statement previously made, that impairment of drainage and interference with ventilation incidentally have more or less to do with promoting the growth of adenoid tissue.

As far as the term "scrofula" is concerned, I consider it a misnomer in this connection, and that it is simply a condition of impaired health due to interference with respiration, which is caused by the enlarged Luschka's tonsil. Furthermore, I will say that I consider the intestinal disturbances of infancy and the so-called disturbances of teething as being to a very large extent due to lymphoid enlargement.

Dr. Corwin spoke of nasal deformities as being a possible cause of adenoids. In my opinion the adenoids always precede the nasal deformities.

As regards the matter of measurements, to which Dr. Holinger referred, I would say that Dr. Talbot, of this city, has made as elaborate experiments in this direction as any one, and the conclusion that he has reached is that the high-arched palate is due to the fact that on account of mouth-breathing the child's inferior maxilla is not brought up, so that the teeth of the lower jaw press against those of the upper jaw, and therefore there is a tendency on the part of the teeth of the upper jaw to grow too far downward. This is the rational explanation he makes in regard to high-arched palates.

As regards the question of whether to advise operation or not, we do not very often have patients brought to our attention unless there is something the matter with them. They are complaining in some way, and if I find present either adenoids or enlarged tonsils, I advise operation. I am not ashamed of classing myself with Rosworth, who has been decried as being too radical. I believe it is the proper thing to remove these growths, and in fact that the line of treatment which we, as rhinologists, should generally follow is to endeavor, as far as possible, to cause each nose and throat we treat to assume as nearly as practicable the form of the ideal standard. On this ground, I do not hesitate to advise the removal of tonsils or adenoids in any case which is brought to my attention.

In reference to the recurrence of adenoids, there is no doubt that the tendency to recurrence is greatly magnified by the incompleteness of the operation. If portions of adenoid tissue are allowed to remain, it is perfectly easy for a recurrence to take place. With the use of the Gottstein curette, owing to its shape, it is very easy to see how difficult it naturally must be to completely remove these growths from the nasopharynx. I have experimented more or less with this curette, and I have arrived at the opinion that the ideal curette should not only cut from above downward, but should be so arranged that it can cut laterally. The cuts from above downward will clean the upper part of the space, whereas the lateral cuts will remove that adenoid tissue which may be lower down.

As to the operation under general anesthesia, I have followed the recommendation of Dr. Keen, of Philadelphia, which is to place the patient in the Trendelenburg position, and after having once done so, I have had no desire to return to any of the previous methods of allowing the head of the patient to drop over the end of the table, or anything of that kind.

The mouth-gag is another little matter which I might with

propriety mention. I have recently been using the Ferguson instrument, and have been so well pleased with it that I have sidetracked all the others, including one of my own design.

The danger from the use of chloroform is owing, in my opinion, to the fact that it is often pushed too rapidly. The child holds its breath, and after a while takes a deep inspiration and inhales too large a quantity; consequently death may be said to be due in part to asphyxia.

As regards the use of medicine internally, I believe that its utility is more to improve the general condition than anything else, and it is doubtful whether medicines can be depended on for the correction of the condition; in other words, an operation will finally have to be done.

DR. OTTO J. STEIN—In regard to anesthesia in these cases, it is an interesting point for discussion. I would like to say that nitrous oxid gas has proved very successful in my hands, and I had been using it almost exclusively at my clinic. I started to use it simply because everybody else was using some other anesthetic, and I thought it would be a good idea to use an anesthetic which was a little different from that used by other people. I became enamored with the results I obtained from its use. Of course, there are some drawbacks to the giving and taking of the gas. In giving it a number of assistants are necessary. Then, too, it requires a cumbersome apparatus. As far as the taking of the gas is concerned, I consider it the safest of all anesthetics. Its safety is borne out by statistical reports. Last year I abandoned the use of this anesthetic for the reasons just given, and have since then been using ethyl bromid, but as far as the results in operating are concerned, I think I can get as long anesthesia, contrary to the experience of other operators, from the nitrous oxid gas as I do from ethyl bromid. I have repeatedly done two or three operations under one anesthesia, namely, the removal of the tonsil and adenoids. But, as I have said, it requires a number of assistants to use nitrous oxid gas who are familiar with the operator and who know how to administer it. I must say, that I have not seen the ill effects we get from the other anesthetics in the administration of the gas, especially vomiting, which sometimes follows. Vomiting is less from ethyl bromid anesthesia than in those cases where general anesthetics are used, and I have not seen any signs of danger whatsoever from its use.

With regard to hemorrhage during and following these operations, I desire to refer to it because I have had quite recently a case of hemorrhage, and I believe no mention was made of its treatment in any of the papers or by those who have preceded me in the discussion. Some time ago this subject was discussed in the East, and the suprarenal extract was recommended to be used prior to the operation of adenectomy. There was some discussion as to whether this was advisable or not, and some of the speakers were of the opinion, particularly those who had used the suprarenal extract, that it seemed to promote secondary hemorrhage. I did not use the suprarenal extract in my case prior to the operation, but I did so following the operation with very gratifying success. The case was one in which I removed both tonsils and the adenoids. There was not very much hemorrhage at the time of the operation, but after I left the hospital it seemed to have increased and kept on increasing until I was called by telephone an hour and a half later and was informed that my patient had lost two quarts of blood. I gave instructions to apply ice to the back of the neck and to use the suprarenal extract if the ice did not do any good. Ice was applied for the first fifteen minutes or more, and as there were no seemingly good results from its application, the suprarenal extract was applied, and the interne reported an immediate favorable result.

As to the particular instrument used, in performing this operation, I steadfastly adhere to the various forms of so-called currettes, the Gottstein instrument, or some of its modifications. There are cases, however, particularly in adults with very high vaults, in which I prefer to use a forceps of some kind. I have a modified curette which was made for use on a young woman, probably 18 or 19 years of age, in whose vault I found much difficulty in reaching the mass, after doing the ordinary operation first, and I reached the remainder of the tissue nicely with this instrument. It is probably three

times as long in the bend or angle as the ordinary Gottstein instrument, and is of a much more acute angle.

DR. PIERCE (closing the discussion on his part)—Dr. Ingals, in his remarks, referred to a hypertrophied mass of glandular tissue, while I, in the beginning of my remarks, referred entirely to the normal pharyngeal tonsil. Of course, the line which I drew was empirical in a manner, at the same time I think the majority of pharyngeal tonsils that have not undergone a change will be found above that region.

If I may be allowed a word more, I would say that there are two points that have not been touched on, and which I regard as rather important. First, the diagnostic point that Chiari just referred to, i. e., the mass of adenoid tissue lying on the floor of the nose which can be seen anteriorly. This is a useful point for the general practitioner to remember in diagnosing adenoids. In a great number of cases—I forget the exact number—he found that this mass was always present when hyperplasia of the pharyngeal tonsil existed.

The other point was one brought out by Fraenkel. He reported two cases in the *Archiv für Laryngologie*. They were sent to him for operation. One case had been previously operated on, I think, by some other physician, and the mouth-breathing still persisted. The other case he himself operated on, if I remember rightly, and the mouth-breathing still continued. Examining the cases more carefully, he found that the children were unable to close their mouths on account of a short labial frenum. The lips were kept apart, and the superior upper lip was not only kept away from the lower, but was drawn upward and outward, giving the typical appearance of a mouth-breather. This condition disappeared only on section of the frenum.

DR. FREER (closing the discussion)—I want to say a word or two in regard to placing operations for adenoid vegetations in the hands of general practitioners. I at least have found these operations hard to learn. I do not think that a general operator should undertake to do them any more than that he should attempt an operation for cataract. To my thinking the removal of Luschka's tonsil requires a touch made thoroughly familiar with the parts of the nasopharynx and the abnormalities occurring there, while a knowledge of the anatomy of the parts and of other conditions of disease which may be found in this region is needed and can only be acquired by those who have time and opportunity to devote to their study. Otherwise the result will be imperfect operations, injury inflicted and mistakes in diagnosis, other rarer conditions being taken for adenoid vegetations.

Luschka's tonsil is simply a lymph-gland. What makes lymph-glands hyperplastic? Infection, whether by the tubercle bacillus or streptococci, staphylococci or some other pathogenic microbe. The pharyngeal tonsil is the first lymphatic gland in the group of cervical lymph-glands, and infection first enters here in nasal catarrh or the infectious fevers, as for instance in scarlatina. Infection of the pharyngeal tonsil may be primary with acute swelling of the parts and later infection of the lymph glands of the neck.

The tissue of lymphatic glands is especially prone to sprout, if they are diseased from any cause. We can see this in open ulcers or in open lymphatic abscesses, which fill with unhealthy, fungus granulations. In an analogous way the partly-removed pharyngeal tonsil will form a base for the luxuriant growth of fungus masses which will soon reproduce what has been removed, if it is visited by fresh infections. Considering this tendency of lymphatic tissue to proliferate and form granulation tissue, the only way to treat a chronically diseased lymphatic gland is to extirpate it, so that its remains can not be the source of its reformation. Therefore, the only proper method of operation of adenoid vegetation is their entire removal by any safe means that will accomplish this purpose.

STERILIZATION OF SPONGES.—We notice in the *Nord Medical*, of September 15, a communication which states that hydrogen peroxid—10 to 12 volumes—even diluted three times, effectively sterilizes sponges in a few minutes.

TUBERCULOSIS OF THE TESTICLE.

WITH SPECIAL CONSIDERATION OF ITS CONSERVATIVE TREATMENT.

JOHN B. MURPHY, M.D.

CHICAGO.

(Continued from p. 1279.)

Hemorrhage from the urethra may occur early or late, and is usually not profuse. The blood is passed with the urine, and without obvious cause, in this latter respect differing from the hemorrhage of renal calculus, which is brought on by severe exercise, such as horse-back riding, etc. The source and cause of this hemorrhage are somewhat uncertain, but we believe it is due, as are the symptoms of vesical irritation, to the irritating action of the products of the tubercular process, which are discharged into the prostatic urethra through the vesiculae seminales. This discharge produces a catarrhal condition of the mucous membrane in the posterior urethra and trigone of the bladder, with, in many cases, erosions and superficial ulcerations. That the vesical irritation and hemorrhage are not manifestations of a tubercular process in the bladder and prostate, we are convinced from clinical observation, as in almost all cases in which these symptoms are present, there is an immediate cessation of them after castration or resection of the epididymis, which could not possibly be the case if they were due to tuberculosis of these parts. This rapid subsidence of the symptoms after operation is illustrated in the majority of cases here reported, but strikingly so in one operated upon 10 years ago. In this case the patient was obliged to urinate every 15 or 20 minutes and was entirely incapacitated for his duties as clergyman. Unilateral castration was performed and vesical symptoms disappeared almost immediately. In a letter received several days ago he reports that his weight is now 260 pounds; there has never been a recurrence of the disease or bladder irritability, and since the operation he has worked steadily.

Hydrocele, which is present in about one-third of the cases, may have been the first symptom to attract the patient's attention. It is rarely large, when due to tuberculosis in the epididymis, and there is but little difficulty presented in diagnosis.

At varying intervals from the onset of the trouble softening of the deposit in the epididymis takes place. This, in the acute cases, may be a few weeks, while in the more chronic ones it may not occur for months or even years after the onset. When the abscess is about to rupture, the skin of the scrotum over the fluctuating mass becomes adherent to it, bluish in color, and finally perforates by a small opening, through which the characteristic caseous material is discharged. There is usually no pain attending this process and but little tenderness, except where it is associated with mixed infection, in which event we have all the manifestations of an acute cellulitis. The sinuses formed by rupture of the abscess cavity may be single or multiple, and situated in different parts of the scrotum. They usually remain open indefinitely, and show no tendency to close spontaneously. The amount of discharge is slight.

Hernia testis is rarely seen at the present time, probably because the cases are operated on at an early stage. It is consequent upon the rupture of a tubercular abscess situated in the testicle proper, and consists simply of tuberculous granulation tissue, which is extruded through the opening, forming a fungus mass of greater or less size.

Constitutional symptoms are present in the majority of cases, though they differ greatly in degree. Some patients present the typical tubercular appearance, while others appear to be in perfect general health. In most of the cases, after the process has been present for some time, there is loss of weight and strength, with perhaps some evening temperature, rarely exceeding 100 F., and night sweats.

The sexual desire is usually unaffected, except in the very severe cases, even though, when both epididymi are involved, there may be no seminal discharge during intercourse.

Examination of the patient may reveal the presence of some old tubercular lesions on other parts of the body, such as lupus scars, cicatrices of the neck, or perhaps the evidences of a healed osteomyelitis. In Case No. 10 of our series the diagnosis at first was somewhat doubtful, because of the rapid growth of the testicular

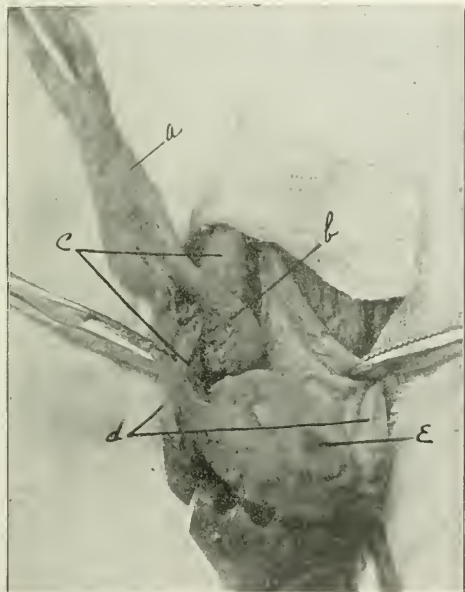

Fig. 11.—Showing epididymis freed from testicle proper. *a*, Epididymis (body). *b*, Globus Minor. *c*, Spermatic artery and veins. *d*, Tunica Vaginalis reflected. *e*, Testicle proper.

tumor, but the presence of a tubercular tendo-synovitis of the hand cleared up all doubt as to its nature.

Rectal examination, for the purpose of ascertaining the condition of the vesiculæ seminales and prostate, should always be made. The seminal vesicles are frequently involved, or if only one is affected, it is more likely to be the one on the side of the affected epididymis. In the early stages the vesicle is soft, swollen, somewhat painful to pressure, and can be outlined throughout its entire length by the examining finger. Later, nodules develop in it, and it presents a very irregular shape, hard, with, perhaps, fluctuating areas in different parts. When both are affected, they can be plainly felt converging toward the prostatic urethra.

It is more difficult to determine tubercular disease of the prostate, especially in its early stages, because the process is usually situated deep in the substance of

the gland. In the early stage of the prostatic disease the gland may be somewhat swollen and tender to pressure, while later, when the process is farther advanced, it may be nodular, and present fluctuating areas. Either lateral lobe may be affected singly, or if the entire gland is involved, it may be more advanced on one side than on the other. The inguinal lymph-glands are rarely involved in tubercular disease of the testicle.

Uranalysis.—The condition of the urine will depend on the stage to which the disease has advanced. Usually when the patient presents himself for treatment small quantities of pus and blood will be found in the centrifuged specimen. By staining the pus for tubercle bacilli they can usually be demonstrated, although almost always in very small numbers. It is of great importance in searching for the bacilli to use special staining methods, so that the smegma bacillus will not be mistaken for the tubercular germ. Various processes for differentiating these two organisms have been proposed, the most reliable being that of Bunge and Trantenroth, which consists of extracting the fat from the bacilli by allowing the preparation to remain for three hours in absolute alcohol, then treating it for fifteen minutes with a 5 per cent. solution of chromic

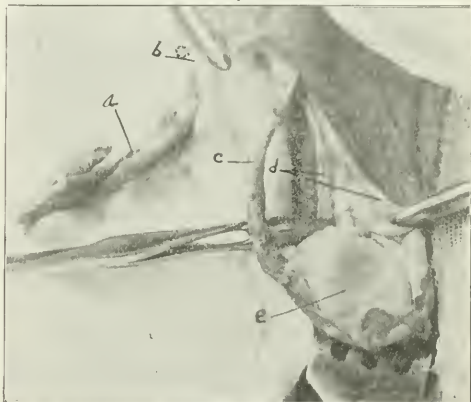

Fig. 12.—Showing entire epididymis free from testicle proper and vas isolated. *a*, Epididymis. *b*, Vas deferens. *c*, Spermatic vessels. *d*, Tunica Vaginalis (reflected). *e*, Testicle proper.

acid, and washing in several changes of water. The preparation is then to be stained with carbol-fuchsin, destained in dilute sulphuric or pure nitric acid for one to three minutes, and further destained and at the same time counterstained, by immersing in a concentrated alcoholic solution of methylene blue for five minutes. By this means the tubercle bacilli retain the stain, while the smegma bacilli become decolorized. Soudan iii, in saturated alcoholic solution, may also be used for differentiating the two.

Complications.—The routes by which extension of the tubercular process takes place are at present the subject of much dispute, many authors claiming that the disease exists primarily above and extends downward to the epididymis along the surface of the mucous membrane, extension, therefore, in an upward direction not taking place. As stated above, it is our opinion that the primary focus is in the epididymis, and that subsequently extension takes place along the lumen of the vas to the vesiculæ seminales, prostate, and in a few cases to the bladder, ureters and kidney.

Jacobson says that after the disease localizes itself in the epididymis it may spread by way of the lymphatics, but this is a very rare exception to the general rule. That it may in rare cases extend by the lymphatics is shown in Sommers' case (quoted by Senn) of a man, aged 36 years, who suffered from tuberculosis of both testicles. The retroperitoneal glands became involved, and later pulmonary tuberculosis developed. In this case the testes were primarily affected, the epididymis remaining free from disease throughout.

Pott's disease of the spine has frequently been observed to follow tuberculosis of the testicle, and this, as well as the cases of general miliary tuberculosis which occasionally develop, must be explained by dissemination of the infectious material through the blood-stream.

DIFFERENTIAL DIAGNOSIS.

In acute cases, where the symptoms come on suddenly and with great intensity, the diagnosis from gonorrhoeal epididymitis may, at first, be difficult. The principal points to be considered are:

1. The presence of an active gonorrhoea, the discharge of which may have suddenly disappeared just before the onset of swelling in the epididymis.

2. Examination of opposite epididymis, vesiculae seminales and prostate shows absence of nodules.

3. Previous history of patient. In tubercular disease there is frequently a history of recurring mild attacks of epididymitis, or enlarged cervical glands in childhood, osteomyelitis, etc. These are more likely to be absent in the gonorrhoeal cases.

4. Occasionally it may be impossible to make an immediate diagnosis, and in these we must await further developments, which will occur after the acute swelling has subsided. The tuberculin test might be valuable here, and in all cases where a urethral discharge is present a bacteriologic examination should be made.

Syphilis.—This disease may affect either the testicle proper or the epididymis, or both, in which latter case they are simultaneously involved.

Syphilis of the Epididymis.

Tuberculosis of the Epididymis.

- | | |
|---|---|
| 1. Infrequently localized. | 1. Frequently localized. |
| 2. Diffuse or nodular enlargement, usually the former. | 2. Usually nodular. In most cases begins in globus minor, but may commence in globus major. |
| 3. Epididymis not sensitive to pressure. | 3. Almost always some tenderness on pressure. |
| 4. Almost always painless. | 4. Usually slight aching pain after exercise. |
| 5. No thickening of the spermatic cord. | 5. Spermatic cord frequently thickened and nodular. |
| 6. Vesiculae seminales not involved. | 6. Vesiculae seminales may be nodular. |
| 7. Usually no vesical symptoms. | 7. Almost always symptoms of vesical irritation and frequently hemorrhage. |
| 8. Rapid disappearance of lesions under KI and mercury. | 8. Antisyphilitic remedies have no effect. |
| 9. Frequently evidence of syphilis elsewhere in the body. | 9. No such evidences; may be signs of old tubercular lesions in the lungs, glands, etc. |
| 10. No tubercle bacilli in the urine. | 10. Tubercle bacilli may frequently be demonstrated in urine. |

Syphilis of Testicle Proper.

Tuberculosis of Testicle Proper.

- | | |
|--|---|
| 1. Usually begins in the body of the testicle. | 1. Body of testicle never primarily affected. Always secondary to epididymitis. |
|--|---|

- | | |
|---|---|
| 2. Usually diffuse involvement, rarely circumscribed. | 2. Disease nearly always circumscribed, having extended from the hilum. |
| 3. Sinuses rarely present, and if they do exist, usually last but a short time. | 3. Sinuses more common, and they persist indefinitely. |
| 4. Fungating form quite common. | 4. Rare. |
| 5. Usually definite history of primary and secondary manifestations. | 5. No such history. |
| 6. Yields promptly to anti-syphilitic treatment. | 6. No effect from anti-syphilitic treatment. |

Sarcoma and carcinoma are anatomically two distinct and separate diseases of the testicle. Clinically and practically, however, from the standpoint of diagnosis and treatment, they may be considered as one.

Malignant Disease of the Testicle.

Tuberculosis of the Testicle.

- | | |
|---|---|
| 1. Usually begins in the body of the testicle as a hard, smooth swelling, which later becomes soft. | 1. Tuberculosis always begins in the epididymis as a nodular enlargement. |
| 2. Growth is very rapid, except in the rare scirrhus form. | 2. Growth is slow. |
| 3. May attain a very large size. | 3. Never attains great size. |
| 4. No inflammatory symptoms present during rapid growth. | 4. Usually some inflammatory manifestations, which may be violent, if mixed infection takes place. |
| 5. Veins of scrotum enlarged and prominent. Skin thin and dark colored. | 5. Veins not enlarged. Skin, if affected, is thickened and adherent to the epididymis. |
| 6. Tumor not tender to pressure. | 6. Nodules usually tender. |
| 7. Vesical symptoms not marked. | 7. Vesical symptoms always prominent. |
| 8. If fungating, the ulcerated mass bleeds in a characteristic way. | 8. Ulcerating surface has no tendency to bleed profusely. |
| 9. Cord is much more often enlarged and swelling is smooth and even. | 9. The cord is nodular and hard. |
| 10. Glands above and below Poupart's ligament may be involved. | 10. Almost never involved. |
| 11. May be metastatic tumors in lungs, abdomen, etc. | 11. Sometimes evidences of old tubercular lesions elsewhere, as lupus scars, cicatrices in the neck, etc. |
| 12. No tubercle bacilli in urine. | 12. Bacilli often present. |

In fibrous induration of the epididymis, due to some previous acute or subacute inflammation, the epididymis, while hard and thickened, is not usually nodular, history of the case is entirely different from that of a tubercular disease.

Of the benign tumors of the testicle, fibromata, enchondromata and osteomata are of such rare occurrence that they need not be considered in the differential diagnosis. Enchondroma and osteoma are sometimes secondary developments in sarcoma, adenoma and myxoma. Myomata have been described, but are very rare.

Adenomata, when they undergo cystic degeneration, may have to be considered in making the diagnosis.

Hydrocele usually presents no difficulty in diagnosis, but it must be remembered that it is often a part of the tuberculosis of the epididymis and testicle, as is serous pleural effusion of pulmonary tuberculosis.

Prognosis.—In tuberculosis of the testicle the prognosis depends upon: 1, the age of the patient; 2,

whether the infection is simple or of a mixed character; 3, the location of the primary focus of infection; 4, whether or not other portions of the genito-urinary tract or more distant parts of the body are involved.

The prognosis in children in localized disease of the epididymis, or even where it has extended into the testicle proper, with or without mixed infection, is usually favorable. Encapsulation takes place in the majority of cases without pus infection, and a portion of the testis is preserved. Even where secondary infection has taken place and the abscess cavity discharged externally, we can always hope for the preservation of at least a small portion of the glandular structure.

This tendency in children to encapsulation and limitation of the process is the same as that observed in tuberculosis of other organs in them, with the exceptions of tubercular meningitis and, to a lesser degree, osteomyelitis.

In adult cases many complications are apt to develop, and it is on these that the prognosis will in large part depend. The most important are: 1, abscess formation with resulting sinuses of the scrotum; 2, involvement of the seminal vesicles and prostate; 3, tuberculosis of the bladder (rare). In addition to these we may have foci develop in any other part of the body, and even general miliary tuberculosis has been known to follow a primary lesion in the epididymis. Whether the affection of the seminal vesicles or prostate precedes or follows the testicular disease or not, the clinical fact remains the same, the removal of the testicle or epididymis causes, in a large percentage of the cases, a complete subsidence of the vesical and prostatic symptoms, and a healing of the tubercular process in these parts. From the symptoms presented by some of the patients who have come under our care, it seemed certain that the tuberculosis had extended to the mucosa of the bladder, but on removal of the diseased testicle or epididymis they entirely subsided. While the prognosis is favorable in prostatic and seminal vesicle involvement, it is distinctly unfavorable when the disease has extended to the bladder. In these cases it very frequently further extends to the ureters and kidneys, and the patient soon succumbs to renal or general miliary tuberculosis.

If the epididymis, which is primarily affected, be removed early, it is probable that the other testicle will not become involved. Should it, however, become implicated, the urinary and vesical symptoms will recur and bacilli will again be found in the urine.

As regards life, Jacobson says: "It is to be looked upon as, if left to itself, an ultimately fatal disorder." This, we believe, is an exaggeration, and is by no means invariably the case, as in some the process becomes encapsulated and remains so throughout life. Even where both testicles are involved and discharging sinuses present, the general health may remain good indefinitely, as in a case reported by E. Albert of ten years' standing.

Tubercle bacilli can, in some cases, be demonstrated in the semen, and in this way infection may be transmitted to the female. It is interesting to observe that Jäckh found tubercle bacilli in the semen from healthy testicles in cases of pulmonary tuberculosis.

Treatment.—This may be divided into 1, palliative; 2, radical.

Under palliative treatment we recognize, *a*, rest; *b*, support to the diseased organ; *c*, constitutional treatment; *d*, the various injection methods, with iodoform, chlorid of zinc, etc.; *e*, the method recently advocated by Mauclair, which consists in excising a section of the spermatic cord between two ligatures.

Radical treatment may be, *a*, orchietomy; *b*, epididymectomy, either partial or complete, with excision of a part or whole of the vas deferens; *c*, incision and drainage, with or without curettage or cauterization with the thermocautery, chlorid of zinc solution, etc.

The disease in children, as before stated, has a tendency to rapid encapsulation, circumscribing the process to a local caseous nodule in the globus major or minor or, in some cases, even extending into the mediastinum testis, but occasionally there is complete destruction of the epididymis and glandular portion of the testicle proper, nothing remaining after a time but an abscess cavity. In children, too, there is a much greater likelihood of mixed infection than in adults, and it is this which usually causes the rapid destruction mentioned above. Felizet years ago made the statement that in acute genital tuberculosis of children castration is the only operation to be considered, and this statement has never been contradicted. (Longuet.) If suppuration, with destruction of the testicle, has already taken place when first seen by the surgeon, incision and drainage may be the only operation necessary. Early incision and drainage, without curettage, is urgently indicated in children where secondary infection is present to prevent the destruction of the glandular portion, which may take place without it. The rule is, in infants and children, that no radical operation is indicated, and the treatment of these patients should be the same as for tuberculosis of the lymphatic glands, namely, syrup of the iodid of iron, cod-liver oil and calcium lactophosphate. Epididymectomy is practically never called for.

The course of the disease is so varied in adults, from an acute inflammatory process to a chronic indolent, almost painless one, that the palliative treatment of each case will depend on the peculiarities presented. Rest and support are of the greatest importance, as is also the constitutional treatment, which is indicated in all cases of tuberculosis, wherever situated. This consists of an abundance of fresh air and sunshine, moderate exercise, plenty of fats in the food and cod-liver oil. Changes of climate and scene, on which so many authors have laid stress, are probably of no great importance.

If there is no mixed infection and no fistula present, iodoform and zinc injections are absolutely contraindicated, and really have no place in the treatment of this disease. They are uncertain, and while, in a few cases, they seem to have been followed by good results, the procedure is not rational.

The method of treatment advocated by Mauclair in his recent paper has not as yet been tested in a sufficient number of cases to say whether or not it will have a place in the treatment of tuberculosis of the epididymis and testicle. It is certainly not radical, and does not seem to be rational if, as he says, the testicle will be nourished by blood-vessels from the tunica vaginalis, after ligation of the spermatic cord. He, however, has noted disappearance of the nodules in several of his cases, and in almost all of them a subsidence of the vesical symptoms, and healing of the lesions in the vesiculae seminales and prostate.

(To be continued.)

RHUS FOR INCONTINENCE IN CHILDREN.—The *Gaz. Méd. Belge* quotes Perlis to the effect that rhus aromatica is a certain cure for incontinence in children. He has never known it to fail in his own or others' experience, which includes 156 cases. He prescribes 15 to 60 drops a day fractioned.

SATURDAY, NOVEMBER 24, 1900.

THE SYMPTOMATOLOGY OF FACIAL PARALYSIS.

The facial nerve may be involved in disease at any point between its cortical representation about the inferior portion of the central fissure and its most peripheral distribution, and the symptoms will vary accordingly. A lesion above the facial nucleus in the medulla oblongata will be attended with loss of power in the muscles on the opposite side of the lower part of the face, the occipitofrontal and the orbicular of the eyelids and the corrugator of the brow usually escaping; paralysis is not marked and degenerative electric reactions are not present. There is likely to be, besides, paralysis of the extremities also on the opposite side. When the lesion is situated in the nucleus or in the root or the trunk of the nerve, the palsy will be situated on the same side, and will be flaccid and atrophic in character; and the occipitofrontal and the orbicular of the eyelids and the corrugator of the brow are likely to be paralyzed in addition to the other facial muscles. In accordance with the exact location of the morbid process, the auditory nerve, the intermediate nerve of Wrisberg, the cerebellar peduncle, the pyramidal tract, and the abduccens nerve, may also be involved, with the production of deafness, loss of the sense of taste, vertigo, forced movements, hemiplegia of the opposite side, and paralytic convergence of the eye on the same side, respectively. Not rarely sensory and vasomotor disturbances are present on the affected side of the face.

In a case of poliencephalitis attended with facial palsy reported by Oppenheim¹ it was found at a late stage of the disease that on stimulation of the healthy facial nerve with weak electric currents, a contraction occurred in the muscles of the lips, chin and brow, on the opposite or paralyzed side, even when current-strengths were employed that were insufficient to cause contraction of the muscles on the sound side, and were entirely without effect on direct stimulation of the muscles and nerves on the opposite side. This contralateral contraction occurred only in muscles close to the middle line, and was attributed by Oppenheim to innervation of the paralyzed muscles by the healthy facial nerves of the opposite side, as a result perhaps of the outgrowth of new branches from this nerve. Bernhardt,² however, dissects from this explanation, having observed that direct or indirect stimulation of the chin-muscles of

the healthy side is attended with active contraction of the paralyzed muscles on the opposite side, although the reaction fails to occur when weak currents are employed. He endeavored to explain the phenomenon on a peculiar anatomic arrangement of the muscles of the chin. According to his statements, the upper, inner angle of the depressor of the lower lip interdigitates, as the continuation of the platysma myoides, with the corresponding angle of the same muscle of the opposite side. In addition, some deep bundles of this muscle unite with the opposite elevator muscle of the upper lip. Further, fibers are said to pass beneath the chin, across the middle line, between the depressors of the angle of the mouth of either side.

For the purpose of deciding which of the two views expressed is the correct one Mohr³ studied four cases of facial paralysis, one of long standing and the others of more recent development. In the first he found the reaction described by Oppenheim well marked, and in one of the others it was partially developed, while in the remaining two it was not present at all. Nor was the reaction obtained in eight patients with healthy facial nerves. This evidence is believed to support the contention of Oppenheim and to oppose that of Bernhardt, and the increased electric irritability of the paralyzed muscles is thought to be due to the greater sensitiveness of the newly developed nerve-fibers.

All of these observers seem to be wholly ignorant of the fact that a similar phenomenon was observed many years ago by Weir Mitchell,⁴ both in health and in disease. "I have noticed," says Mitchell, "that in faradizing the chin or lips near ($\frac{1}{4}$ in.) the middle line, the muscles on the other side of the face, and nearest the mesial limit, may be made to contract. This is best seen in a face where, owing to unilateral facial palsy, the muscles of the diseased side do not themselves stir with the current; but it is also to be seen in health, although the muscles immediately under the conductors are apt, by their normal movement, to mask that of the muscles across the middle line. Far more interesting are the results obtained when we use a constant current, and when the patient is a case of complete unilateral face-palsy. When such a case occurs, as we all know, the power to stir the palsied muscles with induced currents fades, and at last ceases, and the response to constant currents becomes unusually good." At first the movement was supposed to be due to reflex disturbance through the centers, but this view was soon abandoned, as it was found that galvanism of the sound nerve-trunk under the ear, while competent, if powerful, to move the sound muscles, did not stir those of the paralyzed side; and besides, the affected nerve was incompetent to transmit the reflected impression. It was concluded, therefore, that the movements caused were due to the action of currents induced between

² *Ibid.*, 1899, p. 673.

and beyond the two poles, and that these were enabled to excite the palsied muscles because of the acquired sensitiveness of these latter. Some experiments undertaken by Professor Barker, of the University of Pennsylvania, on the request of Dr. Mitchell, appeared to sustain this explanation.

INCREASED INTEREST IN MEDICAL EDUCATION.

One of the most hopeful signs for the future of medical education in this country is the increased interest in professional education in general taken by college presidents and trained educators. We hear from time to time that presidents of large universities more or less unconsciously find themselves especially deeply engrossed by the interests of the medical departments in the institutions under their charge and by the large and important problems of medical education as a whole. Various factors are at work in favor of medical education from this point of view. The purely pedagogic aspect of medical education has been much neglected until within recent years. The olden custom of fixed courses of annual lectures repeated with recurring regularity as to all details, including the stories, did not offer much of a field for the application of the best principles of the science and art of teaching. The introduction of laboratory teaching changed this, and to-day there is a widespread departure from the medical curriculum of former years, the change in many instances being of so radical a character as to constitute a virtual revolution. Naturally such developments would attract the notice and enlist the interests of professional educators.

In the next place, the constantly increasing requirements for admission to medical study have brought the college and the medical school into closer relation, because so many of the students now enter the medical school by way of the college. In many cases colleges and universities have arranged specially adapted pre-medical courses, which have become popular. It has been found that certain branches of study formerly pursued exclusively in the medical school, such as chemistry, bacteriology and physiology, to a certain extent could be taught with greater advantage in the college. This has brought up for discussion the relations of the collegiate courses to the medical courses with quite uniform general results of mutual benefit.

And finally the relation of the strictly collegiate course, the preparatory training in general, to the medical and other professional training has been placed on the tapis and constitutes at the present one of the most important subjects for discussion in academic circles. Much thought is given to the wise adjustment of the various departments of education so as to make each best suited for its specific purpose. Hence, the advantages of the medical department of a large university over the isolated medical school become apparent in a striking manner. In his recent book on "College Administration," President Thwing, of Western Reserve

University, emphasizes especially the grave importance to American society of the movement toward a general improvement of professional education. The need of the hour is not more doctors or more lawyers, but better ones. It is gratifying to find such a student of education in America as President Thwing conclude that "the next movement in the endowment of American education should be directed toward the schools of law and the schools of medicine." The increased public and special interest in medical education will surely redound to the material advantage of medicine.

ENLARGEMENT OF THE SPLEEN IN INTOXICATIONS AND ACUTE INFECTIOUS DISEASES.

Acute enlargements of the spleen are of much clinical importance. In typhoid fever swelling constitutes one of the foundation stones on which the diagnosis is based. What then may be the cause or causes of the enlargement that is so commonly observed? At the outset it may be put down that in all likelihood there is no one factor, but several, operating probably in different ways, underlying the changes which lead to splenic intumescence. Of the numerous hypotheses advanced from time to time in explanation of this phenomenon, none has received general acceptance. As pointed out by Jawein,¹ malaria, typhoid fever, septic diseases and other conditions in which splenic swelling is usually well marked, all have this in common, that they are associated with destruction of red blood-corpuscles.

From this viewpoint Jawein planned several series of experiments with substances that destroy red corpuscles when introduced into the body. Intoxication with the chlorates of potassium and sodium, and with toluylendiamin, was found to give rise to an increase in the size of the spleen that corresponded accurately enough to the diminution in the red corpuscles; the disintegrating corpuscles are taken up by the cells in the splenic pulp, which enlarge and multiply, and this is associated with active hyperemia of the spleen. These results tally well with the observations recorded in the literature. Splenic swelling does not occur in those intoxications in which there is no destruction of the red corpuscles. It appears that the products of corpuscular disintegration exert a direct stimulus on the cells of the splenic pulp and cause an increased functional activity in these cells. Hyperemia and cell multiplication result. This is a simple, tangible explanation borne out fully by the data at hand. The finer mechanisms through which these changes are brought about under these circumstances as yet elude exact exposition; we know too little concerning the fundamental physico-chemical laws of cellular function and proliferation. What has been stated in regard to the relation between various poisons and splenic swelling also seems to hold good with respect to infectious diseases. Those infectious diseases in which there is no enlargement of the

1. Virchow's Archiv, 1900, clxi, 161-507.

spleen show but little diminution of red corpuscles.

The facts bearing on these points are carefully analyzed by Jawein. It is to be remembered that in some of these diseases there may be more or less simple anemia without swelling of the spleen, but in diseases of that character it does not concern actual and excessive destruction of red corpuscles as much as a diminished regeneration of the corpuscles. This is probably the case in tuberculosis and in malignant tumors, in which there is often marked anemia and but little or no splenic swelling. Jawein's experiments and deductions consequently favor a simpler and more direct explanation of swelling of the spleen. Should this view obtain general acceptance, new light would be thrown also on the functions of the normal spleen. An organ that takes the products of corpuscular dissolution in pathologic states is indeed very likely to be directly concerned in removing from the blood corpuscles that go to pieces under physiologic conditions.

ALLOXURIC BASES IN NEPHRITIC CARDIOVASCULAR CHANGES.

Xanthin and hypoxanthin are representative members of the group of alloxuric bases which occur in the urine normally and whose formation and retention are increased in many morbid conditions. They are held by some to play an important part in the causation of many gouty manifestations. Croftan¹ reports that repeated injections under the skin of rabbits of weak, alkaline solutions of xanthin and hypoxanthin produce a typical nephritis, increased arterial pressure and endarteritis—in two cases distinct arteriosclerosis—with hypertrophy of the heart. Should these results be confirmed, an important addition to our rather scanty knowledge concerning the real cause of arteriosclerosis may come from studies along these lines. Abnormal metabolism with increased production of alloxuric bases, as well as renal lesions of whatever character that would lead to retention of alloxuric bases, may be found to play the essential part in production of arteriosclerosis and its consequences.

YELLOW FEVER IN CUBA.

The prevalence of yellow fever this year in Havana has excited some comment and has often been referred to as discrediting the efficacy of the sanitary work done there since the American occupation. In a recent communication to a New York paper, Dr. L. C. Carr, of the United States Army, calls attention to the error of assuming that conditions at Havana are the same as regards this disorder as in other parts of the island. According to him, the eastern section of Cuba has been notably free from the disease this year. In the provinces of Santiago and Puerto Principe, comprising nearly half of the island, there have been so far only four or five cases—in 1900: three at Nuevitas, one at Santiago, and one at Gibara. Two at least of these were rather dubious as regards diagnosis. Since yellow fever has in the past been endemic in Santiago, it would certainly seem that the measures initiated by

Governor Wood have been effective there. It is not difficult to believe that the greater influx of non-immunes is one cause of the present prevalence of the disease in Havana. They are largely Spanish immigrants and presumably of a class that are not especially regardful of personal health-regulations; it is possible, moreover, that there are other local conditions that are responsible to a greater or less extent.

THE NOBLE GOVERNOR THOMAS.

