All the early Beans are generally planted on warm borders, near walls, pales, and hedges; and those which are designed to come first, are usually planted in a single row pretty close to the fence: but here I cannot help taking notice of a very bad custom, which too generally prevails in gentlemen's kitchen-gardens, which is that of planting Beans close to the garden walls, on the best aspects, immediately before the fruit trees, which certainly is a greater prejudice to the trees, than the value of the Beans, or any other early crop, therefore this practice should be every where discouraged; for it is much better to run some Reed hedges across the quarters of the kitchen-garden, where early Beans and Pease may be planted, in which places they may with more conveniency be covered in severe frost; and to these hedges the Beans may be closely fastened, as they advance in their growth; which, if practised against their walls where good fruit trees are planted, will greatly prejudice them.

But to return to the culture of the Beans. Those which are planted early in *October*, will come up by the beginning or middle of *November*; and as soon as they are two inches above ground, the earth should be carefully drawn up with a hoe to their stems, and this must be two or three times repeated, as the Beans advance in height, which will protect their stems from the frost. If the winter should prove severe, it will be very proper to cover the Beans with Pease haulm, Fern, or some other light covering, which will secure them from the injury of frost; but this covering must be constantly taken off in mild weather, otherwise the Beans will draw up tall and weak, so come to little; and if the surface of the border is covered with tanners bark, it will prevent the frost from penetrating of the ground to the roots of the Beans, and be of great service to protect them from the injury which they might otherwise receive.

In the spring, when the Beans are advanced to be a foot high, they should be fastened up to the hedge with pack-thread, so as to draw them as close as possible; which will secure them from being injured by the morning frosts, which are often so severe in *April*, as to lay those Beans flat on the ground, which are not thus guarded; at this time all suckers which come out from the roots should be very carefully taken off, for these will retard the growth of the Bean, and prevent their coming early. When the blossoms begin to open toward the bottom of the stalks, the top of the stems should be pinched off, which will cause those first pods to stand, and thereby bring them forward. If these rules are observed, and the ground kept clean from weeds, or other plants, there will be little danger of their failing.

But lest this first crop should be destroyed by frost, it will be absolutely necessary to plant more about three weeks after the first, and so to repeat planting more every three weeks, or a month, till *February*; but those which are planted towards the end of *November*, or the beginning of *December*, may be planted on sloping banks, at a distance from the hedges; for if the weather should prove mild, these will not appear above ground before *Christmas*; therefore will not be in so much danger as the first and second planting, especially if the surface of the ground is covered with tan to keep the frost out of the ground. The same directions which are before given will be sufficient for the management of these, but only it must be observed, that the larger Beans should be planted at a greater distance than the small ones; as also, that those which are first planted must be put closer together, to allow for some miscarrying; therefore where a single row is planted, the Beans may be put two inches asunder, and those of the third and fourth planting may be allowed three inches; and when they are planted in rows across a bank, the rows should be three feet asunder; but the *Windsor* Beans should have a foot more space between the rows, and the Beans in the rows should be planted five or six inches asunder. This distance may, by some persons, be thought too great; but from many years experience, I can affirm, that the same space of ground will produce a greater quantity of Beans, when planted at this distance, than if double the quantity of seeds are put on it. In the management of these later crops of Beans, the principal care should be to keep them clear from weeds, and other plants, which would draw away their nourishment; to keep earthing them up, and, when they are in blossom, to pinch off their tops, which, if suffered to grow, will draw the nourishment from the lower blossoms, which will prevent the pods from setting, and so only the upper parts of the stems will be fruitful; and another thing should be observed in planting of the succeeding crops, which is, to make choice of moist strong land for the later crops, for if they are planted on dry ground, they rarely come to much, unless the summer proves wet.

These

These after crops should be planted at about a fortnight distance from *February* to the middle of *May*, after which time it is generally too late to plant, unless the land is very strong and moist; for in warm, dry, light land, all the late crops of Beans are generally attacked by the black insects, which cover all the upper part of their stems, and soon cause them to decay.

When the seeds of these Beans are designed to be sowed, a sufficient number of rows should be set apart for that purpose, according to the quantity desired; these should be managed in the same way as those which are designed for the table; but none of the Beans should be gathered, though there are some covetous persons, who will gather all the first ripe for the table, and are contented to save the after crop for seed, but these are never so large and fair as the first; so that if these are for sale, they will not bring near the price as the other, therefore what is gained to the table, is lost in the value of the seed; but those who are desirous to preserve the several varieties as pure as possible, should never suffer two of the varieties to grow for seeds in the same place, for by their farina mixing with each other, they will not continue so pure, but be apt to vary; but in order to keep the early kinds perfect, those which come the earliest should be sowed for seeds, which is what few people choose to do, because they are then the most valuable.

When the seed is ripe, the stalks should be pulled up, and set upright against a hedge to dry, observing to turn them every third day, that they may dry equally; then they may be threshed out and cleaned for use, or otherwise stacked up in a barn, till there is more leisure for threshing them out; and afterward the seed should be drawn over, to take out all those that are not fair, preserving the best for use or sale, and the ordinary beans will feed cattle.

It is a very good method to change the seeds of all sorts of Beans, and not to sow and save the seeds long in the same ground, for they do not succeed so well; therefore if the land is strong where they are to be planted, it will be the best way to procure the seeds from a lighter ground, and so *vice versa*; for by this method the crops will be larger, the Beans fairer, and not so liable to degenerate.

Having given directions for the culture of the Garden Beans, I shall next proceed to that of the Horse Bean, which is cultivated in the fields: there are two or three varieties of these Beans, which differ in their size and colour, but that which is now in the greatest esteem, is called the Tick Bean; this doth not grow so high as the other, is a more plentiful bearer, and succeeds better on light land than the common Horse Bean, so is preferred to it.

The Horse Bean delights in a strong moist soil and an open exposure, for they never thrive well on dry warm land, or in small inclosures, where they are very subject to blight, and are frequently attacked by a black insect, which the farmers call the black dolphin; these insects are often in such quantities, as to cover the stems of the Beans entirely, especially all the upper part of them; and whenever this happens, the Beans seldom come to good; but in the open fields, where the soil is strong and the plants have room, this rarely happens.

These Beans are usually sown on land which is fresh broken up, because they are of use to break and pulverize the ground, as also to destroy weeds; so that the land is rendered much better for Corn, after a crop of Beans, than it would have been before, especially if they are sown and managed according to the new husbandry, with a drill plough, and the horse hoe, used to stir the ground between the rows of Beans, which will prevent the growth of weeds, and pulverize the ground, whereby a much greater crop of Beans may, with more certainty, be expected, and the land will be better prepared for whatever crop it is designed for after.

The season for sowing of Beans is from the middle of *February* to the end of *March*, according to the nature of the soil; the strongest wet land should always be last sown; the usual quantity of Beans, sown on an acre of land, is about three bushels, but this is double the quantity that need be sown, especially according to the new husbandry; but I shall first set down the practice according to the old husbandry, and then give directions for their management according to the new. The method of sowing is after the plough, in the bottom of the furrows, but then the furrows should not be more than five, or, at most, six inches deep. If the land is new broken up, it is usual to plough it early in autumn, and let it lie in ridges till after *Christmas*; then plough it in small furrows, and lay the ground smooth; these two ploughings will break the ground fine enough for Beans, and the third ploughing is to sow the Beans when the furrows should be made shallow, as was before-mentioned.

Most people set their Beans too close; for, as some lay the Beans in the furrows after the plough, and others lay them before the plough and plough them in, so by both methods the Beans are set as close as the furrows are made, which is much too near; for when they are on strong good land, they generally are drawn up to a very great height, and are not so apt to pod as when they have more room, and are of a lower growth; therefore I am convinced by some late trials, that the better way is to make the furrows three feet asunder, or more, which will cause them to branch out into many stalks, and bear in greater plenty than when they are closer; by this method less than half the quantity of Beans will be sufficient for an acre of land, and the air being admitted between the rows, the Beans will ripen much earlier and more equally than in the common way.

What has been mentioned must be understood as relating to the old husbandry; but where Beans are planted according to the new, the ground should be four times ploughed before the Beans are set, which will break the clods, and render it much better for planting; then with a drill plough, to which a hopper is fixed for setting of the Beans, the drills should be made at three feet asunder, and the spring of the hopper set so as to scatter the Beans at three inches distance in the drills. By this method, less than one bushel of seed will plant an acre of land. When the Beans are up, if the ground is stirred between the rows with a horse plough, it will destroy all the young weeds; and when the Beans are advanced about three or four inches high, the ground should be again ploughed between the rows, and the earth laid up to the Beans; and if a third ploughing, at about five or six weeks after is given, the ground will be kept clean from weeds, and the Beans will stalk out, and produce a much greater crop than in the common way.

When the Beans are ripe, they are reaped with a hook, as is usually practised for Pease; and after having lain a few days on the ground they are turned, and this must be repeated several times, until they are dry enough to stack; but the best method is to tie them in small bundles, and set them upright; for then they will not be in so much danger to suffer by wet, as when they lie on the ground; and they will be more handy to carry and stack, than if they are loose. The common produce is from twenty to twenty-five bushels on an acre of land.

The Beans should lie in the mow to sweat, before they are threshed out; for as the haulm is very large and succulent, so it is very apt to give and grow moist; but there is no danger of the Beans receiving damage, if they are stacked tolerably dry, because the pods will preserve the Beans from injury; and they will be much easier to thresh after they have sweat in the mow, than before; and

after they have once sweated, and are dry again, they never after give.

By the new husbandry, the produce has exceeded the old by more than ten bushels on an acre; for if the Beans which are cultivated in the common method are observed when they are in pod, it will be found that more than half way of their stems have no Beans on them; for by standing close, they are drawn up very tall, so the tops of the stalks only produce, and all the lower part is naked; whereas in the new method, they bear almost to the ground; and as the joints of the stems are shorter, so the Beans grow closer together.

FABA ÆGYPTIACA. See Arum Ægyptiacum.

FABA CRASSA. See Anacampeferos, or Sedum.

FABAGO. See Zygophyllum.

FAGONIA. Tourn. Inst. R. H. 265. tab. 141. Lin. Gen. Plant. 475.

The Characters are,

The flower hath five heart-shaped petals, which spread open, and are narrow at their base, where they are inserted in the empalement; it hath ten erect stamina. In the center is situated a five-cornered germen, which afterward becomes a roundish capsule, having five lobes ending in a point, and five cells, each having a single roundish seed.

The Species are,

1. FAGONIA spinosa, foliis lanceolatis planis lævibus. Hort. Upsal. 103. Thorny Trefoil of Candia.

2. FAGONIA inermis. Lin. Sp. Plant. 386. Spanish Fagonia without thorns.

3. FAGONIA spinosa, foliis linearibus convexis. Lin. Sp. Plant. 386. Arabian Fagonia armed with very long spines.

The first sort is a native of the island of Candia, and has been described by some botanists under the title of *Trifolium spinosum Creticum*, which occasioned my giving it the English name of Thorny Trefoil of Crete; though there is no other affinity between this and the Trefoil, than that of this having three leaves or lobes on the same foot-stalk.

It is a low plant, which spreads its branches close to the ground, extending to the length of a foot or more every way, garnished with small trifoliate leaves placed opposite; at each joint, immediately below the leaves, come out two pair of spines, one on each side the stalk; and at the same places come out a single blue flower, standing upon a short foot-stalk, composed of five spear-shaped petals, which are narrow at their base, where they are inserted into the empalement; after these fall away the germen turns to a roundish five-lobed capsule, ending in an acute point, having five cells, each containing one roundish seed: it flowers in July and August, but unless the season proves warm the seeds do not ripen in England.

The second sort grows naturally in Spain; this differs from the first in being smooth, the branches of this having no thorns; and the plant will live two years, whereas the first is annual.

The third sort was discovered by the late Dr. Shaw in Arabia; this is a low plant with a shrubby stalk, from which come out several weak branches armed with long thorns; the leaves of this are thick, narrow, and convex on their lower side; the flowers come out in the same manner as in the first sort.

These plants are propagated by seeds, which should be sown upon a border of fresh light earth, where the plants are designed to remain; when the plants come up they may be thinned out to the distance of ten inches or a foot, and if they are kept clean from weeds they will require no other care.

The first and second sorts are annual plants, which do not perfect their seeds in England, unless the seasons prove very warm, therefore the best way is to sow their seeds upon a warm border in the autumn, and in frosty weather shelter

the plants with mats, or some other covering, to secure them; or if they are sown in pots, and placed under a frame in the winter, and the following spring shaken out of the pots, and planted in a warm border, they will come early to flower, and thereby ripe seeds may be more certainly obtained.

The other sort may be treated in the same way, for as the plants seldom flower the first year from seeds till the autumn, so the plants should be either kept in pots, or sheltered under a frame in winter, or placed in a warm border, where they may be sheltered with mats, or some other covering, to preserve them from the frost; and the following summer, it will flower and produce ripe seeds.

FAGOPYRUM. See Helxine.

FAGUS. Tourn. Inst. R. H. 584. tab. 351. The Beech tree.

The Characters are,

It hath male and female flowers on the same tree; the male flowers are collected into globular heads, and have no petals, but have several stamina included in an empalement of one leaf; the female flowers have a one-leaved empalement cut into four parts, but have no petals; the germen is fixed to the empalement, which afterward becomes a roundish capsule, armed with soft spines, opening in three cells, each containing a triangular nut.

We know but one Species of this genus, viz.

FAGUS. Dod. Pempt. 832. The Beech tree.

There are some planters, who suppose there are two distinct species of this tree; one they call the Mountain Beech, which they say is a whiter wood than the other, and they distinguish it by the title of Wild Beech; but it is certain, that this difference in the colour of the wood, arises from the difference of the soils in which they grow, for I have not seen any specific difference in the trees. There have been seeds of a Beech tree brought from North America, by the title of Broad-leaved Beech; but the plants which were raised from them proved to be the common sort, so that we know of no other variety, excepting that with striped leaves, which is accidental.

This tree is propagated by sowing the mast; the season for which is any time from October to February, only observing to secure the seeds from vermin when early sowed; which, if carefully done, the sooner they are sown the better, after they are fully ripe: a small spot of ground will be sufficient for raising a great number of these trees from seed, for if the plants come up very thick, the strongest of them should be drawn out the autumn following, that those left may have room to grow; so that a seed-bed carefully managed will afford a three years draught of young plants, which should be planted in a nursery; and, if designed for timber trees, at three feet distance, row from row, and eighteen inches asunder in the rows.

But if they are designed for hedges (to which the tree is very well adapted) the distance need not be so great; two feet row from row, and one foot in the rows will be sufficient. In this nursery they may remain two or three years, observing to dig up the ground between the roots, at least once a year, that their tender roots may the better extend themselves each way: but be careful not to cut or bruise their roots, which is injurious to all young trees; and never dig the ground in summer, when the earth is hot and dry, which, by letting in the rays of the sun to the roots, is often the destruction of young trees.

This tree will grow to a considerable stature, though the soil be stony and barren, as also upon the declivity of hills, and chalky mountains, where they will resist the winds better than most other trees; but then the nurseries for the young plants ought to be made upon the same soil, for if they are raised in good ground and a warm exposure, and afterwards transplanted into a bleak barren situation, they seldom

seldom thrive, which holds true in most other trees; therefore I would advise the nursery to be made upon the same soil where the plantation is intended, and to annually draw out plants to extend the plantation.

The tree is very proper to form large hedges to surround plantations, or wilderness quarters; and may be kept in a regular figure, if sheared twice a year, especially if they shoot strong; in which case, if they are neglected but a season or two, it will be difficult to reduce them again. The shade of this tree is very injurious to most sorts of plants which grow near it, but is generally believed to be very salubrious to human bodies.

The timber is of great use to turners for making trenchers, dishes, trays, buckets; and likewise to the joiner for stools, bedsteads, coffins, and is esteemed the best wood for firing, &c. The mast is very good to fat swine and deer, and also affords a sweet oil.

It delights in a chalky or stony ground, where it generally grows very fast; the bark of the trees in such land is clear and smooth, and although the timber is not so valuable as that of many other trees, yet as it will thrive on such soils, and in such situations where few better trees will grow, the planting of them should be encouraged, especially as the trees afford an agreeable shade, and the leaves make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees; therefore in parks, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it.

FEATHERFEW, or FEAVERFEW. See *Matricaria*.

FENNEL. See *Foeniculum*.

FENNEL-FLOWER. See *Nigella*.

FERRARIA. *Burm.*

The Characters are,

The flower is inclosed in a double spatha, or sheath, out of each sheath is produced one flower; the flower has six oblong acute-pointed petals, three of which are alternately larger than the other; these seem to be joined at their tails; their borders are fringed, turned backward, and silky; it has three stamina which rise above the petals, and a roundish three-cornered germen situated under the flower, which afterward turns to an oblong, smooth, three-cornered capsule, crowned by the decayed petals of the flower, with three cells, wrapped in the permanent sheath of the flower; in each cell is lodged many small round seeds.

The Species are,

1. *FERRARIA foliis lanceolatis*. *Burm.* Ferraria with spear-shaped leaves.

2. *FERRARIA foliis ensiformibus*. *Burm.* Ferraria with sword-shaped leaves.

These plants grow naturally at the Cape of Good Hope; the root of the first sort was sent me by Dr. Job Baster, F. R. S. of Zirkzee, who had received it from the Cape of Good Hope; the root is tuberous, roundish, and compressed, shaped like the root of Indian Corn Flag, but larger; in the center of the upper side of the root there is a hollow like a navel, from whence the flower-stalk comes out; the outer cover is of a light brown colour; the stalk rises a foot and a half high, as thick as a man's little finger, garnished with leaves the whole length, which are placed alternate, and embrace the stalks with their base; they are smooth, a little keel-shaped, and of a light green colour: the upper part of the stalk divides into two or three branches, garnished with leaves of the same shape with those below, but much shorter; each of the branches is terminated by a spatha or sheath, which is at first of the same colour with the leaves, but when the flower fades, this withers and dies, but remains upon the stalk; these sheaths are double one within the other. The flower rises out of the top upon a very short foot-stalk; it has six oblong petals, three of which are alter-

nately larger than the other, finely fringed on their edges, and are reflexed at their points; they are of a whitish green on their outside, but of a tawny Violet colour within, having many silky hairs on their surface. In the center of the flower is situated an erect style, which sits upon the germen, and is crowned with three bifid stigmas, which terminate in hairs. On one side the style is situated three stamina, which divide toward the top, and are terminated by roundish twin summits. The germen, which is situated under the flower, afterwards becomes an oblong smooth capsule with three cells, filled with roundish seeds.

There is a great singularity in the root of this plant, which is, that it vegetates but every other year, and sometimes every third year; the intermediate time it remains unactive, though very sound and good.

The second sort is figured by Dr. *Burman*, but I have not seen it as yet in *England*; it differs from the former in having longer leaves, which are sword-shaped and furrowed like those of *Byzantine Corn Flag*. The stalk rises about the same height, but does not divide so much; the flowers are smaller, and the petals are not so much fringed.

These plants are propagated by seeds, when they can be procured from the country where they naturally grow; these should be sown in pots as soon as they arrive, and require the same treatment as the *Ixia*. The roots also send out offsets, but it is sparingly in *England*, and these are some years before they arrive to a size for flowering, which occasions the scarcity of these plants in *Europe*. The roots also require the same culture with the *Ixia* and *Watsonia*, for they are too tender to live through the winter in the open air here, so must be planted in pots filled with light loamy earth, and sheltered under a frame in winter in the same manner as hath been before directed for *Watsonia* and *Ixia*, under which articles the reader will find proper directions for their culture and management; but those years when these roots do not vegetate they should have very little water, and in the summer the pots should be placed where they may have only the morning sun, for if they are exposed to the mid-day sun, the earth will dry too much, so may require water often, which frequently rots the roots when they are in an inactive state.

The mice are very fond of these roots, therefore they should be protected from those vermin, otherwise they will destroy them.

FERRUM EQUINUM. See *Hippocrepis*.

FERULA. *Lin. Gen. Plant.* 305. Fennel Giant.

The Characters are,

It hath an umbellated flower; the principal umbel is composed of several smaller called rays; the involucre is composed of several narrow leaves, which fall off; the principal umbel is uniform. The flowers have five oblong petals, and five stamina of the same length; under the flower is situated a turbinated germen, which afterward becomes an elliptical, compressed, plain fruit, dividing in two parts, each having a large, elliptical, plain seed.

The Species are,

1. *FERULA foliolis linearibus longissimis simplicibus*. *Hort. Cliff.* 95. *Pliny's Female Fennel Giant*.

2. *FERULA foliolis multipartitis, laciniis linearibus planis*. *Hort. Cliff.* 95. Galbanum-bearing Fennel Giant of *Lobel*.

3. *FERULA foliolis laciniatis, lacinulis tridentatis inaequalibus*. *Hort. Cliff.* 95. Broad-leaved shining Fennel Giant from *Tangier*.

4. *FERULA foliis pinnatifidis, pinnis linearibus planis trifidis*. *Hort. Cliff.* 95. Fennel Giant with a broader leaf.

5. *FERULA foliorum pinnis basi nudis, foliolis setaceis*. *Hort. Cliff.* 95. Eastern Fennel Giant, with the leaf and appearance of *Cachrys*.

6. *FERULA foliorum pinnis utrinque basi acutis, foliolis setaceis. Hort. Cliff. 95.* Eastern Lasciwort, with a Spignel leaf and yellow flower of *Tournefort*.

7. *FERULA foliolis appendiculatis, umbellis subsessilibus. Lin. Sp. Plant. 247.* Libanotis, with a Fennel Giant leaf and feed.

8. *FERULA foliis pinnatifidis, pinnis linearibus planis brevioribus.* Fennel Giant, with a narrower leaf of *Tournefort*.

The first of these plants is pretty common in the *English* gardens: this, if planted in a good soil, will grow to the height of ten or twelve feet, and divide into many branches: the lower leaves of this sort spread more than two feet every way, which are subdivided into many small ones, garnished with very long, narrow, small leaves, of a lucid green. From the center of the plant comes out the flower-stalk, which, when the plants are strong, will be near as large as a common broomstick, and will rise ten or twelve feet high, with many joints; if the stalks are cut, there issues from the vessels a foetid yellowish liquor, which will concrete on the surface of the wound. The stalks are terminated by large umbels of yellow flowers, which come out the latter end of *June*, or in the beginning of *July*, which are succeeded by oval compressed seeds, having three lines running longitudinally on each side. These ripen in *September*, and the stalks decay soon after.

The second sort doth not grow quite so large as the first, but the stalks of this will rise seven or eight feet high; the lower leaves are large, and greatly divided; the small leaves are flat and not so long as those of the former, and are of a lucid green colour; the umbels of flowers are smaller, and the seeds are less.

The third sort hath large spreading leaves near the root, which are divided and subdivided into many parts; the small leaves of this are much broader than in any of the other sorts, and are divided at their end into three unequal segments. The stalks are strong, and rise to the height of eight or ten feet, terminated by large umbels of yellow flowers, which are succeeded by large, oval, compressed seeds, like those of the first sort. This flowers and ripens its seeds about the same time as the former sort: it grows naturally in *Spain* and *Barbary*.

The fourth sort grows to much the same height as the second; the smaller lobes or divisions of the leaves are broader than those of the others (excepting the third), but they are longer than those, and of a darker green colour, ending in three points. The umbels of flowers are large, the flowers are yellow, and are succeeded by oval compressed seeds, like those of the other species. This grows naturally in *Sicily*.

The fifth sort is of much humbler growth than either of the former; the stalks of this seldom rise much more than three feet high; the lower leaves branch into many narrow brittle divisions; the umbel of flowers is small, when compared with the others, as are also the seeds. It grows naturally in the *Levant*.

The sixth sort hath very branching leaves, the foot-stalks are angular and channelled; this sends out at every joint two side branches opposite; those toward the bottom are nine or ten inches long, and the others are diminished gradually to the top, garnished with very fine leaves like those of Spignel, which stand round the stalks in shape of whorls; the flower-stalks grow three feet high, with a pretty large umbel of yellow flowers at the top, which are succeeded by oval flat seeds. It grows naturally in the *Levant*.

The seventh sort rises about three feet high; the leaves of this sort are much divided, and the small leaves on the divisions are narrow and entire; the umbels of flowers are small, and situated close to the stalks between

the leaves at the joints; these are like those of the other sorts. It grows naturally in *Istria* and *Carniola*.

The eighth sort is like the second, but the small leaves are much broader; the large leaves are not so long, and the stalk grows taller, but in other respects agrees with that. It grows naturally in *Spain*.

All these sorts have perennial roots, which will continue several years, and run deep in the ground: the stalks are annual, and decay soon after they have perfected their feeds. As these plants spread very wide, so they should have each four or five feet room; nor should they stand near to other plants, for their roots will rob whatever plants grow near them of their nourishment.

They are all propagated by seeds, which should be sown in the autumn; for if they are kept out of the ground till the spring, they frequently fail, and those which succeed remain a year in the ground, so that much time is lost. The seeds may be sown in drills, by which method the ground may be easier kept clean; the drills must not be nearer than a foot, and the seeds may be scattered two or three inches asunder in the drills. When the plants come up, if they should be too close together, they should be thinned, to allow them room to grow, for they will not be strong enough to remove till they have had two years growth; then in the autumn so soon as their leaves decay, the roots should be taken up with great care, so as not to cut or injure the tap or downright root, and planted in the places where they are designed to remain, for after this transplanting they should not be removed. They delight in a soft, gentle, loamy soil, not too wet, and are very rarely injured by the hardest frost.

FICOIDES. See *Mesembryanthemum*.

FICUS. *Lin. Gen. Pl. 1032.* The Fig Tree.

The Characters are,

It hath male and female flowers, which are included within the skin of the fruit, so do not appear unless the covering is opened; the male flowers are but few in number, and are situated in the upper part of the fruit; the female flowers are numerous, situated in the lower part. The male flowers sit each upon a separate foot-stalk; they have no petals, but three bristly stamina; the female flowers sit upon distinct foot-stalks; they have no petals, but a germen, which afterward becomes a large seed, sitting in the empalement.

The Species are,

1. *FICUS foliis palmatis. Hort. Cliff. 471.* Fig Tree with hand-shaped leaves; or, the common Fig Tree.

2. *FICUS foliis cordatis subrotundis integerrimis. Hort. Cliff. 471.* Fig Tree with a Mulberry leaf, bearing fruit on the body or stem, commonly called Sycamore.

3. *FICUS foliis cordatis integerrimis acuminatis. Hort. Cliff. 471.* Malabar Fig with a long-pointed leaf, and small, double, round fruit.

4. *FICUS foliis ovatis integerrimis obtusis, caule inferè radicato. Hort. Cliff. 471.* Bengal Fig, with a roundish leaf and orbicular fruit.

5. *FICUS foliis lanceolatis petiolatis, pedunculis aggregatis, ramis radicanibus. Lin. Sp. Plant. 1060.* Indian Fig of *Theophrastus*.

6. *FICUS foliis lanceolatis integerrimis. Hort. Cliff. 471.* The largest Indian Fig, with an oblong leaf, sending out roots from the tops of the branches, and a small, spherical, blood-coloured fruit.

7. *FICUS foliis ovatis acutis integerrimis, caule arboreo, fructu racemoso. Lin. Sp. Plant. 1060.* Fig Tree with oval, entire, acute leaves, a tree-like stalk, and fruit growing in bunches.

8. *FICUS foliis ovatis acutis integerrimis, caule repente. Lin. Sp. Pl. 1060.* Trailing wild Fig Tree, having single leaves.

9. *Ficus foliis ovato-cordatis integerrimis glabris.* Fig Tree with oval, heart-shaped, entire, smooth leaves, vulgarly called Fig Tree with a Water Lily leaf.

10. *Ficus foliis oblongo-cordatis acuminatis, petiolis longis. fimis.* Fig Tree with a Citron leaf, and small purple fruit.

The first sort, which is the only Fig whose fruit is valuable, is cultivated in most parts of *Europe*; of this there are great varieties in the warm countries. In *England* we had not more than four or five sorts till within a few years past, for as the generality of the *English* were not lovers of this fruit, so there were few who troubled themselves with the culture of it. But some years past I had a large collection of these trees sent me from *Venice*, by my honoured friend the Chevalier *Rathgeb*, all which I planted and preserved to taste of their fruits; several of them proved excellent, these I have preserved and propagated, and those whose fruit were inferior, have been neglected. As the variety of them is very great, so I shall here mention only such of them as are the best worth cultivating, placing them in the order of their ripening.

1. The Brown and Chestnut-coloured *Ischia* Fig, is the largest fruit of any I have yet seen; it is of a globular figure, with a large eye, pinched in near the foot-stalk, of a brown or Chestnut colour on the outside, and a purple within; the grains are large, the pulp sweet and high flavoured: this sort very often bursts open when it ripens, which is the latter end of *July*, or the beginning of *August*. I have had this fruit ripen well on standards, in a warm soil. If this sort is planted against hot walls, two plentiful crops of fruit may be annually ripened; for against a south-east wall, many of the second crop do annually ripen without art.

2. The Black *Genoa* Fig. This is a long fruit, which swells pretty large at the top where it is obtuse, but is very slender toward the stalk; the skin is of a dark purple colour, almost black, and hath a purple farina over it like that on some *Plumbs*; the inside is of a bright red, and the flesh is very high flavoured. It ripens early in *August*.

3. The small, white, early Fig. This hath a roundish fruit a little flatted at the crown, with a very short foot-stalk; the skin, when fully ripe, is of a pale yellowish white colour; is thin, the inside white, and the flesh very sweet, but not high-flavoured. This ripens in *August*.

4. The large white *Genoa* Fig. This is a large globular fruit, a little lengthened toward the stalk; the skin is thin, of a yellowish colour when fully ripe, and red within. It is a good fruit, but the trees are not good bearers.

5. The Black *Ischia* Fig. This is a short fruit, of a middling size, a little flatted at the crown; the skin is black when ripe, and the inside is of a deep red; the flesh is very high flavoured, and the trees produce a good crop of fruit, but the birds are great devourers of them, if they are not protected from them. This ripens in *August*.

6. The *Malta* Fig. This is a small brown fruit, much compressed at the top, and greatly pinched toward the foot-stalk; the skin is of a pale brown colour, as is also the inside; the flesh is very sweet, and well flavoured. If this sort is permitted to hang upon the trees till the fruit is shrivelled, it becomes a fine sweatmeat.

7. The Murrey, or Brown *Naples* Fig. This is a pretty large globular fruit, of a light brown colour on the outside, with some faint marks of a dirty white; the inside is nearly of the same colour, the grains are pretty large, and the flesh is well flavoured. It ripens the latter end of *August*, but is a bad bearer.

8. The Green *Ischia* Fig. This is an oblong fruit, almost globular at the crown; the skin is thin, of a green colour, but when it is fully ripe, it is stained through by the pulp to a brownish cast; the inside is purple, and will stain linen

or paper; the flesh is well flavoured, especially in warm seasons. It ripens toward the end of *August*.

9. The *Madonna* Fig, commonly called here the *Brunswick*, or *Hanover* Fig, is a long pyramidal fruit of a large size; the skin is brown; the flesh is of a lighter brown colour, coarse, and hath little flavour. This ripens the end of *August* and the beginning of *September*; the leaves of this sort are much more divided than of most other.

10. The common Blue, or Purple Fig, is so well known, as to need no description.

11. The long Brown *Naples* Fig. The leaves of this tree are deeply divided. This fruit is long, somewhat compressed at the crown. The foot-stalks are pretty long; the skin of a dark brown when fully ripe, the flesh inclining to red; the grains are large, and the flesh well flavoured. It ripens in *September*.

12. The *Gentile* Fig. This is a middle-sized oval fruit; the skin, when ripe, is yellow, the flesh also inclines to the same colour; the grains are large, and the flesh is well flavoured, but it ripens very late, and the trees are bad bearers, so that it is not propagated much in *England*.

The first, second, third, ninth, and tenth sorts, will ripen their fruits on standards, where they are in a warm situation; but the others require the assistance of walls exposed to good aspects, otherwise their fruit will not ripen well in *England*.

Fig trees generally thrive in all soils and in every situation, but they produce a greater quantity of fruit upon a strong loamy soil, than on dry ground; for if the season proves dry in *May* and *June*, those trees which grow upon very warm dry ground, are very subject to cast their fruit; therefore, whenever this happens, such trees should be well watered and mulched, which will prevent the fruit from dropping off; but the fruit upon these trees are better flavoured, than any of those which grow upon cold moist land. I have always observed those Fig trees to bear the greatest quantity of well flavoured fruit, which were growing upon chalky land, where there has been a foot or more of a gentle loamy soil on the top. They also love a free open air, for although they will shoot and thrive very well in close places, yet they seldom produce any fruit in such situations; and all those which are planted in small gardens in *London*, will be well furnished with leaves, but I have never seen any fruit upon them, which have grown to maturity.

These trees are always planted as standards, in all warm countries, but in *England* they are generally planted against walls, there being but few standard Fig trees at present, in the *English* gardens; however, since some of the sorts are found to ripen their fruit well upon standards, and the crop of Figs is often greater upon them, than upon those trees against walls, it is worthy of our care, to plant them either in standards or espaliers; the latter, I think, will succeed best in *England*, if they were managed as in *Germany*, where they untie the Fig trees from the espalier, and lay them down, covering them in winter with straw or litter, which prevents their shoots being injured by the frost; and this covering is taken away gradually in the spring, and not wholly removed until all the danger of frost is over, by which they generally have a very great crop of Figs; whereas in *England*, where the trees grow in warm situations, if the spring proves warm, the young Figs are pushed out early, and the cold, which frequently returns in *May*, causes the greatest part of the fruit to drop off; so that our crop of Figs is generally more uncertain, than most other sorts of fruit; and it frequently happens, that trees which are planted against north and east aspected walls, produce a greater quantity of fruit in *England*, than those which are planted against south and south east aspects; which must happen, from the latter putting out their fruit so much earlier in the spring than the former;

former; and if there happen cold frosty nights, after the Figs are come out (which is frequently the case in this country), the forwardest of the Figs are generally so injured as to drop off from the trees soon after. In *Italy*, and the other warm countries, this first crop of Figs is little regarded, being few in number; for it is the second crop of Figs which are produced from the shoots of the same year, which is their principal crop, but these rarely ripen in *England*, nor are there above three or four sorts which ever ripen their second crop, let the summer prove ever so good, unless they have hot walls, therefore it is the first crop which we must attend to in *England*; so that when these trees are growing against the best aspectted walls, it will be a good method to loosen them from the wall in autumn; and after having divested the branches of all the latter fruit, to lay the branches down from the wall, fastening them together in small bundles, so that they may be tied to stakes, to keep them from lying upon the ground, the damp whereof, when covered in frosty weather, might cause them to grow mouldy; this will secure the branches from being broken by the wind. When they are thus managed in autumn, if the winter should prove very severe, the branches may be easily covered with Pease haulm, Straw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of frost; and when the weather is mild, the covering must be removed, otherwise the Figs will come out too early; for the intention of this management is, to keep them as backward as possible; then in the spring, when the Figs begin to push out, the trees may be fastened to the wall again. By this management, I have seen very great crops of Figs produced in two or three places.

I have also seen great crops of Figs in some particular gardens, after very sharp winters, when they have, in general, failed in other places, by covering up the trees with Reeds made into pannels, and fixed up against the walls.

In the pruning of Fig trees, the branches must never be shortened, because the fruit are all produced at the upper part of the shoots of the former year, so, if these are cut off, there can be no fruit expected, beside the branches are very apt to die after the knife; so that when the branches are too close together, the best way is to cut out all the naked branches quite to the bottom, leaving those which are best furnished with lateral branches at a proper distance from each other, which should not be nearer than a foot; when they are well furnished with lateral branches, if they are laid four or five inches farther asunder, it will be better.

The best time for pruning of Fig trees is in autumn, because at that time the branches are not so full of sap, so they will not bleed so much, as when they are pruned in the spring; and at this season, the branches should be divested of all the autumnal Figs; and if the bud at the extremity of the shoots are rubbed off with the finger, it will cause them to put out a greater crop of fruit in the spring; the sooner this is done, when the leaves do begin to fall off, the better will the young shoots resist the cold of the winter. There are some seasons so cold and moist, that the young shoots of the Fig trees will not harden, but are soft, and full of juice; when this happens, there is little hope of a crop of Figs the succeeding year, for the first frost in autumn will kill the upper part of these shoots. Whenever this happens, it is the best way to cut off all the decayed part of the shoots, which will prevent the infection from spreading to the lower part of the branches.

Those trees which are laid down from the espaliers, should not be fastened up again till the end of *March*, for the reasons before given, and those against walls may remain some time longer; when the large shoots of these are nailed up, if the small lateral branches are thrust behind them to keep them close to the wall, it will secure the

young Figs from being injured by the morning frosts, and when this danger is over, they may be brought forward to their natural position again; during the summer season these trees will require no other pruning, but to stop the shoots in the spring, where lateral branches are wanting; and as the branches are often blown down by wind, therefore, whenever this happens, they should be immediately fastened up again, otherwise they will be in danger of breaking, for the leaves of these trees being very large and stiff, the wind has great power on them, so that where the branches are not well secured, they are frequently torn down.

Those trees which are planted against espaliers, which are not laid down as before directed, may be protected from the injury of frost in the winter, by placing Reeds on each side the espalier, which may be taken down every day, and put up again at night; but this need not be practised in warm weather, but only at such times as there are cold winds, and frosty mornings; and although there is some trouble and expence attending this management, yet the plentiful crop of Figs, which may be this way obtained, will sufficiently recompense for both: the best way of making this covering is, to fasten the Reeds with rope yarn, in such a manner, as that it may be rolled up like a mat, so that the whole may with great facility be put up, or taken down; and if these Reeds are carefully rolled up, after the season for using them is over, and put up in a dry shed, they will last several years.

I am aware, that what I have here advanced, in relation to the pruning and dressing of Fig trees, will be condemned by great numbers of people, who will not give themselves time to consider and examine the reasons upon which I have founded this practice, nor to make one single experiment to try the truth of it, as being vastly different from the general practice of most gardeners, who always imagine, that Fig trees should never have any pruning, or, at least, that they should always be suffered to grow very rude from the wall, to some distance. By this management I have often seen great quantities of fruit, I cannot deny, but then this has been only after mild winters; for it is very certain, that in sharp frosts few of these outside shoots escape being greatly injured where they are not covered; whereas it rarely happens, that those shoots which are closely fastened to the wall in autumn, or laid down and covered, suffer the least damage, and the fruit are always produced a fortnight sooner upon these branches, than they are upon those which grow from the wall; but although the trees which are suffered to grow rude from the walls may produce a good quantity of fruit for a year or two, yet afterward the trees will only bear at the ends of the shoots, which will then be so far from the wall, as to receive little benefit from it, nor can the trees be reduced again to any regularity, without cutting away the greatest number of their branches, by which a year or two will be lost, before they will come to bear again.

The season also for pruning, which I have laid down, being vastly different from the common practice and opinion of most gardeners, may also be objected to; but I am sure, if any one will but make trial of it, I doubt not his experience will confirm what I have here advanced; for as one great injury to this tree proceeds from the too great effusion of sap at the wounded parts, so by this autumn pruning this is prevented; for, at that season, all the parts of *European* trees, which cast their leaves, are less replete with moisture than at any other time of the year, for by the long continuance of the summer's heat, the juices of plants having been exhausted in the nourishment and augmentation of wood, leaves, fruits, &c. and also great quantities being evaporated by perspiration, the root not being able to send up a supply equivalent to this great consumption, the

branches must contain a much less quantity of sap in autumn than in spring, when it has had several months supply from the root, which though but small in proportion to what is sent up when the heat is greater, yet there being little or no waste, either by perspiration or augmentation, there must be a greater quantity contained in the branches; which also is easily to be observed, by breaking or cutting off a vigorous branch of a Fig tree at both seasons (the sap, being milky, may be readily discerned;) when that cut in autumn shall be found to stop its bleeding in one day's time, or less, whereas that cut in the spring will often flow a week or more, and the wound will be proportionably longer before it heals.

Of late years there has been some of these trees planted against fire walls, which have succeeded very well where they have been properly managed, but where they have been kept too close, and drawn by glasses, they have not produced much fruit; therefore whenever this is practised, the heat should not be too great, nor the glasses, or other covering, kept too close, but at all times, when the weather is favourable, a good share of free air should be admitted; and if the trees are young, that their roots are not extended beyond the reach of the covering, they must be frequently watered when they begin to shew fruit, otherwise it will drop off; but old trees, whose roots are extended to a great distance, will only require to have their branches now and then sprinkled over with water. If these trees are properly managed, the first crop of fruit will be greater than upon those which are exposed to the open air, and will ripen six weeks or two months earlier, and a plentiful second crop may also be obtained, which will ripen early in *September*, and sometimes in *August*, which is about the season of their ripening in the warmer parts of *Europe*; but the fires should not be used to these trees till the beginning of *February*, because when they are forced too early, the weather is frequently too cold to admit a sufficient quantity of fresh air to set the fruit, but the covers should be put over the trees two months before, to prevent the shoots from being injured by the frost.

Fig trees are propagated in *England*, either by the suckers, which are sent out from their roots, and by layers made by laying down of their branches, which in one year will put out roots sufficient to be removed, or by planting of cuttings, which, if properly managed, will take root; the first of these is a bad method, because all those trees which are raised from suckers, are very subject to send out great quantities of suckers again from the roots. Those plants which are propagated by layers, are the best, provided the layers are made from the branches of fruitful trees, for those which are made from the suckers, or shoots, produced from old stools, have very soft branches, full of sap, so are in danger of suffering by the frost, and these will shoot greatly into wood, but will not be very fruitful; for, when the trees have acquired a vicious habit while young, it is seldom they are ever brought to be fruitful afterward; therefore the shoots that are laid down, should be such as are woody, compact, and well ripened, not young shoots full of sap, whose vessels are large and open. The best time for laying down of the branches is in autumn; if the winter should prove very severe, if they are covered with some old tan, or any other mulch, to keep the frost from penetrating of the ground, it will be of great service to them; by the autumn following, these will be sufficiently rooted for removing, when they should be cut off from the old plants, and transplanted where they are to remain. As these plants do not bear transplanting well when they are large, so it is the better way to plant them at first in the places where they are to remain, and after they are planted, the surface of the ground about their roots, should be

covered with mulch to keep out the frost, if the winter should prove very severe; and if the branches are covered with Reeds, Pease haulm, Straw, or some other light covering, it will prevent their tender ends being killed by the frost, which frequently happens where this care is wanting.

If fruitful branches of these trees are cut off, and planted in pots, or tubs filled with good earth, and plunged into a good hot-bed of tanners bark in the stove, they will put out fruit early in the spring, which will ripen the middle of *May*.

We shall now return to the other sorts of Figs, which grow naturally in warm countries, but are preserved in the gardens of those who are curious in collecting of rare exotick plants, for these do not bear eatable fruit in their native soil, but their leaves being large and beautiful, the plants make a pleasing variety in the stove.

The second sort grows naturally in the *Levant*, where it becomes a large tree, dividing into many branches, garnished with leaves shaped like those of the Mulberry, so affords a friendly shade in those hot countries. The fruit is produced from the trunk and large branches of the tree, and not on the smaller shoots, as in most other trees; the shape is like the common Fig, but is little esteemed. This is called the Sycamore, or *Pharaoh's Fig tree*.

The third sort grows naturally in *India*, where the trees are sacred, so that none dare destroy them, it is called by some the *Indian God tree*. It rises with a woody stem to a great height, sending out many slender branches, which are garnished with smooth heart-shaped leaves, somewhat like those of our Black Poplar, ending in a long tail, or point; they are entire, smooth, and of a light green, having pretty long foot-stalks. The fruit comes out on the branches, which are small, round, and of no value.

The fourth sort rises with many stalks, which grow to the height of thirty or forty feet, dividing into a great number of branches, which send out roots from their under side, many of which reach to the ground; so that in such places where these trees grow naturally, their roots and branches are so interwoven with each other, as to render the places impassable. In *India*, the *Banyans* trail the branches of these trees into regular archades, and set up their pagods under them, these being the places of their devotion. In *America*, where these trees are equally plenty, they form such thickets, as neither man or beast can pass through. The leaves of this sort are of a thick substance, smooth, and oval; six inches long, and four broad, with obtuse ends. The fruit is the size of a marble, round, but of no use.

The fifth sort grows naturally in both *Indies*; this rises with a woody stalk, to the height of thirty feet, sending out many branches, garnished with oblong leaves, standing upon long foot-stalks; they are about six inches long, and two broad, ending in an obtuse point, of a dark green, smooth on their upper side, but of a light green, and veined on their under side. The fruit is small, of no value. The branches of these trees send out roots from their lower side, which sometimes reach the ground.

The sixth sort grows naturally in the *West-Indies*, where it rises to the height of thirty or forty feet, sending out many slender branches, which put out roots in the same manner as the former. The leaves of this are eight or nine inches long, and two broad, ending in points. The fruit is small, round, of a blood colour when ripe, but is not eatable.

The seventh sort grows naturally in *India*, where it rises to the height of twenty-five feet, divides into many branches, garnished with oval-pointed smooth leaves, of a lucid green. The fruit is small, and grows in clusters from the side of the branches, but are not eatable.

The eighth sort grows naturally in *India*; this is a low trailing shrub, whose stalks put out roots at their joints, which strike into the ground, so is propagated plentifully where it naturally grows. The leaves are two inches and a half long, and two broad, ending in points; they are of a lucid green; the fruit is small, and not eatable.

The ninth sort rises with a strong, upright, woody stalk, twenty feet high, sending out several side branches, garnished with large, oval, stiff leaves, about fourteen inches long, and a foot broad, rounded at the ends, and indented at the foot stalk; the upper side of the leaves are of a lucid green, the under side is of a gray, or sea-green colour, of a thick substance, and very smooth; this grows naturally in *India*.

The tenth sort grows naturally in the *West-Indies*, where it rises twenty feet high, sending out many side branches, which are covered with a white bark, garnished with oblong heart-shaped leaves, ending in acute points; of a lucid green on their upper side, but of a pale green on their under, standing upon very long foot-stalks. The fruit comes out from the side of the branches, toward their ends; they are about the size of large gray Pease, of a deep purple colour, sitting close to the branches, but are not eatable.

The second sort, I believe, is not in *England* at present. I raised two or three of these plants from seeds in the year 1736, which were destroyed by the severe frost in 1740, since which time I have not been able to procure any of the seeds. The other sorts are preserved in several curious gardens; they are easily propagated by cuttings during the summer season. When the cuttings are taken from the plants, they should be laid in a dry shady place for two or three days, that the wounds may be healed over, otherwise they are apt to rot; for all these plants abound with a milky juice, which flows out whenever they are wounded, for which reason the cuttings should have their wounded part healed over and hardened before they are planted; after which they should be planted in pots filled with sandy light earth, and plunged into a moderate hot-bed, where they should be shaded from the sun, and two or three times a week gently refreshed with water, if the season is warm, but they must not have too much moisture, for that will infallibly destroy them. When the cuttings have taken root sufficient to transplant, they should be each planted into a separate small pot filled with light undunged earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root; then they should have a large share of free air admitted to them at all times, when the weather is favourable, to prevent their drawing up weak, and to give them strength before the cold comes on. In autumn the pots should be removed into the stove, and plunged into the tan-bed, where they should constantly remain, and must be treated in the same manner as other tender plants from the same countries; for although two or three sorts may be treated in a hardier manner, yet they will not make much progress.

FLOWER. A flower is a natural production which precedes the fruit, that includes the grain or seed. Though a flower is a thing so well known, yet the definition of this part of a plant is as various almost as the authors who define it. *Jungius* defines it to be the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the fruit. Yet this author himself confesses,

that this definition is too narrow; for some of those bodies which he allows to be flowers, are remote from the fruit.

A flower may be thus defined, *viz.* it contains the organs of generation of both sexes adhering to a common placenta, together with their common coverings; or of either sex separately, with its proper coverings, if it have any.

FOENICULUM. *Tourn. Inst. R. H. 311. tab. 164.*
Fennel.

The Characters are,

It hath an umbellated flower; the great umbel is composed of many smaller, which have no involucre; the flowers have five incurved petals, and five stamina; the germen is situated under the flower, which afterward turns to an oblong fruit, deeply channelled, dividing into two parts, each containing a single seed.

The Species are,

1. FOENICULUM foliis decompositis, foliolis brevioribus multifidis, semine brevior. Common Fennel.

2. FOENICULUM foliis decompositis, foliolis longioribus, semine longiori. Sweet Fennel having a larger white seed.

3. FOENICULUM humilius, radice caulescente carnosio, seminibus recurvis. radice annua. Sweet Azorian Fennel, called *Finocchio*.

The first sort is the common Fennel which is cultivated in the gardens, and has sown itself in many places, where it has been introduced in such plenty, as to appear as if it were a native in *England*; but it is no where found at a great distance from gardens, so has been undoubtedly brought from abroad. There are two varieties of this, one with light green, the other with very dark leaves, but these I believe are only varieties which arise from the same seeds.

The common Fennel is so well known, as to need no description. It has a strong fleshy root which penetrates deep into the ground, and will continue several years. It flowers in *July*, and the seeds ripen in autumn. The best time to sow the seeds, is soon after they are ripe; the plants will come up in the spring, and require no other care but to keep them clean from weeds; it will grow in any soil or situation. The leaves, seeds, and roots of this are used in medicine; the root is one of the five opening roots, and the seed one of the greater carminative seeds. There is a simple water made from the leaves, and a distilled oil from the seed.

The sweet Fennel has been by many supposed only a variety of the common sort, but I have cultivated it in the same ground with that, where it has retained its differences. The leaves of this are very long and slender, growing more sparsely, and do not end in so many points as those of the common sort; the stalks do not rise so high; the seeds are longer, narrower, and of a lighter colour. These seeds are generally imported from *Germany* or *Italy*, and are by some preferred to those of the common sort for use, being much sweeter.

This may be propagated in the same manner as the former sort, being very hardy, but the roots are not of so long duration.

The third sort is supposed to have been originally brought from the *Azorian Islands*; it has been long cultivated in *Italy* as a salad herb, under the title of *Finocchio*; and there are some few gardens in *England*, where it is now cultivated in small quantities, for there are not many *English* palates which relish it, nor is it easy to be furnished with good seeds; those which are annually brought from *Italy*, seldom prove good, and it is difficult to save it in *England*, because the winter frequently kills those plants which are left for seeds; and when any good plants of the early sowing are left for seeds, they do not ripen, unless the autumn proves very favourable.

This sort hath very short stalks, which swell just above the surface of the ground, to four or five inches in breadth, and

and almost two thick, being fleshy and tender : this is the part which is eaten when blanched, with oil, vinegar, and pepper, as a cold salad. When these plants are permitted to run for seeds, the stalks do not rise more than a foot and a half high, having a large spreading umbel standing on the top. The seeds of this sort are narrow, crooked, and of a bright yellow colour ; they have a very strong smell like Aniseed, and are very sweet to the taste.

The manner of cultivating this plant is as follows : The first care is to procure some good seeds from some person who has been careful in the choice of the plants, otherwise there will be little hope of having it good : then make choice of a good spot of light rich earth, not dry nor very wet, for in either extreme this plant will not thrive. The first crop may be sown about a fortnight in *March*, which, if it succeeds, will be fit for use in *July* ; and so by sowing at several times, there may be a supply for the table till frost puts a stop to it. After having well dug and levelled the ground smooth, the seed should be sown in a shallow rill by a line, scattering them pretty thin, for the plants must be left six inches asunder in the rows ; but however, some of the seeds may fail, therefore they should be scattered two inches distance, then cover the seeds about half an inch thick with earth, laying it smooth : these rills should be made eighteen inches asunder, or more, that there may be room to clean the ground, as also to earth up the plants when they are full grown. When the plants come up, which will be in about three weeks or a month after sowing, all the weeds between them must be cut up, and where the plants are too close, they should be thinned to about four inches distance ; and as they advance, and the weeds spring again, they should, from time to time, be hoed ; and at the last time of thinning them they should be left seven or eight inches asunder at least. If the kind be good, the stems of the plants will increase to a considerable bulk just above the surface of the ground ; which part should be earthed up in the manner of Celery, to blanch, about a fortnight or three weeks before it is used, which will cause it to be very tender and crisp.

The second crop should be sown about three weeks after the first, and so continued every three weeks or a month till the end of *July*, after which time it will be too late for the plants to come to any perfection. But the seeds which are sown in *May* and *June*, should have a moister soil than that which you sowed the first ; as also what is sown the latter part of *July*, should be on a drier soil, and in a warmer situation ; because this crop will not be fit for use till late in autumn, and therefore will be subject to injuries from too much wet or cold, if on a moist soil. If the season should prove dry, the plants must be watered, otherwise they will run up to seed before they are of any size ; therefore there should be a channel made where every row of plants grow, to detain the water which is poured on them, to prevent its running off. In the autumn, if there should happen sharp frosts, it will be very proper to cover the plants with some Pease haulm, or other light covering, to prevent their being pinched, by which method they may be continued for use till the middle of winter.

FOENUM BURGUNDIACUM. See *Medica Sativa*.

FOENUM GRÆCUM. See *Trigonella*.

FRAGARIA. *Lin. Gen. Plant.* 558. The Strawberry.

The Characters are,

The flower hath five roundish petals, which are inserted in the empalement, and twenty stamina, with a great number of germen collected into a head, which afterward becomes a large, soft, pulpy fruit, leaving many small angular seeds in the empalement.

The Species are,

1. FRAGARIA foliis ovatis serratis, calycibus brevibus, fructu parvo. The common, or Wood Strawberry.

2. FRAGARIA foliis oblongo-ovatis serratis, inferne incantis, calycibus longioribus, fructu subrotundo. *Virginia* Strawberry with a scarlet fruit, commonly called the Scarlet Strawberry.

3. FRAGARIA foliis ovato-lanceolatis rugosis, fructu ovato. Strawberry with fruit as large as a small Plum, commonly called Hautboy Strawberry.

4. FRAGARIA foliis ovatis carnosis hirsutis, fructu maximo. Strawberry of *Chili* with a large fruit, and hairy fleshy leaves, called *Fruilla* in *America*.

There are several other varieties of this fruit, which are now cultivated in *England* ; but these, I think, may be allowed to be distinct species, for they never alter from one to the other, by any cultivation, though the fruit is frequently improved, so as to be of a larger size thereby ; I shall next mention the varieties of Strawberries, which are at present to be found in the *English* gardens, under the several species to which they naturally belong.

The first sort is the common Wood Strawberry, which grows naturally in the woods, in many parts of *England*, and is so well known, as to need no description ; of this there are three varieties, 1. The common sort with red fruit. 2. The white Wood Strawberry, which ripens a little later in the season, and is by many persons preferred to it for its quick flavour ; but as it seldom produces so large crops as the red sort, so it is not very generally cultivated. 3. The green Strawberry, by some called the Pine Apple Strawberry, from its rich flavour. The fruit of this is green, with a faint shade of red, when ripe ; it is very firm, hath a very high flavour, and is a late ripe fruit ; but unless it is planted in a moist loamy soil, it is a very bad bearer, but in such land where it does succeed, it merits cultivation as much as any of the sorts. There is also a variety of this which has been raised from seeds by the Right Hon. Lord *Willoughby* of *Parham*, which continues to produce fruit from the first season of Strawberries, till prevented by frost ; the fruit has a higher flavour than the Wood Strawberry, so deserves encouragement.

The Scarlet Strawberry is the sort which is first ripe, for which reason it merits esteem, had it nothing else to recommend it ; but the fruit is so good, as by many persons of good taste to be preferred to all the other sorts ; this was brought from *Virginia*, where it grows naturally in the woods, and is so different from the Wood Strawberry in leaf, flower, and fruit, that there need be no doubt of their being distinct species.

There is a variety of this which hath been of late years introduced from the northern parts of *America*, which has the appearance of a distinct species. The leaves of this are rounder, and not so deeply veined ; the crenatures on their edges are broader and more obtuse. The leaves which compose the empalement, are much longer, and are hairy, the fruit is also much larger ; but in other respects it approaches near to the scarlet Strawberry, so I have chosen to join it to that, rather than make a distinct species of it ; this I have been informed grows naturally in *Louisiana*.

The Hautboy Strawberry, which the *French* call *Capitons*, came originally from *America*, and is very different from the other sorts in leaf, flower, and fruit, as that no one can doubt of their being different species ; there is an improvement of this sort, which is commonly called the Globe Hautboy. The fruit of this is larger, and of a globular form, but this difference has certainly arisen from culture ; for where these have been neglected a year or two, they have degenerated to the common Hautboy again ; where the ground is proper for this plant, and their culture is well managed, the plants will produce great plenty of fruit, which will be large and well flavoured, and by some persons are preferred to all the other sorts.

The *Chili* Strawberry was brought to *Europe* by *Monf. Frazier*, an engineer, who was sent to *America* by the late king of *France*; in the year 1727, I brought a parcel of the plants to *England*, which were communicated to me by *Mr. George Clifford*, of *Amsterdam*, who had large beds of this sort growing in his curious gardens at *Hartecamp*. The leaves of this sort are hairy, oval, and of a much thicker substance, than those of any sort yet known, and stand upon very strong hairy foot-stalks; the runners from the plants are very large, hairy, and extend to a great length, putting out plants at several distances. The foot-stalks which sustain the flowers are very strong; the leaves of the empalement are long and hairy. The flowers are large, and often deformed, so are the fruit also when cultivated in very strong land, in which the plants produce plenty, which are firm and very well flavoured, but as it is a bad bearer in most places where it has been cultivated, so in general it has been neglected.

Strawberries love a gentle hazelly loam, in which they will thrive and bear greater plenty of fruit, than in a light rich soil. The ground should also be moist, for if it is very dry, all the watering which is given to the plants in warm dry seasons, will not be sufficient to procure plenty of fruit; nor should the ground be much dunged, for that will cause the plants to put out many runners, and grow luxuriant, and will render them less fruitful.

The best time to remove these plants is in *October*, that they may get new roots before the hard frost sets in, which loosens the ground, so that if the roots of the plants are not pretty well established, the plants are frequently turned out of the ground after frost by the first thaw; therefore the sooner they are planted when the autumnal rains begin, the better will their roots be established, and sometimes those which are well rooted, will produce a few fruit the first year; there are some who transplant their plants in the spring, but where this is done they must be duly supplied with water in dry weather, otherwise they will not succeed.

The ground in which these are planted should be thoroughly cleaned from the roots of Couch, and all other bad weeds, for as the Strawberry plants are to remain three years before they are taken up, so if any of the roots of these bad weeds are left in the ground, they will have time to multiply so greatly as to fill the ground, and overbear the Strawberry plants. The usual method is to lay the ground out into beds of four feet broad, with paths two feet, or two feet and a half broad between each; these paths are necessary for the convenience of gathering the fruit, and for weeding and dressing of the beds: after the beds are marked out, there should be four lines drawn in each, at a foot distance, which will leave six inches space on each side, between the outside rows and the paths; when the plants should be planted at a foot distance from each other in the rows, in a quincunx order, being careful to close the ground to the roots of the plants when they are planted, and if there should not happen rain soon after, the plants should be well watered to settle the earth to their roots.

The distance here mentioned for the plants to be placed, must be understood for the Wood Strawberries only, for as the other sorts grow much larger, their distances must be proportioned to their several growths; therefore the *Scarlets* and *Hautboy*, should have but three rows of plants in each bed, which should be at fifteen inches distance, and the plants in the rows should be allowed the same space from each other; and the *Chili* Strawberry must have but two rows of plants in each bed, which should also be two feet apart in the rows, for as these grow very strong, if they have not room to spread, they will not be very fruitful.

In the chusing proper plants of any of the sorts, depends the whole success, for if they are promiscuously taken from beds without care, great part of the plants will become barren; these are generally called blind, which is when there are plenty of small flowers but no fruit produced; if these flowers are well examined, they will be found to want the female organs of generation, most of them abounding with stamina, but they have few, if any styles, so that it frequently happens among these barren plants, that some of them will have a part of an imperfect fruit formed, which will sometimes ripen; this barrenness is not peculiar to Strawberries, but is general to all those plants which have creeping roots or stalks; and the more they increase from either, the sooner they become barren, and this in some degree runs through the whole vegetable kingdom; for trees and shrubs which are propagated by cuttings, are generally barren of seeds in two generations, that is, when they are propagated by cuttings, which were taken from plants raised by cuttings; this I have constantly found to hold in great numbers of plants, and in fruit trees it often happens, that those sorts which have been long propagated by grafts and buds, have no kernels: but to return to the choice of the Strawberry plants; these should never be taken from old neglected beds, where the plants have been suffered to spread or run into a multitude of suckers, nor from any plants which are not very fruitful; and those off-sets which stand nearest to the old plants, should always be preferred to those which are produced from the trailing stalks at a farther distance; the Wood Strawberry is best when the plants are taken fresh from the woods, provided they are taken from fruitful plants, because they are not so liable to ramble and spread, as those which are taken from plants which have been long cultivated in gardens; therefore those who are curious in cultivating of this fruit, should be very careful in the choice of their plants.

When the plants have taken new root, the next care is, if the winter should prove severe, to lay some old tanners bark over the surface of the bed between the plants, to keep out the frost; this care is absolutely necessary to the *Chili* Strawberry, which is frequently killed in hard winters, where they are exposed without any covering; therefore where tanners bark cannot be easily procured, saw-dust, or sea-coal ashes may be used; or in want of these, if decayed leaves of trees, or the branches of ever-green trees with their leaves upon them, are laid over the beds, to prevent the frost from penetrating deep into the ground, it will secure the plants from injury.

The following summer, the plants should be constantly kept clean from weeds, and all the runners should be pulled off as fast as they are produced; if this is constantly practised, the plants will become very strong by the following autumn, whereas when this is neglected (as is too frequently seen) and all the runners permitted to stand during the summer season, and then pulled off in autumn, the plants will not be half so strong as those where that care has been taken; therefore there will not be near the same quantity of fruit upon them the following spring, nor will the fruit be near so large and fair; where proper care is taken of the plants the first summer, there is generally a plentiful crop of fruit the second spring, whereas when this is neglected, the crop will be thin and the fruit small.

As this fruit is very common, there are but few persons who cultivate it with proper attention, therefore I shall give some directions for the doing of it, which, if carefully practised, will be attended with success.

The old plants of Strawberries are those which produce the fruit, for the suckers never produce any till they have grown a full year; therefore it appears how necessary it is to divest the old plants of them, for wherever they are suffered

suffered to remain, they rob the fruitful plants of their nourishment, in proportion to their number; for each of these suckers send out a quantity of roots, which interfere, and are so closely matted together, as to draw away the greatest part of the nourishment from the old roots, whereby they are greatly weakened; and these suckers also render each other very weak, so from hence the cause of barrenness arises; for I have known where the old plants have been constantly kept clear from suckers, they have continued very fruitful four or five years without being transplanted; however it is the best way to have a succession of beds, that after three years standing, they may be taken up, because by that time they will have exhausted the ground of those vegetable salts, necessary for the nourishment of that species of plants; for it is always observed, that Strawberries planted on fresh land, are the most fruitful.

The next thing to be observed, is in autumn to divest the plants of any strings, or runners, which may have been produced, and also of all the decayed leaves, and the beds cleared from weeds; then the paths should be dug up, and the weeds buried which were taken from the beds, and some earth laid over the surface of the beds between the plants, this will strengthen and prepare them for the following spring; and if after this, there is some old tanners bark laid over the surface of the ground between the plants, it will be of great service to them. In the spring, after the danger of hard frost is over, the ground between the plants in the beds should be forked, with a narrow three pronged fork, to loosen the ground, and break the clods; and in this operation, the tan which was laid over the surface of the ground in autumn will be buried, which will be a good dressing to the Strawberries, especially in strong land; then about the end of *March*, or the beginning of *April*, if the surface of the bed is covered with moss, it will keep the ground moist, and prevent the drying winds from penetrating the ground, and thereby secure a good crop of fruit; and the moss will preserve the fruit clean, that when heavy rains fall after the fruit is full grown, there will be no dirt washed over them, which frequently happens where this is not practised, so the fruit must be washed before it is fit for the table, which greatly diminishes its flavour.

The soil in which the *Chili* Strawberry is found to succeed best, is a very strong brick earth, approaching near to clay; in this soil I have seen them produce a tolerable good crop, and the fruit has been extremely well flavoured; and where care has been taken to pull off the runners as they are produced from the old plants, they have been as fruitful as the common Hautboy; this I mention from two or three experiments, which have been made by my direction, and not from theory.

There are some persons who are so fond of Strawberries, as to be at any expence to obtain them early in the year, and to continue them as late in the season as possible; therefore should I omit to give some directions for these purposes, they would suppose the book very defective; therefore I shall mention the practice of some few, who have succeeded best in the management of these fruits. I shall begin with directions for obtaining of this fruit early in the spring.

Where there are any hot walls erected in gardens for the producing early fruit, it is very common to see Strawberries planted in the borders, that the fire which is applied for ripening of the fruit against the wall, may serve the purpose of bringing forward the Strawberries; but where this is practised, the Strawberry plants should be annually renewed, and all the earth of the borders should also be taken out at least two feet deep, and fresh earth brought in, which will be equally good for the wall trees; but as was before observed, that the old plants of Strawberries only,

are those which produce the fruit, there should be a sufficient number of plants kept in pots to supply the border annually, and the same must be done if they are to be raised on a common hot-bed, or in stoves; therefore I shall begin with giving directions for the raising and preparing the plants for those purposes.

The sort which is the most proper for forcing early, is the scarlet Strawberry, for the Hautboy grows too large for this purpose, and the Wood is too backward. In the choice of the plants, there should be an especial care taken to have them from the most fruitful plants, and those which grow immediately to the old plants; these should be taken off in the spring, and each planted in a separate pot filled with loamy soil, and placed in the shade till they have taken root, after which they may be removed to a shady situation, where they may remain till the middle of *November*, when the pots should be plunged into the ground up to their rims, to prevent the frost from penetrating through the side of the pots; if these are placed near a wall, pale, or hedge, exposed to an east aspect, they will succeed better than in a warmer situation, because they will not be forced too forward.

Those which are designed for the borders near a hot wall, may then be turned out of the pots, and planted into the borders, that they may have time to get fresh rooting, before the fires are made to heat the walls; when these are planted, they may be placed pretty close to each other, for as they are designed to remain there no longer than till they have ripened their fruit, they will not require much room, because their roots will find sufficient nourishment below, and also from the earth which is filled into the spaces between the balls of earth, about their roots; for it is of consequence to get as much fruit as possible in a small space, where there is an expence to force them early. If the fires are lighted about *Christmas*, the Strawberries in these borders will be ripe the end of *March*; or if the season should prove very cold, it may be the middle of *April* before they are fit for the table.

In the management of the plants there must be care taken to supply them with water when they begin to shew their flowers, otherwise they will fall off without producing any fruit; and, in mild weather, there should be fresh air admitted to them every day; but as fruit trees against the wall must be so treated, the same management will agree with the Strawberries.

If the Strawberries are intended to be forced in a stove, where there are Pine Apples, and no room to plunge them in the tan-bed, then the plants should be transplanted into larger pots in *September*, that they may be well rooted before they are removed into the stove, which should not be till *December*; but if they are placed under a frame the beginning of *November*, where they may be screened from the frost, it will prepare the plants better for forcing; and those who are desirous to have them very early, make a hot-bed under frames, upon which they place their plants the latter end of *October*, which will bring them forward to flower, and then they remove the plants into the stove; when these plants are removed into the stove, they should be placed near to the glassies, that they may enjoy as much of the sun as possible, for when they are placed backward, the plants will draw up weak, and the flowers will drop without producing fruit. The earth in the pots will dry pretty fast when they stand dry upon the pavement of the hot-house, therefore the plants must be duly watered, but it must be done with discretion, and not too much given to them at one time, which will be equally hurtful to them; if these plants are properly managed, they will produce ripe fruit in *February*, which is as early as most people will chuse to eat them. When the fruit is all gathered

thered from the plants, they should be turned out of the stove, for as they will be of no farther service, they should not remain to take up the room; nor should those plants which are planted in the borders near the hot walls, be left there after their fruit is gathered, but immediately taken up, that they may rob the fruit trees of their nourishment as little as possible.

Where there is no conveniency of stoves, or hot walls for this purpose, the fruit may be ripened upon common hot-beds; and though they may not be quite so early as with the other advantages, yet I have seen great crops of the fruit ripe in *April*, which were upon common hot-beds under frames, and done with a small expence in the following manner.

The plants were prepared in pots after the manner before directed, which were placed in a warm situation in the beginning of *October*, and about *Christmas* the hot-bed was made, in the same manner as for Cucumbers, but not so strong, and as soon as the first violent steam of the dung was over, some old rotten dung, laid over the hot-bed to keep down the heat, or where it can be easily procured, neats dung is preferable for this purpose; then the pots should be placed upon the bed as close together as possible, filling up the interstices between the pots with earth; the plants must have air admitted to them every day, and if the heat of the bed is too great, the pots should be raised up, to prevent their roots being scorched, and when the bed is too cold, the sides of it should be lined with some hot dung; this first bed will bring the plants to flower by the middle, or latter end of *February*, by which time the heat of the bed will be spent, therefore another hot-bed should be prepared to receive the plants, which need not be so strong as the first; but upon the hot dung, should be laid some neats dung about two inches thick, which should be equally spread and smoothed, this will prevent the heat of the bed from injuring the roots of the plants; upon this should be laid two inches of a loamy soil; when this has laid two days to warm, the plants should be taken out of the first hot-bed, and turned carefully out of the pots, preserving all the earth to their roots, and placed close together upon this new hot-bed, filling up the vacancies between the balls, with loamy earth; the roots of the plants will soon strike out into this fresh earth, which will strengthen their flowers, and cause their fruit to set in plenty; and if proper care is taken to admit fresh air to the plants, and supply them properly with water, they will have plenty of ripe fruit in *April*, which will be full two months before their natural season.

The methods practised to retard this fruit, is first by planting them in the coldest part of the garden, where they may be as much in shade as possible, and the soil should be strong and cold; when there are such places in a garden, the fruit will be near a month later than in a warm situation; the next is to cut off all the flowers when they first appear, and if the season proves dry, to water them plentifully, which will cause them to put out a fresh crop of flowers; and if they are supplied with water, there will be a late crop of fruit, but these are not so well flavoured as those which ripen in their natural season. But this new Alpine Strawberry will naturally supply the table great part of summer and autumn, and the fruit will be well flavoured.

FRANGULA. *Tourn. Inst. R. H.* 612. *tab.* 383. Berry-bearing Alder.

The Characters are,

The flower hath one petal, cut into five segments. It hath five stamina, which are the length of the petal; in the center is situated a globular germen, which afterward becomes a round berry, inclosing two plain roundish seeds.

The Species are,

1. FRANGULA *foliis ovato-lanceolatis glabris*. Black Berry-bearing Alder.
2. FRANGULA *foliis lanceolatis rugosis*. Berry-bearing Alder with a larger and rougher leaf.
3. FRANGULA *foliis ovatis nervosis*. Low Mountain rocky Berry-bearing Alder, with a round leaf.

The first sort grows naturally in the woods, in many parts of *England*, so is seldom planted in gardens; it rises with a woody stem to the height of ten or twelve feet, sending out many irregular branches, covered with a dark bark, garnished with oval spear-shaped leaves, about two inches long, and one broad, having several transverse veins from the midrib to the sides. The flowers are produced in clusters at the end of the former year's shoots, and also upon the first and second joints of the same year's shoot, each standing upon a short separate foot-stalk; they are small, of an herbaceous colour, and are succeeded by small round berries, which turn first red, but are black when ripe. The flowers appear in *June*, and the berries ripen in *September*; this stands in the Dispensatory as a medicinal plant, but is seldom used.

The second sort hath larger and rougher leaves than the first. It grows naturally on the *Alps*, and other mountainous parts of *Europe*, and is preserved in some gardens for the sake of variety.

The third sort is of humble growth, seldom rising above two feet high; this grows on the *Pyrenean* mountains, and is seldom preserved, unless in botanick gardens for variety; it may be increased by laying down the branches, but must have a strong soil.

These shrubs are easily propagated by seeds, which should be sown as soon as they are ripe, and then the plants will come up the spring following; but if they are kept out of the ground till spring, the plants will not come up till the second year. When the plants come up, they must be kept clean from weeds till autumn, then they may be taken up and planted in a nursery, in rows two feet asunder, and at one foot distance in the rows; in this nursery they may remain two years, and may then be planted where they are to remain; they may also be propagated by layers and cuttings, but the seedling plants are best.

FRAXINELLA. See Dictamnus.

FRAXINUS. *Lin. Gen. Plant.* 1026. The Ash tree.

The Characters are,

It hath hermaphrodite and female flowers on the same tree, and sometimes on different trees. The hermaphrodite flowers have no petals, but a small empalement including two erect stamina. In the center is situated an oval compressed germen, which afterward becomes a compressed bordered fruit, shaped like a bird's tongue, having one cell, inclosing a seed of the same form. The female flowers are the same, but have no stamina.

The Species are,

1. FRAXINUS *foliolis serratis, floribus apetalis*. *Lin. Sp. Plant* 1057. The common Ash.
2. FRAXINUS *foliolis ovato-lanceolatis serratis, floribus coloratis*. Ash tree with a rounder leaf, commonly called Manna Ash.
3. FRAXINUS *foliolis serratis, floribus corollatis*. *Lin. Sp. Plant.* 1057. Dwarf Ash of *Theophrastus*, with smaller and narrower leaves.
4. FRAXINUS *foliolis lanceolatis glabris, floribus paniculatis terminatricibus*. The flowering Ash.
5. FRAXINUS *foliolis integerrimis, petiolis teretibus*. *Flor. Virg.* 122. *New England* Ash, with long acute points to the wings of the leaves.
6. FRAXINUS *foliolis lanceolatis, minimè serratis, petiolis teretibus pubescentibus*. *Carolina* Ash with a broad fruit.

The first sort is the common Ash tree, which grows naturally in most parts of *England*, and is so well known as to need no description. The leaves of this sort have generally five pair of lobes, terminated by an odd one; they are of a very dark green, and their edges are slightly sawed. The flowers are produced in loose spikes from the side of the branches, which are succeeded by flat seeds, which ripen in autumn; there is a variety of this with variegated leaves, which is preserved in some gardens.

The second sort grows naturally in *Calabria*, and is generally supposed to be the tree from whence the manna is collected, which is an exudation from the leaves of the tree. The shoots of this tree are much shorter, and the joints closer together, than those of the first sort; the small leaves are shorter, and deeper sawed on their edges, and are of a lighter green. The flowers come out from the side of the branches, which are of a purple colour, and appear in the spring before the leaves come out. This tree is of humble growth, seldom rising more than fifteen or sixteen feet high in *England*.

The third sort is a low tree, which rises about the same height as the second; the leaves of this sort are much smaller and narrower than those of the first, but are sawed on their edges, and are of the same dark colour. The flowers of this sort have petals, which are wanting in the common Ash.

The fourth sort was raised by the late Dr. *Uvedale* at *Enfield*, from seeds which were brought from *Italy* by Dr. *William Skérard*, where the trees grow naturally; and was supposed to be a different sort from that mentioned by Dr. *Morrison*, in his *Praeludia Botanica*, but by comparing them together they appear to be the same.

The leaves of this sort have but three or four pair of lobes (or small leaves) which are short, broad, and smooth, of a lucid green, irregularly sawed on the edges. The flowers grow in loose panicles at the end of the branches; these are most of them male, having two stamina in each, but no germen or style; they are of a white herbaceous colour, and appear in *May*. As this sort very rarely produces seeds in *England*, so it is propagated by grafting or budding it upon the common Ash.

The fifth sort was raised from seeds, which were sent from *New England* in the year 1724, by Mr. *Moore*. The leaves of this tree have but three, or at most but four pair of lobes, which are placed far distant from each other, and are terminated by an odd one, which runs out into a very long point; they are of a light green and entire, having no serratures on their edges: this tree shoots into strong irregular branches, but doth not grow to a large size in the trunk. It is propagated by grafting it upon the common Ash.

The sixth sort was raised from seeds, which were sent from *Carolina* in the year 1724, by Mr. *Catesby*. The leaves of this sort have seldom more than three pair of lobes, the lower being the least, and the upper are the largest; of a light green colour, and slightly sawed on their edges; the foot-stalk, or rather the midrib of the leaves is taper, and has short downy hairs; the seeds are broader than those of the common Ash, and are of a very light colour. As this sort hath not yet produced seeds in *England*, it is propagated by grafting it upon the common Ash.

These trees are now propagated in plenty in the nurseries for sale, as there has been of late years a great demand for all the hardy sorts of trees and shrubs, which will live in the open air; but all those trees which are grafted upon the common Ash, are not so valuable as those which are raised from seeds, because the stock generally grows much faster than the grafts; whereby the lower part

of the trunk, so far as the stock rises, will often be twice the size of the upper; and if the trees stand much exposed to the wind, the grafts are frequently broken off to the stock, after they are grown to a large size, which is a great disappointment to a person after having waited several years, to see their trees suddenly destroyed. Beside, if the wood of either of the sorts is valuable, it can be of little use when the trees are so raised.

The fourth sort is generally planted for ornament, the flowers making a fine appearance when they are in beauty, every branch being terminated by a large loose panicle; so that when the trees are large, and covered with flowers, they are distinguishable at a great distance.

All the other sorts serve to make a variety in plantations, but have little beauty to recommend them; and as their wood seems to be greatly inferior to that of the common Ash, so there should be few of these planted, because they will only fill up the space where better trees might grow.

The common Ash propagates itself in plenty by the seeds which scatter in the autumn, so that where the seeds happen to fall in places where cattle do not come, there will be plenty of the plants come up in the spring; but where any person is desirous to raise a quantity of the trees, the seeds should be sown as soon as they are ripe, and then the plants will come up the following spring; but if the seeds are kept out of the ground till spring, the plants will not come up till the year after, which is the same with all the sorts of Ash; so that when any of their seeds are brought from abroad, as they seldom arrive here before the spring, the plants must not be expected to appear till the next year; therefore the ground should be kept clean all the summer where they are sown, and not disturbed, lest the seeds should be turned out of the ground, or buried too deep to grow; for many persons are too impatient to wait a year for the growth of seeds, so that if they do not come up the first year, they dig up the ground, and thereby destroy the seeds,

When the plants come up, they must be kept clean from weeds during the summer; and if they make good progress in the seed-bed, they will be fit to transplant by the following autumn, therefore there should be some ground prepared to receive them; and as soon as their leaves begin to fall, they may be transplanted. In the taking of them up, there should be care taken not to break or tear off their roots; to prevent which, they should be taken up with a spade, and not drawn up, as is frequently practised; for as many of the plants which rise first from seeds, will out-strip the others in their growth, so it is frequently practised, to draw up the largest plants, and leave the smaller to grow a year longer before they are transplanted; and to avoid hurting those which are left, the others are drawn out by hand, and thereby many of their roots are torn off or broken; therefore it is much the better way to take all up, little or big together, and transplant them out, placing the large ones together in rows, and the smaller by themselves. The rows should be three feet asunder, and the plants a foot and a half distance in the rows; in this nursery they may remain two years, by which time they will be strong enough to plant where they are to remain; for the younger they are planted out, the larger they will grow; so that where they are designed for use, they should be planted very young; and the ground where the plants are raised, should not be better than that where they are designed to grow; for when any plants are raised in good land, and afterward transplanted into worse, they very rarely thrive; so that it is much the best method to make the nursery upon a part of the same land, where the trees are designed to be planted, and then a sufficient number

ber of the trees may be left standing upon the ground, and these will out-strip those which are removed, and will grow to a larger size.

Where people live in the neighbourhood of Ash trees, they may supply themselves with plenty of self-sown plants, provided cattle are not suffered to graze on the land, for if cattle can come to them they will eat off the young plants, and not suffer them to grow; but where the seeds fall in hedges, and are protected by bushes, the plants will come up and thrive; in these hedges the trees frequently are permitted to grow till they have destroyed the hedge, for there is scarce any tree so hurtful to all kinds of vegetables as the Ash, which robs every plant of its nourishment within the reach of its roots, therefore should never be suffered to grow in hedge-rows; for they not only kill the hedge, but impoverish Corn, or whatever is sown near them. Nor should any Ash trees be permitted to grow near pasture grounds, for if any of the cows eat of the leaves or shoots of the Ash, all the butter which is made of their milk will be rank and of little or no value; which is always the quality of the butter which is made about *Guildford, Godalmin*, and some other parts of *Surry*, where there are Ash trees growing about all their pastures, so that it is very rare to meet with any butter in those places which is fit to eat; but in all the good dairy counties, they never suffer an Ash tree to grow.

If a wood of these trees is rightly managed, it will turn greatly to the advantage of its owner; for by the under-wood, which will be fit to cut every eight or ten years, there will be a continual income more than sufficient to pay the rent of the ground, and all other charges; and still there will be a stock preserved for timber, which in a few years, will be worth forty or fifty shillings per tree.

This timber is of excellent use to the wheelwright and cartwright for ploughs, axle-trees, wheel-rings, harrows, bulls, oars, blocks for pullies, and many other purposes.

The best season for felling of these trees is from *November* to *February*; for if it be done either too early in autumn, or too late in the spring, the timber will be subject to be infested with worms, and other insects; but for lopping of Pollards, the spring is preferable for all soft woods.

FRITILLARIA. *Lin. Gen. Plant.* 372. Fritillary, or chequered Tulip and Crown Imperial.

The Characters are,

The flower hath no empalament; it hath six oblong bell-shaped petals; in the hollow, at the base of each petal, is situated a nectarium; the flower hath six stamina standing near the style. In the center is situated an oblong three-cornered germen, which afterward becomes an oblong capsule with three lobes, having three cells, which are filled with flat seeds ranged in a double order.

The Species are,

1. **FRITILLARIA** *foliis linearibus alternis, floribus terminalibus.* Early, purple, variegated, chequered Tulip.
2. **FRITILLARIA** *foliis infimis oppositis.* *Hort. Cliff.* 81. *Aquitain* chequered Tulip, with an obscure yellow flower.
3. **FRITILLARIA** *floribus ascendensibus.* Fritillary with flowers growing above each other; or, Black chequered Tulip.
4. **FRITILLARIA** *foliis lanceolatis, caule unifloro maximo.* Largest yellow *Italian* Fritillary.
5. **FRITILLARIA** *floribus umbellatis.* Fritillary with flowers growing in umbels.
6. **FRITILLARIA** *racemo nudiusculo, foliis obliquis.* *Hort. Upsal.* 82. The *Persian* Lily.
7. **FRITILLARIA** *floribus racemosis.* Branching Fritillary, or smaller *Persian* Lily.

8. **FRITILLARIA** *racemo comofo infernè nudo, foliis integerrimis.* *Lin. Hort. Upsal.* 82. Crown Imperial.

9. **FRITILLARIA** *racemo comofo infernè nudo, foliis crenatis.* *Lin. Sp. Plant.* 303. Royal Crown, with a crenated Lily leaf.

The first sort grows naturally in *Italy*, and other warm parts of *Europe*; and from the seeds of this there have been great varieties raised in the gardens of the florists, which differ in the size and colour of their flowers; and as there are frequently new varieties produced, so it would be to little purpose to enumerate those which are at present in the *English* and *Dutch* gardens.

The first hath a round compressed root, in shape like that of Corn Flag, but is of a yellowish white colour; the stalk rises about fifteen inches high, having three or four narrow long leaves placed alternately; the top is divided into two slender foot stalks, which turn downward, each sustaining one bell-shaped inverted flower, composed of six petals, which are chequered with purple and white like a chess-board; in the center is situated a germen supporting one style, crowned by a trisid stigma. At the bottom of each petal there is a cavity, in which is situated a nectarium; filled with a sweet liquor; after the flower is fallen, the germen swells to a pretty large, three-cornered, blunt capsule, then the foot-stalk is turned and stands erect; when the seeds are ripe, the capsule opens in three parts and lets out the flat seeds, which were ranged in a double order.

The second sort grows naturally in *France*; the leaves of this are broader, and of a deeper green than the former; the lower leaves are placed opposite, but those above are alternate; the stalk rises a foot and a half high, is terminated by two flowers of an obscure yellow colour, which spread more at the brim than those of the first sort, but are turned downward in the same manner. This flowers three weeks after the first. This grows naturally in some parts of *England*.

The third sort seldom rises more than a foot high, the leaves are narrow like those of the first, but are shorter; each stalk is terminated by three or four flowers, which arise above each other, of a very dark purple, chequered with yellowish spots.

The fourth sort rises about a foot high, the stalk is garnished with spear-shaped leaves, of a Grass green colour; these are sometimes placed opposite, but generally alternate; the stalk is terminated by one large bell-shaped flower of a yellowish colour, chequered with light purple.

The fifth sort rises a foot and a half high; the stalk is garnished with shorter and broader leaves than the first sort, of a grayish colour; the flowers are produced round the stalks like those of the Crown Imperial, of a dark purple colour, chequered with a yellowish green.

The sixth sort is commonly called the *Persian* Lily, and is supposed to grow naturally in *Persia*; the root of this sort is round and large, the stalk rises three feet high; the lower part of it is closely garnished with long twisted leaves of a gray colour, standing on every side of the stalks; the flowers grow in a loose spike at the top of the stalk, forming a pyramid; they are shaped like those of the other species, but are much shorter, and spread wider at their brims, and are not bent downward like those. They are of a dark purple colour, but are seldom succeeded by seeds in *England*, so are only propagated by offsets.

The seventh sort has a much shorter stalk than the last, but is garnished with leaves like those, only they are smaller; the stalks branch out at the top into several small foot-stalks, each sustaining one dark coloured flower. This is commonly called the small *Persian* Lily, from its resemblance to the former sort.

These plants are propagated either by seeds, or offsets from the old roots; by the first of which methods new varieties may be obtained, as also a larger stock of roots in three years, than can be obtained in twenty or thirty years in the latter method: I shall therefore first treat of their propagation by seeds.

Having provided yourself with some good seeds, saved from the fairest flowers, you must procure some shallow pans or boxes, which must have holes in their bottoms to let out the moisture; these should be filled with light fresh earth, laying a few potshards over the holes, to prevent the earth from stopping them; then, having laid the earth very level in the boxes, &c. you must sow the seeds thereon pretty close, covering it with fine sifted earth a quarter of an inch thick. The time for sowing the seed is about the beginning of *August*, for if it be kept much longer out of the ground it will not grow. The farther management of the seeds, being the same as for the seeds of Tulips and Hyacinths, need not be repeated here.

When the seedling plants shew their flowers, which is generally the third year from sowing, you should put down a mark to the roots of all such as produce fair flowers, that at the time of taking them out of the ground (which ought to be soon after their green leaves are decayed), they may be selected for to plant in the borders of the parterre-garden, where; being intermixed with other flowers of different seasons, they will make a good appearance.

When a stock of good flowers are obtained, they may be preserved and increased in the same manner as other bulbous-rooted flowers, which is by offsets sent out from their roots, which should be taken off every other year from the finest sorts; but the ordinary flowers may remain three years undisturbed, in which time they will have multiplied so much, as that each root will have formed a cluster; so that if they are left longer together, the roots will be small, and the flowers very weak; therefore if these are taken up every other year, the roots will be the stronger. These roots may be treated in the same manner as Tulips, and other bulbous rooted flowers, with this difference only, that the roots of this will not bear to be kept out of the ground so long; therefore if there should be a necessity for keeping them out of the ground for a longer time, it will be best to put the roots into sand to prevent their shrinking.

The eighth sort is the Crown Imperial, which is now very common in the *English* gardens. This grows naturally in *Persia*, from whence it was first brought to *Constantinople*, and about the year 1570, was introduced to these parts of *Europe*; of this there are a great variety of sorts now preserved in the gardens of florists, but as they have been produced accidentally from seeds, so they may be included as one species; however, for the satisfaction of the curious, I shall here mention the varieties which have come to my knowledge.

1. The common Crown Imperial; this is of a dirty red colour.
 2. The yellow Crown Imperial; this is of a bright yellow.
 3. The bright red Crown Imperial, called Fusiai.
 4. The pale yellow Crown Imperial.
 5. The yellow striped Crown Imperial.
 6. The large flowering Crown Imperial.
 7. The broad leaved late red Crown Imperial.
 8. The double and triple crowned Crown Imperial.
 9. The double red Crown Imperial.
 10. The double yellow Crown Imperial.
 11. The silver striped leaved Crown Imperial.
 12. The yellow striped leaved Crown Imperial.
- There are some few other varieties which are mentioned

in the catalogues of the *Dutch* florists, but their differences are so minute, that they are not distinguishable, so I shall pass them over.

The Crown Imperial hath a large, round, scaly root of a yellow colour, and a strong odour of a fox; the stalk rises to the height of four feet or upward, it is strong, succulent, and garnished two thirds of the length on every side, with long, narrow, smooth leaves ending in points; the upper part of the stalk is naked, a foot or more in length; then the flowers come out all round the stalk upon short foot-stalks which turn downward, each sustaining one large spreading bell-shaped flower, composed of six spear-shaped petals; at the base of each petal is a pretty large cavity, in which is situated a large white nectarium, filled with a mellous liquor. In the center of the flower is fixed a three-cornered oblong germen, upon which rests the single style, which is the length of the petals, crowned by a spreading obtuse stigma; round the style there are six awl-shaped stamina which are shorter than the style, terminated by oblong four-cornered summits. These flowers hang downward; above and among them, arises a spreading tuft of green leaves which are erect, from between and below these come out the foot-stalks of the flowers; when the flowers decay, the germen swells to a large hexagonal capsule, shaped like a water-mill, having six cells which are filled with flat seeds, and the capsule turns erect.

The sort with yellow flowers, that with large flowers, and those with double flowers, are the most valuable; but that which hath two or three whorls of flowers above each other, makes the finest appearance; though this seldom produces its flowers after the same manner the first year after removing, but the second and third year the stalks will be taller, and frequently have three tier of flowers one above the other, which is called the triple crown.

As this is one of the earliest tall flowers of the spring, so it makes a fine appearance in the middle of large borders, at a season when such flowers are much wanted to decorate the pleasure-garden; but the rank fox-like odour which they emit, is too strong for most people, so hath rendered these flowers less valuable than they would have been, for there is something very pleasing in the sight of them at a distance.

These may be propagated by seeds, or offsets from the root; but the first is too tedious for most of the *English* florists, because the plants, so raised, are six or seven years before they flower; but the *Dutch* and *Flemish* gardeners, who have more patience, frequently raise them from seeds, whereby they get some new varieties, which rewards their labour. The method of propagating these flowers from seeds, being nearly the same as for the Tulip, the reader is desired to turn to that article; where there are full directions for performing it.

The common method of propagating them here, is by offsets sent out from the old roots, which will produce strong flowers the second year, after they are taken from the roots, but in order to have plenty of these, the roots should not be transplanted oftener than every third year, by which time each root will have put out several offsets, some of which will be large enough to flower the following year, so may be planted in the borders of the flower-garden, where they are to remain, and the smaller roots may be planted in a nursery-bed to grow a year or two according to their size; therefore they should be sorted, and the smallest roots planted in a bed together, which should remain there two years, and the larger by themselves to stand one year, by which time they will have acquired strength enough to flower, then may be removed into the pleasure-garden.

The time for taking up of these roots, is in the begin-

ning of July, when their stalks will be decayed; they may be kept out of the ground two months, but they should be laid single in a dry shady room, but not in heaps, or in a moist place, which will cause them to grow mouldy and rot. The offsets should be first planted, for as these are small, they will be apt to shrink if they are kept long out of the ground.

FRITILLARIA CRASSA. See Stape'ia.

FRUTEX PAVONIUS. See Poinciana.

FUCHSIA. Plum. Nov. Gen. 14.

The Characters are,

The flower hath one petal, with a closed tube, slightly cut into eight parts at the brim; it hath four stamina the length of the tube. The oval germen is situated under the flower, which after-ward becomes a succulent berry with four cells, containing several small oval seeds.

We know but one Species of this genus at present, viz.

FUCHSIA. Lin. Sp. Plant. 1191. Three-leaved Fuchsia, with a scarlet flower.

This plant is a native in the warmest parts of America; it was discovered by Father Plumier, in some of the French islands in America, and was since found by the late Dr. William Housloun, at Carthagena, in New-Spain.

It is propagated by seeds, which must be sown in pots, and plunged into a hot-bed of tanners bark, and treated in the same way as other seeds from warm countries. In about a month or six weeks after the seeds are sown, the plants will begin to appear; when they are about two inches high, they should be shaken out of the pots, and separated carefully; planting each into a small pot, and plunged again into a hot-bed of tanners bark, screening them from the sun, until they have taken new root; then they must have fresh air admitted to them, in proportion to the warmth of the season. As the season advances and becomes warm, the glasses of the hot-bed should be raised higher, to admit a greater share of air to the plants; and when the plants are grown so tall as to reach the glasses, they should be removed into the bark stove, and plunged into the tan-bed. In winter these plants require to be kept very warm, and at that season they must not have much water, but in summer it must be often repeated, and have much air in warm weather.

FUMARIA, Lin. Gen. Plant. 760. Fumatory.

The Characters are,

The flower is of the ringent kind, approaching near to the butterfly flowers. The upper lip is plain, obtuse, and reflexed; the nectarium at the base is obtuse, and little prominent. The base is keel-shaped; the nectarium at the base is less prominent. The chaps of the flower is four-cornered, and perpendicularly bifid. In the center is situated an oblong germen, which after-ward becomes a short pod with one cell, including roundish seeds.

The Species are,

1. FUMARIA pericarpis monospermis racemosis, caule diffuso. Lin. Sp. Plant. 700. Common Fumatory with a purple flower.

2. FUMARIA pericarpis monospermis spicatis, caule erecto, foliis filiformibus. Sauv. Monsp. 263. Lesser narrow-leaved Fumatory.

3. FUMARIA siliquis linearibus tetragonis, caulibus diffusis acutangulis. Lin. Sp. Plant. 700. Ever-green Fumatory with a white flower.

4. FUMARIA siliquis teretibus, caulibus diffusis, angulis obtusis. Yellow Tangier Fumatory.

5. FUMARIA siliquis linearibus, foliis cirrhiferis. Lin. Sp. Plant. 701. Fumatory with tendrils.

6. FUMARIA pericarpis monospermis racemosis, foliis scandentibus subcirrhosis. Lin. Sp. Plant. 701. Greater climbing Fumatory with a paler flower.

7. FUMARIA caule simplici, bracteis longitudine florum. Lin. Sp. Plant. 699. Greater bulbous Fumatory with a hollow root.

8. FUMARIA caule simplici, bracteis brevioribus multifidis, radice solidâ. Greater bulbous Fumatory with a solid root.

9. FUMARIA scapo nudo. Hort. Cliff. 351. Tuberous infusid Fumatory.

10. FUMARIA siliquis globosis inflatis. Hort. Upsal. 207. Climbing African Cysticapnos.

11. FUMARIA foliis triternatis, foliolis cordatis. Lin. Sp. Plant. 700. Nine-leaved Rock Fumatory of Spain.

12. FUMARIA siliquis linearibus paniculatis, caule erecto. Hort. Upsal. 207. Bastard Fumatory.

The first sort is the common Fumatory which is used in medicine, which grows naturally on arable land in most parts of England; it is a low annual plant, and flowers in April, May, and June; and very often from plants which rise late in the summer, there will be a second crop in autumn. The juice of this plant is greatly commended for bilious cholics. It is never cultivated in gardens.

The second sort grows naturally in the south of France, Spain, and Portugal, but is preserved in botanick gardens for the sake of variety. It is an annual plant, which rises from the scattered seeds better than when it is sown with care; the stalks of this grow more erect, the leaves are very finely divided, and the flowers grow in a close spike; they are of a deep red colour, and flower about the same time as the common sort.

The third sort grows naturally on the borders of the Mediterranean sea; it was first brought to England from Tangier. This is a perennial plant, which sends out from the root many branching stalks, which rise about six or eight inches high, growing in tufts or bunches; the leaves are very much divided, the stalks are angular, and the flowers grow in loose panicles upon naked foot-stalks, which come out from the divisions of the branches; they are of a whitish yellow colour, and there is a succession of them most part of the year.

The fourth sort hath an appearance very like the third, and by some it is supposed to be only a variety of that, but is undoubtedly a distinct species; for I have cultivated both more than thirty years, and never yet found either of them to vary. The stalks of this sort have blunt angles, whereas those of the third are acute; they are of a purplish colour, and the flowers grow in looser panicles, each having a longer foot-stalk than those of the other; they are of a bright yellow colour, and there is a succession of them great part of the year.

These two sorts continue green all the year, and except in very severe frost, are always in flower, which make a pretty appearance; they grow best on walls or rocks, and are very proper for the joints of grottos, or any rock-work; where, if a few plants are planted, or the seeds scattered, they will multiply fast enough from their scattering seeds, which are cast out of the pods by the elastic spring of the valves when ripe, to a considerable distance; and as the plants will require no care to cultivate them, they should not be wanting in gardens.

The fifth sort grows in stony and sandy places, in some parts of England; it is an annual plant with trailing stalks, sending out claspers from the leaves, which fasten to any of the neighbouring plants. It flowers in May and June, but is never cultivated in gardens.

The sixth sort is an annual plant with many trailing stalks, which grow about a foot long, sending out a few short tendrils, whereby they fasten to any neighbouring support; the flowers come out from the side of the stalks in loose bunches, they are of a whitish herbaceous colour, with a purple

purple spot on the upper lip. This flowers in *May* and *June*. It grows in *France* and *Italy*, on stony places in the shade.

The seventh sort grows naturally in the south of *France* and *Italy*, and was some years past preserved in the *English* gardens by way of ornament, but is now rarely to be found here; it was titled *Radix cava*, or hollow root, from its having a pretty large tuberous root hollowed in the middle. The stalk of this sort rises about six inches high, and does not divide, but is garnished toward the bottom with one ramous leaf, somewhat like the common *Fumatory*, but the lobes are broader; the flowers grow in a spike at the top of the stalk, they are of a pale purplish colour, and appear in *May*. This plant delights in the shade, and is multiplied by offsets, for it rarely ripens seeds in *England*.

The eighth sort is pretty common in many of the old gardens in *England*; it grows naturally in the south of *France*, in *Germany* and *Italy*. It hath a pretty large, round, solid root of a yellowish colour, from which come out branching leaves like those of the last sort, but the lobes are longer; the flowers grow in spikes on the tops of the stalks, they are of a purple colour, and come out early in *April*. The stalks of this sort are single, and rise about four or five inches high.

There is a variety of this with green flowers, which is mentioned in most of the books; but all the plants of this sort which I have yet seen, are only abortive, having no real flower, only a green bractea, which has been generally taken for the flowers.

The ninth sort grows naturally in *North America*; this hath a scaly root about the size of a large Hazel nut, from which comes out three or four leaves upon slender foot-stalks, divided into three parts; each of these parts is composed of many smaller divisions, which have narrow lobes divided into three parts almost to the bottom; the flower-stalk is naked, and eight or nine inches long, terminated by four or five flowers, growing in a loose spike; these have two petals, which are reflexed backward, and form a sort of fork toward the foot-stalk, and at their base are two horned nectariums, which stand horizontal. The flowers are of a dirty white colour and appear in *May*, but rarely produce seeds here.

This is propagated by offsets from the root, it loves a shady situation and a light soil; the best time to transplant the roots is in autumn, when the leaves are decayed, for it shoots pretty early in the spring, therefore it would not be safe to remove them at that season.

The tenth sort grows naturally at the *Cape of Good Hope*; this is an annual plant, with trailing stalks which are two or three feet long, dividing into many smaller, which are garnished with fine branching leaves shaped like those of the common *Fumatory*, but end with tendrils, which clasp to any neighbouring plants, and thereby the stalks are

supported; the flowers are produced in loose panicles, which proceed from the side of the stalks; they are of a whitish yellow colour, and are succeeded by globular swollen pods, in which are contained a row of small shining seeds.

This is propagated by seeds, which should be sown upon a moderate hot-bed in the spring, and when the plants are fit to remove, they must be each planted in a small pot filled with light earth, and plunged again into the hot-bed, and shaded from the sun till they have taken new root; then they should have a large share of air admitted to them, at all times in mild weather; as soon as the season is favourable, they should be inured to bear the open air, into which they may be removed the beginning of *June*, when they may be shaken out of the pots, preserving all the earth to their roots, and planted in a warm border, where their stalks should be supported with sticks to prevent their trailing on the ground; in *July* the plants will flower, and continue a succession of flowers till the frost destroys the plants; the seeds ripen in autumn.

The eleventh sort grows naturally upon old walls, or rocky places in *Spain* and *Italy*; this hath weak trailing stalks which are much divided, garnished with small leaves divided into three parts, each of which hath three heart-shaped lobes; the flowers are produced in small loose panicles from the side of the stalks, they are of a greenish white, and appear most of the summer months. It is an abiding plant, which propagates itself by the seeds that scatter, and thrives best in a shady situation, and on old walls or buildings.

The twelfth sort is an annual plant with an upright stalk, which grows a foot and a half high, sending out several branches upward, garnished with smooth branching leaves of a pale colour, divided like the common sort, but the lobes are larger and more obtuse; the flowers are produced in loose panicles from the sides of the stalks, and at the extremity of the branches; of a pale purple colour, with yellow chaps (or lips); these are succeeded by taper narrow pods, which contain many small shining black seeds. This flowers during most of the summer months, and the seeds ripen in *July*, *August*, and *September*. If the seeds of this plant are permitted to scatter, the plants will come up without any trouble, and require no other care but to thin them where they are too close, and keep them clean from weeds.

The fifth, sixth, seventh, and eighth sorts are propagated by offsets, as other bulbous-rooted flowers; these are pretty ornaments to borders in a small flower-garden early in the spring. They are extreme hardy; they love a light sandy soil, and should be suffered to remain three years undisturbed, in which time they will produce many offsets. The best season for transplanting them is from *May* to *August*, when the leaves die off; for if they are taken up when their leaves are fresh, it will greatly weaken their roots.

FURZ. See *Genista*.

G.

G A L

GALANTHUS. *Lin. Gen. Plant.* 362. The Snow-drop.

The Characters are,

The flower has three oblong concave petals, which spread open; in the bottom is situated the three-leaved nectarium, which is cylindrical; under the flower is situated the oval germen, attended by six stamina, which are gathered together. The germen afterward becomes an oval capsule, opening in three cells, filled with roundish seeds.

We know but one Species of this genus, which is,

GALANTHUS. *Lin. Hort. Cliff.* 134. The common Snow-drop.

There is a variety of this with double flowers.

This is valued for its early appearance in the spring, for the flowers usually blow in February when the ground is often covered with snow. The single sort comes out the first, and though the flowers are but small, yet when the roots are in bunches, they make a very pretty appearance; therefore these roots should not be planted single, as is sometimes practised by way of edging to borders; for when they are so disposed, they make very little appearance. But when there are twenty or more roots growing in a close bunch, the flowers have a very good effect; and as these flowers thrive well under trees or hedges, they are very proper to plant on the sides of wood-walks, and in wilderness quarters; where, if they are suffered to remain undisturbed, the roots will multiply exceedingly. The roots may be taken up the latter end of June, when their leaves decay, and may be kept out of the ground till the end of August, but they must not be removed oftener than every third or fourth year.

GALE. See Myrica.

GALEGA. *Lin. Gen. Plant.* 770. Goat's-rue.

The Characters are,

The flower is of the butterfly kind; the standard is oval, large, and reflexed; the wings are near the length of the standard; the keel is erect, oblong, and compressed; it has ten stamina which join above their middle. In the center is situated a narrow cylindrical germen, which afterward becomes a long pointed pod, inclosing several oblong kidney-shaped seeds.

The Species are,

1. **GALEGA foliolis lanceolato-linearibus, siliquis tenuioribus.** Common Goat's-rue with blue flowers.

2. **GALEGA foliolis lanceolatis, obtusis, floribus spicatis longioribus, siliquis crassioribus.** African Goat's-rue, with larger flowers and thicker pods.

3. **GALEGA foliis ovatis, floribus paniculatis alaribus, caule fruticoso scandente.** American Goat's-rue, with roundish leaves, scarlet flowers, and shrubby climbing stalks.

The first sort grows naturally in Italy and Spain, but is propagated in the English gardens for medicinal use. It hath a perennial root, from which arise many channelled hollow stalks, from two to three feet high, garnished with winged leaves, composed of six or seven pair of narrow spear-shaped lobes, terminated by an odd one; the flowers terminate the stalks growing in spikes, of a pale blue

G A L

colour, and are succeeded by taper pods, with one row of kidney-shaped seeds.

There is a variety of this with white flowers, and another with variegated flowers, which have accidentally been produced from seeds, so are not constant, therefore are only mentioned here.

The second sort grows naturally in Africa; this differs from the former, in having larger leaves, which are composed of eight or ten pair of lobes, broader and blunter at their ends than those of the common sort; the flowers are larger, and the spikes are longer; the seed pods are also much thicker than those of the common sort, but in other respects are very like it.

These plants are propagated by seeds, which may be sown either in the spring or autumn, in an open situation; when the plants come up, and are strong enough to remove, a spot of ground should be prepared, in size proportionable to the quantity of plants designed; which should be well dug, and cleared from the roots of all noxious weeds; then the plants should be carefully taken up and planted in rows at a foot and a half distance every way, observing to water them till they have taken new root; after which they will require no farther care, but to keep them clean from weeds; if their stalks are cut down before the seeds are formed every year, the roots will continue the longer, especially if they grow on a light dry soil. The seeds of these will grow wherever they are permitted to scatter, so that plenty of the plants will come up without any care, and these may be transplanted and managed in the same manner as is before directed.

The third sort was discovered by the late curious botanist Dr. William Houstoun, at Campeachy. This plant is propagated by seeds, which must be sown on a hot-bed early in the spring; when the plants come up, and are fit to transplant, they must be each put into a separate small pot, and plunged into a hot-bed of tanners bark, shading them from the sun till they have taken new root; then they must be treated as hath been directed for other tender plants, which are kept in the bark-stove. With this management they will flower, and in warm seasons will perfect their seeds, but the plants may be preserved through one winter in the bark-stove.

GALENIA. *Lin. Gen. Plant.* 443.

The Characters are,

The flower hath no petals, but eight hairy stamina the length of the empalement. In the center is situated a roundish germen. The empalement afterward becomes a roundish capsule with two cells, containing two oblong angular seeds.

We know but one Species of this genus, viz.

GALENIA. *Hort. Cliff.* 150. Shrubby Galenia.

This plant grows naturally at the Cape of Good Hope, and in other parts of Africa; it rises with a shrubby stalk four feet high, sending out many weak branches, garnished with very narrow leaves placed irregularly, of a light green, with a furrow running longitudinally through the middle; the flowers are produced in loose panicles, from the side

and at the end of the branches; they are very small, and have no petals like the *Chenopodium*.

This plant must be placed in the green-house in winter, with other hardy exotick plants, where it may have a large share of air in mild weather, for it only requires to be protected from frost. In the summer it may be exposed in the open air, with other plants of the same country. It may be propagated by cuttings, which, if planted during any of the summer months, and watered frequently, will take root in about five or six weeks, and may then be treated as is directed for the old plants.

GALEOPSIS. *Lin. Gen. Plant.* 637. Stinking Dead Nettle.

The Characters are,

The flower is of the lip kind; the chaps are broad, from the base to the under lip, it is on both sides sharply indented; the upper lip is concave, and sawed at the top; the under lip is trifid, the middle segment being the largest. It hath four stamina, two being shorter than the other. In the center is situated a quadrifid germen, which afterward become four naked seeds, sitting in the rigid empalement.

The Species are,

1. **GALEOPSIS internodiis caulinis æqualibus, verticillis omnibus remotis.** *Lin. Sp. Plant.* 579. Red narrow-leaved Field Ironwort.

2. **GALEOPSIS internodiis supernè incrassatis, verticillis summis subcontiguis.** *Lin. Sp. Plant.* 579. Common Dead Nettle with a Hemp leaf.

3. **GALEOPSIS corollâ flavâ, labio inferiore maculato.** *Flor. Lapp.* 193. Prickly Hemp Dead Nettle, with a beautiful yellow flower and purple lips.

4. **GALEOPSIS verticillis sexfloris, involucre tetraphyllo.** *Lin. Sp. Plant.* 780. Stinking Dead Nettle with a yellow flower.

These are all of them annual plants, except the fourth sort; they grow naturally in *England*. The first is found upon arable land in many places; the second grows upon dunghills, and by the side of paths, in most parts of *England*. The third sort grows chiefly in the northern counties, but I have accidentally found it growing wild in *Essex*, within ten miles of *London*. These plants are seldom cultivated in gardens, for if their seeds are permitted to scatter, the plants will come up as weeds wherever they are allowed a place.

The fourth is a perennial plant with a creeping root, which grows in the woods and under hedges in most parts of *England*.

GALEOPSIS FRUTESCENS. See *Prasium*.

GALIUM. *Lin. Gen. Plant.* 117. Ladies Bedstraw, or Cheese-rennet.

The Characters are,

The flower hath one petal, divided into four parts, and four awl-shaped stamina. It hath a twin germen situated under the flower, which afterward become two dry berries, joined together, each inclosing a large kidney-shaped seed.

The Species are,

1. **GALIUM foliis octonis linearibus sulcatis, ramis floriferis brevibus.** *Hort. Cliff.* 34. Yellow Ladies Bedstraw.

2. **GALIUM foliis octonis ovatis linearibus subserratis patentissimis mucronatis, caule flaccido, ramis patentibus.** *Lin. Sp. Plant.* 107. Branching broad-leaved Mountain Moluggo.

3. **GALIUM foliis verticillatis lineari-setaceis, pedunculis folio longioribus.** *Hort. Cliff.* 34. Narrow-leaved Mountain Ladies Bedstraw, with a black purple flower.

4. **GALIUM foliis verticillatis linearibus, pedunculis dichotomis, summo caule floriferis.** *Prod. Leyd.* 256. Rock Ladies Bedstraw with a gray leaf.

5. **GALIUM foliis verticillatis linearibus, pedunculis brevissimis.** *Hort. Cliff.* 34. Red Ladies Bedstraw.

6. **GALIUM foliis quaternis lanceolatis trinerviis glabris, caule erecto, seminibus hispidis.** *Flor. Lapon.* 60. Smooth Meadow Madder with an acute leaf.

7. **GALIUM foliis quaternis obovatis inæqualibus, caulibus diffusis.** *Flor. Suec.* 119. White Marsh Ladies Bedstraw.

The first of these plants (which is the sort commonly used in medicine) is very common in moist meadows, and in pasture grounds, in several parts of *England*. The other varieties are preserved in curious botanick gardens, but as they are plants of very little beauty, and are subject to spread very far, and over-run whatever plants grow near them, they are seldom cultivated in other gardens.

These sorts may any of them be propagated by parting their roots, which spread and increase very fast, either in the spring or autumn, and will grow almost in any soil or situation, especially the first sort; all the other sorts except the last, require a drier soil, but will all grow in any situation.

GARCINIA. *Lin. Gen. Plant.* 526. The Mangosteen.

The Characters are,

The flower hath four roundish petals, which are larger than the empalement. It hath sixteen stamina, formed into a cylinder. In the center is situated an oval germen, crowned by a buckler-shaped plain stigma, divided into eight parts, which afterward becomes a thick globular berry with one cell, including eight hairy fleshy seeds, which are convex and angular.

We know but one Species of this genus, viz.

GARCINIA. *Hort. Cliff.* 182. The Mangostan, or Mangosteen.

This tree grows naturally in the *Molucca* islands, and also in the inland parts of *New Spain*, from whence I received perfect specimens, which were sent me by Mr. *Robert Millar*, who gathered them near *Tolu*, but did not know the tree. It rises with an upright stem twenty feet high, sending out many branches placed opposite, which stand oblique to each other, not at right angles; the bark of the branches is smooth, of a gray colour, that on the tender shoots is green. The leaves are spear-shaped and entire, of a lucid green on their upper side, and of an Olive colour on their under, having a prominent midrib with several small veins running from that to both sides of the leaf. The flower is like that of the single Rose, composed of four roundish petals, which are thick at their base, but thinner toward their ends, of a dark red colour. The fruit, which succeeds the flower is round, the size of a middling Orange; the top is covered by a cap, which was the stigma on the top of the style; and remains to the top of the fruit, which is indented in six or seven obtuse rays. The shell of the fruit is like that of the Pomegranate, but softer, thicker, and fuller of juice; the inside of the fruit is of a Rose colour, divided into several parts by thin partitions, as in Oranges, in which the seeds are lodged, surrounded by a soft juicy pulp of a delicious flavour; it is esteemed one of the richest fruits in the world: the trees naturally growing in the form of Pyramolas, whose branches are well garnished with large shining green leaves, make an elegant appearance, and afford a kindly shade in hot countries.

There are but few of the seeds in this fruit which come to perfection (the greatest part of them are abortive) most of those which have been brought to *Europe* have failed; therefore the surest way to obtain the plants, is to sow their seeds in tubs of earth in the country, and when the plants have obtained sufficient strength, they may be brought to *Europe*; but there should be great care taken in their passage, to screen them from the spray of the sea, as also not to give them much water, especially when they arrive in a cool or temperate climate, for these plants are very impatient of wet. When the plants arrive in *Europe*, they should

should be carefully transplanted, each into a separate pot, and plunged into the tan-bed, observing to shade them from the sun till they have taken new root; then they must be treated in the same manner as other tender plants from hot countries.

GARDENS are frequently distinguished into flower-gardens, fruit-gardens, and kitchen-gardens; the first being designed for pleasure and ornament, so should be placed in the most conspicuous parts, *i. e.* next to, or just against, the back front of the house; the two latter being principally intended for use and service, are placed less in sight.

Though the fruit and kitchen-gardens are often mentioned as two distinct gardens, and have by the French gardeners, as also by some of our own countrymen, been contrived as such, yet they are now usually in one; and with good reason, since they both require a good soil and exposure, and to be placed out of the view of the house. As the kitchen-garden should be inclosed with walls, that no person may have access to it, who have no business in it, for the sake of preserving the product, so these walls will answer the purposes of both.

In the choice of a place to plant a garden, the situation and exposure of the ground are the most essential points to be regarded; since, if a failure be made in that point, all the care and expence will in a manner be lost.

The second thing to be considered in chusing a place for a garden, is a good earth or soil.

It is scarce possible to make a fine garden in a bad soil; there are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth over the whole surface, the garden has been ruined, when the roots of the trees have come to reach the natural bottom.

The quality of good ground is neither to be stony; or hard to work; neither too dry, nor too moist; nor too sandy and light, nor too strong and clayey, which is the worst of all for gardens.

The third requisite is water. The want of this is one of the greatest inconveniencies that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry summer.

GARIDELLA: *Tourn. Inst. R. H. 655. tab. 430. Lin. Gen. Plant. 507.*

The Characters are,

The flower hath no petals, but five oblong equal nectariums occupy their place, which are bilabiate. It hath eight or ten awl-shaped stamina, which are shorter than the empalement. In the center is situated three compressed germina, which become three oblong compressed capsules with two valves, inclosing several small seeds.

We know but one Species of this genus, *viz.*

GARIDELLA. *Hort. Cliff. 170.* Garidella with very narrow divided leaves.

This plant is very near akin to the Nigella, or Fennel flower, to which genus it was placed by the writers on botany before Dr. Tournefort, and was by him separated from it, as differing in the form of the flower.

It grows wild in Candia, and on mount Baldus, in Italy, as also in Provence, where it was discovered by Dr. Garidel, who sent the seeds to Dr. Tournefort, for the royal garden at Paris.

This is an annual plant, which rises with an upright stalk, dividing into three or four slender branches, garnished at their joints with very narrow leaves like those of Fennel. The stalks are terminated by one small flower, of a whitish colour, which is succeeded by three capsules, each containing two or three small seeds. It flowers in June and July, and the seeds ripen in September. It is propagated by

seeds, which should be sown in autumn, on a bed of light fresh earth, where the plants are designed to remain; when the plants come up, they must be carefully cleared from weeds, and where they are too close, they must be thinned, leaving them about four or five inches apart; which is all the culture the plants require, and if the seeds are permitted to scatter, the plants will come up without any farther care.

GENISTA. *Lin. Gen. Plant. 766.* Broom.

The Characters are,

The flower is of the butterfly kind; the standard is long and wholly reflexed; the wings are a little shorter, and loose; the keel is erect, and longer than the standard. It hath ten stamina joined, which are situated in the keel. In the center is an oblong germin, which afterward becomes a roundish turgid pod with one cell, opening with two valves, inclosing kidney-shaped seeds.

The Species are,

1. GENISTA *ramis ancipitibus articulatis, foliis ovato-lanceolatis.* *Hort. Cliff. 355.* Dwarf Ance shaped Broom.

2. GENISTA *foliis lanceolatis, ramis striatis teretibus erectis.* *Hort. Cliff. 355.* Narrow-leaved Dyer's Broom.

3. GENISTA *foliis ovato-lanceolatis, ramis striatis teretibus.* Common Dyer's Broom, or Wood-waxen.

4. GENISTA *foliis inferioribus cuneiformibus, ramis floriferis linearibus, floribus majoribus erectioribus.* Greater Portugal Dyer's Broom, called Piurna by the Portuguese.

5. GENISTA *foliis lanceolatis, ramis paniculatis, caule arborescente.* Tree-like Tartarian Broom, with a yellow flower.

6. GENISTA *ramis triquetris subarticulatis, foliis tricuspidadis.* *Lin. Sp. Plant. 710.* Shrubby Portugal Dyer's Broom.

7. GENISTA *foliis lanceolatis obtusis, caule tuberculato decumbente.* *Hort. Cliff. 355.* Branching Broom with leaves like St. Johnswort.

8. GENISTA *spinis simplicibus, ramis floriferis inermibus, foliis lanceolatis.* *Hort. Cliff. 355.* Small English Broom, called Petty Whin.

9. GENISTA *spinis decompositis, ramis floriferis, inermibus, foliis linearibus pilosis.* *Lin. Sp. Plant. 711.* Most hairy small Spanish prickly Broom.

10. GENISTA *spinis compositis, ramis floriferis inermibus, foliis lanceolatis.* *Prod. Leyd. 371.* Smaller German prickly Broom.

The first sort grows naturally in France, Italy, and Germany. It sends out several stalks from the root, which spread flat on the ground, divide into many flat branches which are jointed, and their two sides are edged like a broad sword; they are herbaceous, but perennial. At each of the joints is placed one small spear-shaped leaf, without any foot-stalk. The flowers are produced in close spikes at the end of the branches, they are of the Pea-bloom kind, of a dirty yellow colour, and are succeeded by short hairy pods, which contain three or four kidney-shaped seeds.

This sort is propagated by seeds, which, if sown in the autumn, the plants will come up the following spring; but when they are sown in the spring, the plants rarely come up the same year: when the plants come up, they will require no other culture but to keep them clean from weeds, and thin them where they are too close; at Michaelmas they may be transplanted where they are designed to remain; the plants are very hardy, and will live several years.

The second sort rises with ligneous stalks two or three feet high, garnished with small spear-shaped leaves placed alternate, and are terminated by several spikes of yellow flowers, of the Pea-bloom kind, but small; which are succeeded by short pods, black when ripe, and contain four or five kidney-shaped seeds.

The third sort grows naturally in England. It hath shrubby stalks, three feet high, garnished with spear-shaped leaves,

leaves, which are broader than those of the former; the branches which come out from the side of the stalks, do not grow so upright as those of the second, but are terminated by loose spikes of yellow flowers, which are succeeded by pods like those of the second sort. The branches of the plant are used by dyers, to give a yellow colour, from whence it is called Dyer's Broom, Green-wood, Wood-waxen, or Dyer's-weed.

The fourth sort grows naturally in *Portugal* and *Spain*. This rises with shrubby channelled stalks four feet high, sending out several branches which grow erect; the lower leaves are wedge-shaped, very narrow at their base; those which are higher on the flower branches are narrow, and equal at both ends; the flowers are produced in pretty long spikes at the end of the branches, which are larger than those of the other sorts, and of a paler yellow colour; these are succeeded by pods like the former sorts.

This sort is a little tender, and in very severe frosts is sometimes killed in *England*, where the plants are not protected.

The fifth sort grows naturally in *Tartary*. This rises with a woody stalk to the height of seven or eight feet, sending out many slender branches, garnished with small spear-shaped leaves placed alternate; the upper part of these branches, for more than a foot in length, send out small branches, terminated by loose spikes of flowers, so that each branch terminates in a panicle of flowers. These appear in *June* and *July*, and the seeds ripen in autumn.

The sixth sort hath a low shrubby stalk, which seldom is more than a foot high, sending out several weak branches which are jointed, and garnished with small leaves ending in three acute parts. The flowers are produced in loose spikes at the top of the branches, of a pale yellow colour; the seeds ripen in *September*. This plant grows naturally in *Portugal*.

The seventh sort hath a shrubby stalk which declines toward the ground; it divides into a few small branches, garnished with small obtuse leaves. The flowers are disposed in small loose spikes at the end of the branches; these are small, of a pale yellow colour, and are succeeded by short pods filled with kidney-shaped seeds. This grows naturally in *Germany* and *France*.

The eighth sort grows naturally upon open heaths, in many parts of *England*. It hath a shrubby slender stalk, which rises about two feet high, sending out many weak branches, armed with long single spines, garnished with very small spear-shaped leaves, placed alternate. The flower branches have no spines, are short, and have five or six yellow flowers growing in a cluster at the end. They come out in *April* and *May*, and are succeeded by short turgid pods, which contain four or five small kidney-shaped seeds.

The ninth sort grows naturally in the south of *France* and *Italy*. This hath a shrubby stalk, and ligneous branches, armed with branching thorns, which come out from each other, but the short branches which produce the flowers have no spines, but are garnished with small hairy leaves of different forms, some of them being as narrow as hairs, and others are spear-shaped; the branches are terminated by clusters of yellow flowers, which are succeeded by short compressed hairy pods, filled with kidney-shaped seeds.

The tenth sort grows naturally in *Germany*. This rises with shrubby stalks to the height of three or four feet, divided into many slender branches, armed with compound spines, and garnished with spear-shaped leaves placed alternate; those branches which produce the flowers have no spines, but are terminated by short loose spikes of yellow flowers, which are succeeded by short pods, containing three or four kidney shaped seeds.

All these sorts of Brooms are propagated by seeds, which,

if sown in autumn, will succeed much better than if sown in the spring, and a year will be thereby saved: as these plants send out long, stringy, tough roots, which run deep into the ground, they do not bear transplanting well, especially if they are not removed young; therefore the best way is to sow a few seeds in those places where the plants are designed to remain, and to pull up all except the most promising plants as soon as they are past danger; after this the plants will require no other culture, but to keep them clean from weeds; but where this cannot be practised, the seeds may be sown thin upon a bed of light earth, and when the plants come up, they may remain till the following autumn, when they should be carefully taken up and transplanted where they are designed to remain.

They are all very hardy plants except the fourth and tenth sorts, which must have a warm sheltered situation and dry soil, otherwise they will not live through the winter, but the others will grow in almost any soil or situation.

GENISTA SPINOSA, the Furz, Whins, or Gorse. See Ulex.

GENTIANA. *Lin. Gen. Plant.* 285. Gentian, or Fell-wort.

The Characters are,

It hath a permanent empalement to the flower, cut into five acute segments. The flower hath one petal, which is tubulous. It hath five awl-shaped stamina. In the center is situated an oblong cylindrical germen, which afterward becomes an oblong taper-pointed capsule, with one cell, containing many small seeds fastened to the valves of the capsule.

The Species are,

1. GENTIANA corollis quinquefidis rotatis verticillatis, calycibus spathaceis. *Hall. Helv.* 479. Greater yellow Gentian.
2. GENTIANA corollis quinquefidis campanulatis oppositis pedunculatis, foliis linearibus. *Lin. Sp. Plant.* 228. Greater narrow-leaved autumnal Gentian.
3. GENTIANA corollis quinquefidis campanulatis oppositis sessilibus, foliis amplexicaulibus, *Lin. Sp. Plant.* 227. Gentian with a Swallow-wort leaf.
4. GENTIANA corollâ quinquefidâ campanulatâ, caulem excedente. *Lin. Sp. Plant.* 228. Broad-leaved Alpine Gentian with a large flower, commonly called Gentianella.
5. GENTIANA corollis quinquefidis infundibuliformibus, ramis unifloris alternis. *Lin. Sp. Plant.* 229. Annual Gentian with lesser Centaury leaves.
6. GENTIANA corollis quadrifidis imberbibus verticillatis sessilibus. *Lin. Sp. Plant.* 231. Crosswort Gentian.
7. GENTIANA corollis quadrifidis margine ciliatis. *Lin. Sp. Plant.* 231. Blue Gentian with hairy brims.
8. GENTIANA corollis quinquefidis hypocrateriformibus, calycibus inflatis plicatis. *Lin. Sp. Plant.* 229. Gentian with a bellied tube.
9. GENTIANA corollis quinquefidis infundibuliformibus, caule dichotomo. *Lin. Sp. Plant.* 229. Lesser Centaury.
10. GENTIANA corollis octifidis, foliis perfoliatis. *Lin. Sp. Plant.* 232. Yellow perfoliate Centaury.
11. GENTIANA corollis quinquefidis infundibuliformibus, floribus alternis sessilibus. *Lin. Sp. Plant.* 230. Lesser Centaury with a white spiked flower.
12. GENTIANA corollis quinquefidis infundibuliformibus, pedunculis longissimis. Lesser maritime Centaury with a large blue flower.

The first sort is the common Gentian of the shops, whose root is one of the principal ingredients in bitters.

This hath a large thick root of a yellowish brown colour, and a very bitter taste; the lower leaves are of an oblong oval shape, a little pointed at the end, stiff, of a yellowish green, and have five large veins on the back of each. The stalk rises four or five feet high, garnished with leaves, growing by pairs at each joint, almost embracing
the

the stalk at their base; they are of the same form with the lower, but diminish gradually in their size to the top. The flowers come out in whorls at the joints, on the upper part of the stalks, standing on short foot-stalks, whose origin is from the wings of the leaves; they are of a pale yellow, have one petal, divided almost to the bottom, and an oblong cylindrical germen, which afterward swells to an oblong taper capsule, bifid at the point, and opens in two cells, filled with small flat seeds.

It grows naturally in the pastures in *Switzerland*, and in the mountainous parts of *Germany*, from whence the roots are brought to *England* for medicinal use.

A few years ago there was a mixture of Henbane roots brought over with Gentian, which was unhappily used, and occasioned great disorders in the persons to whom it was administered.

This plant delights in a light loamy soil and a shady situation, where it will thrive much better than in an open exposure. It is propagated by seeds, which should be sown in pots soon after it is ripe, for if it is kept till the spring, it will not succeed; the pots should be placed in a shady situation. In the spring the plants will appear, when they must be duly watered in dry weather; the following autumn they should be carefully shaken out of the pots, so as not to break or injure their roots, and planted in a shady border of loamy earth, at six inches distance each way, observing to let the top of the roots be a little below the surface of the ground, then press the earth close to the roots; after this they will require no farther care, but to keep them constantly clean from weeds. In this border, the plants may stand two years, by which time they will be fit to transplant where they are designed to remain; therefore in autumn, so soon as their leaves decay, they may be removed; but as the roots of these plants run deep into the ground, like Carrots, there must be great care taken in digging them up, not to cut or break them. After the plants are well fixed in their places, they require no other culture, but to dig the ground about them early in the spring, before they begin to shoot. The roots of this plant will continue many years, but the stalks decay every autumn; the roots seldom flower oftener than every third year, but when they flower strong, they make a fine appearance; and as these delight in shady moist ground, where few ornamental plants will thrive, so they should not be wanting in good gardens.

The second sort grows naturally in moist pastures in many parts of *England*, but particularly in the north; it rises with an upright stalk about a foot high, garnished with smooth leaves, placed opposite, without foot-stalks. The flowers are produced on the top of the stalk, three or four in number, standing upon foot-stalks, alternately above each other; they are large, bell-shaped, and divided into five points at the brim, of a deep blue colour, so make a fine appearance; these come out the latter end of *July* in the warm parts of *England*, but in the north they are full a month later.

It may be propagated by seeds in the same manner as the first sort, and the plants may be treated in the same way: but as this sort doth not shoot its roots deep into the ground, it may be transplanted with less hazard; however, if these are removed with a ball of earth to their roots, they will not feel their removal so much as when the earth is all taken from them. This should be planted in strong, moist, loamy soil, in which the plants will thrive and flower annually, but in a warm dry soil they will not thrive or flower.

The third sort grows naturally upon the *Helvetian* mountains; this rises with an upright stalk a foot high, garnished with smooth leaves, which embrace the stalk, but

end in acute points; they are of a fine green, and are diminished in their size as they are nearer the top: and have five longitudinal veins, which join at both ends, but diverge from each other in the middle. The flowers come out by pairs opposite, from the bottoms of the leaves, standing on short foot-stalks; they are pretty large, bell-shaped, and of a fine blue colour, so make a fine appearance when they are open. This sort flowers in *June* and *July*.

It may be propagated by seeds in the same manner as the first sort, and the plants may be treated in the same way, but they must have a moist loamy soil, otherwise they will not thrive. It may also be propagated by offsets, which may be divided from the roots; these should be taken off in autumn, which is the best season for removing all these sorts of plants, but these should not be removed, or parted oftener than every third year, where they are expected to produce strong flowers.

The fourth sort grows naturally on the *Alps* and *Helvetian* mountains; this is commonly known by the title of *Gentianella*. It is a low plant, the stalks seldom growing more than three or four inches high; garnished with smooth leaves placed opposite, which sit close to the stalk. The flower grows erect on the top of the stalk, so stand quite above it; but sometimes, when the plants are strong, there will be two or three at the end of each stalk; they are large, bell-shaped, and of a deep-azure blue. It usually flowers in *May*, but sometimes the plants flower again in autumn.

This is commonly propagated by parting of the roots in the same manner as is before directed for the third sort, but the plants must not be often transplanted, or parted; they should have a soft loamy soil and a shady situation, where the plants will thrive and flower well every year.

It may also be propagated by seeds, which, in a good soil, the plants will produce in plenty; these should be sown in autumn, in the same manner as is before directed for the first sort, and if the plants are planted in a good soil, they will be strong enough to flower the second year after they are come up, and these seedling plants will flower much stronger than those which are propagated by offsets.

The fifth and eighth sorts are low annual plants, which grow naturally upon the *Alps*, and other mountainous places in *Europe*, and are very rarely cultivated in gardens. The fifth seldom rises more than two inches high, branching out from the root into several slender stalks, garnished with very small leaves placed by pairs; each stalk is terminated by one smaller blue flower standing erect. The eighth sort grows about four inches high, with a single upright stalk, of a purple colour. The leaves at the roots are oval, but those upon the stalk are narrow, and stand opposite. The stalk is terminated by one blue flower, with a large bellied empalement, which is plaited, and the petal of the flower rises but little above the empalement, so does not make much appearance. After the top flower decays, there are frequently two smaller flowers which come out from the side of the stalk, at the two upper joints.

As these plants usually grow upon moist spongy ground, it is very difficult to cultivate them in gardens, for unless they have a soil approaching near to that in which they naturally grow they will not thrive; the only method to obtain them is, either to sow them in pots, or upon a moist boggy ground in autumn, but it must be in the shade; and when the plants come up, they may be thinned, and the surface of the ground about them covered with moss, which should be constantly kept moist; with this management I have seen the plants thrive and flower very well.

The sixth sort is a perennial plant, which grows naturally upon the *Apennines*, and the *Helvetian* mountains; this rises with an upright stalk about six inches high, garnished with smooth

smooth spear-shaped leaves, about two inches long, and one broad in the middle, sitting close to the stalk; they are placed opposite, and each pair of leaves cross one another, from whence it is called Crosswort Gentian. The flowers are produced in whorls round the upper part of the stalks, sitting very close to them; at the top there is a large cluster growing in the same form, these are of a light blue colour. This may be propagated by seeds, or offsets, in the same manner as the third and fourth sorts, and the plants must be treated in the same way.

The seventh sort grows naturally upon the *Alps*, and other mountainous parts of *Europe*; this is a low perennial plant, whose stalks are very slender, rarely rising more than three or four inches high, garnished with small, narrow, acute-pointed leaves, placed by pairs; each stalk is terminated by one large blue flower, which is hairy on the inside at the brim. This flowers in *July* and *August*, and may be propagated in the same manner as the third and fourth sorts.

The ninth sort is the Lesser Centaury of the shops, which grows naturally upon dry pastures in most parts of *England*, where it rises in height proportionable to the goodness of the soil, for in good land it is frequently a foot high, but in poor soils not more than three or four inches. It is an annual plant, with upright branching stalks, garnished with small leaves placed by pairs. The flowers grow in form of an umbel at the top, and are of a bright purple colour; they come out in *July*, and the seeds ripen in autumn. This plant cannot be cultivated in gardens.

The tenth sort grows naturally upon chalky grounds in many parts of *England*. It is an annual plant, rising with an upright stalk a foot high, garnished with oval-pointed leaves, placed opposite, whose base surrounds the stalk; they are of a gray colour; the stalks and leaves are very smooth. The flowers grow in form of an umbel on the top of the stalk, of a bright yellow colour, cut into eight parts at the top. These appear in *July*, and the seeds ripen in autumn.

The eleventh sort is an annual plant, which grows naturally in the south of *France* and *Italy*; this rises with an upright stalk about a foot high, sending out several branches toward the top, garnished by small leaves placed opposite. The flowers are produced from the side, and at the top of the stalk, in form of loose irregular umbels; they are white, and about the size of those of the common Centaury.

The twelfth sort grows naturally in the *West-Indies*, where it was discovered by father *Plumier*, and the late Dr. *Houssoun* found it growing in plenty at *La Vera Cruz*, in low moist places where the water stagnates, but at a remote distance from the sea. This rises with an upright stalk near two feet high, garnished with oblong, smooth, acute-pointed leaves, placed opposite: the upper part of the stalk divides into six or seven long naked foot-stalks, each sustaining one large blue flower, divided into five segments at the brim. The flowers are succeeded by oblong capsules, with one cell, filled with small seeds.

This is propagated by seeds, which must be sown on a hot-bed, and the plants afterward treated in the same manner as other tender annual plants from warm countries, being too tender to thrive in the open air in *England*. If the seeds of this plant are sown in autumn, in pots placed in the tan bed of the stove, they will succeed better than when they are sown in the spring, and the plants will flower early, so good seeds may be obtained.

GENTIANELLA. See Gentiana.

GERANIUM. *Lin. Gen. Plant.* 346. Crane's-bill.

The Characters are,

The flowers have oval or heart-shaped petals, spreading open, which are in some species equal, and in others, the upper two are much larger than the three lower. It hath ten stamina,

which are alternately longer. In the bottom of the flower is situated a five-cornered germen, which is permanent. The flower is succeeded by five seeds, each being wrapped up in the husk of the beak, where they are twisted together at the point, so as to form the resemblance of a stork's beak.

The Species are,

1. GERANIUM *pedunculis bifloris, peltatis multipartitis rugosis, pinnato-laciniatis, acutis.* *Hort. Cliff.* 344. Crane's-bill with a Crowfoot leaf, and large blue flowers.

2. GERANIUM *pedunculis bifloris, calycibus inflatis, pistillo longissimo.* *Hort. Cliff.* 343. Long-rooted sweet-smelling Crane's-bill, with a Crowfoot leaf.

3. GERANIUM *pedunculis unifloris, foliis quinquepartitis trifidis orbiculatis.* *Lin. Sp. Plant.* 685. Bloody Crane's-bill with a large flower.

4. GERANIUM *pedunculis unifloris, foliis quinquepartitis laciniis obtusis brevibus, caulibus decumbentibus.* Bloody Crane's-bill with a variegated flower.

5. GERANIUM *pedunculis bifloris, foliis caulinis trilobis integris serratis, summis sessilibus.* *Hort. Cliff.* 343. Knotty Crane's-bill.

6. GERANIUM *pedunculis bifloris, foliisque alternis, calycibus subaristatis, caule erecto.* *Lin. Sp. Plant.* 681. Brown Crane's-bill with reflexed petals, and leaves not spotted.

7. GERANIUM *pedunculis bifloris, foliis quinquelobatis incisis, petalis reflexis.* Brown Crane's-bill with plain petals, and spotted leaves.

8. GERANIUM *pedunculis bifloris, foliis caulinis trilobis obtuse-crenatis, inferne hirsutis.* Roman Crane's-bill with striped flowers.

9. GERANIUM *pedunculis bifloris, foliis peltatis inciso-serratis, caule erecto.* *Flor. Lapp.* 266. Mountain Crane's-bill with a Crowfoot leaf.

10. GERANIUM *pedunculis bifloris, foliisque oppositis, petalis integris, calycibus brevioribus.* Oriental Dove's-foot Crane's-bill with an Asphodel root, and large flowers.

11. GERANIUM *pedunculis bifloris, foliisque oppositis, caule erecto ramoso, petalis bifidis.* Greatest perennial Dove's-foot Crane's-bill of the *Pyrennes*.

12. GERANIUM *pedunculis longissimis multifloris, calycibus aristatis, foliis bipinnatis.* Alpine Crane's-bill with a Coriander leaf, a long root, and a large purple flower.