THE JOURNAL has once before taken notice of the present erratic governor of Colorado, and then it was because of his peculiar stand as regards the medical-practice act passed in that state. His position at that time was one that did no honor to his office or to the constituency that chose him for it, but it was possibly explainable by assumed intellectual defects in his make-up. His veto message reads like the production of a quack—a quack is a fraud, but he may possibly be more of a fool than a knave. No one would expect wisdom from that source, but the facts did not absolutely exclude the possibility of common decency and humanity. Recent events, however, have still further developed his character, and if the facts are truly told there is little room left for charitable surmise. An executive who will deliberately allow a man to be given up to torture, however great his crime may have been, and then plead his legal inability to do otherwise, is fit for more than mere contempt; he deserves the highest punishment for his participation before the act in a most abominable violation of the highest organic law of the land. Unfortunately, the most he and the guilty lesser officials are likely to receive will be to go down in the history of their state and country as worse than cowardly participants in a crime that disgraces the age as well as the community and the state. As a hater of the medical profession we had ranked Governor Thomas with quacks—we would now hesitate to rank them with him.

AGGLUTINATION OF TUBERCLE BACILLUS.

In certain infectious diseases the serum acquires the power of agglutinating the infecting microbe. Applied with practical success in typhoid fever, Arloing, Courmont and others have endeavored to make this test serviceable also in the diagnosis of tuberculosis. A prime requisite for this purpose is homogeneous cultures in which the bacilli are disseminated uniformly, because in cultures on the usual media *B. tuberculosis* is aggregated into dense masses and clumps. Much work has been given to this end. Arloing and Courmont succeeded quite well by means of cultures on potato-soaked in glycerin-water; subcultures on glycerin-bouillon were quite homogeneous, frequent agitation being essential, however, to maintain the even dissemination of the bacilli in the culture-medium. By the action of the serum of tuberculous patients on such cultures the agglutinating reaction has been obtained with a fair degree of constancy. Buard¹ reports success in several instances of tuberculosis not otherwise demonstrable. In fact, the reaction is said to take place in a ratio inverse to the intensity and rapidity of the infection, being less intense and constant the more advanced the cachexia.

¹ *Am. Jour. Med. Sc.*, 1900, cxx, 592-97.

¹ *Jour. de Phys. et Path. Gen.*, 1900, ii, 797-803.

Buard comes to the conclusion that the serum reaction is really one of the best means of demonstrating the tuberculous infection. The method is therefore thought worthy of trial, especially with a view to rendering it easier of practical application so that it might become available for more general use.

MEDICAL COLLEGE ENDOWMENTS.

Endowments to medical colleges have been in the past among the rarest events in this country; not half a dozen institutions have received any considerable sums, and very few anything at all. It would seem, however, that there is possibly a turn in the tide and that of the many liberal donations poured out for the benefit of almost every kind of public institution some may flow in the channel of medical education. We recently noted the generous gift of Dr. Senn to Rush Medical College. We have now to report those of Drs. Quine and Steele to aid respectively in the support of the medical library and pathologic laboratory of the University of Illinois, in other words, the College of Physicians and Surgeons. That these come from members of its own faculty makes it none the less a welcome sign. It shows the interest that these physicians have in the institution with which their names have been connected from the beginning. There are few who appreciate what the medical profession does for the public good. Were it generally recognized and compared with that portion of its work as proves actually remunerative, it would be universally admitted that of all professions it is the altruistic one *par excellence*. There is no other, not even the clerical, that compares with it in this respect. That the public does not appreciate the fact really makes very little difference. An account is kept of it somewhere and in the long run it will be credited up. There are not many physicians, however, even in the large cities that are able to give large gifts, but there are many public-spirited men who only need an example to set them in the right way. With endowed medical colleges we will have progressed a long step in the way of advancing medical education and medical science, but we do not believe it is in the order of things that the endowment should come entirely out of the medical profession itself.

THE STERILIZATION OF CATHETERS.

The danger of infection from the use of catheters and the difficulty at times in sterilizing them are so well known as not to require elaboration, and any method that promises to obviate these conditions will be given a cordial reception at the hands of surgeons. The problem is a simple one in the case of metallic instruments, as these can be readily, effectively and promptly sterilized by heat; but the difficulty has been especially with the silk, cotton, and rubber catheters, which do not tolerate well the action of high temperatures, as well as of the most efficient disinfectants. Influenced by these considerations, Katzenstein¹ was led to devise a method by means of which it is possible with the aid of formaldehyde vapor to sterilize catheters thoroughly in the course of from ten to twenty minutes. For this purpose an apparatus was constructed con-

sisting of two main parts, one a shallow chamber for the generation of the disinfecting vapor, and the other a repository for the catheters. The former was provided with a detachable, vertical cover in front, while the opposed wall is perforated by a number of openings, which can be closed by slides and terminate posteriorly in cylinders cut with screw-threads for the attachment of the catheters. This chamber is air-tight, in order that the gas generated can escape only through the catheters, and from its posterior wall project shoulders intended for the support of wire shelves for holding the catheters. The second part of the apparatus consists in an extensible chamber provided with openings through which the formaldehyde vapor can escape after it has passed through and over the catheters. Sterilization is effected by exposing three grams of trioxymethylene—polymerized formaldehyde—in the smaller chamber to the temperatures of from 70 to 80 C. for from ten to twenty minutes. The temperature in the repository for the catheters is only from 30 to 40 C. The movement of the formaldehyde vapor is favored by introducing into the openings out of the vaporizing chamber phenylhydrazin, which has a strong affinity for formaldehyde and absorbs the vapors that are so irritating to the respiratory tract. It was found that catheters could be made absolutely sterile by means of this apparatus in the course of ten minutes, and without suffering any injury. As a precaution, the instruments should be vigorously rubbed with sterilized gauze before they are used, in order to remove any possible traces of adherent formaldehyde and they should be thoroughly flushed with water after being used.

THE DANGERS OF HYPNOTISM.

In reply to a question of a correspondent of the *International Journal of Surgery*, Dr Robert T. Morris, of New York, who it appears has had some reputation as a user of hypnotism, gives a brief summary of his views as deduced from his experience with the agency. He says hypnotism should be employed with more caution than we observe in giving chloroform or ether; it seems to weaken the subject's resistance to external impressions for a long time—it may be permanently—and the incautious hypnotizer may be the cause of seriously impaired will-power. When he first took up the subject he found it so easy to hypnotize children and a large majority of adults that he was tempted to employ the method frequently for minor operative work, headaches, etc. He observed later that hypnotic subjects had an uncanny tendency to react to the slightest suggestion of any one who hypnotized them, and he did not care to stand in such relation to other people. As he says, he prefers logical methods in his dealings and does not like to be in the presence of a weak will, fearing that his influence may not be best for the individual. There are probably many conscientious physicians whose experience has been similar to that of Dr. Morris, and who have like him practically abandoned the use of hypnotism. There is a real peril in the pathologic subjection of the will by this agency; it may seriously affect the future of the patient and the chance of this, even though it may be a remote one, should be seriously considered. The possibility of in-

1. Berlin. klin. Wochenschr., 1900, No. 37, 818.

convenience to the hypnotizer is also a real one, but is a secondary matter. Hypnotism is, as Dr. Morris says, "a dangerous resource," and its reckless use and recommendation by enthusiasts and injudicious operators is a matter to be deplored and discouraged by the medical profession. It has really very little value in it to the medical practitioner, but it will always be a method of the charlatan and the impostor, hence its associations are neither agreeable nor beneficial. Even the legitimate use of suggestion has its possible dangers, though they are comparatively insignificant; but those of full-fledged hypnotism are real and more than merely possible, they are probable in a certain class of cases. The therapeutic value of its methods is at best limited to very special cases in which they should be employed only with the greatest circumspection. The fact that they have been used and recommended by a few high authorities does not alter the fact that the result of any extensive adoption of them would probably be only the useless production of a lot of more or less damaged brains.

Medical News.

CALIFORNIA.

MEDICAL OFFICERS at the Presidio General Hospital are to have six new houses for their quarters, built near the hospital.

THE DEATH-RATE of Sacramento for October was 11.20 per 1000 per annum. Only one case of contagious disease was reported.

RIVERSIDE NEW COUNTY HOSPITAL was inspected by the board of supervisors on November 10, and accepted. The hospital will be opened in about two weeks.

THE DEATHS in Los Angeles for October exceeded the reported births by 35. Consumption caused 32 deaths. During the month 44 cases of contagious diseases were reported.

THE GERMAN HOSPITAL, San Francisco, is to cost \$250,000, and architects have been invited to submit plans in competition for money prizes amounting to \$4000. The buildings will accommodate 200 patients, and will include a main building, isolated consumption, service and administration buildings.

COLORADO.

THE OURAY HOSPITAL profited to the extent of \$1000 by the fire which closed on November 5.

VACCINATED CHILDREN only will be admitted to the Denver school where smallpox was discovered a few days ago. To obviate similar trouble in future physicians have been notified to report hereafter every case of chickenpox to the health department.

THE TRUSTEES of the National Jewish Hospital for Consumptives at Denver perfected their organization, elected a board of managers and decided to establish a bureau in each large city, where applications for admission to the hospital can be received and acted on.

CONNECTICUT.

THE EXAMINING COMMITTEE for the State Medical Society met at New Haven, November 13, and examined 21 candidates for the practice of medicine, two of whom were women.

DR. CHARLES J. BARTLETT, professor of pathology and bacteriologist in the Yale Medical School, New Haven, has been appointed medical examiner by Coroner Mix, vice Dr. Moses C. White, deceased.

THE PLANS for the new buildings for Yale Medical School are nearly completed, and work on the new site will begin in a week or two. The new buildings are to be erected on Cedar street, opposite the General Hospital.

A COMMITTEE has been appointed by the New Haven Medical Association to confer with a similar committee from the New Haven Hospital regarding the vexed question of physicians not on the staff, attending cases in the hospital.

SUIT has been brought by a patient from Waterbury against a New Haven physician for \$10,000 because, as the plaintiff alleges, the use of medicines wrongfully prescribed by the defendant caused her hair to fall out and spoiled her complexion.

The physician replies that the medicines were not employed in accordance with instructions.

THE BULLETIN of the State Board of Health for October shows an annual death-rate of 15.9 per 1000 and that the percentage of deaths under 5 years of age to the total mortality was 26.3. Infectious diseases caused 18.5 per cent. of the total mortality. The secretary advocates the establishment of a hygienic laboratory and the regular inspection of public schools and school children.

ILLINOIS.

JUDGE GARVER, of Rockford, instructed the jury in the case of "Dr." Gordon, charged with practicing medicine without a license, to find for the defendant, who testified that he used no drugs but only "mental suggestion and muscular manipulation."

IT WAS announced at the annual meeting of the Evanston Hospital Association, November 12, that during the last year \$25,000 had been added to the endowment fund of the hospital in five sums of \$5000 each. Bids have been invited for the construction of the Cable memorial building, for which \$25,000 was donated in March last by Mrs. Herman D. Cable.

Chicago.

PROVIDENT HOSPITAL has completed an addition which more than doubles its present capacity and renders it the largest hospital for colored patients in America.

SCARLET FEVER is spreading on the far North-Side, and it is claimed that the increase is due to the failure of attending physicians to make the proper report to the Health Department.

MAURICE PORTER HOSPITAL for sick children was the beneficiary of two lectures delivered last week by Mr. Ernest Seton-Thompson, on "Personality of Wild Animals," and "Wild Animals I Have Seen."

DRS. WILLIAM E. QUINE and DANIEL A. K. STEELE have each given \$25,000 to the medical department of the University of Illinois—College of Physicians and Surgeons—to endow a library and a pathological laboratory respectively. The new building will be erected on the property recently acquired by the college and formerly occupied by the West Division High School.

THE DEATH-RATE for the week ended November 17 was 12.73 per 1000 per annum. The deaths numbered 415, 54 more than the preceding week, but 36 less than in the corresponding week of 1899. Consumption and pneumonia each caused 46 deaths; heart diseases, 35; Bright's disease, 30; acute intestinal diseases, 23; violence, 22; cancer, 21; nervous diseases, 20; diphtheria, 18; bronchitis, 17; and suicide, 4. Of males, 242 died; of females, 173, of children under 1 year, 76; between 1 and 5 years, 45, and over 60 years, 95. Reports were received during the week of 30 cases of scarlet fever and 86 of diphtheria.

INDIANA.

A SILVER MEDAL has been awarded to the State Board of Health for its exhibit at the Paris Exposition.

THE WILL of Dr. William A. Clapp, New Albany, has been probated, and an administrator has been appointed.

DR. ALEMBERT W. BRAYTON, Indianapolis, editor of the *Indiana Medical Journal*, was elected coroner of Marion County, November 6.

THE FIRST PROSECUTION for violation of health laws in Wells County happened, November 15, when Dr. L. A. Spaulding, Bluffton, was fined \$10 and costs for failing to report two cases of typhoid fever.

A LAW will, it is hoped, be passed, by the incoming legislature rendering examination obligatory on all from outside the state who desire to practice medicine in Indiana. This legislation is suggested by the State Board of Medical Examination and Registration.

THE REPORT of the trustees of the Eastern Indiana Hospital for the Insane, Richmond, makes the following requests: That the maintenance appropriation and per capita be continued; that \$2500 be added to the repair fund; that \$62,000 be appropriated for two cottages, \$8000 for new boiler house, etc., and \$7000 for additional offices, and that 3000 acres of land be purchased for colonization and additional gardens.

IOWA.

MERCY HOSPITAL, Cedar Rapids, was formally opened November 14.

DR. ASSIS E. MURPHEY, Oakley, has obtained by competitive examination the position of surgeon to the Lemhi, Idaho, Indian agency.

DR. LEVI H. SURBER, Indianola, has been appointed a member of the board of pension examiners, vice Dr. Edward L. Baker, resigned.

DR. ROBERT E. CONNIF, Sioux City, will be editor for the alumni, of the new quarterly to be issued by the Iowa University Medical School.

DR. NORMAN E. MICHIEL has been appointed surgeon of the Iowa Central Railway at Marshalltown, in place of Dr. H. Landis Getz, whose resignation was announced last week.

DR. CYRENIUS C. POWELL, South Ottumwa, has been appointed deputy district clerk of Wapello County. To take this position Dr. Powell will resign the office of coroner, which he now holds.

THE TYPHOID-FEVER outbreak at Ames has been investigated by Dr. Josiah F. Kennedy, Des Moines, secretary of the State Board of Health, who reported that the water-supply was pure, but that he considered the disease due to accumulations of filth and possibly to the use of contaminated milk.

KANSAS.

WINFIELD now has a hospital completed and equipped, with 24 rooms.

THE ATTORNEY-GENERAL has decided that the county commissioners of Shawnee county must take charge of all smallpox cases outside of Topeka, and that the city is bound to take care only of the cases occurring within its limits.

DR. JOHN P. WOOD, Coffeyville, is probably the oldest active practitioner in the United States. He was graduated in 1823 from the Transylvania University, Lexington, Ky. He was a surgeon in the Mexican war and has practiced continuously for more than three-quarters of a century.

LOUISIANA.

"THE PHAGOCYTE," published in the interests of the medical department of Tulane University, New Orleans, has made its appearance.

IN NEW ORLEANS during October, 18 cases of diphtheria occurred with 7 deaths; 35 of scarlet fever with 1 death, and 4 of smallpox with 1 death.

THE SENSES HOSPITAL, New Orleans, treated 3536 patients during October and admitted to its wards 452. The treasurer reported a balance on hand of more than \$8000.

THE MEDICAL DEPARTMENT of Tulane University, New Orleans, opened on November 5, for its annual session. Dr. Rudolph Matas delivered the opening address, on the "Application of Anesthetics."

MARYLAND.

DR. LIA, of Berwyn, has been engaged to take charge of the smallpox patients at College Park, Prince George's County, where there is a local endemic of the disease, at a salary of \$10 per day.

THE COUNTY COMMISSIONERS of Baltimore county have engaged the following physicians to vaccinate the pupils in the public schools of the county: J. C. Schofield, Charles L. Mattfeldt, and Frank H. Ruhl.

DIPHTHERIA interferes with the attendance in several of the Baltimore County schools. School 1, district 5, has been closed by order of the physician, and school 3, district 4, has been closed by Commissioner Russell, on the advice of two physicians. There is an epidemic of mumps among the pupils of school 3, district 12.

Baltimore.

THE BOARD OF MEDICAL EXAMINERS held its regular fall examination in the hall of the medical and Chirurgical Faculty, November 7-10.

THE NEED of a hospital for infectious diseases was recently emphasized when a patient suffering from diphtheria who had been turned out of his room, and had been refused admission to the hospitals, was finally cared for in an empty room in the City Hall annex.

THE FIRST meeting of the Johns Hopkins Historical Society was held at the Hospital on Monday, November 12. Papers were read by Dr. William Osler on "The Sympathetic Powder of Sir Kenelm Digby," and by Dr. E. F. Cordell on "The Medicine and Doctors of Horace."

DR. W. H. BISHAM, of Baltimore, has been made assistant-surgeon, U. S. A., and is stationed at Fort Cabanas, Havana, Cuba. He entered the Spanish war as a private in the Fifth Maryland Regiment, was later made a contract surgeon, and has recently passed the medical examination for the assistant surgery.

AN INTERESTING program for the winter has been arranged by the Book and Journal club embracing (Nov. 21) "Reminiscences of an Old New England Surgeon," by Prof. J. Collins Warren, of Harvard University; (Dec. 19) "Harvey as an Embryologist," by Prof. W. K. Brooks, of Johns Hopkins University; (Feb. 20) "On Some Diseases Bearing Names of Saints," by Dr. Robert Fletcher, of the Surgeon-General's Library; (March 20) "A Notice of the Life and Writings of

Valesius de Taranta," by Dr. F. P. Henry, Hon. Librarian, College of Physicians, Philadelphia.

THE MARYLAND State Dental Association proposes an official examination of the teeth of the pupils in the public schools. The plan is to have its members, armed with sterilized instruments and blank diagrams, examine the children, noting on the diagram the cavities and imperfections of each tooth or teeth, if any. This paper would finally go to the parents or guardians, who would decide whether treatment should be secured. For poor children free treatment is proposed. The dentists here are practically unanimous in favor of the plan. It will be considered by the School Board.

MASSACHUSETTS.

BY THE COMPLETION of Dr. Henry M. Swift's term of service at the Worcester City Hospital, Dr. C. D. Wilkins becomes senior, and Dr. Fred Bryant junior house surgeon; Dr. W. W. McKibbin senior and Dr. Downey L. Harris junior house physician.

DR. FRANCIS D. DONOGHUE, Boston, whose marriage on October 15, was noted in THE JOURNAL, was presented with a chest of silver and a large plate mirror at a banquet held at the Copley Square Hotel, November 10, at which he was the guest of honor.

THE ENTIRE APPROPRIATION for the improvements at the United States Naval Hospital, Chelsea, amounting to \$45,000, will be expended for this work. The improvements include the construction of a granite three-story building, repairs to the old buildings, relaying of walks, etc.

THE LEGISLATURE of 1900 passed a law prohibiting the sale of articles containing arsenic, and directed the State Board of Health to make the necessary investigations relative to the existence of arsenic in the articles mentioned in the act, and to adopt such measures as may be deemed necessary to carry out its provisions and to facilitate its enforcement.

MICHIGAN.

THE ANNUAL report of the State University Hospital has just been completed. It shows that during the year 1957 patients were received at the hospital.

THE STATE BOARD OF HEALTH has received official notification that it has been awarded a gold medal for its exhibit in hygiene at the late International Exposition at Paris.

"INDEPENDENT" physicians are said to be banded together to resist registration, claiming that the law is unconstitutional. Only 2 of the 1500 "independents" in the state appeared before the board at Lansing. The board has already commenced to take active measures against the "independents," irregulars and other unlicensed practitioners.

COMPULSORY VACCINATION has been urged by Secretary Baker, of the State Board of Health, in all the lumber counties of the state. Smallpox now exists in thirteen counties. The common council of Negaunee has already passed an ordinance providing for the immediate vaccination of all who have not been vaccinated within the last four or five years.

MISSOURI.

DR. WILLIAM L. WHITTINGTON, acting asst.-surgeon United States Army, has returned to his home in St. Joseph, from the Philippine Islands, on sick-leave.

DR. JOSEPH J. LAWRENCE, St. Louis, proprietor and editor of the *Medical Brief*, has purchased a corner site at Fifth Avenue and Eighty-ninth Street, New York, for \$140,000.

DR. ROBERT M. FUNKHUSER, presiding officer of the St. Louis Medical Society, has been elected coroner of St. Louis. Dr. Funkhouser polled a large vote and received the hearty support of members of the profession, regardless of party lines.

HON. A. M. DOCKERY, who has just been elected governor of Missouri, is also a member of the medical profession, although his interests of late have been more in the line of congressional duties than in the practice of his profession. His record at congress promises for him great success in carrying out the duties of the executive of the State. Both the profession and the State are to be congratulated on his election.

NEW JERSEY.

THE CAMDEN Board of Health held a special meeting November 12 to consider the plans submitted for the erection of a municipal hospital for that city. The plans call for three laboratory buildings; administration building and two ward buildings, covered corridors connecting them.

DR. GEORGE H. FLETCHER, Atlantic City, who it is claimed by the secretary of the State Board of Medical Examiners, is not entitled to practice, and whose death certificates have been ordered to be refused, states his side of the case, from which it appears that he is a regular graduate of Harvard University. He asserts that the charges against him are inspired by spite and jealousy.

IN WOODBURY, seven cases of diphtheria have so far been reported. Dr. H. A. Wilson, on behalf of the board of education, offered a resolution to the effect that the board of health placard every house in which there is a case of contagious disease, and that all school rooms be disinfected. In reply the board of health recommended that the schools be closed, and that each room be fumigated with formaldehyde.

DIPHTHERIA prevails to a great extent in certain localities of Camden. On October 26, 53 cases were reported to the bureau of health, and other cases are being found. The disease appears to be so widespread that some have suggested that the public schools be closed. The parochial school of the Immaculate Conception has been ordered closed on account of the epidemic. In order to protect against a further spread of the disease the board of health has ordered yellow placards to be posted on the houses where diphtheria prevails, and have provided a fine of \$25 for removal of this placard without warrant.

NEW YORK.

DR. FREDERICK W. CORBES, Copake, has disposed of his practice, and, after a trip abroad, will practice in Brooklyn.

THE *Sanitarian*, of Brooklyn, has been awarded a "Diploma of Honorable Mention" for its exhibit of two bound volumes of 1899, at the International Exposition at Paris.

THE HEALTH BOARD of Palmyra has taken steps against those who disregard its quarantine rules. A man who made a social call at a house quarantined on account of yellow fever, was arrested and fined \$5.

FREE PASTEUR TREATMENT will be administered to any resident of Greater New York, at the Willard Parker Hospital, by order of the health department. Persons outside the city will be treated free at the discretion of the board.

THE BOARD OF HEALTH announces that there have been eight or nine deaths in New York City from hydrophobia during the past year—a number far in excess of previous years, the average of late having been only two or three deaths annually. On this account the health authorities announce their readiness to co-operate with the medical profession in investigating doubtful cases.

ONE AMBULANCE SURGEON at least has the satisfaction of knowing that by his readiness in an emergency he has been able to save a life. Dr. Levy, of the Harlem Hospital, was hastily summoned to a woman who was rapidly choking to death. Examination showed that the attack had been brought on by an obstruction in a tracheotomy tube, which she had been wearing for many months. As he had no probe or other suitable instrument at hand at the moment, he snatched a piece of a rattan chair, and with this extemporized bougie, was able to relieve the woman. She had been nearly unconscious at the time of his arrival, but speedily recovered after the tube had been cleared out.

CERTIFIED MILK.

A committee, consisting of Drs. Henry D. Chapin, A. Jacobi and Walter Lester Carr, met a few days ago to take steps towards securing "certified milk" for New York City. The meeting was intended to give an opportunity for informal discussion regarding the milk supply, and it was attended by many prominent dairymen. Dr. Chapin said that milk, if properly handled, should keep pure and fresh for 60 hours. The idea is to have a competent bacteriologist examine the milk supplied by any dealer who desires such an examination, and if it comes up to the desired standard, issue a certificate to that effect. Certain rules have been drawn up which must be conformed to if the milk is to receive a certificate. These rules provide for cleanliness in stabling, milking, storage and transportation. A number of the dealers present expressed their willingness to supply milk of such high grade, but insisted that this would necessitate raising the price from 8 to 10 cents a quart. It was thought, however, that there would be a large market for good milk at this increased price. Two prominent milk dealers declared openly that they had knowledge of the sale in New York City of large quantities of milk containing preservatives, despite the efforts of the board of health to bar out all such milk. One of the speakers produced as proof of this assertion several circulars advertising "freezine" and "iceine," formaldehyde compounds which were claimed to prevent milk from souring for days, even under the most adverse conditions. It was asserted that these compounds were being openly sold in this city.

Buffalo.

BUFFALO had 330 deaths in October—a death-rate of 11.24 per 1000 per annum. Consumption caused 32 deaths; pneumonia, 13; typhoid fever, 14; diphtheria, 5; nephritis, 12, and violence 26.

THE HEALTH COMMISSIONER has again called the attention of the authorities to the necessity of having a quarantine hos-

pital during the Pan-American Exposition. He wishes to be prepared for the importation of epidemic disease at that time by reason of the cosmopolitan attendance.

HERMAN KELLNER, PH.D., who has been associated with Professor Abbe in the optical works of Carl Zeiss, at Jena, has accepted the position of scientific director of a lens company in this city. The remarkable development of optical science in recent years has been very largely due to the genius of Professor Abbe, and to the labors of the five or six associates who have been trained by him. Their efforts have placed the science of applied optics upon a higher plane and have carried its results to more important conclusions than have been reached before. Dr. Kellner is formulating a new series of microscopic objectives, and is engaged in original investigation in other fields of applied optics.

NORTH CAROLINA.

DR. H. MCKEE TUCKER has succeeded Dr. James R. Rogers as physician to the state penitentiary, Raleigh.

THE BUNCOMBE COUNTY MEDICAL SOCIETY has returned to the Asheville Board of Trade 50 per cent. of the board's donation toward the entertainment of the Mississippi Valley Medical Association.

THE HOSPITAL of the Confederate Soldiers' Home at Raleigh is now completed. It occupies some of the buildings which were used in 1861 as the first regular hospital, established by the late Dr. Burke Haywood.

OHIO.

DR. JOHN FRANCIS, of Hamilton, Dr. Christian Storz, of Toledo, and Dr. Joseph H. Ray, of Coalton, have returned from Europe.

THE MEDICAL DEPARTMENT of Ohio Wesleyan University, Cleveland, received a gift of \$10,000 from John D. Rockefeller, November 14.

HEALTH OFFICER DR. LAWRENCE C. GROSH, Toledo, was presented with a gold, diamond-mounted badge, by the employees of his department, on November 14.

A PHYSICIAN of Cleveland was fined \$350 and costs by Judge Rioks in the United States District Court, November 2, for using the mail to convey unlawful information.

DR. WILLIAM U. COLE, Columbus, was appointed by the mayor Director of Public Safety, November 12; at the meeting of the city council the same evening, it refused to approve Dr. Cole's bond of \$25,000, and now the anti-Cole faction talk of impeaching the mayor.

PENNSYLVANIA.

DR. AND MRS. WILLIAM C. SMITH, Linglestown, celebrated their golden wedding, November 12.

A MAN in Lancaster seeks by the medium of the law to obtain \$5000 damages from Dr. Herbert R. Bowers, of that city, who, he alleges, set his broken leg improperly.

DR. J. S. WHITE, of Manheim, and Dr. H. H. Brown, of Philadelphia, who have been connected with the medical department in the Philippine Islands, returned home November 13.

SPECIAL HOSPITAL CARES for patients suffering from infectious diseases were advocated at the meeting of the New York State Association of Railway Surgeons, November 15, by Dr. William L. Estes, South Bethlehem.

THE SCHUYLKILL at Reading is now believed to be at its lowest water mark. A greenish scum covers the surface of the water in certain places, and since this stream furnishes water to cities along its course, an epidemic of sickness is feared. In Reading 19 new cases of typhoid were reported for the week ended November 10.

BY DIRECTION of State Veterinarian Pearson a herd of sixteen cattle owned by Cyrus Williams, near Lancaster, were found to be suffering from tuberculosis and were ordered killed.

TYPHOID FEVER is still on the increase in the town of Cementon, near Allentown. Up to November 12, 118 cases had been reported. Dr. M. F. Cawley, the county medical inspector, has made an inspection of the condition there. The public school has been ordered closed.

Philadelphia.

ON THE evening of November 17, Dr. S. Weir Mitchell, physician, novelist and poet was given a reception at the Penn Club.

BY THE WILL of Edward Wiegel property valued at \$10,300 has been devised to the German Hospital upon the death of the decedent's widow.

THE COMMITTEE on Elementary Schools of the Board of Education have made an adverse report to the resolution asking the council to give the medical inspectors of the public schools \$100 annually for their services.

DR. JOHN V. SHOEMAKER, president of the Department of Charities and Corrections, has notified the Director of Public Safety that hereafter the ambulances of the Philadelphia Hospital will be at the service of the police.

MILK INSPECTION is being made at the suggestion of Mr. J. Lewis Good, chief of the Bureau of Health, of the milk supplied by the various dairies of the city. The bacteriological examinations are being made by Drs. A. C. Abbot and A. H. Stewart, of the health department.

BISHOP WHITTAKER, on behalf of the Board of Managers of the Episcopal Hospital, has issued a pastoral letter appealing for funds to pay the current expenses of the Episcopal Hospital. Its increase of work has been so rapid and its responsibilities so great that last year its expenses were \$30,000 more than the receipts.

ON NOVEMBER 10, articles of incorporation were filed in the county clerk's office for the establishment of an institution to treat tuberculosis. The Pennsylvania Sanitarium Company has made the application and the capital stock is to be \$50,000. The new institution will be established at Clifton Heights. The incorporators are Charles Williams, Clifton Heights, Pa.; Rudolph Daetywyler, Camden, N. J., and Howard K. Heritage, Collingwood, N. J.

UTAH.

DR. WILEY E. FERREBEE, Murray, has been sued for \$5000 by a patient for alleged unskillful treatment.

THE MORTALITY REPORT of Salt Lake City for October shows 61 deaths, 5 of which were due to consumption; 4 to typhoid fever; 3 to bronchitis, and 3 to pneumonia. Of contagious diseases, 28 cases of scarlet fever were reported; 70 of typhoid fever, 27 of smallpox, and 3 of diphtheria.

QUARANTINE OFFICER DR. EVERETT O. JONES, at Murray, has indorsed the petition of citizens of Murray and South Cottonwood, that arrangements be made for caring for smallpox patients at home, and a deputy sheriff has been appointed to see that the quarantine in the district is maintained.

A NEW RULE has been promulgated by the Salt Lake City Board of Health, which requires that not only all cases of scarlet fever, diphtheria, whooping cough, smallpox and typhoid fever, but measles, chickenpox and "any other acute contagious disease characterized by an eruption" shall be immediately reported to the department.

GENERAL.

DR. ALFRED SCHAPER has been called to the Institute of Anatomy at Breslau. He was a pupil of Stiede at Koenigsberg and has been professor of microscopic anatomy at Harvard.

ACTING ASST.-SURGEON W. HAVELBURG reports from Rio de Janeiro, under date of Oct. 15, 1900, that in the treatment of bubonic plague in that city, under Terni, it is assumed that the attack is divided into two stages; 1, the local stage, when the glands are first involved; 2, general infection, after the toxins have passed the lymphatic glands. With this view of the subject, excision of the inflamed glands has been practiced and it is reported that in many cases the temperature dropped and improvement appeared shortly after the operation. Dr. Havelberg promises a further report on this interesting subject.

PAN-AMERICAN CONGRESS.

The following gentlemen are to act as secretaries at the Pan-American Medical Congress, Havana, Dec. 26-29, 1900:

Medicine, Dr. Judson Baland, Philadelphia; Therapeutics, Dr. Hobart A. Hare, Philadelphia; Pediatrics, Dr. I. N. Love, New York City; Mental and nervous diseases, Dr. C. H. Hughes, St. Louis; Medical pedagogy, Dr. Otis K. Newell, New York City; Medical jurisprudence, Dr. H. A. West, Galveston, Tex.; Dermatology and syphilography, Dr. A. Ravogzi, Cincinnati; Surgery, Dr. W. P. Nicholson, Atlanta, Ga.; Gynecology and abdominal surgery, Dr. H. P. Newman, Chicago; Orthopedic surgery, Dr. John Bidlon, Chicago; Railway surgery, Dr. Duncan Eve, Nashville, Tenn.; Dental and buccal surgery, Dr. Eugene S. Talbot, Chicago; Anatomy, Dr. Arthur D. Bevan, Chicago; Physiology, Dr. A. P. Brubaker, Philadelphia; Pathology, Dr. Hunter McAlpine, New York City; Ophthalmology, Dr. John E. Weeks, New York City; Laryngology and rhinology, Dr. G. H. Makuen, Philadelphia; Otolaryngology, Dr. James T. McKernon, Philadelphia; Obstetrics, Dr. Gustav E. Zinke, Cincinnati; General hygiene and demography, Dr. Alvah Doty, New York City; Military medicine and hygiene, Major Jefferson Kean, U. S. A., Quesnados, Cuba; Marine hygiene and quarantine, Dr. R. M. Woodward, U. S. M. H. S., Washington, D. C.

TESTIMONIAL TO DR. I. N. LOVE.

We present herewith an illustration of the loving cup presented to Dr. Love on his departure from St. Louis to New York, last October, mention of which has been made before in these columns. Dr. Wiley Broome presented the cup, with the following words:

"It is with pleasure, mixed, however, with regret, that I present you with this Loving Cup as a token of the esteem in which you are held by your brethren of the medical profession of St. Louis, and other friends whose names you will find inscribed on the side of the cup. I want you to accept it with similar feelings with those which prompted the donors to bestow it, as a slight token of their appreciation of your worth. My regrets are, that I, with the others, will miss your kind counsel and social intercourse, which have been so freely bestowed whenever needed. Again may I express the hope that for generations this Loving Cup will be the means of reminding your posterity of the high estimation in which you have been held by those whose names are engraved upon it; and that you go away from our city with your heart full of the feeling that we wish you unbounded success in your new field."

The following are the names of those who were present at the banquet: Drs. C. H. Hughes, F. R. Fry, Spencer Graves, H. S. Cummings, G. M. Phillips, L. E. Newman, W. W. Graves, H. C. Dalton, O. F. Ball, F. E. Wessler, W. B. Shields, Wm. Johnston, Thos. F. Rumbold, W. F. Kier, Y. H. Bond, J. L. Boogher, H. R. Hall, E. H. Cole, George Homan, H. G. Mudd,

J. Young Brown, B. M. Hypes, E. W. Lee, Wiley Broome, and Messrs. Arthur Lambert, K. D. Mellier, F. W. Sultan, Zack Finker, Thos. Haley and G. B. Rammick.

DR. W. S. NOBLITT, of Honolulu, H. I., it appears, associated with a quack and for this unprofessional conduct lost his license over a year ago. In September Dr. Noblitt brought mandamus proceedings to test the right of the territorial treasurer to refuse him a license, but the presiding judge held that a recommendation from the Board of Health was necessary before it could be granted.

DR. C. L. GARVIN has resigned as executive of the Board of Health of Honolulu. He will resume practice, which he dropped when the epidemic of plague started.

COL. JOHN VAN R. HOFF, who was chief surgeon on General Chaffee's staff in China, has returned on the steamer *China*. He will be stationed at Chicago as chief surgeon of the department of the lakes. He reports that the American troops in China are in excellent health in camp at Pekin and in buildings at Tientsin. Nearly all the wounded have been sent to the United States.

YELLOW FEVER IN HAVANA.

According to the report of the sanitary officer of Havana, issued under date of November 8, there were 74 deaths from yellow fever in that city during October. Of these, 8 were Americans, and 51 Spaniards. The total number of cases was 287—62 Americans and 225 Spaniards. The death-rate for

Americans was 12,90, while that for the Spaniards was 22,66. Attention is called in the report to the exaggerated statements regarding the prevalence of the disease which have been sent out by the newspapers. Out of a population of 242,000 there have been since January 1, 1908, cases, but the Associated Press published widely the statement that every block in Havana had from one to seventeen cases. There are only 857 occupied blocks in the city. Out of these 397 have had cases of yellow fever. Of the blocks which have had cases, 224 had only one case, and only one or two blocks in the city approximated the numbers given in the newspapers. In Havana there are 16,480 houses of which 709 have had cases of yellow fever. Press dispatches of November 20 state that only 56 cases are under treatment, and among these are 2 Americans. It is expected that by keeping out immigrants the city will soon be entirely rid of it.

TUBERCULOSIS AND TENEMENT HOUSES.

The Tenement House Commission appointed by the last New York legislature held its first public hearing in the Charities Building, New York City. The topic for discussion was, "The Relation of Tuberculosis in the Tenement House Problem." It was discussed at considerable length by Dr. John H. Pryor, of Buffalo, and Dr. Hermann M. Briggs, of New York. The former gentleman said that he had given a good deal of attention to the study of this problem in his own city. In 1893 the condition of the tenements in Buffalo had been fully as bad as they are now here, but more stringent city ordinances had resulted in great improvement. He pointed out that while consumption is both a preventable and a curable disease in its early stages, the death-rate from this disease does not decrease, and each year finds about 6000 cases in the city. He insisted that at least 600 cubic feet of air should be allowed for each adult in a tenement, and that all living rooms should have sunlight. Dr. Briggs exhibited some maps that had been prepared by the board of health with regard to the distribution of consumption. They showed certain centers of infection. For instance, in one block on Cherry street, out of a population of 1000, 144 had died from consumption in four years, and on a block in Pell street, near Mott street, there had been in the same period of time 318 deaths from this disease out of a population of 2000. He was opposed to compelling landlords to build very expensive tenements, for he thought the burden would eventually fall on the poor, who would be crowded into these houses in order to make them pay. The chances of death from fire in a tenement house were far less than the danger of death from consumption. Carpets and wall paper should be prohibited in such dwellings. Mr. Lee Frankel, the manager of the United Hebrew Charities, said that the vast majority of consumptive foreigners whom he saw had contracted the disease in this country, although these people had dragged a miserable existence in their native lands. Dr. Anna Daniel was of the opinion that the sweatshop was an important factor in the dissemination of tuberculosis at the present day in spite of legislation against these pest-holes. She had seen consumptives making cigars and moistening with saliva, and knows that it was common for Italian peddlers to sort their fruit daily in their rooms, and store the fruit under their beds.

CANADA.

PROGRESS OF TORONTO CONSUMPTION SANATORIUM.

The medical health officer of the city, Dr. Sheard, who was asked to report to council on this matter, has handed in his report, the text of which is as follows: "The Local Board of Health should request the city council to submit a by-law to the citizens at the coming municipal elections in January for a grant of \$50,000, such sum to be paid to the fund for the purpose when the city treasurer has been handed a similar sum by the philanthropic citizens promoting the interests of the sanatorium; as a condition of this grant, the municipality should not be called on for any additional sum other than the ordinary hospital per diem; that the institution be conducted strictly in accordance with the legislation respecting sanatoria passed at the last session of the provincial parliament; that the institution provide for patients in all stages of the disease, and that it shall be available for the poor patients free of charge; no city patient shall be admitted on a city order unless he or she has been a resident for one year; the sanatorium shall not be distant more than thirty miles from the city, and the land in connection therewith shall not be less than 50 acres." It is altogether likely that the report of the medical health officer will be adopted all along the line.

PEST-HOSPITAL FOR MONTREAL.

A joint meeting of the Boards of Directors of the Montreal General Hospital, the Royal Victoria Hospital, and the Notre

Dame Hospital has been held recently, and an appeal made to the corporation of Montreal to construct and equip a new civic hospital for contagious diseases. It is proposed to raise the money for the purpose by special loan, and a conference is being arranged for between the civic authorities and a committee appointed by the boards of directors of the three hospitals, to deal with the matter.

CAUSE OF RECENT TYPHOID OUTBREAK IN MONTREAL.