13. GERANIUM *pedunculis bifloris, petalis emarginatis, foliis peltatis septempartitis trifidis, tomentoso-sericeis.* *Lin. Syst.* Silvery Alpine Crane's-bill.

14. GERANIUM *pedunculis bifloris, caule dichotomo erecto, foliis quinquepartitis incisis summis sessilibus.* *Flor. Virg.* 78. American spotted Crane's-bill with obsolete blue flowers.

15. GERANIUM *pedunculis bifloris, petalis emarginatis arillis hirtis coteledonibus trifidis, medio truncatis.* *Lin. Syst.* Lesser annual Crane's-bill of *Bohemia*, with a purple violet flower.

16. GERANIUM *pedunculis subunifloris, foliis quinquepartitis acutis, foliolis pinnatifidis.* *Lin. Sp. Plant.* 683. Crane's-bill with one flower on a foot-stalk, leaves divided into five acute parts, and the smaller leaves wing-pointed.

17. GERANIUM *pedunculis multifloris, calycibus pentaphyllis, floribus pentandris foliis pinnatis incisis obtusis.* *Hort. Cliff.* 334. Musk'd Crane's-bill, frequently called *Muscovy*.

18. GERANIUM *pedunculis bifloris, calycibus pentaphyllis, floribus pentandris, foliis pinnato-incisis crenatis.* Broad-leaved annual Crane's-bill, with a blue flower and a very long beak.

19. GERANIUM *pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis pinnatis acutis sinuatis.* *Lin. Sp. Plant.* 680. Crane's-bill with a Hemlock leaf, and very long beaks to the seed.

20. GERANIUM *pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis bipinnatis multifidis, caule erecto viscoso.* Erect viscous Crane's-bill with a Hemlock leaf, and very long beaks to the seed.

21. GERANIUM *calycibus monophyllis, foliis cuculatis dentatis*. Hort. Cliff. 345. African tree Crane's-bill with a round Marshmallow leaf, and the scent of Carline Thistle.

22. GERANIUM *calycibus monophyllis, foliis cuculatis angulosis, acutè dentatis*. African tree Crane's-bill with an angular Marshmallow leaf, and large purple flowers.

23. GERANIUM *calycibus monophyllis, foliis cordato-orbiculatis incisís zonâ notatis*. Hort. Upsal. 196. African tree Crane's-bill, with an hairy Ladies Mantle leaf and red flowers.

24. GERANIUM *calycibus monophyllis, foliis orbiculato-reniformibus tomentosis crenatis integriusculis*. Hort. Upsal. 195. African tree Crane's-bill with a plain shining Mallow leaf, and an elegant scarlet flower, commonly called Scarlet Geranium.

25. GERANIUM *calycibus monophyllis, foliis lobatis undatis villosis*. Hort. Upsal. 196. African shrubby Crane's-bill with a jagged sweet-smelling Mallow leaf, commonly called Rose-scented Geranium.

26. GERANIUM *calycibus monophyllis, foliis adscendentibus lobatis pubescentibus*. Hort. Upsal. 196. African shrubby Crane's-bill with a jagged Mallow leaf, smelling like Balm, and a purplish-coloured flower.

27. GERANIUM *calycibus monophyllis, corollis papilionaceis, vexillo dipetalo maximo, foliis angulatis*. Hort. Cliff. 345. African tree Crane's-bill, with a pointed Mallow leaf, and the under petals of the flower scarce discernible.

28. GERANIUM *calycibus monophyllis, foliis glabris subovatis carnosis crenatis*. Hort. Cliff. 345. African shrubby Crane's-bill with a thick glaucous leaf, and an acid taste like Sorrel.

29. GERANIUM *calycibus monophyllis, petalis linearibus, caule carnosio nodoso, foliis duplicato-pinnatifidis*. Lin. Vir. 67. African shrubby Crane's-bill with a leaf like the Alcea, the petals of the flower white and narrow, and a fleshy jointed stalk.

30. GERANIUM *calycibus monophyllis, caule carnosio gibboso, foliis subpinnatis*. Lin. Sp. Plant. 677. African Crane's-bill, smelling sweet in the night, with knotty tuberous stalks, and leaves like Columbine.

31. GERANIUM *calycibus monophyllis, foliis tripartitis incisís, intermedia majore, pedunculis umbelliferis geminis, caule carnosio*. Lin. Vir. 67. African Crane's-bill with a Vervain Mallow leaf, and a deep scarlet flower.

32. GERANIUM *calycibus monophyllis, foliis quinquelobis integerrimis glabris peltatis*. Hort. Cliff. 345. African Crane's-bill with the under leaves like Asarabacca, and the upper leaves like Staveacre, shining, spotted, and tasting like Sorrel.

33. GERANIUM *calycibus monophyllis, foliis orbiculatis palmatis incisís pilosis, caule herbaceo*. Lin. Vir. 67. African Crane's-bill with a hairy Ladies Mantle leaf, and whitish flowers.

34. GERANIUM *calycibus monophyllis, caule carnosio brevissimo, ramis longis, foliis cordatis*. Hort. Cliff. 345. African Crane's-bill with a thick, soft, sweet-smelling Mallow leaf, and a small white flower composed of five leaves.

35. GERANIUM *calycibus monophyllis, foliis bipinnatis multifidis villosis, radice subrotundo*. American tuberous-rooted Crane's-bill, with a dark flower, smelling sweet in the night.

36. GERANIUM *calycibus monophyllis, foliis duplicato-pinnatifidis, radice subrotundo*. Tuberous-rooted African Crane's-bill with an Anemomy leaf, and a pale flesh coloured flower.

37. GERANIUM *calycibus monophyllis, foliis decompositis villosis pinnatifidis acutis, pedunculis longissimis*. Night smelling Crane's-bill with a tuberous root, broad, woolly, hoary Carrot leaves, and a pale yellowish flower.

38. GERANIUM *calycibus monophyllis, foliis pinnatifidis villosis, laciniis linearibus*. Night smelling Ethiopian Crane's-bill with a tuberous root, and narrow Cicely leaves.

39. GERANIUM *calycibus monophyllis, tubis longissimo sub-*

fessilibus, radice subrotundâ, foliis lobatis. Prod. Leyd. 352. Night sweet smelling African Crane's-bill with a hairy Vine leaf, and a tuberous root.

40. GERANIUM *calycibus monophyllis, corollis papilionaceis, vexillo dipetalo, foliis bipinnatis*. Smaller African Crane's-bill with a Coriander leaf, and a flesh-coloured flower.

41. GERANIUM *calycibus monophyllis, corollis papilionaceis, vexillo dipetalo, foliis bipinnatis, ramis nodosis suffrutescens*. Crane's-bill with empalements of one leaf, a butterfly flower with a standard of two petals, double winged leaves, and knotty shrubby branches.

42. GERANIUM *calycibus monophyllis, foliis palmatis subrotundis crenatis, caulibus filiformibus procumbentibus*. African Crane's-bill with a Gooseberry leaf, and small reddish flowers.

43. GERANIUM *calycibus monophyllis, foliis ovatis inæqualiter serratis planis*. Lin. Sp. Plant. 679. Shrubby Crane's-bill with a broad indented leaf, and large reddish flowers.

The first sort grows naturally in moist meadows in many parts of England, but is frequently planted in gardens for the beauty of its large blue flowers; of this there is a variety with white flowers, and another with variegated flowers, but these are apt to degenerate to the common sort, if they are raised from seeds, but by parting of their roots they may be continued. It hath a perennial root, which sends up many stalks three feet high, garnished with target-shaped leaves, divided into six or seven parts, cut into several acute segments, after the manner of winged leaves, ending in many points. The flowers are produced at the top of the stalks, each foot-stalk sustaining two flowers, whose petals are large and equal; they are of a fine blue colour, and appear in May and June.

The second sort grows naturally in Germany and Switzerland; it hath a thick fleshy perennial root, from which arise several branching stalks one foot high, garnished with leaves divided into five lobes, which are again divided into many short segments, crenated on their edges. The flowers are produced at the end of the branches; each short foot-stalk sustains two flowers, so it may have the title given it by *Linæus*, though at the first appearance it seems as a many flowered foot-stalk, and strictly is so, because the naked foot-stalk sustains the whole bunch. The petals are pretty large, equal, of a fine bright purple colour; the stamina and style are much longer than the petals; the whole plant, when rubbed, emits an agreeable odour. This may be propagated and treated in the same manner as the first.

The third sort grows naturally in many parts of England; this hath pretty thick, fleshy, fibrous roots, from which arise many stalks, garnished with leaves divided into five parts, or lobes, which are again divided almost to the midrib. The flowers stand upon long hairy foot-stalks, which come out from the side of the stalk, each sustaining one flower, composed of five broad regular petals, which are of a deep purple colour. There are two varieties mentioned of this sort as distinct species, one whose stalks grow more erect, and the other hath leaves more deeper divided, but the plants which I have raised from seeds of these do not come up the same as the parent plants, so they are only seminal varieties.

It hath a perennial root, which may be parted in autumn, and thereby propagated, or it may be propagated by seeds, and the plants treated in the same manner as the first.

The fourth sort hath been supposed by some to be only a variety of the third, but is undoubtedly a distinct species. The stalks of this plant are shorter than those of the third, and spread flat on the ground; the leaves are much less, and not so deeply divided, the flowers much smaller and of a pale colour, marked with purple; it grows naturally in Lancashire and Westmoreland, where I saw it in plenty.

This may be propagated and treated in the same manner as the others.

The fifth sort is a perennial plant, of smaller growth than either of the former. It rises with branching stalks about six inches high, garnished with leaves, having three pretty broad lobes, crenated on their edges: those on the lower part of the stalks are placed opposite, upon pretty long foot-stalks, but the upper leaves sit close to the stalks and are single. The flowers are produced at the end of the stalks, standing together upon two short foot-stalks; they are of a dirty purple colour. It grows naturally in *France*. This sort may be propagated and treated in the same manner as the first.

The sixth sort grows naturally on the *Alps* and *Helvetian* mountains, and is found in some places in the north of *England*: it hath a perennial root, from which arise several stalks a foot high, garnished with leaves, which are divided into five or six lobes, lacinated on their edges; those which grow near the root, have long foot-stalks, but those on the upper part of the stalk sit close; the stalk branches out at the top into three or four divisions, each being terminated by two or three foot-stalks, sustaining two flowers of a dark purple colour, with erect petals. This may be propagated by seeds or parting of the roots, in the same manner as the first sort.

The seventh sort is very like the sixth, but the leaves are larger, the lobes shorter, broader, and not so much cut, and are marked with black; the stalks rise higher, the flowers are larger, and the petals are reflexed. This may be propagated and treated in the same manner as the first sort. It grows naturally on the *Alps*.

The eighth sort hath a perennial root, which sends up many branching stalks a foot and a half high, garnished with light green leaves; those on the lower part of the stalk have five lobes, and stand upon long foot-stalks; but those on the upper part have but three, sitting closer to the stalks, and are sharply indented on the edges; the flowers stand upon long slender foot-stalks, each sustaining two flowers composed of five obtuse petals, which are deeply indented at the top; they are of a dull white, with many purple stripes running longitudinally through them. This sort is very hardy, so may be propagated by dividing of the roots, or from seeds, in the same manner as the first sort.

The ninth sort grows plentifully in the meadows in *Lancashire* and *Westmoreland*; it hath a perennial root, which sends out three or four upright stalks about nine inches high, garnished with leaves, having five lobes, which are sawed on their edges, and placed opposite; those on the lower part having pretty long foot-stalks, but those on the upper part sit closer to the stalks. The flowers terminate the stalks, standing upon short foot-stalks, each sustaining two pretty large blue flowers, with entire petals. This may be propagated and treated in the same way as the first sort.

The tenth sort was discovered by Dr. *Tournefort* in the *Levant*; it hath a perennial root, from which arise a few weak stalks about nine inches long, garnished with leaves, divided into five lobes, which are indented at the top, and placed opposite on the stalks. The flowers stand on pretty long foot-stalks, which come out single from the joints of the stalks, each sustaining two purplish flowers with entire petals, having very short empalements. It may be propagated either from seeds, or by parting of the roots, in the same manner as the first sort, but the plants require a drier soil and a warmer situation.

The eleventh sort grows naturally on the *Pyrenean* mountains; it hath a perennial root, sending out many branching stalks a foot and a half high, garnished with round leaves, divided into many obtuse segments at the top. The flowers

are produced by pairs upon short foot-stalks, which come out at the divisions on the sides, and at the top of the stalks; they are in some of a pale purple colour, and in others white. The petals of the flowers are bifid, like those of the common Dove's-foot Crane's-bill, to which the whole plant bears some resemblance, but the stalks are erect, the leaves and flowers much larger, and the root is perennial; this will propagate itself fast enough by its scattered seeds where it has once got possession, and will thrive in any soil or situation.

The twelfth sort grows naturally upon the *Alps*. It hath a perennial root, which runs very deep into the ground. The lower leaves of the plant have very long foot-stalks, they are doubly winged and smooth. The stalk rises a foot and a half high, garnished with leaves of the same form as the lower, but smaller, and stand opposite. The flowers are purple, many growing together upon very long foot-stalks; it hath awns to the segments of the empalement. This seldom produces seeds in *England*. The plant is hardy, and lives in the open air, but as the root puts out no offsets, nor perfects seeds here, we have not been able to propagate it.

The thirteenth sort grows naturally on the *Alps*; this hath a very thick perennial root, and roundish silvery leaves, divided into many parts, standing upon pretty long foot-stalks. The flower-stalks rise about four or five inches high, garnished with one or two small leaves, like those below, which sit close to the stalk. The stalks are terminated by two pretty large pale flowers, whose petals are entire. It flowers in *June*, but rarely ripens seed here; it may be propagated by parting of the roots in the same manner as the first, and must have a shady situation.

The fourteenth sort grows naturally in *North America*; this hath a perennial root, sending out several stalks one foot high, which divide by pairs, and from the middle of the divisions come out the foot-stalks of the flowers, which are pretty long and naked, each sustaining two pale purple flowers with entire petals. The leaves are divided into five parts, which are cut on their edges, and are placed opposite. It flowers in *June*, and frequently ripens seeds, from which the plant may be propagated.

The fifteenth sort grows naturally in *Bohemia*; this is an annual plant, which sends out many stalks, dividing into several parts, garnished with leaves divided into five lobes, crenated on their edges, standing upon long foot-stalks, for the most part opposite. The flowers stand by pairs upon pretty long slender foot-stalks, which come out from the side of the stalk: they are of a fine blue colour, and are succeeded by seeds, whose capsules and beaks are black. If the seeds are permitted to scatter, there will be a supply of plants, which want no other care but to keep them clean from weeds.

The sixteenth sort grows naturally in *Siberia*. It hath a perennial root; the leaves are divided into five acute lobes, which are cut into many sharp wing-like segments on their edges, and are placed opposite upon long slender foot-stalks. The foot-stalks of the flower come out from the wings of the stalk; they are long, slender, each sustaining one pale purplish flower. It ripens seeds very well, so may be easily propagated, and will grow on any soil or situation.

The seventeenth sort is an annual plant, which is sometimes found growing naturally in *England*, but is frequently preserved in gardens for the musky odour of the leaves, which in dry weather is very strong. The leaves of this are irregularly winged, the lobes grow alternate, and are cut into many obtuse segments on their edges. The stalk branches into many divisions, and frequently declines to the ground. The flowers are produced in umbels upon short foot-stalks, which arise from the wings of the stalks;

are small, blue, and have but five stamina in each, their empalements are composed of five leaves. If the seeds are permitted to scatter, there will be a supply of plants without care, which will require no other culture, but to keep them clean from weeds.

The eighteenth sort grows naturally in *Crete*; this is an annual plant with very broad leaves, which are cut on their sides regularly, in form of winged leaves, and are crenated on their borders. The flowers are produced on pretty long foot-stalks, which come out from the wings of the stalk; they are composed of five entire blue petals, and are succeeded by the largest and longest beaks of any species of this genus yet known. It ripens seeds very well, and if they are permitted to scatter, the plants will come up without care; or they may be sown in the spring, where they are designed to remain.

The nineteenth sort grows naturally in *Germany* and *Italy*. It is an annual plant, with several prostrate stalks a foot long, garnished with winged leaves, cut in several acute parts placed opposite. The flowers come out from the wings of the stalk, upon pretty long foot-stalks; some sustaining many flowers, others have no more than two; they are of a pale blue colour, and are succeeded by very long beaks, but not so long or large as those of the former sort. The seeds of this and the former sort are frequently used for hygrometers, to shew the moisture of the air; if the seeds of this are permitted to scatter, the plants will come up and thrive without any other care than to keep them clear from weeds.

The twentieth sort is an annual plant, which hath upright stalks two feet high, garnished with double winged leaves, ending in many points; the whole plant is viscous. The flowers are produced on long naked foot-stalks, standing many together upon each; they are of a pale blue colour, and have but five stamina; their empalements are composed of five leaves, which end with awns. This requires no other culture than the two former sorts.

There are several other sorts of annual Geraniums, some of which grow naturally in *England*, and are troublesome weeds in a garden; others grow naturally in *France*, *Spain*, *Italy* and *Germany*, and are preserved in botanick gardens for the sake of variety, but as they are plants of little beauty, they are rarely admitted into other gardens, therefore I shall not trouble the reader with an enumeration of the species, which would swell this article too much.

The twenty-first sort grows naturally at the *Cape of Good Hope*; it rises with a shrubby stalk eight or ten feet high, sending out several irregular branches, garnished with roundish leaves, whose sides are erect, so form a sort of a hood by a hollow cavity made in the leaf. The base of the leaves is cut in form of a heart-shaped leaf, and from the foot-stalk run many nerves arising from a point, but diverge toward the sides; the borders of the leaves are sharply indented, those on the lower part of the branches have long foot-stalks, but those on the upper part have shorter and stand opposite. The flowers are produced in large panicles on the top of the branches; their empalements are of one leaf, deeply cut into five segments, and closely covered with hairs. The petals are large, entire, and of a blue colour. The flowers are succeeded by seeds with short hairy beaks.

The twenty-second sort has some appearance of the twenty-first, but the leaves are of a thicker substance, divided into many acute angles, and have purple edges which are acutely indented. The stalks and leaves are very hairy. The branches are not so irregular as those of the former, nor are the bunches of the flowers near so large; these differences are permanent in the plants which are raised from seeds, so it is undoubtedly a distinct species.

The twenty-third sort comes from the *Cape of Good Hope*, but is one of the oldest, and the most common sort in the *English* gardens; it rises with a shrubby stalk five or six feet high, and divides into a great number of irregular branches. The branches are garnished with roundish heart-shaped leaves, indented on their edges with several obtuse segments, which are cut in short teeth at their brims; these have a purple circle, or mark, like a horseshoe, through the leaf, going from one side of the base to the other, corresponding with the border of the leaf; the leaves, when gently rubbed, have a scent like scalded Apples. The flowers are produced in pretty close bunches, standing upon long foot-stalks, which come out from the wings of the stalk, toward the end of the branches; they are of a reddish purple colour, and continue in succession great part of summer; there are three or four varieties of this, one with fine variegated leaves, one with crimson, and another with Pink-coloured flowers, which have been accidentally raised from seeds.

The twenty-fourth sort grows naturally at the *Cape of Good Hope*; this rises with a soft shrubby stem to the height of eight or ten feet, sending out several branches, which are generally erect; garnished with roundish kidney-shaped leaves, of a thick substance, and a lucid green, standing on pretty long foot stalks; they are covered with soft hairs on their under side. The flowers grow in loose bunches upon long stiff foot-stalks, which come out from the wings of the stalk; they are of a bright scarlet colour, so make a fine appearance, and there is a succession of these flowers during all the summer months.

The twenty-fifth sort grows naturally at the *Cape of Good Hope*; this rises with a shrubby stalk four or five feet high, dividing into several weak irregular branches, garnished with leaves divided into three unequal lobes, which are hairy and waved on their edges, placed alternate on the branches, and stand upon hairy foot-stalks. The flowers grow in close roundish heads on the top of the foot-stalks, forming a sort of corymbus; they are of a purplish blue colour, and continue in succession great part of the summer. The leaves of this sort, when rubbed, have an odour like dried Roses, from whence many have given it the title of Rose Geranium.

The twenty-sixth sort is a native of the *Cape of Good Hope*; this rises with an upright shrubby stalk seven or eight feet high, sending out many pretty strong branches, garnished with leaves shaped somewhat like those of the Vine; those on the lower part stand upon long foot stalks, but the upper have short ones; when the leaves of this are rubbed, they have a scent of Balm. The flowers grow in compact clusters on the top of long naked foot-stalks, which come out from the wings of the stalk; they are small, and of a pale blue colour, so make no great figure.

The twenty-seventh sort rises with an upright shrubby stalk seven or eight feet high, sending out several side-branches, garnished with large, angular, rough leaves, standing upon long foot-stalks. The flowers are produced in large panicles at the end of the branches, which are shaped somewhat like a Butterfly flower; the two upper petals, which are pretty large, turn upward like a standard in the leguminous flowers; these are finely variegated, but the three under petals are so small, as not to appear at a little distance; these are reflexed downward, so are screened from sight, unless the flowers are viewed near. This sort flowers in *May*, at which time the plants make a fine appearance, but they are not succeeded by any more afterward, as most of the other sorts are.

The twenty-eighth sort is from the same country; this rises with a shrubby stalk six or seven feet high, sending out several side branches, garnished with oblong, oval,

fleshy, smooth leaves, of a gray colour, crenated on their edges, and have an acid flavour like Sorrel. The flowers stand upon pretty long foot-stalks, which arise from the wings of the stalks, each sustaining three or four flowers, whose petals are narrow, and unequal in size; they are of a pale bluish colour, with some stripes of a light red; these continue in succession most part of the summer. There is a variety of this with scarlet flowers, which is said to have been raised from the seeds of this sort. The leaves of it are larger, and seem to be an intermediate species between this and the twenty-fourth sort, for the flowers are larger than those of the twenty-eighth sort, and are of a pale scarlet colour.

The twenty-ninth sort hath a thick, fleshy, knotted stalk, which rises about two feet high, sending out a few slender fleshy branches, garnished thinly with double winged leaves, which, on the lower part of the stalk, stand upon foot-stalks, but those above sit close to the branches. The flowers are produced in small clusters at the end of the branches; these have five narrow white petals, which make no appearance.

The thirtieth sort hath a round fleshy stalk with swelling knots at the joints, which rise about three feet high, sending out several irregular branches, which are smooth, thinly garnished with smooth, fleshy, winged leaves, ending in obtuse points, of a gray colour, and stand upon short foot-stalks. The flowers stand four or five upon each foot-stalk, which arises from the wings of the stalk, and are of a dark purple colour. The petals are broader than those of the former sort, and the flowers have a very agreeable scent in the evening, after the sun has left them some time.

The thirty-first sort hath a fleshy stalk, which seldom rises a foot high, and puts out very few branches; which are garnished with smooth, light, green leaves, divided into three lobes, the middle segment being much larger than the others. The flowers stand upon short foot-stalks, each sustaining two or three flowers on the top, which are of a very deep scarlet colour, and have unequal petals. The leaves of this sort fall off, so that the stalks are frequently destitute of them for three or four months in the summer, and appear as if they were dead, but in autumn they put out fresh leaves again.

The thirty-second sort hath many long, weak, shrubby stalks, which require support to prevent their falling on the ground; garnished with fleshy leaves, divided into five obtuse lobes, which are entire, and have slender foot-stalks, which are fastened to the middle of the leaf, like the handle of a target. The leaves have a circular purple mark in their middle, and have an acid flavour. The flowers are produced upon pretty long foot-stalks, which come out from the wings of the stalk, each foot-stalk sustaining four or five purple flowers, composed of five unequal petals.

The thirty-third sort sends out several herbaceous stalks a foot and a half long, which trail upon the ground, if they are not supported; and are garnished with roundish hand-shaped leaves, which are hairy, and cut into many parts. The flowers are of a pale bluish colour, standing several together upon very long foot-stalks; there is a succession of these during all the summer months, and the seeds ripen accordingly about a month after the flowers are fallen.

The thirty-fourth sort hath a very short fleshy stalk, which divides near the ground into several heads, each garnished with many leaves, which arise on separate foot-stalks from the heads; they are heart-shaped, soft, and downy, and have a strong scent like Aniseed; from these heads come out several slender stalks, which lie prostrate on the ground, garnished with rounder leaves than those near the root, but are of the same texture, and have the like odour. The flowers are produced from the side of these stalks, three,

four, or five, standing together upon slender foot-stalks; they are very small and white, so make little appearance.

The thirty-fifth sort hath a thick, roundish, tuberous root, from which arise several hairy leaves, which are finely divided, almost like those of the garden Carrot; these spread near the ground, and between them come out the stalks, which rise about a foot high, garnished with two or three leaves of the same sort with those below, but are smaller, and sit closer to the stalks; from these arise two or three naked foot-stalks, which are terminated by a truss of yellowish flowers, marked with dark purple spots, which smell very sweet after the sun hath left them; these are frequently succeeded by seeds, which ripen in autumn. It is known by the title of *Geranium noctu olens*, or Night-scented Crane's-bill.

The thirty-sixth sort hath a knobbed tuberous root like the last, from which come out several pretty large leaves, composed of many lobes, set along the midrib in the form of a winged leaf, which are narrow at the base, but are very much enlarged at their ends, where they are rounded and cut into many acute points; the stalks which sustain the flowers, arise immediately from the root, and sometimes have one or two small leaves toward the bottom, where they often divide into two naked foot-stalks, each being terminated by a truss of pale red flowers, which smell sweet at night.

The thirty-seventh sort hath oblong tuberous roots, from which come out several decompound winged leaves, ending in many acute points; the segments of these leaves are broader than those of the thirty-fifth sort, the leaves are very hairy. The stalks rise a foot and a half high, garnished with a single leaf at the two lower joints; these are singly winged, the lobes are narrow, standing at a wider distance, and the segments are more acute than those of the lower leaves; at the two lower knots, or joints, arise two long naked foot-stalks, each being terminated by a truss of yellowish flowers, which have long tubes, and smell sweet in the evening when the sun has left them.

The thirty-eighth sort hath a tuberous root like the former, from which spring out many hairy leaves, which are finely divided like those of the Pulsatilla, which are very hoary, and rise immediately from the root. The foot-stalk of the flower is naked, and rises from the root; this grows about nine inches high, and is terminated by a loose truss of flowers, which are of a very dark purple colour, and smell sweet in the evening.

The thirty-ninth sort hath fleshy tuberous roots like those of the former sorts, from which come out three or four broad hairy leaves, divided on their borders into several lobes, in form of a Vine leaf; which spread flat on the ground, crenated on their edges, standing upon short foot-stalks. The foot-stalks of the flowers are naked, and arise immediately from the root, and grow about a foot high, terminated by a truss of dark purple flowers with long tubes, which have a very agreeable odour in the evening.

The fortieth sort is an annual plant, which grows naturally at the *Cape of Good Hope*; it rises with herbaceous branching stalks a foot high, garnished with doubly winged leaves at each joint; the lower leaves stand upon long foot-stalks, but those on the upper part sit close to the stalks. The flowers stand upon naked foot-stalks, which proceed from the side of the stalks, on the opposite side to the leaves; they grow three or four together upon short separate foot-stalks, and are shaped somewhat like a papilionaceous flower; the two upper petals, which are large, form a kind of standard, the other three petals are narrow, and reflexed downward; they are of a pale flesh colour; the seeds ripen in autumn, soon after which the plants decay.

The forty-first sort hath a pretty thick tuberous root, from which is sent out several irregular stalks, dividing into diffused branches, with swelling joints, which are ligneous; garnished with one double winged leaf at each of the joints, and opposite to the leaves come out the foot-stalks of the flowers; those which are situated on the lower part of the stalk, are very long and naked, but those which terminate the branches are shorter, and have one or two small leaves set at their base; the foot-stalks are terminated by a small truss of flowers, shaped like those of the former sort, but larger, and of a paler colour, which continue in succession most part of the summer.

The forty-second sort is a biennial plant, which grows naturally at the *Cape of Good Hope*; this sends out a great number of very slender trailing stalks, which lie prostrate on the ground, and extend a foot and a half in length, garnished with small, roundish, hand-shaped leaves, crenated on their edges. The flowers are very small, red, and sit upon short slender foot-stalks, which come out at every joint from the side of the stalks; sometimes they are single, and at other times there are two or three flowers upon a foot-stalk. They continue in succession all the summer, and the seeds ripen in about five weeks after the flowers decay.

The forty-third sort hath a shrubby stalk, which rises to the height of four or five feet, sending out several branches, garnished with oblong leaves, indented, and unequally sawed on their edges; the flowers stand upon long foot-stalks, which come out from the side of their branches; they are large, of a red colour, and the two upper petals are larger than the other.

All the sorts of *African Crane's-bill* may be propagated by seed, which should be sown upon a gentle hot-bed toward the middle of *March*, which will bring up the plants in a month or five weeks; afterward they should be gradually hardened to bear the open air, so as not to draw them up weak; when the plants are fit to remove, they should be put into separate small pots, and placed under a common frame, where they should be shaded from the sun till they have taken new root. In the middle of *May*, they should be removed to a sheltered situation with other exotic plants. If these plants are brought forward in the spring, most of the sorts will flower the same summer, and the plants will be very strong before the winter, so will make a better appearance in the green-house.

All the shrubby *African Geraniums*, from the twenty-first to the thirty-second inclusive, and also the forty-first and forty-third sorts, are commonly propagated by cuttings, which, if planted in a shady border, in *June* or *July*, will take good root in five or six weeks, and may then be taken up and planted into separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated in the same manner as the seedling plants. The twenty-ninth, thirtieth, thirty-first and thirty-second sorts, have more succulent stalks than either of the other, so the cuttings of these sorts should be planted in pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they should be shaded from the sun in the heat of the day, and should have but little water, for these are very apt to rot with much moisture; when these are well rooted they may be separated and planted in pots, and placed in the shade till they have taken new root, then they may be removed into a sheltered situation, where they may remain till autumn. These four sorts should be sparingly watered at all times, but especially in winter, for they are apt to take mouldiness with moisture, so will thrive much better in an airy glass-case, where they may have more sun and air, than in a green-house. All the other shrubby sorts are pro-

per furniture for the green-house, where they will only require protection from frost, but should have a large share of free air when the weather is mild. These plants should be hardened in the spring gradually, and in the middle of *May*, they may be taken out of the green-house, and at first placed in the shelter of hedges, where they may remain a fortnight or three weeks to harden, then should be removed into a situation where they may be defended from strong winds, and enjoy the morning sun till eleven o'clock, where they will thrive better than in a warmer situation.

The compost in which I have always found these plants thrive best (where there has not been a conveniency of getting some good kitchen-garden earth) was fresh hazel loam from a pasture mixed with a fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is preferable to dung, but if it is light and warm, then a mixture of neat's dung is best; this compost should be mixed three or four months before it is used, and should be turned over three or four times, that the parts may be well mixed and incorporated; but where a quantity of good kitchen-garden earth can be had, which has been well worked and is clean from the roots of bad weeds, there will need no composition, for in that they will thrive full as well as in any mixture which can be made for them, especially if the earth has laid in a heap for some time, and has been two or three times turned over to break the clods, and make it fine.

The thirty-third sort hath herbaceous stalks, so is best propagated by seeds, which the plants produce in great plenty, but the cuttings of this will take root as freely as either of the other, but the seedling plants are preferable to those propagated by cuttings; and where the seeds of this and many other of the *African* sorts are permitted to scatter, there will be a supply of young plants come up the spring following, provided the seeds are not buried too deep in the ground.

The thirty-fourth sort may be propagated by seeds, or from heads slipped off from the short fleshy stalk; these heads should have their lower leaves stripped off, that the stalk which is to be planted may be clear of them; then they may be planted each into a small pot, but if the heads are small, there may be two or three put into one small pot; then they should be plunged into a very moderate hot-bed, and shaded from the sun, which will forward their putting out roots; then they must be hardened gradually, and removed into the open air, where they may remain till autumn, when they must be removed into shelter for the winter season.

The thirty-fifth, thirty-sixth, thirty-seventh, thirty-eighth, and thirty-ninth sorts, are generally propagated by parting of their roots; the best time for doing this in *August*, that the young roots may be established before the cold comes on. Every tuber of these roots will grow, provided they have a bud or eye to them; these may be planted in the same sort of earth as was before directed, and if the pots are plunged into an old tan-bed, under a good frame, in winter, the plants will thrive better than in a green-house; the glasses of the frame may be drawn off every day in mild weather, whereby the plants will enjoy the free air, and if in hard frost, they are well covered to prevent the cold penetrating to the plants, it is all the shelter they will require; in this situation they should have but little wet in winter, therefore the glasses should be kept over them in heavy rains to keep them dry; in mild weather the glasses may be raised on the upper side to admit fresh air to the plants, which will give them greater slope to carry off the wet. With this management the roots will thrive and flower very strong every year. These sorts may also be propagated by seeds.

The fortieth sort is an annual plant, and is only propagated by seeds, which should be sown upon a gentle hot-bed in the spring, to bring the plants forward, otherwise, if the season should not prove very warm, the plants will not perfect their seeds in this country. When the plants are come up, and grown strong enough to remove, they should be each planted into a separate small pot, and plunged into a moderate hot-bed again, shading them till they have taken new root; then they must be gradually hardened to bear the open air, into which they should be removed in *June*, and shifted into larger pots; the plants will flower in *July*, and the seeds ripen in autumn, and soon after the plants will decay.

The forty-second sort is also propagated by seeds, which may be either sown upon a moderate hot-bed in the spring, or upon a bed of light earth in the open air, where the plants will come up very well, though they will not be so forward as those on the hot-bed. Those which are sown in the open air will require no other care, but to keep them clean from weeds, and thin the plants were they are too close. These plants will flower in *July* and *August*, and if the autumn proves favourable the seeds will ripen in *September*, but if these should fail, those which were raised on the hot-bed will come earlier to flower, so there will be no danger of their perfecting seeds.

GERMANDER. See *Teucrium*.

GESNERA. *Plumier Nov. Gen. 27. tab 9.*

The Characters are,

The flower hath one petal, which is tubulous and first bent inward, and afterward out again like a bugle horn; the brim is divided into five obtuse segments; it hath four stamina, which are shorter than the petal; the germen which sits under the petal, afterward becomes a roundish capsule with two cells, filled with small seeds, which are fixed on each side the partition.

The Species are,

1. GESNERA foliis lanceolatis crenatis hirsutis, pedunculis lateralibus longissimis paniculatis. Gesnera with a large woolly Fox-glove leaf.

2. GESNERA foliis lanceolatis serratis sessilibus, pedunculis ramosis multifloris. *Lin. Sp. Plant. 612.* Low Gesnera with a yellowish flower.

The first sort grows naturally in *Jamaica*; this rises with a shrubby stalk six or seven feet high, and divides into two or three irregular branches, covered with a russet wool, garnished with hairy leaves which are seven or eight inches long, and two and a half broad in the middle, with a russet woolly midrib; the edges are crenated, and they have short foot-stalks; towards the end of the branches come out the foot-stalks of the flowers at the joints, arising from the wings of the stalk; which are naked, branching at the top into many smaller foot-stalks, each sustaining a single flower with a short crooked tube, indented at the top in five obtuse segments of an obsolete purple colour. These are succeeded by roundish capsules sitting close in the empalement, the divisions of which arise above the capsule, which is divided into two cells, filled with small seeds. It flowers in *July* and *August*, but hath not ripened seeds in *England*.

The second sort is a plant of humbler growth, this seldom rises more than three feet high; the leaves are much smaller, sawed on their edges, and sit close to the stalk; the flowers stand upon branching foot-stalks, each sustaining many yellowish flowers, which are deeper cut at their brims than those of the first sort. It grows naturally at *Carthagena* in *New Spain*.

These plants are propagated by seeds, which should be sown in pots and plunged into a hot-bed of tanners bark, as soon as they arrive in *England*, for they sometimes lie long in the ground; those which I have sown in autumn,

came up the following spring; therefore when they happen to arrive here at that season, the pots in which the seeds are sown, should be plunged into the tan-bed in the stove, and during the winter the earth should be now and then gently watered, to prevent its drying too much, but it must not be too moist. In the spring the pots should be removed out of the stove, and plunged into a fresh hot-bed, which will bring up the plants soon after. When these are fit to remove, they should be each planted into a separate pot, and plunged into a good hot-bed of tan, observing to shade them till they have taken new root, then they must be treated in the same way as other tender plants from the same countries.

In autumn they must be plunged into the tan-bed in the stove, where they must constantly remain, for they will not thrive out of the tan-bed. In the summer they should have free air admitted to them, at all times when the weather is warm. As the plants advance in growth they will require larger pots, but there must be care taken not to over-pot them, for they will not thrive in large pots.

GEUM. *Lin. Gen. Plant. 561.* Avens, or Herb-Bennet.

The Characters are,

The flower has five roundish petals, which are narrow at their base, where they are inserted in the empalement, and a great number of awl-shaped stamina, which are the length of the empalement, into which they are inserted. In the center of the flower is situated a great number of germen collected into a head, which afterward become so many flat, rough, hairy seeds, with the style which is bent like a knee adbering to them.

The Species are,

1. GEUM floribus erectis, fructu globofo, aristis uncinatis nudis, foliis lyratis. *Hort. Cliff. 195.* Common Avens or Herb Bennet.

2. GEUM floribus nutantibus, fructu oblongo, aristis plumosis. *Hort. Cliff. 195.* Aquatick Herb Bennet with a nodding flower.

3. GEUM floribus nutantibus, fructu globofo, aristis nudis, foliis lyratis, foliolis rotundioribus. Pyrenean Avens with a very large and rounder leaf, and a nodding flower.

4. GEUM flore erecto solitario, fructu oblongo, aristis plumosis. *Lin. Sp. Plant. 501.* Mountain Avens with a large yellow flower.

5. GEUM flore solitario erecto, fructu globofo, aristis tenuioribus nudis. Smaller Alpine Avens.

6. GEUM floribus erectis, fructu globofo, aristis uncinatis nudis, foliis ternatis. *Hort. Cliff. 195.* Virginia Avens with a smaller white flower, and a scentless root.

The first sort grows plentifully by the side of hedges, and in woods in most parts of *England*, so is rarely admitted into gardens. This stands in the list of medicinal plants, the root is the only part used; it is esteemed cephalick and alexipharmick, and is manifestly of a binding nature, so is useful in all fluxes, &c.

The second sort grows naturally in moist meadows in the northern parts of *England*. This is of humbler growth than the first; the lower leaves have two pair of small lobes at bottom, and three large ones at the top, that which terminates being the largest. The leaves upon the stalks, are composed of three acute lobes which sit close to the stalk; the flowers are of a purplish colour, and nod on one side; they appear in *May*, and the seeds ripen in *July*.

The third sort grows upon the *Alps*, and also on the mountains in the north; this hath some resemblance to the second sort, but the leaves are much larger and rounder, and are indented on their edges; the flowers are larger and of a gold colour. This flowers about the same time as the second.

The fourth sort grows naturally upon the *Alps*; this hath leaves much larger than either of the other species; the lower

lower leaves are composed of three or four pair of small irregular pinnæ set along the midrib, which is terminated by one very broad roundish lobe, crenated on the edge. The flowers are large, of a bright yellow colour, standing single on the top of the stalk, which seldom rises more than five or six inches high. It flowers in *May* and *June*.

The fifth sort grows naturally on the *Alps*; it is a very low plant, the flower-stalks are about three inches long, and bend on one side; they are each terminated by one bright yellow flower, about the size of those of the common sort. This flowers about the same time as the former.

The sixth sort grows naturally in *North America*; the stalks of this sort rise two feet and a half high, and branch out at the top into small foot-stalks, each being terminated by a small white flower; the leaves of this sort are trifoliate, and the root has no scent. These are all very hardy plants which require a shady situation, but will thrive in any soil; they may be easily propagated by seeds which should be sown in autumn, for when they are sown in the spring, they do not grow the same year.

GILLIFLOWER, or JULY-FLOWER. See *Dianthus*.

GILLIFLOWER, or STOCK-GILLIFLOWER. See *Cheiranthus*.

GILLIFLOWER, the Queen's, or Dame's Violet. See *Hesperis*.

GINGER. See *Amomum*.

GINGIDIUM. See *Artedia*.

GLADIOLUS. *Lin. Gen. Plant.* 55. Cornflag.

The Characters are,

The flowers are included in sheaths; the petal of the flower is cut into six parts, and form a short incurved tube with their base; they have three awl-shaped stamina, which are inserted into every other petal. The germen is situated below the flower, which afterward becomes an oblong, swelling, three-cornered capsule, with three cells, filled with roundish seeds.

The Species are,

1. GLADIOLUS *foliis ensiformibus, floribus distantibus*. *Lin. Sp. Plant.* 36. Cornflag with flowers disposed on one side the stalk.

2. GLADIOLUS *foliis ensiformibus, utrinque floribus*. Cornflag with flowers on each side the stalk.

3. GLADIOLUS *foliis ensiformibus, spathis maximis*. Greater Cornflag of *Byzantium*.

4. GLADIOLUS *foliis ensiformibus, floribus maximis incarnatis*. Greatest Indian Cornflag.

5. GLADIOLUS *foliis linearibus, floribus distantibus, corollarum tubo limbis longiore*. *Lin. Sp. Plant.* 37. Cornflag with very narrow leaves, flowers standing at a distance from each other, and the tube longer than the margins of the petal.

6. GLADIOLUS *foliis linearibus sulcatis, caule biflorâ, tubo longissimo, segmentis æqualibus*. Cornflag with very narrow channelled leaves, and a stalk bearing two flowers with a very long tube, and equal segments.

The first sort grows naturally in arable land, in most of the warm countries in *Europe*, and was formerly cultivated in the *English* gardens, where the roots have multiplied so greatly as to become a most troublesome weed, and is very difficult to eradicate; this hath a round, compressed, tuberos root, which is of a yellowish colour, and covered with a brown furrowed skin, like those of the large yellow vernal *Crocus*; from the root arise two flat sword-shaped leaves, which embrace each other at their base, and between these arise the flower-stalk, which grows near two feet high, having one or two narrow leaves embracing it like a sheath; the stalks are terminated by five or six purple flowers, standing above each other at some distance, and ranged on one side of the stalk; each of these has a spatha (or sheath) which covers the flower bud before it expands,

but splits open lengthways when the flowers blow, and shrivel up to a dry skin, remaining about the seed vessel till the seeds are ripe. The flower hath one petal, which is cut almost to the bottom in six parts, so as to appear like a flower of six petals; the three upper segments stand near together, and rise like a labiated flower; the under one turns downward, and the two side segments form the chaps of the flower, and spread open at the top, but are curved downward at the bottom. They are of a purplish red colour: it requires no care, for when it is once planted in a garden, it will multiply too fast, so as to become a troublesome weed.

There is a variety of this with white flowers, and another with flesh-coloured flowers, which have accidentally risen from seeds, so are not different species.

The second sort differs from the first, in having the flowers ranged on both sides the stalk, but in other respects, it is very like to that. Of this there is a variety with white flowers, but these are not so common in the *English* gardens as the former.

The third sort hath larger roots than either of the former, but are of the same form; the leaves are also much broader and longer, the veins or channels of the leaves are deeper; the flower-stalks rise higher; the flowers are much larger, and of a deeper red colour, than those of the former sorts, and the sheaths are longer. This plant makes a fine appearance when in flower, so is worthy of a place in every good garden. This is propagated by offsets, which are sent off from the roots, in the same manner as *Tulips*, in great plenty. The roots may be taken out of the ground in the end of *July*, when their stalks decay, and may be kept out of the ground till the latter end of *September*, or the beginning of *October*, at which time they should be planted in the borders of the flower-garden; they will thrive in any situation, and being intermixed with other flowers of the same growth, they will add to the variety.

The fourth sort grows naturally at the *Cape of Good Hope*. This has been many years cultivated in the *English* gardens, but very rarely flowers here; for in near thirty years that I have cultivated this sort, I have never seen it but once in flower, though I have kept it in all situations, and planted it in various soils. The roots of this sort are broader and flatter than those of any of the other sorts, and are covered with a netted skin; the leaves come out in the same manner, embracing each other as the former sorts; they are longer, smoother, and of a brighter green, than any of the others; these begin to appear in *September*, and continue growing in size till after *Christmas*, and begin to decay in *March*; by the latter end of *May* are quite withered, when the roots may be taken up, and kept out of the ground till *August*; the time of it's flowering is in *January*. The flowers of this sort are placed on each side the stalk, and sit close to it, like the grains of the flat *Barley*; the sheaths between the flowers are not so long as those of the other sorts, and form a kind of scaly covering to them. The flowers are of a pale red colour without, but the three lower segments are yellowish within, with a few stripes of red. The flowers do not all open at the same time, but the lower ones decay before those on the upper part of the spike are in beauty; however, they make a fine appearance at a season when all flowers are valuable.

This sort propagates by offsets very fast; these should be planted in pots, and in winter they must be protected from frost, but they do not require any artificial warmth. I have always found that those plants which were hardily treated, grew much stronger than those which were placed in a moderate degree of warmth; so that where there is a conveniency of covering a warm border with glasses in the winter, if these roots are planted in the full ground, where they

they may be protected from the frost, there will be a greater probability of their flowering, than in any other method of culture.

The fifth sort grows naturally at the *Cape of Good Hope*.

This hath a round, smooth, bulbous root, which is covered with a thin dark coloured skin, from which come out in autumn two or three very narrow grassy leaves, folded over each other at their base, but open flat above; these rise near two feet high. In the spring arises a single stalk from between the leaves, about two feet long, which always bends on one side; toward the upper part of this come out two or three flowers, ranged on one side of the stalk, standing upright, each having a narrow spatha, or hood, with long slender tubes, which swell large upward, and are divided into six almost equal parts. The flower is of a dusky flesh-colour, and each segment of the petal has a rhomboidal mark of a dark red, or purple colour; afterward the tube of the flower opens, and the deep division of the petals is seen, and the three stamina, with their summits, appear, attended by the style with its trifid stigma, arising from the germen. This plant requires protection from the frost in winter, therefore the bulbs should be planted in pots, or in a border where the roots may be kept from frost in winter; or, where there is not such conveniency, they may be put under a hot-bed frame during that season, where they may have air in mild weather, and be screened from the frost; in such situations I have had them thrive and flower very well.

This is propagated by offsets from the root, in the same manner as the last, and also by seeds, which are frequently perfected in *England*, which should be sown the latter end of *August*, in pots, and placed in a shady situation till the middle of *September*; then the pots should be removed where they may have the sun great part of the day, and in *October* they must be placed under a hot-bed frame, where they may be protected from frosts and great rains, but enjoy the free air in mild weather. In *May*, when the danger of frost is over, the pots should be removed to a sheltered situation, where they may have the morning sun till noon. Toward the latter end of *June*, the leaves of these plants will decay, then the roots should be taken up, and may be mixed with sand, and kept in a dry room till the end of *August*, when they should be planted again, and as the roots are small, four or five may be planted into each halfpenny pot, and treated in the same way as the old roots.

The sixth sort is also a native of the *Cape of Good Hope*; the root of this sort is oval, not compressed as those of the other. The leaves are very long and narrow, having two deep furrows running the whole length, the middle one rising very prominent, so as to have the appearance of a four-cornered leaf. There are seldom more than two of these leaves arising from one root; the stalk is slender and round, and rises about two feet high; the top is garnished with two flowers, which are placed about two inches and a half asunder on the same side of the stalk, each having a short spatha, or sheath, embracing the germen and the base of the tube, which is long, narrow, and recurved, but enlarges greatly before it is divided. The upper part of the flower is cut into six equal segments, which end in acute points of a purplish colour, which form a stripe through the middle of each segment. The petal is of a cream colour, and fades to a sulphur colour before it decays. This may be propagated by offsets from the root, or by seeds, in the same manner as the fifth sort, and the plants require the same treatment.

GLASTENBURY THORN. See *Mespilus*.

GLAUCIUM. See *Chelidonium*.

GLAUX, Sea Chickweed, or Milkwort, and by some black Saltwort; it is a low, trailing, perennial plant, with

leave somewhat like Chickweed, but of a thicker consistence, which sit close to the stalks. The flowers come out from the bosom of the leaves, they are white, and like those of Chickweed. This is seldom cultivated in gardens, so I shall not trouble the reader with a further account of it. It grows upon the sea-shores in most parts of *England*.

GLECHOMA, Ground Ivy, Gill go by the Ground, Ale Hoof, or Turn Hoof.

This plant grows naturally under hedges, and upon the sides of banks in most parts of *England*, so is rarely cultivated in gardens, for which reason I shall pass over it, with barely mentioning it here.

GLEDITSIA. *Lin. Gen. Plant.* 1025. Honey Locust, or three-thorned Acacia.

The Characters are,

It hath male and hermaphrodite flowers on the same plant, and female flowers in different plants. The male have a three-leaved empalement, and three roundish petals, with a turbinated nectarium; they have six stamina, terminated by compressed summits. The hermaphrodite flowers have quadrifid empalements, with four petals, and six stamina; and have a germen, style, and pods, like the female, which are situated on different trees; these have a five-leaved empalement, and five petals, with two nectariums, and a broad germen longer than the petals, which afterward becomes a large flat pod, with several transverse partitions, having a pulp in each division, surrounding one hard roundish seed.

The Species are,

1. GLEDITSIA *spinis ternatis, foliis pinnatis, siliquis latis longissimis caule arborico*. Gleditsia with three Thorns, winged leaves, very long broad pods, and a tree-like stalk, commonly called three-thorned Acacia.

2. GLEDITSIA *spinis paucioribus, foliis pinnatis, siliquis ovalibus monospermis*. Gleditsia with a few spines, winged leaves, and oval pods, containing one seed.

These trees grow naturally in most parts of *North America*, where the first is known by the title of Honey Locust; this has been many years cultivated in the *English* gardens, and is known among the gardeners by the title of three-thorned Acacia. It rises with an erect trunk, to the height of thirty or forty feet, armed with long spines, which have two or three smaller coming out from the side; these are frequently produced in clusters at the knots, and are sometimes three or four inches long. The branches of this tree are also armed with the same sort of spines, and are garnished with winged leaves, composed of ten pair of small leaves, which sit close to the midrib, of a lucid green. The flowers come out from the side of the young branches in form of katkins; they are of an herbaceous colour, so make no figure. The hermaphrodite flowers are succeeded by pods near a foot and a half long, and two inches broad, divided into many cells by transverse partitions, each containing one smooth, hard, oblong seed, surrounded by a sweet pulp.

The second sort hath much the appearance of the first, but hath fewer spines, which are very short. The leaves are smaller, and the pods are oval, containing but one seed; this was discovered by the late Mr. *Catesby*, in *Carolina*, from whence he sent the seeds to *England*, by the title of Water Acacia, by which it is known in the gardens.

These trees are propagated by seeds; those of the first sort are annually sent to *England* in plenty, by the title of Locust, or Honey Locust, to distinguish it from the false Acacia, which is frequently called Locust Tree in *America*: the seeds may be sown upon a bed of light earth in the spring, burying them half an inch deep, and if the spring should prove dry, they must be frequently watered, otherwise the plants will not come up the first year, for I have sometimes had the seeds remain two years in the ground before

fore the plants have come up ; therefore those who are desirous to save time, should sow the seeds as soon as they arrive, and plunge the pots into a moderate hot-bed, observing to water them frequently ; by this method, most of the plants will come up the same season : they should be gradually inured to bear the open air, for if they are continued in the hot-bed, they will draw up weak. In autumn, the pots should be placed under a hot-bed frame, to protect them from frost, for these young plants generally keep growing late in the summer, so the upper part of their shoots is tender, and the early frosts of the autumn often kill the ends of them, if they are not protected, and this frequently occasions great part of the shoots decaying in winter ; for which reason those plants in the full ground, should be covered with mats in autumn, on the first appearance of frost, for a small frost in autumn will do more mischief to these young shoots which are full of sap, than severe frost when the shoots are hardened.

The following spring the plants may be transplanted into nursery-beds, at a foot distance, row from row, and six inches asunder in the rows, but this should not be performed till *April*, after the danger of hard frost is over ; for as the plants do not put out their leaves till very late, so there will be no hazard in removing them any time before *May*. If the season should prove dry, they must be watered, and if the surface of the beds is covered with moss, or mulch, to prevent the earth from drying, it will be of great service to the plants. In these beds the plants may remain two years, by which time, if the plants thrive well, they will be fit to transplant to the places where they are to remain, for they do not bear removing when large ; the best season for transplanting of these trees, is late in the spring ; they thrive best in a deep loamy soil, for in strong shallow ground they become mossy, and never grow large ; they should also have a sheltered situation, for when they are much exposed to winds, their branches are frequently broken in the summer season, when they are fully clothed with leaves.

GLOBULARIA. *Lin. Gen. Plant.* 106. Blue Daisy.

The Characters are,

It hath a flower composed of many florets, which are included in one common scaly empalement ; each floret is tubulous, and cut into four parts at the top. They have four stamina, terminated by distinct summits ; in the bottom of the tube is situated an oval germen, which afterward becomes an oval seed, sitting in the common empalement.

The Species are,

1. GLOBULARIA caule herbaceo, foliis radicalibus tridentatis, caulinis lanceolatis. *Flor. Suec.* 109. Common Globularia.
2. GLOBULARIA caule nudo, foliis integerrimis lanceolatis. *Lin. Sp. Plant.* 97. Pyrenean Globularia, with an oblong leaf and naked stalk.
3. GLOBULARIA caule fruticoso, foliis lanceolatis tridentatis integrisque. *Prod. Leyd.* 190. Globularia with a shrubby stalk, and spear-shaped leaves ending in three points.
4. GLOBULARIA foliis radicalibus crenato-aculeatis, caulinis integerrimis mucronatis. *Lin. Sp. Plant.* 96. Prickly Globularia.
5. GLOBULARIA caule subnudo, foliis cuneiformibus tricuspidatis, intermedio minimo. *Lin. Sp. Plant.* 96. Smallest Alpine Globularia, with a wild Marjoram leaf.
6. GLOBULARIA caule subnudo, capitulis alternis sessilibus, foliis lanceolato-ovatis integris. *Lin. Sp. Plant.* 97. Eastern Globularia with flowers scattered along the stalks.

The first of these plants grows plentifully about *Montpelier*, as also at the foot of the mountains *Jura* and *Saleva*, and in many other parts of *Italy* and *Germany*. It hath leaves very like those of the Daisy, but are thicker and smoother. The flowers grow on foot-stalks about six inches high,

and are of a globular form, composed of several florets, which are included in one common scaly empalement ; they are of a fine blue colour, and are succeeded by seeds, which sit in the empalement, and ripen in autumn.

The second sort grows plentifully in the woods, near the convent of the *Carthusians*, and on the *Pyrenean* mountains ; this is much larger than the former, and the foot-stalk is quite naked. The leaves are narrower, and much longer.

The first and second sorts may be propagated by parting of their roots after the manner of *Daisies*. The best season for this is in *September*, that they may take new root before the frosty weather comes on. They should be planted in a shady situation and a loamy soil, in which they will thrive much better than in light ground, and an open situation ; but the plants should not be removed oftener than every other year, if they are required to flower strong.

The third sort grows about *Montpelier* in *France*, and in *Valentia*, and several other parts of *Spain*. This has a hard woody stem, which rises about two feet high, dividing into many woody branches, beset with leaves like those of the *Myrtle* tree. On the top of the branches the flowers are produced, which are of a blue colour, and globe-shaped ; this plant is very difficult to propagate in *England*, where it does not produce seeds ; the cuttings, when carefully managed, will sometimes put out roots, but with great difficulty. In summer the plants may be exposed with other hardy exoticks, and in winter they should be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but should be screened from hard frost, which will destroy them, if they are exposed thereto ; though in mild winters they will live in the open air.

The fourth sort was found in the mountains of *Granada*, by *Dr. Albinus* ; this plant is of low growth, and may be propagated as the first ; as may also the fifth sort, which is the least of all the kinds, and the most hardy, therefore should have a shady situation, and a cool moist soil.

The sixth sort was found by *Dr. Tournefort*, in the *Levant* ; this is tender, and should be sheltered from the frost in winter, under a frame, but in summer it should be exposed with other hardy exotick plants ; it will require to be frequently watered in dry weather, and is propagated by seeds, or by parting of the roots, as was directed for the former sorts.

GLORIOSA. *Lin. Gen. Plant.* 374. The Superb Lily.

The Characters are,

The flower hath no empalement ; it hath six spear shaped petals, which are waved, and reflexed to the bottom. It hath six stamina, which spread each way, terminated by prostrate summits. In the center is situated a globular germen, which afterward becomes an oval thin capsule with three cells, filled with globular seeds disposed in a double range.

The Species are,

1. GLORIOSA foliis longioribus capreolis terminalibus. Superb Lily, with longer leaves ending with clasps.
2. GLORIOSA foliis ovato-lanceolatis acutis. Superb Lily with oval, spear-shaped, acute leaves.

The first sort grows naturally on the coast of *Malabar*, and also in *Ceylon* ; this hath oblong fleshy roots of a whitish colour, and a nauseous bitter taste, from which arises a round weak stalk, which requires support to prevent its trailing on the ground. The stalks grow to the height of eight or ten feet, garnished with leaves placed alternate ; they are smooth, about eight inches long, and one and a half broad at the base, growing narrower till within two inches of the end, which runs out in a narrow point, ending with a tendril or clasper, by which it fastens to the neighbouring plants for support. At the upper part of the stalk the flowers are produced, standing upon slender foot-stalks ; they are composed of six oblong petals, ending with acute points, which, on their first opening, are of a yellowish

lowish herbaceous colour, standing at first erect, but when fully opened, hang downward as the Crown Imperial and Fritillary; the petals turn quite back, and change to a very beautiful red flame colour, their acute points meeting at the foot-stalk; these petals are finely waved on their edges. The six stamina spread out every way almost horizontal, and are terminated by prostrate summits. In the center of the flower is situated a roundish germen, supporting an inclining style, crowned by a triple stigma. It flowers in July, and often perfects seeds in this country. The stalks decay in autumn, and the roots remain inactive all the winter. The roots, and every part of this plant, is very poisonous, so should not be put in the way of children.

The seeds of the second sort were sent me by Monf. Richard, gardener to the French king at Trianon; which were brought from Senegal by Monf. Adanson, who discovered this plant growing there naturally; this is said to have a blue flower, but the plants which are in the Chelsea garden have not yet flowered. This hath a climbing stalk, which is garnished with smooth leaves about two inches long and two broad, ending in acute points, with short tendrils or clasps. The stalks as yet have not grown more than four feet high here. The leaves have a strong disagreeable scent on being handled, so as to be troublesome to the head if too near, or long smelt to.

These plants are propagated by their roots; those of the first sort creep and multiply pretty fast. These roots may be taken out of the ground when their stalks are decayed, and preserved in sand during the winter season, but they must be kept in the stove, or a warm room, where they can receive no injury from the cold, and in the spring they must be planted in pots filled with light earth, and plunged into the tan-bed in the stove; but others chuse to let the roots continue in the ground all the winter, keeping the pots always in the tan-bed; where this is practised, the roots should have very little water in the winter, for as they are then in an inactive state, so moisture at that time frequently rots them.

Toward the latter end of March, or the beginning of April, their stalks will appear, when there should be some tall sticks put down by them to support them, otherwise they will trail over the neighbouring plants, and fasten to them by the tendrils, which are at the ends of the leaves. The stalks will rise ten or twelve feet high, if the roots are strong; some of them will produce two or three flowers, which come out from the wings of the stalk near the top; these flowers make a fine appearance in the stove during their continuance, which is seldom more than ten days or a fortnight. In the summer, when the plants are growing, they will require frequently to be watered, but they must not have it in too large quantities. Those roots which are not taken out of the pots in winter, should be transplanted and parted the beginning of March, before they put out new fibres or stalks, for they must not be removed when they are in a growing state; the pots in which these roots are planted, should not be too large, for unless they are confined, they will not put out strong stalks; the largest roots may be planted in twopenny pots, but the small ones will require only pots of about five or six inches over at the top.

GLYCINE. *Lin. Gen. Plant.* 797. Knobbed-rooted Liquorice Vetch.

The Characters are,

The flower is of the butterfly kind. The standard is deflexed on the sides, and indented at the point. The wings bend backward. The keel is sickle-shaped, turning upward with its point to the standard. The empalement hath two lips. It hath ten stamina, nine of which are joined in one body, and the other stands single. In the center is situated an oblong germen, which

afterward becomes an oblong pod with two cells, inclosing kidney-shaped seeds.

The Species are,

1. GLYCINE *foliis pinnatis ovato-lanceolatis.* Hort. Upsal. 227. Glycine with oval, spear-shaped, winged leaves. This is the *Apios Americana.* Cornut. 200.

2. GLYCINE *foliis pinnatis caule perenni.* Hort Cliff. 361. Glycine with winged leaves and a perennial stalk.

3. GLYCINE *foliis pinnatis conjugatis, pinnis ovatis oblongis obtusis.* Flor. Zeyl. 284. This is commonly called wild Liquorice in the West-Indies.

4. GLYCINE *foliis ternatis hirsutis, racemis lateralibus.* Lin. Sp. Plant. 754. Glycine with hairy trifoliate leaves, and flowers growing in long bunches from the sides of the stalks.

5. GLYCINE *foliis ternatis tomentosis, racemis axillaribus brevissimis, leguminibus dispermis.* Lin. Sp. Plant. 754. Glycine with woolly trifoliate leaves, and very short spikes of flowers proceeding from the sides of the stalks, with pods containing two seeds.

The first sort grows naturally in Virginia; it hath roots composed of several knobs, or tubers, which hang to each other by small strings; from these come out in the spring slender twining stalks, which rise to the height of eight or ten feet, garnished with winged leaves, composed of three pair of oval spear-shaped lobes, terminated by an odd one. The flowers come out in short spikes from the side of the stalks; they are of a Pea blossom kind, of a dirty fresh colour, having little scent. The stalks decay in autumn, but the roots continue; this is propagated by parting of the roots, each of the tubers being separated from the principal root, will grow; the best time for this is about the end of March, or the beginning of April, before they put out shoots. The roots should be planted in a warm situation, and in hard frost covered to protect them, otherwise they will not live abroad in this country; where they have been planted against a south wall, they have thriven and flowered extremely well, which they seldom do in any other situation; and those roots which are planted in pots rarely flower, nor do their stalks rise near so high as those which are planted in the full ground; some ignorant persons call this the Twickenham Climber.

The second sort was brought from Carolina, but has been since observed in Virginia, and some other parts of North America; this has woody stalks, which twist themselves together, and also twine round any trees that grow near, and will rise to the height of fifteen feet, or more. The leaves are winged, and in shape somewhat like the Ash tree, but have a greater number of pinnæ. The flowers are produced from the wings of the leaves, which are of a purple colour; and are succeeded by long cylindrical pods, shaped like those of the scarlet Kidney Bean, containing several kidney-shaped seeds, but these are never perfect in England.

This climbing shrub is raised for sale in several nurseries near London, where it is known by the name of Carolina Kidney Bean tree. It is propagated by laying down the young branches in October, which will be rooted by that time twelvemonth, and may then be transplanted either in a nursery for a year to get strength, or to the place where they are to remain for good, which should be in a warm light soil and a sheltered situation, where they will endure the cold of our ordinary winters very well; and if their roots are covered with Straw, Fern, Pease haulm, or any other light covering, there will be no danger of their being destroyed by great frost.

The third sort grows naturally in both Indies, and also in Egypt. This a perennial plant, with slender twining stalks, which twist round any neighbouring support, and rise to

the height of eight or ten feet, garnished with winged leaves, composed of sixteen pair of oblong blunt lobes, set close together, which have the taste of Liquorice, from whence the inhabitants of the *West-Indies* have given it the name of Wild Liquorice, and use the herb for the same purpose as Liquorice is used in *Europe*. The flowers are produced from the side of the stalks in short spikes or bunches; they are of a pale purple colour, and shaped like those of the Kidney Bean; these are succeeded by short pods, each containing three or four hard round seeds of a scarlet colour, with a black spot or eye on the side, which is fastened to the pod. The seeds are frequently brought to *England* from the *West-Indies*, and are wrought into various forms, with shells and other hard seeds.

It is propagated by seeds, which must be sown upon a good hot-bed in the spring; but as they are very hard, so unless they are soaked in water a day or two before they are sown, they frequently lie in the ground a whole year before they vegetate; but when soaked, the plants will appear in three weeks after the seeds are sown, if they are good, and the bed in a proper temperature of heat. When the plants are two inches high, they should be each transplanted into a separate pot, and plunged into a hot-bed of tanners bark, where they should be shaded from the sun till they have taken new root; after which they must be treated in the same manner as other tender plants from the same countries, always keeping them in the bark-stove, for they are too tender to thrive in any other situation in *England*.

There are two other varieties of this plant, one with a white, and the other a yellow seed, but the plants do not differ from the other in leaf or stalk; but as these have not as yet flowered in *England*, so I do not know how their flowers may differ.

The fourth sort hath a perennial root and an annual stalk. This rises from two to three feet high, with slender herbaceous stalks, garnished with trifoliate hairy leaves, sitting close to them; the small leaves or lobes, are of the oval spear-shape, ending in acute points. The flowers come out from the side of the stalks, upon foot-stalks about two inches long; the spike of flowers is about the same length, and is recurved; they are of the Pea blossom kind, sitting close together, but small, and of a fine blue colour.

This sort grows naturally in *North America*, and is hardy enough to live in the open air in *England*. It may be propagated by seeds, or parting of the roots; the former is the best method, where good seeds can be obtained; these should be sown on a bed of light earth in the spring, and if the season should prove dry, they must be frequently refreshed with water, otherwise they will remain a long time in the ground before they vegetate; in the autumn, when their stalks are decayed, if some rotten tanners bark is spread over the surface of the ground, it will protect the roots from being injured by the frost. In the spring, the roots should be transplanted to the places where they are designed to remain, which must be in a warm sheltered situation and a light soil, where they will thrive and produce flowers annually. If this is propagated by parting of the roots, it should be done in the spring, before the roots begin to shoot, which is the best season for transplanting of the plants.

The fifth sort is a perennial plant with a climbing stalk, which rises six or seven feet high, garnished with woolly trifoliate leaves: the flowers come out in short bunches from the side of the stalks, they are small, of a yellow colour, and are succeeded by short pods, which contain two roundish seeds in each. It grows naturally in *Virginia*, and also in *India*. This is propagated by seeds, but the plants require protection in winter.

GLYCYRRHIZA. *Lin. Gen. Plant.* 788. Liquorice.

The Characters are,

The flower hath a permanent empalement of one leaf, divided into two lips. The flower is of the butterfly kind, having a long erect standard, with oblong wings, and a two-leaved keel which is acute. It hath ten stamina, nine joined and one standing single. In the bottom is situated a short germen, which afterward becomes an oblong, or oval compressed pod with one cell, including two or three kidney-shaped seeds.

The Species are,

1. GLYCYRRHIZA *leguminibus glabris.* Hort. Cliff. 490. Liquorice with smooth pods. This is the common Liquorice.

2. GLYCYRRHIZA *leguminibus echinatis.* Prod. Leyd. 386. Liquorice with prickly pods.

3. GLYCYRRHIZA *leguminibus hirsutis.* Prod. Leyd. 386. Eastern Liquorice with hairy pods.

The first sort is that which is commonly cultivated in *England* for medicine; the other two kinds are preserved in curious botanick gardens for variety, but their roots are not so full of juice as the first, nor is the juice so sweet, though the second sort seems to be that which *Dioscorides* has described and recommended; but I suppose, the goodness of the first has occasioned its being so generally cultivated in *England*.

The roots of this run very deep into the ground, and creep to a considerable distance, especially where they are permitted to stand long unremoved; from these arise strong herbaceous stalks, four or five feet high, garnished with winged leaves, composed of four or five pair of oval lobes, terminated by an odd one; the flowers come out in spikes from the upper part of the stalks, standing erect; they are of a pale blue colour, and are succeeded by short compressed pods, each containing two or three kidney-shaped seeds, which rarely ripen in *England*.

This plant delights in a light sandy soil, which should be three feet deep at least, for the goodness of Liquorice consists in the length of the roots: the greatest quantity of Liquorice which is propagated in *England*, is about *Pontefract* in *Yorkshire*, and *Godalmin* in *Surry*; though of late years, there hath been great quantities cultivated in the gardens near *London*: the ground intended for Liquorice, should be well dug and dunged the year before, that the dung may be perfectly rotted, and mixed with the earth, otherwise it will be apt to stop the roots from running down; and before it is planted, the ground should be dug three spades deep with two shovels; when it is thus well prepared, a sufficient quantity of fresh plants taken from the sides or heads of the old roots should be provided, each of them should have a good bud or eye, otherwise they are subject to miscarry; these plants should be about eight or ten inches long, and perfectly sound.