On October 25 a report was received by the health department of Montreal from Notre Dame Hospital, that two cases of typhoid fever had been received from Mount St. Mary's Convent. An investigation of the institution, which is a boarding school for young ladies, was made and six more were found suffering from the disease. When the milk-supply of the convent came to be inspected it was found that the milk, supplied by a farmer outside the city, was filled with microbes. Two members of the farmer's family were found to be suffering from the disease. In all twenty cases were traced to this source.

FOREIGN.

DR. KARL HOCHSINGER, of Vienna, has received the Cross of the Order of Franz-Josef.

CAPE TOWN, South Africa, reported last week 8 cases of plague and 3 deaths in the densely peopled quarter occupied by natives.

DR. J. WEINLECHNER has resigned the chair of surgery at Vienna, and Dr. A. Vaucher the chair of surgery and gynecology at Geneva.

A CHINESE physician's fee is perhaps the smallest in the world, ranging from 5 to 10 cents, but this is accounted for by the fact that any one can practice.

PROF. G. BRAUN, of Vienna, has retired from his chair of obstetrics, on account of the age limit, and has had a title of nobility conferred upon him by the emperor.

PEKIN sanitary conditions are becoming serious. Fearing that their funerals would be interfered with, the Chinese have retained their dead enclosed in coffins in or about their dwellings.

AMONG the deaths reported abroad we note that of Dr. L. Loew, at Olmütz; Mr. Marini, at Naples; Dr. H. Raab, at Baden, and Dr. Gaskden, professor of legal medicine at Copenhagen.

AN OUTBREAK of typhoid in Lambeth parish, London, involving 42 persons, 25 of whom were females, is attributed to the common use of four mangoes, 26 of the cases having been definitely traced to this source.

THE FIRST volume of the great Latin dictionary, now being compiled by the five chief German Academies of Science, is nearly ready. Each word is treated historically and followed to the sixth century. There are to be twelve volumes of 1000 pages each.

PROFESSOR KOCH, in a recent lecture to his colleagues in Berlin, stated that he believed that mosquitoes passed the malarial parasite from one human body to another, but the parasite was in the body itself. Mosquito nets were useful, but not wholly reliable.

PROF. A. KOSSEL, of Marburg, has been appointed the successor of Prof. W. Kuehne, at Heidelberg.

THE four physicians settled at Mistelbach, a town in Austria, with 3500 inhabitants, have issued a warning to the members of the profession not to respond to the published advertisement of the local sick benefit society for a medical attendant. By advertising for an outsider the society is trying to avoid paying the rates demanded by the resident physicians. Applicants are entreated at least to confer with the national Lower Austria Medical Chamber before accepting the position offered.

PECULIAR RESULTS IN THE TREATMENT OF TYPHOID.

An interesting observation has recently been made by Dr. Renon, of Paris, which formed the subject of a paper read by him before the Hospitals Medical Society of that city. He had under his care last summer at the Necker Hospital 9 cases of typhoid fever which were distributed between the crèche and women's ward in the Peter Block. Of these 9 cases he lost 4 or 44 per cent.; though the disease at first seemed mild. It underwent a sudden change about the sixth day, and of the 5 patients that recovered only one maintained the mild form throughout the disease. These figures can not be put down to the fact that the women were nursing, since only 3 of the 9 were nursing and of these 3 only one died. The treatment, lack of care in nursing, and the severe type of epidemic can be excluded, for in the other wards near by where the disease and other conditions were the same the mortality was nothing to be compared with this. Moreover the mortality in this particular block had been before noticed to be

considerable. During the present year to October 1 its mortality has been 11 out of 19, or 57 per cent., while at the same time in other wards the mortality among the women was five times less. The doctor therefore infers that the proximity of the infants' crèche, in which there was a large amount of enteric trouble in the way of summer diarrheas, etc., was responsible for this mortality. Patients suffering from typhoid fever were affected secondarily with bacteria of infantile and other diarrheal troubles. The observation is a somewhat striking one and suggests additional precautions in the treatment of typhoid fever.

LONDON LETTER.

GLASGOW FREE FROM PLAGUE.

After having lain for three months under the suspicion of being a plague-stricken city, Glasgow is now happily free from the disease. The outbreak was practically confined to one locality, and by the vigorous sanitary measures adopted, was soon placed under effective control. Including doubtful cases, the number of deaths was only 15, which is a very small percentage of the million of inhabitants which live in and around Glasgow. The last patient was admitted to hospital six weeks ago. All the persons who came in contact with plague patients were removed to isolation houses and kept under surveillance. Altogether these numbered 170, and at one time the number reached 120. The last of the plague patients who were in the hospital, numbering 8, were discharged on November 3. According to the agreement of the Powers at the International Sanitary Convention, held at Venice in 1897, Glasgow should be officially recognized as free from plague on November 12, provided no fresh case occurs in the interval. It may be remembered that the first case occurred on August 3, when a child and its grandmother were affected. They died respectively on August 7 and 9, the cause being believed to be enteric fever. The woman's husband sickened on August 12 but was not admitted to hospital until August 27, under the diagnosis of "enteric fever," but the hospital authorities recognized the disease as plague. Altogether 27 persons were removed to hospital. One gave birth to a child, which died; this, with 7 other patients, bring the number of deaths up to 8.

FORMER EPIDEMICS OF PLAGUE IN GREAT BRITAIN.

The Glasgow outbreak is the first instance of the appearance of plague in these islands since the days of the Stuarts. The last was the memorable one of 1665, which Defoe has immortalized in his great work. Sporadic cases occurred for a few years after that period, and a column was left for plague cases in the bills of mortality until 1703. But these were only lingering reminiscences of the fearful period. For two centuries we have been absolutely free from the disease. There is a widespread belief that the epidemic of 1665 was the first instance in which plague ever got a real foothold. Stow mentions an epidemic in the reign of Edward III, which created great devastation, "leaving scarcely a tenth person living"—an obvious exaggeration. Another visitation in the reign of Henry IV is said to have carried off 30,000 persons, and another severer one in 1590 is said to have caused 30,000 deaths in London alone. Throughout the sixteenth century plague showed repeatedly its dread power. In 1562-3 there was an epidemic, followed by a severer one in 1581, which lasted three summers. From that year till the end of the century the disease may be said to have been more or less epidemic. The year 1603 was memorable for a frightful outbreak in Westminster, where 451 persons were buried at the public expense in a few months. This was but the prelude to the graver visitations of 1625 and 1665, which between them carried away 141,000 persons.

THE SOUTH AFRICAN HOSPITALS COMMISSION.

The commission, having returned from South Africa, has resumed its sittings at Burlington House, after an absence of three months at the seat of war. The last and forty-second sitting has been held, after which the commissioners will prepare their report. Mrs. Richard Chamberlain, sister-in-law of the colonial secretary, who has made herself remarkable by the vehemence of her charges against the army-surgeons, was the only witness examined. She said that she landed in South Africa in November, 1899, and had visited Woodstock, Rodebosche and Mafeking, but only considered herself an authority on No. 1 Hospital at Wynberg, Cape Town. She was told on three occasions very politely that no visitors were allowed. She ultimately got an order from General Walker to visit, but not from the principal medical officer. She said that the whole place was in a horrible muddle; that there was no organization, though there was unlimited money and unlimited stores; that they were short of every necessary utensil, from cups and saucers to bed pans; that they were short of nurses, yet Cape Town was full of them, but "red tape" pre-

vented them being employed; that the patients were filthy, and the hospitals swarmed with vermin; that orderlies took the sheets of typhoid patients, washed them in cold water and used them again without disinfection.

Correspondence.

Grooved Director for Vaginal Hysterectomy.

INDIANAPOLIS, Nov. 17, 1900.

To the Editor:—I am very much surprised to read in your issue of November 17 an article by Dr. E. D. Ferguson, of Troy, N. Y., in which he describes a grooved director for vaginal hysterectomy that in every essential feature is identical with the grooved staff devised by Dr. Joseph Eastman twelve years ago.

It is only fair to Dr. Ferguson to assume that he was not aware that he had been antedated twelve years in his invention, although it must be admitted that his acquaintance with the various methods of vaginal hysterectomy was not quite as wide as it might have been before placing his grooved director before the profession.

The staff devised by Dr. Joseph Eastman has been described and illustrated in such prominent medical journals as the *New York Medical Record* of April 1, 1893, the *American Gynecological and Obstetrical Journal* of April, 1898, and numerous less prominent publications.

He has operated, using this staff, in Chicago and Philadelphia, such well-known men as J. B. Murphy, F. Henrofin, F. M. Martin and H. P. Newman, of the former, and E. E. Montgomery of the latter city being present.

The staff is illustrated in the surgical-instrument catalogue of the W. H. Armstrong Co., Indianapolis, and the A. S. Aloe Co., of St. Louis. The instrument as used by Dr. Eastman for twelve years is identical in idea, form, detail, purpose and method of use with that described by Dr. Ferguson.

I trust he will accept this note in the same kindly spirit in which it is written. Very sincerely,

THOS. B. EASTMAN, M.D.

Physicians Impersonated.

CHARLESTON, S. C., Nov. 14, 1900.

To the Editor:—Dr. A. R. Shands, of Washington, D. C., secretary of the committee on arrangements of the last American Congress of Physicians and Surgeons, writes me that a man, claiming to be myself, and to have attended the meeting of the congress in May last, has been victimized many of the profession of that city by pretending to be in distress and borrowing money from them. He claims to have many friends in Richmond, Va. The doctor describes the man as between 60 and 70 years old, clean face, heavy gray mustache, about 5 feet 10 inches tall, and rather spare build. I know of men, in other cities, in former years, who have been victimized in a similar manner, and in one instance the thief proved to be a former governor of this state under carpet-bag rule, and the above description I am told would apply to this same individual.

I was impersonated many years ago and one of my friends in New York City was victimized for a small amount. The thief was never caught. There should be some way in which physicians could protect themselves from this class of scoundrels. I hope that you will give this as much publicity as possible, so that the profession may be put on their guard and perhaps this thief may be arrested.

Yours respectfully, WALTER P. POIRIER, M.D.

Marriages.

EDWARD F. BRUCE, M.D., Pensacola, Fla., to Miss Minna Frottscher, of New Orleans, La., November 7.

JOHN H. SLOAN, M.D., Santa Fe, N.M., to Miss Aletta Early, Des Moines, Iowa, November 14.

JESSE RAMSBURGH, M.D., to Miss Edith Roberts, both of Washington, D. C., November 21.

IRVING PHILLIPS LYON, M.D., Buffalo, N. Y., to Miss Kate P. Lathrop, of Baltimore, Md., October 23, in New York City.

GEORGE W. DOBBIN, M.D., Baltimore, to Miss Beatrice Dunderdale, of Perth Amboy, N. J., October 10.

FRANK WARD HICKIN, M.D., to Miss Gertrude May Throssell, both of Cleveland, Ohio, November 8.

FRED WHITNEY DAVIS, M.D., Scranton, Pa., to Miss Edith Scott, of Bloomfield, N. J., November 6. They will reside at East Orange, N. J.

Deaths and Obituaries.

HORACE TRACY HANKS, M.D., Albany, N. Y., 1861, was born at Randolph, Vt., June 27, 1837, and died at his home in New York City, November 18. Soon after graduation he became house surgeon to the Albany City Hospital, where he remained until appointed an assistant-surgeon of the 30th N. Y. Volunteer Infantry, in which capacity he served in the Armory Square Hospital, Washington, D. C. He was also at the front during the battles of Fredericksburg and Chancellorsville. After his muster out he remained in Royalton, Mass., until 1868, when he removed to New York. In 1872 he became identified with the Demilt dispensary in its gynecological clinic and for ten years was conspicuous for both the quality and amount of his work. He also became active in many medical societies, devised many special instruments, wrote much, held positions of responsibility, and was often quoted as an authority, particularly in his work as surgeon of the Women's Hospital. As a member of the AMERICAN MEDICAL ASSOCIATION he served more than once as a delegate, and was much interested in its work.

HENRY DRURY NOYES, M.D., College of Physicians and Surgeons, N. Y., 1855, of New York City, at Mount Washington, Mass., November 12, aged 68. He was a well-known ophthalmologist, a leading specialist and a member of many societies and of the AMERICAN MEDICAL ASSOCIATION. He was regarded as an expert in medicolegal circles, and his text-book on diseases of the eye is a standard work.

WILLIAM MARSHALL, M.D., Jefferson Medical College, Philadelphia, 1847, president of the Delaware State Medical Society in 1869 and 1870, a member of the AMERICAN MEDICAL ASSOCIATION, secretary of the State Board of Health in 1879, and surgeon of the Sixth Delaware Volunteer Infantry in the Civil War, at his home, Milford, Del., after an illness of two years, November 9, aged 73.

NATHANIEL P. RICE, M.D., Harvard Medical School, from paralysis, at a sanatorium in New York, November 10, aged 72. He served through the Civil War as a surgeon in the regular establishment and was for two years medical director in Virginia and North Carolina.

FRANCIS M. CONFER, M.D., Rush Medical College, 1882, a prominent physician of Monroe, Wis., and a member of the State Medical Society and the AMERICAN MEDICAL ASSOCIATION, from typhoid fever, at his home, November 11, aged 46.

FETTERMAN W. CONN, M.D., College of Physicians and Surgeons, New York, 1871, who formerly practiced at Virginia City, Nev., at his home, Napa, Cal., November 4, from epilepsy, aged 60.

Z. HAWLEY MARSH, M.D., Jefferson Medical College, Philadelphia, 1836, at his home, Howell, Mich., where he had practiced for more than half a century, October 26, aged 89.

GEORGE K. CROSTHWAYTE, M.D., Trinity Medical College, Toronto, 1889, late of Hamilton, Ont., by gunshot-wound, self-inflicted, at Chicago, November 14, aged 34.

WILLIAM A. MOSGROVE, M.D., Miami Medical College, Cincinnati, 1873, from accidental or self-inflicted gunshot wound, at his home, Urbana, Ohio, November 8, aged 50.

EDWIN P. SNOW, M.D., Medical School of Maine, Brunswick, 1849, at his home in Atkinson, Me., where he had practiced for more than half a century, November 10.

HENRY A. LOOK, M.D., Western Pennsylvania Medical College, Pittsburg, 1890, at Allegheny, from a cancer of the tongue, November 12, aged 35.

JAMES S. WALTERS, M.D., M.R.C.S. England, 1869, from diabetes and inflammatory rheumatism, at his home in Pittsburg, Pa., November 8, aged 54.

HENRY GEROLD, M.D., Western Reserve University, Cleveland, Ohio, 1864, at his home in Cleveland, from apoplexy, November 10, aged 71.

WILLIAM T. COLLINS, M.D., Jefferson Medical College, 1857, suddenly, at his home in Camden, N. J., November 10, from rheumatism, aged 71.

JOHN R. SCOTT, M.D., St. Joseph Hospital Medical College, St. Joseph, Mo., at his home, Leona, Kan., after a short illness, November 5.

JAMES N. LOUGHRY, M.D., Jefferson Medical College, at his home in Pittsburg, Pa., after a short illness, November 8, aged 65.

SALOME MERRITT, M.D., New York Free Medical College for Women, 1874, at her home, Somerville, Mass., November 7, aged 57.

CHRISTIAN P. AHLSTROM, M.D., University of Buffalo, 1884, at New York, from asphyxiation by coal gas, November 15, aged 40.

ROBERT R. WASHBURN, M.D., Medical College of Indiana, 1886, at his home in Waldron, Ind., November 11, aged 67.

JAMES E. BLAND, M.D., University of Virginia, 1856, at his home near Shanghai, Va., November 8, aged 66.

Societies.

HOLYOKE (Mass.) PHYSICIANS met November 14 and temporarily organized, with Dr. Carl A. Allen as chairman and Dr. John J. McCabe as secretary.

THE LACKAWANNA (Pa.) MEDICAL SOCIETY, at its meeting at Scranton, November 13, decided to form a union, to establish a fee-table and to blacklist all delinquent debtors.

THE DETROIT (Mich.) PHYSICIANS' ASSOCIATION held its first business meeting November 12 and elected Dr. Guy L. Kiefer president, and Dr. Walter J. Cree, secretary. The association already has more than 100 members.

THE MIDDLETOWN (Conn.) CENTRAL MEDICAL ASSOCIATION has been revived. A meeting was held on November 8. Thirteen new members were elected, and Dr. J. Francis Calef was elected secretary and treasurer.

THE SANGAMON COUNTY (Ill.) MEDICAL SOCIETY held its annual meeting at Springfield, November 12, and elected the following officers: Dr. J. Norman Dixon, president; Dr. Albert L. Brittin, Athens, vice-president; Dr. B. Barrett Griffith, secretary, and Dr. Percy L. Taylor, treasurer.

THE ST. LOUIS ACADEMY OF MEDICAL AND SURGICAL SCIENCE, at its last meeting, elected Dr. Emory Lanphar, president; Drs. Carl Pesold and Harry S. P. Lare, vice-presidents; Dr. Orrill L. Suggett, secretary; Dr. George M. Phillips, treasurer; Dr. William Porter, orator, and Dr. Harry G. Nicks, librarian.

THE WARASH RAILWAY SURGICAL ASSOCIATION held its annual meeting at St. Louis, November 8, and elected the following officers: Dr. Edward H. Griswold, Peru, Ind., president; Dr. Smith A. Spilman, Ottumwa, Iowa, vice-president, and Dr. Christian B. Stemen, Fort Wayne, Ind., secretary and treasurer.

THE GENESSEE COUNTY (N. Y.) MEDICAL ASSOCIATION held its annual meeting at Batavia, November 7, and elected the following officers: Dr. Morris W. Townsend, Bergen, president; Dr. Emerson E. Snow, Batavia, vice-president, and Dr. Annie M. Cheney, Batavia, secretary and treasurer.

THE BUCKS COUNTY (Pa.) MEDICAL SOCIETY held its annual meeting at Doylestown, November 7, and elected Dr. George A. Parker, Southampton, president; Drs. John A. Crewitt, Newtown, and George M. Grim, Ottsville, vice-presidents, and Dr. A. F. Myers, Blooming Glen, secretary and treasurer.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION has elected the following officers: President, Mr. Manning Simons, Charleston; vice-president, Drs. George H. Noble, Atlanta, and L. C. Boshier, Richmond; secretary, Dr. W. D. Haggard, Jr., Nashville; treasurer, Dr. F. W. McRae, Atlanta. Richmond, Va., was selected as the place of next meeting; third Tuesday in November, 1901.

THE FOX RIVER VALLEY (Ill.) MEDICAL ASSOCIATION held its seventy-first semi-annual meeting at Aurora, November 13, president Dr. James E. Bumstead, Dundee, in the chair. A

committee consisting of Drs. Hawley, Chicago, and Henry J. Gahagan, Elgin, was appointed to look into the matter of reorganization. The following officers were elected: Dr. Catherine B. Slater, Aurora, president; Dr. George E. Allen, Aurora, vice-president, and Dr. Henry J. Gahagan, Elgin, secretary and treasurer.

Southern Surgical and Gynecological Association.

*Thirteenth Annual Meeting, held in Atlanta, Ga.,
Nov. 13-15, 1900.*

President Dr. A. M. Cartledge, Louisville, in the chair.

Governor Candler of Georgia, delivered an eloquent address of welcome, which was responded to by President Cartledge.

MEDULLARY NARCOSIS.

Dr. W. L. RODMAN, Philadelphia, read a paper in which he discussed the points of most practical value in connection with this method of anesthesia. No one will think of abandoning ether and chloroform. These trusted agents will continue to enjoy the full confidence of the profession, and the Corning-Bier method will be held in reserve for certain cases in which there is seemingly a clear contraindication to chloroform or ether. Medullary narcosis should be given subjects suffering from bronchial, pulmonary, and renal diseases; to patients affected with fatty or dilated heart, and cardiac diseases in general; to old people in whom the shock of general anesthesia is often great, and from its action in one case, the author believes it to be safer than chloroform or ether, in drunkards. The place where the spinal canal is entered is of some importance. Tuffier, Murphy, Matas, and others, who have had the largest experience with the method, prefer the fourth lumbar space. The author believes that any of the lumbar spaces can be punctured with safety. The fifth interspace, between the last lumbar and the first sacral vertebra, is in some respects the easiest route. Simple puncture of the spinal cord, if aseptically done, is unlikely to be followed by serious changes in the cord or its membranes. If to simple puncture is added the injection of some chemical substance by which anesthesia is produced, a new element of danger is undoubtedly incurred. Therefore, the choice of a local anesthetic becomes of paramount importance. Cocain is difficult to sterilize. Raised to 180 F., it is decomposed into egonin, and becomes comparatively inert. Some have found it practical to boil cocain, and then introduce it into the spinal canal without impairing its anesthetic properties. By raising it to a temperature of 180 F., and repeating this twice, thrice, even six times, as recommended by Tuffier, it should be sterile, and therefore safe, and yet a dose of thirty minims of a 2 per cent. solution of cocain is too large. The essayist recommended half of this amount. A small dose of a 2 per cent. solution is better than a larger one in greater dilution. In his first case he injected 18 minims, in the second, 15 minims, and in a third, 13 minims, and hopes still further to reduce the amount to 10 minims. We should aim to get complete anesthesia with the smallest amount of the drug.

The primary and secondary effects of the injection of cocain into the spinal canal are those of simple puncture exaggerated. Shock is increased; headache, restlessness, delirium, and other symptoms are necessarily more pronounced. He recommended an irido-platinum needle he used. His technique is similar in many respects to that outlined by Tuffier and others. He blind-folds the patient and fills the ears with cotton to avoid psychic pain.

Dr. LEWIS S. McMURTY, Louisville, predicted that medullary narcosis would not take the place of the established methods of anesthesia, and said its field of usefulness would be restricted to the class of cases outlined by the essayist.

Dr. WILLIS G. MACDONALD, Albany, mentioned the case of a man, 42 years of age, who had suffered from hemorrhoids and fissure of the rectum. The patient had always been a hard drinker. Granular and hyaline casts were found in the urine, also a small amount of albumin. Patient likewise had a fatty, dilated heart. He injected 18 minims of a 2 per cent. solution of cocain in the subdural space, and when he was about to begin the operation the patient became cyanotic; a profuse, cold perspiration began, so that it became necessary to give 1/20

grain of strychnia; 1/25 gram of nitroglycerin, when the respirations ran up to 60 or 80. No pulse was discernible at the wrist. The pupils were dilated; patient became unconscious. More than two hours elapsed before the speaker felt safe as to the condition of his patient. The man suffered severely from headache and projectile vomiting during the entire afternoon, and had two or three involuntary bowel movements.

During the summer, while on a visit to Europe, he saw a similar experience in the practice of Professor Kocher.

Dr. A. M. CARLEDGE, Louisville, said his experience was limited to eight cases in which he had used the new method, the results being satisfactory. In two patients severe headache followed its use, which soon disappeared. Analgesia was complete in all cases. In one case he removed the pus-tubes; in a second an enormous fibroid tumor of the uterus; and in a third a large intraligamentous cyst. Some of the patients came off the table in much better condition than if chloroform or ether had been employed.

Dr. E. P. MALLETT, New York City, detailed a case of retroverted adherent uterus in the practice of Dr. Grandin, for which an abdominal section was made. At first, much difficulty was experienced in finding the subdural space or medullary canal, so that the patient complained of intense pain. It was finally found, cerebrospinal fluid escaped, and cocain was injected, the analgesia being apparently complete in eighteen minutes. So much pain was experienced while the operator was making the incision that it became necessary to administer a few whiffs of chloroform to complete the operation. He also detailed another case in which the needle was introduced more quickly and with better success; but slight vomiting, as well as other symptoms occurred. The subsequent course of both patients was uneventful.

Dr. BEVELLY MACMONAGLE, San Francisco, spoke of two cases which he saw, but they suffered a good deal from vomiting after the operation.

Dr. SENECA D. POWELL, New York City, did not think the time is ripe for this method to be presented to the profession at large. The results should be worked out by experienced hands. He pointed out the dangers of cocain, referred to the susceptibility of some patients to the drug, and cited two cases that had occurred in his own practice in which he had used cocain, saying that both patients came very near dying from its effects.

Dr. J. W. LONG, Salisbury, N. C., believed that the method was attended with danger except in the hands of experts.

Dr. RODMAN, in closing the discussion, said he had used medullary narcosis on a man, 45 years of age, who had a bursa in the popliteal space, with marked kidney trouble. The result was satisfactory in every respect. The next case was one of advanced kidney trouble in which he did a suprapubic cystotomy. Result, satisfactory. He would use medullary narcosis in those cases in which there are positive contraindications to ether or chloroform. The surgeon should always obtain the consent of the patient before using the method, on account of any medicolegal complications that might subsequently arise.

(To be continued.)

Chicago Ophthalmological and Otological Society.

Regular Meeting Held Oct. 9, 1900.

Dr. C. D. Wescott in the chair.

PRIMARY MELANOTIC SPINDLE-CELLED SARCOMA OF THE RIGHT EYE.

Dr. CASEY WOOD exhibited the patient and reported the case.

Mrs. C., aged 40, has not suffered from any serious illness, although her family history on the side of her mother, whom she closely resembles, is somewhat peculiar. The mother, two maternal aunts and one maternal uncle died of malignant disease—one of these (an aunt) from recurrent tumor of the eyeball. There is no history of any member of the father's family having been so affected. So far as her own experience is concerned, she never complained of any ocular affection except an asthenopic attack five years ago, probably due to prolonged

insomnia, from which she entirely recovered. Last February she noticed a feeling of fullness in the right eye, and about that time first perceived something growing on the iris. Shortly afterward she suffered from supraorbital neuralgic pains accompanied by lachrymation—all confined to the right side. These symptoms led her to a more careful examination of the eye and she observed two other, but smaller, spots on the colored part of the eye situated one above and one below the pupil. On June 2, 1900, she presented herself at Dr. Wood's clinic at the Post-Graduate Medical School owing to a return of the fullness in the right eye and because she noticed that the brownish deposit in the eye had considerably increased in size.

On examination the tension was found to be +1, while the vision was reduced to 2/7, somewhat improved on a hasty trial with lenses. The superficial scleral vessels were slightly enlarged. Toward the temporal side and directly outward on the anterior surface of the right iris was noticed a dark brown, smooth, irregularly triangular growth, apparently of about the same thickness as the iris, elevated above its plane and evidently growing from it. Its base was 3 mm. wide and was applied to the root of the iris, while its apex did not quite reach the margin of the pupil when that aperture was in a state of medium dilatation. It looked as if a piece of dark-brown velvet had been laid on the iris. With the oblique illumination the edges and some parts of the growth appeared to be translucent. Its borders were sharply defined, its surface seemed homogeneous and the neighboring iris tissue was not discolored or muddy. Two deposits, of apparently the same character as the largest tumor, were readily seen on the nasal half of the iris. They were of the size of pin-heads and were within, respectively, the upper and lower quadrants.

The pupil dilated irregularly with a mydriatic, hardly at all at the seat of the growth, although there are no posterior synechia to be observed and no indication of the tumor bulging behind the iris. The media and fundi, especially the ciliary retina and disc, appear normal. The eye is in all respects healthy, the iris especially being free of any abnormal pigmentation or elevated deposits. After keeping the patient under observation for a short time, a broad, peripheral iridectomy, including the whole of the temporal mass, was done. There was not more than the usual amount of hemorrhage and healing was normal. The excised iris tissue was preserved in 10 per cent. formalin and given for examination to Dr. Brown Pusey, who pronounced it to be a true sarcoma—mainly of the spindle-celled variety. Since June, the ciliary region about the iridectomy wound has been frequently examined by the ophthalmoscope and otherwise for further traces of the growth, but none has been found. The patient complains somewhat of photophobia in a bright light, and of blurring if she tries to do much near work. The remaining pigmented deposits would have been more rapidly seen if she had a light iris for a background, as probably her brown eyes prevented an earlier discovery of the disease. After the operation the tension became almost normal (it is still somewhat raised) and the scleral injection less. On Sept. 20, 1900, R. V. = 1/10; L. V. = 20/15. Ophthalmometer showed, left + or - 1, ax. 90°; right, + or - 3, ax. 105°, with -2 cyl. ax. 15°. R. V. = 20/20 nearly. The field for vision for white is sensibly contracted, probably due to secondary glaucoma. Since it is well established that the early and complete removal of an iritic melanoma is sometimes followed by cure, Dr. Wood has ventured to keep this patient under observation, warning her that a more radical operation will be urgently needed if there is any return of the growth or any increase in the size of the other suspicious deposits in the iris. Dr. Wood thought that from the appearance of the remaining pigmented growths that there had been originally three simple melanomata, that the sarcoma had arisen from one of these and that there was a chance of the others remaining quiescent. The four months that have elapsed since the operation is too short a time to draw conclusions as to the probability of a return of the disease. He promised a supplementary report at a later date.

Dr. F. C. Hotz considers the elevated spots in the iris of a suspicious nature, although the time since the case has been

under consideration is too short to make a positive statement. Early excision of the tumor invariably makes the prognosis a favorable one. He cited two cases of primary sarcoma which occurred in his own practice. One case has been under constant observation for two years, and the other for six years, neither one presenting any recurrence of the tumor. The eyesight has remained perfect. The tumors presented a reddish-gray appearance. The microscope revealed a slight tendency to melanosis. The first case, a woman 43 years old, presented a small flesh-colored, nodular tumor in the lower temporal portion of the iris of the left eye. It was flattened against the cornea, and reached up to the pupillary margin; the pupil was pear-shaped. Vision was 20/20. Tension was not increased, and no sign of any irritation of the eye. The tumor had been developing gradually since two years. In incising the cornea the entire tumor jumped up. It was connected with the iris by a narrow slender pedicle. The portion of the iris to which the tumor had been attached was also removed to prevent the possibility of a recurrence. Recovery was uneventful. The woman has reported from time to time for two years, and there has been no return. Microscopical examination showed the tumor to be a small round-celled sarcoma, with a tendency to become spindle-shaped, but not melanotic.

The second case, a man 32 years old, had a small flesh-colored tumor on the lower nasal portion of the left eye, reaching from the iris angle to the pupillary margin. Blood-vessels were plainly seen on its surface. Pupil was pear-shaped. On attempting to remove the tumor under cocaine anesthesia a strong resistance was felt, creating the impression that extension into the ciliary processes had already occurred. The iris was excised with the tumor and the next day a small hemorrhagic deposit showed on the ciliary processes. This was gradually absorbed, but after a while a grayish mass began to form. The final course of the case disproved the belief that this mass might be a recurrent tumor. The patient was last seen in January, six years after operation, and up to that time there was no recurrence, the eye being perfectly well, with full vision. Dr. Hotz feels positive that the long interval since the removal of the tumors in these two cases warrants the statement that a definite cure was brought about by the timely operation and removal of the tumor.

Dr. WILLIAM H. WILDER said that it is commonly believed by pathologists that the most malignant form of sarcoma is the small round-celled variety. On examining the specimen in Dr. Wood's case he found that in several places the cells exhibit a marked tendency to become spindle-shaped, so that it might be classified as a spindle-celled sarcoma. The tumor would therefore be of a less malignant character. The majority of sarcomata affecting the ciliary body and choroid examined by Dr. Wilder were of the spindle-celled variety.

Dr. WOOD, in closing the discussion, agreed with Dr. Wilder as to the character of the cells in the specimens examined. This, of course, increases the chances of the patient's recovery. Personally, he feels that it is desirable to enucleate the eye where the ciliary body is involved, since cases are reported of the successful excision of the tumor. It would not be right to enucleate in the spindle-celled variety where the ciliary body is not involved, and patients certainly ought to be given every chance unless there be a decided involvement of the root of the iris or a recurrence of the tumor. Dr. WOOD referred to the excellent and recent work on iris sarcoma done in this country by Veasey, and in Russia by Hershbaumer.

MELANOTIC SARCOMA OF THE ORBIT.

Dr. HOTZ reported a case of melanotic sarcoma of the orbit of an unusually rapid growth and malignant type. The patient, 51 years old, who had never had any eye trouble and always enjoyed good sight, stated that last April he was taken with violent neuralgia of the right side of the face and his right eye became inflamed and protruding. After several weeks the pain and inflammation subsided, but the exophthalmus persisted and the sight gradually grew dimmer, though during the last two or three weeks he thought his sight had been better again and the eye-ball less prominent. The examination, July 3, showed a high degree of exophthalmus and marked restriction of the movements of the globe; no down-

ward rotation at all, the upward rotation very limited and the lateral movements but fair. Pupil was dilated, media clear, papilla and surrounding retina edematous and veins enlarged. Vision was 20/100. The retorsal fold of the lower lid was perceptibly crowded forward by a soft elastic apparently fluctuating mass which filled the entire space between the ball and floor of the orbit.

July 5, the following operation was performed: Free division of the external canthus and a transverse incision through the lower fornix down to the tumor, which presented a perfectly smooth surface under the tarso-orbital fascia. When this membrane was incised a dark-brown soft mass like old blood-clots was extruded and many more such clots were removed with a scoop until the examining finger found in the space behind the eye and between the recti muscles nothing more but the optic nerve. To examine the posterior aspect of the globe and the optic nerve the externus was detached, the eye forcibly rotated inward and the nerve drawn into view by means of a strabismus hook. The posterior aspect of the ball appeared perfectly normal, but a few millimeters from it there was a dark-gray patch in the nerve sheath. This discolored portion, about 4 mm. in length, was cut out, the externus re-attached to the ball and a pressure bandage applied.

During the first week the ball seemed to recede into the orbit; but in the second week it was again forced forward; soon the lids could no longer be closed over it and the cornea became cloudy. The removal of the eye became an imperative necessity and was done July 20. As he found the whole orbit filled again with a soft melanotic mass which had permeated even the muscles, especially the inferior and externus, he removed the contents of the orbit, including the periosteum. The operation was concluded by cauterizing the nerve stump and tissue shreds around the optic foramen and packing the cavity with iodoform gauze. By August 4 the orbital walls were covered with healthy looking granulations and the patient left the hospital for his home. Three weeks later he returned with a new growth under the upper lid, a solid tumor immovably attached to, and evidently growing from, the supraorbital margin. Probably some infected shreds of periosteum had been overlooked in spite of the great pains taken to remove everything. In the orbit itself, however, no trace of recurrent melanos was noticed. While in the hospital a tumor had also been discovered in the region of the left kidney and when the patient came back this tumor had increased at a great rate, and a small melanotic tumor was then also found under the large toe of the left foot. No further operation was deemed advisable under these circumstances, as the exitus lethalis seemed a question of a short time.

A remarkable feature of this case is the sudden protrusion of the eye in April, for orbital tumors by their gradual growth push the ball forward slowly and gradually. He thinks there has been a small tumor in the cellular tissue, too small to create any perceptible disturbance, and in April a hemorrhage occurred from this tumor, which caused the rapid protrusion of the eye, and at the same time tearing up the orbital tissues favored the rapid spread of the melanotic growth.

The section of the enucleated eye preserved in formalin jelly and a number of microscopic slides were exhibited. These had been prepared by Dr. E. V. Brown, who gave the following explanation: The microscopic examination shows the main mass to be a small, round-celled melanosarcoma of the soft tissues of the orbit. Here the pigmentation is most marked and the round cells are predominating. More recent involvement had taken place by extension to the adjacent sclera, optic nerve sheath and optic nerve proper, the proximal end of which is invaded to a greater extent than the end nearer the eye-ball. New blood-vessels are in process of formation in the orbital and scleral masses, but very little connective tissue is present.

Dr. J. E. COLBURN cited a case of a large tumor of the orbit which had been diagnosed and treated as an abscess. The case was referred to him and an examination of the discharge showed the tumor to be a melanotic sarcoma. The orbital cavity was scooped out as far back as was possible. The frontal sinuses as well as the inner layer of the frontal bone were found to be involved. The patient died about a month

afterward. Another case, in a young boy, presented a bulging tumor in the conjunctiva above the eye. Examination of the semi-fluid discharge revealed a melanotic sarcoma. Operation was not consented to by the parents. Four months afterward the tumor was of enormous size, involving the entire side of the head. There was some sloughing and a very offensive odor. Dr. Colburn felt that an operation might have lessened the suffering of the patient considerably, but in all probability it would have hastened death as in the previous case.

Dr. WILLIAM H. WILDER considers the subject of recurrence and metastasis of sarcoma an extremely interesting one, especially when we are asking the question whether or not a positive cure has resulted. Some authorities speak of a cure after a period of three years has elapsed during which there has been no recurrence. This time-limit is, of course, a purely arbitrary one. The question which presents itself is that if recurrence takes place after this time we are to speak of it as a metastatic growth, or as an independent process. Some years ago in the laboratory of Professor Kundrath, in Vienna, Dr. Wilder saw a specimen of melanotic sarcoma of the liver in a subject who, thirty-two years before, had had one eye enucleated for sarcoma of the choroid. Post-mortem examination showed that the different organs were involved by the tumor. If this was metastasis, the period surely was a long one. Dr. Wilder said he had never heard of any longer period than that. This case emphasized the importance of being very chary in giving a favorable prognosis in this class of cases.

Dr. WILLIAM E. GAMBLE referred to a case which he exhibited before the Society in 1897. It was supposed to be a melanotic sarcoma of the ciliary body. He subsequently removed the eye, and up to the present there has been no recurrence of the growth in the neighboring tissues or elsewhere.

Dr. E. A. LAWBAUGH saw a case in London of sarcoma of the liver. The patient died. Mr. Loffard remembered that he had removed the eye of that patient seventeen years ago. The eye was found in the museum, and on examination the tumor proved to be a melanotic sarcoma of the eye. This case is similar to the one reported by Dr. Wilder.

Dr. WILLIAM A. FISHER dwelt on the importance of an early diagnosis in these cases, although in Dr. Hotz' case an earlier diagnosis would not have done any good. He cited the case of a boy, 10 years old, who had been having some trouble with his eye for two weeks. After giving him potassium iodid for three weeks the eye was enucleated and an encapsulated alveolar sarcoma was found at the bottom of the orbit.

THE USE OF PROTARGOL IN DISEASES OF THE EYE.

Dr. J. E. COLBURN reported several cases of acute inflammation of the lachrymal sac following an attack of influenza, which he treated with protargol. In one case there was a large swelling of the right, and a smaller one of the left, lachrymal sac, both of about three days' standing. He dilated the punctum with a cone-shaped dilator, and then introduced a dental syringe into the sac. After a few minims of some thickened secretion had been withdrawn, he injected a sufficient amount of 5 per cent. solution of protargol to fill the sac. An ice compress was then applied, and on the second day the inflammation had entirely subsided. On the third day the sac could be washed out through a canal into the nose.

The second case had a small bean-like tumor in the region of the sac. It was treated in the same way as the previous case, the same results accruing.

The third case was that of a man who twice before had had lachrymal abscesses, and once had to have the abscess lanced on the outside. The punctum was dilated, the sac washed out and then filled with a 5 per cent. protargol solution. Four days afterward the inflammation had entirely subsided, and the solution could be forced through the duct without any inconvenience.

Dr. Colburn offered for examination a small syringe devised by Dr. J. Austin. It consists of a metal tube connected with a glass cylinder, a check valve and a rubber bulb, which has a perforation on the side. This perforation is of great importance. The hollow needle can be introduced without holding the bulb compressed, and after introducing it into the

sac the bulb is compressed, the finger held over the little opening and the fluid, if not too thick, will be drawn into the chamber above. When using it as a syringe the tube can be filled with the solution without being obliged to pay any attention to the opening or solution. It is easily cleaned and does not get out of order. Dr. Dunn has applied the same principle to a medicine dropper, which is convenient, clean and easily handled. The quantity of fluid used can be regulated very easily. It is a perfect medicine dropper to use with solutions of atropin, eserin, etc., as it keeps them clean, because the solutions need not be drawn up into the bulb, and accurate dosage is possible. The valve in the glass cylinder prevents dripping from the tube held in any position.

Dr. A. E. BULSON, JR., Fort Wayne, Ind., has had some experience with protargol, but has found weak solutions to be practically inert. Believing stronger solutions to be more valuable, he increased the strength until he reached 50 per cent. He then got results which he could not obtain with the weaker solution. He agrees with Dr. Colburn that protargol in lachrymal abscesses and in the treatment of all forms of dacryocystitis yields very gratifying results. He has his solutions prepared by the druggist, who adds a little glycerin to it. He recollected reading an article in which a 50 per cent. solution was advocated, the weaker solution proving ineffectual. This strength solution will not affect the cornea, even if there are abrasions. Nitrate of silver does not act in the same way.

Dr. Hotz' experience with protargol coincides with that of Dr. Bulson. He had no results with protargol until he adopted a 20 per cent. solution as his standard. In that strength it has proved to be a most valuable remedy in the treatment of pyogenic affections of the eye, especially inflammation of the lachrymal sac. The stronger solution does not cause any more irritation and pain than the weaker solution. He has found this to be one of the great advantages of protargol over nitrate of silver. In a case of blennorrhoeal conjunctivitis, the 5 per cent. solution was absolutely worthless; the 20 per cent. solution was remarkably effectual. Dr. Hotz has discarded the weaker solutions entirely, as his experience with them has been very unsatisfactory.

Dr. C. P. PINCKARD inquired as to whether any of the members have had any experience with protargol staining the tissues. He is afraid to use it as he finds it to stain very rapidly, much more so than nitrate of silver.

Dr. WILLIAM H. WILDER has used protargol extensively, and has found nothing to be so beneficial in certain conjunctive cases, especially in trachoma when the follicles are large and succulent. He uses a 25 per cent. solution in equal parts of glycerin and water, and months of treatment have never resulted in any staining.

Dr. C. D. WESCOTT has seen at least two cases of argyrosis following the use of protargol in 10 per cent. solution. One of them developed much more rapidly than one would expect, even if a silver nitrate solution had been used. The susceptibility of the patient to protargol is certainly an important factor. Some patients complain bitterly of the pain and burning following the use of the same solutions used on others. He feels positive that there is a vast difference in the solutions of protargol as put up by different druggists; as to its effect in some cases, and as to the complaint that the individual patient will make in regard to the effect of different solutions during the treatment of the same case. Organic salts of silver are very liable to decompose, heat and light affecting solutions very rapidly. A great deal of care is necessary to have uniform solutions and uniform effects. In one of his cases staining of the conjunctiva occurred very rapidly from the use of a 10 per cent. solution every day for two weeks.

Dr. W. F. COLEMAN has also noticed the discomfort caused some patients by the protargol. He uses a 25 per cent. solution, as a rule, although in some cases he has been obliged to reduce the strength to 5 per cent. in order to obviate the pain and burning. He has never seen any staining follow the use of protargol.

Dr. J. E. COLBURN said that he uses a 10 to 20 per cent. solution, but always uses a fresh solution, because if they stand

about for any length of time they become inert. He injected a 5 per cent. solution into the lachrymal sac for the reason that it would be retained for some time and there would be considerable pain following its use if a stronger solution were used. The pain in the one case he cited may have been due to the pain of the tumor, but it seemed to him that the degree of pain was greatly exaggerated by the use of the protargol. He has noticed only little staining resulting from its use, and that little has disappeared within two or three hours. He has also noticed that the same solution will produce different effects in the same eye on different days. On one day there may be considerable irritation, and on the next none at all. He always washes the conjunctival sac with sodium borate before using the protargol, and after the patient has been in the office for fifteen minutes, he again washes the conjunctival sac, in order to clean it of little shreds of mucus, which are so aggravating.

Cincinnati Academy of Medicine.

Regular Meeting Oct. 5, 1900.

President Dr. C. L. Bonifield, in the chair.

APPENDICITIS COMPLICATED WITH PREGNANCY; OPERATION.

Dr. EDWIN RICKETTS reported the case of Mrs. B., aged 24, mother of four children, the last having been born in March, 1900. Her menstruation re-appeared in April, but there has been no flow since that time. In September she had a rather severe attack of pain referred to the lower abdominal region, the temperature reaching 104, and pulse 120. She was compelled to remain in bed for one week, after which the symptoms disappeared, not to return until November. On that date she suffered from symptoms indicating a partial obstruction of the bowels, temperature 102.5, pulse 110. Tenderness diffused over the entire abdomen, with periodical attacks of colicky pain. Diagnosis of appendicitis had been made by her attending physician. Examination of the uterus per vaginam showed it to be movable. Abdomen was opened in the median line as he did not know precisely what complications were to be dealt with. He found the bowel flexed and held back by the attached outer end of the appendix, which latter had to be stripped off, ligated and cut away. The bowels were enormously distended with gas so that a single puncture was necessary; after the escape of the gas the incision was stitched up with catgut. Bowels moved on the third day in response to compound licorice powder. The temperature was 98.8, pulse 90, when ninety hours after the operation a five-months fetus was delivered with but little discomfort to the patient. The specimen of the removed appendix was presented, and showed the walls of the same to be greatly thickened, but no pus was present.

STRANGULATED INGUINAL HERNIA.

Dr. B. MERRILL RICKETTS reported a case of a male, aged 83, in whom the hernia had been strangulated for thirty-six hours. The chloroform was easily taken. On opening the sac he found a gangrenous condition of the gut and it was necessary to remove seven inches of the latter. Anastomosis was made by means of the Murphy button. The patient did well for nine days in spite of the extreme warm weather. At no time did his temperature rise above 100 degrees. On the ninth day he suddenly complained of severe pain in the precordial region and died in a few minutes. No necropsy could be obtained. No cause of death could be assigned, unless a heart clot. Dr. Ricketts stated that he was informed by Dr. Murphy, of Chicago, that the patient was the oldest in whom his buttoa has been used.

OSTEOMYELITIS OF LOWER END OF FEMUR.

Dr. B. Merrill Ricketts reported a case of a boy 13 years of age, weight 195 pounds, who was injured very slightly on the left knee. Forty-eight hours later his temperature was 102.5 and he complained of severe pain and tenderness in the affected part. Within a few days the temperature ran to 104.5 and all the symptoms became greatly aggravated. On the thirty-third day operation of open incision was performed and about a quart of pus was removed from the thigh.

This was followed by the same amount of dark blood and clots apparently coming from the popliteal space. On finding extensive degeneration of the lower end of the femur, amputation was done at about the middle third. The lower fragment of the femur was spontaneously detached from the cartilage, ligaments and tendons about the knee-joint, so much so that there was absolutely no attachment. The patient's condition being so critical the removal of the medullary material was not done. For seventy-two hours his condition seemed hopeless but he has now recovered. It will in all probability be necessary to remove the medulla that recovery may be permanent.

GALL-STONES.

DR. B. MERRILL RICKETTS presented specimens from a woman, 58 years, who has complained of a pain and tenderness in the right side for the last six months. Tumor also appeared about six months ago in right hypochondriac region. As the diagnosis was uncertain, an exploratory operation was performed and the tumor was found to be the gall-bladder distended with stones, seven in number, aggregating 815 grains. The introduction of a needle into the tumor did not reveal the grating sound so often manifested in these cases. The stones were surrounded with a thick jelly-like substance, and were removed and the cavity carefully washed out. No urine was secreted from the 24th to the 36th hour, during which time 1/20 gr. nitrate of strychnia was given every two hours subcutaneously. Her condition seemed to be hopeless for four days after the operation, but she has gained so much in the last few days that recovery can be confidently expected.

REPAIR OF THE LEVATOR ANI MUSCLE.

DR. C. A. L. REED gave the anatomical relations of this muscle and called attention to the fact that not only does it, with its fellow on the opposite side, form the floor of the pelvic cavity, but also gives support to the various viscera passing through it. He had for a long time thought that the reason for non-success in the repair of a lacerated perineum was in many instances due to the fact that the anterior fibers of the levator ani, passing as they do downward along the sides of the vagina, were entirely neglected; he was convinced that these fibers were often ruptured in extensive lacerations of the perineum, so-called. His method was to make lateral incisions in the vagina over the muscle, find the divided ends and suture them together. So far in a small number of cases this procedure had met with complete success.

POST-MORTEM EXAMINATIONS.

DR. W. D. HAINES, the essayist, first called attention to the importance of autopsies, the difficulties of making them in private practice, and the generally slovenly manner in which they are performed under such circumstances. He called attention to the important preliminary observations to be made and laid especial stress on the position of the patient, of course referring to official cases. He carefully differentiated between post-mortem staining and ecchymosis, stating that the latter might be a most valuable medicolegal clew. In this relation he stated that the physical condition preceding death and the way in which death was produced greatly modifies the staining which follows. For instance, a man killed by lightning, one who succumbs to hemorrhage, and one dead of some long-continued exhaustive disease, will have little or no staining. On the contrary, those dying from acute diseases or accidents without great hemorrhage have the staining well marked. He then narrated one case in the practice of Dr. George W. Twitchell in which post-mortem staining took place before death. The skin covering the fingers, hands and forearms and that covering the toes, feet and ankles of the patient was livid for several hours before dissolution. Muscular rigidity was absent, the temperature subnormal. The patient, a robust girl, 34 years of age, had been seized suddenly thirty-six hours previously with a fatal malady. On post-mortem examination there was found appendicitis, gangrene of the bowel and perforation. The essayist further stated that probably the most troublesome class of cases that come to the attention of the examiner are those of sudden death, with few or no details as to the health or whereabouts of the deceased for some days

previous to the finding of the body. Such instances are by no means infrequent in any large city, and it is almost always assumed that some crime has been committed or suicide has taken place. The duties of the examiner are numerous and often embarrassing to a degree. Where poisoning is suspected the appearance of the mucous membranes lining the mouth, esophagus and stomach are valuable, but often exceedingly misleading signs. For instance the congestion of an acute stomatitis or pharyngitis from simple cause may resemble exactly that due to poisons; the finding of some poisonous substance in sufficient quantity to produce death is the only reliable proof that the suspicion of poisoning has been confirmed. The essayist then discussed fully the causes of post-mortem rigidity and called attention to the curious attitudes assumed by the deceased in sudden and violent death. Coming down to the examination of the lungs, he said that the fact that these organs floated when thrown into a basin of water was by no means proof positive that the infant had been born alive, and quoted Taylor's "Medical Jurisprudence" very extensively in support of this statement. Attention was then called to the differentiation between the vesicles scattered over the anterior surface of the lungs in case where death had taken place several weeks previously, and the vesicles found in the same location in victims of asphyxiation, and the following case was reported. A mother attempted to kill her two children by chloroform inhalation, and to make everything sure she turned on the gas after carefully sealing the room. The younger child died and the following autopsy report was handed the coroner: "Autopsy twenty hours after death. Post-mortem staining extensive; rigor mortis absent; blood very dark, fluid, and did not coagulate. A great number of vesicles were found over the surfaces of the lungs. Microscopic examination revealed many of the alveoli ruptured." The opinion was given that the child died of asphyxiation by coal gas.

Do the lungs of persons dead of drowning contain water? The essayist made the following experiment to determine this point. A subject dead of uremia was placed in a vat and sufficiently weighted to prevent floating. Water was then added until the body was completely submerged. Twenty-four hours later the chest was opened and, after ligation of the trachea, the lungs were carefully removed and examined. On slitting the trachea and larger divisions of the bronchi, ten grams of a mucous-aqueous fluid was obtained. A large number of examinations of the lungs of persons dead of drowning have been made since the above experiment, with special reference to this feature, and the conditions were similar to those found in the experiment, with the exception that in some instances the lungs contained less fluid than did those the subject of the experiment. It follows from the above that the lungs of persons dead of drowning do not contain water. On the other hand, neither do the lungs of persons known to be dead before being placed in water permit the entrance of fluid. Therefore, one may not say whether the subject was alive or dead when placed in water.

Philadelphia County Medical Society.

Meeting held Oct. 10, 1900.

President Dr. J. H. Musser, in the chair.

SUCCESSFUL REMOVAL OF CATARACTS IN INSANE PATIENTS WITH RECOVERY OF MIND AND SIGHT.

DR. WM. CAMPBELL POSEY read this paper. He reported the case of a man aged 45, whose vision had gradually failed for three years. Soon after the mind also became affected, until finally he became subject to delusions of persecution and was committed to the insane asylum at Norristown. Examination showed cataract affecting each eye. One of them was removed by linear extraction and recovery from operation occurred within one week. Two weeks after the operation the man showed marked improvement of mental symptoms. Some time later the other cataract was removed. Glasses were given and at the end of one month vision was almost normal. At this time the mental functions had so much improved that he was allowed to return home, apparently free from the evidences of insanity, and now, at the end of two years, apparently is well.

The second case was that of a woman aged 60, who had also complained of gradual loss of sight, followed by delusional insanity. She also suffered from cataract affecting each eye. In this case the cataract was removed under cocaine. After the operation almost normal vision was restored and with it the mental symptoms improved rapidly.

DR. CHARLES W. BURR, in discussion, stated that he had seen the first one after the operation had been performed and after the patient was apparently well. The explanation of recovery as given by the man was that he was a laboring man with a family and who, on finding that the vision was gradually failing, became despondent from loss of work and increased care, finally becoming insane. However, as soon as vision was restored he again found that he could once more do manual labor and support his family and the mind once more began to re-assume its normal functions. The speaker believed that in such cases of insanity the eye, like other organs, should be put in the best condition possible.

DR. COLLOCK stated that he had seen two similar cases benefited by operation.

DR. MORDECAI PRICE believed that every deviation from the normal lowered the cerebral functions, the correction of which would be followed by improvement of the symptoms. If the eye was at fault in cases of insanity the sight should be restored if possible and in most cases of insanity in which there is some special organ at fault he thought an early operation is indicated.

DR. GEORGE E. DESCHWEINIZ had operated probably twenty times on insane patients who also suffered from cataract. Some of these cases had been suffering with delusional insanity, senile dementia, alcoholic insanity and other forms of insanity. In one case of melancholia only, there was some improvement shown, such as cheerfulness, but in the others there was no improvement whatever. In his opinion operation for cataract on insane patients was generally followed by no improvement in the mental symptoms.

DR. POSEY, in closing the discussion, stated that in performing the operation on insane patients ether should be preferred. In these two cases presented, improvement of the mental symptoms followed after the operation. He had, however, operated in fifteen other cases without improvement being shown.

CLINICAL LAWS OF IMMUNITY OF DISEASE.

DR. LAMBERT OTT referred to the peculiar characteristics and manifestations of symptoms of such diseases as pneumonia, erysipelas and others which had a tendency to leave the patient more susceptible, while in others, such as scarlet fever, measles and the like, there was the opposite tendency. It had occurred to him that a patient suffering with one form of infectious disease in a measure was immune from some of the other infectious ones. For instance, sufferers of follicular tonsillitis seemed to be somewhat immune from diphtheria. In one family he had seen several members suffering from follicular tonsillitis, while another member of the same family had acute articular rheumatism. Immunity from the paternal side is not so readily transferred as from the maternal. This is well exemplified in the case of syphilis. The combined immunization conferred by different diseases combats infection from certain sources.

DR. JUBSON DALAND stated that the immunity transferred through the influences of heredity was an attractive one. The influences exerted by peculiar body characteristics seemed variable. As for instance, a plethoric person might suffer from a sthenic or asthenic attack of pneumonia. The high mortality in sthenic cases might in some cases depend on the amount of fibrin present, and the coagulability of the blood. As to the coexistence of two infectious diseases, he referred to cases of typhoid, combined with malarial fever. In such a case he had seen the influences of the malarial parasite first exerted, then subsiding while the symptoms of typhoid gained the ascendancy, after which the malarial parasite again became active.

DR. W. M. L. COPLIN referred to the antagonism existing between one organism and another. Admixture of dif-

ferent kinds of bacteria results frequently in certain ones being destroyed. The consensus of opinion seems to be in the specificity of immunity.

DR. SOLOMON SOLIS-COHEN referred to the natural immunity which is evidenced by tracing the history of certain diseases. For instance, syphilis and other diseases are now less virulent than formerly. He desired to know the data on which one might determine the clinical laws governing this subject.

DR. OTT, in closing, stated that his data had been derived solely from clinical experience gained at the bedside of the patient.

HEART DISEASE OR EPILEPSY.

DR. F. SAVARY PEARCE read a paper with the above title. He referred to several cases in which the patients had suffered from attacks of syncope, and marked by such symptoms that it was hard to determine whether the attacks were brought on by cardiac involvement or whether they resulted from cerebral origin.

DR. ERNEST LAPLACE exhibited his new inhaler for ether and chloroform. The apparatus was designed several years ago, and consists of a tortoise-shaped device composed of two thin pieces of nickel-plated metal, with a cross-shaped aperture in the top, and so united by a hinge at one end that they can be opened for the introduction of layers of gauze on which the anesthetic is allowed to drop. The under surface conforms to the shape of the face. The inhaler can be used for ether or chloroform. Its principal advantage is that it can be readily sterilized.

DR. E. W. HOLMES could not see that the new instrument had any advantages over the Allis inhaler, since the latter permitted a more ready inflow of air during inspiration. The idea in giving ether was to administer air saturated with ether, which is obtained by the Allis inhaler.

DR. LAPLACE stated that he had employed the instrument for nearly two years with success. As to the inflow of air in giving an anesthetic, all that is necessary with this apparatus is to slightly elevate the cone. In giving chloroform less gauze should be placed in the apparatus than in the case of ether.

Meeting held Oct. 24, 1900.

Acting President Dr. F. M. Perkins, in the chair.

DR. ARTHUR DARE presented a new hemoglobinometer, with which he has made over a thousand estimations. Compared with other methods, he had found that the results conformed closely with that of the Oliver method, but differed considerably with the Gower instrument. The instrument consists of a series of graduated pieces of colored glass corresponding with certain percentages of hemoglobin and are read off rapidly, using a candle as the light to be projected through the glass.

DR. J. ALLISON SCOTT had used the instrument several times and believed that the results obtained were approximately correct.

DR. H. W. STELWAGON gave a brief account of a report of Professor Finsen's light institute at Copenhagen. The speaker first reviewed the history of the treatment of diseases by the use of light rays in this institution. At the present time twenty people were under treatment every hour, with from 100 to 200 on the waiting list. Of these some were cases of tuberculosis of the skin, alopecia areata, and erythematosis. The light principally used was either direct sunlight or arc light. The rays are focused on certain diseased areas through long lenses. In this way very small surfaces could be treated. The light is transmitted through a piece of glass disc placed in contact with the skin. The eyes of patients and attendants are protected by dark glasses. In addition to the treatment by light, local measures are also employed, such as the application of pyrogallol, the galvanocautery, etc. The results have so far been quite satisfactory. The treatment is carried on for about one hour daily and the course extends over a period of several months. As to relapses, one must express an opinion with a considerable amount of reserve. The criticism has been that other plans of treatment had been of equal value to that of light.

DR. M. R. HARTZELL believed that some of the good results had followed probably from the other local applications employed. Such applications as iodine and pyrogallol are of distinct value in many cutaneous affections. The great expense attending the establishment of a place where the work can be carried on militates against its employment. Under certain conditions he believed the light treatment was of value.

DR. A. A. ESINER reported some anomalous cases of typhoid fever. In some of these cases the Widal reaction had been of decided value in making a diagnosis. In certain types the disease is really a septicemic process, probably depending on the mode of infection. In some instances the symptoms closely resemble military tuberculosis.

TYPHOID BACILLI IN THE URINE AND ITS DISINFECTION.

DR. NORMAN B. GWYNN read a paper on this subject. Reviewing the history, it was found that Bouchard had, in 1881, claimed to have isolated typhoid bacilli from urine in 50 per cent. of the cases. Other writers had spoken of finding the micro-organism in 20 to 30 per cent. of the cases. As a rule, pure cultures are obtained. The urine may appear quite clear and is generally acid in reaction. In one instance he had found five million typhoid bacilli in ice of urine. He had experimented with various reagents to disinfect this urine, such as milk of lime, carbolic acid, bichlorid of mercury, chlorid of lime, formalin, and liquid chlorids. The results obtained with slaked lime, or milk of lime, had not been satisfactory. In a mixture of which two-fifths of the bulk had been milk of lime, living bacilli had been found. Carbolic acid was found to be of value when used in large amount. In a solution of 1 to 40, typhoid bacilli lived for days. Bichlorid of mercury was useful in a strength of from 1 to 40 up to 1 to 20, the latter disinfecting in about one hour. Formalin in a solution of one-tenth of 1 per cent. disinfects completely within half an hour. Chlorinated lime was found to be one of the best disinfectants, especially in those cases in which the urine is acid. To disinfect 1200 c.c. of urine requires 30 c.c. of chlorinated lime solution. Liquid chlorids have been found to be of considerable value, but must be used in large amount.

DR. HOWARD S. ANDERS referred to the atypical cases of typhoid frequently met with. He had always insisted on careful disinfection of the urine in this disease.

DR. J. P. CROZER GRIFFITH referred to certain cases of typhoid in which no intestinal lesions had been found at necropsy. Typhoid fever in children is nearly always anomalous when compared with the disease in adults. As a rule, in children it only lasts from 14 to 17 days. Sometimes it may simulate meningitis.

DR. SOLOMON SOLIS-COHEN spoke of the necessity of disinfection of urine in typhoid cases. He referred to a case that he had treated recently in which there had been cystitis, and in the urine pus and typhoid bacilli had been found.

DR. DAVID RIESMAN thought that since the Widal reaction had been generally used more anomalous cases of typhoid had been discovered than formerly. In these cases in which death had been due to a bacteremia, the pathologist might have overlooked the real disease. At the present time in such cases the typhoid bacillus may be isolated from the spleen.

DR. A. G. ROUSSEL had recently treated an anomalous case of typhoid in which there had been no intestinal lesions post-mortem.

New York Academy of Medicine—Section on Pediatrics.

Meeting held Oct. 11, 1900.

CONCLUSIONS FORMED AFTER SIX YEARS' EXPERIENCE WITH THE ANTITOXIN TREATMENT OF DIPHTHERIA.

DR. HENRY F. KOESTER opened the discussion with a paper having this title. It was founded on a large experience as one of the inspectors of the health department, and on 170 cases seen in private practice. He advised 2000 units as the minimum dose, and recommended giving 3000 units in severe cases, and repeating this dose in twelve or twenty-four hours. If the case were one of nasal diphtheria, he would give 4000 or 5000 units as the initial dose, and if there was laryngeal dip-

theria present, a dose of 4500 to 6000 units. In the cases of mixed infection, or so-called septic cases the first dose should be as high as 5000 or 6000 units. The foregoing figures show that Dr. Koester has absolute confidence in diphtheria antitoxin as a curative remedy in diphtheria, and moreover that he believes it is perfectly harmless. For immunizing purposes he was accustomed to give 200 to 500 units, and as a result of his observations in 1800 cases of immunization he had learned to think very well of this method. In addition to using antitoxin he syringes out the throat with bore acid, or better still with a neutral solution of hydrogen peroxid, taking care to have the patient's mouth open during the syringing to guard against the entrance of fluid into the Eustachian tube. He strongly condemned calomel fumigations in laryngeal diphtheria on the ground that they were unnecessary where antitoxin is used, and by their irritating action predispose to pneumonia or bronchitis. The most common sequelæ of the antitoxin treatment of diphtheria were urticarial eruptions and joint pains. For the former, he advised sponging with cold water and vinegar; for the latter, rest and the internal administration of the salicylates. His conclusions were: 1. Antitoxin is a positive cure for diphtheria when used early and in sufficiently large doses. 2. Even when employed too late to secure its specific curative action, it can not do harm under any circumstances. 3. When administered before the invasion of diphtheria antitoxin possesses a positive immunizing power, which lasts about 30 days.

WHAT QUANTITY AND GRADE OF ANTITOXIN SHOULD BE GIVEN IN DIPHTHERIA AND HOW SHOULD IT BE ADMINISTERED?

DR. WILLIAM H. PARK, of the Health Department, read this paper. He said that he had experimented at the Willard Parker Hospital during the last two months with small doses, giving to the cases in rotation as they were met with, 1000, 2000 and again 1000 units, without regard to the severity of the disease. During the time these experiments on small doses were being carried on the type of the disease was rather mild. Of the 93 cases, 42 received 1000 units. Of this series, 16 per cent. died. Of the 51 cases receiving 2,000 units, 13 per cent. died. Ten cases in the first series, and twelve in the second developed rashes. The local condition seemed to improve more slowly under the smaller doses. For severe cases of ordinary faucial and laryngeal diphtheria, he now advises beginning treatment with a dose of 3000 to 5000 units, and repeating it in 12 or 15 hours if no improvement has been observed. He does not think there is much prospect of our being able to eliminate the antitoxin rashes.

ANTITOXIN IN THE TREATMENT OF DIPHTHERIA.

DR. JOHN H. MCCOLLOM, resident physician of the Boston City Hospital, presented a paper detailing his experience with very large doses of antitoxin. In one desperate case, that of a child admitted on the third day of the disease, a total of 60,000 units of antitoxin had been given in doses of 4000 each, yet the only troublesome symptom had been an urticaria. The patient had recovered. In another "septic" case, occurring in a girl of 4 years, and apparently doomed, recovery followed the use of 48,000 units of antitoxin. This amount had been reached before the characteristic effect of antitoxin had been observed. These cases were fairly illustrative of a large number which Dr. McCollom said had deeply impressed him because recovery had taken place, although from previous experience one would have been justified in assuming that they were hopeless, if not indeed, moribund at the time of their admission. He believes, therefore, it is the physician's imperative duty to resort to these enormous doses of antitoxin if smaller doses do not suffice or if the condition is especially desperate. He said that since September, 1895, 104 cases of clinical diphtheria had developed among the physicians and attendants at the Boston City Hospital. Antitoxin had been used in all of them, and every one had recovered. Paralysis had not occurred, and the duration had been below the average. Frequent urinary examinations had been made in 633 cases. In 42.3 per cent. there was no albumin; in 57 per cent. there was a minute trace. While the prognosis varies with the quantity of albumin in the urine, it is of no great significance. Of the 71

autopsies, not one showed a state of the kidneys such as could have had much to do with the fatal issue. Paralysis had not been observed more frequently among the cases receiving antitoxin than among those treated without it. The author's conclusions were as follows: 1. The ratio of mortality of diphtheria per 10,000 living was very high in Boston prior to 1895. 2. This ratio has been very materially reduced since the introduction of diphtheria antitoxin. 3. The percentage of mortality in the South Department of the Boston City Hospital is lower than in any other of the hospitals used in his paper for purposes of comparison. 4. Since the larger doses of antitoxin have been used there has been a decided diminution in the mortality in apparently moribund cases. 5. There have been no injurious effects from the use of the serum. 6. To obtain the best results the diphtheria antitoxin must be given at the earliest possible moment.

DR. W. C. DEMING opened the general discussion, speaking from an experience in the Health Department represented by 277 cases of diphtheria and 479 cases of immunization. For ordinary cases he preferred an initial dose of 2000 units, and for severe or for laryngeal cases, a dose of 4000 units. For immunizing purposes he uses 200 units for infants, 300 to 400 in young children, and 500 units for adults.

DR. L. K. NEFF said that in "septic" cases or in laryngeal diphtheria he used about 7000 units for a child of 10 years, and gave half this quantity as a second dose within twenty-four hours, if no improvement had occurred. In ordinary tonsillar diphtheria, 3000 units would effect a cure.

DR. JOSEPH E. WINTERS commented on the very large number of cases of diphtheria developing in the Boston City Hospital. He said that on three different occasions he had observed a higher rate of mortality at the Willard Parker Hospital in those cases of diphtheria receiving the larger doses of antitoxin. This had been the experience last summer; the highest mortality had coincided with the use of the very large doses, and the lowest mortality with the period in which the small doses had been employed.

DR. H. W. BERG said that after careful observation of the cases at the Willard Parker Hospital he had become impressed with the fact that those that had received the very large doses of antitoxin had not done as well as those treated with the smaller doses. He had also noticed more albuminuria, the more frequent occurrence of erythematata and a larger proportion of these cases of broncho-pneumonia during the period when the large dosage had prevailed. In his private practice he never used more than 1000 units at a single dose, though he often repeated this two or three times. He was opposed to the very large doses simply because of the large quantity of heterogeneous serum that must be introduced at one time.

DR. CHARLES HERMANN said that it was generally stated that an immunizing dose of antitoxin confers immunity for 30 days, yet it had been demonstrated recently that this period is not over 21 days. Where measles and diphtheria are associated, the immunity lasts only two weeks, and the immunizing dose should be 500 instead of 300 units. It is well to remember that the antitoxin eruption may at times very closely simulate the eruption of scarlatina.

Philadelphia Pediatric Society!

Meeting, Oct. 9, 1900.

Dr. Alfred Stengel in the chair.

DR. W. O. XANDER presented two cases of infectious nephritis secondary to mumps before the Society and gave their histories briefly as follows: The boys were cousins, nearly the same age, and both lived practically under the same circumstances. Neither of the cases had suffered from scarlet fever, typhoid, nor diphtheria. The speaker did not see the first case until recovery had practically occurred, but the history had been that there had been enlargement of the glands of the neck. There was general edema, pallor of the skin and glandular enlargement. The urine contained blood, casts and albumin (one-third by volume). In the other case there were distinct evidences of nephritis. Neither gave a history of desquamation of the skin.

DR. A. A. ESHNER did not concur entirely as to the nomenclature employed. Calling these cases nephritis of infectious origin resulting from mumps might be open to some doubt, since such a condition is very rare and the infectious nature which was supposed to have caused the nephritis occurred some time before. The fact that nephritis arose did not necessarily imply that the cause was due entirely to some infection. Parainfections seemed a better name to use.

DR. W. M. WELCH believed that nephritis following mumps was very rare. He had seen certain cases of scarlet fever in whom there had been but very slight cutaneous involvement, but with glandular enlargement, and it was possible that the cases might be of this nature.

DR. ALFRED STENDEL had seen these cases some time after the attack. In his opinion the diagnosis of mumps was somewhat doubtful, since the glandular enlargement had been quite low in the neck. He did not believe these cases had suffered from scarlet fever. It seemed probable that they had had the type of acute glandular enlargement described by Pfeiffer and others as a glandular fever.

DR. XANDER, in closing, stated that he did not think these cases had scarlet fever, since there had not been any desquamation, even between the fingers, where it was prone to occur. There had been no epidemic of scarlet fever in the neighborhood.

DR. T. S. WESTCOTT read a paper entitled "A Method for Differential Modification of the Proteids of Milk in Percentage Mixtures." The method for determining these proportions he had arrived at by mathematical calculations. For the most part the calculations were based on the formula of milk as determined by Koenig.

DRS. HAMILL and MACLACHLIN presented a case of supposed congenital syphilis with rapidly destructive lesions. The history was that the child appeared to be normal at birth, but a few days later a deep ulcer developed on the upper lip, which continued to spread until at the end of the twentieth day the upper margin extended almost as high as the outer canthus. Above this diseased area there was a large surface covered with a bright reddish eruption in which there were abundant papules. The child also had nevi affecting the trunk and face. The speaker could determine no manifestations of syphilis on the part of the mother. She had given a history of having had two miscarriages.

DR. JAY F. SCHAMBERG could not altogether agree as to the diagnosis of syphilis. Congenital syphilis was usually accompanied by secondary symptoms and signs, such as blebs and bullae, snuffles and the like. He was rather of the opinion that it was due to a trophic disturbance such as occurs in herpes, leprosy, etc.

DR. J. H. MCKEE and others had seen this case on the twelfth day after birth, and it was the consensus of opinion that it was not syphilis.

DR. D. L. EBSALL coincided with the view of Dr. Schamberg. He believed that the condition was due to vascular disturbance. He had seen a case in which there had been a swelling of both cheeks in an infant about a year old. Both cheeks had within a day assumed a purplish or bluish hue, were cold, and painful on pressure. Subsequently some sloughing occurred and gave rise to a diagnosis of cancerum oris affecting both sides of the face. Within a period of only a few days the condition disappeared and recovery took place. The opinion expressed was that the latter case was due to thrombosis.

DR. F. A. PACKARD, on behalf of the milk commission, appointed by the Society to determine the quality of the milk sold in the market of Philadelphia, stated that since this commission was probably the first one appointed for such a purpose by any society, the work was hard to outline and for that reason time would be required to develop the methods. This commission had, however, gone to work and had endeavored to learn the methods of improving the quality of the milk in different cities. The commission which he represented had obtained legal advice as to the necessary powers to be given and other matters. They had sent out notices to dairymen of the work of the commission, asking if such producers desired their product examined. Of three examined, two came up to

the required standard. The work of the commission will be continued.

DR. M. OSTHEIMER (by invitation) reported a case of fatal intestinal hemorrhage of unknown cause in an infant of 5 months.

DR. J. M. JOPSON reported a case of stricture of larynx following intubation, occurring in a boy 5½ years of age. In this case the tube had been left in the larynx 45 days, and the stricture doubtless resulted from cicatricial contraction due to pressure of the tube.

The conclusions as to the mode of action to relieve suffering from shock and effects of hemorrhage:

1. Hypodermoclysis at a temperature of 110 F. is a direct tonic to the sympathetic nerve-centers.
2. It is a tonic to the muscles of the blood-vessels.
3. It is a tonic to the heart, by distending its chambers with increased bulk of fluid.
4. It washes out the tissues and dissolves the toxins, urea and other excrementitious products and passes through the kidneys rapidly.
5. A short time after a normal salt solution is injected into a vein a chill may occur, followed by perspiration and labored respiration. With subcutaneous injections these symptoms do not occur.

—John R. Maynes: *South Cal. Pract.*

The Treatment of Leprosy with Oil of Chaulmugra.

At a recent meeting of the Charité Society of Berlin, Dömitz (*Berliner klin. Wochenschrift*, 1900, No. 36, p. 733) reports successful results from the treatment of two cases of leprosy with subcutaneous injections of chaulmugra-oil. The drug has long been administered internally for this purpose, but it is not always well borne. It was found that the subcutaneous injection was followed by both local and general reaction, the former consisting in redness of the affected areas and the latter in distinct elevation of temperature continuing for several days. Pericyclic redness of both eyes, persisting for some time, was especially noteworthy. The injection was repeated only when the ocular irritation had subsided. There was soon no doubt that the infiltrations were disappearing. Their turgescence diminished; the skin became finely wrinkled and again mobile; and the color improved. In the course of four months, extensive infiltrates disappeared, leaving only a bluish discoloration. The face, from having presented a typical leonine appearance, acquired its normal expression. In this case sulphur-baths also were employed, and it is thought these may have exerted a salutary effect; but the other patient received only injections of oil. In the latter instance also the results were eminently satisfactory. In both vision was improved through a clearing up of the cloudy cornea. The dose selected was that just small enough to excite reaction, and it was not repeated until the effects of the previous injection had subsided. For this purpose 0.1 or 0.2 grams were required at intervals of from ten to fourteen days. It is suggested that possibly the same method of treatment may be successful with regard to other cutaneous affections, as for instance those of syphilis.

Medicolegal.

Expert May Give Opinion on Facts He Relates.—While it is true that an expert can not be asked to give his opinion based merely on the testimony heard by him, whenever there is a conflict in such testimony, yet, when the material facts are within such expert's own knowledge, and related by him in his own testimony, he may, the Supreme Court of Utah holds, in *Wells vs. Davis*, give an opinion based wholly on such personal examination and knowledge, without having such facts hypothetically stated.

Professional Secrecy in the French Courts.—The plaintiff, in a recent case decided in France, insured in May the life of a man who died in November. The insurance company claimed that it had been fraudulently induced to insure an incurable, and proved this fact by the testimony of the physician of the deceased. The testimony, however, was thrown out by the supreme court as inadmissible on account of its having been obtained by violation of professional secrecy. The company was therefore compelled to pay the insurance.

Still Liable for Medical Attendance for Wife.—In *Ort vs. Hentall*, brought to recover from a husband for medical attendance, nursing and board, furnished his wife, at her request, she pledging his credit, after he had so treated her as to seriously injure her health, in consequence of which she had left him, the Supreme Court of New Hampshire holds that the statutes of the state enabling married women to hold to their own use property acquired by them, and enlarging their rights and liabilities, do not affect the wife's authority to pledge his credit, in such a case as this, for necessities.

Conclusive Determinations as to Sick Benefits.—In *Myers vs. Jenkins*, the Supreme Court of Ohio holds that when a member of such an order as that of the Independent Order of Odd Fellows claims to be entitled to sick benefits, he must seek his remedy, in the first instance, in the lodge and the tribunals of the order. And the determination of the matter by such lodge and tribunals, in substantial accordance with the laws of the order, it declares, will be final and conclusive of the right to receive such benefits. If the lodge refuses or neglects upon proper demand to have the right to such benefits determined in substantial accordance with the laws of the order, or refuses to pay such benefits after the same have been awarded to such member, then, it says, such member may sue in the civil court for the recovery of such benefits.

Contract With Physician Not Binding on New Board.—The Supreme Court of New York holds, at a trial term in Ulster county, in the case of *Connelly vs. the Commissioners of the Alms House of the City of Kingston*, that a contract made with a physician to render surgical and medical services to the city poor for a term of years, as for instance for two years, by a board constituting a department of the city government, is not binding upon a succeeding board, formed in consequence of the term of office of one-third of the members of the board expiring each year. It says that the good of the public service would seem to demand that, apart from legislative provision, incoming boards should not be bound, against their will, by contracts made by outgoing boards extending far into or through the term of the new board. And it holds that one who deals with the officers or agents of a corporation is bound to know their powers, and the extent of their authority. Besides which, it suggests that, the duration of the position of physician to render medical and surgical services to the city poor not being prescribed by law, treating the position as an office, or an employment under contract merely, it would seem to be one that could be terminated by the employing board at pleasure, in that state, although it does not find it necessary to here pass upon that point.

Manager Not Authorized to Employ Physician.—In the case of the *Pittsburg Coal and Coke Company vs. Shaley*, it appears that an employee, at a place in Indiana, of a corporation having its principal office in Chicago, was injured, while in the line of duty, so that he suffered extreme torture and severe pain, and required immediate relief in the way of

medical attention. The manager of the company's office and yards at that place, who was at the time the highest officer there, employed, on its behalf, a physician to render to such employee such medical aid and attention as he required and his injuries demanded. But a statement of these facts, the Appellate Court of Indiana holds, was not sufficient to withstand a demurrer where it was sought to hold the company for services so rendered, there being no allegation that the employment of a physician for injured employees came within the scope of the duties of the manager mentioned. The court declares that it can not hold as a matter of law that such employment would come within the scope of the duties of the manager of the coal company. It has often been held, it says, that the manager of a railroad has authority to employ physicians and to bind his company for their services, and the same power has been given subordinate officers of railroads in cases of emergency. But the reasons for such a rule as is applied to railway companies, the court holds, do not obtain in such a case as this.

Board of Health Orders Must be Reasonable.—An order was issued, in the name of the Mississippi State Board of Health, which provided, "On account of yellow fever at several places along the coast in this state, and several cases of yellow fever at Edwards, and reported suspected cases at various other points through this state, until further ordered by this board no person will be allowed to get off trains and boats at any point or station in the state of Mississippi," etc. Now, this order, the Supreme Court of Mississippi holds, in the case of *Wilson vs. the Alabama Great Southern Railroad Company*, must be held void by unreasonableness. All orders of the board of health, it declares, must stand the test of reasonableness, and their reasonableness is for the court to determine. Regard, it goes on to say, must, of course, be had to the maxim, "Salus populi suprema lex," or "the welfare of the people is the supreme law," but regard must be also had to the liberty of the citizen, and both principles must be given reciprocal play. The public health must be vigilantly cared for, but with due caution that no order intended to secure it shall be so sweeping and arbitrary as to interfere unreasonably with the citizen's rights, say, of return to his home, neither be nor it having been exposed to infection. For example, the plaintiff in this case was from Meridian, Miss., a noninfected point, and had a duly-issued health certificate, and was returning from Nashville, Tenn., a noninfected point, to his home, in Meridian, on a valid excursion return ticket. He had not been exposed to infection. Yet he was put off the train in compliance with the above-quoted order. The order, as will be observed, and the court points out, was not that no person who had been exposed to infection, or who came from an infected point, or who was destined for an infected point, should be allowed to come into the state, but that no person whatsoever, from any point whatsoever, should be allowed to get off anywhere in the state. The authorities, it insists, are uniform that this sort of order is wholly indefensible, so it pronounces this order void for unreasonableness, and holds that it was error to grant a peremptory instruction for the defendant railroad company, in this action for damages against it. A railroad company, it holds, must take the risk—as all citizens do—as to the validity of such orders, when it yields to the order alone. But when its defense is, not that it yielded obedience because of the order only, but because, also, of vis major, or irresistible force—a shotgun quarantine, for example—its defense, the court adds, will be maintained, if it shall appear that such vis major, such uncontrollable necessity, was the real cause of action. It need not go to the extent of actual collision with force marshaled by necessity; but it must show that its action was due to such force, existing and capable of controlling its action.