The best season for planting them is toward the end of *February*, or the beginning of *March*, which must be done in the following manner; viz. First strain a line cross the ground, beginning at one end of the piece, then with a long dibble made on purpose, put in the shoot, so that the whole plant may be set straight into the ground, with the head about an inch under the surface in a straight line, about a foot asunder, or more, in rows, and two feet distance row from row; and after having finished the whole spot of ground, it may be sown with a thin crop of Onions, which do not root deep into the ground, nor spread much above, so will do the Liquorice no damage the first year; for the Liquorice will not shoot very high the first season, and the hoeing of the Onions will also keep the ground clear from weeds; but in doing this, care should be taken not to cut off the shoots of the Liquorice plants, as they appear above ground, which would greatly injure them, and to cut up all the Onions which grow near the heads of the Liquorice; after the Onions are

are full grown and pulled up, the ground should be cleared from weeds; and in *October*, when the shoots of the Liquorice are decayed, a small quantity of very rotten dung spread upon the surface of the ground, will prevent the weeds from growing during the winter, and the rain will wash the dung into the ground, which will greatly improve the plants.

In the beginning of *March* following, the ground between the rows of Liquorice should be slightly dug, burying the remaining part of the dung; but in doing this, care must be taken not to cut the roots. This stirring the ground will not only preserve it clean from weeds a long time, but also greatly strengthen the plants.

The distance I have allowed for planting these plants, will, I doubt not, by some, be thought too great; but, in answer to that, I would only observe, that as the largeness of the roots is the chief advantage to the planter, the only method to obtain it, is by giving them room; besides, this will give a greater liberty to stir and dress the ground, which is of great service to Liquorice; and if the plantation designed were to be of an extraordinary bigness, I would advise the rows to be made at least three feet distant, whereby it will be easy to stir the ground with a hoeing plough, which will greatly lessen the expence of labour.

These plants should remain three years from the time of planting, when they will be fit to take up for use; which should not be done until the stalks are perfectly decayed, for when it is taken up too soon, it is subject to shrink greatly, and lose of its weight.

The ground near *London* being rich, increases the bulk of the root very fast; but when it is taken up, it appears of a very dark colour, and not near so light as that which grows upon a sandy soil in an open country.

The second sort grows naturally in some parts of *Italy*, and the *Levant*; the stalks and leaves of this are very like those of the first, but the flowers are produced in shorter spikes, and the pods which succeed them are very short, broad at their base, ending in acute points, and are armed with sharp prickles. This flowers about the same time as the first, and in warm seasons will perfect seeds in *England*.

The third sort grows naturally in the *Levant*. This hath much the appearance of the other two species, but the pods of it are hairy, and longer than those of the other. Both these sorts may be propagated in the same manner as the first, or from seeds, which may be sown in the spring on a bed of light earth; but as neither of these are used, so they are seldom propagated, unless for the sake of variety.

GNAPHALIUM. *Lin. Gen. Plant.* 850. Goldylocks, or Eternal Flower.

The Characters are,

It hath a compound flower, made up of hermaphrodite florets and female half florets, included in one shining scaly empalement; the hermaphrodite florets are tubulous, and cut into five parts at the brim; these have five short hairy stamina. In the center is situated a crowned germen, which afterward becomes a single seed, which in some species is crowned with a hairy down, and in others a feathery down. The female florets have no stamina, but a crowned germen supporting a slender style. These are in some species fruitful, and in others they are barren.

The Species are,

1. **GNAPHALIUM tomentosum**, foliis caulinis linearibus, caule fruticoso, corymbo composito. Cassidony, or narrow-leaved Goldylocks.

2. **GNAPHALIUM foliis linearibus**, caule fruticoso ramoso, corymbo composito. *Hort. Cliff.* 401. Goldylocks with a branching shrubby stalk, very narrow leaves, and a compound corymbus of flowers.

3. **GNAPHALIUM foliis alternis**, acutè dentatis, subtus villosis, pedunculis longissimis unifloris. Goldylocks with alternate

leaves sharply indented, hairy on their under side, with very long foot-stalks sustaining one flower.

4. **GNAPHALIUM foliis semiamplexicaulibus ensiformibus**, repandis obtusis, utrinque pubescentibus, floribus conglomeratis. *Prod. Leyd.* 149. Broad-leaved wild Goldylocks, with heads growing in clusters.

5. **GNAPHALIUM caule ramoso diffuso**, floribus confertis terminalibus. *Flor. Lapp.* 300. Goldylocks with a diffused branching stalk, and flowers in clusters at the top.

6. **GNAPHALIUM caule simplicissimo**, floribus sparsis. *Flor. Lapp.* 298. Goldylocks with a single stalk, and flowers growing scatteringly.

7. **GNAPHALIUM caule simplicissimo corymbo simplici terminali**, sarmentis procumbentibus. *Hort. Cliff.* 400. Goldylocks with a single stalk terminated by a single corymbus, and trailing branches.

8. **GNAPHALIUM foliis confertis angusto-lanceolatis**, caule fruticoso, corymbo composito. *Hort. Cliff.* 402. Eastern Goldylocks, called Immortal Flower.

9. **GNAPHALIUM foliis linearilanceolatis obtusis**, utrinque tomentosis, corymbo composito terminali. German Goldylocks, with a reddish gold-coloured empalement.

10. **GNAPHALIUM foliis linearilanceolatis acuminatis**, alternis, caule supernè ramoso corymbis fastigiatis. *Hort. Cliff.* 401. Broad leaved *American* Goldylocks.

11. **GNAPHALIUM foliis amplexicaulibus**, ovatis, nervosis, utrinque lanuginosis. *Lin. Sp. Plant.* 850. Goldylocks with oval nervous leaves embracing the stalks, which are downy on both sides.

12. **GNAPHALIUM foliis amplexicaulibus integerrimis acutis**, subtus tomentosis, caule ramoso. *Hort. Cliff.* 402. Most stinking *African* Goldylocks, with a very large leaf, and a silvery empalement to the flower.

13. **GNAPHALIUM foliis decurrentibus acutis**, undatis, subtus tomentosis, caule ramoso. *Hort. Cliff.* 402. Stinking Goldylocks, with an acute leaf and winged stalk.

14. **GNAPHALIUM foliis lanceolatis semiamplexicaulibus**, caule infernè ramoso terminali. *Hort. Cliff.* 401. Goldylocks with spear-shaped leaves embracing the stalks, whose under branches are terminated with flowers.

15. **GNAPHALIUM foliis linearilanceolatis**, caule infernè ramoso, corymbo composito terminali. *Hort. Cliff.* 401. Goldylocks with narrow spear-shaped leaves, the under part of the stalk branching, and a compound corymbus terminating the branches.

16. **GNAPHALIUM foliis linearibus tomentosis**, integerrimis sessilibus, corymbis alternis conglobatis, floribus globosis. *Prod. Leyd.* 149. Goldylocks with a soft red flower.

17. **GNAPHALIUM fruticosum**, foliis infernè lanceolatis caulibus linearilanceolatis, utrinque tomentosis, corymbo composito terminali. Shrubby *African* Goldylocks, with longer and narrower leaves, which are hoary.

18. **GNAPHALIUM foliis decurrentibus obtusis infernè villosis**, corymbis conglobatis terminalibus. Goldylocks with obtuse running leaves, hoary on their under side, and a clustered corymbus of flowers terminating the stalk.

The first sort hath a shrubby stalk about three feet high, dividing into many slender branches garnished with obtuse leaves; those upon the flower-stalks are very narrow, ending in acute points; the whole plant is very woolly, the flowers terminate the stalks in a compound corymbus; their empalements are of a silvery colour at first, and very neat, but afterward turn of a yellowish sulphur colour. If these are gathered before the flowers are much open, the heads will continue in beauty many years, especially if they are kept from the air and dust. This is generally supposed to be the true golden Cassidony of the shops, but the second sort is usually substituted for it in *England*.

It is propagated by slips or cuttings, which may be planted in *June or July*, in a bed of light earth, and covered with glasses, or shaded with mats, they will put out roots in five or six weeks; when they are well rooted, they should be taken up and planted in pots, and placed in a shady situation till they have taken new root; then they may be removed to an open situation, and placed among other hardy exoticks, till about the middle or end of *October*; at which time they should be placed under a common frame, where they may be protected from frost, but in mild weather they should be exposed to the open air. With this management, in winter, the plants will be much stronger than those which are kept in the green house, where they generally draw too weak; for they are so hardy, as in very mild winters to live abroad in warm borders near walls, with little shelter.

The second sort hath a shrubby stalk, which divides into many slender branches, covered with a white bark; these form a bushy under shrub, near three feet high, garnished with very narrow leaves, hoary on their under side, but green on their upper, placed without order on every side the stalks; the flowers are produced in a compound corymbus at the end of the branches; their heads are small, and are of a yellow colour when fully blown. This grows naturally in *France and Germany*, and is hardy enough to live in the open air in *England*. It is propagated by slips or cuttings, in the same way as the former, and in the autumn they may be transplanted into the place where they are designed to remain.

The third sort is an annual plant, which grows naturally in *Italy and Sicily*; this hath an herbaceous stalk, little more than a foot high, garnished with acute indented leaves, which are hoary on their under side; the flowers stand upon long foot-stalks, which rise far above the branches, each sustaining one small whitish flower. It is propagated by seeds, which should be sown upon a bed of light earth where the plants are designed to remain; and when the plants come up, they should be thinned where they are too close, and kept clean from weeds, which is all the culture they require.

The fourth sort is an annual plant, with woolly stalks about eight inches high, garnished with oblong leaves, which embrace them with their base; the flowers grow in close clusters, at the top and from the side of their stalks, which are included in dry silvery empalements.

There is another species of this with narrower leaves, not quite so woolly; the stalks rise higher, and are more branched; the flowers grow in close bunches on the top of the stalks, and are of a pale yellow colour.

Both these sorts will come up better from the scattered seeds, than when they are sown by art; but if the seeds are sown, it must be soon after they are ripe, otherwise they will not succeed. The plants require no other care, but to be kept clean from weeds, and thinned where they are too close.

The fifth sort is an annual plant, which grows naturally in many parts of *England*, on places which are covered with water in the winter; this is a low branching plant with silvery leaves and dark heads of flowers, but being of no use is not cultivated in gardens.

The sixth sort is also an annual plant with narrow leaves, which are hoary on their under side; the stalks grow erect about a foot high, and at every joint is produced a short spike of white flowers. This is found growing naturally in some parts of *England*, so is not often admitted into gardens. If the seeds of this sort are permitted to scatter, the plants will come up in the spring with greater certainty than if sown, and they will require no culture.

The seventh sort grows naturally in the northern parts of *England*, upon the tops of hills and mountains, where the shoots which are sent out from every side of the plant put out roots, whereby it is propagated in great plenty: the leaves of this grow close to the ground, they are narrow at their base, but rounded at the end where they are broad; they are not an inch long, and hoary on their under side; the stalks are single, and rise about four inches high, terminated by a corymbus of flowers which is single.

There are two varieties of this, one with a purple and the other a variegated flower, and continue their difference in the gardens. They are easily propagated by offsets, which should be planted in the autumn, in a shady situation, where they will require no other care but to keep them clean from weeds. This plant is called *Pes Cati*, or Catsfoot.

The eighth sort is supposed to have been brought first from *India to Portugal*, where it has been long propagated for the beauty of its golden heads of flowers, which, if gathered before they are too open, will continue in beauty several years; so that in the winter season, they ornament their churches with these flowers, and many of them are annually brought to *England*, and sold for ornaments to the ladies. These plants have a short shrubby stalk, seldom rising more than three or four inches high, putting out many short branches; the leaves are narrow and woolly on both sides, and come out without order; the flower-stalks grow eight or ten inches high, garnished all the way with narrow hoary leaves, terminated by a compound corymbus of bright yellow flowers, with large heads. This is propagated by slipping off the branches during any of the summer months, and after stripping off the lower leaves, planted in a bed of light earth, covering them with hand glasses, which must be shaded every day when the sun is warm; when these are rooted, they should be planted in pots, and treated in the same manner as hath been directed for the first sort. These plants in mild winters will live abroad in a very warm border with very little shelter, and the hardier they are treated, the greater number of flowers they will produce; for when they are grown weak in a green-house, they never flower so strong.

The ninth sort hath very woolly stalks and leaves, which are much longer than those of the eighth; the stalks rise a foot high, sending out a few side branches, terminated by a compound corymbus of flowers, whose heads are small, and of a gold colour, changing a little red as they fade. This is propagated by slips in the same manner as the last mentioned, but the plants will live in the open air, if they are planted on a dry soil.

The tenth sort grows naturally in *North America*, but has been long in the *English* gardens. This hath a creeping root, which spreads far in the ground, so as to become a troublesome weed very often, unless it is kept within bounds; the stalks of this are woolly, rising a foot and a half high, garnished with long, narrow, woolly leaves, ending in acute points, placed alternate; the upper part of the stalk branches into two or three divisions, each being terminated by a close corymbus of flowers, with pretty large silvery empalements, which, if gathered and properly dried, will retain their beauty several years. This sort will thrive in almost any soil or situation, and is easily propagated by its creeping roots.

The eleventh sort grows naturally at the *Cape of Good Hope*. It is an annual plant, which sends out many oblong blunt leaves near the root; the stalks rise a foot and a half high, garnished with leaves placed alternate, which are broad at their base, where they embrace the stalks, but end in acute points; they are woolly, and, when handled,

emit

emit a very rank odour; the stalks are terminated by a corymbus of flowers, in large silvery empalements, which will retain their beauty several years.

The twelfth sort grows naturally at the *Cape of Good Hope*, and is an annual plant, very like the former sort, but the leaves are of a yellowish green on the upper side, and woolly on the under; the stalks, branch, and the heads of flowers, are of a bright yellow colour, and these differences are permanent.

Both these plants are propagated by seeds, which, if sown in the autumn on a warm border, will more certainly succeed, than when they are sown in the spring; or if the seeds are permitted to scatter, the plants will come up without care, and may be transplanted while they are young, to the places where they are designed to remain; when the plants have taken root, they will require no other care, but to keep them clean from weeds. They flower in *July*, and the seeds ripen in autumn.

The thirteenth sort grows in *Africa*, and also in *North America*, from both these countries I have received the seeds. It is an annual plant, with oblong leaves at the bottom, which are a little waved, and hoary on their under side. The stalks rise about a foot high, garnished with acute pointed leaves; from their base runs a border or wing along the stalk; the whole plant has a disagreeable odour. The flowers grow in a corymbus on the top of the stalks, they are white, and appear in *July*. The seeds ripen in the autumn, which, if permitted to scatter, the plants will come up without care, as the two former sorts.

The fourteenth sort rises with a shrubby stalk three or four feet high, sending out many branches at bottom, garnished with narrow spear-shaped leaves, which half embrace the stalks with their base; they are of a dark green on their upper side, but hoary on their under; the stalks are terminated by a compound corymbus of yellow flowers, whose heads are small: these continue in succession great part of the summer, but are rarely succeeded by seeds in *England*. It is easily propagated by cuttings in any of the summer months, which may be planted in a shady border. These will take root in a month or five weeks, and may then be taken up and planted in pots, placing them in a shady situation till they have taken fresh root; then they may be removed to a sheltered situation, and placed with other hardy green-house plants till autumn, when they must be carried into the green-house, where, during the winter season, they should have as much free air as possible in mild weather, for they only require protection from frost, so they should be treated in the same manner as other hardy green-house plants.

The fifteenth sort grows naturally at the *Cape of Good Hope*; this rises with a slender shrubby stalk, which sends out many lateral branches, garnished with very narrow leaves, which are hoary on their under side. The flowers are produced in a compound corymbus at the end of the branches; they are at their first appearance of a pale red colour, but afterward change to a gold colour; the empalements of this sort are small, and dry like other species of this genus. This sort is propagated by cuttings, in the same manner as the former, and the plants require the same treatment.

The sixteenth sort grows naturally in *Isria*. This is a perennial plant, whose under leaves spread on the ground, which are obtuse, and woolly on their under side; the stalks rise about six inches high; the leaves upon these are narrow, ending in acute points; at each of the joints on the upper part of the stalks, is produced a compact corymbus of flowers, which are placed alternate on each side, the stalk is terminated by a larger corymbus sitting very close; these are of a fine soft red colour, so make a pretty appearance in the month of *June*, when they are in beauty.

This sort is propagated by offsets from the roots, in the same manner as the seventh sort, but this doth not produce them in plenty, so is very uncommon in the *English* gardens at present: it requires a drier soil than the seventh, and a warmer situation, but not too much exposed to the mid-day sun, so should be planted to an east aspect, for it is rarely injured by the cold in *England*.

The seventeenth sort grows naturally at the *Cape of Good Hope*, but has been long preserved in many curious gardens in *Europe*. Dr. *Linnaeus* supposes this and the eighth to be but one species, which he might easily be inclined to do, by seeing the dried specimens only; for these seem only to differ in colour of their flowers or heads, which he never admits as a specific difference. But those who have observed the growing plants, cannot doubt of their being two distinct species; for the stalks of this rise three or four feet high, sending out several long irregular branches, which are terminated by a compound corymbus of flowers; whereas the eighth sort never rises with a stalk, but the branches sit close to the ground, and never divide: the branches of this sort are garnished with leaves, which are much longer than those of the other, and the heads of the flowers are of a bright silver colour. This is propagated by cuttings, which should be planted in the same manner as hath been directed for the eighth sort, and the plants should also be treated the same way.

The eighteenth sort was raised from seeds in the *Chelsea* garden, which came from the *Cape of Good Hope*. The lower leaves of this are oblong and blunt; the stalks are shrubby, and divide into many irregular branches, which rise about three feet high, garnished with oblong blunt-pointed leaves, hoary on their under side, but of a dark green above; from the base of the leaves runs a border along the stalk, like a wing of the same consistence with the leaves, which Dr. *Linnaeus* calls a running leaf. The stalks are terminated by a compound corymbus of flowers, which are very closely joined together, of a bright gold colour, but the flowers are small, and change to a darker colour as they fade; there is a succession of these flowers most part of the summer, and the early flowers are frequently succeeded by seeds in *England*. This sort may be propagated by slips or cuttings, in the same manner as the former, and the plants may be treated accordingly.

GNAPHALODES. See *Micropus*.

GOMPHRENA. *Lin. Gen. Plant.* 279.

The Characters are,

The flower hath a large coloured empalement, which is permanent. The petal is erect, and cut into five parts at the brim, which spread open; it hath five stamina, scarcely discernable, situated in the brim of the nectarium. In the center is situated an oval-pointed germen, which germen afterward becomes one large roundish seed, inclosed in a thin crusted capsule with one cell.

The Species are,

1. GOMPHRENA caule erecto, foliis ovato-lanceolatis capitulis solitariis, pedunculis diphyllis. *Hort. Cliff.* 86. Globe Amaranthus with large purple heads.
2. GOMPHRENA caule erecto spicâ interruptâ. *Prod. Leyd.* 419. Gomphrena with an erect stalk, and an interrupted spike of flowers.
3. GOMPHRENA foliis lanceolatis, capitulis diphyllis, flosculis perianthio proprio distinctis. *Lin. Sp. Plant.* 224. Perennial Globe Amaranthus, with radiated Straw-coloured flowers.
4. GOMPHRENA foliis carnosis obtusis, capitulis oblongis terminalibus. *Lin. Sp. Plant.* 224. Low Globe Amaranthus of *Curasso*, with shining Onion leaves and white heads.
5. GOMPHRENA caule repente, capitulis rotundis sessilibus, foliis lanceolato-ovatis. *Lin. Sp. Plant.* 225. Gomphrena with a creeping stalk, round heads sitting close to the stalks, and oval spear-shaped leaves.

6. GOMPHRENA

6. *GOMPHRENA caule procumbente, foliis inferioribus lanceolatis, superioribus rotundatis capitulis laxis terminalibus.* Globe Amaranthus with a Campion leaf, and smaller purple heads.

7. *GOMPHRENA pedunculis oppositis bifidis tricapitalis capitulo intermedio sessili.* Lin. Sp. Plant. 224. Climbing Globe Amaranthus with a Campion leaf, and yellowish heads of flowers.

The first sort grows naturally in *India*, but it has been many years cultivated in all the curious gardens in *Europe*; it is an annual plant, which rises with an upright branching stalk about two feet high, garnished with spear-shaped leaves, placed opposite. The branches also come out opposite; the foot-stalks of the flowers, which are long and naked, have two short leaves, close under each head of flowers. The heads, at their first appearance are globular, but as they increase in size, become oval; these are composed of dry scaly leaves, placed imbricatum, like the scales of fish; under each of these is situated a tubulous flower, which just peeps out of the covering, but are not much regarded by the generality of people, for it is the scaly empalement which covers them that is so beautiful as to attract the eye, and these, if gathered before they are too much faded, will retain their beauty several years. After the flowers are past, the germen, which is situated in the bottom of each, becomes a large oval seed, inclosed in a chaffy covering, which ripens late in autumn, and the plant decays soon after.

There are two varieties of this sort, one with fine bright purple heads, the other hath white or silvery heads, which never alter, so that they are permanent varieties, though, in other respects they do not differ; there is also one with mixed colours, but whether this arose accidentally from the seeds of either of the former, I cannot determine, for this variety continues from seeds, and the other two I have cultivated more than thirty years, and have never found either of them vary.

The second sort hath much slenderer stalks than the first, it grows taller. The leaves are smaller, but of the same shape. The flowers grow in spikes at the end of the branches, which are broken, or divided into three or four parts, with spaces between them. They are small and of a pale purple colour.

The third sort hath slender upright stalks, garnished with hairy spear-shaped leaves placed opposite, which sit close to the stalks; these are terminated by small heads of flowers, which spread open from each other, so as that their empalements appear distinct; they are of a pale Straw-colour, so make no great appearance. The seeds, sometimes, will ripen in *England*, but the plants will live two or three years, if they are preserved in a stove.

The fourth sort hath creeping stalks, which put out roots at their joints, as they trail upon the ground; which are garnished with narrow, fleshy, succulent leaves, of a lucid green. The flowers are produced on foot-stalks, which grow at the end and side of the stalks; they are collected in small, oblong, silvery heads, which have dry empalements like the other sorts. This grows naturally in most of the islands of the *West-Indies*.

The fifth sort hath creeping stalks, which put out roots at the joints as they trail on the ground, garnished with small, spear-shaped, oval leaves, placed opposite. The flowers are produced at the joints in round silvery heads, sitting close to the stalks, and are succeeded by a single oval seed, wrapped up in a down. It grows naturally in all the *West-Indies*.

The sixth sort hath trailing stalks, which are garnished with small, spear-shaped leaves at the bottom, but at the top they are hairy. The leaves of this are hairy. The

flowers terminate the stalks in small round purple heads, which are loose; these are succeeded by single seeds, wrapped up in a down.

The seventh sort hath climbing stalks, which rise upward of twenty feet, where they meet with support, garnished with leaves like Campion, placed opposite. The flowers are produced upon long foot-stalks, which come out opposite; these branch out into smaller foot-stalks, each sustaining three heads of yellow flowers, the middle one sitting close to the stalk.

The two sorts which are first mentioned, one with a purple, and the other with silver-coloured heads, are very ornamental plants in gardens, and are now very commonly cultivated in the *English* gardens as choice annuals. In *Portugal*, and other warm countries, they are cultivated to adorn their churches in the winter, for if these are gathered when they are in perfection, and dried in the shade, they will retain their beauty a long time, especially if they are not too much exposed to the air: these plants are propagated by seeds, which should be sown in a good hot-bed the beginning of *March*; but if the seeds are not taken out of their chaffy covering, it will be proper to soak them in water for twelve hours before they are sown, which will greatly facilitate their growing. When the plants are come up half an inch high, they should be transplanted on a fresh hot-bed, at about three inches distance, observing to shade them till they have taken root; then they should have fresh air admitted to them every day, in proportion to the warmth of the season. In about a month or five weeks the plants will have grown so large, as to nearly meet, so they will require more room, otherwise they will draw up weak; then a fresh hot-bed should be prepared, into which there should be a sufficient number of three farthing pots plunged, filled with light rich earth, and when the bed is in a proper temperature of warmth, the plants should be carefully taken up with balls of earth to their roots, and each planted into a separate pot, observing to shade them till they have taken new root, and afterward they must be treated in the same manner as other tender exotick plants. When the plants have filled these pots with their roots, they should be shaken out of them, and their roots on the outside of the ball of earth must be carefully pared off; then they should be put into larger pots, and where there is conveniency of a deep frame, to plunge the pots into another gentle hot-bed, it will bring the plants early to flower, and cause them to grow much larger than those which are placed abroad. In *July* the plants should be inured gradually to bear the open air, into which some of them may be removed about the middle of that month, and intermixed with other annual plants to adorn the pleasure-garden, but it will be proper to keep a plant or two of each sort in shelter for seeds, because when the autumn proves cold or wet, those plants which are exposed abroad, seldom produce good seeds.

The other sorts are all of them tender plants, so require to be raised on a hot-bed, and the plants afterward treated in the same manner as hath been directed for the former sorts; and if the trailing sorts are turned out of the pots, when the roots have filled them, and planted upon a hot-bed, their stalks will put out roots at their joints, and their branching stalks will extend to a considerable distance on every side, and will produce their heads of flowers at every joint; but unless the glasses are kept over them, and only a proper share of air admitted to them, they will not perfect seeds in *England*.

The perennial climbing sort must be removed into the bark-stove, and plunged into the back side of the tan-bed, where it may have room to grow in height; the plants will live three or four years, if they are preserved in a stove.

These sorts are not very ornamental, so they are seldom cultivated but in botanick gardens for the sake of variety.

GOOSEBERRY. See *Grossularia*.

GORZ. See *Ulex*.

GOSSYPIUM. *Lin. Gen. Plant, 755.* Cotton.

The Characters are,

The flower has a double empalement. It hath five plain heart-shaped petals, which join at their base, and a great number of stamina, which are joined at bottom in a column, and are inserted into the petals. It hath a round germen, supporting four styles, joined in the column. The germen afterward becomes a roundish capsule, ending in a point, having four cells, which are filled with oval seeds, wrapped up in down.

The Species are,

1. *GOSSYPIUM foliis quinquelobis, caule herbaceo.* Hort. Upsal. 203. Cotton with leaves having five lobes, and an herbaceous stalk.

2. *GOSSYPIUM foliis trilobis integerrimis.* Hort. Upsal. 204. Cotton with entire leaves having three lobes.

3. *GOSSYPIUM foliis palmatis, lobis lanceolatis, caule fruticoso.* *Lin Sp. Plant. 693.* Cotton with hand-shaped leaves, having five spear-shaped lobes, and a shrubby stalk.

4. *GOSSYPIUM foliis trilobis & quinquelobis acutis, caule ramo hirfuto.* Finest American Cotton with a green seed.

The first sort is the common *Levant* Cotton, which is cultivated in several islands of the *Archipelago*, as also in *Malta*, *Sicily*, and the kingdom of *Naples*; it is sown in tilled ground in the spring of the year, and is ripe in about four months after, when it is cut down in harvest as Corn in *England*, the plants always perishing soon after the seeds are ripe: this plant grows about two feet high, with an herbaceous stalk, garnished with smooth leaves divided into five lobes. The stalks send out a few weak branches upward, which are garnished with leaves of the same form but are smaller. The flowers are produced at the extremity of the branches; these have two large empalements, the outer is cut into three parts, and the inner into five. The petals of the flower are of a pale yellow colour, inclining to white; these are succeeded by oval capsules, which open in four parts, having four cells, which are filled with seeds wrapped up in a down, which is the Cotton.

The second sort grows naturally in several islands of the *West-Indies*; this rises with a shrubby smooth stalk four or five feet high, sending out a few side branches, which are garnished with smooth leaves, divided into three lobes. The flowers are produced at the end of the branches, which are shaped like those of the former sort, but are larger, and of a deeper yellow colour. The pods are larger, and the seeds are black.

The third sort hath a perennial shrubby stalk, which rises six or eight feet high, and divides into many branches, which are smooth, and garnished with hand-shaped leaves, having four or five lobes. The flowers are produced at the end of the branches; these are larger than those of the two former sorts, and are of a deep yellow colour. The pods of this sort are larger than those of the former.

The fourth sort is a native of the *East* and *West-Indies*; this is an annual plant, which perishes soon after the seeds are ripe. It rises to the height of three feet or more, and sends out many lateral branches, where they are allowed room to grow; these are hairy, and garnished with leaves, having in some three, and others five acute-pointed hairy lobes. The flowers are produced from the side, and at the ends of the branches, which are large, of a dirty sulphur colour, each petal having a large purple spot at the base; the flowers are succeeded by oval pods, which open in four cells, filled with oblong green seeds, wrapped up in a soft down. The staple of this is much finer than either of the other species, therefore it is well worth the attention of the

British colonies in *America* to cultivate and improve this sort, since it will succeed in *Carolina*, where it has been cultivated for some years; and might be a commodity worthy of encouragement by the publick, could they contrive a proper gin to separate the Cotton from the seeds, to which this sort adheres much closer than any of the other sorts, the Cotton from this shrub being preferable to any other yet known.

All these sorts are tender plants, therefore will not thrive in the open air in *England*, but they are frequently sown in curious gardens for variety; the first and fourth sorts will produce ripe seeds in *England*, if their seeds are sown early in the spring, upon a good hot-bed, and the plants afterwards planted each into separate pots, and plunged into a hot-bed of tanners bark, to bring them forward; when they are grown too tall to remain under the frames, they should be removed into the tan-bed in the stove, and shifted into larger pots, if their roots have filled the other; with this management their flowers will appear in *July*, and towards the end of *September* the seeds will ripen, and the pods will be as large as those produced in the *East* and *West-Indies*; but if the plants are not brought forward early in the spring, it will be late in the summer before the flowers will appear, and there will be no hopes of the pods coming to perfection.

The shrub Cotton will rise from the seeds very easily, if they are sown upon a good hot-bed; and when they are sown early in the spring, and brought forward in the same manner as hath been directed for the former sorts, the plants will grow to be five or six feet high the same summer; but it is difficult to preserve the plants through the winter, unless they are hardened gradually in *August* during the continuance of the warm weather; for when they are forced on in summer, they will be so tender, as to render them incapable of resisting the least injury. The plants of this sort must be placed in the bark-stove in autumn, and kept in the first class of heat, otherwise they will not live through the winter in *England*.

GRAFTING is the taking a shoot from one tree, and inserting it into another, in such a manner, as that both may unite closely, and become one tree; this is called, by the ancient writers in husbandry and gardening, incision, to distinguish it from inoculation, or budding, which they call *inferere oculos*.

The use of grafting is to propagate any curious sorts of fruits, so as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as are not worth cultivating: but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock, or tree, on which they are grafted; for though the grafts receive their nourishment from the stocks, yet they are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration is, that when the stocks on which they are grafted do not grow so fast, nor afford a great supply of nourishment to the grafts, they will not make near so great progress as they otherwise would do, nor will the fruit they produce be so fair, and sometimes not so well flavoured.

The shoots to be ingrafted are termed cions, or grafts; in the choice of these, the following directions should be carefully observed. 1st, That they are shoots of the former year, for when they are older, they never succeed well. 2dly, Always to take them from healthy fruitful trees, for if the trees are sickly from whence they are taken, the grafts very often partake so much of the distemper, as rarely to get the better of it, at least for some years, and when they are taken from young luxuriant trees, whose vessels are generally

large, they will continue to produce luxuriant shoots, and are seldom so fruitful as those which are taken from fruitful trees, whose shoots are more compact, and the joints closer together, at least it will be a great number of years before these luxuriant grafts begin to produce fruit, if they are managed with the greatest skill. 3dly, You should prefer those grafts which are taken from the lateral or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given.

These grafts, or cions, should be cut off from the trees before their buds begin to swell, which is generally three weeks or a month before the season for grafting; therefore, when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood is cut off with the cion, it will preserve it the better, and when they are grafted, this may be cut off; for at the same time the cions must be cut to a proper length, before they are inserted to the stocks, but, till then, the shoots should remain their full length, as they were taken from the tree; if these cions are to be carried to a considerable distance, it will be proper to put their cut ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month, or longer.

In the choice of young stocks for grafting, you should always prefer such as have been raised from the seed, and that have been once or twice transplanted. Next to these, are those stocks which have been raised from cuttings, or layers, but those which are suckers from roots of other trees, should always be rejected, for these are never so well rooted as the others, and constantly put out a great number of suckers from their roots, whereby the borders and walks of the garden will be always pestered with them during the summer season, which is not only unsightly, but they also take off part of the nourishment from the trees.

If these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened, and more compact than those which have grown close, and have been thereby drawn up to a greater height; the wood of which will be soft, and their vessels large, so that the cions grafted into them will shoot very strong, but they will be less disposed to produce fruit than the other; and when trees acquire an ill habit at first, it will be very difficult to reclaim them afterwards.

Having directed the choice of cions and stocks, we come next to the operation, in order to which you must be provided with the following tools.

1. A neat small hand-saw to cut off the heads of large stocks.
2. A good strong knife with a thick back, to make clefts in the stocks.
3. A sharp penknife to cut the grafts.
4. A grafting chissel and a small mallet.
5. Bals strings, or woollen yarn, to tie the grafts with, and such other instruments and materials as you shall find necessary, according to the manner of grafting you are to perform.
6. A quantity of clay, which should be prepared a month before it is used, and kept turned and mixed like mortar every other day, which is to be made after the following manner:

Get a quantity of strong fat loam (in proportion to the quantity of trees intended to be grafted) then take some new stonchorse dung, and break it in amongst the loam, and if you cut a little straw, or hay, very small, and mix amongst it, the loam will hold together the better; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather; these must be well stirred to-

gether, putting water to them after the manner of making mortar; it should be hollowed like a dish, and filled with water, and kept every other day stirred; but it ought to be remembered, that it should not be exposed to the frost, or drying winds, and that the oftener it is stirred and wrought the better.

Of late years some persons have made use of another composition for grafting, which they have found to answer the intention of keeping out the air, better than the clay before prescribed. This is composed of turpentine, bees wax, and rosin, melted together, which when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied, and though it be not above a quarter of an inch thick, yet will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by frost, which is very apt to cause the clay to cleave, and sometimes fall off; and when the heat of summer comes on, this mixture will melt, and fall off without any trouble. In using of this, there should be a tin, or copper pot, with convenience under it to keep a very gentle fire with small coal, otherwise the cold will soon condense the mixture, but you must be careful not to apply it too hot, lest you injure the graft. A person who is a little accustomed to this composition, will apply it very fast, and it is much easier for him than clay, especially if the season should prove cold.

There are several ways of grafting, the principal of which are four:

1. Grafting in the rind, called also shoulder-grafting, which is only proper for large trees; by some called crown-grafting, because the grafts are set in form of a circle, or crown, and is generally performed about the latter end of *March*, or the beginning of *April*.

2. Cleft-grafting, which is called stock, or slit-grafting; this is proper for trees or stocks of a lesser size, from an inch, to two inches or more diameter; this grafting is to be performed in the month of *March*, and supplies the failure of the escutcheon way, which is practised in *June*, *July*, and *August*.

3. Whip-grafting, which is also called tongue-grafting; this is proper for small stocks of an inch, half an inch, or less, diameter; this is the most effectual way of any, and that which is most in use.

4. Grafting by approach, or ablastation; this is to be performed when the stock you would graft on, and the tree from which you take your graft, stand so near together, that they may be joined; this is to be performed in the month of *April*, and is also called inarching; it is chiefly used for *Jasmines*, oranges, and other tender exotick trees.

The manner of performing the several ways of grafting being generally known, need not be here mentioned.

The next thing which is necessary to be known by those who would practise this art, is, what trees will take and thrive by being grafted upon each other; in this article there have been no sure directions given by any of the writers on this subject, for there will be found great mistakes in most of the books which have treated on this subject; but as it would swell this article too great, if all the sorts of trees were to be here enumerated, which will take upon each other by grafting, I shall only mention such general directions, as, if attended to, will be sufficient to instruct persons, so as they may succeed.

All such trees as are of the same genus, *i. e.* which agree in their flower and fruit, will take upon each other; for instance, all the Nut bearing trees may be safely grafted on each other, as may all the Plumb bearing trees, under which head I reckon not only the several sorts of *Plumbs*, but also the *Almond*, *Peach*, *Nectarine*, *Apricot*, &c. which agree exactly in their general characters, by which they

they are distinguished from all other trees ; but as many of these are very subject to emit large quantities of gum from those parts of the trees where they are deeply cut and wounded, so the tender trees of this kind, *viz.* Peaches and Nectarines, which are most subject to this, it is found to be the surest method to bud or inoculate these sorts of fruits, for which see INOCULATION.

Secondly, all such trees as bear cones will do well upon each other, though they may differ in one being ever-green, and the other shedding its leaves in winter, as is observable in the Cedar of *Lebanus*, and the Larch tree, which are found to succeed upon each other very well ; but these must be grafted by approach, for they abound with a great quantity of resin, which is apt to evaporate from the graft, if separated from the tree before it is joined with the stock, whereby they are often destroyed ; as also the Laurel on the Cherry, or the Cherry on the Laurel. All the mast-bearing trees, which also take upon each other, and those which have a tender soft wood, will do well, if grafted in the common way, but those that are of a more firm texture, and are slow growers, should be grafted by approach.

By strictly observing this rule we shall seldom miscarry, provided the operation be rightly performed, and at a proper season, unless the weather should prove very bad, as it sometimes happens, whereby whole quarters of fruit trees miscarry ; it is by this method that many kinds of exotick trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air ; for, being grafted upon stocks of the same sort, which are hardy, the grafts are rendered more capable to endure the cold ; as hath been experienced in most of our valuable fruits now in *England*, which were formerly transplanted hither from more southerly climates, and were at first too impatient of our cold to succeed well abroad, but have been by budding or grafting upon more hardy trees, rendered capable of resisting our severest cold.

GRAMEN. *Tourn. Inst. R. H.* 516. Grass.

To enumerate all the species of Grass which are found growing naturally in *England*, would swell this article greatly beyond the design of the work ; therefore I shall only mention a few species, which are either used in medicine, or cultivated as a pabulum for cattle ; for there is scarce a pasture in this country, where at least twenty different species are not to be found intermixed, and in most of them more than twice that number.

1. GRAMEN *spicâ triticeâ repens vulgare, caninum dictum.* *Raii Syn.* 2. p. 247. Common creeping Grass with a spike like Wheat, called Dog or Couch Grass.

2. GRAMEN *loliaceum, angustiore folio & spicâ.* *C. B. P.* Darnel with a chaffy spike, commonly called Ray, or Rye Grass.

3. GRAMEN *pratense, paniculatum majus, angustiore folio.* *C. B. P.* 2. Meadow Grass, with larger panicles and a narrower leaf.

4. GRAMEN *pratense paniculatum majus, latiore folio.* *C. B. P.* 2. Meadow Grass, with a larger panicle and broader leaf.

5. GRAMEN *avenacium pratense clatius, paniculâ flavescente, locustis parvis.* *Raii Syn.* 407. Taller Meadow Oat Grass, with a yellowish panicle and small husks.

6. GRAMEN *secalinum.* *Ger. Emac. lib.* 1. cap. 22. n. 4. Tall meadow Rye Grass.

7. GRAMEN *tremulum maximum.* *C. B. P.* 2. Greatest quaking Grass, or Cowquakes.

The first sort of Grass is that which is directed to be used in medicine ; the roots of this are chiefly used, and are accounted aperitive and diuretick, opening obstructions of the reins and bladder, provoking urine, and are of service against the gravel and stone. The juice of the leaves and stalks was greatly esteemed by *Dr. Boerhaave*, who gene-

rally prescribed this in all cases where he supposed there were any obstructions in the bile conduit.

This hath a creeping root, which spreads far in the ground, and is a very troublesome weed in gardens and arable land ; for every small piece of the root will grow and multiply exceedingly, so it is very difficult to extirpate where it once gets possession in gardens ; the common method of destroying it is, to fork out the roots as often as the blades appear above ground ; where this is two or three times carefully repeated, it may be totally rooted out ; but when the surface of the ground is very full of the roots of this Grass, the shortest way of destroying it, is to trench the ground two spits and a shovelling deep, turning all the couch into the bottom, where it will rot, and never shoot up ; but this can only be practised, where there is sufficient depth of soil, for in shallow ground the roots cannot be buried so deep, as to lie below the depth which they naturally shoot.

Where the roots of this Grass get possession in arable fields, it is very difficult to root out again ; the usual method is by laying the land fallow in summer, and frequently harrowing it well over to draw out the roots ; where this is carefully practised, the ground may be so well cleaned in one summer, as that the roots cannot much injure the crop which may be sown upon it ; but such land should be cropped with such things as require the horse hoeing culture, for where the land can be frequently stirred and harrowed afterward, it will be of great service in cleaning it from the roots of this Grass and other bad weeds. The blade of this Grass is so rough, that cattle will not feed upon it.

The second sort is frequently cultivated, especially in strong cold land, upon which this Grass will succeed better than any other species, and is an earlier feed in the spring ; but this is a very coarse Grass, and unless it is cut very early for hay, it becomes hard and wieri in the stalks, so that few cattle care to eat it : this species has few leaves, running all to stalk, so is usually called bents, and in some counties bennet ; when this Grass is fed, it will be proper to mow off the bents in the beginning of *June*, otherwise they will dry, and have the appearance of a stubble field all the latter part of the summer ; so that it will not only be very disagreeable to the sight, but also troublesome to the cattle that feed on it, by tickling their nostrils ; so that the want of better pasture only, will force them to eat of the young Grass which springs up between these bents, for those they will not touch ; therefore those who suppose that these are eaten in scarcity of feed by the cattle, are greatly mistaken, for I have many years closely attended to this, and have always found these bents remaining on the ground untouched, till the frost, rain, and winds destroy it in winter ; and by permitting these to stand, the after growth of the Grass is greatly retarded, and the beautiful verdure is lost for three or four months ; so that it is good husbandry to mow them before they grow too dry, and rake them off the ground ; if these are then made into hay, it will serve for cart-horses feed in winter, and will pay the expence of mowing it.

There is another species of this Grass called Red Darnel, which is of a worse nature than the first, the stalks growing hard much sooner, and having narrower leaves : this is very common in moist pasture grounds, for as it comes early to flower, so the seeds are generally ripe before the hay is cut, and from the falling seeds the ground is supplied with plenty of this sort ; therefore those who are desirous to keep their pastures as clear from this Grass as possible, should always mow it before the seeds are ripe.

This Grass is usually sown with Clover, upon such lands as are designed to be ploughed again in a few years, and the common method is to sow it with spring Corn ; but from many repeated trials, I have always found, that by sowing

these seeds in *August*, where there has happened a few showers to bring up the Grass, that the crop has answered much better than any which has been sown in the common way; so that I am convinced of that being the best season for sowing these Grasses, though it will be very difficult to persuade those persons to alter their practice, who have been long wedded to old customs. The quantity of seeds which I allow to an acre is about two bushels, and eight pounds of the common white Clover, which, together, will make as good plants upon the ground as can be desired; but this is not to be practised upon such lands where the beauty of the verdure is principally regarded, therefore is fit for those who have only profit in view.

The third and fourth sorts are the two best species of Grass for pastures, so that if the seeds of these were carefully collected and sown separately, without any other mixture of Grass seeds, they would not only afford a greater quantity of feed on the same space of land, but the Grass would also be better, the hay sweeter, and the verdure more lasting than of any other sort; but there requires some attention to the saving of these seeds pure without mixture. I have tried to save the seeds of several species of Grass separately, in order to determine their qualities, but have found it very difficult to keep them distinct in gardens where the seeds of other sorts of Grass have been scattered; the only method in which I could succeed, was by sowing each species in a distinct pot, and when the plants came up, to weed out all the other kind of Grass which came up in the pots; by this means I preserved a great variety of the grassy tribe several years, but not having ground enough to propagate the most useful species in any quantity, I was obliged to abandon the pursuit; but I must recommend this to persons of leisure and skill, who have a sufficient quantity of land for the purpose, to carry this project into execution, which may be of singular benefit to the publick; for we have an instance of the advantage which the inhabitants of the *Netherlands* have made, by saving the seeds of the White Clover, or Honeyfuckle Trefoil, which is a plant common to most of the *English* pastures, yet no person in this country ever gave themselves the trouble, till within a few years past, to collect the seeds from the fields for sowing, but have purchased vast quantities of it annually, at a considerable price from *Flanders*, where the peasants have been so industrious, as to collect the seeds and sow great quantities of land with it, with a view of sale to this country only.

The fifth and sixth sorts are also very good Grasses for pastures, and have perennial roots, so are the next best sorts for sowing to those before-mentioned, which, in my opinion, deserve the preference to all the other; but as it will be difficult to save a sufficient quantity of seeds of those alone, to supply the demand which may be for their seeds, so these two species may be admitted in aid of the other, as they are very leafy kinds of Grass, and their stalks do not become stiff and harsh like many other species, but with proper care may be made very fine, and if duly rolled, their roots will mat and form a very close sward, therefore these should be included in the number of sown Grasses.

The seventh sort is mentioned for the sake of variety, and not for use; this hath an annual root, which sends up many broad hairy leaves, between which arise slender stiff stalks from a foot to near two feet high, dividing upward into a large loose panicle, garnished with heart-shaped small spikes, each having about seventeen small floscules or florets, which have a single seed succeeding them; the heads hang by slender long foot-stalks, which are moved by every wind, so that they generally appear shaking, from whence it had the title of Quaking Grass. There are four species of this Grass, two of them grow naturally in *England*,

which coming to head in *May*, occasioned the following *English* proverb, *May, come she early come she late, makes the cow quake.* The large sort here mentioned, grows naturally in the south of *France* and *Italy*, and is only preserved in some *English* gardens for the sake of variety.

The land upon which Grass seed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, especially if the Grass is to remain for pasture, such as Couch Grass, Fern, Rushes, Heath, Gorse, Broom, Rest-harrow, &c. which, if left in the ground, will soon get the better of the Grass, and over-run the land. Therefore in such places where either of these weeds abound, it will be a good method to plough up the surface in *April*, and let it lie some time to dry; then harrow the roots into small heaps, and burn them. The ashes so produced, when spread on the land, will be a good manure for it. But where Couch Grass, Fern, or Rest-harrow is in plenty, whose roots run far under ground, the land must be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off after each ploughing, which is the most sure method to destroy them. Where the land is very low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some under-ground drains to carry off the wet; which, if detained too long on the ground, will render the Grass sour.

Before the seed is sown, the surface of the ground should be made fine and level, otherwise the seed will be buried unequal. When the seed is sown, it must be gently harrowed in, and the ground rolled with a wooden roller, which will make the surface even, and prevent the seeds being blown in patches. When the Grass comes up, if there should be any bare spots, where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds; and the first kindly showers will bring up the Grass, and make it very thick.

The proper management of pasture land, is certainly the least understood of any part of agriculture; the farmers never have attended to this, being more inclined to the plough; though the profits attending it have not of late years been so great, as to encourage them in that part of husbandry; but these people never think of laying down land for pasture, to continue longer than three years, at the end of which time they plough it up again, to sow it with grain.

GRANADILLA. See *Passiflora*.

GRAPES. See *Vitis*.

GRATIOLA. *Lin. Gen. Plant.* 27. Hedge Hyssop.

The Characters are,

The flower hath one petal of the grining kind, cut at the top into four small segments. It hath five awl-shaped stamina; the other two are longer, and adhere to the tube of the petal. In the center is situated a conical germen, which after-ward becomes an oval capsule, ending in a point, having two cells which are filled with small seeds.

The Species are,

1. GRATIOLA *floribus pedunculatis, foliis lanceolatis serratis.* *Lin. Mat. Med.* 18. Hedge Hyssop with flowers standing on foot-stalks, and spear-shaped sawed leaves.

2. GRATIOLA *foliis lanceolatis obtusis sub dentatis.* *Flor. Virg.* 6. Hedge Hyssop with obtuse indented leaves.

3. GRATIOLA *floribus subsessilibus.* *Lin. Sp. Plant.* 17. Hedge Hyssop with flowers sitting close to the branches.

The first sort grows naturally on the *Alps*, and other mountainous parts of *Europe*. It hath a thick, fleshy, fibrous creeping root, which propagates very much when planted in a proper soil or situation, from which arise several upright square stalks, near a foot high, garnished with narrow spear-shaped leaves placed opposite; the flowers are produced on the side of the stalks at each joint, they are shaped like those of the Foxglove, but are small, and of a pale yellowish colour.

It is easily propagated by parting of the roots; the best time to do this is in the autumn, when the stalks decay; the plants should have a moist soil and a shady situation, in which they will thrive exceedingly; but in dry ground they often decay in summer, unless they are plentifully watered.

The second sort grows naturally in *North America*, where it rises more than a foot high, but in *England* I have not seen it more than eight inches; the leaves are blunt and indented at their extremities; the flowers are white, and come out from the side of the stalks, like those of the other, but are not succeeded by seeds here. It may be propagated in the same manner as the first sort, and requires the same treatment.

The seeds of the third sort were sent me from *Carthage*, where it was found growing naturally in places where there had been standing waters, which were then dried up; this plant grew about nine inches high, with a weak stalk, and the leaves placed opposite; they were about three quarters of an inch long, and half an inch broad, sawed on their edges; the flowers came out single on each side the stalk, they were white, and much smaller than those of the first sort, but were not succeeded by seeds, so the plant was lost here.

GRAVEL and Grasse are naturally ornaments to a country seat, and the glory of the *English* gardens, in which we excel most other nations. Indeed, most people who have had the designing of gardens, have too much considered gravel as an ornament, so have made too many walks in gardens, and those have been much too broad, for the sight of gravel is not very pleasing, so it ought only to be considered as useful; a dry walk quite round, or to each part of a garden being absolutely necessary; but these, in gardens of great extent, need not be more than nine or ten feet wide, and in small ones five or six.

There are different sorts of gravel, but for those who can conveniently have it, I approve of that gravel on *Blackheath*, as preferable to most that we have in *England*; it consisting of smooth even pebbles, which, when mixed with a due quantity of loam, will bind exceeding close, and look very beautiful, and continue handsome longer than any other sort of gravel which I have yet seen.

There are many kinds of gravel which do not bind, and thereby cause a continual trouble of rolling, to little or no purpose; as for such,

If the gravel be loose, or sandy, you should take one load of strong loam, to two or three of gravel, and so cast them well together, and turn this mixture over three or four times, that they may be well blended together; if this is done in proper proportion, it will bind well, and not stick to the feet in wet weather.

There are many different opinions about the choice of gravel; some are for having the gravel as white as possible, and in order to make the walks more so, they roll them well with stone rollers, which are often hewn by the masons that they may add a whiteness to the walks; but this renders it very troublesome to the eyes, by reflecting the rays of light too strongly; therefore this should ever be avoided, and such gravel as will lie smooth, and reflect the least, should be preferred.

Some are apt to lay gravel walks too round, but this is likewise an error, because they are not so good to walk upon, and, besides, it makes them look narrow; one inch rise is enough in a crown for a walk of five feet, and it will be sufficient if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each side.

For the depth of gravel walks, six or eight inches may do well enough, but a foot thickness will be sufficient for any; but then there should always be a depth of rubbish laid under the gravel, especially if the ground is wet, in which case there cannot be too much care taken to fill the bottom of the walks with large stones, flints, brick rubbish, chalk, or any other materials which can be best procured, which will drain off the moisture from the gravel, and prevent its being poachy in wet weather; but as it may be difficult in some places to procure a sufficient quantity of these materials to lay in the bottom of the walks, so there may be a bed of heath, or furze, which ever can be procured at the least expence, laid under the gravel to keep it dry: if either of these are used green, they will lie a long time, as they will be covered from air, and these will prevent the gravel from getting down into the clay, and will always keep the gravel dry; where there is not this precaution in the first laying of gravel upon clay, the water being detained by the clay, will cause the gravel to be poachy whenever there is much rain.

In the making of gravel walks, there must be great regard had to the level of the ground, so as to lay the walks with easy descents toward the low parts of the ground, that the wet may be drained off easily, for when this is omitted, the water will lie upon the walks a considerable time after hard rains, which will render them unfit for use, especially where the ground is naturally wet or strong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have sink-stones laid by the sides of the walks, at convenient distances to let off the wet; and where the ground is naturally dry, that the water will soon soak away, the drains from the sink-stones may be contrived so as to convey the water into cesspools, from which the water will soak away in a short time; but in wet land there should be under-ground drains to convey the wet off, either into ponds, ditches, or the nearest place to receive it, for where this is not well provided for, the walks will never be so handsome or useful.

The month of *March* is the properest time for laying gravel; it is not prudent to do it sooner, or to lay walks in any of the winter months before that time.

If constant rolling them after the rains and frost will not effectually kill the weeds and moss, you should turn the walks in *March*, and lay them down at the same time.

In order to destroy worms that spoil the beauty of gravel, or grass walks, some recommend the watering them well with water, in which Walnut tree leaves have been steeped, and made very bitter, especially those places most annoyed with them; and this, they say, as soon as it reaches them, will make them come out hastily, so that they may be gathered; but if, in the first laying of the walks, there is a good bed of lime rubbish laid in the bottom, it is the most effectual method to keep out the worms, for they do not care to harbour near lime.

GREEN-HOUSE, or Conservatory.

As of late years there have been great numbers of curious exotic plants introduced into the *English* gardens, so there has been an increase of conservatories to preserve them; and not only a greater skill in the management and ordering of these plants has increased therewith, but also a greater knowledge of the structure and contrivance of these places, so as to render them both useful and ornamental, hath been acquired. Therefore I have not only given the best instructions

for this I was capable of, but also a design of one in the manner I would choose to erect it, upon the annexed copper plate.

As to the length of these houses, that must be proportioned to the number of plants they are to contain, or the fancy of the owner, but their depth should never be greater than their height in the clear, which in small, or middling houses, may be sixteen or eighteen feet, but for large ones, from twenty to twenty-four feet, is a good proportion; for if the green-house is long, and too narrow, it will have a bad appearance both within and without, nor will it contain so many plants, if proper room be allowed for passing in front, and on the backside of the stands on which the plants are placed; and, on the other hand, if the depth of the green-house is more than twenty-four feet, there must be more rows of plants placed to fill the house, than can with conveniency be reached in watering and cleaning; nor are houses of too great depth so proper for keeping of plants, as those of a moderate size.

The windows in front should extend from about one foot and a half above the pavement, to within the same distance of the ceiling, which will admit of a cornice round the building, over the heads of the windows. As it is necessary to have these windows so long, it will be impossible to make them in proportion as to their breadth; for if in the largest buildings the sashes are more than seven, or seven feet and a half broad, they will be so heavy, and troublesome to move up and down, as to render it very difficult for one person to perform; besides, their weight will occasion their soon decaying. There is also another inconvenience in having the windows too broad, which is, that of fixing proper shutters to them, in such a manner, as that they may fall back close to the piers, so as not to be incommo- dious, or, when open, to obstruct any part of the rays of light from reaching the plants. The piers between these windows should be as narrow as possible to support the building, for which reason I should choose to have them of stone, or of hard well-burnt bricks, for if they are built with fine rubbed bricks, those are generally so soft, that the piers will require to be made thicker, or the building will be too weak to support the weight, especially if there are rooms over the green-house; which is what I would always advise, as being of great use to keep the frost out in very hard winters. If these piers are made of stone, I would advise them to be two feet and a half in front, and sloped off backward to about eighteen inches broad, whereby the rays of the sun will not be taken off, or obstructed by the corners of the piers, which it would be if they were square; but if they are built with bricks, it will be proper to make them three feet in front, otherwise they will be too slender; these I would also advise to be sloped off, in the manner directed for the stone.

At the back of the green-house there may be erected a house for tools, and many other purposes, which will be extremely useful to prevent the frost from entering the house that way, so that the wall between these need not be more than two bricks and a half in thickness; whereas, were it quite exposed behind, it should be at least three bricks or three and a half in thickness; by having a shed behind, if you are willing to make a handsome building, and to have a noble room over the green-house, you may make part of the room over the tool-house, and carry up the staircase in the back, so as not to be seen in the green-house, and hereby a room twenty-five or thirty feet in width may be contrived, and of a proportionable length; and under this staircase there may be a private door into the green-house, at which the gardener may enter in hard frosty weather, when it will not be safe to open any of the glasses in front. The floor of the green-house, which

should be laid either with *Bremen* squares, *Purbeck* stone, or broad tiles, according to the fancy of the owner, must be raised two feet above the surface of the ground whereon the house is placed, which, in dry ground, will be sufficient; but if the situation is moist and springy, and thereby subject to damps, it should be raised at least three feet above the surface; and if the whole is arched with low brick arches under the floor, it will be of great service in preventing the damps rising in winter, which are often very hurtful to the plants, especially in thaws, when the air is often too cold to be admitted into the house, to take off the damps. Under the floor, about two feet from the front, I would advise a flue of about twelve inches in width, and two feet deep, to be carried the whole length of the house, which may be returned along the back part, and be carried up in proper funnels adjoining to the tool-house, by which the smoke may pass off. The fire place may be contrived at the ends of the house, and the doors at which the fuel is put in, as also the ash grate, may be contrived to open into the tool-house, so that it may be quite hid from the sight, and be in the dry, and the fuel may be laid in the same place, whereby it will always be ready for use.

I suppose many people will be surprised to see me direct the making of flues under a green-house, which has been disused so long, and by most people thought of ill consequence, as indeed they have often proved, when under the direction of unskilful managers, who have thought it necessary, whenever the weather was cold, to make fires therein; but however injurious flues may have been under such management, yet, when skilfully used they are of very great service; for though, perhaps, it may happen, that there will be no necessity to make any fires in them for two or three years together, when the winters prove mild, yet in very hard winters they will be extremely useful to keep out the frost, which cannot be effected any other way, but with great trouble and difficulty.

Withinside of the windows, in front of the green-house, you should have good strong shutters, which should be made with hinges, to fold back, that they may lie quite close to the piers, that the rays of the sun may not be obstructed thereby. These shutters need not to be above an inch and a half thick, or little more, when wrought, which, if made to join close, will be sufficient to keep out our common frost; for when the weather is so cold as to endanger the freezing in the house, it is but making a fire in your flues, which will effectually prevent it, and without this conveniency it will be very difficult to effect; for where persons are obliged to nail mats before their windows, or to stuff the hollow space between the shutters and the glass with straw, this is commonly suffered to remain till the frost goes away; which if it should continue very long, the keeping the green-house closely shut up, will prove very injurious to the plants; and as it frequently happens, that we have an hour or two of sun-shine in the middle of the day, in continued frosts, which is of great service to plants, when they can enjoy the rays thereof through the glasses, so, when there is nothing more to do than to open the shutters, which may be performed in a very short time, and as soon shut again when the sun is clouded, the plants may have the benefit thereof whenever it appears; whereas, where there is so much trouble to uncover, and as much to cover again, it would take up the whole time in uncovering and shutting them up, and thereby the advantage of the sun's influence would be lost. Besides, where there is so much trouble required to keep out the frost, it will be a great chance if it be not neglected by the gardener; for if he be not as fond of preserving his plants, and as much in love with them, as his master, this labour will be thought too great by him; and if he takes the pains to cover the glasses up with mats, &c. he will

F

J. Haynes Sculp.

will not care to take them away again until the weather alters, so that the plants will be shut up close during the whole continuance of the frost.

The back part and ends of the house should be either laid over with stucco, and painted white, or plastered with good mortar, and white washed, for otherwise the air in severe frost will penetrate through the walls, especially when the frost is attended with a strong wind, which is often the case in most severe winters.

Where green-houses are built in such places as will not admit of rooms over them, they should be contrived after the manner of stoves, with upright glasses in front, and sloping glasses over these toward the back. If the building is well executed, with proper flues in it, plants may be better preserved therein, and have more air and sun, than in the most extensive buildings of the other sort.

In the green-house there should be moveable tressels, which may be carried out and into the house occasionally, upon which should be fixed rows of planks, for the pots, or tubs of plants to stand in regular rows one above another, whereby the heads of the plants may be so situated, as not to interfere with each other. The lowest row of plants, which should be the forwardest towards the windows, should be placed about four feet therefrom, that there may be a convenient breadth left next the glasses to walk in front; and at the back side of the house there should be allowed a space of at least four feet, for the convenience of watering and passing behind the plants. The plants should never be crowded too close to each other, but room left for the air to pass freely between them.

To avoid the inconvenience which attends the placing of plants of very different natures in the same house, it will be very proper to have two wings added to the main green-house, which, if situated in the manner expressed in the annexed plan, will greatly add to the beauty of the building, and also collect a greater share of heat. In this plan the green-house is placed exactly fronting the south, and one of the wings faces the south south east, and the other the south south west; so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it is constantly reflected from one part to the other, and the cold winds are also better kept off from the front of the main green-house hereby; and in the area of this place may be contrived a place where many of the most tender exotic plants, which will bear to be exposed in the summer season to be set abroad; and in the spring, before the weather will permit to set out the plants, the beds and borders of this area may be full of Anemonies, Ranunculuses, early Tulips, &c. which will be past flowering, and the roots fit to take out of the ground by the time the plants can be carried out, which will render this place very agreeable during the spring season, when the flowers are blown: and here a person may walk and divert himself in a fine day, when, perhaps, the air in most other parts of the garden will be too cold for those who are not much used thereto.

In the center of this area may be contrived a small basin for water, which will be very convenient for watering of the plants, and add much to the beauty of the place; besides, the water, being thus situated, will be softened by the heat which will be reflected from the glasses upon it, whereby it will be rendered much better than raw cold water for these tender plants.

The two wings of the building should be contrived so as to maintain plants of different degrees of tenderness, which may be effected by the situation and manner of conducting the flues, a particular account of which will be exhibited under the article of STOVES. But I would here observe, that the wing facing the south south east should always be pre-

ferred for the warmest stove, its situation being such, as that the sun, upon its first appearance in the morning, shines directly upon the glasses, which is of great service in warming the air of the house, and adding life to the plants, after having been shut up during the long nights in the winter season. These wings, being in the draught annexed, allowed sixty feet in length, may be divided in the middle by partitions of glass, with glass doors to pass from one to the other. To each of these there should be a fire place, with flues carried up against the back wall, through which the smoke should be made to pass, as many times the length of the house, as the height will admit of their number; for the longer the smoke is passing before it is vented, the more heat will be given to the house, with a less quantity of fuel, which is an article worth consideration, especially where fuel is dear. By this contrivance you may keep such plants as require the same degree of heat in one part of the house, and those which will thrive in a much less warmth in the other part, but this will be more fully explained under the article of STOVES.

In the building these wings, if there are not sheds running behind them their whole length, the walls should not be less than three bricks thick; and if they are more, it will be better, because, where the walls are thin, and exposed to the open air, the cold will penetrate them, and when the fires are made, the heat will come out through the walls, so that it will require a larger quantity of fuel, to maintain a proper temperature of warmth in the house. The back part of these houses having sloping roofs, which are covered either with tiles or slates, should also be lined with reeds, &c. under the covering, which will keep out the cold air, and save a great expence of fuel; for the closer and better these houses are built, and the closer the glasses of the slope and front shut, the less fuel will be required to warm the houses; so that the first expence in building these houses properly, will be the cheapest, when the after expence of fires is taken into consideration.

The sloping glasses of these houses should be made to slide, and take off, so that they may be drawn down more or less, in warm weather, to admit air to the plants; and the upright glasses in front may be so contrived, as that every other may open as doors upon hinges, and the alternate glasses may be divided into two; the upper part of each should be contrived so as to be drawn down like sashes, so that either of these may be used to admit air, in a greater or less proportion, according as there may be occasion.

GREWIA. *Lin. Gen. Plant.* 914.

The Characters are,

The flower has a thick coloured empalement. It hath five petals, which are indented at their base, where is situated a scaly nectarium to each. It hath many bristly stamina. In the center is situated the roundish germen, which is lengthened in form of a column, afterward becomes a four-cornered berry with four cells, each inclosing one globular seed.

The Species are,

1. GREWIA *foliis subovatis crenatis.* Grewia with oval crenated leaves.

2. GREWIA *foliis ovato-lanceolatis serratis.* Grewia with oval spear-shaped leaves, which are sawed.

The first sort has been long preserved in many curious gardens, both in England and Holland, and is figured by Dr. Plukenet, by the title of *Ulmifolia arbor Africana baccifera, floribus purpureis.* It grows naturally at the Cape of Good Hope, from whence I have received the seeds.

This will grow to the height of ten or twelve feet; the stem and branches are very like those of the small leaved Elm, the bark being smooth, and of the same colour as that when young; the leaves are also very like those of the Elm, and fall off in autumn; the flowers are produced singly along

along the young branches, from the wings of the leaves, which are of a bright purple colour.

This may be propagated by cuttings, or layers; if by cuttings they should be taken off, and planted in *March*, before the buds begin to swell, for they do not succeed so well after; these cuttings should be planted in small pots filled with loamy earth, and the pots plunged into a moderate hot-bed of tanners bark, and shaded from the sun in the middle of the day; these will take good root in about four months, and may then be gradually inured to bear the open air, in to which they should be removed, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the green-house; the best time to lay down the layers of this plant is in the spring, before the buds come out, and these will be rooted by the same time the following year, when they may be cut off from the old plants, and planted each into a separate pot filled with soft loamy earth.

The best time to remove or transplant this plant is, either in the spring, just before the buds begin to swell, or in autumn, when the leaves begin to drop; for in summer, when the plants are in full leaf, it will not be so proper to disturb them.

In winter these plants should be placed in the green-house, for they are too tender to live abroad in *England*; but they should have as much free air as possible in mild weather, as they only require to be protected from frost, and after the leaves are fallen, they will require very moderate watering, but in summer they should have it more constantly in dry weather.

The seeds of the second sort were sent me by *Monf. Richard*, gardener to the king of *France*, at *Marseilles*, which were brought from *Senegal*, in *Africa*, by *Monf. Adanson*; it rises in this country with a shrubby stalk five or six feet high, sending out many lateral branches, which are covered with a brown hairy bark, and garnished with oval spear-shaped leaves, having several transverse veins from the mid rib to the sides, where they are sawed; they are placed alternately on the branches; the plants are young, so have not as yet flowered in *England*, therefore I can give no further account of them.

This sort is tender, so will not thrive in *England*, unless it is placed in a warm bark stove; for the plants which have been placed on shelves in a dry stove have made little progress; therefore the only method to have them succeed, is to place them in the bark-bed in the tan-stove, where the plants have grown very well. In summer these plants require a good share of free air to be admitted to them, and should have water three or four times a week in warm weather; but in winter they must be sparingly watered, and require to be kept warm.

GRONOVIA. *Martyn. Cent. 4. Lin. Gen Plant. 248.*

The Characters are,

The flower hath a permanent coloured empalement. It hath five small petals which are fixed to the cuts of the empalement, and five hairy stamina, which are inserted into the empalement. The germen is situated under the flower, which afterward becomes a roundish coloured fruit with one cell, inclosing one large roundish seed.

We know but one Species of this genus, viz.

GRONOVIA. *Hort. Cliff. 74. Houst. Climbing Burry Gronovia.*

This plant was discovered by the late *Dr. Houstoun* at *La Vera Cruz*. It is an annual plant, which sends forth many trailing branches like those of the Cucumber, which are closely set with broad green leaves, in shape like those of the Vine; which are covered with small spines on both sides, which sting like the Nettle; the branches have many tendrils or clasps, by which they fasten themselves to what-

ever plants they grow near, and will rise to the height of six or eight feet; the flowers are small, and of a greenish yellow colour, so make no great appearance.

This being a very tender plant, must be raised on a hot-bed early in the spring, and afterward placed in the bark-stove, and treated in the same way as the *Momordica*, with which management it will produce ripe seeds; but this, having neither use or beauty, is rarely cultivated but in botanick gardens for the sake of variety.

GROSSULARIA. *Raii Meth. Plant. 145. Gooseberry.*

The Characters are,

The flower has a permanent empalement, cut into five parts at the top, which is concave and coloured. It hath five small, obtuse, erect petals, which rise from the border of the empalement; and five awl-shaped stamina, which are inserted into the empalement. The germen is situated below the flower, and afterward becomes a globular berry having a navel, with one cell which is filled with roundish compressed seeds included in a pulp.

This and the common Currant agreeing with each other in their characters, are by botanists joined in the same genus, but I have chosen to treat of them separately, for the benefit of those who have not any knowledge in botany.

The Species are,

1. GROSSULARIA *ramis reclinatis aculeatis, pedunculis triphyllis.* Prickly Gooseberry with a dark purplish fruit.

2. GROSSULARIA *ramis aculeatis, baccis hirsutis.* Gooseberry with prickly branches and hairy berries.

3. GROSSULARIA *ramis aculeatis, erectis, baccis glabris.* Gooseberry with erect prickly branches, and smooth berries.

4. GROSSULARIA *ramis undique aculeatis.* Gooseberry whose branches are armed on all sides with spines.

5. GROSSULARIA *aculeis subaxillaribus, baccis aculeatis racemosis.* Gooseberry with spines on the lower part of the branches, and prickly berries growing in clusters.

The sorts which are here enumerated, are supposed to be distinct species, but there are several other varieties which have been obtained from seeds, and are propagated for sale in the nurseries; most of these are titled from the persons who raised them, as *Lamb's* Gooseberry, *Hunt's* Gooseberry, *Edwards's* Gooseberry, &c. and as there are frequently new varieties obtained, so it is needless to enumerate them here, therefore I shall proceed to their culture.

These are propagated either by suckers taken from the old plants, or by cuttings; the latter of which I prefer to the former, because those plants which are produced from suckers are always more disposed to shoot out a greater number of suckers from their roots, than such as are raised from cuttings, which generally form much better roots.

The best season for planting these cuttings is in autumn, just before their leaves begin to fall; observing always to take the handsomest shoots, and from such branches as generally produce the greatest quantity of fruit; for if you take those which are produced from the stem of the old plants (which are commonly very luxuriant) they will not be near so fruitful as those taken from bearing branches: these cuttings should be about six or eight inches long, and must be planted in a border of light earth, exposed to the morning sun, about three inches deep; in the summer, when they have put out shoots, those near the bottom should be rubbed off, leaving only the uppermost or strongest, which should be trained upright to form a regular stem. In *October* following, these plants will be fit to remove; at which time should be prepared an open spot of fresh earth, which should be well dug, and cleansed from noxious weeds, roots, &c. and being levelled, the plants should be taken up, and their roots trimmed; then plant them at three feet distance row from row, and one foot asunder in the rows. In this place they may remain one year, being careful to keep

keep them clear from all lateral shoots which are produced below the head of the plant, so that they may have clear stems about a foot in height above the surface of the earth, which will be tall enough: as the branches are generally produced very irregular, so such of them as cross each other, or where they are too close, should be cut out, whereby the head of the plant will be open, and capable of admitting the air freely into the middle, which is of great use to the fruit.

After these plants have remained in this nursery one year, they will be fit to transplant to the places where they are designed to remain; for they should not grow in the nurseries too large, because when their roots become woody, there is a hazard in removing of the plants. The soil in which these plants thrive to the greatest advantage, is a rich light earth, though they will do very well upon middling soils, which are not too strong or moist, and in most situations; but where the fruit is cultivated, to have it in the greatest perfection, they should never be planted in the shade of other trees, but must have a free open exposure. The distance they ought to be planted is eight feet row from row, and six feet asunder in the rows, where they are planted for a full crop. The best season for transplanting them is in *October*, when their leaves begin to decay; observing, as was before directed, to prune their roots, and trim off all lateral shoots, or such as cross each other, shortening all long branches, so as to make the head regular.

In pruning of these shrubs, most people make use of garden shears, observing only to cut the head round, as is practised for ever-greens, &c. whereby the branches become so much crowded, that what fruit is produced, never grows to half the size it would do, were the branches thinned, and pruned according to art; which should always be done with a pruning knife, shortening the strong shoots to about ten inches, and cutting out all those which grow irregular, thinning the fruit-bearing branches where they are too close, observing always to cut behind a leaf bud. With this management the fruit will be near twice as large as those which are produced upon such bushes as are not thus pruned, and the shrubs will continue in vigour much longer; but the ground should be dug at least once a year, and every other year a little rotten dung should be dug into the ground, which will greatly improve the fruit.

It is a common practice with the gardeners near *London*, who have great quantities of these bushes in order to supply the markets, to prune them soon after *Michaelmas*, and then to dig up the ground between the rows, and plant it with *Coleworts* for spring use, whereby their ground is employed all the winter, without prejudicing the *Gooseberries*; and in hard winters these *Coleworts* often escape, when those which are planted in an open exposure are destroyed; and these are generally pulled up for use in *February* or *March*, so that the ground is clear before the *Gooseberries* come out in the spring: it is a piece of husbandry well worth practising where ground is dear, or where persons are confined for room.

GROVES are the greatest ornaments to a garden, nor can a garden of any extent be complete which has not one or more of these. In small gardens there is scarce room to admit of groves, yet in these there should be a few trees, disposed in imitation of a grove.

These groves are not only great ornaments to gardens, but are also the greatest relief against the violent heats of the sun, affording shade to walk under, in the hottest part of the day, when the other parts of the garden are useless; so that every garden is defective which has not shade.

Groves are of two sorts, *viz.* open and close groves; open groves are such as have large shady trees, which stand at such distances, as that their branches may approach so

near each other, as to prevent the rays of the sun from penetrating through them; but as such trees are a long time in growing to a proper size for affording a shade, so where new groves are planted, the trees must be placed closer together, in order to have shade as soon as possible; but in planting of these groves, it is much the best way to dispose all the trees irregularly, which will give them a greater magnificence, and also form a shade sooner, than when the trees are planted in lines; for when the sun shines between the rows of trees, as it must do some part of the day in summer, the walks between them will be exposed to the heat, at such times, until the branches of these trees meet; whereas in the irregular plantations, the trees intervene, and obstruct the direct rays of the sun.

When a person, who is to lay out a garden, is so happy as to meet with large full grown trees upon the spot, they should remain inviolate, if possible; for it will be better to put up with many inconveniences than to destroy them; so that nothing but that of offending the habitation, by being so near as to occasion great damps or obstructing fine views, should tempt the cutting of them down.

Most of the groves which have been planted either in *England*, or in those celebrated gardens of *France*, are composed only of a few regular lines of trees; but these do not appear so grand, as those which have been made in woods, where the trees have grown accidentally, and at irregular distances; where they have large spreading heads, and are left at such distance, as to permit the grass to grow under them, then they afford the greatest pleasure: for nothing is more noble than fine spreading trees, with large stems, growing through grass, especially if the grass is well kept, and has a good verdure; besides, most of these planted groves have generally a gravel walk, made in a straight line between them, which greatly offends the sight of persons who have true taste; therefore whenever a gravel walk is absolutely necessary to be carried through these groves, it will be much better to twist it about, according as the trees naturally stand, than to attempt regularity; but dry walks under large trees are not so useful as in open places, because the dropping of the trees will render these walks useless after rain, for a considerable time.

Close groves have frequently large trees standing in them, but the ground is filled under these with shrubs, or under wood; so that the walks which are made in them are private, and screened from winds, whereby they are rendered agreeable for walking, at such times when the air is too violent or cold for walking in the more exposed parts of the garden.

These are often contrived so as to bound the open groves, and frequently to hide the walls, or other inclosures of the garden; and when they are properly laid out, with dry walks winding through them, and on the sides of these sweet-smelling shrubs and flowers irregularly planted, they have a charming effect; for here a person may walk in private, sheltered from the inclemency of cold or violent winds, and enjoy the greatest sweets of the vegetable kingdom: therefore where it can be admitted, if they are continued round the whole inclosure of the garden, there will be a much greater extent of walk; and these shrubs will appear the best boundary, where there are not fine prospects to be gained.

These close groves are by the *French* termed *Bosquets*, from the *Italian* word *Boschetto*, which signifies a little wood, and in most of the *French* gardens there are many of them planted; but these are reduced to regular figures, as ovals, triangles, squares, and stars, which have neither the beauty or use which those have that are made irregularly, and whose walks are not shut up on each side by hedges, as those in *France* generally are, which prevents the eye from

seeing the tall trees growing in the quarters; and these want the fragrantcy of the shrubs and flowers, which are the great delight of these private walks; add to this the keeping of the hedges in good order, which is attended with a great expence, which is a capital thing to be considered in the making of gardens.

GUAIABARA. See Coccolobos.

GUAJACANA. See Diospyros.

GUAJACUM. Plum. Nov. Gen. 39. tab. 17. Lignum Vitæ, or Pockwood.

The Characters are,

The flower hath a concave empalement. It hath five oblong, oval, concave petals, which are inserted in the empalement, and ten erect stamina inserted in the empalement. The germen, which is oval and pointed, afterward becomes a berry, which is roundish, with an oblique point and deeply furrowed, inclosing one oval hard seed.

The Species are,

1. GUAJACUM foliolis bijugatis obtusis. Lin. Sp. Plant. 381. Guajacum with obtuse lobes placed by pairs.

2. GUAJACUM foliolis multijugatis obtusis. Lin. Sp. Plant. 382. Guajacum with many pair of obtuse lobes.

3. GUAJACUM foliolis multijugatis acutis. Lin. Sp. Plant. 382. Guajacum with many pair of acute pointed leaves.

The first sort is the common Lignum Vitæ, or Guajacum, which is used in medicine, which grows naturally in most of the islands in the West-Indies, where it becomes a very large tree, having a hard, brittle, brownish bark, not very thick; the wood is firm, solid, and ponderous, very resinous, of a blackish yellow colour in the middle, and of a hot aromatick taste; the smaller branches have an Ash-coloured bark, and are garnished with leaves, divided by pairs, each pair having two pair of small, oval, blunt pinnæ, of a stiff consistence, and a lucid green; the flowers are produced in clusters at the end of the branches, composed of five oval concave petals, of a fine blue colour; in the center of these is fixed a style with an oval germen, crowned by a slender stigma; and round this is situated a great number of stamina, which are as long as the style, terminated by sickle-shaped summits. Dr. Linnaeus supposes the flowers to have but ten stamina, whereas they certainly have twenty, so it should be ranged in his twelfth class of plants; nor is it the empalement, but the germen which becomes the fruit.

The bark and wood of this tree are much of the same nature, only the wood is accounted hotter: they are used in diet drinks, to purify and cleanse the blood, and to cause sweating; they are esteemed good for the gout and dropsy, the king's evil, and particularly for the French pox. The gum or resin, which is black, shining, and brittle, and when powdered of a greenish white colour, of an aromatick smell, and poignant taste, is somewhat cathartick, and a good purge in rheumatick cases, to the quantity of two scruples mixed with the yolk of an egg, and given in a convenient vehicle.

The wood of this tree is so hard as to break the tools in felling them, so they are seldom cut down for fire-wood, being difficult to burn; but it is of great use to the sugar planters, for making of wheels and cogs for the sugar mills, &c. It is also frequently brought to Europe, and wrought into bows, and other utensils.

This tree can only be propagated by seeds, which must be procured from the countries where it naturally grows; these should be fresh, otherwise they will not grow; they should be sown in pots, and plunged into a good hot-bed: if the seeds are good, and the bed in which they are plunged is of a proper temperature of heat, the plants will appear in six or eight weeks after, and in six weeks or two months more will be of strength enough for transplanting;

they should be carefully taken out of the seed-pots, so as to preserve their roots as entire as possible, and each planted in a separate small pot, and plunged into a new hot-bed of tanners bark, where they must be shaded from the sun till they have taken fresh root; then they must be treated in the same manner as other tender exotick plants from warm countries, admitting a large share of free air to them when the weather is warm. While the plants are young, they may be kept during the summer season in a hot-bed of tanners bark under a frame; but in the autumn they must be removed into the bark stove, and plunged into the hot-bed of tan, where they should constantly remain, and must be treated in the same manner as other tender plants, being careful not to give them too much water in the winter: in summer they should have a large share of free air admitted to them every day. With this treatment the plants will thrive very well, but they are plants of slow growth in their own country, so cannot be expected to make great progress in Europe.

The second sort hath many small leaves placed along the midrib by pairs, which are rounded and obtuse at their ends, but narrow at their base: they are of the same consistence with those of the former sort, but of a darker green colour; the flowers are produced in loose bunches toward the end of the branches, which are of a fine blue colour, their petals are fringed on their edges. This is called in some of the islands bastard Lignum Vitæ; I received it from Antigua by that title. It requires the same treatment as the first sort, and is propagated by seeds in the same way.

I have also received specimens from the island of Barbuda of one, which seems different from either of those before-mentioned: the branches have the same appearance with those of the first sort, but the leaves are larger, indented at their extremities, and are placed all round the branches, on very short foot-stalks; the flowers were broken off, so I cannot determine the difference between them, but by all appearance they seem to be of the same genus.

The third sort has been long an inhabitant in some of the curious gardens in England and Holland, but seldom produces flowers here. This grows naturally at the Cape of Good Hope; however, Dr. Linnaeus has removed it from the Acacia, where it had been placed, and has added it to this genus; and as I have not yet seen the flowers, so I do not know if it is right placed. The plants retain their leaves all the year, and will live in a good green-house in winter, but in summer must be placed abroad with other green-house plants. It is of slow growth, and is with difficulty propagated by layers.

GUAJAVA. See Psidium.

GUANABANUS. See Annona.

GUAZUMA. See Theobroma.

GUIDONIA. See Samyda.

GUILANDINA. Lin. Gen. Plant. 464. The Nickar tree.

The Characters are,

The empalement of the flower is bell-shaped, cut at the rim into five equal parts; the flower has five concave spear-shaped petals which are equal, inserted into the empalement, and ten awl-shaped stamina inserted in the empalement. In the center is situated an oblong germen, which afterward becomes a rhomboid pod, with a convex future on the upper side, having one cell, including oval hard seeds which are separated by partitions.

The Species are,

1. GUILANDINA aculeata, foliis bipinnatis, foliolis ovatis oppositis integerrimis. Prickly Guilandina with doubly winged leaves, whose lobes are oval, opposite, and entire, called yellow Nickar.

2. GUILANDINA aculeata, foliolis ovalibus oppositis sessilibus. Prickly Guilandina with oval small leaves placed opposite, and sitting close, called grey Nickar.

3. GUILAN-

3. *GUILANDINA inermis foliis bipinnatis*. Smooth Guilandina with doubly-winged leaves.

4. *GUILANDINA inermis, foliis subpinnatis, foliolis inferioribus ternatis*. Flor. Zeyl. 155. Smooth Guilandina with winged leaves, whose under small leaves are trifoliate, called Morunga.

5. *GUILANDINA inermis foliis bipinnatis, basi apiceque simpliciter pinnatis*, Lin. Sp. Guilandina with smooth branches, doubly winged leaves; but those at the top and bottom are singly winged, called Canada Nickar tree.

The first and second sorts grow naturally in most of the islands in the *West-Indies*, where they twine their stalks about any neighbouring support, and rise to the height of twelve or fourteen feet. The leaves of the first sort are near a foot and a half long, composed of six or seven pair of pinnæ, or wings, each of which has as many pair of lobes, or small leaves set along the midrib; these are oval and entire; the foot-stalk or principal midrib of the leaf is armed with short crooked thorns, which are placed irregularly; the stalks are also closely armed with the like thorns, which are larger. The stalks at first grow erect, but as they advance twine about the neighbouring trees or shrubs, being too weak to stand without support: the flowers come out in long spikes from the wings of the stalk, composed of five concave yellow petals, which are equal; in the center is situated the oblong germen, surrounded by ten stamina. After the flower is past, the germen becomes a pod about three inches long and two broad, closely armed with slender spines, opening with two valves, each inclosing two hard seeds about the size of children's marbles, of a yellowish colour.

The second sort differs from the first, in having much smaller leaves, which are set closer together; and below each pair of lobes are situated two short, stiff, crooked spines, which are placed opposite; the flowers are of a deeper yellow colour than those of the first sort, and the seeds are of an Ash colour.

The third sort was discovered by the late Dr. *Houfston* at *Campeachy*, from whence he sent the dried samples to *England*, but there was no fruit on the trees at the time when he was there; but he mentions that this sort had an upright stem, which was of a large size, dividing into many branches, garnished with smooth double-winged leaves; the wings come out opposite, each leaf being composed of four pair, but the lobes are placed alternate upon the middle rib; they are oval, but end in a point, and are of a light green colour.

The fourth sort grows naturally in the island of *Ceylon*, and in several places on the *Malabar* coast. This in its native country rises to the height of twenty-five or thirty feet, with a strong stem, covered with a smooth bark, which in the young branches is green, but on the older it is of an Ash colour; the root grows knobbed and very thick. This, when young, is scraped and used by the inhabitants as Horse-radish in *Europe*, having much the same sharp taste; the branches are garnished with decompound winged leaves; those which are situated at the base, have but three leaves, but above the leaves are branched out into several divisions, which are again divided into smaller, which have five or six pair of oval lobes, terminated by an odd one; they are of a light green, and a little hoary on their under side. The flowers are produced in loose bunches from the side of the branches, composed of an unequal number of petals, from five to ten; they have ten short stamina surrounding the germen, which afterward turns to a long taper pod, including several angular seeds, covered with a thin membrane. These have a flavour like the root.

These four sorts are natives of warm countries, so will not live through the winter in *England*, unless they are placed

in a warm stove, and the pots plunged into the tan-bed. They are propagated by seeds, but those of the two first sorts are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain years in the ground without vegetating; when the plants come up they will be fit to transplant in a short time, when they should be each transplanted into a small pot, and plunged into a moderate hot-bed of tanners bark, shading them till they have taken fresh root; then they must be treated in the same manner as other tender exotic plants, giving them a large share of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they must be removed into the bark-stove and plunged into the hot-bed, where they will make great progress, provided they have not too much water, especially during the winter season, for these plants are very impatient of moisture in cold weather.

The fourth sort requires the same treatment as those before-mentioned, but the seeds will grow without being steeped in water, and the plants are with difficulty shifted from one pot to another, for their roots are large, fleshy, and have but few fibres; so that unless great care is taken, all the earth will fall away from them, which often causes their stalks to decay almost to the root, and sometimes occasions the loss of the plants. This plant must be sparingly watered at all times, but particularly in cold weather, when moisture will cause them to rot in a short time.

The fifth sort grows naturally in *Canada*, from whence the plants were brought to *Paris*, where it has been some years cultivated, and a few years past it was brought to *England*. This in the country where it naturally grows, rises with an erect stem to the height of thirty feet or more, dividing into many branches, which are covered with a bluish Ash-coloured bark very smooth, garnished with large decompound winged leaves which are of the oval shape, very smooth and entire, but are ranged alternate on the midrib; these fall off in the autumn, and new ones come out late in the spring.

There are male and female of this sort in different plants; as these have not as yet flowered in any of the *English* gardens, so I can give no farther account of it, nor of the fruit, having never seen either of them. This sort lives abroad in the open air, and is never hurt by the frost. It is only propagated by cutting off some of the roots and planted in pots, which should be plunged into a gentle hot-bed, which will cause them to shoot upward, so may be taken from the old root and multiplied. It requires a light soil, not too moist.

GUNDELIA. Tourn. Cor. 51. tab. 486.

The Characters are,

It hath an uniform tubulous flower, composed of many hermaphrodite florets, which have but one petal slightly cut into five parts: they have five short hairy stamina. The oval germen is situated at the bottom of the flower, which afterward becomes a roundish single seed inclosed in the common receptacle, which is conical, and the seeds are separated by a chaffy down.

We have but one species of this genus at present in *England*, viz.

GUNDELIA. Lin. Sp. Plant. 814. There is no *English* title to this plant, but there are two varieties of it mentioned by *Tournefort*, which are supposed to arise from the same seeds, as they were found growing promiscuously together. These are,

1. *GUNDELIA Orientalis, acanthi aculeati foliis, floribus intense purpureis, capite araneosâ lanugine obsito*. Tourn. Cor. 51. Eastern Gundelia with prickly Bearsbreech leaves, deep purple flowers, and a head covered with a down like a cobweb.

2. *GUNDELIA Orientalis, acanthi aculeati folio, capite glabro.* Tourn. Cor. 51. Eastern Gundelia, with a prickly Bear-breech leaf, and a smooth head.

This plant was discovered by Dr. Gundelscheimer, in company with Tournesfort, near Baibout in Armenia, but has since been found growing naturally in several places in the Levant. The stalks of this plant seldom rise more than two feet high; the under leaves are long, narrow, and sawed on their edges, their teeth ending in a spine; the other leaves are broader, which are irregularly slashed to the midrib, and armed at the points with sharp prickles; the stalks divide upward into several branches, which are armed with leaves of the same form, but are narrower, and each is terminated by a conical head of flowers, resembling those of fuller's Thistle, being surrounded at the base by a circle of long narrow prickly leaves: these heads are composed of many hermaphrodite florets, which are shut up in the scales, each having a germen with five stamina surrounding it; but the seeds do not all ripen perfectly in each head, in the natural places of its growth. It has perfected seeds in Chelsea garden.

These plants are propagated by seed, which should be sown the beginning of March in a warm border of fresh earth, in the place where the plants are designed to remain; for these plants have tap roots which run very deep in the ground, so do not bear transplanting well. When the plants come up, they must be carefully cleared from weeds; and as they grow large they should be thinned, leaving the plants, which are designed to remain, about two feet asunder, that they may have room to spread. After this there is no other culture required, but to keep them clear from weeds; in two years from seeds the plants will produce their flowers, which will make a fine appearance amongst other hardy plants in the pleasure-garden: the roots will continue several years in a dry soil.

GYP SOPHYLA. Lin. Gen. Plant. 498. We have no English title for this genus.

The Characters are,

The flower hath a permanent bell-shaped empalement, cut into five parts at the top. It hath five oval blunt petals, and ten awl-shaped stamina. In the center is situated a globular germen, which after-ward becomes a globular capsule with one cell, opening with five valves, filled with small roundish seeds.

The Species are,

1. *GYP SOPHYLA foliis mucronatis recurvatis, floribus aggregatis.* Lin. Sp. Plant. 406. Gypsophyla with pointed recurved leaves, and flowers gathered in a head.

2. *GYP SOPHYLA foliis lanceolato-linearibus, obsolete triquetris lævibus obtusis secundis.* Lin. Sp. Plant. 407. Gypsophyla with narrow spear-shaped leaves, having three blunt angles, and smooth obtuse leaves in clusters.

3. *GYP SOPHYLA foliis lanceolatis lævibus, caulibus diffusis, pistillis corollâ campanulatâ longioribus.* Lin. Sp. Plant. App. 1195. Gypsophyla with smooth spear-shaped leaves,

diffused stalks, and the pointal longer than the petal, which is bell-shaped.

4. *GYP SOPHYLA foliis ovato-lanceolatis, semiamplexicaulis.* Lin. Sp. Plant. 408 Gypsophyla with oval spear-shaped leaves, half embracing the stalks.

5. *GYP SOPHYLA foliis lanceolatis scabris, corollis revolutis.* Lin. Sp. Plant. 407. Gypsophyla with rough spear-shaped leaves, and the petals of the flowers recurved.

The first sort grows naturally in the south of France, in Spain, and Italy, upon the mountains. This hath a perennial root, from which arise many narrow leaves ending in acute points, which are recurved; the stalks rise about a foot high, garnished with narrower leaves placed opposite, and at some of the joints there are smaller leaves growing from the stalks in clusters; the upper part of the stalk divides into smaller branches, each being terminated by a close bunch of small white flowers. These appear in July, and are succeeded by small oval capsules, filled with small seeds.

The second sort is somewhat like the first, but the leaves are much narrower, and almost three cornered; they are placed in clusters, which come out from the side of the stalk; the bunches of flowers are smaller, and not so closely joined. This hath a perennial root, and grows naturally upon the Helvetian mountains.

The third sort hath a perennial root; from which arise smooth spear-shaped leaves in clusters; the stalks are near a foot long, but lie prostrate upon the ground; the flowers have a purplish cast, and the stamina are much longer than the petals of the flowers. This flowers in June and July, and the seeds ripen in autumn.

The fourth sort grows naturally in the Levant, and also in Spain. It hath a strong, fleshy, fibrous root, which strikes deep in the ground, sending up several thick fleshy stalks, which rise two or three feet high, garnished with oval spear-shaped leaves, which half embrace the stalks with their base; the upper part of the stalk divides into many smaller branches, which are terminated with loose bunches of small white flowers, which make but little appearance.

The fifth sort grows naturally in Siberia and Tartary. This hath a perennial root, from which arise many branching stalks a foot and a half high, garnished with narrow smooth-pointed leaves, shaped like those of Gilliflower; at the top of the stalks are produced loose clusters of very small white flowers, which appear at the same time with the former sorts, and the seeds ripen in the autumn.

These plants have no great beauty, so are rarely cultivated but in botanick gardens, for the sake of variety.

They are propagated by seeds, which should be sown in a bed of light earth, and when the plants are fit to remove, they may be transplanted into the places where they are designed to remain, and will require no other culture but to keep them clean from weeds; for the roots will continue several years, and annually produce flowers and seeds.

HÆMANTHUS. *Tourn. Inst. R. H. 657. tab. 433.* Blood-flower.

The Characters are,

The flower has a permanent empalement of six leaves, shaped like an umbel. It hath one erect petal, cut into six parts, and six awl shaped stamina, which are inserted in the petal. The germen is situated under the flower, which afterward becomes a roundish berry with three cells, each containing one triangular seed.

The Species are,

1. HÆMANTHUS *foliis linguiformibus planis.* *Prod. Leyd.*
42. Blood-flower with plain tongue-shaped leaves.
2. HÆMANTHUS *foliis longioribus carinatis,* Blood-flower with longer keel-shaped leaves.
3. HÆMANTHUS *foliis lanceolatis undulatis.* *Hort Cliff.*
127. Blood-flower with spear-shaped waved leaves.

The first sort has been many years in several curious gardens in *Europe*. This hath a large bulbous root, from which in the autumn comes out two broad flat leaves, of a fleshy consistence, shaped like a tongue, which turn backward on each side, and spread flat on the ground, so have a singular appearance all the winter; in the spring these decay, so that from *May* to the beginning of *August*, they are destitute of leaves: this produces its flowers always in the autumn, just before the new leaves come out. The stalk rises a foot or more in height, supporting a cluster of bright red tubulous flowers, inclosed in a common leafy empalement; with one petal cut into six parts, each having six long stamina, standing out beyond the petal, and in the center appears the germen sitting under the flower, supporting a single style, crowned with a stigma. The germen never ripens to a seed in *England*, but decays with the flower, and then the green leaves grow and spread on the ground.

The second sort hath a large bulbous root like the first, which sends out three or four leaves, which grow a foot long or more; these are not flat like those of the other, but are hollowed like the keel of a boat, and stand more erect than those of the former sort, but are not quite so broad; the flowers of this are like those of the first, but the stalk is taller, and they are of a paler red; this is certainly a different species from the other, and their differences are permanent.

The third sort hath roots composed of many thick fleshy tubers, which join at the top, where they form a head, out of which arises a fleshy spotted stalk, like that of the *Dragon*, which spreads out at the top into several spear-shaped leaves, waved on their edges. The stalks grow about a foot high; the leaves are six or eight inches long, and two broad in the middle; from the side of the stalk near the ground, breaks out a strong fleshy foot-stalk, about six or eight inches long, sustaining at the top a large cluster of flowers, included in one common empalement or covering, which is permanent; the flowers are shaped like those of the other sorts, but are of a yellowish red colour. These appear in *May*, *June*, or *July*, and are succeeded by berries which are of a beautiful red colour when ripe.

H Æ M

The two first sorts do not propagate very fast in *Europe*; their roots seldom putting out many offsets; the gardens in *Holland* have been supplied with roots from the *Cape of Good Hope*, where they naturally grow, and produce seeds; they are too tender to thrive in this country in winter, if planted in the full ground, and exposed to the open air, therefore the roots are generally planted in pots, and, in winter, placed in a green-house, where by their large leaves spreading upon the pots, they make a pretty appearance, but with this treatment the roots seldom flower here: the only way to have the flowers in perfection, is to prepare a bed of good earth in a bricked pit, where they may be covered with glasses, and in hard frosts with mats and straw; the earth in the bed should be two feet deep, and the frame should rise two feet higher, to allow height for the flower-stems to grow. The roots should be planted nine or ten inches asunder, and in winter, if they are protected from frost, and not suffered to have too much wet, but in mild weather exposed to the open air, the roots will flower every year, and the flowers will be much stronger than with any other management.

The third sort is a native of the *Cape of Good Hope*; this may be propagated by parting of the roots, in the spring, before the plants put out new stalks, which is also a right time to shift and new pot them; but as the roots do not multiply very fast in offsets, so the best way is to propagate them from seeds, which they ripen plentifully in *England*; these should be sown soon after they are ripe, in pots, and kept in the stove all the winter; if these pots are plunged into the tan-bed in the bark-stove, in the vacancies between the plants, the seeds will be sooner prepared to vegetate in the spring, when the pots may be taken out of the stove, and plunged into a moderate hot-bed, which will bring up the plants in a little time; soon after they are up, they must have air admitted to them every day in mild weather, to prevent their drawing up weak; and when they are fit to remove, they may be each planted in a separate small pot filled with light earth, and plunged into the hot-bed again, to promote their taking new root; then they must be gradually hardened, and afterward may be removed into the dry stove, where they should constantly remain, otherwise the plants will not thrive and flower in this country. In the winter season they must not have too much wet, for as their roots are fleshy and succulent, so they are apt to rot with moisture. In the summer they must have a large share of air in warm weather, and require to be frequently watered, especially during the time of their flowering.

HÆMATOXYLUM. *Lin. Gen. Plant. 417.* Blood-wood, Logwood, or *Campeachy Wood*.

The Characters are,

The flower hath a permanent empalement, cut into five oval segments. It hath five oval petals; and ten awl-shaped stamina, which are longer than the petals. In the center is situated an oblong oval germen, which afterward becomes a compressed obtuse capsule, with one cell, opening with two valves, containing two or three oblong, flat, kidney-shaped seeds.

We have but one *Species* of this genus, *viz.*

HÆMATOXYLUM. *Hort. Cliff.* 160. Logwood or Campeachy Wood.

This tree grows naturally in the bay of *Campeachy*, at *Honduras*, and other parts of the *Spanish West-Indies*, where it rises from sixteen to twenty-four feet high. The stems are generally crooked, and very deformed, they are seldom thicker than a man's thigh. The branches which come out on every side, are crooked, irregular, and armed with strong thorns, garnished with winged leaves, composed of three or four pair of obtuse lobes, indented at the top. The flowers come in a racemus from the wings of the leaves, standing erect; they are of a pale yellowish colour, with a purple empalement, and are succeeded by flat oblong pods, each containing two or three kidney-shaped seeds.

The wood of this tree is brought to *Europe*, where it is used for dying purples, and for the finest blacks, so is a valuable commodity; but the *Spaniards*, who claim a right to the possession of those places where it naturally grows, are for excluding all other countries from cutting of the wood, which has occasioned many disputes with their neighbours, but particularly with the *English*; this it is to be hoped will soon be over, as there are some of the planters in *Jamaica*, and the other islands in *America*, belonging to the crown of *Great-Britain*, who have propagated this tree in so great plenty, as to have hopes of supplying the demand for this wood in *Britain* in a very few years; for the trees grow so fast there, as to be fit for use in ten or twelve years from seed; and as they produce great plenty of seeds in the *British* colonies, so those seeds scattering about, the plants come up in all the neighbouring lands, therefore will soon be like an indigenous plant of the country.

This plant is preserved in some curious gardens in *England*, for the sake of variety. The seeds are frequently brought from *America*, which, if fresh, readily grow when sown upon a good hot-bed; and if the plants are kept in a moderate hot-bed, they will grow to be upward of a foot high the same year; and, while the plants are young, they are generally well furnished with leaves, but afterward they make but little progress, and are frequently but thinly clothed with leaves. The plants are very tender, so should be constantly kept in the bark-stove, where, if they are duly watered, and the stove kept in a good degree of heat, the plants may be preserved very well. There are some of these plants now in *England*, which are upward of six feet high, and as thriving as those in their native soil.

HALICACABUM. See *Physalis*.

HALICACABUS PEREGRINA. See *Cardiospermum*.

HALIMUS. See *Atriplex*.

HALLERIA. *Lin. Gen. Plant.* 679. African Fly Honey-suckle.

The Characters are,

The flower hath a permanent empalement of one leaf. It hath one petal of the grining kind, whose chaps are swollen and inflexed. It hath four stamina, which are bristly, two being longer than the other. In the bottom of the tube is situated an oval germen, which afterward becomes a roundish berry with two cells, each containing one hard seed.

We have but one *Species* of this genus, *viz.*

HALLERIA. *Hort. Cliff.* 323. This plant has its title from *Dr. Haller*, who was professor of botany at *Gottingen* in *Germany*. African Fly Honey-suckle.

The *English* name which I have here added, has been given to this plant by some gardeners, who observed that the shape of the flower had some resemblance to that of the Upright, or Fly Honey-suckle, and, for want of an *English* name, gave this to it.

This plant grows to the height of six or eight feet, with a woody stem, which is well furnished with branches, gar-

nished with oval sawed leaves, placed opposite, which continue green through the year; the flowers come out singly, and are of a red colour, but, being intermixed with the leaves, are not seen unless they are looked after, for they grow scatteringly on the branches; these come out in *June*, and the seeds ripen in *September*: the plants make a variety in the green-house during the winter season.

It may be propagated by cuttings, which, if planted in pots in the spring, and plunged into a gentle hot-bed, will soon take root; these plants must be exposed in summer, and will require plenty of water in that season; in the winter they must be housed with *Myrtles*, and other hardy exotick plants, which require a large share of air in mild weather.

HAMAMELIS. *Lin. Gen. Plant.* 155. The Witch Hazel.

The Characters are,

It is male and female in different plants; the male flowers have a four-leaved empalement, four narrow petals, which are reflexed, and four narrow stamina, which are shorter than the petals. The female flowers have a four-leaved involucre, in which are four flowers, with a four-leaved coloured empalement; they have four narrow petals, and four nectariums adhering to the petals. In the center is situated an oval hairy germen, which afterward becomes an oval capsule, sitting in the involucre, having two cells, each containing one hard, oblong, smooth seed.

We have but one *Species* of this genus in the *English* gardens at present, *viz.*

HAMAMELIS. *Flor. Virg.* 129. The Witch Hazel.

This plant grows naturally in *North America*, from whence the seeds have been brought to *Europe*, and many of the plants have been raised in the *English* gardens, where they are propagated for sale by the nursery gardeners. It hath a woody stem, from two to tree feet high, sending out many slender branches, garnished with oval leaves, indented on their edges, having great resemblance to those of the Hazel; these fall away in autumn, and when the plants are destitute of leaves, the flowers come out in clusters from the joints of the branches; these sometimes appear the latter end of *October*, and often not till *December*, but are not succeeded by seeds in this country.

As the flowers of this shrub make very little appearance, so it is only preserved in the gardens of the curious, more for the sake of variety than its beauty.

It is propagated by laying down the young branches in autumn, which will take root in one year, and may then be taken from the old plants, and planted where they are to remain. The seeds of this plant always remain a whole year in the ground, so they should be sown in pots, which may be plunged into the ground in a shady part of the garden, where they may remain all the summer, and will require no other care but to keep the pots clean from weeds, and in very dry weather to water them now and then; in autumn the pots may be removed to a warmer situation, and plunged into the ground under a warm hedge, and if the winter should prove very severe, they should have some light covering thrown over them, which will secure the seeds from being destroyed. In the spring the plants will come up, and as the season advances, the pots may be removed where they may have the morning sun till eleven o'clock. In the autumn they should be transplanted, either into small pots, or in a nursery-bed, where in one, or at most two years time, they will be strong enough to plant where they are designed to remain; they love a moist soil, and a shady situation.

HARMALA. See *Peganum*.

HAWTHORN. See *Mespilus*.

HAZEL. See *Corylus*.

HEDERA. *Lin. Gen. Plant.* 249. The Ivy tree.

The Characters are,

The flowers are disposed in form of an umbel. The empalement is cut into five parts, and sits upon the germen. The flower hath five oblong petals, and five awl-shaped stamina. The germen, which is situated below the flower, afterward becomes a globular berry with one cell, inclosing four or five large seeds, convex on one side, and angular on the other.

The Species are,

1. HEDERA foliis ovatis lobatisque. Flor. Lapp. 91. Ivy with oval and lobed leaves; common Ivy.

2. HEDERA foliis quinatis, ovatis, serratis. Hert. Cliff. 74. Ivy with leaves composed of five lobes, which are sawed; commonly called Virginia Creeper.

The first sort grows naturally in most parts of England, and where it meets with any neighbouring support, the stalks will fasten to it, and rise to a very great height, sending out roots on every side, which get into the joints of walls, or the bark of trees, and thereby are supported; or if there is no support near, the stalks trail upon the ground, and take root all their length, so that they closely cover the surface, and are difficult to eradicate, for where any small parts of the stalks are left, they will soon spread and multiply. While these are fixed to any support, or trail upon the ground, their stalks are slender and flexible; but when they have reached to the top of their support, they shorten and become woody, forming themselves into large bushy heads, and their leaves are larger, more of an oval shape, and not divided into lobes like the lower leaves, so that it hath a different appearance, which has occasioned some to take them for distinct species.

There are two varieties of this, one with silver-striped leaves, and the other with yellowish leaves on the top of the branches; these are preserved in some gardens for the sake of variety.

The plants are easily propagated by their trailing branches, which send forth roots their whole length; which branches, being cut off and planted, will grow in almost any soil or situation, and may be trained up to stems, or suffered to remain climbers, to cover walls, pales, &c.

They may also be propagated by seeds, which should be sown soon after they are ripe, which is in the beginning of April; if these are kept moist and shaded, they will grow the same spring, otherwise they will remain a year in the ground, therefore few persons trouble themselves to propagate the plants in this way, the other being much more expeditious.

While the stalks of this plant trail, either on the ground, or upon walls, or other support, they seldom produce flowers, which has occasioned its being called sterile, or barren Ivy; but when the branches get above their support, or grow from it, they produce flowers at the end of every shoot; these appear in September, and are succeeded by berries, which turn black before they are ripe, and are formed into round bunches, which are called *corymbi*, and from these the epithet of *corymbus*, so frequently used by botanists, is taken.

There is another species of Ivy, which grows naturally about Constantinople, and other parts of the Levant, with yellow berries, titled *Hedera Poetica*, by Caspar Baubin; but as I have not seen this plant, I cannot give a farther account of it. Dr. Linnaeus supposes it to be only a variety, though he has not seen the plant; but Tournefort, who gathered it in the Levant, puts it down as a different sort.

The second sort grows naturally in all the northern parts of America; it was first brought to Europe from Canada, and has been long cultivated in the English gardens, chiefly to plant against walls, or buildings to cover them, which these plants will do in a short time, for they will shoot almost twenty feet in one year, and will mount up to

the top of the highest building; but as the leaves fall off in autumn, the plants make but an indifferent appearance in winter, and as it is late before they come out in the spring, they are not much esteemed, unless it is for such situations, where better things will not thrive; for this plant will thrive in the midst of London, and is not injured by smoke, or the closeness of the air, so is very proper for such situations. The stalks of the plants put out roots, which fasten themselves into the joints of the walls, whereby they are supported.

It may be propagated by cuttings, which, if planted in autumn on a shady border, will take root, and by the following autumn will be fit to plant where they are designed to remain.

HEDERA TERRESTRIS. See Glechoma.

HEDGES. Hedges are either planted to make fences round inclosures, or to part off and divide the several parts of a garden; when they are designed as outward fences, they are planted either with Hawthorn, Crabs, or Black Thorn, which is the Sloe; but those hedges which are planted in gardens, either to surround wilderness quarters, or to screen the other parts of a garden from sight, are planted with various sorts of plants, according to the fancy of the owner, some preferring ever-green hedges, in which case the Holly is best, next the Yew, then Laurel, Laurustinus, Phillyrea, &c. Others, who make choice of the deciduous plants, prefer the Beech and Hornbeam, English Elm, or the Alder, to any other; I shall first treat of those hedges which are planted for outside fences, and afterward briefly touch on the other.

These hedges are most commonly made of Quick, yet it will be proper, before planting, to consider the nature of the land, and what sort of plants will thrive best in that soil, whether it be clay, gravel, sand, &c. As for the size, the sets ought to be about the bigness of a goose quill, and cut within about four or five inches of the ground; they should be fresh taken up, frait, smooth, and well rooted. Those plants which are raised in the nursery are to be preferred to all others, and if raised on a spot near the place, it will be best.

Secondly, If the hedge has a ditch, it should be made six feet wide at top, and one foot and a half at bottom, and three feet deep, that each side may have a proper slope; for when the banks are made too upright, they are very subject to fall down after every frost, or hard rain; besides, if the ditches are made narrower, they are soon choked up in autumn by the falling leaves, and the growth of weeds, nor are they a sufficient fence to the hedge against cattle, where they are narrower.

Thirdly, If the bank be without a ditch, the sets should be set in two rows, almost perpendicular, at the distance of a foot from each other, in the quincunx order, so that in effect they will be but six inches asunder.

The usual method of planting Quick hedges, is to lay the plants sloping on the side of the bank, in two rows, one above the other, which is by no means right; for the wet cannot get to the roots of the Quick, when they are planted in such position, for the slope of the bank throws it off; therefore I recommend it as the best method to plant the sets upright upon the top of the bank where they will be farther from the reach of cattle; and if they are duly cleared from weeds, they will grow as much in one year, as those which are laid on the side of the bank will do in three. But if there are not two ditches, one on each side the bank to fence against cattle, there should be a dead hedge made within for that purpose; otherwise, where cattle are admitted into the field, they will browse upon the young shoots of the Quick, and spoil the hedge.

In making of these dead hedges, there should be stakes driven in to the earth, at about two feet and a half distance, so low as to reach the firm ground.

Oak stakes are the best, and Black Thorn the next; then for the small bushes be laid at bottom, but not too thick, for that will cause the bushes to rot, but the upper part of the hedge should be laid with long bushes to bind the stakes in with, by interweaving them.

And, in order to render the hedge yet stronger, you may edder it (as it is called,) *i. e.* bind the top of the stakes in with some small poles on each side, and when the eddering is finished, drive the stakes anew, because the waving of the hedge and eddering is apt to loosen the stakes.

When a hedge is of about eight or nine years growth, it will be proper to plash it; the best time for this work is either in *October* or *February*.

In plashing Quicks, there are two extremes to be avoided; the first is, laying it too low, and too thick; because it makes the sap run all into the shoots, and leaves the plashes without nourishment, which, with the thickness of the hedge, kills them.

Secondly, It must not be laid too high, because this draws all the sap into the plashes, and so causes but small shoots at the bottom, and makes the hedge so thin, that it will neither hinder the cattle from going through, nor from cropping of it.

If the stems are very old, cut them quite down, and secure them with good dead hedges on both sides, till the young shoots are got up tall enough to plash, and plant new sets in the void spaces.

If you would have a good hedge, or fence, you should new lay it once in fourteen or fifteen years, and constantly root out Elder, Travellers Joy (which some call Bull-bine), Bryony, &c. and do not leave high standards, or pollards in it, nor any dead wood is to be left in the bottom of the hedges, for that will choke the Quick; but if there be a gap, the dead hedge should be made at a distance.

The Crab is also frequently planted for hedges, and if the plants are raised from the kernels of the small wild Crab, they are much to be preferred to those which are raised from the kernels of all sorts of Apples without distinction, because the plants of the true small Crab never shoot so strong as those of the Apples, so may be better kept within the proper compass of a hedge; and as they have generally more thorns upon them, they are better guarded against cattle, &c. than the other; besides, the plants of the Crab will grow more equal than those which are raised from the kernels of various kinds of Apples, for these always produce a variety of plants, which differ from each other in their manner of growth, as much as in the size and flavour of their fruits, so that hedges made of these will not appear so neat, nor can be so well managed as the other.

The Black Thorn, or Sloe, is also frequently planted for hedges, and is a strong durable plant for that purpose, especially as it is so strongly armed with thorns, that cattle seldom care to brouze upon it; but where this is planted, the best way is to raise the plants from the stones of the fruit; for all those which are taken from the roots of old trees, spawn, and put out suckers in such plenty from their roots, as to spread over, and fill the neighbouring ground to a considerable distance on each side of the hedge; and this plenty of suckers drawing away the nourishment from the old plants of the hedge, they never grow so well as where there are few or no suckers produced, which those plants which are propagated from the stones send not forth, or at least but sparingly,

therefore may with little trouble be kept clear of them. The best method of raising these hedges is, to sow the stones in the place where the hedge is intended (where it can be conveniently done), for then the plants will make a much greater progress than those which are transplanted; but the objection to this method will arise from the difficulty of securing the young plants from the cattle; but this can have little force, when it must be considered, that if the hedge is planted, it must be fenced for some years, to prevent the cattle from destroying it; therefore the same fence will do for it when sown, nor will this require a fence much longer than the other. For the plants which stand unremoved, will make a better fence in seven years, than that which is planted, tho' the plants should be of three or four years growth when planted. The stones of this fruit should be sown early in *January*, if the weather will permit, but when they are kept out of the ground longer, it will be proper to mix them with sand, and keep them in a cool place. The bushes of the Black Thorn are by much the best of any, for making of dead hedges, being of longer duration, and having many thorns, neither the cattle nor the hedge-breakers, will care to meddle with them; these bushes are also the best to be used for under ground drains, for the draining of land, for they will remain sound a long time, when the air is excluded from them.

The Holly is sometimes planted for hedges, and is a very durable strong fence, but where it is exposed, there will be great difficulty to prevent its being destroyed, otherwise it is by far the most beautiful plant; and being an ever-green, will afford much better shelter to cattle in winter, than any other sort of hedge, and the leaves being armed with thorns, the cattle will not care to brouze upon it. Another objection to this plant is the slow growth, so that hedges planted with this plant, require to be fenced a much longer time than most others. This is a reason which must be admitted; but in such grounds as lie contiguous to, or in sight of gentlemen's houses, these sort of hedges will have an exceeding good effect, especially when they are well kept, as they will appear beautiful at all seasons of the year; and in the spring of the year, when the sharp winds render it unpleasant to walk abroad in exposed places, these hedges will afford good shelter, and will appear beautiful at all seasons of the year; they will also effectually keep off the cold winds, if they are kept close and thick. The surest method of raising these hedges is, by sowing the berries in the place where they are to stand; but these berries should be buried in the ground one year before they are sown, by which method they will be prepared to grow the following spring. The way of doing this is, to gather the berries about *Christmas* (which is the time they are usually ripe), and put them into larger flower-pots, mixing some sand with them; then dig holes in the ground, into which the pots must be sunk, covering them over with earth about a foot thick; in this place they may remain till the following *October*, when they should be taken up, and sown in the place where the hedge is intended. The ground for this hedge should be well trenched, and cleared from the roots of all bad weeds, bushes, trees, &c. Then two drills should be made at about a foot distance from each other, and about two inches deep, into which the seeds should be scattered pretty close, lest some should fail: for it is better to have too many plants come up, than to want. The reason of my advising two drills is, that the hedge may be thick to the bottom, which in a single row rarely happens, especially if there is not great care taken of them in the beginning. When the plants come up, they must be carefully weeded, for if the weeds are permitted to grow among them, they will

will soon destroy them, or weaken them so much, that they will not recover their strength in a long time.

When these Holly hedges are designed to be kept very neat, they should be sheared twice a year, in *May* and *August*; but if they are only designed as fences, they need not be sheared oftener than once a year, which should be about the latter end of *June*, or the beginning of *July*; and if this is well performed, the hedges may be kept very beautiful.

When a hedge of Holly is intended to be made by plants, the ground should be well trenched, as was before advised for the seeds, and (unless the ground be very wet) the plants should be set in *October*, but in wet ground *March* is preferable. The plants should not be taken from a better soil than that in which they are to be planted; for when it so happens, they are much longer before they recover this change than those are which are taken from a leaner soil. If the plants have been before removed two or three times, they will have better roots, and will be in less danger of miscarrying, because they may be removed with balls of earth to their roots. When the frost comes on, if some mulch be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may then have been put out, from being destroyed by the cold. I would never advise the planting of hedges with Holly plants, of above four or five years growth from the berries; for when the plants are older, if they take to grow, they seldom make so close a fence at the bottom as young ones; and if the plants have been twice before transplanted, they will more certainly grow.

In the old method of laying out gardens it was a general practice to surround the wilderness quarters and other parts of the garden with hedges of ever-green, or deciduous trees, which were then esteemed ornamental; but since a better taste has been introduced, these have rarely been admitted. For if the expence of-keeping hedges in good order, together with the litter occasioned whenever they are sheared be considered, it will be found to greatly exceed any pleasure arising from them; therefore as these are not likely to take place again in the *English* gardens, it is needless to give farther directions for planting and the after-management of them, especially as the instructions here given for the raising of Holly hedges may, with a little variation, serve for any other sort.

HEDYPNOIS. See *Hyoseris*.

HEDYSARUM. *Lin. Gen. Plant.* 793. French Honey-suckle.

The Characters are,

The flower hath a permanent empalement of one leaf. It is of the butterfly kind; the wings are oblong and narrow; the keel is compressed, and convex at the base. It hath nine stamina joined, and one standing separate. In the center is situated a long narrow germen, which afterward becomes a jointed compressed pod, each joint being roundish, and incloses a single kidney-shaped seed.

The Species are,

1. HEDYSARUM foliis pinnatis, leguminibus articulatis aculeatis, nudis, rectis, caule diffuso. *Hort. Cliff.* 365. French Honey-suckle with winged leaves, naked, prickly, jointed pods, and a diffused stalk.

2. HEDYSARUM foliis pinnatis, leguminibus articulatis, aculeatis, tomentosis, caule diffuso. *Hort. Upsal.* 231. French Honey-suckle with winged leaves, jointed, prickly, woolly pods, and a diffused stalk.

3. HEDYSARUM foliis simplicibus ternatisque, floribus racemosis. *Hort. Cliff.* 232. French Honey-suckle with single and trifoliate leaves, and flowers in bunches, called French Honey-suckle of *Canada*.

4. HEDYSARUM foliis pinnatis, leguminibus articulatis, acu-

leatis, flexuosis, caule diffuso. *Lin. Sp. Plant.* 750. French Honey-suckle with winged leaves, jointed prickly pods which are waved, and a diffused stalk.

5. HEDYSARUM foliis binatis petiolatis, floralibus sessilibus. *Flor. Zeyl.* 291. French Honey-suckle with two leaves upon a foot-stalk, and those upon the flower-stalks sitting close.

6. HEDYSARUM foliis ternatis, foliolis obovatis, floribus paniculatis terminalibus, leguminibus intortis. French Honey-suckle with trifoliate oval leaves, flowers growing in panicles at the ends of the stalks, and intorted pods.

7. HEDYSARUM foliis ternatis subtus nervosis, caule glabro frutesco decumbente floribus spicatis terminalibus. Three-leaved French Honey-suckle, with veins on their under side, a smooth shrubby declining stalk, with flowers growing in spikes at the ends.

8. HEDYSARUM foliis ternatis, foliolis ovatis subtus sericeis, floribus spicatis alaribus terminalibusque. Three-leaved French Honey-suckle, with oval leaves, fatteny on their under side, and flowers in spikes from the side and at the end of the stalks.

9. HEDYSARUM foliis ternatis, caulibus diffusis villosis, floribus spicatis terminalibus, calycibus villosissimis. Three-leaved French Honey-suckle, with diffused stalks which are hairy, flowers growing in spikes at the ends of the branches, and very hairy empalements.

10. HEDYSARUM foliis ternatis, caulibus procumbentibus racemosis, floribus laxè spicatis terminalibus, leguminibus contortis. Three-leaved French Honey-suckle, with branching trailing stalks, flowers growing in loose spikes at the ends of the branches, and twisted pods.

11. HEDYSARUM foliis ternatis, foliolis obcordatis, caule erecto triangulo villoso, racemis terminalibus, leguminibus articulatis incurvis. French Honey-suckle with trifoliate leaves, whose lobes are heart-shaped, a triangular, upright, hairy stalk, flowers growing in long bunches at the ends of the branches, and jointed incurved pods.

12. HEDYSARUM foliis ternatis obcordatis, caule paniculato, leguminibus monospermis glabris. French Honey-suckle with trifoliate heart-shaped leaves, a paniculated stalk, and smooth pods containing one seed.

13. HEDYSARUM foliis ternatis, foliolis obversè-ovatis, caule volubili, spicâ longissimâ reflexâ. Three-leaved French Honey-suckle with obverse oval lobes, a twining stalk, and a very long reflexed spike of flowers.

14. HEDYSARUM foliis ternatis obcordatis, caulibus procumbentibus villosis, pedunculis unifloris. Three-leaved French Honey-suckle with oval heart-shaped leaves, trailing hairy stalks, and foot-stalks with a single flower.

15. HEDYSARUM foliis simplicibus ovatis obtusis. *Hort. Cliff.* 449. French Honey-suckle with oval, obtuse, single leaves.

16. HEDYSARUM foliis ternatis ovato-lanceolatis, subtus villosis, caule frutescente villoso. Trifoliate French Honey-suckle, with oval spear-shaped leaves, hairy on their under side, and a shrubby hairy stalk.

17. HEDYSARUM foliis ternatis, foliolo intermedio longiore, racemis alaribus erectis longissimis. French Honey-suckle with trifoliate leaves, the middle lobe standing on a longer foot-stalk, and very long bunches of flowers coming from the sides of the stalks.

18. HEDYSARUM foliis simplicibus lanceolatis obtusis, caule fruticoso spinoso. *Lin. Sp. Plant.* 745. French Honey-suckle with single, spear-shaped, obtuse leaves, and a prickly shrubby stalk, or the *Alhagi* of the *Moors*.

19. HEDYSARUM foliis simplicibus, cordato-oblongis integerrimis glabris. French Honey-suckle with single, oblong, heart-shaped leaves, which are smooth and entire.

The first sort has been long cultivated in the *English* gardens for ornament. It grows naturally in *Italy*; there are

two varieties of this, one with a bright red, and the other a white flower, which very rarely vary from one to the other; but as there is no other difference but in the colour of their flowers, so they are allowed to be the same species.

It is a biennial plant, which decays after the seeds are ripe. This sends up several hollow smooth stalks, which branch out, and rise from two to three feet high, garnished with winged leaves, composed of five or six pair of oval lobes, terminated by an odd one; from their base comes out foot-stalks, which are five or six inches long, sustaining spikes of beautiful red flowers, which are succeeded by compressed prickly-jointed pods; in each of the joints is lodged one kidney-shaped seed. This sort flowers in *June* and *July*, and the seeds ripen in *September*. The white is only a variety of this, and as such is sometimes preserved in gardens,

They are propagated by sowing their seeds in *April*, in a bed of light fresh earth; and when the plants are large enough to remove, they should be transplanted into other beds in an open situation, at about six or eight inches distance from each other, leaving a path between every four rows, to go between them to hoe, and clear them from weeds. In these beds they may remain until *Michaelmas*, when they may be transplanted into the large borders of a parterre or pleasure-garden, allowing them at least three feet distance from other plants, amongst which they should be interspersed, to continue the succession of flowers; where they will make a fine appearance when blown, especially the red sort, which produces very beautiful flowers.

As these plants decay after they have perfected their seeds, so there should annually be a fresh supply of plants raised. They are very proper ornaments for large borders, or to fill up vacancies among shrubs, but they grow too large for small borders.

The second sort is an annual plant, which grows naturally in *Spain* and *Portugal*. The leaves of this are narrow and oblong, four or five pair being placed along the mid-rib, with an odd one at the end; the stalks are terminated by small spikes of purple flowers, which are succeeded by small rough pods, shaped like those of the former sort. This plant is preserved in botanick gardens for the sake of variety; it is propagated by seeds, which should be sown the beginning of *April*, in the place where the plants are to remain, and will require no other culture but to thin them where they are too near, and keep them clean from weeds.

The third sort hath a perennial root, which will abide many years, if planted in a dry soil. This is propagated by sowing the seeds in the manner directed for the former; but when the plants are come up two inches high, they should be transplanted where they are to remain for good; but if they are not too thick in the seed-bed, they may be suffered to remain there until the following autumn; at which time they should be carefully taken up, and transplanted into the borders where they are designed to stand; for their roots generally run down very deep, so that it is not safe to remove them after they are large.

The fourth sort is an annual plant, which grows naturally in the *Levant*. This hath some resemblance of the first, but is much smaller; the stalks rise near a foot high, garnished with winged leaves, composed of two or three pair of oval lobes, terminated by an odd one; the flowers come out in spikes at the top of the stalks, which are of a pale red, intermixed with a little blue. This is propagated in the same way as the second sort, and is equally hardy.

The fifth sort grows naturally in both *Indies*. This is an annual plant, with a long tap-root, which runs deep in the ground, sending out one or two stalks, which rise about

nine inches high, the lower part being garnished with oval leaves by pairs on each foot-stalk, but the upper part of the stalk, where the flowers come out, is garnished with small leaves, ending in acute points, sitting close to the stalks; at each of these is situated a single, small, yellow flower, inclosed by the two leaves, and are succeeded by oblong pods, containing one kidney-shaped seed.

The sixth sort grows naturally at *La Vera Cruz*, and also in *Jamaica*. It is an annual plant, which rises with a shrubby stalk upward of four feet high, dividing into several branches, garnished with oblong, oval, trefoil leaves, standing upon pretty long foot-stalks, the middle lobe standing an inch beyond the other two; the branches are terminated by long loose panicles of purple flowers, which are succeeded by narrow, jointed, twisted pods. This flowers in *July*, and the seeds ripen in the autumn.

The two last mentioned are tender plants, so their seeds must be sown in the spring upon a hot-bed; and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a hot-bed, shading them from the sun till they have taken new root; then they must be treated in the same way as other tender plants from hot countries, always keeping them in the stove or glass-case, otherwise they will not flower or produce seeds in *England*.

The seventh sort grows naturally in *Jamaica*. This is a shrubby plant, which rises about five feet high, and divides into several branches, garnished with trifoliate leaves which are oval, the middle lobe being much larger than the other two; the stalks are terminated by long spikes of small purple flowers, which are succeeded by narrow pods, frait on one side, but jointed on the other.

The eighth sort grows at *La Vera Cruz*. This rises with a shrubby stalk six or seven feet high, dividing into several branches, garnished with trifoliate oval leaves, silky and white on their under side, but of a pale green on their upper; the flowers come out in long narrow spikes from the wings, and at the end of the branches, sitting close to the stalks; they are small, of a bright purple colour, and are succeeded by flat, smooth, jointed pods, about one inch long, each joint having one kidney-shaped seed.

The two last sorts will continue two or three years, if the plants are placed in the bark-stove. They are propagated by seeds, which must be sown upon a hot-bed, and the plants treated in the same manner as those just before-mentioned.

The ninth sort is an annual plant, which grows naturally at *La Vera Cruz*. This seldom rises more than eight or nine inches high, sending out several branches from the root, which are diffused and hairy, closely garnished with small, oval, trifoliate leaves, a little hoary. The flowers grow in close short spikes; they are purple, and have very hairy empalements.

The tenth sort grows naturally in *Jamaica*. This hath ligneous trailing stalks a foot and a half long, sending out several branches on each side, garnished with small, round, trifoliate leaves, of a pale green colour; the flowers are produced in very loose spikes at the end of the branches; they are of a pale purplish colour, and are succeeded by narrow twisted pods, which are jointed, containing a single, small, compressed seed.

The two last sorts being annual, require the same treatment as the fifth and sixth sorts before-mentioned, with which they will flower and ripen their seeds in this country.

The eleventh sort grows in *Jamaica*. It is a shrubby plant, which rises with triangular stalks five or six feet high, dividing into several branches, garnished with heart-shaped trifoliate leaves, ending in acute points; the flowers are produced in very long spikes at the end of the branches, which

which are of a pale purple colour, and are succeeded by narrow jointed pods, which are variously twisted; the seeds are small and compressed.

The twelfth sort is annual, it grows at *Campeachy*. This hath a paniculated stalk, which rises about two feet high, garnished with heart-shaped trifoliate leaves; the upper part of the stalk branches out into panicles of flowers, which are of a pale purple colour, and are succeeded by lunulated compressed pods, standing oblique to the stalk, each containing one compressed kidney-shaped seed. This sort is propagated by seeds, and requires the same treatment as the fifth and sixth sorts.

The thirteenth sort grows at *La Vera Cruz*. This hath a twining stalk, which twists round the trees and shrubs which grows near it, and climbs to the height of ten or twelve feet, garnished with obverse, oval, trifoliate leaves, standing upon pretty long foot-stalks; the flowers are produced in very long spikes, which are reflexed; they are of a dark purple colour, and sit close to the stalk. This is an abiding plant, which requires a stove to preserve it in this country, so the plants should be treated in the same manner as the seventh and eighth sorts.

The fourteenth sort is an annual plant, which grows naturally in both *Indies*. It hath trailing branches near a foot long, garnished with round trifoliate leaves, a little indented at the top, very like in shape to those of the Strawberry Trefoil; the stalks and under side of the leaves are hairy; the flowers are produced toward the end of the branches, sometimes single, and at other times two at a joint: they are of a purple colour and small; these are succeeded by pods about an inch long, which are strait on one side, and jointed on the other.

The fifteenth sort is a low annual plant, having slender stalks near a foot long, their lower part being garnished with single oval leaves, standing upon slender foot-stalks; their upper is adorned with flowers, which come out by pairs above each other, to the end of the stalk; they are but small, and of a reddish yellow colour, and are succeeded by jointed, narrow, sickle-shaped pods, which sit close to the stalk. The two last mentioned are annual plants, which require the same culture as the fifth and sixth sorts.

The sixteenth sort grows in *South Carolina*. This hath a perennial root, from which arise two or three shrubby hairy stalks two feet high, branching on every side near the top, garnished with oval, spear-shaped, trifoliate leaves, which are hairy on their under side, and stand upon short foot-stalks; the flowers are produced at the end of the branches in short spikes; they are of a purplish yellow colour and small; the stalks of this sort decay every autumn, and new ones arise in the spring. It is propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be planted in separate small pots, and plunged into a moderate hot-bed, observing to shade them until they have taken new root; then they should have a large share of air admitted to them in warm weather; in summer they must be exposed to the open air, but in the autumn they must be placed under a frame to screen them from frost; the following spring some of these plants may be shaken out of the pots, and planted in a warm border, where, if the summer proves warm, they will flower; but these seldom perfect their seeds, therefore two or three plants should be put into larger pots, and plunged into a moderate hot-bed, which will bring them early into flower; so that if the glasses are kept over them in bad weather, these will ripen their seeds in autumn, and the roots will continue some years, if they are screened from frost in winter.

The seventeenth sort also grows in *South Carolina*. This

hath a perennial root and an annual stalk, which grows erect about two feet high, garnished with long trifoliate leaves, rounded at their base where they are broadest, and narrowed all the way to a point; they are near three inches and a half long, and half an inch broad at their base, of a light green and smooth; the two side lobes sit pretty close to the stalk, but the middle one sits upon a foot-stalk an inch long; the flowers are produced in long spikes from the wings of the stalk, growing erect; the lower part of the spike is but thinly set with flowers, but on the upper part they are disposed very close; these are small, and of a bright yellow colour, sitting very close to the stalks, and are succeeded by jointed pods strait on one side.

This plant is propagated by seeds, and requires the same treatment as the last mentioned, with which it will flower and produce ripe seeds.

The eighteenth sort grows naturally in *Syria*, where it is one of the beauties of the country. It rises with shrubby stalks about three feet high, which branch out on every side, garnished with single smooth leaves, shaped like those of the broad-leaved Knot-grass, of a pale green, and stand on short foot-stalks; under these leaves come out thorns, which are near an inch long, of a reddish brown colour; the flowers come out from the side of the branches in small clusters; they are of a purple colour in the middle, and reddish about the rims; these are succeeded by pods, which are strait on one side, and jointed on the other, bending a little in shape of a sickle. This plant is at present pretty rare in the *English* gardens; it is propagated by seeds, which will frequently lie a year in the ground before they vegetate, therefore should be sown in pots filled with light earth, and plunged into a moderate hot-bed; and if the plants do not appear by the beginning of *June*, the pots should be taken out of the bed, and placed where they may have only the morning sun, keeping them clean from weeds; and in the autumn, they should be plunged into an old bed of tanners bark under a frame, where they may be screened from the frost and hard rains in the winter; in spring they should be plunged into a fresh hot-bed, which will bring up the plants: when these are fit to remove, they should be each planted into a separate small pot, and plunged into a very moderate hot-bed, shading them from the sun till they have taken new root; then they should be gradually hardened to bear the open air, into which they should be removed in *June*, placing them in a sheltered situation, where they may remain till the autumn, when if they are plunged into an old tan-bed under a frame, where in mild weather they may enjoy the free air, and be protected from frost, they will succeed better than if placed in a greenhouse, or tenderly treated. I have seen this plant growing in the full ground, in a very warm border, where by covering it in frosty weather, it had endured two winters, but a severe frost happening the third winter, entirely killed it.

From this shrub the *Persian* manna is collected, which is an exudation of the nutritious juice of the plant. This drug is chiefly gathered about *Tauris*, a town in *Persia*, where the shrub grows plentifully. Sir *George Wheeler* found it growing in *Tinos*, and supposed it was an undescribed plant. *Tournefort* found it in plenty in many of the plains in *Armenia* and *Georgia*, and made a particular genus of it, under the title of *Alhagi*.

The nineteenth sort grows naturally in *India*, from whence the seeds have been lately brought to *Europe*, and several plants have been raised in the *English* gardens; these have leaves so like those of the Orange tree, as scarcely to be distinguished while young; but as there are not any plants here of a large size, so I can give no further account of it at present.

HEDYSARUM Zeylanicum majus & minus. See *Æschynomene*.

HELENIUM. *Lin. Gen. Plant.* 863. Bastard Sun-flower.

The Characters are,

It hath a flower composed of several hermaphrodite florets, which form the disk, and female half florets, which compose the rays. The hermaphrodite florets are tubulous; these have each five short hairy stamina, and an oblong germen, which afterward becomes an angular single seed, crowned by a small five-pointed empalement. The female half florets in the border are stretched out on one side like a tongue to form the ray; these are cut into five segments at their points; they have no stamina, but an oblong germen, which turns to a single seed, like those of the hermaphrodite flowers; these are all included in one common single empalement.

The Species are,

1. HELENIUM *foliis lineari-lanceolatis integerrimis glabris, pedunculis nudis unifloris*. Helenium with spear-shaped narrow leaves, which are smooth, entire, and naked foot-stalks with single flowers.

2. HELENIUM *foliis lanceolatis acutis serratis, pedunculis brevioribus, calycibus multifidis*. Helenium with pointed, spear-shaped, sawed leaves, shorter foot-stalks, and a many-pointed empalement.

These plants rise to the height of seven or eight feet in good ground; the roots when large send up a great number of stalks, which branch toward the top; those of the first sort are garnished with smooth leaves, which are three inches and a half long, and half an inch broad in the middle, with entire edges fitting close to the stalks, and from their base is extended a leafy border along the stalk, so as to form what was generally termed a winged stalk, but *Linnaeus* calls it a running leaf; the upper part of the stalk divides, and from each division arises a naked foot-stalk, about three inches long, sustaining one yellow flower at the top, shaped like a Sun-flower, but much smaller, having long rays, which are jagged pretty deep into four or five segments.

The second sort hath the appearance of the first, but the leaves are shorter and broader, ending in acute points, and are sharply sawed on their edges. The flowers stand upon shorter foot-stalks, growing closer together.

These plants are natives of *North America*, where they grow wild in great plenty. They may be propagated by seeds, or by parting their roots; the latter is generally practised in this country.

The best season to transplant and part the old roots is in *October*, when their flowers are past, or the beginning of *March*, just before they begin to shoot; but if the spring should prove dry, they must be duly watered, otherwise they will not produce many flowers the same year: these plants should not be removed oftener than every other year, if they are expected to flower strong; they delight in a soil rather moist than dry, provided it be not too strong, or hold the wet in winter.

HELENIUM. See *Inula*.

HELIANTHEMUM. *Tourn. Inst. R. H.* 248. tab. 128. Dwarf Cistus, or Sun-flower.

The Characters are,

The flower has a three-leaved empalement. It hath five roundish petals, with a great number of erect stamina. In the center is situated an oval germen, which afterward becomes a roundish or oval capsule of one cell, opening in three parts, filled with small roundish seeds.

The Species are,

1. HELIANTHEMUM *caulibus procumbentibus suffruticosis, foliis oblongis subpilosis, stipulis lanceolatis*. Dwarf Cistus with trailing shrubby stalks, oblong hairy leaves, and spear-shaped stipulæ.

2. HELIANTHEMUM *caulibus procumbentibus suffruticosis ramosissimis, spicis florum longioribus*. Dwarf Cistus with trailing shrubby stalks full of branches, and longer spikes of flowers.

3. HELIANTHEMUM *caulibus suffruticosis pilosis, foliis lanceolatis obtusis, spicis reflexis*. Dwarf Cistus with hairy shrubby stalks, blunt spear-shaped leaves, and reflexed spikes of flowers.