3. **Ruptured Urethra.**—Four cases of this accident are reported by Jacobson, who has selected them from a number treated in hospitals and private practice. They show, in his opinion, that only a slight degree of force is necessary, not only to lacerate but to completely sever the urethra, that the necessity for early diagnosis is apparent and immediate relief imperative. If urinary leakage and constant infection of the soft parts is not prevented, gangrene and danger to life from sepsis may be expected. The author does not consider repeated catheterization wise or the wearing of a permanent catheter advisable. On the other hand, satisfactory drainage of the bladder and soft parts is readily accomplished by perineal incision. He believes that the perineal catheter, after having been worn forty-eight hours, can, on removal, be replaced in the dark, so readily and thoroughly do the tissues cement. It should be removed once a day for thorough cleansing and this, with daily irrigation of the bladder, keeps the parts in good condition. Granulation tissues spring up on all sides and the mucous membrane grows in from the severed ends of the urethra until the tube is relined. The shaping of the canal is accomplished by the daily passage of a full-sized curved sound into the bladder or, if this is very painful, the sound can be inserted on alternate days for two weeks. Its use should be begun on the third or not later than the fourth day, and if systematically carried out, using a sound of 32 to 36 French, no danger of stricture is to be feared. He calls special attention to the recognition of the proximal end of the severed urethra by palpation and feels sure that careful search will often locate this end and permit the ready introduction of the catheter into the bladder.

5.—See abstract in THE JOURNAL of October 20, p. 1051.

7. **Meralgia Paresthetica.**—This condition, first noticed within the last five years, has been since frequently observed, but the majority of cases are atypical. The operative treatment of the external cutaneous nerve by resection is the method for its relief. Gordon reports a case which varied from the usual type in the involvement of other branches of the cutaneous nerve and in producing the intermittent lameness described by Charcot and Goldflam. The whole of the external cutaneous nerve, with both its branches, and also the cutaneous branches of the crural nerve, were involved. The patient declined surgical intervention and therefore remains un cured.

8.—See abstract in THE JOURNAL of November 10, p. 1232.

9. **Subarachnoidean Injections of Cocain.**—Murphy's article is similar to, though not identical with, the one recently noticed in THE JOURNAL of October 20, 176, p. 1056, and the illustrations are similar. He reports, however, a number of additional cases and believes that the range of usefulness of the method is increasing as confidence and security are assured by the results. He ranges it, however, after nearly all other anesthetics as regards safety, and recognizes for it after all only a limited utility so far as present experience warrants.

12. **Bronchial Disease and Ether.**—Reamy maintains that the existence of bronchitis is by no means a contraindication to the use of ether and, in fact, he uses ether in all cases excepting those of strongly-marked disease of the kidneys or respiratory organs. He insists on the purity of the ether used and the use of a modified Trendelenberg position in case of weak heart or bronchial trouble, and on care in the method of administration. He prefers the closed inhaler in cases of bronchitis, reports cases in which he has used it, and remarks that his records show that he has also employed it in the acute stage of bronchial disease with the result of arresting the cough and destroying the congestion present. In conclusion he reiterates the statement that his clinical studies justify him in the belief that in properly selected cases ether inhalation

tion is positively curative of bronchitis. Its action in these cases is largely local. To avoid unpleasant complications and to secure the desired results, the following points are essential: 1, proper preparation of the patient; 2, preparation of the operating-room with a temperature of 98 to 100 F.; 3, pure ether; 4, a proper inhaler; 5, proper methods of administration; 6, due caution against exposure in removing the patient from the operating-room to her own room. The temperature of her room should not be below 80 degrees for several hours after the operation; 7, proper care of the patient during convalescence. She should be permitted to drink large quantities of water and should keep the bowels freely open.

15. **Treatment of Syphilis.**—Ayres reports his experience in the treatment with mercurio, a remedy which he thinks is of great value. It caused gastric irritation in but one case, and he thinks it better in this respect than any other preparation of mercury used internally. It controls skin eruptions better than other preparations, while the mucous eruptions are affected by it as well as any other. It offers the further advantage that it can be taken in pill form.

17.—See abstract in THE JOURNAL of September 1, p. 579.

20. **Gout.**—Robinson's paper is a somewhat critical one on the prevailing views on gout. He is sceptical as to dietetic treatment, maintaining that no absolute theory of gouty treatment based on mere diet will answer many of the requirements of the condition and that functional disturbances of various forms may arise seemingly without cause. There is little doubt, he thinks, that many gouty manifestations which appear to be functional are really inflammatory in their nature, and credits some disorders of the prostate, uterus and ovaries, more rarely the intestines, and also appendicitis, to this taint. He says there are forms of peritonitis not connected with appendicitis and that there is much operative interference for the local conditions when the disease is one of general systemic taint and, of course, is untouched. The general tone of his article is to emphasize the value of long experience, utilizing all the data, as against scientific and especially operative enthusiasm with less experience.

21. **Prostatic Enlargement.**—Bissell recapitulates his article by stating that dissections of the pathological prostate show that hypertrophy is almost never confined to the middle lobe alone, but that the whole of the prostate is involved. This involvement is glandular and fibroid in character. The older the case, the greater the predominance of the fibroid element. At times there is a venous congestion and a stasis also of the capillaries, which adds a vascular element to the size of the prostate and its adjacent tissues. Any operation which does not attack the hypertrophy of the lateral lobes is not radical and can not effect a permanent cure. The removal or destruction of the middle lobe, in the great majority of cases, only partially if at all removes the cause of the obstruction, although the multiple cauterizations may so relieve the capillary stasis and edema of this portion as to give a very decided temporary relief; and if most of the obstruction in any special case is due to this condition the relief may be marked and last for considerable time, provided the bladder and kidneys have little or no secondary disease, and provided sepsis does not follow. From the above he assumes that prostatectomy with drainage is an operation, under modern aseptic conditions, as little dangerous as an interval-operation for appendicitis in properly selected cases where general tissue-degeneration of the body has not progressed to a hopeless extent, the bladder and kidneys are not too seriously damaged and septic infection, if it exist, is not too profound. Even with a part of these conditions existing, complete removal of the prostate with free drainage is rational and scientific treatment, and offers the best hope of relief and the best chance of a permanent cure with the least danger to life.

22. **Climatic Treatment of Tuberculosis.**—The various climates for tuberculosis are discussed by Campbell, who enumerates the following conditions as destroying to germ life: High percentage and volume of sunlight; temperature of sun sufficiently high to promote sterilization; dryness of

atmosphere; porousness of soil; constant freezing temperature; infrequency of habitation, and unfavorable conditions for the formation of dust. The first three of these conditions are actually germicidal and positive in their action, the last four simply unfavorable for the formation of germ-life. He thinks each case should be treated individually and speaks of the lower regions of Arizona and their advantages for tuberculous patients.

23. **Chronic Copper Poisoning.**—The accidents to which artisans in copper are especially liable are noticed by Kurth, who finds the true characteristic symptoms to be the dyspepsia, which is the earliest to appear, anemia, which is also early and comes before emaciation, loss of strength or painful facial expression, and lastly, nervous irritability. If, together with these facts, the patient works in copper or brass, the diagnosis is not difficult. The facial expression is drawn and anxious, like that of marked phthisis. The complexion is darker than that usually seen in anemia. The term "sallow" comes close to describing it. Nervousness is very pronounced. The prognosis is uniformly good when organic changes have not occurred. The treatment is prophylactic above all. If the patient can not give up his occupation, a vacation for two or four weeks will sometimes be of the greatest benefit. He suggests intermittent occupation in this particular line of work, similar to that prescribed by law in Germany as regard lead-workers in potteries. The chief reliance, however, must be on prophylaxis and change of occupation.

28. **A New Test-Meal.**—A new test-meal suggested by Austin consists in 2 grams of dried egg-albumin compressed into tablets to be taken with two glasses of water and the contents withdrawn one hour later. He considers that this better meets the conditions, as it is free from the objections of indefiniteness of the amount of the food elements employed and the clogging of the tube in the removal of the usual test-meals. He compares this with Ewald's test-meal commonly employed and discusses the different features observed in patients subjected to his experiments. He considers that the unreliability of the presence of lactic acid as a diagnostic symptom is well brought out in these experiments, and maintains that the tablets fill all the necessary conditions of the usual test-meal for testing the stomach secretions.

31. **Agglutination of the Bacteria in Cystitis and Pyelitis.**—Brown has experimented with the bacteria found in four cases of cystitis, in one of which the kidney was also involved. In two of the three cases in which a complete test was made there was an absolute positive agglutination reaction and a suggestive reaction in the third, with the patient's serum. This suggests that it may be frequently found to occur in cases of cystitis and pyelitis and may be a means of differentiating the bacteria where there is doubt. One notable point made was the pleomorphism of many micro-organisms, the bacillus coli in particular. He finds that by cultures and transplantations on the different media the chromogenic properties of the staphylococci are notably changed: starting for instance with a growth almost white in color after six successive transplantations, colonies were obtained of the typical color of the staphylococcus pyogenes aureus. He offers the suggestion that many which we now consider separate species originated from a common source and that the variations in cultural peculiarities and chromogenic tendencies may have been directly dependent on the favorable and other factors surrounding the organisms.

33.—See abstract in THE JOURNAL of October 20, p. 1046.

39. **Blood in Neurasthenia.**—Romeiser and Collins find that while the hematology of neurasthenia is by no means invariable and while some cases have apparently normal blood, the following conditions are usually present: A relative increase of the large and small lymphocytes with a corresponding decrease of neutrophils, a relative increase of eosinophils and degenerate leucocytes, a leucopenia often, oligochromemia, microcytes, and variation in size of the erythrocytes, which often show nucleoids or are associated with an increase of platelets. In general these conditions correspond with what we might

expect. The variations in individual cases also correspond with the clinical types of the disease.

41. **Pernicious Anemia.**—Billings reports nineteen cases with special reference to the blood-count. The symptoms noticed are: general weakness, gastric disturbance, nervous symptoms, yellow tint, cardiovascular disorders, elevated temperature, hemorrhage, etc. The hemoglobin varied from 15 to 74 per cent.; the red corpuscles from 156,000 to 1,000,000; the color-index in 53 of the 65 observations was below normal. The specific gravity bore more constant relation to the number of red corpuscles than the hemoglobin. During rapid improvement, it was noticed there was a tendency of the hemoglobin to lag behind the other solids of the blood. The leucocytes in the average where below normal generally corresponded to the degree of anemia. The average percentage of mononuclear cells were about normal. The eosinophiles tended to increase with improvement and to diminish with failing health, though their behavior was too fickle to formulate a rule. The myelocytes were most abundant, generally speaking, when the patient was low, but they were of little diagnostic or prognostic import. These cases seem to show that the nucleated red cells are an essential feature of the disease. They are present in every case though they may disappear when the patient makes a decided gain in health. The actual number was sometimes very large, but more often it was small, averaging 71 cubic millimeters. In individual cases, a comparison of these cells taken from time to time was of value, but a small number was not necessarily a favorable sign. The quality seems to be of greater significance than the number. The regenerative forms of normoblasts are of little consequence, but the degenerative forms of megaloblasts are very characteristic. Their proportion varied with the severity and stage of the disease, usually gaining as the disease advanced. The irregularity of the megaloblasts is more often extensive in the process of degeneration and absorption and this peculiarity was noticed in almost every one of the series. It is rare if at all seen in secondary anemias. Poikilocytosis was present at some time in all cases, but was not a constant factor during the course of the disease and especially during the stage of improvement.

42. **Filaria.**—Lothrop and Pratt describe two cases in which filaria were found in the blood, both coming from Barbadians and members of the same family. They discuss the general pathology and treatment of the condition at some length.

43. **Cyclic Vomiting.**—Four cases of this condition are described by Crozer-Griffith, who notices the paucity of the literature in regard to it. Vomiting may be the first and most striking symptom. From the offset it is obstinate and oft-repeated. It may cease temporarily and then re-commence. Generally it continues very frequent until the close of the attack and then gradually or suddenly ceases. Constipation is a very constant but not necessary symptom. The abdomen was retracted and flat in two cases. Abdominal pain is almost entirely absent. Thirst is intense, appetite lost. The tongue is not usually very greatly coated; the breath is bad. There is no rule in regard to the temperature which may be febrile, sub-febrile or normal. Respiration is decidedly affected and may be irregular and rapid. The urine is affected, but no conclusion can be drawn in regard to it. Asepsis was present in two cases at least. The nervous symptoms are interesting. Convulsions occurred in one case reported by Snow. Exhaustion is extreme; emaciation is marked, but consciousness is not usually lost. The duration of the attack is variable, and recovery rapid. The longest duration of any of Crozer-Griffith's cases was ten days, the shortest, possibly a week. Even with extreme exhaustion and excessive vomiting, recovery is rapid. The symptoms suggest that it may be a gastric neurosis but he is not satisfied as to the nature. He thinks it may be of toxic origin in some connected with fatty metabolism. The diagnosis is easy in well-marked attacks. Obstruction of the bowels may be suspected or meningitis may cause confusion, but they are distinctly characteristic to this disease. Nephritis is to be excluded by a study of the urine. The prognosis is generally good, though not necessarily so. Two of

the cases reported have died. Treatment is generally unsatisfactory. Alterations in diet should be tried. If prodromal symptoms threaten, a purgative may possibly do good by removing the poisonous matter. Care should be taken to keep up a constant action of the kidneys. If the attack has actually commenced, he opens the bowels with a saline injection, but after this it is not well to give anything by the mouth. Calomel or bismuth may be given in enemata and morphia has done good in some cases. Stimulants by the rectum, and strychnin and digitalis by the skin are to be used as needed. Hypodermolysis seems to offer some help in severe cases. Ice or counter-irritants to the epigastrium may be tried. If a full in the vomiting ceases, as disease advances, it may be well to give Rochelle salts or phosphate of soda, but there is nothing to be gained by merely emptying the bowels, as if the constipation were the cause of the disease.

46. **Biologic Studies with Reference to Pathology.**—This will be noticed editorially.

47. **Alloxuric Bases in Nephritis.**—Croftan reports experiments to determine the cause of cardiovascular changes in the forms of nephritis in which retention of the excrementitious substances precedes a lesion of the heart and arteries, and this he finds in xanthin and hypoxanthin as representative members of the group of alloxuric bases. He concludes that these play an important rôle in the production of cardiac changes observed in all forms of nephritis with the exception of the chronic indurative form sometimes seen as a result of senile arteriosclerosis.

48. The abstract in THE JOURNAL of October 20, p. 1051.

49. **Leucopathia Unguium.**—The whitening of the nails often seen in small patches and which has been a matter of superstition, etc., for generations is noticed by Heidsingfeld. He mentions the three divisions made by Unna, viz., leuconychia punctata, where the predominating lesions are in the form of spots; leuconychia striata, where they are in the form of bands or striae; and leuconychia totalis where they involve the nail in its entirety, and criticizes the classification. Leuconychia striata is not so uncommon a condition as has been supposed. He has seen seven well-marked cases in fourteen months, while slight degrees of the condition have been observed in almost twice as many. Several cases are illustrated and he finds that in all well-marked ones the cuticle knife has been used to trim and keep back the nail fold. There are no doubt other agencies than traumatism which cause leuconychia. It is a well-established fact that it has been noticed in anemia, multiple neuritis, typhoid, measles and other febrile diseases associated with general malnutrition. The striate and punctate forms indicate an intermittent cause, while the total form indicates a constant factor or one with but slight intermittence so that normal nail substance has not been produced. The almost universal statement that the pathologic change in leuconychia is due to infiltration of air is opposed by the author on the basis of microscopic examinations. He finishes his paper by saying that leuconychia is the result of some pathologic change of structure of a plane of nail-cells, approximating a failure of the affected cells to undergo normal, physiologic keratinization. The cause may be trauma, malnutrition, febrile diseases, neuroses, or any agency which disturbs the growth, development or keratinization of matrix cells in their change to nail structure. Infiltration of air is absent and there is no rational physiologic basis for such a theory.

50. **Monilethrix.**—This disorder is a disease of the hair characterized by a nodose or beaded condition and resulting in baldness of the involved area of the scalp or other parts of the body. It is a very rare affection and the case here reported by Ruggles is said to be the fourth one observed in this country. This case and one observed by Gilchrist are the only ones on record where other parts than the scalp were involved. The contracted portion of the hair is the seat of the disease, and fracture usually occurs there without much fringing out of the ends. The microscope shows the cuticle to be intact throughout save that in a very few hairs transverse cracks or splitting at the ends is found. The etiology is very obscure; no bacterial cause has been discovered and the most plausible

theory is that the disease is an intermittent trophoneurosis as yet unexplained. The origin is intrafollicular since the hair emerges from the follicle with the nodes already formed. Hereditarily seems to have something to do with the cause as it has been discovered in several generations. There is practically no treatment for the affection, though Crocker advises attention to defects of the general health, and stimulation of the scalp with the faradic brush.

57. **Skiagraphic Study of Normal Epiphyses.**—Corson's paper is a very thoroughly illustrated study of the epiphyses of the long and short bones at the age of 13, impossible to be fully abstracted here.

58. **Omental Torsion.**—Wiener reports personal observations of omental torsion in cases of hernia and gives a summary of the literature on the subject, condensing and reporting briefly all the cases that have been published, including his own. He says "from these it will be seen that omental torsion occurs more often in males than in females (presumably on account of the more frequent occurrence of inguinal hernia in men), that it is not met with in youth, and that it is found only in persons who have a hernia; although the diseased omentum is not always found in relation with the hernia. The portion of omentum affected may be small or may be composed of almost the entire omentum. The etiology of the cases in which the omentum is not connected with a hernia is very obscure. In other cases the etiology can generally be traced to forcible attempts at reduction of the hernia. In not a single case was the diagnosis made before operation. The cause for this is not far to seek. Not only are omental tumors extremely rare, but they have no characteristic symptoms; the symptoms they call forth are those produced by an abdominal tumor through its mechanical action. When the tension takes place in connection with a hernia, the diagnosis is naturally made of an incarcerated hernia. In all the cases the urgency of the symptoms was recognized, and prompt operation was performed. There is a practical point of some value. If we cut down on a hernia that produces the symptoms of strangulation and find only a strand of omentum in the inguinal canal, we should always investigate the intra-abdominal portion of the omentum to make sure that there is no torsion present there."

59. **Retrenchment of Lipomatous Abdominal Wall.**—In the case reported by Bullitt the subject was a very adipose woman, 38 years old, suffering from umbilical hernia. The operation performed consisted in taking a reef in the abdominal wall by dissecting out and removing a large portion of skin and muscle, which weighed several pounds. The abdomen, though greatly reduced, was still somewhat pendulous, and he thinks it somewhat of a mistake that the retrenchment was not more extensive. He remarks that resection of a fatty abdomen, which he has described, constitutes a procedure of which he has not been able to find a description, though doubtless it has been done before. The incision down to the deep fascia is at right angles to the line of least resistance of the deep abdominal wall. Its extent gives ready access to the hernial ring and permits unembarrassed closure of the deeper structures. Most of all, it reduces the ponderous, distressing and entirely superfluous abdominal pouch. If this case can be taken as an index, there need be no fear of failure. The patient, writing under recent date, reports herself in excellent condition, able to attend to her household duties, and with no signs of recurrence.

62. **Acute Intestinal Obstruction.**—Gibson's article is included in this issue and his summary is given as follows: "**Intestinal Obstruction.**—The most frequent causes of intestinal obstruction are intussusception and bands. The mortality is 47 per cent. The mortality of resection is 74 per cent. The mortality of artificial anus is 77 per cent. The mortality depends on the duration of obstruction and on its nature, being least in foreign bodies inflicting little or no damage to the intestine (25 per cent.), and most in such conditions as produce a tight constriction as 'openings' (67 per cent.). **Hernia.**—The ratio of mortality of inguinal hernia to femoral is as one is to two. The proportion of femoral hernia is 59 per cent.

The ratio of mortality of inguinal hernia to femoral is as three is to four. The mortality of resection and primary enterorrhaphy is 26 per cent. The mortality of artificial anus is 53 per cent. **In General.**—Resection and primary reünion by apparatus (including Murphy button), mortality, 36 per cent. A large proportion of deaths is due to failure of technic, such as removal of too little intestine or imperfect suture. At least 13 per cent. of resections are attended with defects of technic, either resulting fatally or in the formation of intestinal fistula. **Artificial Anus.**—The mortality is lowest in internal obstruction, such as a foreign body, and highest in obstruction by an unyielding constriction, such as a band, and lower in hernia than in internal obstruction, chiefly because the surface exposed to absorption is less. The chief sources of mortality are: The desperate character of the majority of the cases. Failure to establish the opening above the site of constriction. Failure to provide for the relief of absorption of gangrenous changes in the intestine; death often necessarily occurring on this account, although the obstruction is perfectly overcome. Prominent among the drawbacks of artificial anus is the fact that it must subsequently be repaired. For in most cases there is no tendency to spontaneous closure, while minor plastic operations are rarely efficient. Formal liberation of the intestine and secondary resection is usually an exceedingly difficult operation, as is evident by its mortality—after intestinal obstruction, 43 per cent.; after gangrenous hernia, 27 per cent.; average, 30 per cent. The causes of death after operation fall into three main groups: 1. From causes inherent to the condition and little amenable to treatment, such as shock and pre-existing peritonitis—these causes accounting for the majority of fatalities. Improvement can only be hoped for by earlier recognition of the condition, thereby securing the performance of operative relief before the severer changes take place. 2. From causes depending chiefly on the nature and details of the operation, such as failure to relieve obstruction and defects in technique or failure to take account of the conditions to be dealt with. 3. On intercurrent conditions. **Prognosis.**—The most essential feature in the prognosis is the duration of the obstruction. In early interference there is generally only one condition to be fulfilled, removal of the obstruction. With long continuance of this condition, secondary changes of the greatest gravity supervene, requiring for their relief measures of great extent and difficulty. The nature of the obstruction is the next most important factor, acting in the same way as in the first instance as to changes in the intestinal walls, the prognosis being best in internal obstruction, and worst in tight external constrictions."

71. **Amyloid Substances.**—The pathologic findings of a case of apparently specific disease, the neurologic aspects of which will be discussed in *extenso* elsewhere by Dr. Newmark, are described by Ophuls with special reference to the origin and nature of the amylaceous bodies found. The general conclusions reached are: The substance of the amylaceous bodies is identical with, or at least similar to, amyloid substance. In the amylaceous bodies this material is present in crystalline form, in the amyloid substance in amorphous form. It would be advisable to use the word "lardaceous" instead of "amyloid," and perhaps to include under this term the peculiar form of "hyaline" which sometimes precedes and accompanies the amyloid substance.

74. **Necrotic Bronchopneumonia With Streptothrix.**—Two cases are reported by Norris and Larkin of bronchopneumonia characterized by intense catarrhal and necrotic inflammation of the bronchi and by the presence of streptothrix colonies in the bronchial lumina. Inoculation experiments on rabbits produced pulmonary abscess and empyema of the pleura and pericardium in two cases. The empyeal pus of these rabbits contained filaments and rods morphologically identical with those found in the human subject. The previous observations of various authors are noticed and they conclude that the streptothrix found was closely related if not identical with the streptothrix Israeli, obtained from typical cases of actinomycosis by Wolff and Israel in 1889, and the species isolated by Kruse in the case of a diabetic barber last year.

87. **Antitoxin Unit in Diphtheria.**—Smith reviews the facts in regard to the antitoxin unit as accepted and shows its unreliability. The old method of using ten times the minimum fatal dose to test the antitoxin strength of sera is not reliable, even when the toxins are prepared under uniform conditions, and at present we can do no better than utilize the standard provided by Ehrlich, and using the entire unit instead of only one-tenth unit in the operation of standardizing.

88. **Artificial Divisions in the Unfertilized Eggs.**—Matthews reports experiments similar to those of Loeb in the development under special chemical and physical conditions of the sea-urchin's egg. He gives credit to Morgan for the first experiments in this direction and to Loeb for the first carrying out of the embryo to full development. His own experiments were carried on coexistent with, though independent of Loeb, and he has succeeded in setting up a cell-division in the unfertilized sea-urchin's egg by depriving the egg of oxygen, by the action of heat and by exposure to ether, alcohol and chloroform. All the methods thus found for inducing cells to divide are those in common use to cause protoplasm to liquefy, and strongly indicate that the old view of Butschli that the karyokinetic figure is but the expression of the movement of the liquid cell, is true, hence he concludes that any means that will produce localized liquidation will set up karyokinesis. In closing he emphasizes the analogy between the egg and the nerve cell. The means which cause cell division or liquefaction are strong stimulants to nerve cells, indicating that in the production of nerve impulses we are dealing also with liquefaction of some portion of the cell body.

89. **Experiments With Formalin and Formaldehyde.**—Experiments have been carried on by Fischer on the toxic effects of formalin and formaldehyde, and he notes and gives in his preliminary communication the results. He finds that they produce intense congestive phenomena and edema and believes the fact explainable on the ground that the osmotic pressure of injected formalin is higher than that of the body fluids and thinks that trying to establish a mean between the two causes these symptoms. He therefore thinks that formalin causes the death of the cell in two ways: 1. By surrounding the cell with a fluid that has a higher osmotic pressure than the cell itself, thereby causing abstraction of the water from the cell. 2. By a deleterious chemical action on the cell. From certain histological evidence it is believed that it is a reducing property of the chemical which produces the death of the cell.

90. **Pyloric Stenosis.**—The hypertrophy of stenosis is especially noted by Scott and the possibility of its occurring when the muscular apparatus is such as to make dilatation of the stomach very slow. These cases are difficult to diagnose and may be even serious before dilatation occurs. The results of operation in, of course, the non-malignant, is so uniformly successful that it is often demanded for the best interests of the patient.

98.—See abstract in THE JOURNAL of October 13, p. 974.

99.—Ibid.

103.—Ibid.

104. **Sanatoriums for Consumptives.**—After describing one or two of the sanatoriums in the Black-Forest region of Germany, Schaffer reproduces in a somewhat condensed form an article on the treatment of pulmonary tuberculosis by Fraenkel, of Badenweiler, which was previously published in the *Munchener medicinische Wochenschrift*, June 3 and 20, 1899. He does not lay much stress himself on the curative effect of these institutions, as he says the percentage of really cured is exceedingly small even under the best conditions. Fraenkel's article insists on the importance of early diagnosis and believes in the value of the tuberculin test, which he does not seem to consider dangerous. The importance of dietetic and hygienic treatment are the principal features of his article. He considers the sanatorium a resource for cases difficult to control in the initial stages as a sterner school and intermediate station for the open-air cures, and

recommends it as the best asylum for all seriously ill who are alone in the world.

105. **Domestic Animals in Typhoid Fever.**—Stokes reviews the history and reports experiments made on chickens, rats, and cattle and concludes as follows: "In our experiments we have endeavored to produce infection through the natural route and by natural means by simply allowing the various animals to take in very large quantities of typhoid bacilli in their daily food. Although at least 500 colonies from the feces were carefully tested, we were not able to demonstrate the presence of any typhoid bacilli in two chickens, two white rats, two rabbits, two guinea-pigs, one calf, and two pigs. Although we have not employed a large number of animals, we feel justified in expressing the opinion that the typhoid bacillus can not, as a rule, maintain its struggle for existence in the intestines of the domestic animals. We therefore conclude that the dejecta of animals play no considerable part in the distribution of typhoid fever."

109.—See also ¶135.

114. **The Vectis.**—Bartlett describes the mechanism and use, as well as the history, of this somewhat antiquated instrument and shows that it has certain advantages even with other modern methods in obstetrics. His clinical experience has been limited, but in a few cases it has been very satisfactory. The reader is referred to the paper for details.

115. **The Management of the Defective Classes.**—Skellon reviews the facts in regard to the production of defectives, criminals, epileptics, idiots, etc., and holds that their prevention and the purification of the stock is the best remedy for this social evil. He formulates tentatively: 1. The obliteration of the stock of the worst cases of defectives by the removal of the procreative organs. 2. The same remedy applied to the insane with strong hereditary and nervous instability, especially those discharged from asylums as improved, slightly improved, etc., and generally classified under the general head of recovery with defects. 3. Medical examination of applicants for marriage licenses, the benefit of which he thinks would be largely indirect and educational. The efficacy of the examination would be sometimes counterbalanced by the deception of the examined, as it would be looked on as an infringement of personal rights. Lastly, proper education and knowledge of the facts in the case. A certain proportion of society would avoid evil consequences when they were explained to them. Heretofore the facts of heredity and evolution and the relation of these to disease have been unknown to the general public, but in their place we have metaphysics, mysticism, diabolism and deism, etc., supplanting physiologic and pathologic knowledge.

122. **Physical Training.**—McKenzie finishes an illustrated article on the subject of physical training, in which he shows its value in correcting deformities, meeting the conditions of diseases, etc., with the following conclusions: 1. Special physical training is rendered necessary for the young by the conditions of modern life. 2. The work is made special and scientific, having for its object the development and strengthening of every organ and faculty of the patient. 3. As we conduct this work it is mainly educative. Force from without the patient, however, is largely employed in such cases as can not of their own volition correct the deformity. To name affections benefited in the order in which good results have been observed I would place them thus: Hysteria, rotolateral curvature, flat-foot, round shoulders, pigeon-breast, flat chest, anemia, parietic weakness, chorea, imbecility. In this list I have placed hysteria first, because I have not known any method by which this condition, generally so unsatisfactory to deal with, has been brought so successfully under control.

129. **Abuse of Cardiac Remedies.**—Baumgarten notes the employment of digitalis and alcohol beyond the early desirable effects into their later undesirable ones in cases of disease. Strychnin also is noticed in the same connection, and is liable also to be abused. Digitalis is valuable only when it is necessary to raise the blood-pressure, alcohol simply for its

stimulating effect and not its later depressing effects. Strychnin should be given only when low blood-pressure exists, not so much by any immediate effect on the heart, but by its increasing the velocity and functions of the blood in vital organs—the brain, kidneys, etc., including of course the muscles of the heart itself. Over-stimulation of the spinal centers by strychnin may so increase the tension of the peripheral arteries as to overwork the weakened heart. He also notices the abuse of nitroglycerin, which is often carelessly used as a substitute for digitalis and has exactly opposite effects. The action of digitalis can be supplemented or modified, but never substituted by nitroglycerin. It is of use in collapse when the enfeebled heart is no longer able to keep up the blood-pressure to the lowest degree necessary for bare life. When we have arrived at the end of the utility of one drug, digitalis for instance, and have still to keep up the fight, we should try other remedies, caffeine and strychnin in cases of low pressure, or in cases of contracted arteries nitroglycerin. The piling in of stimulants has never helped a failing heart and is strongly condemned.

130.—See also ¶135.

135. **Ectopic Pregnancy.**—Baldwin first notices the earlier dicta of Lawson Tait as to the impossibility of diagnosing ectopic pregnancy before rupture, and remarks that in the last ten years we have come to know a great deal more of that condition, and there are many cases in which symptoms arise where a presumable working diagnosis is possible. There are no pathognomonic symptoms, but usually we find the following: There is a history of several years of sterility (with many exceptions); missing of a menstrual period or two (with exceptions); some unusual pain in the pelvis situated usually in the region of an ovary, possibly for a few days more or less irregular hemorrhage, while there is generally to be found on one side or another of the uterus or back of it a fusiform cystic tumor, quite symmetrical in outline, painful on pressure, with usually evidence of pulsation. With these phenomena it is reasonable to suspect extrauterine pregnancy. Too much stress, however, must not be laid on menstruation or sterility. The pain is usually sharp and colicky or it may be of a dull throbbing constant character. When the presumable diagnosis has been made operation is advisable. He reports eleven cases.

British Medical Journal, November 3.

The Diagnosis of Diphtheria. H. B. DONKIN.—The distinction between croup and diphtheria, and the discovery of the bacteria, are noticed by Donkin, who calls attention to the fact that certain evils follow too much dependence on the bacteriologist by the physician. The practical teaching that the present stage of knowledge seems to demand is, according to Donkin, somewhat as follows: 1. Diagnosticians should at once regard and treat, without waiting for a bacteriologic report, all cases as diphtheria, in which the clinical signs and symptoms are such as would have raised little or no doubt in their minds as to their nature in the days before the coming of the bacillus. 2. They should also regard and treat as diphtheria all cases which, although lacking the usual clinical "stigmata," are shown by bacteriologic examination to be associated with bacilli whose products kill animals and cause the characteristic lesions; albeit even here they may be in error, though on the better side. 3. The mere presence of bacilli—in the nose or elsewhere—"morphologically indistinguishable" from the pure diphtheria bacillus, the host being healthy and inoculation results negative, may probably be ignored in practice, and so also are any clinically recognized symptoms or signs of the concrete disease. In fine, does not the diagnosis of diphtheria still rest mainly for its surest foundation on the old ground of careful clinical observation, tempered and aided in some cases, it may be, by a judicial study of the report of the bacteriologist?

Myelopathic Albumosuria. T. R. BRADSHAW.—Myelopathic albumosuria may be defined, according to the author, as a disease characterized by the invasion of the cancellous

tissues of the bones of the trunk by cellular growths, by the disappearance of osseous tissue, and by the presence in the urine of large quantities of peculiar albuminous substances belonging to a class of bodies known as the albumoses. The morbid anatomy of the disease consists in the peculiar change of the bones, chiefly the ribs, sternum and bodies of the vertebrae, in which the hard substance is reduced to a mere shell. The cancellous tissue almost entirely disappears and spontaneous fractures become common. The interior of the bone is occupied by a reddish gelatinous mass something like splenic pulp, which can be readily squeezed out by pressure on the thin and brittle bone. Microscopically it consists of a vascular mass of cells round or spindle-shaped, in some cases islets of cartilage. The whole structure resembles sarcoma and the condition is generally known as "multiple myeloma," a term which we owe to von Ruszizky, who described four cases of multiple tumors in the bone, in 1873. It is not certain whether the disease is the same condition, as there was no reference made to the condition of the urine. The organs, as a rule, are healthy. The kidneys seem to show nothing characteristic, excepting an occasional blocking of tubules and more or less degenerative changes. The disease usually occurs in the second half of life, and is apparently more frequent in men than in women. The symptoms may be classed under two heads, those connected with the bones and those with the urine. The first complaint is generally of pain in the lumbar region, generally aggravated by movement. The patient probably looks anemic, the pains do not yield to treatment, but there is nothing to suggest the serious condition excepting the urine. The pains become aggravated and the patient declines to exert himself. They are referred to the bones, tender spots arising in the course of the bones, the chest wall seems to yield, and actual fractures takes place, curvature of the spine appears and the mobility of the vertebral column is lost. In spite of all this the patient is still able to leave his bed and walks about until nearly the end, which is in striking contrast with another disorder sometimes confounded with it, namely, osteomalacia, in which the long bones are early affected. The characteristic feature of the urine is the presence of a proteid resembling albumin, but that differs in several ways. It coagulates at the low temperature of 140 F. and coagulation is redissolved on boiling. It is readily precipitated by hydrochloric acid and uric acid and the precipitations are dissolved on boiling. The hydrochloric-acid precipitate is, according to Bradshaw, the most satisfactory test.

The diagnosis presents no special difficulties, but the condition of the urine might lead to the diagnosis of large white kidney, or, if the albumose is spontaneously coagulated, to that of chyluria. The disease is apparently almost always fatal, but sometimes is very prolonged in its course. In one instance it began eight years before death. As a rule, the patients seldom go long without the symptoms causing them to seek advice. Intermissions are frequently noticed, which given rise to false hopes. Death occurs from exhaustion or from some intercurrent disease, usually pneumonia. No treatment seems to do any good, and great care must be used in handling the patient in the advanced stages. The association of albumosuria with new growths in the bone has no close analogy in any other disease, and the author considers its formation and excretion in the urine no less an essential part than the lesions of the bones. He suggests therefore the term myelopathic albumosuria. He concludes his paper with a tabulated list of published cases and a bibliography.

Suprarenal Gland Extract as a Hemostatic. O. F. F. GREENBAUM.—Having earlier suggested the administration of suprarenal gland in cases of hemorrhage from the walls of the alimentary canal, the author briefly notices the physiologic action and therapeutics. The rationale of his suggestion was that the suprarenal extract caused the contraction of the plain muscular fibers of the blood-vessels when locally applied, its evident use in epistaxis together with the results of a series of experiments which led him to conclude that the administration of the gland by the mouth did not cause rise of the blood-pressure in normal individuals. One or two crushed 5-grain tablets given by the mouth is the most satis-

factory method of administration in hematemesis. The advantage of the extract over the more popular hemostatics arises in the fact that it acts in very dilute solution and does not tend to combine with albumin and become inert. It must, however, be remembered that it does not cause coagulation of the blood and therefore does not seal the bleeding points with clots. Very small doses can be given, as the drug acts in dilute solution, but it must be repeated at short intervals, for the vessel wall will only remain contracted while under its influence and coagulation is not accelerated. Two or three crushed tablets, mixed with a few ounces of water, injected into the rectum is the most satisfactory way of applying the remedy in hemorrhage from that viscus. He has not found it of any advantage in hemophilia and would not expect it if we accept the theory that congenital hypoplasia of the vessel-walls is the associated condition of the disease.

Mode and Rapidity of Reduction of Temperature by Quinin. WILLIAM SYKES.—Observations are here reported on the action of quinin as an antipyretic given in cases of high temperature in single large doses. The temperature was closely watched for two or three hours in each case. He finds that the quinin was rapidly absorbed, the temperature began to fall in forty-nine minutes, probably in less time in the first case, and in the second and third series within twenty minutes. The size of the dose did not seem to affect the rapidity of the diffusion. In the cases experimented on we have respectively 20, 40 and 20 grains without corresponding differences in the time of its effect. The methods of its action are obscure: 1. Destruction of pathogenic bacteria, which he thinks is negated by the temporary nature of deferescence. 2. Neutralization of their resulting toxins, which is improbable, as they seem to bear no relation to each other. There remain only two probable methods of action, namely, on the heat-centers and on the sweat-centers. He thinks if it acted on the heat-centers the proportional decrease of temperature after exhibition of the drug would not be as irregular as it is, and the speed would not be affected by the amount of dosage. The drug acting on the nerve-centers might be liable to produce an immediately great and regular effect on its function which would be expected to agree in rapidity of action with the size of the dose administered. If, however, we accept the notion of its action on the sweat centers as true, an explanation of many of the difficulties is furnished. Since deferescence by diaphoresis depends on the sweating itself and not on its action, it is obvious that the size of the dose of the drug administered, so long as it was sufficient to produce perspiration at all, would have no result on the speed of the deferescence. Since slight movements in bed, by which the surface becomes chilled, would temporarily stop the diaphoresis, the stationary and even retrogressive intervals would be quite explicable. Moreover, most or all the antipyretic groups possess one quality in common when given for reduction of temperature; they produce violent diaphoresis: it also occurs in night-sweats produced by the toxins of the tubercle bacilli, which are in like manner succeeded by a normal or subnormal temperature.

Bulletin de l'Academie de Medecine (Paris), October 23.

Method of Hemostasis in the Xiphopagus Operation. PORAK.—In this official report on Chapot-Prévost's communication in regard to his operation on the xiphopagus, Porak describes the method of hemostasis as compression on each side of the proposed incision in the connecting band by rolls of gauze placed on the skin and drawn tight together with a double, No. 5, silk thread which passed through all the layers of the abdominal wall on both sides and the liver at the same time. The compression was preliminary to the operation and kept up for a week afterward. The connecting band measured .155 by .0975. In the Indian twins it was .015 by .08, and in the Siamese twins, .075 by .06. Porak defines the monster as a monophalian intermediate between the xiphopagi and thoracopagi. The surviving twin has five of the stigmata of hereditary syphilis; malformation of the head and body, dextrocardia, displacement of the liver, disturbances in vision and stammering; but there are no syphilitic antecedents known in the family and the three other pregnancies

resulted in normal children before and since 1893, the date of the birth of the monster. Porak summarizes the latest research on the production of monsters: that it is due to a disturbance in nutrition, in either the ovum or the mother. Any infectious disease of the mother may make its influence felt on the development of the embryo. He rejects the conception of a pathologic heredity, observing that heredity is a preserving force, perpetuating the remotest ancestral characteristics of the race. It is pre-eminently preservative, fixed, constant, immutable, durable. What is called pathologic heredity, on the other hand, is destructive and conflicts with true heredity. It is necessarily accidental, variable and exceptional in its appearance and brief in its persistence. Porak adds that a certain number of apparently normal twins are in reality a monstrosity, due to the development of two germinal discs grafted on a single vitellus. This can be surmised when the twins are of the same sex, when the membrane separating the ova is absent or only constituted by the two amnions, and when there is a vascular communication between the placental circulation of the two amnions.

Echo Medical du Nord (Lille), October 28.

Needle in the Heart. R. LE MORR.—A lad of 11, in falling, drove a needle in his coat into the wall of the thorax in the fifth intercostal space. It was removed without trouble after a transverse incision one-half centimeter above the entering point. From the length and direction of the needle it was evident that it had penetrated deep into the right ventricle, but after a brief disturbance of the circulation—the pulse becoming imperceptible for twenty seconds—the conditions returned to normal and the lad was at play in a day or two. In 23 cases of the kind collected by Loison the mortality amounted to 60.8 per cent., always due to internal hemorrhage when cause is specified. In 3 cases the needle was extracted without incision and 3 times with incision, all recovering. The present case makes the fourth of the latter class. Seventeen new cases of surgical intervention on the heart have been reported during the last two years. The total number of successful sutures of the heart is now 9 out of 24, with 2 cases of long survival. Podrez deliberately undertook the search of a foreign body in the heart, with the intention of incising for it between preventive sutures if a trace had been found of it in the course of bimanual exploration and ten exploratory punctures.

Revue Internationale de Therapie Physique (Rome), Oct. 20.

Absorption Under the Influence of Massage. A. KELLGREN and C. COLOMBO.—The experimental research described in this communication, concluded from the preceding number, was conducted at London on rabbits. It was impossible to obtain governmental sanction for control experiments on dogs. The fluid injected was Prussian blue and lycopodium spores in gelatin. Massage invariably favored the absorption in all the organs to which it could be applied. It is logical to conclude that the same effect occurs in case of pathologic exudates. The absorption always takes place through the nearest lymphatics and their ganglia, supplemented by absorption through the veins. Deep "effleurage" is more effective in case of fluids injected under the skin or into muscles or articulations, but kneading or "petrissage" best promotes absorption in the deeper tissue.

Presse Medicale (Paris), October 31.

Treatment of Hydrocele by Turning the Vaginalis Inside Out. L. LONGUET.—Excellent results have been attained in the cure of hydrocele by inversion or eversion of the vaginalis, after subserous deortication and hemostasis. The principle is to turn the serous membrane with the secreting surface outward, when the secretion is absorbed as it forms. Longuet has modified the original procedure and claims several advantages for his new technique, which requires neither deortication nor hemostasis. A transverse fold is taken up over the testis and cut with the scissors down to the vaginalis, which is then drawn up into a cone and cut in the same way with the scissors and the wound enlarged to 3.5 cm. The testis is then drawn out and up as far as possible, the assistant pulling the scrotum down at the same time. The vaginalis follows and

turns inside out with this maneuver. A couple of stitches are taken to hold it in place. The testis is not replaced in its former position, but a new cavity is made for it in the middle of the inner lip of the incision, lightly separating the tissues with the forefinger. The recess thus formed is inside of and parallel to the old cavity. The testis is not in normal anteversion, but in retroversion, twisted inward a quarter of a circle, the elements of the cord twisting with it. The entire operation is complete in a minute. Not a drop of blood is lost and the patient returns to business next day as usual. Out of twenty-two cases thus operated on nearly two years ago, twelve have been seen recently, and all are completely cured of their hydrocele, with no inconveniences at any time. If the hydrocele is very large, Longuet excises a portion of the vaginalis, otherwise proceeding as above. He reports six cases thus treated in 1898 with perfect success. He operates with local or general anesthesia or none, according to the sensitiveness of the patient.

Semaine Medicale (Paris), October 31.

Ozenous Pleurisy. G. DIEULAFOY.—There are three varieties of fetid pleurisy, simple fetid, putrid, and gangrenous. They can not be diagnosed without an exploratory puncture, which should be prompt. Immediate surgical intervention is the only treatment. There is little difference between the putrid and gangrenous forms. They may develop parallel or successively. The putrid effusion usually occupies the large pleural cavity, while the fetid is encysted. The former is frequently due to embolism; the original focus may have been in the vagina or appendix or elsewhere. It is usually distinguished by a pneumothorax without perforation of the pleura. Several instances are described of recovery after prompt evacuation of a gangrenous pleuritic effusion, uncomplicated by gangrene of the lung.

Deutsche Med. Wochenschrift (Leipzig), October 18 and 25.

Tuberculosis of the Bladder. L. CASPER.—Among the points emphasized in this article are the necessity of refraining from cystoscopy, in case of tuberculosis of the bladder and also from distending the organ with fluids. The amount introduced should never be sufficient to cause pain nor even a sense of fullness. Casper believes that the combination of appropriate hygienic, internal and local measures will always relieve and frequently cure this affection. In his experience with thirty-five cases he has had no success with local remedies except with lactic acid and sublimate, and he has been compelled to discard the former on account of the pain it induces. In 20 cases treated with instillations of sublimate, 14 have been improved, 2 cured, and 4 were unaffected. He first instills about 20 c.c. of a 1 per 10,000 to 1 per 1000 solution, repeating every fourth to eighth day, and progressively increasing to a 1 per 10,000 to a 1 per 5000 solution, the fluid retained as long as possible without much pain. He has never noted any symptoms of intoxication from the sublimate, but discontinues it if no benefit is apparent after three or four applications. He finds gonorrhoea a frequent predisposing factor.

October 25.

Gonorrhoeal Nervous Affections. A. EULENBURG.—This address by the editor of the *Wochenschrift* was delivered at the recent Congress of Physicians and Naturalists. He stated that nervous affections of gonorrhoeal origin have been too much neglected hitherto, and that they deserve at least as much attention as syphilitic nervous affections. He classifies them as neuralgia, atrophy of the muscles and atrophic paralysis, and neuritis or myelitis. The continuance of a gonorrhoeal lesion elsewhere, with or without the discovery of gonococci, suggests gonorrhoea in the etiology, and certain special characteristics of the nervous affection aid in differentiating it. Ischialgia is the most frequent manifestation of the neuralgic process. The lumbosacral nerve roots are usually involved, especially the genital nerves, more rarely the nerves of the arm. The symptoms appear as a sudden violent paroxysm of pain, sometimes accompanied by intermittent fever with no indications of any other cause than the preceding or concomitant gonorrhoeal affection. It is frequently accompanied

by sexual or general neurasthenic manifestations. Atrophy of the muscles and atrophic paralysis usually affect the shoulder or knee in the form of periarticular atrophy of the muscles or atrophying myositis, occasionally as neuritic atrophy, progressively spreading and involving symmetric portions of the opposite side of the body. The gonorrhoeal forms of spinal affections present a clinical picture with a superficial resemblance to that induced by degeneration of the posterior column. They are distinguished, however, by greater involvement of the motor sphere, manifested as atrophy of the muscles on a basis of neuritic or poliomyelitic degeneration. The absence of the eye and pupil symptoms is also specific. Eulenburg concluded with the statement that he has found iodipin remarkably effective in the treatment of severe neuralgias and gonorrhoeal ischialgia, as others have reported in various venereal nervous affections. "The introduction of iodipin and bromipin into therapeutics can be considered one of the most important advances in the application of iodine and bromine to the treatment of nervous diseases."

Muenchener Medicinische Wochenschrift, October 23.

Bacteriotherapy and Yeast for Constipation. E. ROOS.—The influence of the bacteria in the intestines on their normal function has been very little studied. Roos conceived the idea that by introducing bacteria from a normal intestine in cases of constipation, the conditions might be made to approximate normal. Cultures of the bacillus coli from healthy individuals were ingested by himself and seven other physicians. In three the effect was surprisingly favorable. After the second day they had one or two stools a day of soft consistency, for the first time in ten years in one case. Of the two subjects with normal stools, one was unaffected and the other had diarrhea. The effect of the bacteriotherapy continued for two weeks after taking the cultures and then gradually subsided. Experiments with killed bacilli were negative. Roos also administered yeast to relieve constipation. The results were negative in four out of twenty cases. In all the remainder a marked influence of the yeast on the stools was manifest. They became soft, regular, and sometimes more frequent. Similar results were obtained with yeast killed by heat. All but four out of eighteen were cured of their constipation. The effect of the yeast persisted for weeks after its discontinuance. In all the experiments the cultures or yeast were taken in capsules coated with collodion and then with keratin, to avoid contact with the gastric juice.

Surgical Treatment of Noma of the Face. H. VON RANKE.—The writer had occasion to observe five cases of noma of the face consecutive to measles in a severe epidemic of the latter in 1885. Since then he has not seen a case until after a mild epidemic of measles last winter, when three cases of noma were brought to his clinic. Each was treated with extensive excision and thermocauterizing of the region involved, without waiting for the gangrene to assume large proportions. Each was cured and with comparatively little disfigurement. All his previous patients had died from the effects of the progressive gangrenous process.

Wiener Klinische Rundschau, October 7.

Surgical Treatment of Anasarca. MENKO.—The writer's experience with the tapping of anasarca has been extremely favorable. He reports, among others, a severe case complicated by gangrene of the lungs and acute nephritis completely cured by continuous drainage of one extremity in combination with other measures. He uses a Curschmann canula, slightly modified, and prevents infection afterward by a spring bandage, something like a tourniquet. A strip of iodoform gauze is placed over the wound and the metal spring is applied with the convex side toward the skin, fastening it in place with moderate pressure. This prevents oozing and the wound closes effectively in three days, with none of the maceration or inflammation that frequently follows other methods.

Wiener Klinische Wochenschrift, October 11.

Trachoma. C. ZIEM.—In this long article Ziem shows how the prevalence of trachoma has kept pace with the destruction of forests and consequent production of dust and sand storms,

and also with the amount of decaying vegetation and soil in marshy or inundated regions. He traces this connection from the remotest antiquity. The influence on the eye may be direct or by the mediation of a nasal catarrhal affection. Treatment is certain to be ineffectual unless the nasal affection is cured and the frequent relapses in trachoma are usually due to neglect of this precaution. Miasmatic surroundings may affect the eye indirectly by inhalation of the malarial emanations and consequent catarrhal lesions of the upper respiratory passages, or by way of the circulation after ingestion of decaying organic matter in the drinking water or cooked with the food. He makes a convincing plea for international forest laws and prophylactic measures in miasmatic regions. Mesopotamia and Egypt have suffered most, perhaps, from the destruction of the forests mentioned by the ancient writers. The present dust and sand swept treeless region is the home of trachoma, especially where the inundations of the Nile add another element. Contagion is a subordinate factor in the etiology of trachoma.

Toe Reflex in Children. F. PASSINI.—Investigating the Babinski sign in large numbers of children, Passini's experience has confirmed the invariable occurrence of extension instead of the normal flexion of the big toe in case of organic injury of the pyramidal tracts. In tubercular meningitis the sign varied from day to day, probably due to periodical edema in the tracts. In children less than a year old, the pyramidal tracts are still so undeveloped that extension occurs as in case of a lesion.

St. Petersburg Med. Wochenschrift, October 20.

Symptoms of Latent Syphilis. C. STROHEMBERG.—Three or four weeks after the primary manifestation, the glands may swell and for a long time remain the only appreciable lesion. Indications of fever, circumscribed reddish spots and erosions on the mucous lining of the mouth and lips, especially at the corners, and on the genitals, herald the arrival of pronounced symptoms of syphilitic infection. A catarrhal cold in the head is also a frequent premonitory symptom. Much harm results from contagion during this period if the physician waits for unmistakable symptoms before starting treatment. General lymphadenitis is the cardinal symptom of the latent stage, and the occasional accompanying anemia. Leucoderma of the back and sides of the neck is a positive sign of the condylomatous period. It is found ten times more frequently in women than in men. Neisser has noted it in 45 per cent. of his female patients in the condylomatous stage and the writer in 74 per cent. In men buccal leucoplasia, psoriasis of the tongue with pachydermia of the mucosa of the ear are more frequent. These manifestations can be considered "independent latent symptoms," as also the falling of the hair and indistinct ring, horse-shoe or arch-shaped erythematous. Slight wounds and scratches heal with extreme slowness and leave pigmented scars. Consecutive phenomena are the predisposition to tuberculosis, rachitis, scorbutus and carcinoma. Among the subjective symptoms of the latent stage are fatigue, cephalalgia, insomnia, psychic depression, neuralgia, rheumatoid pains in the muscles and joints, loss or increase of appetite, palpitations and disturbances in sight or hearing. Among the rarer manifestations of latent syphilis are affections of the nails, swollen lymphatics leading from the primary lesion, brownish spots after rosola, slight swelling of certain joints, periosteum, tendon sheaths and bursa and also of the muscles, with enlargement of liver or spleen, bronchial or intestinal catarrh, icterus, stricture of the rectum, albuminuria or diabetes, premature arteriosclerosis and endocarditis. Central or peripheral disturbances in the central nervous system have also been observed during the condylomatous stage, also disturbances in speech, memory or mind, and hemiplegia, neuritis, especially in the domain of the trigeminal and optic nerves, and circumscribed paralysis of the facial, oculomotor nerves, etc. Iritis, cyclitis, choroiditis and retinitis have also been noted and catarrh of the middle or internal ear. The cases of syphilis precox warn against concluding that persons with gummatous manifestations are necessarily non-infectious. Hemorrhages from lungs or stomach are extremely rare at an early stage.

Queries and Minor Notes.

DRUGGISTS AND PRESCRIPTIONS.

KANSAS CITY, Mo., Nov. 12, 1900.

To the Editor:—As a solution to the problem referred to in the issue of November 10, by two correspondents concerning the rights of physicians and druggists in relation to prescriptions, I beg leave to submit the following, which I will maintain until refuted by legal authority.

When a physician delivers a prescription to a patient, and the patient pays for it, or it is charged to his account, or is given to him gratuitously, the transfer is the same as in other property: to all meaning and intent, the physician sells the prescription to the patient, and it becomes the property of the purchaser, and he has the right to deliver it to any druggist he chooses; but after delivering it to a druggist who fills it, he loses his title to it, and the prescription becomes the property of the druggist, who should preserve it for his own protection, as well as for that of his customer. The druggist should not hold the prescription for the purpose of refilling it without the advice of the physician who wrote it, but as a voucher to protect himself in case of alleged poisoning, or violation of the law. As an example, where intoxicants, or other poisons have been furnished on a prescription, the druggist becomes the sole owner of the prescription, and neither the physician nor patient is entitled to any property interest in it. When a prescription is filled it becomes the property of the druggist who fills it, and he has a moral and legal right to preserve it; and he has the same legal right to refill it, that he has to sell the same preparation without a prescription; but he has no moral or legal right to refill any prescription without permission, which contains an ingredient, the sale of which is prohibited by law, when not prescribed by a physician; and he has no moral, social, or professional right to refill, or to transfer to be refilled, any prescription, no matter how harmless its ingredients may seem to him, without the written request of the prescriber.

Have your own prescription blanks, without the name of any druggist on them, and have printed on the backs, in plain, but fine type, the following:

Notice: Never have a prescription filled a second time, without the advice of your physician to that effect; because a medicine which has a curative effect in one attack, may not be the proper remedy in a subsequent one; owing to new complications which may set in.

Never use a preparation which has been prescribed for some other person; because a medicine which will cure one patient, may not be a safe remedy for others, even though they have some of the same symptoms; owing to the fact, that different diseases may present similar symptoms, and yet require different treatment.

For the safety of patients, druggists are requested not to fill this prescription a second time, without the written advice of the prescriber.

After considerable deliberation of both the professional and legal faces of this subject, I devised the foregoing plan, which has assisted me, and will probably aid in reviving "a Slain Victim," and be worth something to Bro. J. B., of Essex, and other readers of THE JOURNAL. Respectfully,

J. L. SNORT, M.D.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 1 to 7, 1900, inclusive.

Charles N. Barney, acting asst.-surgeon, from Fort Monroe, Va., to Fort Dade, Fla., for temporary duty during the absence of Acting Asst.-Surgeon J. J. Shafer.

Edward G. Beeson, captain and asst.-surgeon, U. S. V., recently appointed from first lieutenant (36th U. S. V. Inf.), with rank from Oct. 30, 1900, is assigned to the 29th U. S. V. Inf.

John E. Bingham, acting asst.-surgeon, when relieved from duty at Fort Walla Walla, Wash., by Acting Asst.-Surgeon Whitney, to report by letter to the surgeon-general for assignment of contract.

Isaac W. Brewer, captain and asst.-surgeon, Vols., recently appointed from first lieutenant and asst.-surgeon, 26th U. S. V. Inf., with rank from Oct. 12, 1900, is assigned to the 36th U. S. V. Inf. William H. Brooks, acting asst.-surgeon, from Fort Hamilton, to temporary duty at Fort Schuyler, N. Y. after which he will proceed to San Francisco, Cal., for duty with troops en route to Manila, P. I., and on arrival at Manila will report for assignment in the Division of the Philippines.

Lawrence C. Carr, major and surgeon, U. S. V., relieved from further duty in the Division of Cuba, to report to the surgeon-general at Washington, D. C., for instructions.

Henry R. Carter, acting asst.-surgeon, previous orders revoked; he will proceed from Seattle to Vancouver Barracks, Wash., for port duty at the latter place.

Jefferson R. Keen, major and surgeon, Vols., previous orders revoked; his duty in the Division of Cuba and assigning him to port duty at Fort McHenry, Md., revoked.

James H. McCall, acting asst.-surgeon, leave of absence granted. George J. Newgard, captain and asst.-surgeon, U. S. A., previous orders directing him to proceed from Fort McHenry, Md., to Fort D. A. Russell, Wyo., revoked.

Seaton Norman, major and surgeon, Vols., recently appointed from captain and asst.-surgeon, 29th U. S. V. Inf., with rank from Oct. 30, 1900, is assigned to the 29th U. S. V. Inf.

J. J. Shafer, acting asst.-surgeon, leave of absence granted.

Samuel S. Turner, acting asst.-surgeon, from the recruiting office at Chicago, to duty at Fort Sheridan, Ill.
 Walter Whitney, acting asst.-surgeon, from Fort Sheridan, Ill., to duty at Fort Walla Walla, Wash.
 Robert N. Wynn, lieutenant and asst.-surgeon, U. S. A., leave of absence granted; thereafter to report for duty at Fort Riley, Kan.
 Edwin P. Wolfe, lieutenant and asst.-surgeon, U. S. A., relieved from further duty in the Department of Eastern Cuba and assigned to post duty at Fort Hamilton, N. Y.
 Charles L. Wych, acting asst.-surgeon, from St. Louis, Mo., to San Francisco, Cal., for duty with troops destined for service in the Division of the Philippines and on arrival in Manila, to report for assignment in the Division.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy, for the week ending Nov. 10, 1900:
 Medical Inspector C. Boyd, detached from the *New York* when out of commission, and ordered to the *Kearsarge*.
 P. A. Surgeon E. S. Bogert, Jr., detached from the *New York* when out of commission, and to duty on the *Massachusetts*.
 P. A. Surgeon M. S. Elliott, detached from the naval station, Port Royal, S. C., and ordered to the *Annapolis*, when placed in commission.
 Asst.-Surgeon W. M. Garton, detached from the *Massachusetts*, and ordered to the *Washington*.
 Asst.-Surgeon J. St. J. Butler, appointed asst.-surgeon from Oct. 26, 1900.
 P. A. Surgeon J. M. Moore, ordered to the naval station, Port Royal, S. C.
 P. A. Surgeon E. M. Shipp, detached from Norfolk Hospital and ordered to duty on the *Michigan*.
 P. A. Surgeon H. D. Wilson, detached from the *Michigan* and ordered to Norfolk Hospital, Va.
 P. A. Surgeon L. W. Sprating, detached from Yokohama Hospital, and ordered to Cavite naval station.
 Pharmacist S. Douglass, ordered to additional duty on the *Massachusetts*.

Marine Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned service for the seven days ended Nov. 8, 1900:
 Surgeon D. A. Carmichael, granted leave of absence for thirty days from Oct. 23.
 Surgeon G. M. Magruder, granted leave of absence for seven days from Nov. 17.
 P. A. Surgeon W. P. Wertenbaker, to proceed to Natchez and Jackson, Miss., on special temporary duty.
 P. A. Surgeon G. B. Young, granted leave of absence for two days. Granted leave of absence for five days, on account of sickness.
 Asst.-Surgeon M. H. Foster, to proceed to Seattle and Tacoma, Wash., on special temporary duty.
 Hospital Steward R. H. Gibson, granted leave of absence for thirty days from Dec. 7.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ending Nov. 10, 1900:

SMALLPOX—UNITED STATES.
 Colorado: Arapahoe County, Oct. 13-25, 5 cases; Elber County, Oct. 19, 1 case; Saguache County, Oct. 14, 1 case.
 District of Columbia: Washington, Nov. 3, 1 case.
 Kansas: Wichita, Oct. 27-Nov. 3, 3 cases.
 Kentucky: Lexington, Oct. 27-Nov. 3, 2 cases.
 Louisiana: New Orleans, Oct. 27, Nov. 3, 2 cases.
 Massachusetts: Fannin, Oct. 27-Nov. 3, 1 case.
 Michigan: Detroit, Oct. 27-Nov. 3, 1 case.
 Ohio: Cleveland, Oct. 28-Nov. 3, 1 case.
 Oregon: Portland, Oct. 31, 1 case.
 South Dakota: Sioux Falls, six months ended Oct. 31, 1 case.
 Utah: Salt Lake City, Oct. 27, Nov. 3, 5 cases.
 Tennessee: Memphis, Oct. 27-Nov. 3, 1 case.

SMALLPOX—FOREIGN.
 Bohemia: Prague, Oct. 13-20, 2 cases; West Hartlepool, Oct. 13-20, 1 case.
 France: Paris, Oct. 13-20, 11 deaths.
 Greece: Athens, Oct. 6-13, 1 case.
 Italy: Rimini, Oct. 24, black smallpox reported present.
 Mexico: Mexico, Oct. 14-21, 1 case; Vera Cruz, Oct. 20-27, 3 cases, 1 death.
 Russia: Moscow, Oct. 6-13, 1 case, 2 deaths; Odessa, Oct. 13-20, 4 cases, 4 deaths; Warsaw, Oct. 6-13, 18 deaths.
 Scotland: Glasgow, Oct. 19-26, 29 cases, 2 deaths.
 Spain: Oct. 13-20, 1 case.

YELLOW FEVER—UNITED STATES.
 Mississippi: Natchez, Nov. 6, 1 case.

YELLOW FEVER—FOREIGN AND INSULAR.
 Colombia: Barranquilla, Oct. 13-21, 2 cases, 2 deaths; Bocas del Toro, Oct. 24, 1 case.
 Cuba: Cienfuegos, 16, 1 death; Havana, Nov. 2, 16 cases, 1 death; Sagua, Nov. 2, 1 case.
 Mexico: Mexico, Oct. 14-21, 1 death; Tampico, Oct. 21-28, 3 cases, 1 death; Vera Cruz, Oct. 20-27, 12 cases, 7 deaths.

CHOLERA.
 India: Bombay, Oct. 9, 30 deaths; Karachi, Oct. 7, 3 cases, 2 deaths.

PLAGUE—UNITED STATES.
 California: San Francisco, Oct. 14-Nov. 6, 4 deaths.

PLAGUE—FOREIGN AND INSULAR.
 Germany: Bremen, Nov. 6, one death from plague, a seaman on a vessel from Buenos Ayres.
 India: Bombay, Oct. 30, 87 deaths.
 Japan: Kobe, Nov. 2, reported present; Osaka, Sept. 11-Oct. 7, 25 cases, 20 deaths.
 Mauritius: Port Louis, Sept. 7, 7 cases, 4 deaths.
 Scotland: Glasgow, Oct. 19-26, 10 cases.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the AMERICAN MEDICAL ASSOCIATION. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive THE JOURNAL free. Subscribers to THE JOURNAL may become members of the ASSOCIATION without additional expense if they are members of medical societies recognized by the ASSOCIATION. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to THE JOURNAL, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the AMERICAN MEDICAL ASSOCIATION is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the ASSOCIATION at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends statement to each member. Such members, however, are entitled to THE JOURNAL for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this ASSOCIATION and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the ASSOCIATION." The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the ASSOCIATION or either of the Sections, unless specially instructed to the contrary by vote of the ASSOCIATION." (From Article V of the By-Laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscripts.

Half-tones, zinc etchings and other illustrations will be furnished by THE JOURNAL when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "JOURNAL AMERICAN MEDICAL ASSOCIATION," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

GASTRIC ULCER: NON-PERFORATING—HEMORRHAGE.*

WILLIAM L. RODMAN, M.D.

Professor of the Principles of Surgery and Clinical Surgery, Medical-Chirurgical College, Philadelphia; Professor of Principles and Practice of Surgery in the Woman's Medical College of Philadelphia.
PHILADELPHIA, PA.

One need not believe that gastric ulcer is so common an affection as Ewald¹ claims, before admitting that its treatment is of the greatest importance.

Ewald thinks that 5 per cent. of the Germans suffer with ulcer of the stomach, and this estimate is supported by clinical statistics and post-mortem records drawn from various German hospitals. DaCosta² and Welch³ think it less common in America, and in this opinion they are supported by a preponderance of authors and practitioners.

When one recalls how constantly the stomach is at work, the great variety of substances taken into it in the form of food and drink—regularly and irregularly—the wonder is that its diseases—resulting in inflammation particularly—are not more frequently encountered.

While gastric ulcer was until recently looked on as strictly a medical disease, some of its complications are now generally recognized as beyond the physician's province, and to have only a surgical bearing; others, again, occupying intermediate ground, claim the best consideration of both physician and surgeon.

Perforation and subphrenic abscess must always be met by prompt surgical interference; hemorrhage may be in many cases, and must be in some; while pain, vomiting, and other symptoms common in the evolution of an ulcer may be so pronounced as to not only justify, but demand, surgical intervention.

There is no disease, I take it, not even excepting the protean one, appendicitis, in which it is more necessary for a perfect understanding between physician and surgeon than in the treatment of gastric ulcer. When it is recalled that in mild cases—even latent ones—the worst complications may unexpectedly develop, whereas, in seemingly the most severe cases they may be escaped, there is but one safe rule to follow, and that is for the physician to either treat all cases of ulcer in a hospital, or at a residence, in conjunction with a surgeon.

The rather careless and slipshod fashion, altogether too common, of treating such cases by office consultation, and allowing them to continue their business, can only result, as it now does, in patients frequently falling

in the streets with perforation and hemorrhage, and being hopelessly lost, when they could, under better environments, have been easily saved. A joint interest in such cases will lead to a more accurate knowledge of the subject. Notwithstanding his unquestioned superior knowledge and greater acumen in the diagnosis of internal diseases, the physician has not found it so necessary to study the subject of ulcer topographically to the same extent and with the same accuracy as the surgeon undoubtedly will. It makes little difference to the physician where the ulcer is situated, as his treatment is not materially influenced thereby; it makes every difference to the surgeon, and will decide for or against operative procedures.

Morbid Anatomy.—Welch,⁴ who is quoted by every medical authority I have read, reports 793 cases, in which the ulcers were situated as follows:

Lesser Curvature	288	36.3 per cent.
Posterior wall	235	29.6 " "
Pylorus	95	12 " "
Anterior wall	69	8.7 " "
Cardia	50	6.3 " "
Fundus	29	3.7 " "
Greater curvature	27	3.4 " "

"From this table, it is apparent that ulcers occupy the lesser curvature, the posterior wall, and the pyloric region three and a half times more frequently than they do the remaining larger segment of the stomach."

It is also maintained by Welch that ulcers of the posterior border and lesser curvature were generally at or about the pylorus. Nolte, on the contrary, found ulcers more frequently on the anterior wall of the stomach than elsewhere.

In one case in five, or more frequently, the ulcers are multiple; generally, there are but two or three, but in one of his cases, Osler⁵ saw five, and refers to another case on record—Berthold's—with 34 ulcers.

Cicatrices are more frequently found and in greater number at autopsies than fresh ulcers. Mikulicz⁶ found them three times as common.

Etiology.—Owing to time limits and the occasion, it will be impossible for me to review all of the different theories as to the factors, predisposing and exciting, of gastric ulcer.

The theory so forcefully advocated by Reigel and his followers, namely, that an excess of acid—hyperchlorhydria—is always found in the gastric secretion in case of ulcer, while denied by few, notably Ewald, is admitted by practically all to be true of a great majority of cases.

Ewald, Leube, and others maintain,⁶ however, that the hyperchlorhydria is only one, and probably not the essential, factor, being of less importance probably than a coexisting anemic state of the blood. Ulcer of the stomach is found too frequently associated with anemia, chlorosis, and after acute hemorrhage not to have some

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

TABLES COMPILED WITH THE ASSISTANCE OF DRs. STILLWELL C. BURNS AND W. HERSEY THOMAS, GIVING DETAILS

NO.	OPERATOR.	SEX AND AGE.	OCCUPATION.	HISTORY.	SYMPTOMS.	DIAGNOSIS.	DATE OF OPERATION.
1	Armstrong, O. E.	F. 46.		Suffered with indigestion for 8 to 10 years. Diagnosis of ulcer made 9 years ago, at which time she had a slight hemorrhage.	Pain, vomiting and recurring hematemesis.	Gastric ulcer.	Oct. 12, 1899.
2	Berg, I.					Gastric ulcer.	
3	Berg, I.					Gastric ulcer.	
4	Berg, I.					Gastric ulcer.	
5	Berg, I.					Gastric ulcer.	
6	Bernays.		Laundress. Servant.	Four and a half years ago had two attacks of hematemesis. These were severe. No trouble for a year after these two hemorrhages. Gastric disturbances for 12 years.	Pain, vomiting, loss of weight, gastric dilation. Vomit contains sarinæ, blood-corpuscles, red and white, acid in reaction. Vomiting. Violent pain in stomach. Tumor beneath left costal margin.	Gastric ulcer.	Nov. 14, 1898.
7	Billroth.	F. 50.					Dec. 4, 1888.
8	Brenner.	F. 52.		Healthy until 23 years of age, when she began to vomit after eating. Had similar attacks at 28, 32, 41. At 42 pain and vomiting became still more marked.	Vomiting, pain. During the last year has had very severe pain in abdomen and left leg. Systolic murmur.	Gastric ulcer.	Sept. 15, 1896.
9	Brenner.	F. 53.		Gastric symptoms since July, 1895.	Loss of weight, vomiting. Pain in epigastrium. Melena on several occasions.	Gastric ulcer.	Sept. 16, 1896.
10	Cordua.	F. 46.			Gastralgia for 10 years. Movable tumor in the left hypochondriac region.		
11	Czerny,	M. 41.			Gastric symptoms for 3 years. Hard movable tumor above umbilicus.		
12	Czerny.	M. 41.	Cabinetmaker.	Previous good health.	Two years ago taken with pain in epigastrium radiating to back, with vomiting which continued on and off up to time of operation.	Dilation of stomach. Gastric ulcer.	1882.
13	Doyen.	F. 59.			All the symptoms of pyloric stenosis. Hard tumor felt in the neighborhood of the umbilicus.	Diagnosed as carcinoma. Proved subsequently to be an immense callous ulcer.	
14	Elliot.	M. 47.	His work entails constant pressure of tools on abdomen. Servant.	Markedly tubercular family history. Moderate drinker. Diseases of childhood. Morning cough for 30 years. Subject to attacks of indigestion.	For last 3 months constant pain in epigastrium, not relieved by food. Five days ago vomited 2 quarts of thick brown matter. Since then has had coffee-ground vomit.	Gastric ulcer, recurring hemorrhage.	
15	Gilford, Hastings.	F. 19.	Servant.	Had 3 attacks of dyspepsia in course of 2 years; epigastric pain and vomiting. Had on two occasions hematemesis. Had been ill for past two years.	Sudden, acute abdominal pain, tenderness over whole epigastrium, vomiting. After taking food had pain, nausea, and vomiting, with occasional hematemesis.	Gastric ulcer.	
16	Grad, Herman.	F. 32.				Chronic gastric ulcer.	
17	Hofmeister.	F. 34.		Stomach trouble since 17. In January, 1892, noticed tumor in abdomen which was painful.	Frequent attacks of vomiting and pain.		July 18, 1895.
18	Keen, W. W.	F. 61.		Good personal and family history. Her attacks began before 1886 and were insidious, but had gradually become severer.	Repeated attacks of pain and vomiting and on one occasion hematemesis. Weight 88 pounds. Absence of HCl. Lactic acid present. Dyspnea and irregular attacks of fever. Constipation obstinate. A small tumor could be felt in the epigastrium a little to left of median line.	The diagnosis lay between cancer and possible non-malignant gastric tumor due to ulcer.	Feb. 25, 1892.
19	Klausner.	F. 21.	Servant.	Symptoms began September 18, 1891, and recurred again in following year. During last 3 years has never been free from pain.	Intense pain and vomiting. Mass between xiphoid cartilage and costal margin.		Feb. 29, 1896.
20	Könlg, Jr.				Continual hematemesis.	Gastric ulcer.	
21	Krogfus.	F. 51.	Fish dealer.		Gastric symptoms for the last 3 or 4 years. Vomited blood on one occasion. Mass in epigastrium.		June 11, 1895.
22	Lange.	M. 25.	Butcher.		Pain in region of stomach. Vomited only twice during illness. Never any blood.	Owing to absence of symptoms of gastric ulcer the gall-bladder was thought to be the seat of trouble.	Oct. 25, 1891.
23	Lindner.	F. 30.		Had been ill a long time.	For some weeks had been vomiting all food. A large, hard, and tender tumor could be felt under xiphoid cartilage.	Tumor of inflammatory product. Gastric ulcer.	

OF FORTY CASES OF ULCER OF THE STOMACH TREATED BY PYLORECTOMY, PARTIAL GASTRECTOMY AND EXCISION.

CONDITIONS FOUND AT OPERATION.	OPERATION.	REMARKS.	RESULT.	REFERENCE.
Deeply excavated ulcer on lesser curvature, two inches from pylorus. Blood flowed freely from several points around margin.	Excision of ulcer. Opening in stomach closed as in a Heineke-Mikulicz pyloroplasty.	Patient did well. Convalescence complicated on fourteenth day by femoral thrombosis. All pain, sickness and discomfort have gone. She is gaining flesh rapidly.	Recovery.	<i>British Med. Journal</i> , March, 1900, p. 574.
	Pylorectomy.		Recovery.	<i>Nordiskt Medicinskt Arch.</i> , xxxi, 1898, Nos. 22-25.
	Partial gastrectomy.		Recovery.	<i>Nordiskt Medicinskt Arch.</i> , xxxi, 1898, Nos. 22-26.
	Partial gastrectomy.		Recovery.	<i>Nordiskt Medicinskt Arch.</i> , xxxi, 1898, Nos. 22-26.
	Partial gastrectomy.		Recovery.	<i>Nordiskt Medicinskt Arch.</i> , xxxi, 1898, Nos. 22-26.
Simple ulcer anterior wall of stomach 3 inches from pylorus.	Partial gastrectomy. Wound closed by 3 rows of sutures.	Total abstinence for 48 hours. Milk diet resumed on third day. Thirteen months after operation in best of health.	Recovery.	Not reported. Details sent in private letter to author.
Great retraction on anterior surface of stomach near greater curvature. Stomach opened in separating adhesions.	Partial gastrectomy. Callous area excised.	Six months after operation patient had gained 13 pounds. Eats food of all kinds. No pain since operation.	Recovery.	Reported by Eiselsberg in <i>Arch. f. klin. Chirurgie</i> , 1899, 30, page 845.
Ulcer near lesser curvature surrounded by an area of infiltration.	Ulcer excised by extensive partial gastrectomy. Mucous membrane united by continuous suture, muscularis and serosa by interrupted sutures of silk.	Left hospital November 7, 1896. Free from pain. Eats food of all kinds.	Recovery.	<i>Wiener Klin. Wochenschr.</i> , 1896, p. 1117.
Ulcer on posterior wall near lesser curvature. Firm adhesions. Very small ulcer on anterior wall, size of linseed. Ulcer found on the anterior wall of stomach.	Partial gastrectomy, continuous suture of mucosa, interrupted suture of muscularis and serosa.	Discharged November 7, 1896. Had gaueia in weight, feels well and strong. Gave excellent result.	Recovery.	<i>Wiener Klin. Wochenschr.</i> , 1896, p. 1117.
Tumor located on greater curvature.	Resection of affected portion followed by suture.	On the inner surface of excised portion 2 round ulcers were found. Tumor also presented histological peculiarities of myxosarcoma. Patient well at the end of 2 years.	Recovery.	<i>Rev. de Sciences Medicales</i> , xxxiv, p. 279.
On the lesser curvature was found a hardness which extended to the left and posteriorly. Posterior surface of stomach adherent.	Partial gastrectomy.	Microscopic examination confirmed the diagnosis. No digestive trouble after operation.	Recovery.	<i>Beiträge zur klin. Chirurgie</i> , ix, p. 681.
	Pylorectomy. Gastric and duodenal wounds closed and anterior gastroenterostomy performed.	Patient collapsed and died at end of 48 hours.	Death.	Reported in Doyen's <i>Travail. Chirurgicale des Maladies de l'estomac et du duodenum</i> , 1895.
Pyloric stenosis complete or nearly so.	Partial gastrectomy. Excision of pylorus and all diseased tissue which included $\frac{1}{2}$ of stomach, including whole of lesser curvature.	Stood operation well. On third day awoke in pain. Gradually sank and died. Cause of death not determined.	Death.	Reported by E. G. Cutler in <i>Boston Med. and Sur. Jour.</i> , 1897 p. 54.
Ulcer found near greater curvature on anterior aspect of stomach.	Excision of ulcer.	Vomiting and retching continued after operation and lasted until her death, 32 hours after operation.	Death.	<i>Guy's Hosp. Reports</i> vol. III, 1896.
Ulcer found on anterior wall near cardiac orifice, about $\frac{1}{2}$ inch in diameter.	Partial gastrectomy.	After operation patient improved steadily. For first few days fed per rectum, then food by mouth cautiously given. Recovery slow but uneventful.	Recovery.	<i>Medical Record</i> , N. Y., 1898, iv.
Tumor densely adherent.	Partial gastrectomy. A piece of spleen as large as a cherry was excised with the ulcer, as well as a large piece of the gastric wall, and a piece of the liver. Length of operation 2 $\frac{1}{2}$ hours. This mass was excised by a partial gastrectomy.	The excised portion showed an ulcer on its inner surface as large as a dollar. Microscopic diagnosis: Simple ulcer. Patient rapidly recovered.	Recovery.	<i>Beiträge zur klinischen Chirurgie</i> , xv, p. 356.
Hard dense mass, 3 cm. in diameter and 5 cm. to left of pylorus on lesser curvature.	Partial gastrectomy.	Patient in best of health 5 months after operation. A careful examination of tumor showed ulcer with greatly thickened edges and no signs of malignancy.	Recovery.	PHILADELPHIA MEDICAL JOURNAL, May, 1898.
Immediately beneath the skin several layers of scar-tissue were found which were removed. In doing this the stomach was opened. Opening packed with gauze and a secondary resection done several days later.	Partial gastrectomy. Excision of entire infiltrated area. All adhesions carefully broken up.	When seen 6 months after operation had no pain. Complete cure.	Recovery.	<i>Münchener medicinische Wochenschrift</i> , 1896, p. 863.
Ulcer situated near the pylorus.	Resection.	The resulting cicatrix caused obstruction and the abdomen was opened again and a gastrointestinal anastomosis made. A third celotomy was made necessary by the closure of this opening.	Recovery.	PHILADELPHIA MEDICAL JOURNAL, April, 1899, p. 529.
Stomach adherent to liver and anterior abdominal wall.	Partial gastrectomy. Removal of part of stomach as large as the hand. In separating adhesions stomach was opened.	Microscope showed the case to be one of simple ulcer. Pain ceased immediately after operation. Patient now in good health.	Recovery.	<i>Centralblatt f. Chirurgie</i> , 1896, Band 23, S. 538.
On opening the abdomen palpation revealed a hard disc on anterior wall of stomach.	Partial gastrectomy, the affected portion being excised.	The ulcer occupied a central area of this excised portion 3 inches in diameter. Pain has never recurred.	Recovery.	<i>New York Med. Journal</i> , May, 1892, p. 584.
Stomach adherent to liver.	Partial gastrectomy. Resection of the whole of the inflamed tissue.		Recovery.	<i>Med. Press and Circ.</i> , 1898, p. 334.