4. HELIANTHEMUM *incanum, caulibus suffruticosis erectis, foliis lanceolatis hirsutis*. Hoary dwarf Cistus with erect shrubby stalks, and hairy spear-shaped leaves.

5. HELIANTHEMUM *caule procumbente non ramoso, foliis linearibus incanis oppositis*. Dwarf Cistus with an unbranched trailing stalk, and narrow hoary leaves placed opposite.

6. HELIANTHEMUM *caule suffruticoso procumbente, foliis linearibus alternis, floribus auriculatis*. Dwarf Cistus with a shrubby trailing stalk, very narrow leaves placed alternate, and auriculated flowers.

7. HELIANTHEMUM *caule suffruticoso procumbente, foliis lanceolatis oppositis, pedunculis longioribus, calycibus hirsutis*. Dwarf Cistus with a shrubby trailing stalk, spear-shaped leaves placed opposite, longer foot-stalks to the flowers, and hairy empalements.

8. HELIANTHEMUM *caule suffruticoso procumbente, foliis linearibus oppositis, floribus umbellatis*. Dwarf Cistus with a shrubby trailing stalk, very narrow leaves placed opposite, and flowers growing in an umbel.

9. HELIANTHEMUM *caulibus procumbentibus suffruticosis glabris, foliis ovato-lanceolatis oppositis, pedunculis longioribus*. Dwarf Cistus with shrubby trailing stalks, which are smooth, oval spear-shaped leaves placed opposite, and longer foot-stalks to the flowers.

10. HELIANTHEMUM *caule lignoso perenne, foliis radicalibus ovatis trinerviis tomentosissimis caulibus glabris lanceolatis alternis*. Perennial dwarf Cistus with a woody stalk, whose lower leaves have three veins, are oval, woolly, and those on the stalks smooth, spear-shaped, and placed alternate.

11. HELIANTHEMUM *caulibus sessilibus suffruticosis, foliis lanceolatis oppositis tomentosissimis caule florali racemoso*. Dwarf Cistus with very short shrubby stalks, woolly spear-shaped leaves placed opposite, and a branching flower-stalk.

12. HELIANTHEMUM *caule suffruticoso procumbente, foliis ovatis nervosis, subtus incanis*. Dwarf Cistus with a shrubby trailing stalk, and oval veined leaves, white on their under side.

13. HELIANTHEMUM *caule suffruticoso, foliis lineari lanceolatis oppositis subtus tomentosissimis*. Dwarf Cistus with a shrubby stalk, and narrow spear-shaped leaves placed opposite, which are woolly on their under side.

14. HELIANTHEMUM *caule suffruticoso erecto, foliis linearibus margine revolutis subtus incanis*. Dwarf Cistus with a shrubby erect stalk, and narrow leaves reflexed on their edges, with their under side hoary.

15. HELIANTHEMUM *caulibus suffruticosis procumbentibus, foliis oblongo-ovatis subhirsutis, petalis acuminatis reflexis*. Dwarf Cistus with trailing shrubby stalks, oblong oval hairy leaves, and acute-pointed reflexed petals to the flowers.

16. HELIANTHEMUM *caule suffruticoso erecto, foliis lanceolatis incanis glabris caule florali ramoso*. Dwarf Cistus with a shrubby upright stalk, hoary spear-shaped leaves, which are smooth, and branching flower-stalks.

17. HELIANTHEMUM *caule suffruticoso, foliis oblongo-ovatis oppositis, summis linearibus alternis*. Dwarf Cistus with a shrubby stalk, oblong oval leaves placed opposite, those toward the top being narrow and alternate.

18. HELIANTHEMUM *caule herbaceo hirsuto, foliis lanceolato-linearibus pilosis, pedunculis longioribus*. Dwarf Cistus with an herbaceous stalk, which is hairy, narrow, spear-shaped,

shaped, hairy leaves, and longer foot-stalks to the flowers.

19. *HELIIANTHEMUM caule herbaceo, foliis subovatis pilosis, flore fugaci.* Dwarf Cistus with an herbaceous stalk, hairy oval leaves, and a fugacious flower.

20. *HELIIANTHEMUM caule herbaceo erecto, foliis lanceolatis oppositis, floribus solitariis, capsulis maximis.* Dwarf Cistus with an erect herbaceous stalk, spear-shaped leaves placed opposite, flowers growing singly, and very large capsules.

21. *HELIIANTHEMUM caule herbaceo ramoso, foliis oblongo-ovatis oppositis, summis alternis, floribus solitariis.* Dwarf Cistus with a branching herbaceous stalk, oblong oval leaves placed opposite, those toward the top, growing alternate, and solitary flowers.

22. *HELIIANTHEMUM foliis fasciculatis.* Royen. Dwarf Cistus with leaves growing in bunches.

23. *HELIIANTHEMUM caule fruticoso succulento, foliis ovatis carnosiss, floribus racemosis.* Dwarf Cistus with a shrubby succulent stalk, oval fleshy leaves, and branching flowers.

24. *HELIIANTHEMUM caule herbaceo procumbente, foliis ovatis tomentosis sessilibus.* Dwarf Cistus with an herbaceous trailing stalk, and oval woolly leaves sitting close to the branches.

The first sort grows naturally on the chalky hills and banks in many parts of *England*; the stalks of this plant are ligneous and slender, trailing upon the ground, extending themselves near a foot each way, garnished with small oblong leaves, of a dark green on their upper side, but of a grayish colour on their under. The flowers are produced at the end of the stalks, in loose spikes; they are composed of five deep yellow petals, which spread open in the day, but shut close in the evening.

The second sort grows naturally in *Germany*; the stalks of this are much larger, and extend farther than those of the first; the leaves are longer and hoary: there are three acuminate stipula at each of the lower joints, which are erect. The spikes of flowers are much longer than those of the former, and the flowers are white and larger.

The third sort grows naturally in the south of *France*, in *Italy*, and *Germany*. The stalks of this grow more erect than either of the former, and are ligneous. The joints are farther asunder; the leaves are longer and hairy; the spikes of flowers are generally reflexed; they are white, and the size of those of the second; the stipula of this are very narrow.

The fourth sort grows naturally on the *Apennine* mountains; the stalks of this are more erect than those of the third. The leaves are not so long, the stipula are very small, and the whole plant is very hoary. The flowers are white, and the spikes are shorter and more compact than either of the former.

The fifth sort grows naturally in the south of *France*, in *Spain*, and *Istria*; this hath low trailing stalks, which are ligneous, but seldom branch, and are not more than four or five inches long. The leaves are narrow and hoary, and have no stipula at their base. The flowers are white, and grow in small clusters at the end of the stalks; this sort seldom continues longer than two years.

The sixth sort hath trailing shrubby stalks, which extend a foot in length, garnished with very narrow smooth leaves placed alternate; these have no stipula at their base. The flowers are placed thinly toward the end of the branches, they are yellow and auriculated; this grows in the south of *France* and *Italy*.

The seventh sort hath very long, trailing, ligneous stalks, garnished with spear-shaped leaves, placed opposite, which are very hairy, and gray on their under side, having at their base three long narrow stipula. The spikes of flowers

are near a foot in length, but grow thinly; they are large, and of a deep yellow colour, with very hairy empalements; this grows naturally in the south of *France* and *Spain*.

The eighth sort hath very shrubby crooked stalks, covered with a purplish brown bark like the common Heath. The branches are slender, garnished with narrow stiff leaves, like those of Thyme, which stand opposite, having no stipula at their base. The flowers are produced on naked foot stalks, which terminate the branches in a sort of umbel; they are of a pale yellow colour, and smaller than those of the common sort; this grows naturally on the sands near *Fontainebleau*, in *France*.

The ninth sort grows naturally in *Germany*; this sends out from a ligneous root, a great number of trailing stalks, which extend more than a foot each way; they are smooth, with a dark brown bark, garnished with oval, spear-shaped, smooth leaves, placed opposite, having at their base three spear-shaped stipula. The flowers are large, yellow, and grow in short clusters at the end of the branches.

The tenth sort grows naturally in *Spain*; this hath a short, thick, woody stalk, from which come out several side branches, garnished with oval woody leaves, having three longitudinal veins. The flower-stalk which arises from the main stem, grows about nine inches high, having two or three narrow leaves placed alternate. The flowers are produced on pretty long pedicles toward the top of the stalk, and have very smooth empalements.

The eleventh sort was sent from *Verona*, where it grows naturally; this hath a low shrubby stalk, from which come out a few short branches, garnished with small, woolly, spear-shaped leaves, placed opposite. The flower-stalk rises about six inches high, it branches toward the top, where the flowers are produced on pretty long foot-stalks; they are white, and smaller than those of the common sort.

The twelfth sort hath long shrubby stalks, which trail on the ground, and divide into many branches, garnished with oval veined leaves of a light green on their upper side, but grayish below, with three narrow erect stipula at their base. The flowers are pretty large, white, and grow in clusters at the end of the branches.

The thirteenth sort hath shrubby stalks, which grow pretty upright, garnished with narrow spear-shaped leaves, placed opposite, woolly on their under side, with three very narrow stipula growing at their base. The flowers are white, growing in long spikes at the end of the branches; this grows naturally in the south of *France*.

The fourteenth sort hath an erect shrubby stalk, which sends out many side branches, whose joints are pretty close, garnished with very narrow leaves, placed opposite, whose borders are reflexed; their upper side is of a lucid green, and their under side hoary. The flowers are pretty large, white, and grow in small clusters at the end of the branches; this grows naturally in *Spain*.

The fifteenth sort was found by Mr. *Edmund du Bois*, near *Croydon*, in *Surry*, and was at first only supposed to be an accidental variety of the common sort, but the seeds of this always produce the same. This is very like the common sort, but the leaves are hairy. The petals of the flowers are star-pointed, and smaller than those of the common sort.

The sixteenth sort hath shrubby stalks, which rise a foot and a half high, sending out branches the whole length, garnished with small, spear-shaped, smooth, silvery leaves, placed opposite. The flower-stalks branch, and the flowers, which are white, are produced in short spikes at the end of the branches.

The seventeenth sort was found growing naturally by the late Dr. *William Sberard*, near *Smyrna*; this hath shrubby stalks,

stalks, garnished with oblong oval leaves placed opposite, but those toward the top are narrow, and placed alternate. The flowers are produced at the end of the branches in long loose spikes, they are of a Rose colour, and the size of those of the common sort.

The eighteenth sort is annual; this grows naturally in *France, Spain, Italy*, and in *Jersey*, where the late Dr. *William Sherrard* found it; this hath a branching herbaceous stalk, which rises four or five inches high, garnished with narrow spear-shaped leaves, placed opposite, which are covered with hairs; those on the upper part of the stalks are placed alternate, and are narrower. The flowers are produced in loose spikes at the end of the branches, standing upon long foot-stalks, they are small, and composed of five yellow petals, with a dark purple spot at the base of each; these flowers are very fugacious, for they open early in the morning, and their petals drop off in a few hours after, so that by ten of the clock the flowers are all fallen.

The nineteenth sort grows naturally upon mount *Baldus*; this is an annual plant, which sends out many herbaceous stalks from the root, garnished with oval leaves, which are hairy. The flowers are produced in loose spikes at the end of the branches, they are of a pale yellow colour, and very fugacious, seldom lasting two hours before the petals fall off; there is another variety of this which grows about *Verona*, with upright stalks.

The twentieth sort grows naturally in the south of *France* and *Italy*, and was found by the late Dr. *William Sherrard*, growing near *Smyrna*, who sent the seeds to *England* and *Holland* by a new title, supposing it to be a different plant; but when it was cultivated here, it proved to be the same with that growing in the south of *France*, for this plant puts on different appearances, according to the soil and situation where it grows; where the plants stand single, and are not injured by weeds, they will rise near a foot and a half high, the leaves will be two inches and a half long, and near half an inch broad in the middle; but in a poor soil, or where the plants stand too close, or are injured by weeds, or neighbouring plants, they do not rise more than half that height; the leaves are much narrower, and the seed vessels not half so large, so that any person finding these plants, in two different situations, may be deceived, and take them for different species; but when they are cultivated in a garden in the same soil and situation, they do not differ in any particular. This is an annual plant, which perishes soon after the seeds are ripe.

The twenty-first sort is an annual plant, which grows naturally in *Spain* and *Portugal*; this hath branching stalks, which rise a foot high, garnished with oval oblong leaves, placed opposite, on the lower part of the stalk, but on the upper part, they are alternate and narrow, a single leaf being placed between each flower, which occasions the title of Solitary Flowers, for they grow in loose spikes at the end of the branches, in the same manner as the other species.

The twenty-second sort was sent me by Dr. *Adrian Van Royen*, who received the seeds from the *Cape of Good Hope*. This rises with a shrubby stalk about nine inches high, garnished with very narrow fine leaves, growing in clusters; the flowers come out from the side and at the end of the branches, standing upon slender foot-stalks; they are of a pale straw colour, and are very fugacious, seldom continuing longer than two hours before the petals fall off. This seldom continues longer than two years.

The twenty-third sort was sent me by the late Dr. *William Housoun* from *Campeachy*, where he found it growing naturally. This hath a succulent stalk, which rises near three feet high, garnished with oval, fleshy, succulent leaves, like those of Purslain, which are placed

alternate; the flower-stalks arise from the main stem, which are naked and near two feet high, branching out on each side in smaller foot-stalks, which are again branched into many smaller, each sustaining a small Kote-coloured flower.

The twenty-fourth sort grows naturally about *Kendal* in *Westmoreland*, and in some parts of *Lancashire*, upon rocky situations. This hath trailing herbaceous stalks, which seldom extend more than three or four inches, garnished with oval leaves, which are very woolly, and sit close to the branches; the flowers are produced at the upper part of the branches, they are white and small, so make no great appearance.

All the perennial sorts of dwarf *Cistus* (except the twenty-third) are hardy, so will thrive in the open air in *England*; they are propagated by seeds, which may be sown in the places where the plants are to remain, and will require no other care but to keep them clean from weeds, and thin them where they are too close, always observing to leave those sorts at a farther distance, whose stalks trail on the ground, and grow to the greatest length. These plants will continue several years, especially in a poor dry soil, but in rich ground or moist situations, they seldom last long; but as they ripen seeds in plenty, so they may be easily repaired. They all flower about the same time as the common sort, and their seeds ripen in the autumn.

The annual sorts may be propagated with as great facility, for if their seeds are sown upon a bed of common earth in *April*, the plants will come up in *May*, and require no other culture, but to thin them where they are too close, and keep them clear from weeds. These will flower in *July*, and the seeds ripen in the autumn. The twenty-second sort will thrive in the full ground in the same manner as the other, but unless the summer proves favourable, the seeds will not ripen: the roots have stood through the winter when the season has proved mild, without any shelter, and have flowered the following summer.

The twenty-third sort grows naturally in the warm parts of *America*. Father *Plumier* discovered it first in some of the *French* islands, and Dr. *Housoun* found it growing plentifully about *Campeachy*. This sort is propagated by seeds, which should be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a small pot filled with light, sandy, undunged earth, and plunged into a moderate hot-bed of tanners bark, and treated in the same manner as other tender plants from the same country; in the autumn they must be placed in a warm stove, and the second year the plants will flower, but they have not as yet produced seeds in *England*.

The twenty-fourth sort requires a shady situation, otherwise it will not thrive here.

HELIANTHUS. *Lin. Gen. Plant.* 877. Sun-flower.

The Characters are,

It hath a compound radiated flower, the border or rays being composed of female half florets, which are barren, and the disk of hermaphrodite florets which are fruitful, contained in one common scaly empalement. The hermaphrodite florets are cylindrical, cut at the brim into five acute segments; these have five stamina. The germen, which is situated at the bottom of the tube, afterward becomes an oblong, blunt, four-cornered seed. The female half florets, which compose the border, are not fruitful.

The Species are,

1. HELIANTHUS *foliis omnibus cordatis, nervis pone basin unitis, extrorsum denudatis. Lin. Sp. Plant.* 904. Sun-flower whose leaves are all heart-shaped, veins uniting behind at the base, but toward the border naked; commonly called annual Sun-flower.

2. HELIANTHUS *foliis inferioribus cordatis, nervis pone basin unitis denudatis, superioribus ovatis. Lin. Sp. Plant.* 905. Sun-

Sun-flower whose under leaves are heart-shaped, veins united behind at their base, and the upper leaves oval; commonly called perennial Sun-flower.

3. *HELIANTHUS foliis ovato-cordatis, nervis intra folium unitis.* Lin. Sp. Plant. 905. Sun-flower with oval heart-shaped leaves, whose nerves unite in the leaf; commonly called Jerusalem Artichoke.

4. *HELIANTHUS radice fussi formi.* Hort. Cliff. 420. Sun-flower with a spindle-shaped root.

5. *HELIANTHUS foliis lanceolatis scabris caule striato, infernè glabro.* Lin. Sp. Plant. 905. Sun-flower with rough spear-shaped leaves, a slender stalk, smooth toward the bottom.

6. *HELIANTHUS foliis oppositis sessilibus ovato-oblongis trinerviis, panicula dichotoma.* Lin. Sp. Plant. 906. Sun-flower with oblong, opposite, oval leaves, having three veins, and sitting close to the stalk, and a dichotomous panicle.

7. *HELIANTHUS foliis lanceolatis oppositis, supernè scabris, infernè trinerviis, caule dichotomo romoso.* Sun-flower with spear-shaped leaves placed opposite, whose upper surface is rough, the under leaves having three veins, and a divided stalk.

8. *HELIANTHUS caule ramosissimo, foliis lanceolatis scabris, inferioribus oppositis, summis alternis petiolatis, calycibus foliosis.* Sun-flower with a very branching stalk, rough spear-shaped leaves placed opposite at bottom, but alternate toward the top, having foot-stalks, and leafy empalements.

9. *HELIANTHUS foliis ovatis crenatis trinerviis scabris, squamis calycinis erectis longitudine disci.* Flor. Virg. 103. Sun-flower with oval, rough, crenated leaves, having three nerves, the scales of the empalement being erect, and as long as the disk of the flower.

10. *HELIANTHUS caule infernè lævi foliis lanceolato-cordatis, radiis decapetalis.* Lin. Sp. Plant. 905. Sun-flower, with a stalk smooth on the upper side, heart spear-shaped leaves, and ten petals in the rays.

All these species of Sun-flowers are natives of *America*, from whence we are often supplied with new kinds; and it is very remarkable, that there is not a single species of this genus that is *European*; so that before *America* was discovered, we were wholly unacquainted with these plants. But although they are not originally of our own growth, yet are they become so familiar with our climate, as to thrive and increase full as well as if they were in their native country (some of the very late flowering kinds excepted, which require a longer summer than we generally enjoy, to bring them to perfection;) and many of them are now so plentiful in *England*, that persons unacquainted with the history of these plants, would imagine them at least to have been inhabitants of this island many hundred years: particularly the *Jerusalem Artichoke*, which, though it doth not produce seeds in our climate, yet doth so multiply by its knobbed roots, that, when once well fixed in a garden, it is not easily to be rooted out.

The first sort is annual, and so well known as to require no description. There are single and double flowers of two different colours, one of a deep yellow, and the other of a sulphur colour; but these vary, so are not worthy to be mentioned as different. They are easily propagated by seeds, which should be sown in *March*, upon a bed of common earth; and when the plants come up, they must be thinned where they are too close, and kept clean from weeds; when the plants are grown six inches high, they may be taken up with balls of earth to their roots, and planted into the large borders of the pleasure-garden, observing to water them till they have taken new root, after which they will require no other care, but to keep them clear from weeds.

In *July* the great flowers upon the tops of the stems will

appear, amongst which, the best and most double flowers of each kind should be preserved for seeds; for those which flower later upon the side branches are neither so fair, nor do they perfect their seeds so well, as those which first appear: when the flowers are quite faded, and the seeds are formed, they should be carefully guarded from the sparrows, which will otherwise devour most of the good seeds: about the beginning of *October*, when the seeds are ripe, the heads should be cut off, with a small part of the stem, and hung up in a dry airy place for about a month, by which time the seeds will be perfectly dry and hard; when they may be easily rubbed out, and put up in bags or papers, to preserve them from vermin until the season for sowing them.

The seeds of this sort of Sun-flower are excellent food for domestic poultry, therefore where a quantity of it can be saved, it will be of great use, where there are quantities of these fowls.

The other perennial sorts rarely produce seeds in *England*, but most of them increase very fast at their roots, especially the creeping rooted kinds, which spread too far for small gardens. The second sort, which is the most common in the *English* gardens, is the largest and most valuable flower, and is a very proper furniture for large borders in great gardens, as also for bosquets of large growing plants, or to intermix in small quarters with shrubs, or in walks under trees, where few other plants will thrive; it is also a great ornament to gardens within the city, where it grows in defiance of the smoke, better than most other plants; and for its long continuance in flower, deserves a place in most gardens, for the sake of its flowers for basons, &c. to adorn halls and chimneys in a season when we are at a loss for other flowers. It begins flowering in *July*, and continues until *October*. The sort with single flowers is now little valued, since that with double flowers is become common.

The third, fourth, fifth, sixth, and seventh sorts, may also have a place in some large borders of the garden, for the variety of their flowers; which, though not so fair as those of the common sort, yet will add to the diversity; and as many of them are late flowerers, so by encouraging these plants we may continue the succession of flowers longer.

These sorts are all of them very hardy, and will grow in almost any soil or situation; they are propagated by parting their roots into small heads, which in one year's time will spread and increase greatly. The best season for this work is in the middle of *October*, soon after the flowers are past, or very early in the spring, that they may be well rooted before the droughts come on; otherwise their flowers will be few in number, and not near so fair.

The *Jerusalem Artichoke* is propagated in many gardens for the roots, which are by some people esteemed; but they are watery and flashy, and very subject to trouble the belly by their windy quality, which hath brought them almost into disuse.

These are propagated by planting the smaller roots, or the larger ones cut into pieces, observing to preserve a bud to each separate piece, either in the spring or autumn, allowing them a good distance, for their roots will greatly multiply; the autumn following when their stems decay, the roots may be taken up for use. These should be planted in some remote corner of the garden, for they are very unsightly while growing, and their roots are apt to over-run whatever grows near them, nor can they be easily destroyed when they are once well fixed in a garden.

The other species which have been ranged under this genus by *Tournefort* and others, are now removed to the following genera, under which titles they may be found:

Corona Solis. See { Coreopsis.
Helenium.
Rudbeckia.
Silphium.

HELICTERES. *Lin. Gen. Plant.* 913. Screw tree.

The Characters are,

The flower has a coriaceous empalement of one leaf. It hath five oblong equal petals, which are fixed to the empalement, and ten short stamina at the base of the germen, with five nectariums surrounding the germen, which have the appearance of petals. The style supports the germen at the top, which afterward turns to a twisted spiral fruit with one cell, inclosing many kidney-shaped seeds.

The Species are,

1. HELICTERES *foliis cordato-ovatis serratis, subtus tomentosis, fructu tereti contorto.* Helicteres with oval heart-shaped leaves which are sawed, woolly on their under side, and a taper twisted fruit,

2. HELICTERES *foliis cordatis acuminatis serratis, subtus tomentosis, fructu brevi contorto.* Helicteres with heart-shaped, pointed, sawed leaves, woolly on their under side, and a short twisted fruit.

3. HELICTERES *caule arboreo villoso, foliis cordatis crenatis nervosis subtus tomentosis fructu ovato contorto villosissimo.* Helicteres with a tree-like hairy stalk, heart-shaped, nervous, crenated leaves, woolly on their under side, and an oval, twisted, very hairy fruit.

The first sort grows naturally in the *Babama* islands. This rises with a shrubby stalk five or six feet high, sending out several lateral branches, covered with a soft yellowish down, and garnished with heart-shaped leaves four inches long, and two inches and a half broad, sawed on their edges, woolly on their under side, standing on long foot-stalks; at the upper part of the branches the flowers come out opposite to the leaves, upon slender foot-stalks, which are jointed; these are composed of five oblong white petals, and in the center arises the style, which is three inches long, and curved; upon the top of which is situated the germen, crowned by an acute stigma. The germen afterward turns to a taper fruit two inches and a half long, composed of five capsules, which are closely twisted over each other like a screw; these are hairy, and have each one cell, containing several kidney-shaped seeds.

The second sort grows naturally in *Jamaita*. This rises with a shrubby stalk nine or ten feet high, sending out many lateral branches, covered with a smooth brown bark, garnished with heart-shaped sawed leaves, which end in acute points, woolly on their under side; the flowers are produced on the side of the branches, on shorter foot-stalks than the former: they are composed of five petals, the style in the center is strait, upright, and not half so long as in the other; the fruit is thicker, not an inch long, but twisted in the same manner.

The third sort rises with a strong woody stalk twelve or fourteen feet high, sending out many ligneous branches, closely covered with hairy down, and garnished with large heart-shaped leaves, which are crenated on their edges, having large veins running from the midrib to the sides; the leaves are of a yellowish green, and a little woolly on their under side: the flowers are produced from the side of the branches, and are of a yellowish white colour, larger than those of the other sorts. The style is near four inches long, curved like that of the first sort; the fruit is oval, about one inch long, very thick at the bottom, and closely covered with hairy down. This sort grows naturally at *Carthagena*.

These plants are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are strong enough to remove, they should be each planted in a separate small pot, and plunged into a moderate hot-

bed of tan, observing to shade them from the sun till they have taken new root; then they should be treated in the same way as other tender plants from hot countries, raising the glasses every day in proportion to the weather, that the plants may enjoy fresh air, which will strengthen them, and prevent their drawing up weak. In the summer the plants may remain under the frames, if there is a sufficient height for them to grow; but in autumn they must be plunged into the tan-bed in the stove, where they should always remain, being careful to shift them into larger pots when they require it, and not to give them too much wet in winter; in summer they should have a large share of air in warm weather, and require to be often refreshed with water: the second year from the seeds these plants have often flowered in the *Chelsea* garden, and the seeds have some years ripened there, but the plants will live several years with proper management.

HELIOCARPOS. *Lin. Gen. Plant.* 533.

The Characters are,

The flower hath one petal which is cut into five segments. It hath an empalement of one leaf, which is cut into five parts. In the center is situated a roundish germen, attended by several stamina, which afterward becomes an oval compressed capsule, about three lines long and two broad, with a transverse partition dividing it in two cells, each containing a single roundish seed ending in a point; the borders of the capsule are set with hairs, resembling rays.

We know but one Species of this plant, viz.

HELIOCARPOS. *Hort Cliff.* 211. *tab.* 16.

This plant was discovered by the late Dr. *Houssoun*, growing naturally about *Old Le Vera Cruz* in *New Spain*. It rises with a thick, soft, woody stalk, from fifteen to eighteen feet high, sending out several lateral branches toward the top, garnished with heart-shaped leaves full of veins, sawed on their edges and ending in acute points; the flowers are produced at the end of the shoots, in branching clusters; they are of a yellowish green, and are succeeded by flat compressed seed vessels of an oval shape, whose borders are closely set with threads, representing rays, of a brownish colour when ripe; these capsules are divided into two cells by an intermediate partition, in each of these is lodged a single roundish seed ending in a point.

The plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a hot-bed, treating them in the same way as other tender plants. While the plants are young, they require to be plunged in the tan-bed, but after they have acquired strength, they will thrive in the dry stove: in winter they should have but little water, and must be kept warm; but in summer they should have plenty of fresh air in mild weather, and must be frequently refreshed with water. With this management the plants will flower the third year, and produce good seeds, but may be preserved several years with proper care.

I have sowed seeds of this plant which had been kept ten years, and came up as well as if it had been sowed the former year; though from the appearance of the seeds, it seems as unlike to grow after the first year as any which I know.

HELIOTROPIUM. *Lin. Gen. Plant.* 164. Turnsole.

The Characters are,

The empalement of the flower is of one leaf, cut into five segments at the brim. The flower hath one petal with a tube the length of the empalement, cut into five parts, which are alternately larger than the other; the chaps of the tube is closed, and hath five prominent scales, joined in form of a star. It hath five short stamina and four germen at the bottom of the tube, which afterward becomes so many seeds, sitting in the empalement.

The Species are,

1. *HELIOTROPIUM foliis ovatis integerrimis tomentosus rugosis, spicis conjugatis.* Hort. Upsal. 33. Heliotrope with oval, entire, woolly, rough leaves, and conjugated spikes.

2. *HELIOTROPIUM foliis cordato-ovatis acutis scabrisculis, spicis solitariis, fructibus bifidis.* Flor. Zeyl. 70. Heliotrope with heart-shaped oval leaves which are pointed, rough single spikes of flowers, and bifid seeds.

3. *HELIOTROPIUM foliis ovato-lanceolato-acuminatis rugosis, spicis solitariis gracilioribus alaribus & terminalibus.* Heliotrope with spear-shaped oval leaves, which end in acute points, and a rough, slender, single spike of flowers proceeding from the sides and tops of the stalks.

4. *HELIOTROPIUM foliis oblongo-ovatis integerrimis glabris subtus incanis, floribus capitatis alaribus, caule arborecente.* Heliotrope with oblong, oval, entire, smooth leaves, which are hoary on their under side, flowers growing in heads from the wings of the stalks, and a tree like stalk.

5. *HELIOTROPIUM foliis ovatis crenatis oppositis, floribus capitatis alaribus dichotomis, caule arborecente.* Heliotrope with oval crenated leaves placed opposite, flowers growing in heads from the wings of the stalks, which diverge, and a tree-like stalk.

6. *HELIOTROPIUM foliis ovato-lanceolatis, spicis plurimis confertis, caule fruticoso.* Heliotrope with oval spear-shaped leaves, many spikes of flowers growing in clusters, and a shrubby stalk.

7. *HELIOTROPIUM foliis lanceolato linearibus glabris aveniis, spicis conjugatis.* Hort. Cliff. 45. Heliotrope with narrow, spear-shaped, smooth leaves without veins, and conjugated spikes of flowers.

8. *HELIOTROPIUM foliis lineari-lanceolatis obtusis tomentosus, floribus alaribus sessilibus, caule arboreo.* Heliotrope with narrow, obtuse, spear-shaped, woolly leaves, flowers sitting close to the side of the branches, and a tree-like stalk.

9. *HELIOTROPIUM foliis lanceolatis sessilibus, spicis solitariis alaribus & terminalibus, caule fruticoso.* Heliotrope with spear-shaped leaves sitting close to the branches, single spikes of flowers proceeding from the sides and tops of the stalk, which is shrubby.

10. *HELIOTROPIUM caule procumbente, foliis ovatis tomentosus integerrimis, spicis solitariis terminalibus.* Heliotrope with a trailing stalk, oval, woolly, entire leaves, and single spikes of flowers terminating the branches.

11. *HELIOTROPIUM foliis oblongo-ovatis tomentosus, spicis conjugatis terminalibus, caule fruticoso.* Heliotrope with oblong, oval, woolly leaves, and double spikes of flowers terminating the stalk, which is shrubby.

The first sort grows naturally in the south of France, in Spain, Italy, and most of the warmer countries in Europe. It is an annual plant, which succeeds better from seeds which scatter in the autumn, or if sown at that season, than in the spring; for when they are sown in the spring, they seldom come up the same year; but if the plant is once obtained, and the seeds suffered to shed, it will maintain itself without any trouble, requiring no other culture but to keep it clean from weeds, and thin the plants where they are too close.

This rises about seven or eight inches high, dividing into two or three branches, garnished with oval rough leaves, of a light green, standing upon pretty long foot-stalks alternately; the flowers are produced at the end of the branches in double spikes joined at the bottom, which are about an inch and a half long, turning backward like a scorpion's tail. The flowers are white, and appear in June and July; the seeds ripen in the autumn, soon after which the plant decays.

The second sort grows naturally in the West-Indies. This is annual, the stalk rises two feet high, branching out to-

ward the top; the leaves are rough and hairy, standing upon pretty long foot-stalks; the flowers are produced toward the end of the branches in single spikes, which are six inches long, turning backward at the top like the other species. The flowers are blue, and appear in July and August; the seeds ripen in September and October.

The third sort grows naturally in the West-Indies. This is a smaller plant than the former, seldom growing above a foot high; the leaves are one inch and a half long, and about half an inch broad; the spikes of flowers are very slender, and not more than two inches long; the flowers are small, and of a light blue colour. They appear at the same time with the former, and the seeds ripen in autumn.

The seeds of these two sorts must be sown on a hot-bed in the spring, and when the plants come up they must be transplanted on another hot bed to bring them forward, treating them in the same way as the Balsamine, and other tender annual plants; in June they may be taken up with balls of earth, and planted in the borders of the flower-garden, where they will flower and produce ripe seeds.

The fourth sort rises with a shrubby stalk six or seven feet high, the young branches are closely covered with a white down; the leaves on those are very hoary and entire, but those on the older branches are greener, and notched on their edges; at each joint of the stalks come out two short branches opposite, garnished with small hoary leaves placed opposite: these when bruised emit a strong odour, which to some persons is very disagreeable, but others are pleased with it. These plants rarely flower in England. The flowers are white, collected in roundish heads, which turn backward, and sit close to the branches; the leaves continue all the year, for which the plants are preserved in green-houses, to add to the variety in winter.

The fifth sort grows naturally in the Canary Islands. This rises with a woody stalk three or four feet high, dividing into many branches, garnished with oval hairy leaves, notched on their edges, growing opposite upon long foot-stalks, of an Ash-colour on their under side; the flowers are produced from the side of the branches on pretty long foot-stalks, each sustaining four short roundish spikes or heads, which divide by pairs, and spread from each other. The flowers are white, and appear in June and July, but are not succeeded by seeds in England. The leaves of this plant when bruised emit an agreeable odour, for which it is by some persons much esteemed; the gardeners have given it the title of Madam Maintenon.

The two last sorts are too tender to live through the winter in the open air in this country, so must be kept in a green-house during that season, but they only require to be screened from frost, so may be placed with Myrtles, and the other hardy green-house plants, where they may have a large share of air in mild weather, and be treated in the same way; they are easily propagated by cuttings during any of the summer months, which, if planted in a shady border, and duly supplied with water, will take root in five or six weeks, then they may be potted and placed in a shady situation till they have taken new root, after which they may be treated as the old plants.

The sixth sort grows naturally in Peru, from whence the seeds were sent by the younger Jussieu to the royal garden at Paris, where the plants produced flowers and seeds; and from the curious garden of duke D'Ayen, at St. Germain, I was supplied with some of the seeds, which have succeeded in the Chelsea garden, where the plants have flowered and perfected their seeds for some years.

This rises with a shrubby stalk three or four feet high, dividing into many branches, garnished with oval, spear-shaped, hairy, rough leaves, set on without order on short

foot-stalks. The flowers are produced at the end of the branches, in short reflexed spikes growing in clusters. The foot-stalks divide into two or three, and these divide again into lefs, each sustaining a spike of bluish flowers, which have a strong sweet odour. The plants continue in flower great part of the year, and those flowers which come out in summer are succeeded by ripe seeds in autumn.

It may be propagated either by seeds or cuttings. The seeds should be sown upon a moderate hot-bed in the spring, and when the plants are fit to remove they should be transplanted into small pots, and plunged into a hot-bed, where they should be shaded till they have taken new root; then they should be inured to the open air by degrees, into which they should be removed in summer, placing them in a sheltered situation, and in autumn they must be housed with other exotick plants in a good green-house, where they will flower great part of winter, so will make a good appearance among the Orange trees, and other green-house plants, with whose culture this plant will thrive. If the cuttings of this plant are put into pots during any of the summer months, and plunged into a moderate hot-bed, they will take root very freely, but these do not make so good plants as those raised from seeds.

The seventh sort grows naturally on the sea-shore in the *West-Indies*. This is an annual plant, whose branches trail upon the ground, and grow a foot long, garnished with narrow grayish leaves, which are smooth. The flowers are produced in double spikes from the side of their branches; they are white and small, so make no great appearance. It is propagated by seeds, and requires the same treatment as the second and third sorts.

The eighth sort rises with an upright woody stalk six or seven feet high, with a hoary bark full of marks where the leaves have grown; the upper part of the stalk divides into two or three strong woody branches, which grow erect, and are very closely garnished with long, narrow, woolly leaves, which stand on every side the branches without order. The flowers come out from the side of the stalks, to which they fit close; they are short and reflexed, like those of the other species: the flowers are purple, sitting in very woolly empalements, which are divided into five parts; the whole plant is very white and woolly, like the sea Cudweed, so makes an odd appearance. This is propagated by seeds, which must be procured from the places where it naturally grows, and should be sown in a tub of earth in the country; for when the dried seeds come over they seldom grow, and if they do it is not before the second year; so that if the seeds are sown as soon as they are ripe in a tub of earth to preserve them, when they arrive in *England*, the tub should be plunged into a hot-bed of tanners bark, which will bring up the plants; and when these are fit to remove they should be each planted in a separate small pot filled with earth, composed of sand and light undunged earth, with a little lime rubbish well mixed together, then plunged into a hot-bed of tanners bark, and shaded until they have taken new root, after which they must be treated as other tender exotick plants, always keeping them in the tan-bed in the stove, giving them but little water, especially during the winter season.

The ninth sort is a native of the *West-Indies*, where it grows plentifully on the sea-shore; it rises with an upright shrubby stalk a foot and a half high, garnished with small spear-shaped leaves, scarce one inch long, and one third of an inch broad in the middle, ending in acute points, sitting close to the stalk; they are hoary on their under side, but smooth above. The flowers are produced in single slender spikes, which come out from the side, and at the top of the stalks; they are but little recurved, especially those on the side, but those at top are more bent; they are white, so make but little appearance.

The tenth sort was sent me from *Cartbagena* in *New Spain*, where it grows naturally on the sandy shores. This is an annual plant with trailing stalks, which grow six or seven inches long, garnished with small oval leaves, which are woolly and entire. The flowers are produced at the end of the branches in single short spikes, which are reflexed; they are small and white, so make little appearance.

The eleventh sort was sent me by the late Dr. *Houfoun*, from *La Vera Cruz*, where he found it growing in plenty. This rises with a shrubby stalk three feet high, dividing into slender branches, which are closely garnished with oblong, oval, woolly leaves, placed without order. The flowers are produced at the end of the branches in double spikes, which are slender, short, and strait, not recurved as the other species. The flowers are small, white, and the plant is perennial.

These three last mentioned are propagated by seeds, but the difficulty of getting them fresh from *America*, and the uncertainty of their growing, unless they are sown abroad, and brought over in earth, has rendered them rare in *Europe*, and as they are plants of little beauty, so few persons have taken the trouble to procure them; besides, as they require a stove to preserve them in this country, and must have a peculiar soil and management like the eighth sort, so, unless for the sake of variety in botanick gardens, they are not worth cultivating here.

HELLEBORE. See Helleborus.

HELLEBORINE. See Serapias and Limadorum.

HELLEBOROIDES HYEMALIS. See Helleborus.

HELLEBORO RANUNCULUS. See Trollius.

HELLEBORUS. *Lin. Gen. Plant.* 622. Black Hellebore, or *Christmas Flower*.

The Characters are,

The flower hath no empalement; it hath five large, roundish, permanent petals, and many small nectaria, placed circularly. It hath a great number of stamina, and several compressed germen, which afterwards turn to compressed capsules with two keels, the lower being short, and the upper convex, filled with round seeds adhering to the seam.

The Species are,

1. HELLEBORUS caule multifloro folioso, foliis pedatis. *Lin. Sp. Plant.* 588. Hellebore with many flowers on a stalk, which are intermixed with leaves, and ramose leaves sitting on the foot-stalk; Bears Foot, or Setterwort.

2. HELLEBORUS caule multifloro folioso, foliis digitatis. *Lin. Sp. Plant.* 558. Hellebore with many flowers on a stalk, which are intermixed with leaves, and fingered leaves.

3. HELLEBORUS scapo sub-unifloro sub-nudo, foliis pedatis. *Hort. Upsal.* 157. Hellebore with one flower on a stalk, which is naked, and hand-shaped leaves sitting on the foot-stalk; true Black Hellebore, or *Christmas Rose*.

4. HELLEBORUS caule multifloro, foliis ternatis integerrimis. Hellebore with many flowers on a stalk, and leaves composed of three entire lobes.

5. HELLEBORUS flore folio insidente. *Hort. Cliff.* 227. Hellebore with the flower sitting upon the leaf, or *Winter Aconite*.

6. HELLEBORUS caule multifloro folioso, foliis digitatis ferratis amplioribus. Hellebore with many flowers upon a stalk, intermixed with leaves, and large fingered leaves, which are sawed.

The first sort grows naturally in woods in several parts of *England*, but particularly in *Suffex*, where I have seen it in great plenty. This hath a jointed herbaceous stalk, which rises two feet high, dividing into two or three heads, garnished with leaves, composed of eight or nine long narrow lobes, which join at their base. These are sawed on their edges, and end in acute points; those on the lower part of the stalk are much larger than the upper, which are small and

and narrow. The flower-stalk arises from the center of the plant, dividing into many branches, each sustaining several smaller foot-stalks, with one entire spear-shaped leaf upon each, and one large greenish flower at the top with purplish rims; these appear in winter, and the seeds ripen in the spring, which, if permitted to scatter, the plants will rise without care, and may be transplanted into woods, or in wilderness quarters, where they will grow in great shade, and make a good appearance at a season when there are but few plants in beauty.

The second sort grows naturally at *Ditton*, near *Cambridge*, and in the woods near *Stoken Church*, in *Oxfordshire*. The stalks of this sort grow more upright than those of the first, and do not branch so much. The leaves are composed of nine long lobes, which unite to the foot-stalk at their base, and are sharply sawed on their edges; they are of a lighter green than those of the first sort. The flowers are produced at the top of the stalk; they are composed of five oval green petals, with a great number of stamina surrounding the germen, situated in the middle; these appear the beginning of *February*, and the seeds ripen the end of *May*, which if sown soon after they are ripe the plants will come up early the following spring, and when they have obtained strength may be planted in shady places under trees, where they will thrive and flower very well. The leaves of this sort decay in autumn, and new ones arise from the roots in the spring, but the first sort is always green.

The third sort is supposed to be the Hellebore of the ancients; this grows naturally on the *Alps* and *Apennine* mountains, and also in the *Archipelago*. The root of this sort is composed of many thick fleshy fibres, which spread far into the ground, from which arise the flowers upon naked foot-stalks immediately from the root, each supporting one large white flower, composed of five roundish petals, with a great number of stamina in the middle. The leaves of this are composed of seven or eight thick, fleshy, obtuse lobes, which are slightly sawed on their edges, and unite with the foot-stalk at their base; this plant flowers in winter, from whence the title of *Christmas Rose* was applied to it. This is propagated by parting of the roots in autumn, for the seeds seldom ripen well in *England*.

The fourth sort is like the second, but differs from it in having trifoliate leaves, which are broader. This flowers early in winter, and the stalks rise higher than either of the former sorts, but is at present rare in *England*.

The fifth sort is the common Winter Aconite, which is so well known as to need no description. It flowers very early in the spring, which renders it worthy of a place in all curious gardens, especially as it requires but little room. This is propagated by offsets, which the roots send out in plenty. These roots may be taken up and transplanted any time after their leaves decay, which is generally by the beginning of *June* till *October*, when they will begin to put out new fibres; but as the roots are small, and nearly of the colour of the ground, so if care is not taken to search them many of the roots will be left in the ground. These roots should be planted in small clusters, otherwise they will not make a good appearance; for single flowers scattered about the borders of these small kinds, are scarce seen at a distance; but when these and the *Snowdrops* are alternately planted in bunches, they will have a good effect, as they flower at the same time, and are much of a size.

The sixth sort is like the first, but the lobes of the leaves are broader, and the stalks grow taller. This grows naturally in *Isria* and *Dalmatia*, from whence I received some of the seeds; it has been supposed to be only a seminal variety of the first, and as such I sowed the seeds, but the plants had a very great appearance, and the first winter proving severe they were all destroyed, so that it is not so hardy as

our common sort, and depending on their being so, occasioned the loss of the plants.

HELLEBORUS ALBUS. See *Veratrum*.

HELMET FLOWER, or MONK'S HOOD. See *Aconitum*.

HEMEROCALLIS. *Lin. Gen. Plant.* 391. Lily Asphodel, or Day Lily.

The Characters are,

The flower has no empalement; in some species the flower is of one petal cut into six parts, in others it hath six petals. There are six awl-shaped declining stamina surrounding the style. The roundish furrowed germen is situated in the middle, which afterward becomes an oval three-cornered capsule with three lobes, opening with two valves, filled with roundish seeds.

The Species are,

1. HEMEROCALLIS scapo ramoso, corollis monopetalis. *Hort. Upsal.* 88. Day Lily with a branching stalk, and the flower of one petal.

2. HEMEROCALLIS scapo compresso corollis monopetalis campanulatis. Day Lily with a compressed stalk, and a bell-shaped flower of one petal.

3. HEMEROCALLIS scapo ramoso, corollis monopetalis staminibus longioribus. Day Lily with a branching stalk, flowers of one petal, and longer stamina.

4. HEMEROCALLIS scapo simplici, corollis hexapetalis campanulatis. *Hort. Cliff.* 128. Day Lily with an unbranched single stalk, and bell-shaped flowers with six petals, or *St. Bruno's Lily*.

The first sort grows naturally in *Hungary*, *Dalmatia*, and *Isria*, but has long been an inhabitant in the *English* gardens. This hath strong fibrous roots, to which hang knobs, or tubers, like those of the *Asphodel*, from which come out keel-shaped leaves a foot and a half long, with a rigid midrib, the two sides drawing inward, so as to form a sort of gutter on the upper side. The flower-stalks are naked, and rise a foot and a half high, having two or three longitudinal furrows; at the top they divide into three or four short foot-stalks, each sustaining one pretty large yellow flower shaped like a Lily, having but one petal with a short tube, spreading open at the brim, where it is divided into six parts: these have an agreeable scent, from whence some have given it the title of yellow *Tuberose*. It flowers in *June*, and the seeds ripen in *August*: this plant is easily propagated by offsets, which the roots send out in plenty, which may be taken off in autumn, that being the best season for transplanting of the roots, and planted in any situation, for they are extremely hardy, and will require no other culture but to keep them clean from weeds, and to allow them room, that their roots may spread: they may also be propagated by seeds, which, if sown in autumn, the plants will come up the following spring, and these will flower in two years; but if the seeds are not sown till spring, the plants will not come up till the year after.

The second sort grows naturally in *Siberia*. This hath roots like those of the former sort, but are smaller. The leaves are not near so long, nor more than half the breadth of the former, and of a dark green colour. The flower-stalk rises a foot high, is naked and compressed, but has no furrows; at the top is produced two or three yellow flowers, which are nearer the bell-shape than those of the other species, and stand on shorter foot-stalks. It is propagated by offsets from the root, or by seeds in the same manner as the former, but the roots do not increase so fast; it should have a moist soil and a shady situation, where it will thrive much better than in dry ground.

The third sort is a much larger plant than either of the former, the roots spread and increase much more, therefore is not proper furniture for small gardens. The leaves are near three feet long, hollowed like those of the former,

turning back toward the top. The flower-stalks are as thick as a man's finger, and rise near four feet high; they are naked, without joints, and branching at the top, where are several large copper-coloured flowers, shaped like those of the red Lily, and as large. The stamina of this sort are longer than those of the other, and their summits are charged with a copper-coloured farina, which sheds on being touched; or if a person smells to the flowers it will fly off and spread over the face, dying it all over of a copper colour, which is a trick often played by some unlucky people to the ignorant. These flowers never continue longer than one day, but there is a succession of flowers on the same plants for a fortnight or three weeks. The roots of this sort, propagate too fast for those gardens where there is but little room. It will grow on any soil or situation; the best time to transplant the roots is in autumn.

The *Savoy Spiderwort*, or, as the *French* call it, *St. Bruno's Lily*, is a plant of humbler growth than either of the former: there are two varieties of this, one is titled *Liliastrum Alpinum majus*, and the other *Liliastrum Alpinum minus*, by *Tournefort*; the first of these rises with a flower-stalk more than a foot and a half high. The flowers are much larger, and there is a greater number upon each stalk than of the second; but as there is no other essential difference between them, I have not put them down as different species, but the first is by much the finer plant, though not common in *England*. The leaves of this sort are somewhat like those of the Spiderwort, are pretty firm, and grow upright; the flower-stalks grow about a foot high, and have several white flowers at the top, shaped like those of the Lily, which hang on one side, and have an agreeable scent; these are but of short duration, seldom continuing in beauty above three or four days, but when the plants are strong they will produce eight or ten flowers upon each stalk, so they make a good appearance while they last.

These sorts are usually propagated by parting the roots; autumn is the best season for doing this work, as it also is for transplanting of the roots; for when they are removed in the spring, they seldom flower the same year; or, if they do, it is but weakly. These plants should not be transplanted oftener than every third year, when the roots may be parted to make an increase of the plants, but they should not be divided too small, for if they are it will be two years before they flower: they delight in a light loamy soil, and in an open exposure, so must not be planted under the drip of trees; but if they are planted to an east aspect, where they may be protected from the sun in the heat of the day, they will continue in beauty longer than when they are more exposed.

HEMIONITIS, Moonfern.

This is a plant which is seldom propagated in gardens, therefore I shall not trouble the reader with any account of it more than this, That whoever hath a mind to cultivate any of the sorts, must procure the plants from the countries where they naturally grow. There are two sorts which are natives of the warmer parts of *Europe*, but in *America* there is a great number of very different kinds; these must be planted in pots filled with loamy undunged earth, and such of them as are natives of hot countries must be placed in the stove, the others may be sheltered under a common frame in winter, and during the summer they must be frequently watered, but in winter they will require but little. In summer they should also have plenty of free air admitted to them; with this management the plants will thrive.

HEPATICA. *Boerb. Ind. Plant.* Hepatica, or Noble Liverwort.

The Characters are,

The flower hath a three leaved empalement. It hath six petals, which are oval, with a great number of slender stamina,

shorter than the petals, and several germen collected into a head, which afterward turn to acuminated seeds sitting round the styles.

The Varieties of this plant are,

1. HEPATICA trifolia, cœruleo flore. *Clus.* The single blue Hepatica, or Noble Liverwort.
2. HEPATICA trifolia, flore cœruleo pleno. *Clus.* The double blue Hepatica, or Noble Liverwort.
3. HEPATICA trifolia, flore albo simplici. *Boerb. Ind.* The single white Hepatica, or Noble Liverwort.
4. HEPATICA trifolia, rubro flore. *Clus.* Single red Hepatica, or Noble Liverwort.
5. HEPATICA trifolio, flore rubro pleno. *Boerb. Ind.* Double red, or Peach-coloured Hepatica.

These plants are some of the greatest beauties of the spring; their flowers are produced in *February* and *March* in great plenty, before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight longer in flower than the single, and the flowers are much fairer. I have seen the double white kind often mentioned in books, but could never see it growing, though I do not know but such a flower might be obtained from seeds of the single white, or blue kinds. I have sometimes known the double blue sort produce some flowers in autumn, which were inclining to white, and thereby some people have been deceived, who have procured the roots at that season, and planted them in their gardens, but the spring following their flowers were blue as before; and this is what frequently happens, when the autumn is so mild as to cause them to flower.

The single sorts produce seeds every year, whereby they are easily propagated, and also new flowers may be that way obtained. The best season for sowing of the seeds is in the beginning of *August*, either in pots or boxes of light earth, which should be placed so as to have only the morning sun until *October*, when they should be removed into the full sun, to remain during the winter season; but in *March*, when the young plants will begin to appear, they must be removed again to a shady situation, and in dry weather should be frequently watered; about the beginning of *August* they will be fit to be transplanted, at which time you should prepare a border, facing the east, of good fresh loamy earth, into which you should remove the plants, placing them at about six inches distance each way, closing the earth pretty fast to their roots, to prevent the worms from drawing them out of the ground, which they are very apt to do at that season; the spring following they will begin to shew their flowers, but it will be three years before they flower strong; till then you cannot judge of their goodness, when, if you find any double flowers, or any of a different colour from the common sorts, they should be taken up and transplanted into the borders of the flower-garden, where they should continue at least two years before they are taken up or parted; for it is remarkable in this plant, that where they are often removed and parted, they are very subject to die; whereas, when they are permitted to remain undisturbed for many years, they will thrive exceedingly, and become very large roots.

The double flowers, which never produce seeds, are propagated by parting their roots, which should be done in *March*, at the time when they are in flower; but you should be careful not to separate them into very small heads, nor should they be parted oftener than every third or fourth year, if you intend to have them thrive, for the reason before given. They delight in a loamy soil, and in an eastern position, where they may have only the morning sun.

HEPATORIUM. See Eupatorium.

HEPTAPHYLLUM. See Potentilla.

HERACLEUM. See *Spondylium and Panax*.

HERBA GERARDI. See *Angelica sylvestris minor*.

HERBA PARIS. See *Paris*.

HERMANNIA. *Tourn. Inst. R. H. 656. tab. 432.*

The Characters are,

The flower hath a pitcher shaped permanent empalement. It hath five petals, which twist against the sun within the tubulous empalement, but spread open above. It hath five broad stamina, joined in one body. In the center is situated a roundish five-cornered germen, which afterward becomes a five-cornered roundish capsule, with five cells opening at the top, inclosing many seeds.

The Species are,

1. HERMANNIA *foliis cuneiformibus plicatis, crenato-emarginatis. Hort. Cliff. 342.* Hermannia with wedge-shaped folded leaves, which are crenated and indented.

2. HERMANNIA *foliis obovatis acutè incis, pedunculis bifloris. Prod. Leyd. 347.* Hermannia with oval leaves acutely cut, and foot-stalks having two flowers.

3. HERMANNIA *foliis obovatis plicatis crenatis tomentosis. Hort. Cliff. 343.* Hermannia with oval, folded, woolly leaves, which are crenated.

4. HERMANNIA *foliis lanceolatis obtusis serratis. Hort. Cliff. 342.* Hermannia with obtuse spear-shaped leaves, which are sawed.

5. HERMANNIA *foliis oblongo-ovatis crenatis tomentosis flore mutabili.* Hermannia with oblong, oval, crenated, woolly leaves, and a changeable flower.

6. HERMANNIA *foliis pinnatifidis linearibus. Hort. Cliff. 342.* Hermannia with narrow leaves ending in many points.

7. HERMANNIA *foliis lanceolatis obtusis integerrimis. Hort. Cliff. 342.* Hermannia with obtuse spear-shaped leaves, which are entire.

The first sort rises with a shrubby stalk six or seven feet high, dividing into many irregular branches, covered with a brown bark, garnished with wedge-shaped leaves, which are narrow at their base, but broad and round at the top. The flowers are produced in short spikes on the upper part of the branches, of a deep colour, but small; these appear in *April* and *May*, but are rarely succeeded by seeds in *England*.

The second sort is a shrub of lower stature than the first, but sends out a great number of branches, garnished with smaller leaves than those of the former, which are rough, and sit close to the branches. The flowers are produced in short close spikes at the end of every shoot, so that the whole shrub seems covered with flowers; they are of a bright yellow, and appear toward the end of *April*, but are not succeeded by seeds in *England*.

The third sort is a plant of humbler growth than the former, seldom rising more than two feet and a half high; the stem is not so woody, and the branches are soft and slender, garnished with oval woolly leaves which are plaited, and crenated on the edges; the flowers are produced in loose panicles at the end of the branches; they are larger than those of the other species, and have very hairy empalements. This sort flowers in *June* and *July*.

The fourth sort has been longer in the *European* gardens, than either of the other. This rises with a shrubby upright stalk to the height of seven or eight feet, sending out many ligneous branches from the side, which also grow more erect than any of the other; these are clothed with obtuse spear-shaped leaves, sawed on the edges toward the end; the flowers come out in small bunches from the side of the stalk: they are of a pale straw colour, and appear in *May* and *June*; these are frequently succeeded by seeds, which ripen the latter end of *August*.

The fifth sort seldom rises more than two feet high, with

a soft ligneous stalk, sending out slender irregular branches, garnished with oblong, oval, woolly leaves, standing upon pretty long foot-stalks; the flowers are produced in loose spikes at the end of the branches; these are at their first appearance of a gold colour, but after they have been some days open they change to yellow. This flowers in *June* and *July*.

The sixth sort rises with a shrubby stalk near three feet high, sending out many slender branches, covered with a reddish bark, garnished with narrow wing-pointed leaves; the flowers come out from the side of the branches in small clusters; they are small, and of a deep yellow colour.

The seventh sort hath shrubby branching stalks, which are very bushy, but seldom rise more than a foot and a half high; the branches are very slender, garnished with hairy, pale, green leaves of different sizes; they are entire, and sit pretty close to the branches; the flowers come out from the side of the stalk singly; they are small, and of a deep yellow colour. This sort flowers most part of summer.

All the species of this genus yet known, are natives of the country about the *Cape of Good Hope*.

The plants are generally propagated by cuttings, which may be planted in any of the summer months, on a shady border, observing to water them until they are well rooted, which will be in about six weeks after planting; then they should be taken up, preserving a ball of earth to their roots, and planted into pots, placing them in a shady situation, until they have taken fresh root; after which they may be exposed to the open air, with *Myrtles*, *Geraniums*, &c. until the middle or latter end of *October*, when they must be removed into the green-house, observing to place them in the coolest part of the house, where they may have as much free air as possible; for if they are too much drawn in the house, they will appear sickly, and seldom produce many flowers; whereas, when they are only sheltered from the frost, and have a great share of free air, they will appear strong, healthy, and produce large quantities of flowers: they must be frequently watered, and will require to be new potted at least twice every year, otherwise their roots will be so matted as to prevent their growth.

HERMODACTYLUS, the *Hermodyl*, commonly called *Snakes-head Iris*.

This genus is, by *Dr. Linnæus*, joined to *Iris*, the characters of the flower agreeing pretty well with those of that genus, from which *Tournefort* has separated it by the difference of the root. As this plant requires a particular treatment, so I have continued it under *Tournefort's* title.

The Characters are,

It hath a *Lily-shaped* flower, consisting of one leaf, shaped exactly like an *Iris*, but has a tuberous root, divided into two or three dugs, like oblong bulbs.

We have but one Species of this plant, viz.

HERMODACTYLUS *folio quadrangulo. C. B. P.* This is also called, *Iris tuberosa Belgarum, i. e. Tuberous Iris of the Dutch*.

This plant is easily propagated by its tubers, which should be taken off soon after the green leaves decay, which is the proper season for transplanting the roots; but they should not be kept long out of the ground lest they shrink, which will cause them to rot when they are planted. They should have a loamy soil, not too strong, and must be planted to an east aspect, where they will flower very well. These roots should not be removed oftener than once in three years. The distance at which these roots should be planted is six inches square, and four inches deep in the ground. These produce their flowers in *May*, and their seeds are ripe in *August*; but as they multiply pretty fast by their roots, few people are at the trouble of raising them

them from seeds; but those who have an inclination so to do, must treat them in the manner directed for the bulbous Irises.

The roots of this plant are very apt to run deep into the ground, and then they seldom produce flowers; and many times they shoot so deep as to be lost, especially where the soil is very light; therefore to prevent this, it will be proper to lay a thickness of rubbish under the border where these are planted, to hinder them from getting down. This should always be practised in light ground, but in strong land there will be no occasion to make use of this precaution, because they do not shoot downward so freely in that.

HERNANDIA. *Plum. Nov. Gen. 8. tab. 40.* Jack-in-a-box, *vulgò.*

The Characters are,

It hath male and female flowers on the same plant; the male flowers have a partial involucre, composed of four oval small leaves, which inclose three flowers; each of these has a proper bell-shaped empalement of one leaf; the petal is funnel-shaped, cut into six parts at the brim; it hath three short stamina inserted in the empalement. The female flowers are shaped like the male, but want stamina; they have a roundish germen. The empalement afterward becomes a large, swollen, oblong fruit, perforated at each end, inclosing one hard globular nut.

There is but one Species of this genus, *viz.*

HERNANDIA. *Hort. Cliff. 485. tab. 13.* commonly called in the *West-Indies*, Jack-in-a-box.

This plant is very common in *Jamaica, Barbadoes, St. Christopher's*, and many other islands in the *West-Indies*, where it is known by the name of Jack-in-a-box. The fruit of this plant when ripe is perforated, and the nut in the inside becomes hard; so that when the wind blows through the fruit, it makes a whistling noise, which may be heard at a distance; from whence, I suppose, the inhabitants gave this name to the plant. It grows in the gullies, where there are rills of water.

In *Europe* this plant is preserved in curious gardens, with other tender exotick plants. It is propagated by sowing the seeds on a hot-bed in the spring, and when the plants are two inches high they should be transplanted each into a separate pot, and plunged into the hot-bed again, observing to water and shade them until they have taken root; after which time they must have air admitted to them, in proportion to the warmth of the air, or the heat of the bed in which they are placed. As the plants advance, they should be removed into larger pots; but in doing this, care should be taken not to break the roots, as also to preserve a good ball of earth to them; the plants must be screened from the sun until they have taken new root. The best time to shift these plants is in *July*, that they may be well rooted before the cold approaches; they must be constantly kept in the bark-stove; in winter they should have a moderate share of heat, and in the summer they must have plenty of air in hot weather. With this management the plants will grow to the height of sixteen feet or more, and the leaves being very large, will make a beautiful appearance in the stove. It hath not as yet flowered in *England*.

HERNIARIA. *Tourn. Inst. R. H. 507. tab. 288.* Rupturewort.

The Characters are,

The flower hath a coloured empalement of one leaf. It hath five small stamina, situated in the divisions of the empalement, and five others which are barren, placed alternately between them. In the center is an oval germen, which afterward turns to a small capsule inclosed in the empalement, having one oval pointed seed.

The Species are,

1. HERNIARIA *glabra. J. B. 3. 378.* Smooth Rupturewort.

2. HERNIARIA *hirsuta. J. B. 3. 379.* Rough or hairy Rupturewort.

3. HERNIARIA *alfines folio. Tourn. Inst. 507.* Rupturewort with a Chickweed leaf.

4. HERNIARIA *caulibus fruticosis floribus quadrifidis. Lin. Syst.* Rupturewort with shrubby stalks, and four-pointed flowers.

The two first sorts grow naturally in *England*, but not very common; they are low trailing plants, their branches lying on the ground; they have leaves like the smaller Chickweed, the first is smooth, and those of the second are hairy; the flowers come out in clusters from the side of the stalks at the joints; they are small, of a yellowish green, so make no appearance.

The third sort is an annual plant, which grows naturally in *France* and *Italy*. This doth not spread so much as either of the other sorts, but the flowers and leaves are somewhat like the first, but larger.

The fourth sort hath shrubby stalks, which trail upon the ground, garnished with small hairy leaves like the second sort; the flowers are also very like, but are four-cornered.

These plants are seldom cultivated but in botanick gardens, for the sake of variety. The three first are annual plants, which do not continue longer than one year, so should be permitted to shed their seeds, whereby they are better preserved than if sown with art. The fourth sort is an abiding plant, which may be propagated by cuttings; but as they are plants of no beauty, they are rarely preserved in gardens.

HESPERIS. *Tourn. Inst. R. H. 222. tab. 108.* Dame's Violet, Rocket, or Queen's Gilliflower.

The Characters are,

The flower is composed of four oblong petals, in form of a cross. It hath six awl shaped stamina, two of which are much shorter than the other. It hath a honey gland situated between the two short stamina, and a four-cornered germen the length of the stamina, but no style. The germen afterward becomes a plain, long, compressed pod with two cells, divided by an intermediate partition, inclosing many oval compressed seeds.

The Species are,

1. HESPERIS *caule simplici erecto, foliis lanceolatis denticulatis, petalis emarginatis.* Dame's Violet with a single erect stalk, spear-shaped indented leaves, and the petals of the flower indented at the top.

2. HESPERIS *caule simplici erecto, foliis ovato-lanceolatis integerrimis, petalis integris.* Dame's Violet with a single upright stalk, oval, spear-shaped, entire leaves, and the petals of the flower entire.

3. HESPERIS *caule simplici erecto, foliis lanceolatis acutis serratis, petalis mucrone emarginatis.* Dame's Violet with a single upright stalk, spear-shaped, acute, sawed leaves, and the tips of the petals indented.

4. HESPERIS *caule hispido ramoso patente. Hort. Upsal. 187.* Dame's Violet with a prickly, branching, spreading stalk.

5. HESPERIS *caule erecto, ramoso, hirsuto, foliis oblongo-cordatis, acutis sessilibus denticulatis, petalis integris.* Dame's Violet with a hairy, erect, branching stalk, oblong, heart-shaped, pointed, indented leaves, sitting close to the stalk, and the petals of the flower entire.

6. HESPERIS *caule ramosissimo diffuso, foliis lineari-lanceolatis dentatis, siliquis apice truncatis.* Dame's Violet with a very branching diffused stalk, narrow, spear-shaped, indented leaves, and the points of the pods shaped like a truncheon.

7. HESPERIS *foliis dentato-pinnatifidis, caule hervi. Lin. Sp. Plant. 664.* Dame's Violet with wing-pointed indented leaves, and a smooth stalk.

8. HESPERIS *caule ramosissimo diffuso, foliis lanceolatis serratis scabris, siliquis sessilibus. Lin. Sp. Plant. 663.* Dame's

Violet with very branching diffused stalks, spear-shaped, rough, sawed leaves, and the pods fitting close to the stalks.

9. *HESPERIS caule erecto ramofo, foliis cordatis amplexicaulibus serratis villofis. Lin. Sp. Plant. 664.* Dame's Violet with an erect branching stalk, and hairy, sawed, heart-shaped leaves embracing the stalk.

10. *HESPERIS caule ramofo diffuso, fliquis teretibus. Hort. Upsal.* Dame's Violet with a diffused branching stalk, and taper pods.

The first fort grows naturally in *Italy*. This was formerly in greater plenty in the *English* gardens than at present, having been long neglected because the flowers were single, and made but little appearance; however, as the flowers have a very grateful scent, so the plant is worthy of a place in every good garden. This rises with an upright stalk two feet and a half high, garnished with spear-shaped leaves, which fit close to the stalk; they are slightly indented on their edges, and end in acute points: the flowers are produced in a loose thyrse on the top of the stalks, composed of four roundish petals, indented at their points, of a deep purple colour, and smell very sweet, especially in the evening or in cloudy weather. It flowers in *June*, and the seeds ripen the latter end of *August*. It is a biennial plant, so that young plants should be raised every year, to supply the place of those which decay: if the seeds are permitted to scatter, the plants will come up without trouble in the spring; and if the seeds are sown, it should be in the autumn; because those which are sown in the spring often fail if the season proves dry, or will remain a long time in the ground before they vegetate.

There is a variety of this with double flowers in some of the gardens in *France*, but that which we have in *England* is a variety of the third fort with unfavoury flowers.

The second fort has been generally supposed only a variety of the first, differing in the colour of the flower, but is certainly a distinct species; the leaves of this are not so long, but much broader than those of the first, and their borders are entire; the flowers are not quite so large, nor do they form so good spikes; they are white, and have not so fine a scent as the first. This is also a biennial plant, requiring the same treatment as the first.

The third fort grows naturally in *Hungary* and *Austria*. This rises with an upright stalk two feet high, garnished with spear-shaped leaves, ending in acute points, sharply indented on their edges, of a dark green, and fit close to the stalks; the flowers grow in loose spikes on the top of the stalks; in some they are white, in others purple, and sometimes both colours striped in the same flower; these have no odour, so are not deserving of a place in gardens, but may be propagated in the same manner as the two former.

From this fort the double white and purple Rockets have been accidentally obtained, which are much esteemed for the beauty of their flowers; and if they had the agreeable odour of the garden Rocket, they would be some of the best furniture for the borders of the flower-garden, but they are without scent; however, for the beauty of their flowers, they are by some greatly esteemed.

These plants with single flowers rarely survive the second year; nor will those with double flowers continue much longer, therefore young plants should be annually raised to supply the place of the old ones, otherwise there will soon be a want of them, which is what few persons are careful enough to observe, but thinking the roots to be perennial, trust to their putting out offsets, and finding them decay, are apt to think their soil very improper for them, and are at a loss to account for their decaying; whereas, when the plants have flowered, they have finished their period, and seldom continue to flower a second time from the same root;

though in poor land they will often put out a few weak offsets, which may flower again, but seldom so strong as the principal roots; therefore those who are desirous to propagate these plants, should do it in the following manner:

There should be some strong roots of each fort kept apart for this purpose, which should have their flower-stalks cut down soon after they come out, which should be planted in a gentle loamy soil, to an east exposure, where they may have only the morning sun, and covered with hand or bell-glasses, which should be put over them, after the cuttings have been well watered, and closely shut down, drawing the earth round the rim of the glasses to exclude the air; the glasses should be shaded with mats every day when the sun is hot. With this management the cuttings will put out roots in five or six weeks, and will begin to shoot above; then the glasses should be gently raised on one side to admit the air to them, and so gradually harden the plants to the open air, to prevent their drawing up weak. When these have made good roots, they should be carefully removed, and planted in an east border at about eight or nine inches asunder, observing to shade and water them until they have taken new root; after which they will require no other care, but to keep them clean from weeds till the autumn, when they may be transplanted into the borders of the pleasure-garden, where they are designed to flower.

The roots, whose stalks are thus cut down, will put out many heads or offsets, which may be divided when they have proper strength, and treated as the former; by this method, a supply of plants for the flower-garden may be always obtained.

These plants are very subject to canker and rot when they are planted in a light rich soil, but in strong ground I have seen them thrive and flower in the utmost perfection, where the stems of flowers have been as large, and the flowers as fair as the finest double Stock-gilliflowers. Their season of flowering is in *June*; I have frequently raised young plants from the stalks after the flowers have decayed, by cutting them in lengths, and planting them in the manner before directed; but these seldom make so good plants as the young cuttings, nor are they so certain to grow, therefore the other method is to be preferred.

The fourth fort grows naturally in *Hungary*. This is much cultivated in the gardens abroad, for the great fragrancy of its flowers, which in the evening is so strong, as to perfume the air to a great distance, especially where there are any number of the plants. The ladies in *Germany* are very fond of this plant, and during the season of their flowering, have the pots placed in their apartments every evening, that they may enjoy the fragrancy of their flowers; for they have but little beauty, being smaller than those of the garden Rocket, and of a pale colour, but the scent of their flowers is much preferable to them; though in the day time, if the weather is clear, they have very little odour; but when the sun leaves them, their fragrancy is expanded to a great distance. To this species it is supposed that the title of Dame's Violet was first applied.

This fort is very rarely seen in the *English* gardens: I suppose it has been neglected, because the flowers make no appearance. It is a biennial plant, like the garden Rocket, which is propagated by seeds in the same manner; but the plants are not quite so hardy, and are very subject to rot in winter, especially on a moist soil, or in rich land, where they are apt to grow very rank, so are soon injured by wet and cold in the winter; therefore the plants of this fort should be planted in a dry poor soil, and a warm situation; and if some of them are planted in pots to be placed under a common frame in winter, where they may be sheltered from hard rains and frost, and enjoy the free air at all times when the weather is mild, it will be a sure way to preserve them.

The leaves of this sort are much larger, of a paler green than those of the garden Rocket; the stalks are closely set with bristly hairs, the flowers grow in loose panicles at the top of the stalk, and appear about the same time with the garden Rocket.

The seeds of the fifth sort were sent me from *Germany* without any title, nor any account of the country from whence it came; but as it was sent with the seeds of some *Siberian* plants, I suppose this came from the same country. This is a biennial plant, which rises with a strong branching stalk three feet high, which is hairy, garnished with oblong heart-shaped leaves, ending in acute points, sitting close to the stalk, and are slightly indented on their edges; the upper part of the stalk divides into many branches, garnished with small leaves of the same shape with those below, and are terminated with loose panicles of single, large, purple flowers, of great fragrancly.

The sixth sort grows naturally in the warm parts of *Europe*. This is annual; the stalks rise about eight or nine inches high, branching out greatly on every side in a confused order, garnished with small, narrow, indented leaves, and are terminated by clusters of small yellow flowers, which make no appearance.

The seventh sort grows naturally in *Sicily*. This is an annual plant, which seldom rises more than six inches high; the stalk branches toward the top into three or four smaller, which are terminated by small white flowers.

The eighth sort grows naturally in *Africa*. This is an annual plant, with a very branching stalk, which rises about nine inches high, garnished with rough spear-shaped leaves, sawed on their edges, terminated by loose panicles of small purple flowers, which appear in *June* and *July*, which are succeeded by long pods sitting close to the stalks, filled with small seeds, which ripen in *September*.

These three sorts are rarely cultivated, except in botanick gardens, for the sake of variety. If the seeds of these are permitted to scatter, the plants will come up without care, and only require to be kept clean from weeds; or they may be sown either in the spring or the autumn where they are to stand, for they do not bear transplanting well.

The ninth sort is an annual plant, which grows naturally in the south of *France*. This sends out several heart-shaped hairy leaves from the root, which spread on the ground; the stalk rises nine inches high, branching toward the top, garnished with leaves of the same shape, which embrace the stalks with their base; the flowers are produced in loose panicles at the end of the branches, of a lively purple colour. If these seeds are sown in the autumn, they succeed much better than in the spring.

The tenth sort is a native of the same country as the former. It is a biennial plant, which rises with a branching stalk about a foot high, garnished with narrow smooth leaves, ending in acute points, indented on their edges: the flowers are produced toward the end of the branches; they are small, and of a worn-out purple colour, so make but little appearance. This is propagated by seeds, in the same way as the first sort.

HEUCHERA. *Lin. Gen. Plant.* 283. Sanicle.

The Characters are,

The flower is composed of five narrow petals, which are inserted in the border of the empalement. It hath five stamina, which are much longer than the empalement, and a roundish bifid germen, which afterward turns to an oval-pointed capsule, with two horns, which are reflexed, having two cells filled with very small seeds.

We have but one Species of this genus, viz.

HEUCHERA. *Hort. Cliff.* 82. American Sanicle, with a dirty purple flower.

This plant grows naturally in *Virginia*. It hath a peren-

ennial root, which sends out many heart-shaped oval leaves, indented into four or five lobes, crenated on their edges, of a lucid green, and smooth; from between these come out the foot-stalks of the flower, which are naked, and rise a foot high, dividing at the top into a loose panicle, sustaining many small hairy flowers, of an obsolete purple colour. This flowers in *May*, and the seeds ripen in *August*.

It is propagated by parting of the roots in autumn, and should be planted in a shady situation; there is little beauty in this plant, but it is preserved for the sake of variety.

HIBISCUS. *Lin. Gen. Plant.* 756. Syrian Mallow.

The Characters are,

The flower hath a double permanent empalement; the outer hath eight or ten narrow leaves, the inner is of one leaf, cut at the brim into five acute points. It hath five heart-shaped petals, which join at their base into one; and many stamina, which are joined in form of a column, but expand toward the top. It has a round germen, which afterward turns to a capsule with five cells, opening in five parts, inclosing kidney-shaped seeds.

The Species are,

1. HIBISCUS foliis ovato-lanceolatis, supernè inciso-ferratis, caule arboreo. *Hort. Cliff.* 350. Hibiscus with oval spear-shaped leaves, whose upper parts are cut and sawed, and a tree-like stalk; commonly called *Althea frutex*.

2. HIBISCUS foliis cordato quinquangularis osoleto ferratis, caule arboreo. *Hort. Upsal.* 205. Hibiscus with heart shaped leaves, having five angles, which are bluntly sawed, and a tree-like stalk; commonly called *China Rose*.

3. HIBISCUS foliis subpeltato-cordatis septemangularibus, ferratis hispida Hort. Cliff. 349. Hibiscus with heart-shaped target leaves, having seven angles, which are sawed, and set with prickly hairs; commonly called *Musk*.

4. HIBISCUS foliis palmato digitatis quinquepartitis, laciniis supernè dentatis, caule lævi. Hibiscus with fingered leaves, which are divided into five parts, indented toward the top, and a smooth stalk.

5. HIBISCUS foliis cordatis angulatis serratis tomentosis, caule arboreo. Hibiscus with angular, heart-shaped, sawed, woolly leaves, and a tree-like stalk.

6. HIBISCUS foliis cordatis integerrimis. *Flor. Zeyl.* 258. Hibiscus with entire heart-shaped leaves.

7. HIBISCUS foliis ovatis acuminatis serratis glabris, caule arboreo. *Flor. Zeyl.* 260. Hibiscus with oval, pointed, sawed, smooth leaves, and a tree-like stalk.

8. HIBISCUS foliis serratis, inferioribus ovatis indivisis, superioribus quinquepartitis, caule aculeato. Hibiscus with sawed leaves, the lower oval and undivided, the upper divided into five parts, and a prickly stalk.

9. HIBISCUS foliis serratis, inferioribus cordatis, mediis tripartitis, summis quinquepartitis, caule aculeato. Hibiscus with sawed leaves, the lower ones being heart-shaped, the middle divided into three parts, the upper into five, and a prickly stalk.

10. HIBISCUS foliis quinquelobatis serratis, caule glabro. Hibiscus with sawed leaves divided into five lobes, and a smooth stalk.

11. HIBISCUS foliis quinquifido-palmatis, caule aculeato. *Hort. Cliff.* 498. Hibiscus with hand-shaped five-pointed leaves, and a prickly stalk.

12. HIBISCUS foliis quinquepartitis, lobis ovato-lanceolatis hirsutis crenatis, caule spinosissimo. Hibiscus with leaves divided into five lobes, which are oval, spear-shaped, hairy, and crenated, and a very prickly stalk.

13. HIBISCUS foliis cordatis hirsutis crenatis, floribus lateralibus, caule arboreo ramoso. Hibiscus with heart-shaped, hairy, crenated leaves, flowers growing from the sides of the branches, and a tree-like branching stalk.

14. HIBISCUS foliis oblongo-cordatis glabris, denticulatis, subtus incanis, floribus amplissimis. Hibiscus with oblong, heart-

heart-shaped, smooth, indented leaves, hoary on their under side, and very large flowers.

15. *HIBISCUS foliis quinquepartito pedatis, calycibus inferioribus latere rumpentibus. Lin. Sp. Plant. 696.* Hibiscus with leaves like a foot, divided into five parts, and the lower empalement torn sideways.

16. *HIBISCUS foliis inferioribus cordatis angulatis, superioribus subbasatis, floribus subnutantibus, pistillo cernuo. Lin. Sp. Plant. 697.* Hibiscus with lower leaves, heart-shaped and angular, the upper ones somewhat spear-shaped, nodding flowers, and a recurved pistil.

17. *HIBISCUS foliis ovatis acuminatis serratis, caule simplicissimo, petiolis floriferis. Hort. Upsal. 205.* Hibiscus with oval, pointed, sawed leaves, a single stalk, and flowering foot-stalks.

18. *HIBISCUS caule herbaceo simplicissimo, foliis ovatis subtrilobis, subtus tomentosus, floribus axillaribus. Lin. Sp. Plant. 693.* Hibiscus with a single herbaceous stalk, oval leaves, having three lobes, woolly on their under side.

19. *HIBISCUS foliis tripartitis incisus, calycibus inflatis. Hort. Upsal. 206.* Hibiscus with tripartite cut leaves, and a bladderly empalement.

20. *HIBISCUS foliis tripartitis dentatis, lobis angustioribus caule hirsuto calycibus inflatis.* Hibiscus with tripartite indented leaves, having narrower lobes, a hairy stalk, and bladderly empalements.

21. *HIBISCUS foliis inferioribus trilobis, summis quinquepartitis obtusis crenatis calycibus inflatis, caule hispido.* Hibiscus with under leaves having three lobes, the upper ones being cut into five obtuse segments, which are crenated, swollen empalements, and a prickly stalk.

22. *HIBISCUS foliis cordatis-crenatis, angulis lateralibus extimis parvis, caule arboreo. Hort. Cliff. 349.* Hibiscus with heart-shaped crenated leaves, whose outward lateral angles are small, and a tree-like stalk.

The first sort is commonly called *Althæa frutex* by nursery gardeners, who propagate the shrubs for sale; of this there are four or five varieties, which differ in the colour of their flowers; the most common hath pale purple flowers with dark bottoms, another hath bright purple flowers with black bottoms, a third hath white flowers with purple bottoms, a fourth variegated flowers with dark bottoms; there are also two with variegated leaves, which are by some much esteemed.

These shrubs grow naturally in *Syria*, they are great ornaments in the autumn season to a garden. They rise with shrubby stalks to the height of eight or ten feet, sending out many woody branches, covered with a smooth gray bark, garnished with oval spear-shaped leaves, whose upper parts are frequently divided into three lobes. The flowers come out from the wings of the stalks at every joint of the same year's shoot, they are large, and shaped like those of the Mallow, having five large roundish petals, which join at their base, but spread open at the top, in shape of an open bell; these appear in *August*, and, if the season is not too warm, there will be a succession of flowers part of *September*, and are succeeded by short capsules with five cells, filled with kidney-shaped seeds; but unless the season proves warm, they will not ripen in this country.

These plants are generally propagated by laying down the young branches in the spring, which in one year will take root, so may be cut off from the old plants, and planted in a nursery, at three feet distance row from row, and one foot asunder in the rows; where they may remain two or three years to get strength, and then may be transplanted to the places where they are to remain. But when good seeds can be procured, the plants which are raised from them, will grow larger and more upright than those which are propagated by layers. The several varieties may

be propagated by grafting upon each other, which is the common method of propagating the sorts with striped leaves.

The second sort grows naturally in *India*, from whence the *French* first carried the seeds to their settlements in the *West-Indies*, and the inhabitants of the *British* colonies have been supplied with the seeds from them, so have given it the title of *Martinico Rose*, of this there are the double and single flowering; the seeds of the double frequently produce plants with single flowers, but the seeds of the single seldom vary to the double. The flowers of these plants alter in their colour; at their first opening they are white, then they change to a blush Rose colour, and as they decay turn to a purple. In the *West-Indies*, all these alterations happen the same day, as I suppose the flowers in those hot countries are not of longer duration, but in *England*, where the flowers last longer in beauty, the changes are not so sudden.

This plant hath a soft spongy stem, which, by age, becomes ligneous and pithy. It rises to the height of twelve or fourteen feet, sending out branches toward the top, which are hairy, garnished with heart-shaped leaves, cut into five acute angles on their borders, and are slightly sawed on their edges, of a lucid green on their upper side, but pale below. The flowers are produced from the wings of the leaves; the single one is composed of five large petals, which spread open, and are first white, but afterward change in the manner before-mentioned; these are succeeded by short, thick, blunt capsules, which are very hairy, having five cells, which contain many small kidney-shaped seeds, having a fine plume of fibrous down adhering to them.

It is propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a moderate hot bed, where they must be shaded till they have taken new root; then they must be treated as other plants from warm countries, but not too tenderly, for these require a large share of air in warm weather, otherwise they will draw up very weak; they will bear the open air in summer, in a warm sheltered situation, and will live through the winter in a very good green-house, provided they have not too much wet, but the plants thus hardily treated, will not make so great progress, nor flower so well as with a little additional warmth in winter; and if they are too tenderly managed, they will draw up weak, so will be less likely to flower. This sort flowers at different times of the year, as in its native country.

The third sort grows naturally in the *West-Indies*, where it is commonly known by the title of *Musk*; the *French* cultivate great quantities of these plants in their *American* islands, the seeds of which are annually sent to *France*, so that they certainly have some way of rendering it useful, as it seems to be a considerable branch of their trade. This rises with an herbaceous stalk about three or four feet high, sending out two or three side branches, garnished with large leaves cut into six or seven angles, which are acute, sawed on their edges, have long foot-stalks, and are placed alternately. The stalks and leaves of this are very hairy. The flowers come out from the wings of the leaves upon pretty long foot-stalks, which stand erect; they are large, of a sulphur colour, with dark purple bottoms, and are succeeded by pyramidal five-cornered capsules, which open in five cells, filled with large kidney-shaped seeds of a very musky odour.

This sort seldom lives more than two years in *England*, but in its native country continues much longer. It is propagated by seeds, which, if sown on a good hot-bed in the spring, and the plants afterward planted in pots, and

plunged into a fresh hot-bed, treating them afterward in the same way as the *Amaranthus*, to bring them forward, they will flower in *July*, and their seeds will ripen in autumn.

The fourth sort grows naturally in both the *Indies*; this rises with an herbaceous smooth stalk three or four feet high, garnished with leaves divided into five segments, almost to the bottom, which are indented at their extremities, having long foot-stalks. The flowers are produced from the wings of the leaves toward the top, standing on short foot-stalks; they are composed of five large sulphur-coloured petals, which, when open, spread five inches wide, and have a dark purple bottom, with a column of stamina and styles rising in the center; they are succeeded by large, pyramidal, five-cornered seed vessels, opening in five cells, which are filled with pretty large kidney-shaped seeds, which have little smell or taste.

It is propagated by seeds in the same manner as the former sort, and if so managed, will produce flowers and perfect seeds the same season, but the plants may be continued through the winter in a moderate warmth.

The fifth sort grows naturally in the *West-Indies*, where it rises with a woody stalk seven or eight feet high, sending out many side branches toward the top, covered with a whitish bark, garnished with angular heart-shaped leaves, which are woolly. The flowers are produced from the wings of the leaves, upon long foot-stalks; they are composed of five roundish petals, which are joined at their base, of a yellow colour, turning to red as they decay; these are succeeded by large, obtuse, five-cornered, hairy seed vessels, which open in five cells filled with large kidney-shaped seeds.

This is propagated by seeds, which must be sown upon a hot-bed in the spring, and the plants afterward treated in the same way as the two last mentioned, during the first summer, but in autumn they must be plunged into the tan-bed in the stove, where they should constantly remain, and be treated in the same way as other tender plants from the same country; the second year the plants will flower, but they have not as yet perfected seeds in *England*.

The sixth sort grows naturally in both *Indies*; this rises with a woody pithy stem eight or ten feet high, dividing into several branches toward the top, which are covered with a woolly down, garnished with round heart-shaped leaves, ending in acute points; they are of a lucid green on their upper side, and hoary on their under, full of large veins, and are placed alternately on the stalks. The flowers are produced at the end of the branches, in loose spikes; they are of a whitish yellow colour, and are succeeded by short acuminate capsules, opening in five cells, filled with large kidney-shaped seeds.

This sort is propagated in the same way, and the plants require the same treatment as the fifth; they flower the second year, provided they are brought forward, otherwise they will not flower before the third or fourth season, but they will bear the open air in summer, in a warm situation, though they will not make great progress there.

The seventh sort grows naturally on the coast of *Malabar*; this rises with a woody stalk twelve or fourteen feet high, dividing into many small branches toward the top, garnished with oval sawed leaves, ending in acute points, of a lucid green above, but pale on their under side, placed without order. The flowers come out from the side of the branches, at the wings of the leaves, on pretty long foot stalks; they are composed of many oblong roundish petals of a red colour, which expand like the *Rose*, the flowers being as large when fully blown, as the common red *Rose*, and as double. This is a perennial plant, which is propagated by cuttings; the plants must constantly be kept in the tan-bed in the stove, giving them a large share of air in warm weather,

and but little water in winter. The flowers of these plants are used by the ladies in *India* to colour their hair and eyebrows black, and by the men to black their shoes. It is from this use called *Shoe-flower*.

The eighth sort is an annual plant, which rises with an upright stalk seven or eight feet high; the lower leaves are oval, serrated, and entire, but the upper leaves are divided almost to the foot-stalk, into five spear-shaped segments, like the fingers of a hand, standing on very long foot-stalks, having thorns at their base. The flowers come out from the wings of the stalks, they are large, of a pale sulphur colour, with a purple bottom, and are succeeded by oval, acuminate, prickly capsules, which open in five cells, filled with large kidney-shaped seeds.

This sort is propagated by seeds, which must be sown upon a hot-bed, and the plants treated in the same way as the third sort.

The ninth sort is near of kin to the eighth, but the stalks do not grow so tall, the lower leaves are heart-shaped and entire, the middle leaves are divided into three, and the upper into five segments, almost to the foot-stalks; they are sawed on their edges, and the stalk is prickly. The flowers come out from the wings of the stalks, they are of a very pale sulphur colour, with dark bottoms, but are not so large as those of the last.

This is propagated by seeds in the same way as the eighth, and the plants require the same treatment.

The bark of both these plants is full of strong fibres, which I have been informed the inhabitants of the *Malabar* coast prepare, and make into a strong cordage; and by what I have observed it may be wrought into fine strong thread of any size, if properly manufactured.

The tenth sort grows naturally in the *West-Indies*, where the inhabitants use the green pods to add an acid taste to their viands: there are two varieties of this, one with a light green, and the other a deep red pod, which always maintain their difference, but as there is no other difference but that of the colour of their pods, they do not deserve separate titles. This rises with an herbaceous stem about four feet high, sending out a few lateral branches, garnished with smooth leaves, divided into three or five lobes. The flowers come out from the side of the branches, they are of a dirty white, with dark purple bottoms, and are succeeded by obtuse seed vessels divided into five cells, which are filled with kidney-shaped seeds.

This sort is propagated in the same way as the third, and will flower and perfect seeds the same year, so is seldom preserved longer in *England*.

The eleventh sort is a native of *Ceylon*; this rises with an herbaceous stalk which is prickly, from two to three feet high, dividing upward into small branches, garnished with hand-shaped leaves, divided into five parts. The flowers come out from the wings of the leaves, they are small, white, with purple bottoms, and are succeeded by short obtuse capsules with five cells filled with kidney-shaped seeds.

This plant is annual, so must be treated in the same way as the third.

The twelfth sort is also annual with us; this rises with an herbaceous stalk three feet high, which hath prickly hairs, and divides into branches upwards, garnished with hand-shaped leaves, divided into five spear-shaped lobes, ending in acute points, crenated on their edges, standing upon very long foot stalks; the flowers come out from the wings of the leaves, they are very like those of the third, and the plants must be treated the same way.

The thirteenth sort grows naturally in the island of *Cuba*. This rises with a woody stalk twelve or fourteen feet high, sending out many lateral branches, garnished with hairy, heart-

heart-shaped leaves, crenated on their edges; the flowers come out single from the wings of the leaves; they are of a very bright yellow colour, but not so large as either of the former sorts, and are succeeded by short capsules ending in acute points, divided into five cells, which are filled with kidney-shaped seeds. This plant requires the same treatment as the fifth, and other tender kinds.

The fourteenth sort hath a perennial root, but an annual stalk. This rises with several stalks from the root, which grow four feet high, garnished with oblong, heart-shaped, smooth leaves, ending in acute points, of a light green on their upper side, but hoary on their under, and are slightly indented on their edges; the flowers are produced on the top of the stalks, they are very large, of a light purple colour with dark bottoms, and are succeeded by short capsules divided into five cells, filled with kidney-shaped seeds.

This is propagated by seeds, which must be sown on a moderate hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a separate pot, and plunged into a hot-bed, treating them in the same way as the other tender sorts, but allowing them a greater share of air in warm weather; those plants which flowered in the *Chelsea* garden, were plunged into a tan-bed whose heat was declining, under a deep frame, where they produced plenty of flowers, but they came too late to ripen seeds. The stalks decay in the autumn, but if the pots are sheltered from frost in winter under a hot-bed frame, they will continue several years, and put out new stalks in the spring.

The fifteenth sort is very common in the *West-Indies*, where the inhabitants cultivate it for the pods or seed-vessels, which they gather green to put into their soups; these, having a soft viscous juice, add a thickness to their soups, and renders them very palatable; it is called *Ocra*. It rises with a soft herbaceous stalk three or four feet high, dividing upward into many branches, garnished with hand-shaped leaves, divided into five parts; the flowers are produced from the wings of the stalk, they are of a pale sulphur colour, with dark purple bottoms, but are smaller than either of the other sorts, and of very short duration, opening in the morning with the rising sun, but fade long before noon in warm weather. These are succeeded by capsules of very different forms, in the different varieties; in some the capsules are not thicker than a man's finger, and five or six inches long; in others they are very thick, and not more than two or three inches long; in some plants they grow erect, in others they are rather reclined; and these varieties are constant, for I have many years cultivated these plants, and have not found them vary.

This sort is propagated by seeds in the same way as the third, and the plants require the same treatment, for they are too tender to thrive in the open air in this country; I have often transplanted the plants into warm borders, after they have acquired proper strength, and have sometimes in very warm seasons had them thrive for a short time, but the first cold bad weather their leaves have all dropped off, and then they have decayed gradually, so that they have but rarely flowered, and have never in the best seasons perfected their seeds in the open air; therefore those who are inclined to cultivate these plants, must constantly shelter them in bad weather.

The sixteenth sort grows naturally near *Venice*, in moist land. This hath a perennial root and an annual stalk, which rises three or four feet high; the lower leaves are angular and heart-shaped, but the upper are spear-shaped, and slightly indented on their edges; the flowers are produced from the wings of the leaves, upon long foot-stalks; they are of a purple colour, with a dark bottom, and are

succeeded by five-cornered compressed capsules, filled with kidney-shaped seeds.

This sort is propagated by seeds, which must be sown on a hot-bed, and the plants should be treated in the same way as the fourteenth sort, otherwise they will not flower; for although the roots will live in the full ground here, yet the summers are not warm enough to bring them to flower.

The seventeenth sort grows naturally in *North America*. This hath a perennial root and an annual stalk; the roots of this sort will live in the full ground, but unless the summer is warm, the flowers seldom open. It rises with single stalks from the root two or three feet high; the leaves are oval and sawed, the flowers are large and purple.

The eighteenth sort grows naturally in *North America*, in moist ground. This hath a perennial root and an annual stalk like the former, which is herbaceous and never branches; the leaves are oval, with three lobes which are not deeply divided: they are of a bright green on their upper side, but of an Ash colour on their under; the flowers are produced from the wings of the stalk; they are large, of a bright purple colour. This sort, like the former, seldom flowers in the open air here, unless the summer proves very warm; but the roots will live in the full ground, if they are planted in a sheltered situation.

The nineteenth sort is an annual plant, which grows naturally in some parts of *Italy*, and has been long cultivated in the *English* gardens by the title of *Venice Mallow*. *Gerard* and *Parkinson* title it *Alcea Veneta*, and *Flos Hora*, or Flower of an Hour, from the short duration of its flowers, which in hot weather continue but few hours open; however, there is a succession of flowers which open daily for a considerable time, so that a few of these plants may be allowed a place in every curious garden.

It rises with a branching stalk a foot and a half high; the leaves are divided into three lobes, which are deeply jagged almost to the midrib; these jags are opposite, and the segments are obtuse; the flowers come out at the joints of the stalks upon pretty long foot-stalks, having a double empalement, the outer being composed of ten long narrow leaves, which join at their base; the inner is of one thin leaf, swollen like a bladder, cut into five acute segments at the top, having many longitudinal purple ribs, and is hairy; both these are permanent, and inclose the capsule after the flower is past. The flower is composed of five obtuse petals, which spread open at the top, the lower part forming an open bell-shaped flower; these are of a sulphur colour, with dark purple bottoms, the stamina and apices are joined in a column; after the flower is past, the germen turns to a blunt capsule opening in five cells, which are filled with small kidney-shaped seeds. This sort is propagated by seeds, which should be sown where the plants are designed to remain. These require no other culture but to keep them clean from weeds, and thin them where they are too close; if the seeds are permitted to scatter, the plants will come up full as well as when sown, so that it will maintain its situation, unless it is weeded out.

The twentieth sort grows naturally at the *Cape of Good Hope*; this is also an annual plant which resembles the former, but the stalks grow more erect, are of a purplish colour; and very hairy; the leaves are composed of three narrow lobes, which are divided almost to the foot-stalk, the middle lobe stretching out more than twice the length of the two side ones; the flowers are larger and their colour deeper, than those of the other.

The twenty-first sort grows naturally at the *Cape of Good Hope*. This is an annual plant, having at first sight some resemblance of the sorts before-mentioned; but it has strong, hairy, branching stalks, garnished with much

broader leaves than either of the former, the lower being divided into three, and the upper into five obtuse lobes, which are crenated on their edges; the flowers are large, but of a paler colour than those of the other.

All these are as hardy as the nineteenth sort, so may be treated in the same way.

The twenty-second sort grows naturally at *Campeachy*; this differs so essentially from the other species in its fructification, as to deserve another title, for all the other have dry capsules with five cells, including many kidney-shaped seeds, but this hath a soft viscous berry, with a hard shell inclosed, containing five roundish seeds: it rises with a shrubby stalk ten or twelve feet high, dividing into many branches, garnished with smooth, heart-shaped, angular leaves, which are crenated on their edges; the flowers comes out from the wings of the stalks singly, standing on short foot-stalks; they are composed of five oblong petals, which are twisted together and never expand; they are of a fine scarlet, and are succeeded by roundish berries of a scarlet colour when ripe, inclosing a hard shell which opens in five cells, each containing a single roundish seed.

This sort is generally propagated here by cuttings, because the seeds do not often ripen in *England*; if the cuttings are planted in pots, and plunged into a gentle hot-bed, keeping the air from them, they will soon take root, and should be gradually inured to bear the open air. The plants require a moderate stove to preserve them through the winter, and if they are kept in warmth in summer, they will flower, and sometimes ripen fruit, though they may be placed abroad in a sheltered situation for two or three months in summer, but the plants so treated seldom flower.

HIERACIUM. *Lin. Gen. Plant.* 818. Hawkweed.

The Characters are,

It hath a flower composed of many hermaphrodite florets, included in one common scaly empalement; the florets are equal and uniform; they have one petal shaped like a tongue, indented in five parts at the point; they have each five short hairy stamina. At the bottom of the petal is situated the germen, which afterward becomes a short four-cornered seed crowned with down, sitting in the empalement.

There are a great number of species of this genus, many of which grow naturally as weeds in *England*, therefore I shall only select those which are best worth cultivating, for to enumerate all the species would swell this work greatly beyond its intended bulk.

1. HIERACIUM *foliis oblongo-ovatis dentatis tomentosis, caule erecto ramoso lanuginoso.* Hawkweed with oblong, oval, woolly, indented leaves, and an erect branching stalk covered with down; or Woolly Mountain Hawkweed.

2. HIERACIUM *caule ramoso, foliis radicalibus ovatis dentatis, caulino minori.* *Hort. Cliff.* 388. Hawkweed with a branching stalk, whose lower leaves are oval and indented, and those on the stalks smaller.

3. HIERACIUM *foliis integris, caule subnudo simplicissimo piloso corymbifero.* *Hort. Cliff.* 388. Hawkweed with entire leaves, and a single, hairy, naked stalk, terminated by a corymbus of flowers.

4. HIERACIUM *foliis radicalibus obovatis denticulatis, caulibus oblongis semiamplexicaulibus.* *Prod. Leyd.* 124. Hawkweed with oval indented leaves at the root, those on the stalks oblong, and half embracing them.

5. HIERACIUM *foliis lanceolatis amplexicaulibus dentatis, floribus solitariis, calycibus laxis.* *Hort. Cliff.* 387. Hawkweed with spear-shaped indented leaves embracing the stalks, flowers growing singly, and loose empalements.

6. HIERACIUM *foliis amplexicaulibus cordatis subdentatis, pedunculis unifloris hirsutis, caule ramoso.* *Hort. Cliff.* 387. Hawkweed with heart-shaped indented leaves embracing the stalks, hairy foot-stalks bearing one flower, and a branching stalk.

The first sort grows naturally on the *Appennine* mountains; this sends out from the root many oblong, oval, indented, woolly leaves; from between these arise a branching stalk, little more than a foot high, covered over with a woolly down, garnished with downy leaves of the same shape as the lower, but smaller, these fit very close to the stalks; the flowers are produced singly at the end of each branch, they are large, of a bright yellow, composed of many florets, which are succeeded by four-cornered, oblong, black seeds, crowned with a white down. The flowers appear by the beginning of *June*, and the seeds ripen in about five or six weeks after, but there is frequently a succession of flowers till the autumn.

It is propagated by seeds, which should be sown in an east aspected border in *March*; and when the plants are strong enough to remove, they should be transplanted to a shady border of undunged ground, at six inches distance, observing to water them if the weather should prove dry, till they have taken new root; after which, if they are kept clean from weeds, they will require no other culture: in the autumn they should be transplanted where they are designed to remain, the following summer they will flower and produce ripe seeds; the roots will continue two years if they are not planted in a rich or moist soil, which frequently occasions their rotting in winter.

The second sort hath very hairy, oval, indented leaves; the stalks rise about the same height as the former, branching into several divisions, which are each terminated by a large, single, yellow flower, of the shape of the former. This flowers in *June*, and the seeds ripen in *August*; it grows naturally in some places in the north of *England*; it is a perennial plant, and may be propagated in the same manner as the former sort.

The third sort grows naturally in *Syria*, but has been long an inhabitant of the *English* gardens, where it is cultivated for its fine purple flowers. This was formerly known by the title of Grim the Collier, which was probably given it from the dark colour of the empalement.

This hath a perennial fibrous root, which sends out many oblong, oval, entire leaves, between which arises a single stalk near a foot high, which is naked toward the bottom, and terminated by a corymbus of gold-coloured flowers, which appear in succession from the beginning of *June* to *September*, and are succeeded by seeds crowned with down, which ripen in *August* and *September*. This sort sends out many offsets from the root, by which it is easily propagated, or it may be raised from seeds in the same manner as the first sort: the best time to transplant them is the autumn. This will thrive in any soil or situation.

The fourth sort grows naturally on the *Pyrenean* mountains. It is a perennial plant, whose lower leaves are oval, indented, and of a grayish colour; those on the stalks are smaller, but of the same shape and colour, and half embrace the stalks with their base; the stalks rise a foot high, branching into several divisions, each being terminated by one young flower. This is propagated by seeds as the first sort.

The fifth sort also grows on the *Pyrenees*; this hath a perennial root, which sends up several erect stalks, garnished with spear-shaped leaves which are indented, and embrace the stalks with their base; the flowers are produced from the wings of the stalks, upon short foot-stalks, each sustaining one large yellow flower. This flowers in *June*, but seldom perfects seeds here, so is propagated by parting of the roots in autumn; it will thrive in any situation.

The sixth sort rises with a branching stalk a foot and a half high, garnished with heart-shaped leaves which are indented at their base, where they embrace the stalks; each division of the branches terminate in a hairy foot-stalk, sustaining

taining one large yellow flower, which appears in *May*, and the seeds ripen in *July*. This is a perennial plant, which is propagated by seeds as the first sort, and requires the same treatment.

HIPPOCASTANUM. See *Æsculus*.

HIPPOCRATEA. *Lin. Gen. Plant.* 1098.

The Characters are,

It hath a large spreading empalement of one leaf, cut into five segments; the flower hath one oval petal which is entire; it hath six slender short stamina, and an oval germen situated below the petal, which afterward becomes an oblong capsule winged at the top, inclosing a single seed.

We have but one Species of this genus, viz.

HIPPOCRATEA fructu trigemino subrotundo, caule volubili. Hippocratea with a triple roundish fruit, and a twining stalk.

The seeds of this plant were brought from *Campeachy*, and several of the plants were raised in *England*, which continued two years in several gardens, but none of them lived to flower; they grew to the height of eight or ten feet, twining round stakes, but their stalks are very slender, and decayed at the bottom, probably from their having too much wet.

It is a very tender plant, so must be constantly kept in the bark-bed in the stove, and should have but little wet in winter.

HIPPOCREPIS. *Lin. Gen. Plant.* 791. Horseshoe Vetch.

The Characters are,

The empalement of the flower is permanent, divided into five parts, the flower is of the butterfly kind; it hath ten stamina, nine joined and one separate, and an oblong narrow germen, sitting on an awl-shaped style, which afterward becomes a long, plain, compressed pod, cut into many parts from the under seam to the upper, each part forming a roundish sinus with obtuse three cornered joints, connected to the upper seam, each joint being shaped like a horseshoe, inclosing a single seed.

The Species are,

1. HIPPOCREPIS leguminibus sessilibus solitariis. *Hort. Cliff.* 364. Horseshoe Vetch, with single pods sitting close to the stalk.

2. HIPPOCREPIS leguminibus pedunculatis confertis, margine exteriore repandis. *Prod. Leyd.* 384. Horseshoe Vetch, with pods growing in clusters upon foot-stalks, whose outer border is turned inward.

3. HIPPOCREPIS leguminibus pedunculatis confertis, margine altero lobatis. *Hort. Cliff.* 364. Horseshoe Vetch, with pods growing in clusters upon foot-stalks, one border of which has lobes.

The first sort grows naturally in *Italy* and *Spain*; this is an annual plant, which sends from the root several trailing stalks a foot long, that divide upward into smaller branches, garnished with winged leaves, composed of four or five pair of small lobes, terminated by an odd one; these are obtuse, and indented at their ends; from the wings of the stalk come out single flowers of the butterfly kind, which are yellow, and are succeeded by single pods sitting close to the stalks, which are about two inches long, and a third of an inch broad, bending inward like a sickle, and divided into many joints shaped like a horseshoe: this flowers in *June* and *July*, and the seeds ripen in the autumn, soon after which the plants decay.

The second sort is found growing naturally in some parts of *England*, upon chalky hills; this is a smaller plant than the former, and hath a perennial root, sending out slender trailing stalks about ten inches long, which are garnished with narrow winged leaves; the flowers grow in clusters on the top of long foot-stalks, which are succeeded by shorter pods twisted inward in roundish curves, but have joints shaped like those of the former sort.

The third sort grows naturally in the south of *France*,

Germany, and *Italy*. This is an annual plant with trailing stalks, greatly resembling the first, but the flowers are produced in clusters on the top of pretty long foot-stalks; they are shaped like those of the other sorts, and the pods are jointed in like manner, but the joints are fixed to the opposite border. These plants flower in *June* and *July*, and the seeds ripen in *August* and *September*.

These are propagated by seeds, which should be sown in the autumn, where the plants are designed to remain; and when the plants come up, they must be kept clean from weeds, and thinned where they are too close, which is all the culture they require. The two annual sorts will decay in the autumn, after they have perfected their seeds, but the roots of the other will continue two or three years, provided they are not in too good ground.

HIPPOLAPATHUM. See *Rumex*.

HIPPOMANE. *Lin. Gen. Plant.* 1099. The Manchincel.

The Characters are,

It hath male and female flowers in the same spike; the male flowers come out in small clusters, from a short cup-shaped empalement, and have no petals; the female flowers have no petal, but an oval germen, which afterward becomes a roundish fruit with a fleshy cover, inclosing a rough hard shell with several cells, each inclosing one seed.

The Species are,

1. HIPPOMANE foliis ovatis serratis. *Hort. Cliff.* 484. Hippomane with oval sawed leaves.

2. HIPPOMANE foliis ovato-oblongis serratis, basi glandulosis. *Lin. Sp. Plant.* 1191. Hippomane with oval oblong leaves which are sawed, and have glands at their base.

3. HIPPOMANE foliis subovatis dentato-spinosis. *Lin. Sp. Plant.* 1191. Hippomane with oval leaves, which have prickly indentures.

The first sort grows naturally in most of the islands in the *West-Indies*; it is a very large tree in its native soil, almost equalling the Oak in size; the wood is much esteemed for making of cabinets, book-cases, &c. being very durable, and taking a fine polish; it is also said, that the worms will not eat it: but as the trees abound with a milky caustick juice, so before they are felled, they make fires round their trunks to burn out their juice, otherwise those who fell them, would be in danger of losing their sight, by the juice flying in their eyes; for where-ever this falls on the skin, it will raise blisters; and if it comes upon linen it will immediately turn it black, and on being washed will come in holes: it is also dangerous working of the wood after it is sawn out, for if any of the saw-dust happens to get into the workmens eyes, it causes inflammations, and the loss of sight for some time; to prevent which, they generally cover their faces with fine lawn, during the time they are working the wood.

This tree hath a smooth brownish bark, the trunk divides upward into many branches, garnished with oblong leaves, ending in acute points, slightly sawed on their edges, and are of a lucid green, standing on short foot-stalks. The flowers come out in short spikes at the end of the branches, being of both sexes in the same spike, but having no petals they make but little appearance; these are succeeded by fruit about the size and of the same shape as the Golden Pippin, turning of a yellow colour when ripe, which has often tempted strangers to eat of them to their cost, for they inflame the mouth and throat to a great degree, causing violent pains in the throat and stomach, which is dangerous, unless remedies are timely applied.

The inhabitants of *America* believe it is dangerous to sit or lie under these trees, and affirm, that the rain, or dew, which falls from the leaves, will raise blisters; but it is very certain, that unless the leaves are broken, and the juice of them mix with the rain, it will do no injury.

The second sort grows naturally at *Carthagen*, in *New-Spain*, and the third at *Campeachy*. The second sort grows to as large a size as the first; the leaves of this are much longer than those of the first, and have two small glandules growing at their base; they are sawed on their edges, and are of a lucid green.

The third sort is of humbler growth, seldom rising more than twenty feet high; the leaves of this greatly resemble those of the common Holly, and are set with sharp prickles at the end of each indenture; they are of a lucid green, and continue all the year.

These plants are preserved in some of the curious gardens in *Europe*, where they can never be expected to rise to any great height, for they are too tender to live in these northern countries, but in stoves; they rise easily from seeds, provided they are good. The seeds must be sown upon a good hot-bed, and when the plants come up, they should be each planted in a small separate pot, and plunged into a good bed of tanners bark, treating them in the same way as other tender plants, but they must not have much wet, for these plants abound with an acrid milky juice, and it is certain that such plants are soon killed by much moisture; these plants must be removed into the stove; and plunged into the tan-bed in autumn, where they should constantly remain, giving them very little water in winter; and in summer when the weather is warm, they should have a good share of air admitted to them, and gently refreshed with water.

HIPPOPHAE. *Lin. Gen. Plant.* 980. Sea Buckthorn.

The Characters are,

It is male and female in different plants; the male flowers have an empalement of one leaf, cut into two parts; they have no petals, but have four short stamina. The female flowers have no petals, but a one-leaved empalement, which is oval and bifid at the brim; these have no stamina, but in the center is situated a small roundish germen, which afterward turns to a globular berry with one cell, inclosing one roundish seed.

The Species are,

1. **HIPPOPHAE foliis lanceolatis.** *Lin. Sp. Plant.* 1023. Hippophae with spear-shaped leaves, or Sea Buckthorn with a Willow leaf.

2. **HIPPOPHAE foliis ovatis.** *Lin. Sp. Plant.* 1024. Hippophae with oval leaves, called *Canada* Sea Buckthorn.

The first sort grows naturally on the sea banks in *Lincolnshire*, and also on the sand banks between *Sandwich* and *Deal*, in *Kent*; there are two varieties of this, one with yellow, and the other with red fruit, but it is the first only which I have observed growing naturally in *England*, the other I saw growing on the sand banks in *Holland*.

These rise with shrubby stalks eight or ten feet high, sending out many irregular branches, which have a brown bark silvered over, garnished with very narrow spear-shaped leaves, of a dark green on their upper side, but hoary on their under, having a prominent midrib; the two borders of the leaves are reflexed like the *Rosemary*; the flowers come out from the side of the younger branches, to which they sit very close. The male flowers growing in small clusters, but the female come out singly; these make but little appearance. They appear in *July*, and the berries on the female plants are ripe in autumn.

This sort is easily propagated by suckers from the root, for the roots spread wide, and send up a great number of shoots, so as to form a thicket; if these are taken off in autumn, and transplanted into a nursery, they will be fit to transplant after one year's growth, to the places where they are to remain; as there is little beauty in this plant, so one or two of them may be allowed a place in a plantation of shrubs for the sake of variety.

The second sort grows naturally in *North America*; this hath much the appearance of the former sort, but the leaves

differ in their shape, these being much shorter and broader, and are not so white on their under side; this may be easily propagated by suckers or layers.

HIPPOSELINUM. See *Smyrnum*.

HIRUNDINARIA. See *Aclepias*.

HOLCUS. *Lin. Gen. Plant.* 1015. *Indian Millet*, or *Corn*.

The Characters are,

It hath male and hermaphrodite flowers on the same plant; the male flowers are small, and have a twisted bivalve chaff, ending with an acute beard; they have neither petals, or any proper empalement, but have three hairy stamina. The hermaphrodite flowers are single, sitting in a stiff bivalve chaff; they have three hairy stamina with a roundish germen, which afterward becomes an oval single seed wrapped up in the chaff.

The Species are,

1. **HOLCUS glumis villosis, seminibus aristatis.** *Hort. Upsal.* 301. Holcus with hairy chaff, and bearded seeds.

2. **HOLCUS glumis glabris, seminibus muticis.** *Lin. Sp. Plant.* 1047. Holcus with smooth husks, and seeds without awns.

There are several other of the grassy tribe which belong to this genus, but as they are not cultivated for use, so I shall not enumerate them here.

The two sorts here mentioned, grow naturally in *India*, where their grain is often used to feed poultry, and the seeds of these are frequently sent to *Europe* for the same purpose, but the summers are seldom warm enough to ripen the seeds in the open air in *England*. The stalks of these plants rise five or six feet high, with strong reedy stalks, like those of the *Maize*, or *Turkey Wheat*. The leaves are long and broad, having a deep furrow through the center of the leaf, where the midrib is depressed on the upper surface, and is very prominent below. The leaves are two feet and a half long, and three inches broad in the middle, embracing the stalks with their base. The flowers come out in large panicles at the top of the stalks, resembling, at first appearance, the male spikes of the *Turkey Wheat*; these are succeeded by roundish seeds, which are wrapped round with the chaff.

These plants are propagated in a few gardens for the sake of variety, but as they are late in ripening their grain here, so they are not worth cultivating for use. The seeds should be sown on a warm border the beginning of *April*, and when the plants come up, they should be thinned to the distance of a foot asunder in the rows, and the rows should be three feet distance; the culture after this, is to keep the ground clean from weeds, and draw the earth up with a hoe to the stems of the plants; if the season proves warm, their panicles will appear in *July*, and the grain will ripen in *September*, but in bad seasons their grain will not ripen here.

HOLLOW ROOT. See *Fumaria*.

HOLLY. See *Ilex*.

HOLLYHOCKS. See *Alcea*.

HONEYSUCKLE. See *Periclymenum*.

HOPS. See *Lupulus*.

HORDEUM. *Lin. Gen. Plant.* 94. *Barley*.

The Characters are,

It hath a partial involucre, which contains three flowers; the petal of the flower opens with two valves; the flower hath three hairy stamina shorter than the petal, and an oval turned germen, which afterward becomes an oblong bellied seed, pointed at both ends, having a longitudinal furrow, surrounded by the petal of the flower, which does not fall off.

The Species are,

1. **HORDEUM flosculis omnibus hermaphroditis aristatis ordinibus duobus erectioribus.** *Lin. Sp. Plant.* 84. Barley with all the flowers hermaphrodite, and two orders of beards, which are erect; or *Spring Barley*.

2. **HORDEUM flosculis lateralibus masculis muticis, seminibus angularibus imbricatis.** *Hort. Upsal.* 23. Barley with male flowers

flowers on the side, without awns, and angular seeds placed over each other; or common long-eared Barley.

3. *HORDEUM flosculus lateralibus masculis muticis, seminibus angularibus patentibus corticatis. Hort. Upsal. 23.* Barley with male flowers on the side, without awns, and angular spreading seeds with husks; commonly called Sprat, or Battledore Barley.

4. *HORDEUM flosculus omnibus hermaphroditis aristatis, seminibus sexfariam aequaliter positis. Hort. Upsal. 23.* Barley with all the flowers hermaphrodite and bearded, and six rows of seeds equally ranged; called Winter, or Square Barley, Bear Barley, or Big.

The first sort is the common Spring Barley, which is principally cultivated in *England*; of this the farmers make two sorts, *viz.* the common and Rath-ripe Barley, which are the same; for the Rath-ripe has only been an alteration occasioned by being long cultivated upon warm gravelly lands. The seeds of this, when sown in cold or strong land, will, the first year, ripen near a fortnight earlier than the seeds taken from strong land, therefore the farmers in the vales, generally purchase their seed Barley from the warm land, for if saved in the vales two or three years, it will become full as late in ripening as the common Barley of their own product, and the farmers on the warm land are also obliged to procure their seed Barley from the strong land, otherwise their grain would degenerate in bulk and fulness, which by thus changing is prevented. This sort of Barley is easily distinguished by the two orders of beards, or awns, which stand erect; the chaff is also thinner than that of the two last species, so is esteemed better for malting.

The second sort is the long-eared Barley, which is cultivated in many parts of *England*, and is an exceeding good sort, but some farmers object to this sort, because they say the ears being long and heavy, it is more apt to lodge; this hath the grains regularly ranged in a double row, lying over each other like tiles on a house, or the scales of fish. The husk, or chaff of this Barley is also very thin, so is much esteemed for malting.

The third sort is usually called Sprat Barley; this hath shorter and broader ears than either of the other sorts; the awns, or beards, are longer, and the grains are placed closer together, the awns being long, the birds cannot so easily get out the grains; this seldom grows so tall as the other species, the straw is shorter and coarser, so not very good fodder for cattle.

The fourth sort is rarely cultivated in the southern parts of *England*, but in the northern counties, and in *Scotland* is generally sown, being much hardier than the other species, so will bear the cold; this hath its grains disposed in six rows; the grain is large and plump, but is not so good for malting, which is the reason of its not being cultivated in the southern parts of *England*, where the other sorts which are much better for that purpose do thrive so well.

All the sorts of Barley are sown in the spring of the year, in a dry time; in some very dry light land it is sown early in *March*, but, in strong clayey soils, it is not sown till *April*, and sometimes not until the beginning of *May*; but when it is sown so late, if the season doth not prove very favourable, it is very late in autumn before it is fit to mow, unless it be the Rath-ripe sort, which is often ripe in nine weeks from the time of sowing.

Some people sow Barley upon land where Wheat grew the former year, but when this is practised, the ground should be ploughed the beginning of *October* in a dry time, laying it in small ridges, that the frost may mellow it the better, and this will improve the land greatly; and if this can be ploughed again in *January*, or the beginning of *February*, it will break and prepare the ground better; in *March* the ground should be ploughed again deeper, and laid even where it is not very wet; but in strong wet lands the ground

should be laid in round lands, and the furrows made deep to receive the wet. When this is finished, the common method is to sow the Barley seed with a broad cast at two sowings; the first being harrowed in once, the second is harrowed until the seed is buried; the common allowance of seed is four bushels to an acre.

This is the quantity of grain usually sown by the farmers, but if they could be prevailed on to alter this practice, they would soon find their account in it, for if a third of that quantity is sown, there will be a much greater produce, and the corn will be less liable to lodge, as I have many times experienced; for when corn or any other vegetable stands very close, the stalks are drawn up weak, so are incapable to resist the force of winds, or bear up under heavy rains; but when they are at a proper distance, their stalks will be more than twice the size of the other, so are seldom laid. I have frequently observed in fields where there has been a foot-path through their middle, that the corn which has stood thin on each side the path hath stood upright, when all the rest on both sides has been laid flat on the ground; and whoever will observe these roots of corn near the paths, will find them tiller out (*i. e.* have a greater number of stalks) to more than four times the quantity of the other parts of the field. I have seen experiments made by sowing Barley in rows a-crofs divers parts of the same field, and the grains sowed thin in the rows, so that the roots were three or four inches asunder in the rows, and the rows a foot distance; the intermediate spaces of the same field were at the same time sown broad cast in the usual way; the success was this, the roots which stood thin in the rows tillered out from ten or twelve, to upward of thirty stalks on each root, the stalks were stronger, the ears longer, and the grains larger than any of those sown in the common way; and when those parts of the field where the corn was sown in the usual way has been lodged, these parts sown thin have supported their upright position against wind and rain, though the rows have been made not only lengthways, but crofs the lands, in several positions, so that there could be no alteration in regard to the goodness of the land, or the situation of the corn; therefore where such experiments have been frequently made, and always attended with equal success, there can be no room to doubt which of the two methods is more eligible, since if the crops were only supposed to be equal in both, the saving two thirds of the corn sown, is a very great advantage, and deserves a national consideration, as such a saving, in scarce times, might be a very great benefit to the public. This saving of seed corn must be understood to regard such as is sown broad cast; for if it is sown in drills, an eighth part of the seeds usually sown will be sufficient for an acre of land, and the produce will be greater; for all sorts of corn is naturally inclined to send out several stalks from each root, which they rarely fail to do where the roots are at a proper distance and have room; nor do the stalks grow in this case near so tall, but are much stronger than when they are near together, when they rarely have more than two or three stalks, whereas those roots which have proper room, seldom have less than ten or twelve. I have had eighty-six stalks upon one root of Barley, which were strong, produced longer ears, and the grain was better filled than any which I ever saw grow in the common method of husbandry, and the land upon which this grew was not very rich; but I have frequently observed on the sides of hot-beds in the kitchen-gardens, where Barley straw has been used for covering the beds, that some of the grains left in the ears has dropped out and grown, the roots have produced from thirty to sixty stalks each, and those have been three or four times larger than the stalks ever arrive at in the common way; but to this I know it will be objected, that although upon rich land in a garden, these roots of corn

may probably have so many stalks, yet in poor land they will not have such produce; therefore unless there is a greater quantity of seeds sown, their crop will not be worth standing, which is one of the greatest fallacies that can be imagined; for to suppose that poor land can nourish more than twice the number of roots in the same space as rich land, is such an absurdity, as one could hardly suppose any person of common understanding guilty of; and yet so it is, for the general practice is to allow a greater quantity of seed to poor land, than for richer ground, not considering that where the roots stand so close, they will deprive each other of the nourishment, so starve themselves, which is always the case where the roots stand close, which any person may at first sight observe in any part of the fields where the corn happens to scatter when they are sowing it; or in places, where, by harrowing, the seed is drawn in heaps, those patches will starve, and never grow to a third part of the size as the other parts of the same field; and yet common as this is, it is little noticed by farmers, otherwise they surely would not continue their old custom of sowing. I have made many experiments for several years in the poorest land, and have always found that all crops which are sown or planted at a greater distance than usual, have succeeded best upon such land; and I am convinced if the farmers could be prevailed on to quit their prejudices, and make trial of this method of sowing their corn thin, they would soon see the advantage of this husbandry.

The noblemen and gentlemen in *France* are very busy in setting examples of this husbandry in most of their provinces, being convinced by many trials of its great utility, and it were to be wished the same was done in *England*.

After the Barley is sown, and harrowed in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth; which will render it better to mow the Barley, and also cause the earth to lie closer to the roots of the corn, which will be of great service to it in dry weather.

Where Barley is sown upon new broken up land, the usual method is, to plough up the land in *March*, and let it lie fallow until *June*, at which time it is ploughed again, and sown with Turneps, which are eaten by sheep in winter, by whose dung the land is greatly improved, and then in *March* following the ground is ploughed again, and sown with Barley as before.

There are many people who sow Clover with their Barley, and some have sown the Lucern with Barley; but neither of these methods is to be commended, for where there is a good crop of Barley, the Clover or Lucern must be so weak as not to pay for standing, so that the better way is to sow the Barley alone without any other crop among it, and then the land will be at liberty for any other crop, when the Barley is taken off the ground; but this practice of sowing Clover, Rye Grass, and other Grass seeds, with corn, has been so long and universally established among farmers, that there is little hope of prevailing with those people to alter a custom which has been handed down to them from their predecessors, although there should be many examples produced to shew the absurdity of this practice.

When the Barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground, which will be of singular service in dry seasons; and this rolling of it before it stalks, will cause it to till out into a greater number of stalks; so that if the plants should be thin, this will cause them to spread so as to fill the ground, and likewise strengthen the stalks.

The time for cutting of Barley is, when the red colour of the ears is off, and the straw turns yellow, and the ears

begin to hang down: in the north of *England* they always reap their Barley, and make it up in sheaves, as is practised here for Wheat, by which method they do not lose near so much corn, and it is also more handy to stack; but this method cannot so well be practised where there are many weeds amongst the corn, which is too frequently the case in the rich lands near *London*, especially in moist seasons; therefore when this is the case, the Barley must lie on the sward till all the weeds are dead; but as it is apt to sprout in wet weather, it must be shook up, and turned every fair day after rain to prevent it. When it is carried, it should be thoroughly dry, otherwise if it be stacked wet, it will turn musty; or if too green, it is subject to burn in the mow. The common produce of Barley is two and a half, or three quarters on an acre, but I have sometimes known eight or ten quarters on an acre.

HORMINUM. *Tourn. Inst. R. H.* 178. Clary.

The Characters are,

The empalement of the flower is permanent, of one leaf, having two lips; the upper ending in three acute points, the under ending in two. The flower has one petal, divided into two lips; the upper is concave, and incurved with a slight indenture at the point, the lower is broader and more indented. It hath two short stamina situated in the tube of the flower. In the bottom of the tube are four roundish germen, which afterward become four seeds, lodged in the empalement.

The Species are,

1. HORMINUM *foliis sinuatis obtusis crenatis, calycibus acutis*. Clary with obtuse sinuated leaves which are crenated, and the empalement ending in acute points; called Wild Clary.

2. HORMINUM *foliis pinnato-sinuatis rugosis, calycibus corollâ longioribus*. Clary with wing-shaped sinuated leaves which are rough, and the empalements longer than the petal of the flower; or, Oak-leaved Clary.

3. HORMINUM *foliis cordatis crenato-dentatis, verticillis subnudis, stylo corollarum labio inferiore incumbente*. Clary with heart-shaped, crenated, indented leaves, naked whorls, and the style lying upon the under lip of the petal.

4. HORMINUM *foliis radicalibus pinnato-incisis, caulibus cordatis crenatis, summis semiamplexicaulibus*. Clary with lower leaves cut and winged, those on the stalks heart-shaped and crenated, and those on the top half embracing the stalks.

5. HORMINUM *foliis obtusis crenatis, bracteis summis sterilibus majoribus coloratis*. Clary with obtuse crenated leaves, and the bractæ on the top of the stalks, large, coloured, and barren; Clary with a purple-violet top.

The first sort grows naturally on sandy and gravelly grounds in many parts of *England*, so is rarely cultivated in gardens; but as it has been long used in medicine, I have enumerated it to introduce the other species.

This is sometimes called *Oculus Christi*, from the supposed virtues of its seeds in clearing of the sight, which it does by its viscous covering; for when any thing happens to fall into the eye, if one of the seeds is put in at one corner, and the eye-lid kept close over it, moving the seed gently along the eye, whatever happens to be there will stick to the seed, and so be brought out. The virtues of this are supposed to be the same as the garden Clary, but not quite so powerful.

The second sort grows naturally in the south of *France* and *Italy*. This is by some supposed to be a variety of the first; but the leaves of this are regularly sinuated on both sides, in form of a winged leaf; the stalks rise about the same height with the former, but all the leaves upon the stalks are sinuated in the same manner as the lower; the flowers are smaller than those of the first, but grow in whorled spikes like them. It is a perennial plant, very hardy, and will propagate in plenty by its scattered seeds.

The third sort is a perennial plant, which grows naturally in *Austria* and *Bohemia*. This sends out from the root a great number of heart-shaped leaves, which are sawed on their edges and deeply veined, standing upon pretty long foot-stalks which are hairy; the stalks are square, and grow two feet and a half high, garnished with two heart-shaped leaves at each joint, whose base half embraces the stalks, which are garnished with whorls of small blue flowers, not much unlike those of the common sort, but larger; the spikes are more than a foot long, and toward the top the whorls are nearer together.

The fourth sort grows naturally in the south of *France*, and in *Italy*. This is also a perennial plant, which has some resemblance of the third, but the lower leaves of this are cut at their base to the midrib, into one or two pair of ears or lobes, which are small, and at a distance from each other; the leaves are not sawed, but bluntly indented; the stalks of this are slenderer, and do not grow so tall as those of the third, nor are the spikes of flowers so long.

Both these sorts may be easily propagated by seeds, which, if sown in the spring on an open spot of ground, the plants will come up, and require no other care but to keep them clean from weeds, and allow them room to grow; for they should not be nearer than two feet apart, as they grow very large, and will last several years.

The fifth sort is an annual plant, which grows naturally in *Spain*; of this there are three varieties which are constant, one with purple tops, another with red tops, and a third with green tops. As they differ in nothing but the colour of their bractææ on the top of the stalks, so I have not put them down as different species, though from more than thirty years cultivating them, I have not known them alter from one to the other.

These plants have obtuse crenated leaves, shaped like those of the common red Sage; the stalks are square and grow erect, about a foot and a half high; their lower parts are garnished at each joint, with two opposite leaves of the same shape, but gradually diminishing in size toward the top: the stalks are garnished upward with whorls of small flowers, and are terminated by clusters of small leaves, which in one are red, in another blue, and a third green, which make a pretty appearance, and are preserved in gardens for ornament.

The seeds of these are sown in the spring, in the places where they are designed to remain, and require no other care but to keep them clean from weeds, and thin them where they come up too close.

Garden Clary. See *Sclarea*.

HORNBEAM. See *Carpinus*.

HORSE CHESTNUT. See *Æsculus*.

HORSE-DUNG is of great use in gardens, first to make hot-beds for the raising of all sorts of early garden crops, as Cucumbers, Melons, Asparagus, Sallading, &c. for which purpose no other sort of dung will do so well, this fermenting the strongest; and, if mixed with litter, and sea-coal ashes in a due proportion, will continue its heat much longer than any other sort of dung whatsoever; and afterwards when rotted, becomes an excellent manure for most sorts of lands, more especially for such as are of a cold nature; and for stiff clayey lands, when mixed with sea-coal ashes, and the cleansing of *London* streets, it will cause the parts to separate much sooner than any other compost will do; so that where it can be obtained in plenty, I would always recommend the use of it for such lands.

HOT-BEDS are of general use in these northern parts of *Europe*, without which we could not enjoy so many of the products of warmer climes as we do now; nor could we have the tables furnished with the several products of the garden, during the winter and spring months, as they are at present in most parts of *England*, better than in any other

country in *Europe*; for although we cannot boast of the clemency of our climate, yet the *London* markets and noblemens tables are better furnished with all sorts of esculent plants, much earlier in the season, and in greater quantities, than any of our neighbours, which is owing to our skill in hot-beds.

The ordinary hot-beds which are commonly used in the kitchen gardens, are made with new horse-dung, in the following manner:

1st, There is a quantity of new horse-dung from the stable (in which there should be part of the litter or straw which is commonly used in the stable, but not in too great proportion to the dung,) the quantity of this mixture must be according to the length of the bed intended; which, if early in the year, should not be less than one good load for each light; this dung should be thrown up in a heap, mixing therewith some sea-coal ashes, which will be of service to continue the heat of the dung; it should remain six or seven days in this heap, then it should be turned over, and the parts well mixed together, and cast into a heap again, where it may continue five or six days longer, by which time it will have acquired a due heat; then in some well sheltered part of the garden, a trench should be dug out in length and width proportionable to the frames intended for it; if the ground is dry, about a foot, or a foot and a half deep; but if wet, not above six inches; then the dung should be wheeled into the opening, and every part of it stirred with a fork, to lay it exactly even and smooth through every part of the bed; as also to lay the bottom of the heap (which has commonly less litter) upon the surface of the bed; this will prevent the steam from rising so plentifully as it would otherwise do. To prevent this, and the heat from rising so violently as to burn the roots of whatever plants are put into the ground, it will be a very good way to spread a layer of neats dung all over the surface of the horse-dung, which will prevent the mould from burning: if the bed is intended for Cucumbers or Melons, the earth should not be laid all over the bed at first, only a hill of earth should be first laid in the middle of each light, on which the plants should be planted, and the remaining space should be filled up from time to time, as the roots of the plants spread, but this is fully explained under those two articles. But if the hot-bed is intended for other plants, then after the bed is well prepared, it should be left two or three days for the steam to pass off before the earth is laid upon the dung.

In the making of these hot-beds, it must be carefully observed to settle the dung close with a fork; and if it be pretty full of long litter, it should be equally trod down close in every part, otherwise it will be subject to heat too violently, and consequently the heat will be much sooner spent, which is one of the greatest dangers these sort of beds are liable to. During the first week or ten days after the bed is made, the glasses should be but slightly covered in the night, and in the day time they should be raised to let out the steam, which is subject to rise very copiously while the dung is fresh; but as the heat abates, so the covering should be increased.

But although the hot-bed I have described is what the kitchen-gardeners commonly use, yet those made with tanners bark are much preferable, especially for all tender exotick plants or fruits, which require an even degree of warmth to be continued for several months, which is what cannot be effected by horse-dung only: the manner of making these beds is as follows:

There must be a trench dug in the earth about three feet deep, if the ground be dry; but if wet, it must not be above six inches deep at most, and must be raised in proportion above ground, so as to admit of the tan being laid three feet thick. The length must be proportioned to the frames

intended to cover it, but that should never be less than eleven or twelve feet, and the width not less than six, which is but a sufficient body to continue the heat. This trench should be bricked up round the sides to the above-mentioned height of three feet, and should be filled with fresh tanners bark (*i. e.* such as the tanners have lately drawn out of their vats, after they have used it for tanning leather) which should be laid in a round heap for a week or ten days before it is put into the trench, that the moisture may the better drain out of it, which, if detained in too great a quantity, will prevent its fermentation; then put it into the trench, and gently beat it down equally with a dung fork; but it must not be trodden, which would also prevent its heating, by settling it too close; then you must put on the frame over the bed, covering it with the glasses, and in about a fortnight it will begin to heat; at which time may be plunged pots of plants or seeds into it, observing not to tread down the bark in doing of it.

HOTTONIA. *Boerb. Ind. alt. 1. p. 207.* Water Violet.

The Characters are,

The flower has one petal, cut above into five oblong oval segments; it hath five short awl-shaped stamina, standing on the tube of the petal. In the center is situated a globular germen, which afterward becomes a capsule of the same form with one cell, filled with globular seeds, sitting upon the empalement.

We know but one Species of this genus, *viz.*

HOTTONIA. *Boerb. Ind. alt. 1. p. 207.* Water Milfoil, or Water Violet, with a naked stalk.

This plant grows naturally in standing waters, in many parts of *England*; the leaves which are for the most part immersed in the water, are finely winged and flat, like most of the sea plants, and at the bottom have long fibrous roots, which strike into the mud; the flower-stalks rise five or six inches above the water, they are naked, and toward the top have two or three whorls of purple flowers, terminated by a small cluster of the same. These flowers have the appearance of those of the Stock-gilliflower, so make a pretty appearance on the surface of the water.

It may be propagated in deep standing waters, by procuring its seeds when they are ripe, from the places of their natural growth; which should be immediately dropped into the water where they are designed to grow, and the spring following they will appear; and if they are not disturbed, they will soon propagate themselves in great plenty.

HOEING is necessary and beneficial to plants, for two things: first, for destroying of weeds; 2dly, because it disposes the ground the better to imbibe the night dews, keeps in a constant freshness, and adds a vigour to the plants and trees, whose fruit by that means, becomes better conditioned than otherwise it would be.

HUMULUS. See *Lupulus*.

HURA. *Lin. Gen. Plant. 965.* Sand Box tree.

The Characters are,

It hath male and female flowers on the same plant. The male flowers have no petal, but a column of stamina, which are joined at bottom into a cylinder. The female flowers have a swelling empalement of one leaf, with one tubulous petal; the roundish germen is situated in the bottom of the empalement, which afterward becomes an orbicular ligneous fruit, depressed at top and bottom, having twelve deep furrows, with so many cells, which open at the top with an elasticity, each containing one round flat seed.

We know but one Species of this genus, *viz.*

HURA. *Hort. Cliff. 486.* Commonly called in the *West-Indies* Sand Box tree.

This grows naturally in the *Spanish West-Indies*, from whence it has been introduced into the *British* colonies of *America*, where some of the plants are preserved for their

shade, and by some for curiosity. It rises with a soft ligneous stem to the height of twenty-four feet, dividing into many branches, which abound with a milky juice, and have scars on their bark, where the leaves have fallen off. The branches are garnished with heart-shaped leaves, those which are the biggest are eleven inches long, and nine inches broad in the middle, indented on their edges, having a prominent midrib, with several transverse veins from that to the sides, which are alternate. The male flowers come out from between the leaves, upon foot-stalks which are three inches long; these are formed into a close spike, or column, lying over each other like the scales of fish. The female flowers are situated at a distance from the male; these have a swelling cylindrical empalement, out of which arises the petal of the flower, which hath a long funnel-shaped tube, spreading at the top, where it is divided into twelve parts, which are reflexed. After the flower is past, the germen swells and becomes a round, compressed, ligneous capsule, having twelve deep furrows, each being a distinct cell, containing one large, round, compressed seed; when the pods are ripe, they burst with an elasticity, and throw out their seeds to a considerable distance.

It is propagated by seeds, which should be sown in pots, and plunged into a hot-bed of tanners-bark. If the seeds are fresh, the plants will appear in about five weeks after the seeds are sown. As the plants will advance very fast, where due care is taken of them, so they should have a large share of fresh air admitted to them in warm weather, otherwise they will draw up too weak. When the plants are about two inches high, they should be transplanted each into a separate small pot, and plunged again into the hot-bed of tanners bark, and shaded from the sun, until they have taken new root, after which they must have free air admitted to them, by raising the glasses in proportion to the warmth of the season. In this hot-bed they should remain till *Michaelmas*, provided the plants have room to grow, without touching of the glasses, at which time they must be removed into the bark-shove, and plunged in the warmest part thereof: during the winter season they must be sparingly watered, for as the plants have succulent stalks, abounding with a milky juice, so much moisture will rot them. In summer they must have a large share of fresh air in warm weather, but should not be removed into the open air, for they are too tender to live abroad in the warmest part of the year in this country.

As this plant has ample leaves, which are of a beautiful green colour, it makes an agreeable variety among other tender exotick plants in the stove; for where they are kept warm and duly refreshed with water, they retain their leaves all the year in verdure.