TABLES COMPILED WITH THE ASSISTANCE OF DRs. STILLWELL C. BURNS AND W. HEISEY THOMAS,

NO.	OPERATOR.	SEX AND AGE.	OCCUPATION.	HISTORY.	SYMPTOMS.	DIAGNOSIS.	DATE OF OPERATION.
24	Maydl.
25	Murphy, J. B.	F. 58	Emaciation, emesis after every meal. Marked gastrectasis.	Pyloric occlusion probably malignant.	Nov., 1899.
26	Navaro.	F. 65	Extremely emaciated. Presented a hard tumor the size of hen's egg above umbilicus.	1889.
27	Postemski.
28	Robson, Mayo.	M. 54	Ulcer of pylorus.	June 25 1881.
29	Robson, Mayo.	F. 44	Well until 2 years ago, when patient had colic and lost flesh. On September 15, 1897, same kind of attack.	Pain on right side over pylorus. Loss of weight and strength.	Ulcer of pylorus.	July 23, 1898.
30	Roux.	M.	Brewer.	Hematemesis. One liter, one half liter, and two liters several days before operation.
31	Rydygier.	F. 30.	Since 1875 has felt a sense of constriction in gastric region.	Frequent sour belchings, vomiting several times weekly, finally becoming daily. On one occasion hematemesis.	Gastric ulcer. Dilation of stomach.	Nov. 21, 1881.
32	Rydygier.	M. 48.	Gastric disturbances for 6 years.	Hematemesis on several occasions.	Gastric ulcer.	1894.
33	Rydygier.	M. 33.	Dilation of stomach. Pylorus thickened.
34	Schuchardt.	M.	Very cachectic. Presenting all symptoms of gastric ulcer.
35	Van Kleef.	F. 37	Had suffered with gastric disturbances for 15 years. Came under my care in 1876.	Dilation of stomach. Periods of violent gastralgia. Vomiting. Several severe gastric hemorrhages.	Gastric ulcer. Pyloric stenosis.	Jan. 27, 1882.
36	Price, Joseph.	F. 31	Typical history of benign ulcer. She for a year prior to operation had frequently recurring small hemorrhages.	Hemorrhage, pain, and progressive emaciation.
37	Price, Joseph.	F. 37	Hemorrhages frequently repeated in Europe and after immigration to this country, where she was operated on largely on this account.	She had a fresh hemorrhage about 3 weeks before operation, being pale and anemic, so much so that the operation was postponed for a time until she became in better general condition.
38	Brown, F. Tilden.	M. 5t.	Admitted to hospital December 29, 1898. During September preceding this date, was seized with severe pain in epigastrium and vomited blood-stained food. Pain persisted.	Emaciation, pain, tenderness in epigastrium. Examination of stomach-contents showed free HCl. Ten days after being admitted, and while in hospital, had a number of copious black stools.	Gastric ulcer.	About Jan. 2, 1899.
39	McCosh, A. J.	Gastric ulcer.
40	Czerny.	Acute gastric hemorrhage.	Gastric ulcer.

NOTE.—Several operations by Mikulicz are not included in these tables for want of accurate details.

direct etiologic connection with the condition of the blood.

It is this changed or abnormal composition of the blood more than the hyperacidity of the gastric juice, which predisposes to ulcer. Both facts are of great importance from a diagnostic, as well as an etiologic, standpoint.

All agree that the female is more liable than the male (60 per cent. females, 40 per cent. males—Welch), some placing the difference as two to one, and three to one respectively. Occupation has a doubtful significance. It has been claimed, but by no means proved, that female servants, especially cooks who habitually taste hot food, suffer frequently. It is very unlikely that one would take food or drink at such a temperature as to immediately injure the mucous membrane of the stomach, for when hot enough to be a menace, it would either be expelled from the mouth or at once mixed with water and its temperature reduced before reaching the stomach, as the custom of drinking water freely with meals is practically a universal one.

Certain occupations which lead to more or less constant traumatism of the region over the stomach, such as shoemaking, weaving, turning, etc., have been credited with producing ulcer. Tight lacing has also been considered a cause. It would seem a priori that if such were the case, ulcers would be more frequently situated upon the anterior wall of the stomach, instead of, as they are, upon the posterior wall, which is certainly more favored, so far as traumatism from without is concerned.

The same line of reasoning would discredit the statement so frequently made by authors, that hot food may cause ulcer. Food and drink passing into the stomach first come in contact with its anterior wall and greater curvature, while we have shown by Welch's statistics that ulcer of the anterior wall is about one-fourth as common as it is on the posterior wall—8.7 to 29.6—and only one-twelfth as frequent on the greater curvature as the lesser—3.4 to 36.3. This, I take it, destroys confidence in these theories, if it does not actually dispose of them.

GIVING DETAILS OF FORTY CASES OF ULCER OF THE STOMACH, ETC.—CONTINUED.

CONDITIONS FOUND AT OPERATION.	OPERATION.	REMARKS.	RESULT.	REFERENCE.
.....	Partial gastrectomy. Resection of stomach to great extent for tumor simulating carcinoma.	It was a cicatricial tumor surrounding 3 simple ulcers.	<i>Semaine Médicale</i> , 1891, p. 174.
Pyloric ulcer originally in stomach, extending out through pylorus and down the duodenum $\frac{3}{4}$ of an inch.	Pylorotomy. End of duodenum approximated with button to posterior wall of stomach. Stomach wound closed.	Uninterrupted recovery. All symptoms have subsided. Patient has gained in weight.	Recovery.	Not reported. Details sent in private letter to author.
.....	Pylorotomy.	Microscopical examination showed cicatrizing ulcer. Patient died of bronchopneumonia 12 days later.	Death.	Contributo alla Chirurgia dello stomaco, <i>Semaine Médicale</i> , 1890, p. 46.
Cicatrizing ulcer. Pylorus narrowed.	Pylorotomy.	Recovery.	Eighth Congress of Italian Surgeons, 1891, <i>Lancet</i> , London, March 10, 1900, p. 680.
.....	Pylorotomy. Some adhesions broken up.	Gained flesh rapidly and went home within a month. Tumor proved to be thickening around an ulcer of the pylorus.	Recovery.	<i>Lancet</i> , London, March 10, 1900, p. 680.
The ulcer at the pylorus was adherent to the liver, which formed its base. There was also pyloric stenosis.	Excision of ulcer followed by pyloroplasty.	Patient lived for several years. After death old erosion of coronary artery was found.	Recovery.	<i>Lancet</i> , London, March 10, 1900, p. 680.
Circumscribed ulcer at lesser curvature near pylorus.	Excision of ulcer. Ligation of arteries of lesser curvature.	Patient died of erosion of coronary artery was found.	Recovery.	<i>Congrès de Chirurgie</i> , p. 203.
Ulcer on posterior wall of pylorus. Pyloric stenosis.	Pylorotomy.	Patient made a quick recovery. Eight months after operation was in the best of health.	Recovery.	<i>Berliner Klin. Wochenschrift</i> , 1882, Bd. 19, S. 29.
A loop of small intestine was found adherent to pylorus. The effort to detach it resulted in a perforation at the site occupied by the ulcer.	Pylorotomy. The perforation having been temporarily closed the pylorus was resected and the open end of the duodenum was brought into the wound in stomach. Opening in stomach closed.	At end of 7 weeks patient had gained 11 kilograms in weight and digested all his food.	Recovery.	<i>Med. Week.</i> , Vol. iii, No. 39, p. 459.
Pylorus contained an ulcer, at the bottom of which an open vessel was seen. The patient had never had hæmatemesis.	Pylorotomy.	Death caused by bronchopneumonia 4 days after operation.	Death.	<i>Wien. Min. Wochenschrift</i> , 1894, March 8-15-22.
An ulcer was found at the level of the lesser curvature.	Excision of ulcer.	Death after 2 weeks. Autopsy showed a second inaccessible ulcer, although the cavity of the stomach had been examined with great care at the time of operation.	Death.	<i>Semaine Médicale</i> , 1894, p. 203.
Pylorus very much contracted. Round ulcer 1 centimeter on anterior wall.	Pylorotomy.	Patient gained in weight and made an excellent recovery.	Recovery.	<i>Centralblatt f. Chirurgie</i> , 1882, Band ix, No. 46.
Ulcer found at pylorus on posterior wall.	Partial gastrectomy. Removal of ulcer and part of gastric wall 1 x 3 inches.	Recovery uneventful. Is still living. No symptoms of stricture since operation.	Recovery.	Case not reported. Details sent to author in private letter.
The ulcer was located on the anterior wall near cardia.	Partial gastrectomy. A portion of the stomach-wall as large as the hand being removed with the ulcer.	Recovery was uneventful, and she is still in good health. No microscopic examination was made.	Recovery.	Case not reported. Details sent to author in private letter.
Stomach presented a $\frac{3}{4}$ -inch ulcer, about 1 inch from the cardia and $1\frac{1}{2}$ inches from the junction of the posterior wall with the fundus.	Ulcer excised by a partial gastrectomy. Component layers of the wound were brought together with chromicized catgut, except the serous coat, which was inverted with two rows of fine silk.	Microscopic examination proved simple ulcer to be the correct diagnosis. Patient made a good recovery.	Recovery.	<i>Annals of Surgery</i> , July, 1899, p. 95.
.....	Excision of ulcer.	Recovery.	Not reported. Details sent in private letter to author.
.....	Excision and gastroenterostomy.	Checked the hemorrhage immediately.	Recovery.	Reported by Petersen in <i>Deutsche medicin. Wochenschrift</i> , 1899, No. 24-25.

If ulcers are common, and I do not question that they are, in housemaids, cooks, tailors, weavers, and shoemakers, can not their frequency be explained in all by a common cause, namely, unhygienic surroundings, insufficient food and clothing, want of sunlight, and exercise in the open air? Are not such persons usually anemic and therefore predisposed to ulcer?

Stockton believes that gastric ulcers are neuropathic in origin.

Age.—The following table from Welch, based upon 607 autopsies, and therefore accurate, shows the age incidence for each decennium.

Age	1-10	10-20	20-30	30-40	40-50	50-60	60-70	70-80
No. of cases.....	1	32	119	107	114	108	84	30
		226		222		114		
Age	80-90	90-100	over 100					
No. of cases.....	6	0	1					

While from the above statistics it will be apparent that young persons frequently suffer from ulcer of the stomach, it will be none the less striking that it is about equally common during the four decades from 20 to 60, and that contrary to what is generally taught, it is

relatively more common between 40 and 60 as there are fewer persons living at that time of life than between 20 and 40. While many of these ulcers may, and undoubtedly did, exist for years prior to death, no one would hesitate on this account to estimate them as of more value than statistics based upon clinical data alone. The following tables were compiled by Lebert from diagnoses made during life:

Age	5-10	11-20	21-30	31-40	41-50	51-60	61-70
No. of cases	1	24	87	84	34	17	5
Per cent.		25	92	171	51	5	
				67.85	20.24	1.99	

The mean age at which ulcer begins is greater in males than females.

Age.....	10-20	20-30	30-40	40-50	50-60	60-70	70-80	80-90	Total
Males.....	9	33	44	39	37	20	5	1	188
Females....	13	35	25	25	18	18	9	0	143

(Welch, Pepper's System of Medicine.)

Symptoms.—Pain, severe and boring in character, situated one or two inches below the xiphoid cartilage, also felt at a point nearly opposite, near the heads of the last two ribs and materially increased by the taking of

food, and which attains its maximum intensity about two hours after eating, is perhaps the most constant and reliable symptom. There is, in addition, as a rule, marked tenderness on pressure over a very circumscribed spot, so much so that the patient will point to it with a finger rather with the entire hand. While vomiting is present in a majority of cases of ulcer, it is so usual a symptom in other gastric disorders as to be far from characteristic. If, however, the stomach empties itself about two hours or more after eating, the ejected matter contains an excess of HCl, and pain hitherto severe is now relieved, the probability is that such symptoms in a person under 40, especially a female, indicate gastric ulcer.

Hemorrhage.—If in addition to the above symptoms there is added occasional hematemesis or melena, the diagnosis may be considered as practically certain. Von Leube⁶ states that in 1000 cases treated by him hematemesis occurred in 46 per cent. Gerhardt saw it in 47 per cent. of his cases, while Brinton places it as low as 29 per cent. Ewald thinks it considerably less than 50 per cent. Other writers think that hemorrhage occurs in 80 per cent. of all cases.

The amount and color of the vomited blood will depend, of course, upon the rapidity with which it is poured out into the stomach, and the time it has remained undergoing disintegration. A large hemorrhage would provoke prompt emesis and show bright blood, whereas a small and slowly-forming accumulation would give the coffee-grounds vomit. The latter variety of hemorrhage into the stomach may not provoke vomiting but pass off per rectum as it not infrequently does. Hemorrhage causes death in 8 per cent. of the cases in which it occurs. (Leube.) It causes death in 3 to 5 per cent. of all cases. (Welch.)

Physical Signs.—A tumor may be present in ulcers with thick, callous edges, and in those which have formed adhesions or attached themselves to pancreas, omentum or other tissues. Such benign ulcers are not common, and are usually diagnosed as carcinoma. Introducing a stomach-tube for diagnostic purposes is no longer necessary or justifiable, and even physicians, as Ewald and Sée, strongly advise against it, as perforation and hemorrhage may follow its use.

Prognosis.—There is little uniformity in the mortality statistics of ulcer, varying from 2.4 per cent. of Leube, 10 per cent. of Lebert, to 50 per cent. as given by Debove and Rémond. Welch estimates the mortality as 15 per cent., of which 3.5 per cent. are due to hemorrhage and 6.5 per cent. to perforation. Anders⁵ places the mortality at 25 per cent.

Treatment.—The audience, the occasion, and the time-limits placed upon papers, all prevent consideration in detail of the ordinary medical treatment of gastric ulcer. Let it suffice to say that one-half or three-fourths of all cases (Leube) will be cured by four or five weeks' medical treatment. Patients with ulcer should be kept in bed; all solid food withdrawn; and the stomach, as far as possible, placed at rest. Giving liquids largely or wholly digested in the intestines, with rectal feeding, when well borne, so as to lessen the amount of nourishment taken by the stomach, constitutes the usual and best treatment of gastric ulcer.

We, as surgeons, are more interested in that smaller class of intractable ulcer, little or not at all influenced by medical treatment, than in the larger number of cases which will be successfully treated by the physician. That this class is a growing one, now that surgery offers a substantial hope for relief, can not be questioned. Even

Leube, the most optimistic of medical men, says that ulcers that are not cured in four or five weeks by medical means will not be cured by a longer treatment.

Kocher,⁷ from the surgeon's standpoint, emphasizes this opinion of Leube and insists that chronicity, especially in those past middle life, may mean incipient carcinoma. It is in such cases, particularly, that one should remember the teaching of Hauser that 6 per cent. of gastric ulcers become carcinomata, and that other observers, notably Doyen,⁸ would estimate the probability of malignant degeneration as very much greater.

With Tricomi advocating the radical treatment of ulcer by gastroenterostomy, just as he would do a radical cure for hernia; with Mikulicz' statement that "the danger to life from gastric ulcer is at least not less, but probably far greater, than the danger of a complete modern operation;" and Heydenreich's terse and forceful statement that gastroenterostomy gives, as it does, a mortality of 16.2 per cent., we have very positive ground taken by advanced surgeons and sufficient warrant for surgical intervention in serious if not in all cases of gastric ulcer. We have shown, moreover, that there is not wanting excellent medical authority for placing the mortality of ulcer higher than Heydenreich does. If all cases of gastric ulcer would not give so great a percentage of deaths, it is scarcely to be doubted that those finding their way to surgeons on account of their severe type and the previous failure of medical means, would if classed by themselves, yield a very heavy mortality, certainly not less than 25, and more likely 50, per cent.

This, it occurs to me, is the only way to consider the matter. The statistics we have are not of as great value as they should be, or will become very soon, now that ulcer is an operable disease. Kocher's insistence that cases be turned over to the surgeon before they are either moribund or so greatly reduced as to be unable to bear the shock of an operation has the right ring to it and should be generally followed.

Given then a case of gastric ulcer resisting medical treatment for a reasonable time, what is to be done in the face of uncontrollable vomiting leading to inanition, severe pain and other symptoms—excluding hemorrhage, or cases in which it was not the prominent symptom—due to its presence?

1. *Shall the ulcer be excised?* If it were certain that individual operators had been as ready in reporting unsuccessful as they have successful cases, it would not be difficult to answer this question. It is, of course, the ideal operation and method of treatment; absolutely prevents malignant degeneration, and leaves the stomach in the best condition for future use.

I have been able to collect from literature and extensive personal correspondence detailed reports of 40 pylorotomies, partial gastrectomies and excisions, with 6 deaths. Certainly this is a good showing when the nature of many of the cases is considered, operation in them having been undertaken for supposed malignant disease on account of a tumor with dense adhesions, and other conditions not conducive to a favorable operative result. This, furthermore, includes cases operated on since 1881, when Rydygier performed the first operation of the kind. (This operation was soon followed—1882—by an equally successful case in the hands of Czerny.)

Certainly the radical treatment of gastric ulcer has steadily gained in favor, and no one would now do as the editor of the journal in which Rydygier published his report of "The First Successful Excision of a Gas-

THE CIRCULATION OF THE HUMAN STOMACH.

(From a photograph.)

Arteries and veins injected with colored plaster by Dr. J. B. Roxy. Halftone engraving made from a wash-drawing over the photograph.

tric Ulcer," namely, to write under it the sharp criticism, "and let us hope the last."

Still, it can not be said in candor that an operation with a mortality of 15 per cent. should be advised in all cases of gastric ulcer, but rather held in reserve for severe ones that will probably not yield to surgical measures less formidable in character.

The size, location, and duration of the ulcer, and, above everything else, the presence or absence of dense adhesions to surrounding organs, as the pancreas, liver, omentum, gall-bladder, etc., will each have great weight in deciding between the merits of a partial gastrectomy and gastroenterostomy, or other less radical procedure. If the lesion is situated at the pylorus, or upon the anterior wall, and is, therefore, accessible and easily removed, pylorotomy is preferable, especially in persons past middle life, and in ulcers that run a chronic course. Per contra, if the ulcer be situated posteriorly, as it so frequently is, and at the same time adherent to adjacent tissues, requiring a difficult and prolonged operation for its removal, gastroenterostomy should, unless we are facing probable malignant degeneration, be preferred, being less dangerous and almost equally as satisfactory in its ultimate results as partial gastrectomy.

It acts by rapidly emptying the stomach, putting the ulcer at rest, and promptly relieving the hyperchlorhydria; all of which facilitates the healing of the ulcer, and in time results in cure. That it will occasionally fail to cure, we must admit, since Kocher had a fatal case of hemorrhage after the gastroenterostomy wound had healed.

I would here emphasize the fact that many cases, supposed to be malignant at the time of operation, on account of enlarged lymphatic glands, induration of tissue, etc., and, therefore, too advanced for resection, have yielded entirely to gastroenterostomy, time demonstrating in several of them that either mistakes in diagnosis actually were, or could easily have been, made, subsequent observation having proved that the enlarged glands were inflammatory, and had entirely passed away. Bidwell⁹ records two such mistakes in his own practice.

2. When there are two or more ulcers suspected, resection of each is out of the question, and gastroenterostomy is the operation of choice. In all cases when the element of shock is presumably to be an important one gastroenterostomy by one of the quicker methods—the Murphy button preferably—should be chosen.

It is not my intention to contrast the merits of the many different methods of performing gastroenterostomy with one another, or the best of them with pyloroplasty, Loreta's operation, and all other methods less radical than resection. I will say, however, that breaking up adhesions, a practice advocated by some, is hazardous, and has very generally resulted in perforation—making immediate resection imperative. In ulcer situated upon the anterior gastric wall with adhesions to the abdominal wall, all attempts, save one, to break up such adhesions have been followed by tearing into the stomach. It so happened to Krogius, Klausner, Hofmeister, and Billroth.

Mikulicz was more fortunate, and separated the stomach without causing a traumatic perforation. Therefore it should be remembered that any attempt to break up adhesions in this situation will, in all probability, lead to a partial gastrectomy.

Before dismissing the subject of non-perforating ulcer without hemorrhage, it is of interest to note that Mr. Mayo Robson¹⁰ in his recent Hunterian Lectures re-

ported 188 operations upon the stomach with a mortality of 16.4 per cent. for gastric ulcer, excluding perforation and hemorrhage. This is a very favorable showing when contrasted with the results following medical treatment, and certainly should encourage a more frequent resort to surgical intervention in intractable ulcers which have resisted dietetic and medicinal measures for a reasonable length of time. I here quote the conclusions of this distinguished English surgeon: "My own experience and a careful study of the subject would lead me to say that the time has not yet come for a sweeping change to be made in the treatment of uncomplicated gastric ulcer except in the way of more rigid and more prolonged medical treatment, but that when the ulcers prove intractable, or when complications supervene, medical should give place to surgical treatment at a much earlier stage than has hitherto been the custom. It is unfair to the surgeon to hand over to him moribund patients, as is at present so often done, and it is, in my mind, unjust to the patients to persist in dosing them with medicine or otherwise treating palliatively cases that can only be benefited or cured by surgical means."

Hemorrhage.—The frequency of hemorrhage as a symptom of gastric ulcer, either in the form of hematemesis, melena, or both, is variously estimated by different writers; some, as Mayo Robson¹⁰ and others, think it present in 80 per cent. of all cases. It may, of course, be arterial, venous, or capillary, and, as with hemorrhages elsewhere, either slowly or rapidly poured out, and in great or small quantity. Its treatment, as we shall see later on from an analysis of every accessible published case, and others reported to me in private communications for the first time, is quite in harmony with the principles underlying the treatment of external hemorrhage in most respects—but not all. There are, too, a sufficient number of cases on record to make conclusions based thereon reasonably reliable.

1. It would be highly injudicious, in my judgment, to subject a patient to laparotomy during the first hemorrhage, even if the surgeon should see the case then, as he rarely will. The treatment of such cases should be absolute rest to the stomach, with astringents, opium, and, possibly best of all, high enemata, as advised and practiced by Tripier.¹¹ Here the treatment is entirely different from that of external hemorrhage: Dienlaffoy,¹² so far as I know, being the only one to advise operation during the first hemorrhage if so much as half a liter of blood is lost.

2. The surgeon has been called in to see a case that has had one severe hemorrhage, but which has probably ceased, and the patient is successfully rallying from shock. Here, too, I take it, "a masterly inactivity" on the part of the surgeon will yield the best results.

Only 8 per cent. of those who bleed die; now, if we knew what per cent. of this number die in or from the first hemorrhage, non-intervention would doubtless seem imperative. The free use of normal salt solution and other approved methods for combating shock should be the only thought of the surgeon at this time. A similar course is often pursued in external hemorrhage, dependence being placed on a firm clot which forms in the mouth of the bleeding vessel, usually preventing subsequent hemorrhage. Certainly a line of practice followed and justified in external hemorrhage is more than allowable here, as a serious operation—one with a mortality *per se*—must be performed if inaction is not to govern.

3. A case has bled freely once, recovers, and in a few days bleeds seriously again. What should be the treatment?

Inaction may be justified even in the face of a second hemorrhage, and if I mistake not, the majority of those who have written upon the subject rather lean to, if they do not positively advise, this course.

I can not, however, do so, unless it be to await reaction and not operate in great shock. A careful study of my tables, in which there are tabulated 40 cases, will convince the hesitating that too great delay after the second hemorrhage is hazardous. Elder's patient was lost by a too long delayed operation, so Armstrong,¹³ who saw the case, had reason to think, and the patients of Tubby and Michaux would in all probability have recovered if they had been operated on after the second hemorrhage.

Per contra, we have quite a number of successful operations after the second hemorrhage, as the cases of Armstrong, Andrews, and Hirsch, all operated upon in a condition of extreme anemia, and the cases of Cazin, Robson and Roux operated on after each had sustained three severe hemorrhages. It will, therefore, be seen that the conclusions drawn by Mr. Mayo Robson from his tables reporting a smaller number of cases are misleading. In the first place that distinguished surgeon has included in his tables 3 cases of Petersen's operated for vicarious menstruation, and 2 cases of Reichard for post-operative hematemesis. Such cases must be thrown out. In the second place, as Mr. Robson intimates, some of Hartman's 12 cases—all I think—are reported twice. These early cases happened to be in a majority of instances fatal, and counting them twice in estimating the mortality from surgical intervention, would naturally make it seem out of the question.

In the third place, I have in my tables several successful operations for acute hemorrhage, not reported by Mr. Robson at all. So that instead of the prohibitive mortality of 64.2 per cent. as given by Mr. Robson's tables for operations in acute hemorrhage, we find it 37.5—32 acute cases with 12 deaths—when all reported cases of hemorrhage from gastric ulcer only are considered.¹⁹

This is a heavy mortality, but certainly not a prohibitory one when all things are considered. In the first place, the cases of hemorrhage operated on thus far have been extreme ones, and only turned over to the surgeon when death seemed inevitable without surgical intervention. This is true of every new operation; as it must demonstrate its *raison d'être* by saving cases admittedly hopeless without it.

Consider the history of operations for perforated ulcer, how they have grown better within the last year, week by week, almost day by day, until the mortality is now certainly not more than one-third of what it was a few years ago.

The conditions are alike up to a certain point, for it is frequently the case that the hemorrhagic and non-perforating ulcer of to-day may in a short time become a perforating one. This is one of the strongest reasons for intervening in hemorrhage, for it has been shown that operations for hemorrhage—even those less radical than partial gastrectomy and excision—have cured the ulcer and therefore prevented subsequent perforation; the only exception thus far reported being a case of Mayo Robson, in which he practiced curettage of the ulcer with application of pure carbolic acid; perforation followed on the eighth day.

Encouraging as have been the results of operation for acute hemorrhage, a great deal more can be said of the results thus far attained in frequently repeated small hemorrhages, which slowly, but none the less surely, lead to anemia, exhaustion and death. An analysis of

all cases thus far operated on give a mortality of 16.1 per cent., there having been 31 operations, with 5 deaths.

Methods.—The following operative measures have been carried out in treating gastric hemorrhage:

1. Partial gastrectomy: pylorotomy, according to location of ulcer.
2. Gastroenterostomy.
3. Gastrotomy.
4. Excision.
5. Excision of ulcer with ligation of artery.
6. Ligation en masse of mucous membrane.
7. Suture of ulcer.
8. Cauterization.
9. Pyloroplasty.
10. Gastrorrhaphy.
11. Ligation of principal artery.
12. Curettage of ulcer with and without cauterization.

Pylorotomy.—As in non-perforating ulcer without hemorrhage, pylorotomy, if at the pylorus, or partial gastrectomy in ulcers situated elsewhere, is the ideal operation in hemorrhagic cases. The presence of hemorrhage and probability of perforation in such cases are two additional and cogent reasons for a complete operation if conditions are favorable. If the ulcer is situated either at the pylorus, or upon the anterior gastric wall, and is reasonably free from adhesions, it should be removed. One is justified in undertaking a radical operation, even in the face of moderate adhesions, on account of the actual danger from hemorrhage and the probability of subsequent perforation. Of the 10 cases thus treated, 8 recovered promptly, giving a mortality of 20 per cent.

Gastroenterostomy.—Up to the present, this has been the most generally practiced operation for open ulcer, and judging from the opinions expressed in a large number of personal communications received from representative American and foreign surgeons, it is likely to remain so for a time. It has also been carried out in a greater number of hemorrhagic cases than any other procedure. Questionable as its choice may be in certain well-selected hemorrhagic and non-hemorrhagic cases, there are many reasons why it is likely to retain its popularity as the preferable method in a majority of instances of bleeding ulcer.

1. One can never be certain that the case in hand is not one of multiple ulcers, as we may expect several ulcerated points once in every five cases—perhaps more frequently. In any case where multiple ulcers are suspected, gastroenterostomy should be selected; putting, as it does, the stomach at rest and thereby leading to the formation of a firm clot in the bleeding vessel, and to the subsequent healing of all the ulcers.

2. It has been found in many cases to be a somewhat difficult procedure to locate the bleeding even after gastrotomy has been done and the entire mucous membrane carefully inspected—with and without the aid of a suitable electric light—and in at least 7 instances it has been altogether impossible to discover the open vessel. This is what might be expected, when we remember that it is at times impossible to locate the bleeding point at autopsy. M. Savariaud¹⁵ records in his very complete and valuable thesis, reports of 55 autopsies following sudden death from gastric hemorrhage, and in 4 of them it was impossible, after the most careful examination, to locate the source of the hemorrhage. The cases operated on have, on account of the delay occasioned by looking for, and inability to find, the bleeding vessel, usually been fatal.

Such failures are less frequent now than formerly, it is true, and will be still rarer with improved technique and a better understanding of *how* and *where* to look for a probable ulcer; but it is altogether unlikely that the possibility of failure to locate the bleeding point—even after the stomach is opened—can be entirely eliminated. Therefore, gastroenterostomy, which cures the hemorrhage by an entirely different principle, would be better in such cases, and the opening made in the stomach-wall in performing gastrotomy can be utilized in doing the subsequent gastroenterostomy.

Of gastroenterostomies for hemorrhage, there have been thus far, 13 cases, with 3 deaths, or 23.07 per cent.

Excision of ulcer with ligation of the principal artery has been done once, and then successfully, by Roux, of Lausanne. Suture of the bleeding ulcer with catgut has been practiced in 5 cases, with 2 deaths, or a mortality of 40 per cent.

Ligation.—Treatment of the ulcer by ligation of the mucous membrane en masse has been practiced three times, once by Cazin and twice by Andrews. All were successful. Andrews draws all of the coats of the stomach forward, so as to make a decided cone, and then ligates. Andrews and Eisendrath¹⁶ afterward experimented on dogs, and found this practice dangerous on account of too great sloughing, unless there was careful

Arterial blood-supply of the interior of stomach. (Original.) The arteries were well injected with plaster, the stomach removed and tacked upon a board and photographed. As soon as the mucous membrane became dry, the vessels in the submucosa were prominent. C. A. Coronary artery; G. E. D. Gastroepiploica dextra; C. Cardia; A. W. Anterior wall; G. E. S. Gastroepiploica sinistra; G. C. Greater curvature; P. W. Posterior wall; P. Pylorus; L. C. Lesser curvature.

mortality, not a bad showing when it is remembered that it was done after other methods had failed in several instances. In small but frequently repeated hemorrhages the operation finds its best field. In 12 cases of this kind its mortality has been nil—a most encouraging showing, and one which should lead to more frequent operation in cases of this kind.

Gastrotomy, or simply cutting into the stomach, can not control hemorrhage, and is only done as a preliminary to something else, as excision of the ulcer, suture, ligation en masse, etc. In the 7 cases in which it and nothing else was done because the bleeding could not be located, 6 died, or a mortality of 85.7 per cent.

Excision of the ulcer has been done three times, with two recoveries and one death.

extrinsic suturing of the stomach-wall at the same time. They therefore advise the placing of Lembert's sutures on the outside of the stomach over the ligated portion. Time is lost in doing this, and it may be just as well to make a less decided cone before ligating.

For all practical purposes, we may say that methods 4, 5, 6 and 7 are essentially the same and involve like principles; so combining all such cases we have eleven operations reported, with three deaths, or a mortality of 27.2 per cent.

Simple Gastrotomy with Cauterization.—This has been practiced but once, and then successfully. The cautery has been used in a number of other cases, but the wound in the stomach has been closed by a gastroenterostomy, as in Küster's two successful cases, and as in,

pyloroplasty in three successful cases operated by Armstrong.

Pyloroplasty.—Though a rival of gastroenterostomy—declining in favor, it is true, but still a rival in the treatment of open ulcers and the stenosis following them—pyloroplasty can in no sense be considered as rational an operation for hemorrhage. There have been 11 pyloroplasties, with 3 deaths, giving a mortality of 27.2 per cent. It should be noted, however, that three of the successful cases were cauterized with the thermocautery, and the good result was probably more due to this than the subsequent pyloroplasty.

Gastrorrhaphy has even less to recommend it than pyloroplasty, and has been followed by death in two of the three cases in which it has been practiced—mortality 66.6 per cent.

Curettage, either with or without cauterization, would seem, a priori, to be unsafe on account of the danger of subsequent perforation. This actually happened on the eighth day after operation in the only case thus treated—Mayo Robson's.¹⁰

Ligation of the Principal Arteries.—If, as we have seen, the bleeding vessel and ulcer can not always be found, even after the stomach is opened, how can it be possible to locate it beforehand? Until the source of the hemorrhage is known one could scarcely tell which vessel to ligate, and at best it would be nothing more than a guess based upon probabilities anatomic and pathologic. We know, of course, that hemorrhage from the coronary and splenic arteries occurs more frequently than it does from other vessels, but the first is difficult to tie, and the second, which bleeds three times as often, is so situated as to be, under the circumstances, almost inaccessible. It has, however, been tied once by Korte,¹⁷ though unsuccessfully. Savariaud¹⁷ has found it both practicable and safe in dogs, and therefore advises it in man, describing how it should be done.

Overlooking, for the present, the impossibility already pointed out, of knowing definitely the source of the hemorrhage and, the additional objection to ligation on account of its difficulty, I should still be opposed to ligation in continuity upon general principles. The anastomoses of the blood-vessels of the stomach are so free that a recurrence of the bleeding from the distal end of the affected vessel would be probable, if not certain. Roux's plan of ligating both ends of the bleeding vessel would be the only safe procedure.

It will here be interesting to give the result of 55 autopsies collected from various sources, and reported by Savariaud.¹⁷ None were operative cases.

Ulcerations of the splenic artery 17	cases.
Ulcerations of the coronary artery 6	"
Ulcerations of the pancreatico-duodenal 7	"
Ulcerations of the gastric arterioles 10	"
Branches of the coronary vein 2	"
Other veins 2	"
Vessel not determined 2	"
No vascular orifice visible 4	"
Vessel not mentioned 4	"

As the pancreatico-duodenalis would be opened in duodenal ulcers, which will frequently be mistaken for gastric lesions and should anyhow be treated in the same general way—as by excision and gastroenterostomy—we may as well include them as is done above.

The splenic artery and vein have both been opened by the same ulcer—Gaillard's case.¹⁷

Contrary to what would be expected, it will be seen from the tables below that there is no constant relation between the amount of the hemorrhage, size of the

vessel opened, and the rapidity with which death ensues. Death may be delayed many days after the aorta or heart are opened, and sudden from capillary hemorrhage. It is then impossible to diagnose the source of the hemorrhage from its amount, or the rapidity with which blood is lost. In a case where the aorta was opened at the duodeno-jejunal angle hemorrhages lasted ten days, notwithstanding the fact that there was an opening into it as large as a haricot bean—Grünfeld.

In Oser's perforation of the heart itself hemorrhages continued for three days before ending in death.

Savariaud's table gives:

Vessel.	No. of cases.	Sudden death.	Rapid death.	Survived considerable time.
Heart 4	1	1	2 (3 days.)
Aorta 2	1	1	1 (10 days.)
Hepatic 2	1	1	1 (10 days.)
Splenic 17	3	7	7 (2 to 8 days.)
Coronary 6	1	3	2
Pancreatico-				
duodenal 6	1	3	2 (8 to 15 days.)
Arterioles 10	1	1	8 (4 to 15 days.)
Small veins 4	1	1	2 (7 to 11 days.)
Invisible veins 3	2	1	2 (21 days.)

Ligation of the bleeding vessel in situ which theoretically looks simple enough, has been attempted in several cases with failure to arrest the hemorrhage in every instance. The mucous membrane is so friable, tears so easily, and bleeds so freely that hemorrhage is more likely to be increased, rather than lessened by an attempt to tie the open vessel, as is done in external hemorrhage with firmer and different kind of tissues to deal with.

DISCUSSION.

DR. FENTON B. TURCK, Chicago—The indication for surgical procedures in gastric disturbances of various kinds, is now attracting the attention of surgeons throughout the world, not only because of the possibilities of removing the lesion for which the surgeon may operate, but because of the general improvement in the patient, and the restoration of the patient to health as a result. The indications in pyloric obstruction are so well understood that it is unnecessary for me to repeat them. There seems to be considerable doubt in regard to those benign conditions of pyloric obstruction in which we have spasmodic contractions of the pylorus without apparently any tumor. It is in this class of cases that our worst symptoms occur, as they seem to be more marked, owing to the irritation and the apparent stenosis which accompanies spasmodic contraction of the pylorus. As you all know, these conditions as a rule are attributed to lesions located in the region of the pylorus and the indication for surgical procedure is that of gastric myasthenia. It would seem that such a procedure would be unnecessary, as we ought to be able to restore the muscle walls to renewed functional activity, but we know that we usually fail in all medical means, and relapses continually occur. Frequently we have hyperchlorhydria with this condition and considerable general symptoms of auto-intoxication with associated hypertrophy of the gastric glands. This is

caused by the infection of the walls of the stomach due to the mucus accumulation, and as a result we have decomposition and toxin from the micro-organisms present. It will be found that the same toxic condition is present in pyloric obstruction. What occurs in many cases is atrophy of the glands themselves, and I have seen two operations performed on such cases with remarkable success. The indications for operation are: 1, local lesions, and 2, general condition of the patient. Before we can arrive at a knowledge of the indications for operation we must be more exact in our examination and diagnosis. Simply because a patient has dyspeptic symptoms would be no excuse for stating that the patient must be operated on. The methods of determining whether or nor the pylorus is obstructed, are important. In most cases we are able to pass an instrument through the pylorus into the duodenum and in such cases no operation is indicated, as in cases of obstruction demanding operation no instrument could possibly pass. Recently a surgeon made an exploratory incision into the abdomen and subsequently found by blood examination that the case was one of leukemia. The heart and circulation should be considered in all of these cases and any disturbances should be corrected before operation, as all operations on the stomach cause much shock. Patients frequently die from auto-intoxication, which is often present in these cases, and should be diagnosed before operation. Although albumin may not be present, insufficiency of the kidney frequently exists, and in such cases the patients sometimes die on the fourth or fifth day after operation.

The success of the operation depends on the technique, the dexterity of the operator, and the rapidity of the operation. These are all important, but a serious question in opening the stomach is that of infection. We are now able to close the field of operation entirely with rubber dam, and if a portion of the stomach is drawn through the rubber dam the peritoneal cavity will be completely closed off.

In operations such as gastroenterostomy, the shock produced by the handling of the viscera is important. Since the operation of Woller in 1881 down to the present time, surgeons everywhere have been endeavoring to find some method with which they could do the operation with greater facility and procure better results. We find many surgeons of the present day using the Murphy button in order to accomplish these objects, but a number have attempted to discard its use, especially surgeons abroad, their objection being not so much to the button itself as to the fact that it is a foreign body. For this reason some suture is generally preferred, and it is my experience in experimental work on dogs that by rapid suturing I am able to do the operation in a very short time, the dexterity of the operator having much to do with this matter. As to the choice of operation I do not believe the posterior method will ever become popular. Tearing through the omentum and pulling on the tissues produces considerable shock. Gastroduodenostomy, in select cases, will continue to be a popular operation, as we do not have so much regurgitation from the stomach in these cases; in addition, less handling is necessary. In experimental work many different methods have been employed, and I have used them all. But gastroduodenostomy has been the most successful. It is almost as easy to perform as Heinrich's operation, but this is for the operator to decide.

I have simply tried to present the more important facts in connection with the diagnosis of these conditions and the better care of the patient before, during, and after operation.

PATHOGENESIS OF ICTERUS.—Ammonia and the biliary salts seem to be the chief factors in the pathogenesis of grave icterus. This conclusion is announced by A. Bickel after comprehensive research on frogs, rats and rabbits. Intoxication from this source affects the nervous system and induces the icterus. His results suggest the necessity of suppressing nitrogenized elements in the food of persons threatened with this affection.—*Sem. Méd.*, October 17.

THE DIAGNOSIS AND TREATMENT OF CHOLELITHIASIS.*

W. J. MEANS, A.M., M.D.

Professor Principles and Practice of Surgery, Ohio State University; Member Ohio State Medical Society, etc.
COLUMBUS, OHIO.

An early diagnosis of cholelithiasis is important for the welfare of the patient. When we consider the complications and sequelæ that may arise after prolonged irritation from the presence of gall-stones in the bladder or ducts, this becomes more apparent.

These complications may be septicæmia, ulceration of the gall-bladder and ducts, permitting the calculi to escape into the adjoining viscera, derangement of the liver from obstruction or abscess, cancer from irritation, obstruction of the pylorus, various nervous phenomena, and general debility. Unfortunately there are no pathognomonic symptoms in the early stages that serve to make a positive diagnosis.

From a careful study of 20 cases coming under my notice in the last few years, of which full clinical records are made, I have been able to make some deductions that may prove interesting and valuable to the profession.

My records show quite a number of other cases in which the bile apparatus was affected, but the symptoms were not sufficiently clear to make a diagnosis of gall-stones. These have been excluded, and only those cases reported that I was reasonably certain were cholelithiasis. A study of those not reported in comparison with those of gall-stones would, no doubt, develop some valuable data.

Of the 20 cases diagnosed cholelithiasis, 10 were operated on, and the diagnosis confirmed in 9. The exception was an obstruction of the common duct due to cholangitis.

Of the 10 unoperated cases 3 died, and post-mortems confirmed the diagnosis. Of the other 7 that recovered, there can scarcely be any doubt of the correctness of the diagnosis. Gall-stones were found in the stools of 2 of them.

A summary of the subjective and objective symptoms, and the pathologic conditions will be sufficient for our purpose.

Of the 20 cases, 14 were female, and 6 male. The youngest was aged 26, and the oldest 65 years; the average age was 50. Seven gave the history of "liver trouble" in their ancestors. A permanent biliary fistula followed in one case. This occurred where the gall-stones had passed through the fundus of the bladder. In 7 the fistula closed in four weeks to six months. In the other 2 the opening in the gall-bladder was closed after the removal of the calculi.

The number of the calculi ranged from a single one to two hundred and thirty. In the case where only one existed, the bladder had been largely dilated, and the calculus was found in the folds. Twelve hours before the operation the bladder was distended to the size of a quart cup, but later the tumor disappeared. The stone was three-fourths of an inch in diameter, round and had no facets. It evidently acted as a ball valve in the common duct. The cystic duct was dilated to a large diameter. The patient gave a history of previous attacks similar to the one for which he was operated on. The attacks were followed by jaundice.

The gall-bladder was contracted in 3. In 4 the calculi were found in the bladder alone. In 3 they had

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

lodged in the cystic duct, and in one in the common duct.

In the case where no gall-stones were found, there was obstruction of the common duct, and the bladder contained about a quart of semi-purulent fluid.

There was evidence of cholecystitis in 7 of the operated cases, and thickening of the ducts in 7, indicating more or less cholangitis. The gall-stones were found in the gall-bladder and ducts with one exception; in this case they had passed through the fundus of the bladder and lodged in the right inguinal region, where they were encysted. In one case the gall-bladder was displaced downward, and attached to the cecum. In 6 cases there were adhesions to the parietal peritoneum or surrounding viscera.

Of the three cases that died without operation, post-mortems developed gall-stones in all, with carcinoma in one; in one the liver was enormously hypertrophied; and in one there was obstruction of the duodenum, with a necrotic condition of the common duct and surrounding tissues.

Of the 20 cases, all gave a history of recurrent attacks of colic, except 4. All suffered more or less from gastric disturbances. There was a history of typhoid fever in 4, with symptoms of trouble in the region of the gall-bladder, following. Fever was a more or less constant symptom in all the cases, during the attacks. Rigors, at the onset, occurred in 15, and were periodical in 5. Nausea and vomiting were noted in 15. Emaciation existed in 2 of the operated cases, and in the unoperated ones that died.

Jaundice was present in 13. It was constant in the 3 cases that died, and in the 2 operated cases where there was obstruction of the common duct. Jaundice followed the biliary colic in twenty-four to thirty-six hours, and disappeared in ten days to five weeks. Pruritis was an annoying symptom in all of the recurrent jaundice cases.

Constipation was a prodromic symptom in 15; recurrent attacks of diarrhea in 5. Enlargement of the gall-bladder could be detected in 10. The liver was more or less enlarged in 8.

Tenderness in the upper right quadrant of the abdomen was found in all cases. In some the tenderness extended toward the region of the kidney; in others, down the ascending colon, and beyond the median line to the left. There was rigidity of the muscles on the right side of abdomen in several cases, similar to that found in appendicitis.

Pain was a characteristic symptom in all the cases. It varied from an uneasiness over the gall-bladder to lancinating pains extending to the right shoulder, requiring hypodermic injections of morphin to control them. Local peritonitis was a marked symptom in 8 cases. Of the 20 cases ashy-colored stools were found in 15. Biliary calculi were found in the stools of 4. The urine was high colored in all the cases, with bile present in varying quantities.

There were prodromic symptoms in all the cases, extending over a period of several months to several years. The more marked of these symptoms were constipation, flatulency, erratic appetite, migraine, uneasy sensation in epigastrium and right hypochondriac region, sallowness of skin, slight yellowness of the sclera, and at times scanty and high-colored urine.

At this place the writer wishes to emphasize the importance of an early appreciation of the prodromic symptoms just mentioned. While they may not be sufficiently pronounced to warrant a diagnosis of gall-stones,

yet they are suggestive of a disease of the bile apparatus, and early and proper treatment may be followed by permanent relief.

It is evident from this summary that the general diagnostic symptoms of gall-stones may be primarily, pain, nausea, vomiting, jaundice, ashy-colored stools, high-colored urine, tenderness over the region of the liver, tumor, and nervous phenomena. When these symptoms are considered separately, they do not have much significance pointing to cholelithiasis. They are found in other diseases of the biliary apparatus and surrounding viscera. It is, therefore, necessary to consider them both separately and collectively.

Pain may be produced by cholangitis, by the passage of inspissated mucus, local inflammation of surrounding tissues or a gall-stone. In the latter the pain is usually quite severe, comes on suddenly, and terminates quickly. It is usually along the line of the cartilaginous border of the ribs on the right side, and may extend upward over the right thorax to the shoulder. The pain sometimes extend to the stomach, producing severe gastralgia. It comes on usually two or three hours after eating.

Nausea and vomiting are almost constant symptoms, and continue throughout the attacks. In this particular the gastric disturbances differ from those in appendicitis. Nausea and vomiting are more severe when the obstruction is in the common duct. Jaundice as a diagnostic symptom must be carefully considered. When it makes its appearance in a day or two after an attack of colic, and reaches its maximum intensity in a few days, and then gradually decreases, it points strongly to temporary obstruction of the common duct.

A difference must be made between hepatogenous and hematogenous jaundice. The former is due to some trouble with the ducts, causing back pressure of the liver, thus controlling its function. Hematogenous jaundice is due to other causes, such as absorption of toxins, and other foreign products; it comes on gradually, is usually chronic, and marked by absence of pain. Hepatogenous jaundice may be produced by a tumor of adjacent viscera, pressing against the common duct. When it is due to cholangitis, it comes on suddenly, with paroxysmal pain, pruritus, and usually occurs in young subjects. Recurrent attacks are not likely to follow. When due to foreign bodies within the duct, we have to differentiate between inspissated mucus, and gall-stones. When due to gall-stones, there have been prodromic symptoms. The tendency to intermission and remission of the attacks of colic followed by jaundice, in a person who is beyond 35, are perhaps the most distinguishing features.

Murphy, of Chicago, claims that jaundice induced by cholangitis will disappear under the use of hypodermic injections of 1/60 grain pilocarpin, three times daily, while it will have no effect on jaundice induced by gall-stones, or other mechanical obstructions.

That jaundice is not a constant symptom of gall-stones is evidenced by the fact that in post-mortem gall-stones are frequently found where there had been an absence of marked symptoms pointing to their presence during the sickness of the person. Then, again, surgery has demonstrated the same fact on the living. The writer believes that a careful study of the clinical history of such cases would develop symptoms pointing to a disease of the biliary apparatus. In 10 cases operated on by the writer, jaundice was present in 7, and in 2 of these it was permanent. In three of the cases where jaundice was a symptom, it could not have been

due to the passage of gall-stones through the common duct. The calculi were found in the cystic duct, and judging from their size and number none others could have escaped. In these cases the jaundice evidently was produced by cholangitis. It is fair, however, to assume that the acute inflammation was caused by the presence of the calculi.

The urine is always high colored in any form of biliary trouble, therefore it is not particularly diagnostic of cholelithiasis. Tenderness over the gall-bladder is a constant symptom in cholelithiasis, as well as cholecystitis, and cholangitis; and therefore is only symptomatic of disease of these organs and not alone of gall-stones.

A tumor in the region of the gall-bladder is a significant symptom. It is necessary to differentiate from a tumor of the kidney, or a floating kidney. In tumors of the kidney, the overlying tissues are pushed forward, carrying the hepatic flexure of the colon to the front. Percussion, therefore, elicits resonance. If the tumor is an enlarged gall-bladder, the percussion sounds will be dull. A floating kidney, having no fixed position, is easily displaced. A tumor of the gall-bladder is pear-shaped, and extends toward the umbilicus. When quite large it may be mistaken for a cystic tumor of one of the viscera. Enlargement of the liver is a condition that follows in a large percentage of cases, especially where there is obstruction of the common duct.

In making a diagnosis of cholelithiasis, it is important to remember that gall-stones never occur in the first decade of life, rarely in the second, infrequently in the third, and occur more frequently in advanced life; and also that they occur more frequently in women than men. The only pathognomonic symptom is the discovery of gall-stones in the feces; this, unfortunately, does not occur in very many cases.

A summary of the symptoms shows a paucity of characteristic ones. However, with the presence of gastric disturbances, paroxysmal pains in the region of the gall-bladder, tenderness in the right hypochondriac, jaundice with pruritus, ashy-colored stools, highly-colored urine with the presence of bile, enlargement of the liver, age of the patient beyond 30, with sedentary habits, a diagnosis of cholelithiasis can be made with a great deal of certainty.

The treatment of cholelithiasis resolves itself into medicinal and operative. Medicinal treatment includes preventive as well as curative. While we are unable to determine when gall-stones have formed, enough is known of the predisposing causes to recognize the value of increasing the watery constituent of the bile, thus rendering the flow more rapid. To accomplish this, proper exercise, with calomel, saline cathartics, mineral water drinks, and restricted diet should be prescribed. After gall-stones have formed, the value of treatment by internal medication is problematical. Of the 7 cases reported as recovering without operation, there arise two questions: one, as to the correctness of the diagnosis; and the other, as to the permanency of the treatment. They were treated with large doses of olive-oil, Karlsbad salts, phosphate of soda, and calomel. In 3 of the cases that have been under my observation, something over two years have elapsed since the last attack, and from all indications, they are quite well. I am not able to give any data of the other 4. It might be stated that the cases operated on had been subjected to medicinal treatment without any apparent benefit.

While these clinical observations seem to indicate the possibility of relief through internal medication, the mortality attending this form of treatment compared

with the results of the operative treatment, and the fact that 10 cases received no benefit from the same medicines, speak most favorably for the latter method. To cure without an operation is the ideal method. It saves the inconvenience, danger, and terrors of an anesthetic; resulting adhesions often cause disagreeable conditions, and a biliary fistula that continues sometimes for an indefinite period. On the other hand, the operation is practically free from danger. The gall-bladder and ducts can be cleaned of calculi and then drained, thus relieving the liver of pressure and giving it an opportunity of resuming its normal function. The same may be said for the restoration of obstructed ducts from cholangitis. After the removal of the irritating foreign bodies, the inflammation subsides, and in many cases the function of the ducts is restored.

My experience leads me to believe that every case should be operated on that presents a train of symptoms indicating trouble in the bile apparatus, that can not be relieved by a course of medicine along the line indicated. It is my judgment also, based on personal observation, and from the recorded experience of others, that early operative procedure will reduce the mortality of cholelithiasis as much as early operations have reduced the mortality in appendicitis. Procrastination may lead to complications, making an operation quite difficult and dangerous, if not impossible.

The preparation for the operation should be the same as for other abdominal work. An incision should be made, beginning $\frac{1}{2}$ inch below the eighth costal cartilage, along free border of rectus muscle, to a point 2 inches above the umbilicus. If it is necessary to enlarge the incision, it can be done by extending both ends, making the incision somewhat the shape of the letter S, as suggested by Dr. Bevan, of Chicago. In this way the incision does not interfere with the eighth and tenth intercostal nerves. When the abdominal cavity is reached, in uncomplicated cases the gall-bladder, if enlarged, may appear in the incision. If it is contracted, and there is enlargement of the liver, some manipulation may be required to bring the bladder into view. The gall-bladder should then be carefully examined, to determine the presence or absence of calculi. It is well to examine the ducts to ascertain if there is a stone impacted in either of them. The next step is to aspirate the gall-bladder, if distended with bile. This precaution is necessary to prevent an escape of the contents into the abdominal cavity. It has been demonstrated that the escape of normal bile into the peritoneal cavity does not necessarily produce peritonitis; but it is not possible to determine the character of the contained fluid. It may be septic, so it is safer to prevent the escape of the fluid into the cavity. This can be done by packing with gauze pads, leaving nothing exposed but the bladder. In some cases this precaution should be taken before aspirating. An incision is then made into the cyst of sufficient size to remove the stones. A spoon curette is the best instrument for their removal. When the stones have been removed and the duct carefully examined and found free, the incised wall of the bladder is united by interrupted sutures, placed not more than $\frac{1}{4}$ inch apart, to the parietal peritoneum and aponeurosis of the muscle. A large rubber drainage-tube, with no side openings, is then placed in the gall-bladder and allowed to extend beyond the external opening $\frac{1}{2}$ inch. The incision is then closed, leaving the tube in place. The drainage of bile, amounting to some 40 ounces in twenty-four hours, will necessitate a change of dressings at frequent intervals.

Calculi should be examined as to their shape, size, formation and number of facets, the latter indicating the presence of others. As a rule where there are a number, they are triangular in shape; if only a few are present they may be oval. An oval-shaped stone with one facet at the end indicates the presence of another, which probably will be found in the cystic duct. The number of stones vary from a single one to several hundred. When there are a great number they are usually quite small.

Some operators suggest the closure of the incision in the gall-bladder, without drainage. Where the conditions are favorable, this is, perhaps, an ideal operation; but unless the operator is perfectly certain that no obstruction of the ducts exists, it should not be done. The writer did this in two cases, and the result was satisfactory. The clinical history and the absence of any thickening led him to believe that the ducts were patent.

It is often very difficult to determine whether the ducts are open or not. Exploring the ducts with a probe is both difficult and dangerous. The safer method is to drain. The fistula closes up in a few weeks, and the patient gets entirely well. The restoration of the normal function of the bile apparatus after cholecystectomy is an interesting subject. There is ample clinical evidence that the bile apparatus may resume its normal condition in a few weeks after an operation. Enforced rest during the period the bile is escaping through the fistula is, perhaps, an important factor in this restoration.

The removal of a stone from the cystic duct is a more delicate operation. The duct is about $1\frac{1}{2}$ inches long, and the wall is thin and easily torn. When it is impossible to remove an impacted stone through the bladder it becomes necessary to crush the stone and remove it by piece-meal. The incision should be closed with Lembert sutures.

The removal of a stone from the common duct, which is about twice the length of the cystic duct, is not only an operation of great difficulty, but is dangerous and requires all the skill of the surgeon who is experienced in abdominal work. The technic of this operation differs only in degree from that of removing a stone from the cystic duct. The greater difficulties lie in the dislocation of the common duct.

CHOLECYSTECTOMY.

WITH ESPECIAL REFERENCE TO THE REMOVAL OF THE MUCOUS MEMBRANE OF THE GALL-BLADDER AS A SUBSTITUTE. REPORT OF A CASE IN WHICH THE GALL-BLADDER WAS REMOVED FOR MALIGNANT DISEASE.*

W. J. MAYO, M.D.
ROCHESTER, MINN.

Excision of the gall-bladder is clearly indicated in four groups of cases: 1, for traumatism, such as gunshot wounds or crushing injuries; 2, phlegmonous cholecystitis and gangrene of the gall-bladder; 3, for malignant disease. In these three groups all of the coats of the gall-bladder are involved in the diseased process or injury and complete cholecystectomy is a logical sequence. 4, for the relief of permanent obstruction of the cystic duct, the common duct being patent. In this last group only the mucous membrane is at fault; if this were not present there would be nothing

to drain and obliteration of the cystic duct would be harmless. It is this class of cases in which removal of the mucous membrane of the gall-bladder offers a quick and safe method of relief. In the complete operation of cholecystectomy the close relation which exists between the gall-bladder and the liver, and the deep situation of the pedicle at the cystic duct introduces certain elements of danger which can not be ignored, and renders the operation in every way much more serious than simple removal of the mucous membrane. The latter procedure adds but little to the risks of an ordinary cholecystectomy.

Traumatism to the gall-bladder requiring its ablation are but rarely met with and are usually associated with grave injuries to the liver. A small number of cases have been reported and not infrequently the result of indirect violence. In the one case I have met with of this kind, free drainage enabled repair of the ruptured gall-bladder to take place without excision. In acute phlegmonous cholecystitis and gangrene of the gall-bladder two courses are open: to freely drain the gall-bladder and pack the surrounding space with gauze, or to remove at once the offending organ. The principles are essentially the same as the treatment of appendicular abscesses by drainage, leaving the appendix or to remove the appendix, if possible, at the primary operation.

In three cases of this character the writer has excised the gall-bladder and drained freely, the bleeding surface of the attached liver and the infected stump being covered with gauze held firmly in position by sutures of fine catgut. The stitches hold the gauze in place until adhesions form and the catgut is absorbed before removal of the drainage is indicated. In this manner sufficient pressure can be obtained to check the oozing and limit extravasation.

For malignant disease, the gall-bladder, with adjacent liver substance, has been removed on a number of occasions, either by cutting instruments, the Paquelin cautery or by the elastic ligature. Such a case was operated on by the author recently and on account of its rarity is reported somewhat in detail.

Mrs. E. R., American, aged 65, Byron, Minn., was admitted to St. Mary's Hospital, Rochester, Minn., April 18, 1900.

History.—She has been in her usual health until within the past six months. During this time she has suffered from a boring pain in the right side, which has of late become almost constant. Stomach symptoms have been of moderate severity. There has been some loss of appetite and constipation with a decrease of fifteen pounds in weight. No jaundice, nor history of colics. Examination reveals a somewhat movable tumor in the right hypochondriac region evidently connected with the liver. The mass has a nodular feel. Exploratory incision, April 21, 1900. A carcinomatous gall-bladder involved the adjacent portion of the liver and the cystic duct. There was some infiltration along the common duct and extending to the duodenum at one place was a considerable area of adhesions. A few glands in the angle between the cystic and hepatic ducts were infected. The disease was so definitely circumscribed with such slight glandular involvement that its removal was decided on. The excision was begun at the common duct, two inches of which was removed with one inch of the hepatic duct. The vessels were caught and tied as divided; an area of adherent duodenum the size of a silver dollar was included in the excision. The opening in the intestine was closed by circular purse-string sutures. The lower end being thus freed, the gall-bladder with the attached liver was removed with the Paquelin cautery knife. The larger vessels were grasped with forceps. The free venous oozing from the liver substance was not controlled by the cautery, although easily checked by slight pressure, the blood current being of little force. A piece

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

of sterile gauze, the size of the wrist, was placed in the cavity and a continuous suture of fine catgut was run through the liver substance on each side of and around the gauze, compressing the bleeding liver margins against it, and controlling the hemorrhage efficiently. The portal vein was exposed to a considerable extent in the bottom of the cavity. Adequate drainage was afforded, the bile being conducted to the surface. Recovery was uneventful. The gall-bladder contained a single stone $\frac{3}{4}$ inch in diameter.

The fourth class of cases in which a permanent obstruction exists in the cystic duct are far more numerous. The obstruction may be the result of adhesive inflammation in the outer coats, causing angulation, or the long lodgement of a stone in the cystic duct, with resulting ulceration and cicatrization or stricture from any cause.

Of 132 operations on the gall-bladder and bile ducts which have been made in St. Mary's Hospital, Rochester, Minn., during the past nine years, eleven were cholecystectomies, and seven of these were for the relief of obstruction in the cystic duct, causing mucous fistulæ or recurrent attacks of colic, due to retention of the secretions in the gall-bladder. The indication in these cases is clear. It is the continuous secretion from the mucous membrane prevented by the obstruction from draining through the natural channel, which causes the trouble, the peritoneal and muscular coats are harmless and by removing the mucous membrane down to the obstruction, relief is afforded. In my own experience, obstruction of the cystic duct is met with either primarily—cystic gall-bladder—or occurs secondarily after operation for gall-stone disease in about 10 per cent. of cases. It seems hardly necessary to say anything about technique. The mucous membrane of the gall-bladder is easily detached, and as all of the adhesions are to the peritoneal and muscular coats the separation is readily effected. The gall-bladder partly inverts itself as the cystic duct is approached, rendering easy the removal of an impacted stone. If it is small and deeply placed, removal of the mucous membrane is more difficult, but can be accomplished more readily than complete extirpation. One or two small vessels require ligation. The muscular and peritoneal coats are sutured to the upper angle of the wound in the abdominal wall and drainage established as in ordinary cholecystotomy. It is as a secondary operation that removal of the mucous membrane is most serviceable. Drainage has failed to cure and the adhesions formed by the previous union of gall-bladder to the external incision vastly increases the difficulty of complete extirpation. The operation in these cases is best accomplished as follows:

An incision is made into the abdominal cavity on the inner—median—side of the site of the former operation, but these external attachments of the gall-bladder are not severed. The adhesions are separated to a limited extent on the inner side to enable careful exploration of the ducts to be made. The adhesions in other directions are purposely left and act as a protection to the outer and lower portion of the operative field. After proper gauze protection, the gall-bladder is opened on the inner side in the explored area, about $1\frac{1}{2}$ inches down, and this incision is carried outward toward the external attachments. The separation of the mucous membrane is begun at the middle and the enucleation carried down to the cystic duct, where it is divided at the point of obstruction. The separation is then proceeded with from within outward until completed. The scar tissue at the place where the gall-bladder is attached to the abdominal wall renders detachment difficult if

commenced at that point, but by beginning well below the mucous membrane can be readily separated.

The muscular and peritoneal coats are drained in the usual manner, a piece of sterile gauze being tacked about the inner divided wall by a few catgut sutures, which renders the drainage quite perfect.

THE IMPORTANCE OF EARLY OPERATION IN GALL-STONES.*

MAURICE H. RICHARDSON, M.D.
BOSTON.

It is well established that there is no more valuable life and health conserving operation than the removal of an offending appendix in the period of health.

The analogy between the appendix and the gall-bladder is in many ways striking, but it is not perfect. The appendix always contains within itself elements of sepsis, which by their escape into the peritoneal cavity threaten life; the gall-bladder does not; its contents threaten life only when, after prolonged irritation, it has yielded to infections brought from more or less remote areas. The appendix often becomes completely infected without warning; the gall-bladder seldom does. The appendix often contains one or more fecal stones which, septic in themselves, cause ulceration of the mucous lining and give opportunity for direct infection from bacteria right at hand; the gall-bladder may also contain stones, but it is questionable whether they have within themselves bacteria capable of causing direct infections of bile or of gall-bladder. Their presence in the gall-bladder contributes to infection indirectly.

In a much smaller degree than the appendix, and less frequently, the gall-bladder becomes the seat of an extensive septic process. Yet occasionally the progress of infection is quite as fulminating and overwhelming as is the same process in the appendix. The analogy between the two organs is imperfect too as to anatomical structure, capacity and situation—attributes which influence unfavorably the progress of appendicular infections, but favorably those of the gall-bladder.

The acute infections of the gall-bladder, for instance, result in changes in the bile, distention of the gall-bladder walls, infections of these walls and a pericholecystitis. The distensibility of these walls, however, prevents, except in the rarest instances gangrenes and perforations.

Infections of the gall-bladder concern its contents more than its walls; sterile bile becomes a culture-medium of micro-organisms, which later involve the gall-bladder walls themselves. In appendicitis the contents, always septic, must invade the walls of the appendix to produce any lesion whatsoever—other than distention with septic fluids. Moreover, infections of the gall-bladder walls do not often cause gangrene, necrosis being rather the result of pressure from over-distention than from an infectious thrombophlebitis. In the occasional gangrene of thickened gall-bladders it is not improbable that necrosis is caused directly by infection of the thickened and poorly-nourished wall with thrombosis of its vessels and hemostasis. In such cases the course is not unlike that of the thickened appendix, the gangrenous process being quite as rapid and as fatal.

The situation of the gall-bladder, even when infected and inflamed, is one of comparative isolation. The

*Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

isolation makes general peritoneal infections difficult, for they rarely take place unless the gall-bladder wall gives way entirely and the abdomen is flooded with septic bile.

Infections of the appendix rarely cause remote changes—tuberculosis and carcinoma—gall-bladder lesions, on the contrary, frequently cause cancer.

Although the analogy between the gall-bladder and the appendix is imperfect, the brilliant results of operations on the appendix can not but stimulate renewed enthusiasm in the surgical treatment of the gall-bladder. In diseases of the appendix one is led by the disasters of the acute cases to forestall them whenever there is good reason to believe that the appendix is in the least degree diseased. I, for one, have been carried by abundant personal experience from the position of grave doubt, which I held up till 1893, as to the wisdom of the so-called interval operations in appendicitis, to one of confident enthusiasm at the present time. So great are the dangers of an acute appendicitis, as I have observed them, whether in the hands of ultra-conservatives, or in those of ultra-radicals, that the dangers of appendectomy in the period of health are not for a moment to be compared to them. I advise removal of the appendix even when the diagnosis is doubtful, believing that the suspicion of a chronic appendicitis justifies, if it does not demand, intervention. I have been brought to this belief not only by abundant experiences in the disasters of the appendix, as I have said, but by an uninterrupted series of some 300 consecutive successful appendectomies of my own.

The analogy between the gall-bladder and the appendix is very close in connection with operative dangers and favorable results. The neglected gall-bladder endangers life quite as surely, though not as rapidly, as the neglected appendix. Its immediate course may be less fulminating, but the agony is more prolonged and the sum total of suffering is greater.

The gall-stone of the affected gall-bladder bears a relation to the person of apparent good health similar to that which the connection in the appendix does; it threatens, if not life, health, and it means, if not immediate death, changes remote, far reaching and lethal.

The dangers of removing gall-stones by modern methods in the hands of skilful surgeons are truly estimated as trivial. It does not seem unreasonable to say that this danger is exceeded by the danger of the passage of a single stone from the gall-bladder to the duodenum—just as it may truly be said that the danger of a single attack of acute appendicitis vastly exceeds that of the intercurrent operation.

The proposition which I wish to prove may be laid down as follows: Gall-stones should be removed from the gall-bladder as soon as their presence is reasonably sure, unless the diseased condition of the other viscera makes the hazard of the operation greater than the hazard of the gall-stones themselves.

As proof of this proposition, which I think will receive the support of most if not all of the surgeons experienced in this lesion, I will present facts which have come under my own observation. If I bring forward arguments which to men especially skilled and experienced in gall-stone affections, seem trite, it must be remembered that this discussion is especially directed to the general practitioner who does not often have as good an opportunity as the consulting surgeon of seeing the remote and vicious changes brought about by prolonged gall-stone irritations.

The strongest arguments in favor of early operations are based on the pathological changes, immediate and remote, wrought by the gall-stones themselves.

These changes, which the surgeon has a better opportunity than the pathologist of observing, are seen in the gall-bladder, the cystic and the common duct, and the parts contiguous. They vary between the normal, non-adherent gall-bladder, and the thickened, contracted gall-bladder, buried among adhesions which glue together the viscera of the right upper quadrant—between a gall-bladder normally distended with bile and suspended gall-stones, and a thickened gall-bladder contracted upon large and irregular stones with ulcerated mucous membrane and infected secretions. The surgeon sees gall-bladders in every state of contraction and dilatation; with adhesions recent and easily separated, or old, cartilaginous, and inseparable; containing bile varying from normal to purulent and even to putrid; with a single gall-stone or with several hundred; in not a few instances malignancy beginning or fully developed. The cystic duct will often be found plugged by a stone, causing dilatation of the gall-bladder. The surgeon may find an acute cholecystitis, and dilatation even to bursting with purulent secretions; impacted gall-stones in the common duct, with enlarged liver and jaundice; cholemia and all its serious manifestations. In not a few cases the most fatal complications will have arisen before the surgeon has had a chance to attempt relief; rupture of the gall-bladder and general peritonitis, purpura, hemorrhage, exhaustion, and those other and rarer complications by which the history of gall-stones is ended. On the other hand, the family physician sees, it must be admitted, not a few patients who, after one or two attacks of gall-stones, remain permanently well—patients in whom none of these immediate or remote pathological changes are ever noted. Furthermore, the pathologist will often find the gall-bladder distended with gall-stones, which have never given the least sign of their presence.

The evidence from bacteriology shows that micro-organisms play an important rôle in the prognosis, at least of gall-stone affections. My own cases investigated in the laboratory of the Massachusetts General Hospital by my brother, Dr. Mark W. Richardson, go to show that the micro-organisms have an important influence in the causation of gall-stone lesions. In most cases of gall-stones accompanied by fever, bacteria have been found in the bile; in some the colon bacillus; in some the bacillus typhosus. In five cases my brother has been able to isolate the micro-organism from the center of the gall-stone.

As far as the evidence based on bacteriology goes, gall-stones, if not themselves dependent on micro-organisms, unmistakably promote infections, and often infections of the gravest character.

In communications before a body of representative surgeons, what is wanted, I take it, in the discussion of treatment, is the writer's opinion based on his own observations. This is the evidence after all which gives weight to opinions. My own views on the question of surgical intervention in gall-stones have been formed almost entirely from what I have done myself and from what I have seen others do; not that I have been uninfluenced by the experience of others. When that experience has been similar to my own, I have felt encouraged to further efforts; when it has been contrary, it has tended to make my steps more cautious. On the whole, the tendency has been toward the more radical

treatment of gall-stones at the time of their earliest manifestations.

I have observed that the earlier the operation, the less danger and the greater the success. The removal of gall-stones from a normal gall-bladder is without mortality. I can say, with Robson and others, that all my patients have recovered after the simple removal of gall-stones from a normal gall-bladder. The proportion of such cases, however, has not been as large as it should be, and as I hope it will be, for but few patients have come to operation until they have been forced to it by years of repeated attacks, or by the unbearable suffering of a permanent jaundice.

It must be admitted, as I have said before, that early operation on patients otherwise well has little if any mortality. A simple cholecystotomy in health is probably somewhat more dangerous than a simple appendectomy in health. The number of my cases of cholelithiasis is, however, too small, compared with those of appendicitis, for a comparison of value. Then, too, the greater average age at which patients are liable to gall-stones is alone a sufficient reason for greater mortality. Moreover, in gall-stone surgery success may be compromised by the giving away of a suture, by the pressure-ulceration of a drainage-tube, by extension of infection into the liver through the bile ducts. These facts can not but influence unfavorably the prognosis of early operation on the gall-bladder as compared with the interval operation in appendicitis. True, these dangers are, as far as my observation go, matters of theory rather than of experience; yet I should not expect a series of several hundred simple cholecystotomies, performed at the usual ages of patients with gall-stones, to be without some slight mortality.

Operations for the removal of gall-stones, even under unfavorable conditions, as those on cases of long standing, on patients with contracted gall-bladders, with ulcerated surfaces and infected secretions, with constitutional disturbances and systemic depression, present a mortality much lower than one would expect.

Operations on the cholemic are attended by a relatively high mortality. In this class of cases the operation has often to be performed on the common duct, where the dissection is broadest and deepest, and the patient's power of resistance feeblest. The significant and unfavorable factor, however, is the jaundice, and not the dissection; for an even larger percentage of deaths has followed simple exploration for malignant disease blocking the biliary passages than has followed simple operation for gall-stones in prolonged jaundice. Indeed, all my cholecystotomies have been successful. The fatal operations of this class have been cholecystotomies with removal of stones from the hepatic and cystic ducts through the gall-bladder. Considering the gravity of the acute infections of the gall-bladder, this class of cases has been most brilliant, for nearly all the patients have recovered after simple drainage.

The most impressive argument for early operation in biliary calculi lies in the suffering and death which so frequently attend delayed surgical treatment. Even when health is finally restored, it is only after prolonged suffering and illness. In many cases cure is attainable only after repeated, complicated and dangerous operations. My cases fatal after surgical operations number sixteen. In this list are included every case in which cure has been attempted. Besides these cases there have been six deaths following simple explorations in which nothing was accomplished beyond the demonstration of

inoperable malignant disease. There have been several deaths in cases seen too late for operation.

The successful operations number about a hundred. Of these only a small percentage can be classed as early, an early operation being understood to be one performed before secondary changes have taken place in or about the biliary tract, and before the patient's strength has been reduced by the suffering of many attacks of biliary colic. It is only when they are forced by unendurable pain, by jaundice, or by failing strength, that they come under the surgeon's observation. When brought to operation by frequent attacks of biliary colic, without jaundice or loss of strength, the conditions are usually extremely favorable, even if extensive changes are found in the gall-bladder. A large proportion of my cases of cholecystotomy have been of this class, and the results have been almost invariably good.

Little need be said of the successful operations. It is enough to say that they include almost all possible varieties of gall-bladder surgery for lesions dependent on gall-stones. All my operations on the common duct have been successful. One or two operations involving the cystic duct have been fatal. A few operations on old and contracted gall-bladders have been fatal. It is safe to say that the fatalities in these cases, as will be detailed later, were due to lesions of long standing, either biliary tracts themselves or in other important viscera.

Though much may be learned from the successful cases, it seems to me that more can be learned from the unsuccessful ones. No cases in my experience have impressed me so strongly with the necessity for early operations as the fatal ones. Perhaps to the fatal ones should be added those in which success was a matter of hope rather than of expectation—cases in which recovery eventually took place, though only after an operation of extreme difficulty, and a convalescence of great anxiety.

A word as to remote results following operation may not be out of place. A patient on whom I performed cholecystotomy—one of my earlier cases—died some years afterward from malignant disease of the liver. Such a result may, in the course of time follow some of my later cases. In not a few instances I have found associated with gall-stones malignant disease of the gall-bladder, pancreas, or liver. The frequent association of malignant disease with gall-stones furnishes a potent argument in favor of early operation. It is an argument also in favor of the removal of a thickened and contracted gall-bladder, though I have not removed many such gall-bladders. My fatal cases are as follows:

CASE 1.—A woman of 34, with a history of acute attacks of cholecystitis. There was marked jaundice; temperature 104; pulse 144. Under the liver were found nodules which apparently were cancerous, but which proved to be gall-stones in a contracted gall-bladder. The patient died within twenty-four hours of the operation.

CASE 2.—A man of 32, with a typical history of gall-stones lasting seventeen years. This patient died of pneumonia after the operation. His general condition was poor; he was leukemic.

CASE 3.—A woman of 78, on whom I felt obliged to operate for unendurable pain. She was deeply jaundiced. Though she bore the operation well, she died of exhaustion at the end of eight days.

CASE 4.—A woman of 62, who had suffered for seven years with gall-stone colic. She had typical symptoms of acute intestinal obstruction. Through a median incision below the umbilicus no obstruction was found. Her symptoms were due to an acute peritonitis of the right upper quadrant following

acute cholecystitis with extravasation of infected bile. The lesion was essentially fatal and the woman died.

CASE 5.—A woman of 34, deeply jaundiced for six weeks. This patient had a history of colic of ten years' duration. Eight or ten gall-stones of considerable size were removed by cholecystotomy. Though it was not necessary to apply a single ligature, the woman died within twenty-four hours of uncontrollable capillary hemorrhage involving the cut surfaces, and the whole surface of the peritoneum.

CASE 6.—In this case exploration was made for symptoms suggestive of cancer of the stomach. A number of large stools were found in the gall-bladder and were removed. The patient was doing well when suppression of urine occurred, and she died uremic.

CASE 7.—My first fatal case at the Massachusetts General Hospital followed the removal of stones from the cystic duct and common duct through the gall-bladder. This woman died of sepsis at the end of some six weeks.

CASE 8.—A woman of 64, with a history of gall-stones of three years' duration. Three gall-stones were removed. The gall-bladder was drained. The patient died three days later, without any apparent cause. Death was attributed to exhaustion, and was undoubtedly due to her enfeebled powers of resistance.

CASE 9.—This case was fulminating cholecystitis. The gall-bladder contained three quarts of septic-looking bile. Patient died at the end of twenty-four hours, a result fully expected from the operation, which was performed as a last resort. At the autopsy gall-stones were found impacted in the common duct and there was a purulent hepatitis.

CASE 10.—Woman of 55; ten stones were removed from the gall-bladder, two from the cystic duct, and one from the hepatic. This patient died without regaining consciousness.

CASE 11.—Man of 64, with a distended gall-bladder, following intermittent attacks of pain. The acute cholecystitis was found dependent on a single stone impacted in the common duct. This patient did well for a week, then began to fail, and finally died of exhaustion. It was supposed that the disease in this case was complicated with cancer, although it was not known.

CASE 12.—Mrs. R.; prolonged hemorrhage, apparently from a tumor of the gall-bladder wall.

CASE 13.—Woman of 50; symptoms of gastric cancer. The gall-bladder was found contracted on numerous stones. Stomach was healthy. The patient died of persistent vomiting, after some weeks. She had been much reduced by continuous vomiting before operation.

CASE 14.—A woman of advanced age, extremely jaundiced, and much reduced in strength by pain and malnutrition. This patient died of exhaustion a few days after operation.

Besides these, there were six deaths after simple exploration in which malignant disease of either gall-bladder, liver or pancreas was found. In all the fatal non-malignant cases the patients were suffering from the prolonged mechanical effects of gall-stones.