HYACINTHUS. *Tourn. Inst. R. H. 344. tab. 180.* Hyacinth.

The Characters are,

The flower has no empalement. It has one bell-shaped petal, whose rim is cut into six parts, and three nectariums on the point of the germen, with six short awl-shaped stamina. In the center is situated a roundish three-cornered germen, having three furrows, which afterward becomes a roundish three-cornered capsule, having three cells, which contain roundish seeds.

The Species are,

1. **HYACINTHUS** *corollis campanulatis sexpartitis apice revolutis.* *Hort. Cliff. 125.* Hyacinth with bell-shaped petals, divided into six parts, which are reflexed at their tops; *English* Hyacinth, or Hare Bells.

2. **HYACINTHUS** *corollarum exterioribus petalis distinctis, interioribus coadunatis.* *Lin. Sp. Plant. 317.* Hyacinth, whose exterior part of the flower hath distinct petals, but the interior are joined.

3. *HYACINTHUS corollis campanulatis sexpartitis, floribus utrinque dispositis.* Hyacinth with bell-shaped petals, which are divided into six parts, and flowers ranged on each side of the stalk.

4. *HYACINTHUS corollis campanulatis sexpartitis racemo cernuo.* *Lin Sp. Plant.* 317. Hyacinth with bell-shaped petals, which are divided into six parts, and a nodding branch of flowers.

5. *HYACINTHUS corollis campanulatis semiflexidis basi cylindricis.* *Hort. Upsal.* 85. Hyacinth with bell-shaped petals, cut half way into six parts, and a cylindrical base.

6. *HYACINTHUS corollis infundibuliformibus semiflexidis basi ventricosis.* *Hort. Upsal.* 85. Hyacinth with funnel-shaped petals cut half into six parts, and swelling at the base; or early, white, eastern Hyacinth.

The sorts here mentioned are all of them distinct species, of which there are great varieties, especially of the sixth, which have been cultivated with so much art, as to render some of them the most valuable flowers of the spring; in *Holland* the gardens abound with them, especially at *Haerlem*, where the florists have raised so many varieties as to amount to some hundreds; and some of their flowers are so large, double, and finely coloured, as that their roots are valued at twenty or thirty pounds sterling each root. To enumerate these varieties here, would swell this work to very little purpose, as every year produces new kinds.

The first sort grows naturally in woods, and near hedges, in lands which have lately been woods, in many parts of *England*, so is seldom admitted into gardens; but the poor people, who make it their business to gather the wild flowers of the fields and woods for nosegays, &c. bring great quantities of these in the spring to *London*, and sell them about the streets.

There is a variety of this with white flowers, which is kept in some gardens, and only differs in the colour of their flowers from the other.

The second sort is preserved in some gardens for the sake of variety; but as it hath as little beauty as the first, so is seldom allowed a place in the flower-garden. The flowers of this are narrower than those of the first sort, and seem as if their petals were divided to the bottom, three of the outer segments being separated from the other, standing at a small distance from the three interiors, but they are all joined at their base; the flowers are of a light blue colour, but they fade to a worn-out purple.

The third sort grows naturally in *Spain* and *Italy*. This hath blue flowers of the open spread bell-shape, which are divided into six segments almost to the bottom, and are disposed on every side the stalk.

The fourth sort seems to be a variety of the first, the flowers being ranged for the most part upon one side of the stalk, and the top of the bunch is always bent on one side. The flowers are of a blush Peach colour, and appear about the same time as the first.

The fifth sort grows naturally in *Spain*. This hath a smaller flower than either of the former sorts, and comes earlier in the season. The petal is cut into six parts half the length, and is reflexed at the brim; the lower part is cylindrical, a little swelling at the base, and is of a deeper blue than either of the former. This was formerly called by the gardeners the *Coventry* blue Hyacinth.

The sixth sort is the eastern Hyacinth, of which we formerly had very few varieties in the *English* gardens, but the single and double white and blue flowering; but from the seeds of these there has been many others raised in *England*; but the gardeners in *Holland* have, within the last fifty years, raised so many fine varieties, as to render the former sorts of no value.

Those who are desirous to preserve any of the old sorts,

need not be at much trouble about it, for their roots propagate in great plenty in any soil or situation, and will require no other care but to take up their roots every other year, soon after their leaves decay, and plant them again in autumn; for if they are permitted to remain longer in the ground, their roots will have multiplied to so great a degree, as to render their flowers very small and weak.

All the different sorts of Hyacinths are propagated by seeds or offsets from the old bulbs; the former method has been but little practised in *England* till very lately, but in *Holland* and *Flanders* it hath been followed for many years, whereby they have obtained so great a variety of most beautiful flowers. Few florists in *England* think it worth their trouble to wait four or five years for the flowers of a plant, which when produced perhaps might not deserve to be preserved; but they do not consider, that it is only the loss of the four or five first years after sowing; for if they continue sowing every year after they begin, there will be a succession of flowers annually, which will constantly produce some sorts different from what they are before possessed of; and new flowers being always the most valuable to skilful florists (provided they have good properties to recommend them), it will always be a sufficient recompence for the trouble and loss of time.

The method of raising these flowers from seeds is as follows: first, to be provided with some good seed (which should be saved from either semi-double, or such single flowers as are large, and have good properties): secondly, one or more shallow boxes or pots should be provided, which must be filled with fresh, light, sandy soil, laying the surface very level; then the seeds should be sown thereon as equally as possible, covering it about half an inch thick with the same light earth: the time for this work is about the middle of *August*. These boxes or pots should be placed where they may enjoy the morning sun only until the latter end of *September*, at which time they should be removed into a warmer situation, and towards the end of *October* they should be placed under a common hot-bed frame, where they may remain during the winter and spring months, to be protected from hard frosts; but they should be exposed to the open air when the weather is mild, by taking off the glasses. In *February* or *March* the young plants will begin to appear above ground, at which time they must be carefully screened from frosts, otherwise they will be destroyed when they are so young; but they must not be covered at that season except in the night, or in very bad weather; for when the plants are come up, if they are too close covered, they will draw up tall and slender, and thereby prevent the growth of their roots. At the end of *March*, if the weather proves good, they may be removed out of the frame, placing them in a warm situation; and if the season proves dry, they should now and then have a little water, and kept very clear from weeds, which would soon overspread the tender plants and destroy them.

Towards the latter end of *April*, or the beginning of *May*, these boxes should be removed into a cooler situation; for the heat of the sun at that season would be too great for these tender plants, causing their blades to decay much sooner than they would, if they were screened from its violence. In this shady situation they should remain during the heat of summer, observing to keep them constantly clear from weeds; but you must not place them under the dripping of trees, &c. nor should you give them any water after their blades are decayed, for that would infallibly rot the roots. About the latter end of *August* you should sift a little light rich earth over the surface of the boxes, and then remove them again into a warmer situation, and treat them, during the winter, spring, and summer months, as was before directed; and the second year, about the mid-

ble of *August*, should be prepared a bed of light, rich, sandy soil, in proportion to the quantity of seedling roots, the surface of which should be very even; then take out the earth from the boxes in which the plants were raised, into a sieve, in order to get out all the roots, which by this time (if they have grown well) will be about the size of small Pease: these roots should be placed upon the bed at about three inches asunder, observing to set the bottom part of their roots downwards; then they should be covered over two inches thick with the same light earth; but as it will be impossible to get all the small roots out of the earth in the boxes, the earth should be spread upon another bed equally, and covered over with light earth, by which method none will be lost, be they ever so small.

These beds must be arched over with hoops, and in very hard frosty weather must be covered with mats, &c. to protect them from frost; and in the spring, when the green leaves are above ground, if the weather should be very dry, they should have a little water sparingly, for nothing is more injurious to these bulbs than too great quantities of moisture. During the summer season the beds must be kept clear from weeds, but after the blades are decayed, should not have any water; in autumn the surface of the bed should be stirred with a very short hand-fork, being exceeding careful not to thrust it so deep as to touch the roots, which, if hurt, are very subject to perish soon after. Then a little fresh, light, rich earth should be sifted over the bed about an inch thick, or somewhat more; in winter the bed should be covered again (as before). In this bed the roots may continue two years; the third summer, when the leaves are decayed, the roots should be carefully taken up, and may be kept out of the ground till *August*, when they should be planted into new beds prepared as before, at the distance of six inches asunder; in these beds the roots may remain till they flower, during which time they should be treated as before, with this difference only, that instead of covering them with mats in the winter, the surface of the ground should be covered with tanners bark.

When their flowers begin to shew themselves, those which have good properties should be marked, by thrusting a small stick down by each root; which root, at the time for taking them up, should be selected from the rest, and planted by themselves, though I would by no means advise the rejecting any of the other roots, until they have blown two years, before which their worth cannot be ascertained. When their roots are taken up they should be laid into the earth again in a horizontal position, leaving the green leaves hanging downwards from the roots, whereby the great moisture contained in their very succulent leaves and flower-stalks will be exhaled, and prevented from entering the roots, which, when suffered to return into them, is very often the cause of their rotting. In this position the roots should remain until the leaves are quite dried off, when they must be taken up, and after being cleared from all manner of filth, which would be hurtful to them, they must be laid up in boxes, where they may be preserved dry until *September*, which is the proper season for planting them again.

I shall now proceed to the culture of such Hyacinths as have either been obtained from *Holland*, or have been produced from seeds in *England*. The want of skill in this particular, has occasioned the ill success most people have had with them here, which has occasioned their being so much neglected, supposing their roots to degenerate after they have flowered in *England*; which is a great mistake, for were the roots managed with the same art as is practised in *Holland*, I am fully convinced they would thrive full as well as there; for, from some hundreds of roots which I have received from *Holland* at different times, I have had a

very great increase of their roots, which were as large, and produced as many flowers upon their stems, as the same sorts do in most parts of *Holland*.

The soil in which these flowers succeed best, is a light, sandy, fresh, rich loamy, which may be composed after the following manner: Take half fresh earth from a common, or pasture-land, which is of a sandy loam; this should not be taken above eight or nine inches deep at most; and if taken with the turf, or green sward with it, it will still be better, provided it has time to rot; to this should be added a fourth part of sea-sand, and the other fourth part of rotten cow-dung; these should be well mixed together, and cast into a heap, where it may remain until it is wanted, but it should be turned over once every month. If this compost be made two years before it is used, it will be much the better, but if used sooner it should be oftener turned, that the parts may the better unite.

This soil should be laid two feet deep in the beds which are designed for Hyacinths, and a little rotten cow-dung, or tanners bark, may be layed at the bottom, which will be within reach of the fibres, but should by no means touch the bulb. If the soil be very wet where these beds are made, they should be raised ten or twelve inches above the surface, but if it be dry, they need not be raised above three or four.

The best season for planting these roots is towards the middle or latter end of *September*, according to the earliness or lateness of the season, or the weather which then happens; but I would advise never to plant them when the ground is extreme dry, unless there is a prospect of some rain soon after; for if the weather should continue dry for a considerable time after, the roots will receive a mouldiness, which will certainly destroy them.

These beds will require no farther care until the frost comes on, at which time they should have some rotten tan spread over the bed, about four inches thick; and if the alleys on each side of the bed are filled up, either with rotten tan, dung, or sand, it will prevent the frost from penetrating the ground to the roots, and secure them from being destroyed; but when the winters prove very severe, it will also be proper to have some Pease haulm, or such like covering laid over them, which will keep out the frost better than mats. But this covering should be taken off whenever the weather is mild, and only continued on in very hard frosts; for where the beds are covered with tan or sea-coal ashes, no common frost can penetrate through, so the other coverings are useless, except in very severe frost. In *February*, when the leaves begin to appear, the beds must be arched over with hoops, that they may be covered either with mats, canvas, or some other light covering, to prevent the frost from injuring the buds as they arise above ground; but these coverings must be constantly taken off every day when the weather is mild, otherwise the flower-stems will be drawn up weak, and the foot-stalks of the flowers will be slender, and so rendered incapable of supporting the bells, which is a great disadvantage to the flowers. When these hoops are fixed over the beds, the rotten tan should be taken off; in the doing of which, great care should be taken not to bruise or injure the leaves of the Hyacinths which are then coming up.

When the stems of the flowers are advanced to their height, before the flowers are expanded, short sticks should be placed by each root, to which, with a wire formed into a hoop, the stem of the flowers should be fastened, to support them from falling, otherwise, when the bells are fully expanded, their weight will incline them to the ground.

During their season of flowering they should be covered in the heat of the day from the sun, and also from all heavy rains; but they should be permitted to receive gentle showers,

as also the morning and evening sun; but if the nights are frosty, they must be constantly defended therefrom. With this management the flowers may be continued in beauty at least three weeks or a month, and sometimes more, according to their strength, or the favourableness of the season.

When their flowers are quite decayed, and the tops of their leaves begin to change their colour, the roots should be lifted with a narrow spade, or some other handy instrument: in the doing of this, the instrument must be carefully thrust down by the side of the root, so as not to bruise or injure it, as also to put it below the bottom of the root; then by the forcing of this instrument on one side, the fibres of the root are raised and separated from the ground. The design of this is to prevent their receiving any more nourishment from the ground, for by imbibing too much moisture at this season, the roots frequently rot after they are taken up; about a fortnight after this operation the roots should be entirely taken out of the ground, and then the earth of the beds should be raised into a sharp ridge, laying the roots into it in a horizontal position, with their leaves hanging out, by which means a great part of the moisture contained in their thick succulent stalks and leaves will evaporate, which, if permitted to return back to the roots, would cause them to rot and decay after they are taken up, which has been the general defect of most of the Hyacinths in England.

In this position the roots should remain until the green leaves are entirely decayed, which perhaps may be in three weeks time. This is what the Dutch gardeners term, the ripening of their roots, because by this method the roots become firm, and the outer cover is smooth, and of a bright purple colour; whereas those roots which are permitted to remain undisturbed, till the leaves and stalks are quite decayed, will be large, spongy, and their outer coats will be of a pale colour, for the stems of many of these flowers are very large, and contain a great quantity of moisture, which, if suffered to return into the roots, will infallibly cause many of them to perish. After they are so ripened, they may be taken out of the ground, and wiped clean with a soft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie singly, and be exposed to the air, but they must be preserved carefully from moisture, nor should they be suffered to remain where the sun may shine upon them; in this manner they may be preserved out of the ground until September, which is the season for planting them again, at which time you must separate all the strong flowering roots, planting them in beds by themselves, that they may make an equal appearance in their flowers; but the offsets and smaller roots should be planted in another separate bed for one year, in which time they will acquire strength, and by the succeeding year will be as strong as the older roots.

There are some persons who let their Hyacinth roots remain two or three years unremoved, by which they have a much greater increase of roots than when they are annually taken up; but the roots by this great increase are frequently degenerated, so as to produce single flowers; therefore I should advise the taking up of the roots every year, which is the most certain method to preserve them in their greatest perfection, though the increase may not be so great; those roots which are annually removed will be rounder and firmer, than such as stand two years unremoved.

For the other sorts of Hyacinth, see Muscari and Ornithogalum.

HYACINTHUS TUBEROSUS. See Crinum.

HYDRANGEA. Gron. Flor. Virg. 50.

The Characters are,

The flower hath a small permanent empalement of one leaf, and five roundish petals which are equal. It hath ten stamina, which

are alternately longer than the petal. Under the flower is situated a roundish germen, which afterward turns to a roundish capsule, crowned by the two horned stigmas, divided transversely into two cells, filled with small angular seeds.

We know but one Species of this genus, viz.

HYDRANGEA. Gron. Flor. Virg. 50.

This plant grows naturally in North America, from whence it has been brought within a few years past to Europe, and is preserved in gardens for the sake of variety more than its beauty. It hath a spreading fibrous root, from which is sent up many soft, pithy, ligneous stalks, which rise about three feet high, garnished at each joint with two oblong heart-shaped leaves placed opposite; the leaves are three inches long and two broad near their base, sawed on their edges, and have many veins running from the middle upward to their borders; the flowers are produced at the top of the stalks, in form of a corymbus; they are white, composed of five petals, with ten stamina surrounding the style.

This is easily propagated by parting of the roots; the best time for this is the latter end of October, which is also the best time to transplant them: the plants should have a moist soil, for they grow naturally in marshy places; they require no other culture but to keep them clear from weeds, and dig the ground between them every winter. The roots are perennial, and if in very severe frost the stalks are killed, they will put out new ones the following spring.

HYDROCOTYLE, Water Navelwort.

This plant grows in great plenty in moist places in most parts of England, and is never cultivated for use, so I shall pass it over with only naming it.

HYDROLAPATHUM. See Rumex.

HYDROPHYLLON. Lin. Gen. Plant. 187. Water Leaf.

The Characters are,

The flower has a permanent empalement of one leaf, cut into five segments. It hath one bell-shaped petal, divided into five parts; under each of these segments is fixed a nectarium, which is situated about the middle. It hath five stamina, which are longer than the petal, and an oval-pointed germen, which afterward becomes a globular capsule with one cell, inclosing one large round seed.

We know but one Species of this genus, viz.

HYDROPHYLLON Morini. Jonq. Hort. Water Leaf of Morinus.

This plant grows naturally in Canada, and many other parts of America, on moist spongy ground. The root is composed of many strong fleshy fibres, from which arise many leaves with foot-stalks five or six inches long, jagged into three, five, or seven lobes, almost to the midrib, indented on their edges, and have several veins running from the midrib to the sides. The flowers rise with foot-stalks from the roots, having one or two small leaves of the same shape with the lower; the flowers are produced in loose clusters hanging downward, they are of a dirty white and are bell-shaped, so make no great figure.

This plant is very hardy in respect to cold, but requires a moist rich soil; for if it is planted in dry ground it will not live, unless it is constantly watered in dry weather. It may be propagated by parting of the roots, which should be done in autumn, that the plants may be well rooted before spring, otherwise they will require a great deal of water.

HYMENÆA. Lin. Gen. Plant. 1100. Locust tree.

The Characters are,

The outer involucre of the flower is divided into two parts, the inner is of one leaf indented in five parts; the flower hath five equal petals. It hath ten short declining stamina. In the center is situated an oblong germen, which afterward becomes a large oblong pod, with a thick ligneous shell, divided into several

partitions

partitions transversely, in each of which is lodged one compressed large seed, surrounded with a farinaceous pulp.

We know but one Species of this genus, viz.

HYMENÆA. Hort. Cliff. 484. commonly called Locust tree in America.

This is a very large spreading tree in the *West-Indies*, where it grows in great plenty; the stem is covered with a russet bark, which divides into many spreading branches, garnished with smooth stiff leaves, which stand by pairs, their base joining at the foot-stalk, to which they stand oblique, the two outer sides being rounded, and their inside strait, so that they resemble a pair of sheep-shears. The flowers are produced in loose spikes at the end of the branches, some of the short ligneous foot-stalks supporting two, and others three flowers, which are composed of five yellow petals striped with purple; the stamina are much longer than the petals, of a purplish colour; the flowers are succeeded by thick, fleshy, brown pods, shaped like those of the garden Bean, but much larger, of a purplish brown colour, and of a ligneous consistence, with a large suture on both edges; these contain three or four roundish compressed seeds, divided by transverse partitions.

The wood of this tree is esteemed a good timber in the *West-Indies*, and it yields a fine clear resin which is called *Gum Anime* in the shops, which makes an excellent varnish.

It is easily raised from the seeds if they are fresh, which should be sown in pots, and plunged into a hot-bed of tanners bark: there should be but one seed put into each pot, or if there is more, when the plants appear, they should be all drawn out but one soon after they come up, before their roots entangle, when it will be hazardous doing it; for if great care is not taken, the plant intended to be left may be drawn out with the other. As the roots of this plant are but slender, so they are very difficult to transplant; for unless a ball of earth is preserved to them, they seldom survive their removal, therefore they must be seldom transplanted from one pot to another. The plants must constantly remain in the tan-bed in the stove, and should be treated in the same way with other tender plants of the same country, giving but little water to them, especially in the winter. When these plants first appear, they make considerable progress for two or three months, after which time they are at a stand perhaps a whole year without shooting, being in their growth very like the *Anacardium*, or *Cashew Nut*, so is very difficult to preserve long in this country.

HYOSCYAMUS. Tourn. Inst. R. H. 117. tab. 42. Henbane.

The Characters are,

The flower has a cylindrical empalement of one leaf, which is permanent. It hath one funnel-shaped petal, cut into five obtuse parts, with five inclined stamina. In the center is situated a roundish germen, which afterward becomes an obtuse capsule, divided into two cells by an intermediate partition, opening with a lid at the top, to let out the many small seeds which adhere to the partition.

The Species are,

1. HYOSCYAMUS *foliis amplexicaulibus*. Hort. Cliff. 56. Henbane with leaves embracing the stalks; or common black Henbane.

2. HYOSCYAMUS *foliis petiolatis, floribus pedunculatis terminalibus*. Henbane with leaves having foot-stalks, and flowers with foot-stalks terminating the branches.

3. HYOSCYAMUS *foliis petiolatis, floribus sessilibus*. Hort. Upsal. 56. Henbane with leaves having foot-stalks, and flowers sitting close to the branches.

4. HYOSCYAMUS *foliis lanceolatis infernè pinnato-incisis summis integerrimis*. Henbane with spear-shaped leaves, the lower being cut into regular segments, and the upper ones are entire.

5. HYOSCYAMUS *foliis petiolatis acutè dentatis, pistillo corollâ longiore*. Henbane with acute indented leaves standing on foot-stalks, and a pointal longer than the petal of the flower.

6. HYOSCYAMUS *foliis lanceolatis subdentatis, calycibus spinosis*. Hort. Upsal. 44. Henbane with spear-shaped leaves somewhat indented, and a prickly empalement.

The first of these sorts is the common black Henbane, which grows wild in *England* upon the sides of banks and old dunghills almost every where. It is a biennial plant, with long fleshy roots, which strike deep into the ground, sending out several large soft leaves, which are deeply slashed on their edges; the following spring the stalks come out, which rise about two feet high, garnished with leaves of the same shape, but smaller, which embrace the stalks with their base; the upper part of the stalk is garnished with flowers standing on one side in a double row, sitting close to the stalks alternately; they are of a dark purplish colour with a black bottom, and are succeeded by roundish capsules, sitting within the empalement; these open with a lid at the top, and have two cells filled with small irregular seeds. This is a very poisonous plant, and should be rooted out in all places where children are suffered to come; for in the year 1729, there were three children poisoned with eating the seeds of this plant, near *Tottenham Court*; two of which slept two days and two nights before they could be awakened, and were with difficulty recovered; but the third being older and stronger, escaped better.

The roots of this plant are used for anodyne necklaces to hang about children's necks, being cut to pieces and strung like beads, to prevent fits and cause an easy breeding of their teeth, but they are very dangerous to use inwardly. Some years past there was a mixture of these roots brought over with *Gentian*, and used as such, which was attended with very bad effects, as hath been mentioned under the article of *Gentian*, so I shall not repeat it here.

The second sort grows naturally in the islands of the *Archipelago*. This hath rounded leaves, which are obtusely sinuated on their borders, and stand upon long foot-stalks; the stalks branch more than those of the first, and the flowers grow in clusters at the end of the branches, standing upon short foot-stalks; they are of a pale yellow colour, with very dark purple bottoms.

The third sort is much like the second, but the flowers are in closer bunches, sitting very close on the ends of the branches; they are of a greenish yellow colour, with green bottoms. It grows naturally in the warm parts of *Europe*, and is the sort whose seeds should be used in medicine, as the white Henbane of the shops.

The fourth sort grows naturally in *Syria*; this rises with a branching stalk two feet high, garnished with long spear-shaped leaves sitting close to the stalk; the lower leaves are regularly cut on both sides into acute segments, but the upper leaves are entire; the flowers grow at the end of the stalks in close bunches; they are of a worn-out red colour, and shaped like those of the common sort.

All these are biennial plants, which perish soon after they have perfected their seeds. They flower in *June* and *July*, and their seeds ripen in the autumn, which, if permitted to scatter, will produce plenty of the plants the following spring; or if the seeds are sown at that season, they will succeed much better than in the spring; for when they are sown in spring, the plants seldom come up the same year. They are all hardy, and require no other culture but to keep them clean from weeds, and thin the plants where they are too close. The fourth sort should have a warm situation and a dry soil, in which it will stand much better through the winter than in rich ground.

The fifth sort grows naturally in *Candia*. This is a perennial plant, with weak hairy stalks, which require support; the leaves are roundish, hairy, and acutely indented on their edges, standing upon pretty long foot-stalks; the flowers come out at each joint of the stalk; they are large, of a bright yellow, with a dark purple bottom; the style of this sort is much longer than the petal. It flowers most part of summer, but seldom ripens seeds in *England*. This sort will continue several years, if they are kept in pots and sheltered in winter, for they will not live in the open air; it only requires to be protected from frost; therefore if these plants are placed under a common hot-bed frame in winter, where they may enjoy as much free air as possible in mild weather, they will thrive better than when they are more tenderly treated. It may be easily propagated by cuttings, which, if planted in a shady border, and covered with hand-glasses in any of the summer months, they will take root in a month or six weeks, and may be afterward planted in pots, and treated like the old plants.

HYPECOUM. *Tourn. Inst. R. H. 230. tab. 115.*

The Characters are,

The flower hath four petals, and a two-leaved empalement. It hath four stamina situated between the petals. In the center is placed an oblong cylindrical germen, which afterward becomes a long, compressed, jointed pod, which is incurved, with one roundish compressed seed in each joint.

The Species are,

1. HYPECOUM *siliquis arcuatis compressis articulatis. Hort. Upsal. 31.* Hypecoum with compressed jointed pods bent inward.

2. HYPECOUM *siliquis cernuis teretibus cylindricis. Hort. Upsal. 31.* Hypecoum with taper, cylindrical, nodding pods.

3. HYPECOUM *siliquis erectis teretibus torulosis. Hort. Upsal. 32.* Hypecoum with taper, erect, wreathed pods.

The first sort hath many wing-pointed leaves, of a grayish colour, which spread near the ground, and slender branching stalks, which lie prostrate on the ground; they are naked below, but at the top are garnished with two or three small leaves of the same shape and colour with those below; from between these leaves come out the foot-stalks of the flower, each sustaining one yellow flower with four petals, and a pointal stretched out beyond the petals, which afterward turns to a jointed compressed pod about three inches long, which bends inward like a bow, having one roundish compressed seed in each joint.

The second sort hath slender stalks which stand more erect; the segments of the leaves are longer, and much narrower than those of the first; the flowers are smaller, and come out at the division of the branches, which are succeeded by narrow taper pods hanging downward.

The third sort grows in the east. This hath much the appearance of the second sort in leaf and flower, but the pods grow erect and are wreathed and twisted about.

These plants are all of them annual, so their seeds should be sown in the autumn, on a bed of fresh earth where they are to remain, for they seldom succeed when they are transplanted. When the plants are come up, they should be carefully cleared from weeds, and where they are too close they must be thinned, leaving them about six or eight inches apart; after this they will require no other culture, but to keep them constantly clear from weeds.

The juice of this plant is of a yellow colour, resembling that of *Celandine*, and is affirmed by some eminent physicians to have the same effect as opium.

HYPERICUM. *Tourn. Inst. R. H. 254. tab. 131.* St. Johnswort.

The Characters are,

The flower has a permanent empalement, divided into five oval

concave segments; it hath five oblong oval petals, and a great number of hairy stamina, joined at their base in five distinct bodies. It hath in the center a roundish germen, supporting one, three, or five styles. The germen afterward becomes a roundish capsule, having the same number of cells as there are styles in the flower, which are filled with oblong seeds.

The Species are,

1. HYPERICUM *floribus trigynis, caule ancipiti, foliis obtusis pellucido-punctatis. Hort. Cliff. 380.* St. Johnswort with three styles to the flower, and obtuse leaves having pellucid punctures; or common St. Johnswort.

2. HYPERICUM *floribus trigynis, caule quadrato herbaceo. Hort. Cliff. 380.* St. Johnswort with three styles to the flowers, and a square herbaceous stalk; or St. Johnswort with a square stalk, commonly called St. Peterwort.

3. HYPERICUM *floribus trigynis, staminibus corollâ longioribus, caule fruticoso ancipiti. Hort. Cliff. 331.* St. Johnswort with three styles to the flower, stamina longer than the petals, and a shrubby stalk looking two ways; stinking shrubby St. Johnswort.

4. HYPERICUM *floribus trigynis, calycibus obtusis, staminibus corollâ longioribus caule fruticoso.* St. Johnswort with three styles to the flower, obtuse empalements, stamina longer than the petals, and a shrubby stalk; shrubby St. Johnswort from the *Canaries*.

5. HYPERICUM *floribus trigynis, calycibus acutis, staminibus corollâ brevioribus, caule fruticoso. Hort. Cliff. 380.* St. Johnswort with three styles to the flower, acute empalements, stamina shorter than the petals, and a shrubby stalk.

6. HYPERICUM *floribus trigynis, calycibus obtusis, staminibus corollâ longioribus, capsulis, coloratis, caule fruticoso.* St. Johnswort with three styles to the flower, obtuse empalements, stamina longer than the petals, coloured seed vessels, and a shrubby stalk.

7. HYPERICUM *floribus pentagynis, caule tetragono herbaceo simplici, foliis lævibus integerrimis. Hort. Upsal. 236.* St. Johnswort with five styles to the flower, a square, single, herbaceous stalk, and smooth entire leaves.

8. HYPERICUM *floribus pentagynis, caule fruticoso, foliis ramisque cicatrifatis. Lin. Sp. Plant. 783.* St. Johnswort with five styles to the flower, a shrubby stalk, and scarified leaves and branches.

9. HYPERICUM *floribus trigynis, fructu baccato, caule fruticoso ancipiti. Hort. Upsal. 237.* St. Johnswort with three styles to the flower, a fleshy seed vessel, and a shrubby stalk looking two ways; common Tutsan, or Park Leaves.

10. HYPERICUM *floribus pentagynis calycibus obtusis, staminibus corollâ æquantibus, caule erecto herbaceo.* St. Johnswort with five styles to the flower, obtuse empalements, stamina equalling the petals, and an erect herbaceous stalk.

11. HYPERICUM *floribus monogynis, staminibus corollâ longioribus, calycibus coloratis, caule fruticoso.* St. Johnswort with one style to the flowers, stamina longer than the petals, coloured empalements, and a shrubby stalk.

The first and second sorts are both very common plants, growing in the fields in most parts of *England*; the first is used in medicine: these are rarely admitted into gardens, but I mention them in order to introduce the other, which are more deserving.

The first sort hath a perennial root, from which arise several round stalks a foot and a half high, dividing into many small branches, garnished at each joint with two small oblong leaves, standing opposite without foot-stalks; the branches also come out opposite. The leaves have many pellucid spots in them, which appear like so many holes, when held up against the light. The flowers are numerous on the top of the branches, standing on slender foot-stalks; they are composed of five oval petals, of a yellow colour, with a great number of stamina, not quite so long

long as the petals, terminated by roundish summits. In the center is situated a roundish germen, supporting three styles, crowned by single stigmas. The germen afterward becomes an oblong angular capsule, with three cells, filled with small brown seeds. The leaves and flowers of this are used in medicine; it is esteemed an excellent vulnerary plant, and of great service in wounds, bruises, and contusions; there is a compound oil made from this plant, which is of great use in the foregoing accidents.

The second sort hath square stalks, which rise about the same height with the first, but do not branch so much. The leaves are shorter and broader, and have no pellucid spots. The flowers sit upon short foot-stalks at the end of the branches, which are shaped like those of the other.

The third sort grows naturally in *Sicily*, *Spain*, and *Portugal*. This rises with shrubby stalks about three feet high, sending out small branches at each joint opposite, garnished with oblong oval leaves, placed by pairs, sitting close to the stalks, which have a rank scent like a he-goat. The flowers are produced in clusters at the end of the branches, they are composed of five oval yellow petals, with a great number of stamina, which are longer than the petals, and three styles which are longer than the stamina. The germen which supports these, afterward becomes an oval capsule with three cells, filled with small seeds.

The fourth sort grows naturally in the *Canary Islands*, so was formerly preserved in green-houses during the winter season, but is found to be hardy enough to resist the greatest cold of this country, and is now cultivated in the nurseries as a flowering shrub; this rises with a shrubby stalk six or seven feet high, dividing into branches upward, garnished with oblong leaves set by pairs close to the branches, which have a rank scent like the former. The flowers are produced at the end of the stalks in clusters, are very like those of the former sort, having a great number of stamina, which are longer than the petals.

These two sorts are propagated by suckers, which are plentifully sent forth from the old plant. They should be planted in a light dry soil, in which they will endure the severest cold of our climate very well.

The fifth sort grows naturally on mount *Olympus*, where it was discovered by Sir *George Wheeler*, who sent the seeds to the *Oxford* garden. This rises with many upright ligneous stalks about a foot high, garnished with small spear-shaped leaves sitting close to the stalks opposite. The flowers are produced at the top of the stalks three or four together, composed of five oblong petals, of a bright yellow colour, with a great number of stamina, which are of unequal lengths, some being longer, and others shorter than the petals, terminated by small roundish summits. In the center is situated an oval germen, supporting three slender styles, which are longer than the stamina. The germen afterward becomes an oval capsule, with three cells filled with small seeds.

This plant is usually propagated by parting of the roots, because the seeds do not always ripen in this country; the best time for doing of this is in *September*, that the plants may have time to get root before winter: it will live in the open air, if it is planted in a warm situation and a dry soil, but a plant or two should be kept in pots, to be sheltered under a frame in winter, lest in very severe frost, those in the open air should be destroyed. If this is propagated by seeds, they should be sown soon after they are ripe, in pots filled with light earth, and placed under a frame in the winter, to shelter them from frost, and in the spring the plants will appear; when these are fit to remove, some of them may be planted in a warm border, and others into pots, and treated in the same way as the old plants.

The sixth sort rises with a shrubby stalk seven or eight

feet high, with a reddish bark, and divides into small branches, garnished with oval heart-shaped leaves, sitting close to the stalks opposite. The flowers are produced at the end of the stalks in clusters; they are smaller than those of the third sort, and have obtuse empalements. The stamina are longer than the petals, and of a deeper colour. The flowers are succeeded by conical capsules of a purplish red colour, having three cells, filled with small seeds. This is now propagated in the nurseries as a flowering shrub, and may be treated in the same way as the third and fourth sorts.

The seventh sort was first brought from *Constantinople*, but has long been very common in the *English* gardens, for the roots spread and increase very fast, where it is permitted to stand long unremoved. The stalks of this are slender, and incline downward; they are garnished with oval, spear-shaped, smooth leaves, placed by pairs. The flowers are produced at the end of the stalks; they are very large, and of a bright yellow colour, with a great number of stamina, which stand beyond the petals; there are five styles in each flower, which are of the same length with the stamina.

This plant is easily propagated by parting of the root in *October*, that the plants may be well established before the drought of spring. As this will grow under trees, so it is a very proper plant to place under shrubs and trees to cover the ground, where they will make a good appearance during their season of flowering.

The eighth sort grows naturally in the island of *Minorca*, from whence the seeds were sent to *England* by Mr. *Salvador*, an apothecary at *Barcelona*, in the year 1718. This rises with a slender shrubby stalk about two feet high, sending out several weak branches with a reddish coloured bark, marked where the leaves have fallen off with a cicatrice. The leaves are small, oval, and waved on their edges, having several small protuberances on their surface, and sit close to the stalks, half embracing them with their base. The flowers are produced at the top of the stalks; they are large, of a bright yellow colour, with a great number of stamina, which are a little shorter than the petals; the flowers have five styles, and are succeeded by pyramidal capsules with five cells, which have a strong smell of turpentine, and filled with small brown seeds. This plant has a succession of flowers great part of the year, which renders it valuable; it is too tender to live through the winter in the open air in *England*, but requires no artificial heat; if the plants are placed in a dry airy glass-case in winter, where they may be protected from frost, and enjoy a good share of fresh air in mild weather, they will thrive better than in a warmer situation, but in a damp air their shoots soon grow mouldy and decay; nor should the plants have much water during the winter, but in summer they should be exposed in the open air, and in warm weather they should be frequently watered. This is propagated by cuttings, which should be planted in *June*, in pots filled with light earth, and plunged into a gentle hot-bed, and covered with a hand-glass. These will put out roots in six or seven weeks, when they should be carefully taken up, and each planted into a separate small pot, placing them in the shade till they have taken new root, then they may be removed to a sheltered situation, where they may remain till the frost comes, when they should be removed into shelter.

If these are propagated by seeds, they should be sown in autumn, in the same way as is before directed for the fifth sort, and the plants treated in the same manner as those raised from cuttings.

The ninth sort is the common *Tutsan*, or *Park Leaves*, which is sometimes used in medicine. It grows naturally in woods in several parts of *England*, so is not often admitted into gardens. This hath a shrubby stalk, which rises two feet high; the stalks are garnished with oval heart-shaped

shaped leaves, sitting close to them with their base, which are placed opposite. The flowers are produced in small clusters at the end of the stalk, they are yellow, but smaller than either of the sorts before-mentioned, and have many long stamina, which stand out beyond the flower with three styles. The germen afterward turns to a roundish fruit, covered with a moist pulp, which, when ripe, is black. The capsule has three cells, containing small seeds. It hath a perennial root, and may be propagated by parting it in autumn; it loves shade, and a strong soil.

The tenth sort grows naturally in *North America*; this rises with an upright herbaceous stalk three feet high, garnished with oblong leaves, placed opposite, which half embrace the stalk with their base. At the end of each stalk is produced one pretty large yellow flower, with an obtuse empalement, having many stamina, which are equal in length with the petals, and five styles which are so closely joined as to appear but one. The stigmas are reflexed, which denote their number; it is propagated by parting of the roots; the best time for this is in autumn; it should have a light soil, and an open situation.

The eleventh sort grows naturally in *China*, from whence the seeds were brought to the Right Hon. the Earl of *Northumberland*, and the plants were raised in his lordship's curious garden at *Stanwick*, and by his lordship's generosity, the *Chelsea* garden was furnished with this plant.

The root of this is composed of many ligneous fibres, which strike deep in the ground, from which arise several shrubby stalks, near two feet high, covered with a purplish bark, garnished with stiff smooth leaves, about two inches long, and a quarter of an inch broad, placed opposite, sitting close to the stalk, of a lucid green on their upper side, and gray on their under, having many tranverse veins running from the midrib to the border. The flowers are produced at the top of the stalks, growing in small clusters, each standing upon a short distinct foot-stalk; they have an empalement of one leaf, divided into five obtuse segments, almost to the bottom, which is of a deep purple colour. The flower is composed of five large obtuse petals of a bright yellow colour, which are concave, and in the center is situated an oval germen supporting a single style, crowned by five slender stigmas, which bend on one side; the style is attended by a great number of stamina, which are longer than the petals, and terminated by roundish summits.

This plant continues in flower great part of the year, which renders it the more valuable, and if it is planted in a very warm situation, it will live in the open air; but those plants which stand abroad will not flower in winter, as those do which are removed into shelter in autumn.

It may be propagated by slips from the root, or by laying down of the branches; if by slips, they should be planted in the spring on a moderate hot-bed, which will forward their putting out new roots; the layers should also be laid down at the same time, which will have taken root by autumn, when they may be transplanted into pots, and sheltered under a frame in winter, and in the spring, part of these may be planted in a warm border, and the others planted in pots to be screened in winter, lest those in the open air should be killed.

HYPERICUM FRUTEX. See Spiræa.

HYSSOPUS. Tourn. R. H. 200. tab. 95. Hyssop.

The Characters are,

The empalement of the flower is cylindrical and permanent. The flower is of one petal, of the grinning kind, with a narrow cylindrical tube; the chaps are inclining; the upper lip is short, plain, roundish, erect, and indented at the top. It hath four stamina, which stand apart, two of them are longer than the petal, the other two are shorter, and four germen, which afterward becomes so many oval seeds sitting in the empalement.

The Species are,

1. HYSSOPUS spicis fecundis. Hort. Cliff. 304. Hyssop with fruitful spikes; or the common Hyssop.

2. HYSSOPUS spicis brevioribus, verticillis compactis. Hyssop with shorter spikes, and whorls more compact; Hyssop with a red flower.

3. HYSSOPUS caule acuto quadrangulo. Hort. Upsal. 163. Hyssop with an acute square stalk.

4. HYSSOPUS corollis transversefalibus, staminibus inferioribus corollâ brevioribus. Hort. Upsal. 162. Hyssop with transverse petals, and the lower stamina shorter than the petal.

The first sort, which is the only one cultivated for use, hath a perennial root; the stalks are first square, but afterward become round, garnished with small spear-shaped leaves, placed opposite, with seven or eight very narrow erect leaves (or bractæa) rising from the same joint. The upper part of the stalk is garnished with whorls of flowers in a spike. There are four stamina in each flower, which spread at a distance from each other, the two upper are the shortest, which are situated on each side the upper lip; the two longer stand close to the two side segments, they are terminated by twin summits. At the bottom of the tube are situated four naked germen, which afterward becomes four oblong black seeds, sitting in the empalement; it grows naturally in the *Levant*. There is a variety of this with white flowers, but doth not differ from the blue in any other particular.

The second sort doth not grow so tall as the first; the stalks branch more, and the spikes of flowers are much shorter than those of the first. The whorls are closer together, and have long narrow leaves situated under each; the flowers are of a fine red colour. This sort is not quite so hardy as the common, for in 1739, the plants were all destroyed by the cold; this is certainly a distinct species.

These sorts of Hyssop are propagated either by seeds or slips; if by the seeds, they must be sown in *March*, upon a bed of light sandy soil, and when the plants come up, they should be transplanted out to the places where they are to remain, placing them at least a foot asunder each way; but if they are designed to abide in those places for a long time, two feet distance will be small enough, for they grow pretty large, especially if they are not frequently cut, to keep them within compass; they thrive best upon a poor dry soil, in which situation they will endure the cold of our climate better than when they are planted on rich ground. If they are propagated by slips, they should be planted either in spring or autumn in a bed of light earth, where they will take root in about two months, after which, they may be transplanted where they are to continue, managing them as was before directed for the seedling plants.

The third sort grows naturally in *North America*; this hath a perennial root, and rises with an upright square stalk, four or five feet high, garnished with oblique heart-shaped leaves sawed on their edges, ending in acute points; they are placed by pairs on short foot-stalks. The flowers grow in close thick spikes, four or five inches long at the top of the stalks: there are two varieties of this, one with pale yellow, and the other has purple flowers; the seeds of both sorts never vary to each other.

The fourth sort grows naturally in *Siberia*; this is a perennial plant with a strong fibrous root, sending out many square stalks, garnished with oblong leaves placed opposite. The flowers are produced at each joint toward the upper part of the stalks in small clusters, arising from the base of the leaves. The tube of the petal is longer than the empalement; the lips of the flower are oblique to it, being situated horizontally. The two upper stamina, and the style, stand out beyond the petal, but the other are shorter. The flowers are blue.

Both these sorts are very hardy, and may be easily propagated by seeds, which should be sown in autumn, for those sown in the spring do often lie a year in the ground before they vegetate; when the plants come up, they must be kept

clean from weeds, and thinned where they are too close. The following autumn they should be transplanted where they are to remain, for the roots will abide some years.

JACEA. See Centaurea.

JACOBÆA. See Senecio and Othonna.

JALAPA. See Mirabilis.

JASIONE. *Lin. Gen. Plant.* 896. Rampions with scabious heads. This plant grows naturally on sterile ground, in most parts of England, and is rarely admitted into gardens.

JASMINOIDES. See Cestrum and Lycium.

JASMINUM. *Tourn. Inst. R. H.* 597. *tab.* 368. *Lin. Gen. Plant.* 17. The Jasmine, or Jessamine tree.

The Characters are,

The flower hath a tubulous empalement, which is permanent, cut into five segments at the brim; the flower is of one petal, cut into five segments at the top, which spread open. It hath two short stamina, situated within the tube of the petal. In the center is situated a roundish germen, which afterward turns to an oval berry, with a soft skin inclosing two seeds, which are flat on those sides which join, and convex on the other.

The Species are,

1. **J**ASMINUM *foliis oppositis pinnatis, foliolis acuminatis.* Jasmine with winged leaves placed opposite, whose lobes end in acute points; or the common white Jasmine.

2. **J**ASMINUM *foliis alternis ternatis pinnatisque, ramis angulatis.* *Hort. Upsal.* 5. Jasmine with trifoliate and winged leaves placed alternate, and angular branches; or the Italian yellow Jasmine.

3. **J**ASMINUM *foliis alternis ternatis simplicibusque, ramis angulatis.* *Hort. Cliff.* 5. Jasmine with trifoliate and single leaves placed alternate, and angular branches; or the common yellow Jasmine.

4. **J**ASMINUM *foliis oppositis pinnatis, foliolis brevioribus obtusis.* Jasmine with winged leaves placed opposite, whose lobes are shorter and obtuse; or Catalanian Jasmine.

5. **J**ASMINUM *foliis alternis ternatis, foliolis ovatis, ramis teretibus.* Jasmine with trifoliate leaves placed alternate, whose lobes are oval, and taper branches; or the yellow Indian Jasmine.

6. **J**ASMINUM *foliis oppositis ternatis, foliolis cordato acuminatis.* Jasmine with trifoliate leaves placed opposite, whose lobes are heart-shaped and pointed; the Azorian Jasmine, commonly called, the Ivy-leaved Jasmine.

7. **J**ASMINUM *foliis lanceolatis oppositis integerrimis, calycibus acutioribus pedunculis unifloris.* Jasmine with spear-shaped leaves placed opposite, and entire acute empalements, and one flower upon each foot-stalk.

The first sort is the common white Jasmine, which is a plant so generally known, as to need no description. This grows naturally at Malabar, and in several parts of India, yet has been long inured to our climate, so as to thrive and flower extremely well; but never produces any fruit in England. It is easily propagated by laying down the branches,

J A S

which will take root in one year, and may then be cut from the old plant, and planted where they are designed to remain: it may also be propagated by cuttings, which should be planted early in the autumn, and if the winter should prove severe, the surface of the ground between them should be covered with tan, sea-coal ashes, or saw-dust, which will prevent the frost from penetrating deep into the ground, and thereby preserve them.

When these plants are removed, they should be planted where they are designed to be continued, which should be either against some wall, pale, or other fence, where the flexible branches may be supported. These plants should be permitted to grow rude in the summer, otherwise there will be no flowers, but after they are past, the luxuriant shoots should be pruned off, and the others must be nailed to the support.

There are two varieties of this with variegated leaves, one with white, and the other yellow stripes, but the latter is the most common: these are propagated by budding them on the plain Jasmine, and it often happens, that when the buds do not take, yet they will communicate their gilded miasma to the plants; so that in a short time after, many of the branches both above and below the places where the buds have been inserted, have been thoroughly tintured.

The two striped sorts should be planted in a warm situation, especially the white striped, for they are much more tender than the plain, and are very subject to be destroyed by great frosts, if they are exposed thereto; therefore the white striped should be planted to a south or south-west aspect, and in very severe winters their branches should be covered with mats or straw, to prevent their being killed: the yellow striped is not so tender, so may be planted against walls to east or west aspects; but these plants with variegated leaves, are not so much in esteem as formerly.

The second sort is frequently called Italian Jasmine by the gardeners, the plants being annually brought from thence by those who come over with Orange trees; these are generally grafted upon the common yellow Jasmine stocks, so that if the graft decays, the plants are of no value. This sort is somewhat tenderer than the common, yet will endure the cold of our ordinary winters, if it is planted in a warm situation. The flowers of this kind are generally larger than those of the common yellow sort, but have very little scent, and are not produced so early in the season. It may be propagated by laying down the tender branches, as was directed for the common white sort; or by budding or inarching it upon the common yellow Jasmine; the latter of which is preferable, by making the plants hardier than those which are obtained from layers.

The third sort was formerly more cultivated in the gardens than at present, for as the flowers have no scent, so few persons regard them. This hath weak angular branches, which require support, and will rise to the height of eight or ten feet, if planted against a wall or pale; but the plants do often produce a great number of suckers from their roots, whereby they become troublesome in the borders of the pleasure-garden; it is easily propagated by suckers or layers.

The fourth sort grows naturally in *India*, and also in the island of *Tobago*, where the woods are full of it; this hath much stronger branches than the common white sort, the leaves are winged, and are composed of three pair of short obtuse lobes, terminated by an odd one, ending in obtuse points; these lobes are placed closer than those of the common *Jasmine*, and are of a lighter green; the flowers come out from the wings of the stalks, standing on long foot-stalks, each sustaining three or four flowers, which are of a blush red on their outside, but white within; the tube of the flower is longer, the segments are obtuse, twisted at the mouth of the tube, and are of a much thicker texture than those of the common sort, so that there is no doubt of its being a distinct species; and the reason for Dr. *Linnaeus's* supposing it to be so was a mistake; for as these plants are generally grafted upon stocks of the common *Jasmine*, so there are always shoots coming out from the stocks below, which, if permitted to stand will produce flowers; and these do often starve and kill the grafts, so that there will be only the common sort left; and this has been the case with some plants which he examined, therefore supposed the difference of the other sort was wholly owing to culture; whereas if he had only observed the difference of their leaves, he would have certainly made two distinct species of them.

This plant is propagated by budding or inarching it upon the common white *Jasmine*, on which it takes very well, and is rendered hardier than those which are upon their own stocks. But those of this kind being brought over from *Italy* every spring in so great plenty, they are seldom raised here: I shall therefore proceed to the management of such plants as are usually brought into *England*, which are generally tied up in small bunches, containing four plants; their roots are wrapped about with Moss to preserve them from drying, which, if it happen that the ship has a long passage, will often occasion them to push out strong shoots from their roots, which must always be taken off before they are planted, otherwise they will exhaust the whole nourishment of the plant, and destroy the graft.

In the making choice of these plants, you should carefully observe if their grafts are alive, and in good health: for if they are brown and shrunk they will not push out, so that there will be only the stock left, which is of the common sort.

When you receive these plants, you must clear the roots of the Moss, and all decayed branches should be taken off; then place their roots into a pot or tub of water, which should be set in the green-house, or some other room, where it may be screened from the cold; in this situation they may continue two days, after which you must prune off all the dry roots, and cut down the branches within four inches of the place where they are grafted, and plant them into pots filled with fresh light earth; then plunge the pots into a moderate hot-bed of tanners bark, observing to water and shade them, as the heat of the season may require. In about three weeks or a month's time they will begin to shoot, when you must carefully rub off all such as are produced from the stock below the graft; they must now have a great share of air to strengthen them, and by degrees they must be hardened to endure the open air, into which they should be removed in *June*, placing them in a warm situation the first summer; for if they are too much

exposed to the winds, they will make but indifferent progress, being rendered tender by the hot-bed. If the summer proves warm, and the trees have succeeded well, they will produce some flowers in the autumn following, though they will be few in number, and not near so strong as they will be the succeeding years, when the trees are stronger and have better roots.

These plants are preserved in green-houses, with Oranges, Myrtles, &c. in the winter season, and require the same treatment: but notwithstanding most people preserve these plants in green-houses, yet they will endure the cold of our ordinary winters in the open air, if planted against a warm wall, and covered with mats in frosty weather, in which situation they will produce ten times as many flowers in one season as those kept in pots, and the flowers will likewise be much larger; but they should not be planted abroad till they have some strength, so that it will be necessary to keep them in pots two or three years; and when they are planted against the wall, which should be in *May*, that they may take good root in the ground before the succeeding winter, you must turn them out of the pots, preserving the earth to their roots, and nail up their shoots to the wall, shortening such of them as are a very long, that they may push out new shoots below to furnish the wall, continuing to nail up all the shoots as they are produced. In the middle, or toward the latter end of *July*, they will begin to flower, and continue to produce new flowers until the frost prevents them.

Toward the middle of *November*, if the nights are frosty, you must begin to cover your trees with mats, which should be nailed over them pretty close; but this should be done when the trees are perfectly dry, otherwise the wet being lodged upon the branches, will often cause a mouldiness upon them, and the air being excluded therefrom, will rot them in a short time: it will also be very necessary to take off these mats when the weather will permit, to prevent this mouldiness, and only keep them close covered in frosty weather; if a little mulch is laid upon the surface of the ground about their roots, and some bands of hay fastened about their stems, to guard them from the frost in very severe weather, it will preserve them: in the spring, as the weather is warmer, so by degrees the covering should be taken off, but they should not be exposed too soon to the open air, for the morning frosts and dry easterly winds, which often reign in *March*, do frequently pinch these plants if they are too early exposed. When the covering is taken off, the trees should be pruned, and cut out all decayed branches, shortening the strong shoots to about two feet long, which will cause them to shoot strong, and produce many flowers.

The fifth sort grows naturally in *India*; this rises with an upright woody stalk eight or ten feet high, covered with a brown bark, sending out several strong branches which want no support, garnished with trifoliate leaves of a lucid green, which are placed alternate on the branches; they are oval and entire, continuing green all the year: the flowers are produced at the end of the shoots in bunches of a bright yellow, and have a most grateful odour. They come out in *July*, *August*, *September*, and *October*, and sometimes continue to the end of *November*; they are frequently succeeded by oblong oval berries, which turn black when ripe, and have each two seeds.

This sort of *Jasmine* is propagated by laying down the tender branches; the shoots should be laid down in *March*, and if they are slit at the joint, as is practised in laying of Carnations, it will promote their rooting: when the weather is dry these layers must be frequently watered, which, if carefully attended to, the plants will be rooted by the succeeding spring, fit to be transplanted, when they must be

planted in pots filled with light earth, and managed as was before directed for the seedling plants.

This sort is frequently propagated, by inarching the young shoots into stocks of the common yellow Jasmine, but the plants so raised do not grow so strong as those which are upon their own stock; besides, the common yellow Jasmine is very apt to send out a great number of suckers from the root, which renders the plants unsightly; and if these suckers are not constantly taken off, as they are produced, they will rob the plants of their nourishment. The cuttings of this plant will also take root, if they are planted in pots in the spring, and plunged into a moderate hot-bed, covering them close with hand-glasses; when these are well rooted, they may be transplanted into separate pots and treated as the layers.

The sixth sort grows naturally in the *Azores*; this hath long slender branches which require support, which may be trained twenty feet high, garnished with trifoliate leaves, whose lobes are large and heart-shaped, of a lucid green, placed opposite on the branches. The flowers are produced at the end of the branches, in loose bunches, which are cut into five segments spreading open; they are of a clear white, and have a very agreeable scent. This the gardeners call the Ivy-leaved Jasmine.

This Jasmine is also pretty hardy, and requires no more shelter than only from hard frosts; and I am apt to think, if this sort was planted against a warm wall, and managed, as hath been directed for the *Catalonian* Jasmine, it would succeed very well; for I remember to have seen some plants of this kind growing against a wall in the gardens in *Hampton-court*, where they had endured the winter, and were in a more flourishing state than ever I saw any of the kind in pots, and produced a greater quantity of flowers. These plants are propagated in the same manner as the yellow *Indian* Jasmine, and both require the same treatment as the *Catalonian*.

The seventh sort was brought from the *Cape of Good Hope* by Capt. *Hutchinson* of the *Godolphin*, who discovered it growing naturally, a few miles up the land from the sea, being drawn to it by the great fragrantcy of its flowers, which he smelt at some distance from the plant, which was then in full flower; and after having viewed the plant, and remarked the place of its growth, he returned thither the following day with proper help, and a tub to put it in, and caused it to be carefully taken up, and planted in the tub with some of the earth on the spot, and conveyed it on board his ship, where it continued flowering great part of the voyage to *England*, where it arrived in good health; and for some years continued flowering, in the curious garden of *Richard Warner*, Esq; at *Woodford* in *Essex*, who was so obliging as to favour me with branches of this curious plant in flower, to embellish one of the numbers of my figures of plants, where it is represented in the 180th plate.

This plant seems not to have been known to any of the botanists, for I have not met with any figure or description of it in any of the books; there is one sort which is figured in the *Malabar* garden, and also in *Burman's* plants of *Ceylon*, which approaches near this; it is titled, *Nandi ervatum major*. *Hort. Mal.* But it differs from this in having longer and narrower leaves, the tube of the flower is larger, and the segments do not spread so open as this; but it is surprising that this plant should be unknown to the people at the *Cape of Good Hope*, for there was not one plant of it in their curious garden, nor could the captain see any other plant of it but that which he brought away.

The stem of this plant is large and woody, sending out many branches, which are first green, but afterward the bark becomes gray, and is smooth; the branches come out

by pairs, and have short joints; the leaves, which are of a thick consistence, are also set by pairs close to the branches; they are five inches long, and two inches and a half broad in the middle, lessening to both ends, terminating in a point, of a lucid green, having several tranverse veins from the midrib to the borders, which are entire. The flowers are produced at the end of the branches, sitting close to the leaves, one upon each foot-stalk; they have a tubulous empalement, with five corners or angles, cut deep at the brim, into five long narrow segments, ending in very acute points: the flower hath but one petal, for although it is cut into many deep segments at the top, yet these are all joined in one tube below; some of these flowers are much more double than others, having three or four orders of petals. In those flowers which I have examined, where they have been the most double, there has not been more than one stamen; but in some that were less double I have found two and in others three stamina, so that it is impossible to determine the class to which this plant belongs by them, nor indeed can any class of plants be distinguished by double flowers, whose parts of generation vary according as the flowers are more or less full of petals; nor can the genus be determined (as some have ignorantly pretended) by the imperfect germen below the flower, which, when first formed, viewed with glasses which magnify greatly, seemed as if composed of a capsule containing many seeds (which may be the case of many berries with one seed when examined in the like manner by persons who are fond of their own imaginations:). but as I have since received seeds of the single plants of this sort of Jasmine from *Ceylon*, which are berries divided into two seeds like the *Coffee* and *Azorian* Jasmine, which have grown in the *Chelsea* garden; so till these plants have produced flowers, it cannot be determined whether this should be placed in the genus of *Coffee*, or that of *Jasmine*; but to one of them it certainly belongs; and therefore the supposing it to be a new genus, is doing great injury to the science of botany. This plant is easily propagated by cuttings, which, if taken from the young branches, and planted in pots filled with a loamy soil, and plunged into a moderate hot-bed, covering them close down with hand-glasses, will soon put out roots: then they may be transplanted each into a separate small pot, filled with the like loamy earth, and plunged again into the hot-bed, to forward their putting out new roots. When these young plants have obtained strength, they may be treated hardily; for some plants I have kept under a common frame, where the pots have been plunged into an old bed of tanners bark which had no heat, others I have kept through the winter in a glass-case without any artificial heat, both which have succeeded, and the plants have flowered very well, and they have been more vigorous than those which were treated tenderly. This flower, when fully blown, is as large as a middling *Rose*, and some of them are as double as the *Damask Rose*, having a very agreeable odour; on the first approach it is something like that of the *Orange-flower*, but when more closely smelt to, has the odour of the common double white *Narcissus*. The season of this plant flowering in *England*, is in *July* and *August*, but in its native country it is supposed to flower great part of the year; for Capt. *Hutchinson*, who brought the plant over, said there was a succession of flowers on it, till the ship arrived in a cold climate, which put a stop to its growth.

JASMINUM ARABICUM. See *Coffee* and *Nyctanthes*.

JASMINUM ILICIS FOLIO. See *Lautana*.

JASMINE, the *Persian*. See *Syringa*.

JATROPHA. *Lin. Gen. Plant.* 961. *Cassada*, or *Cassava*.

The Characters are,

It hath male and female flowers in the same plant; the male flowers are salver-shaped of one petal, whose brim is cut into five roundish

roundish segments which spread open; they have ten awl-shaped stamina, five being alternately shorter than the other. The female flowers, which are situated in the same umbel, have five petals spread open like a Rose. In the center is a roundish germen with three deep furrows, which afterward becomes a roundish capsule with three cells, each containing one seed.

The Species are,

1. *JATROPHA foliis palmatis, lobis lanceolatis integerrimis lævibus.* Lin. Sp. Plant. 1007. Jatropha with hand-shaped leaves, whose lobes are spear-shaped, entire, and smooth; or Cassava of John Bauhin.

2. *JATROPHA foliis quinquelobatis, lobis acuminatis, acutè dentatis lævibus, caule fruticoso.* Jatropha with leaves composed of five smooth lobes ending in points, which are sharply indented on their edges, and a shrubby stalk.

3. *JATROPHA aculeata, foliis quinquelobatis acutè incis, caule herbaceo.* Prickly Jatropha with leaves having five lobes which are sharply cut on their edges, and an herbaceous stalk.

4. *JATROPHA aculeata, foliis trilobis, caule herbaceo.* Lin. Sp. Plant. 1007. Prickly Jatropha with leaves having three lobes, and an herbaceous stalk.

5. *JATROPHA foliis palmatis dentatis aculeatis.* Hort. Cliff. 445. Jatropha with hand-shaped, indented, prickly leaves.

6. *JATROPHA foliis multipartitis lævibus, stipulis setaceis multifidis.* Hort. Cliff. 445. Jatropha with leaves divided into many parts, and bristly stipulæ with many points; commonly called French Physick Nut in America.

7. *JATROPHA foliis cordatis angulatis.* Hort. Cliff. 445. Jatropha with angular heart-shaped leaves; commonly called Physick Nut in America.

8. *JATROPHA foliis quinquepartitis, lobis ovatis integris, setis glandulosis ramosis.* Flor. Leyd. Prod. 202. Jatropha with leaves divided into five parts, the lobes whereof are oval and entire, and branching bristles arising from the glands; commonly called Belly-ach Weed in America.

The first sort here mentioned, is the common Cassava or Cassava, which is cultivated for food in the warm parts of America, where, after the juice is expressed out of the root (which has a poisonous quality) it is ground into a kind of flour, and made up in cakes or puddings, and is esteemed a wholesome food.

This rises with a shrubby stalk six or seven feet high, garnished with smooth leaves, composed of seven lobes, which are joined at their base in one center, where they are narrow, but increase in their breadth till within an inch and a half of the top, where they diminish to an acute point. The flowers are produced in umbels at the top of the stalks, these are some male and others female, composed of five roundish petals which spread open; the male flowers have ten stamina joined together in a column, and the female flowers have a roundish germen with three furrows in the center, supporting three styles, crowned by single stigmas. The germen afterward turns to a roundish capsule with three lobes, each having a distinct cell, containing one seed.

The second sort was discovered by the late Dr. Housoun, at the Havana: this rises with an upright stalk ten or twelve feet high, which is first green and herbaceous, but afterward becomes ligneous, sending out a few branches at top, which are garnished with smooth leaves composed of five oval lobes, which end in acute points; the edges are indented in several irregular acute points. The flowers are produced in an umbel at the extremity of the stalks, of an herbaceous white colour, and are male and female in the same umbel, as the other sort; the capsule is smooth and has three cells, each including a single seed.

The third sort was discovered by the late Dr. Housoun, growing naturally about the town of La Vera Cruz: this hath a very thick fleshy root, in shape like the white Spanish Ra-

dish; the stalk rises from one to two feet high, it is taper, herbaceous, and branching, closely armed on every side with long white spines, which are pungent and stinging; the leaves are divided into five lobes, which are deeply jagged and waved on their edges; all the veins of the leaves are closely armed with stinging spines, so that it is dangerous handling them. At the end of the branches, the flowers are produced in umbels; they are white, and have empalements closely armed with the same spines as the stalks and leaves: there are male and female flowers in the same umbel, the female flowers are succeeded by tricapsular vessels, containing three seeds.

The fourth sort rises with an herbaceous stalk about a foot high, dividing into two or three branches, garnished with leaves standing alternate upon long foot-stalks, composed of three oblong lobes which are slightly sinuated on their edges, ending in acute points; the whole plant is closely armed with stinging spines. The flowers are small and grow in an umbel at the end of the branches, of a dirty white colour, male and female in the same umbel: the female flowers are succeeded by oval capsules with three lobes; which are covered with the same spines as the plant, and have three cells, each containing a single seed. This plant is annual.

The fifth sort grows naturally at Carthage in New Spain; this hath a thick, swelling, fleshy root, from which arises an herbaceous stalk as big as a man's thumb; which is four or five feet high, divided into several branches, closely armed with long brown spines; the leaves are deeply cut into five lobes, which are jagged deeply on their sides, and the nerves are armed with stinging spines; the flowers are produced in umbels at the top of the branches, standing upon long naked foot-stalks, of a pure white colour, and are male and female in the same umbel: the male flowers appear first, which are composed of five petals, forming a short tube at bottom, and the stamina arise the length of the tube, joined in a column: the petals spread open flat above, and the stamina fill the mouth of the tube, shutting it up: the female flowers are smaller, but of the same shape, having no stamina, but an oval three-cornered germen, which afterward becomes a capsule with three lobes, each having a distinct cell, with one seed inclosed.

The sixth sort is now very common in most of the islands in the West-Indies, but was introduced from the continent, first into the French islands, and from thence it was brought into the British islands, where it is titled French Physick Nut, to distinguish it from the following sort, which is called Physick Nut from its purging quality.

This rises with a soft thick stem eight or ten feet high, dividing into several branches covered with a grayish bark. The leaves come out on strong foot-stalks, they are divided into nine or ten lobes in form of a hand, which are joined at their base, with many jagged points on their borders standing opposite. The upper side of the leaves are of a lucid green, but their under-side gray, and a little cottony. The flowers come out upon long foot-stalks from the end of the branches, formed into an umbel, in which there are male and female flowers, as in the other species; these umbels are large, and the flowers being of a bright scarlet, make a fine appearance; the leaves being also very remarkable for their beauty, has occasioned the plant being cultivated for ornament in most of the islands of the West-Indies.

The seventh sort grows naturally in all the islands of the West-Indies; this rises with a strong stalk twelve or fourteen feet high, divided into several branches; garnished with angular heart-shaped leaves, which end in acute points. The flowers come out in umbels at the end of the branches; they are male and female, of an herbaceous colour, so make but little appearance; the female flowers are succeeded by ob-

long oval capsules with three cells, each containing one oblong black seed.

The seeds of the two last sorts have been used as a purgative by the inhabitants of the *West-Indies*, but they operate so violently, that now they are seldom used; three or four of these nuts have worked upward and downward near forty times, on a person who was ignorant of their effects; but it is affirmed that this purgative quality is contained in a thin film, situated in the center of the nut, which, if taken out, the nuts are harmless, and may be eaten with safety.

The eighth sort grows naturally in all the islands of the *West-Indies*, where it is sometimes called wild Cassava, or Cassava, and at others Belly-ach Weed, the leaves of this plant being accounted a good remedy for the dry belly-ach. This plant rises with a soft herbaceous stalk to the height of three or four feet, covered with a purple bark, the joints having branching bristly hairs, rising in small bunches, not only upon the principal stalk, but also on the branches, and the foot-stalks of the leaves. The stalk divides upward into two or three branches, garnished with leaves standing on very long foot-stalks, which are divided into five oval entire lobes, ending in acute points. The flowers are produced at the end of the branches, upon slender naked foot-stalks, in small umbels; they are of a dark purple colour, having male and female flowers in the same umbel; the female flowers are succeeded by oblong, smooth, tricapsular vessels, in each of the cells is lodged one seed.

All these plants are natives of the warm parts of *America*, so are too tender to thrive in the open air in *England*. The first sort is cultivated in the *West-Indies* for food, where it is propagated by cutting the stalks into lengths of seven or eight inches, which, when planted, put out roots; the method of doing this having been mentioned in various books, I shall not repeat it here.

The other sorts are easily propagated by seeds, which should be sown on a good hot-bed in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot, and plunged into a fresh hot-bed of tanners bark, carefully shading them till they have taken fresh root, after which they must be treated in the same manner as other tender plants from hot countries, admitting fresh air to them daily, in proportion to the warmth of the season; but as many of the sorts have succulent stalks, some of which have a milky juice, they should have but little water given them, for they are soon destroyed by wet.

The fourth sort is an annual plant, so if the seeds are sown early in the spring, and the plants are brought forward, they will perfect their seeds the same year; but the other sorts are perennial, so do not flower till the second or third year, therefore the plants should be plunged into the tan-bed in the stove, where they should constantly remain, giving them a large share of air in warm weather, but in winter they must be tenderly treated, and then must have very little water. With this management the plants will continue several years, and produce their flowers, and frequently perfect their seeds in *England*.

IBERIS. *Dillen. Nov. Gen.* 6. Sciatica Crefs.

The Characters are,

The flower hath an empalement of four oval leaves, which fall away. It hath four unequal petals. It hath six awl-shaped erect stamina, the two on the sides being shorter than the rest. In the center of the tube is situated a round compressed germen, which afterward becomes a roundish compressed vessel, having two cells, each containing one oval seed.

The Species are,

1. *IBERIS frutescens, foliis cuneiformibus obtusis integerrimis.* *Lin. Hort. Cliff.* 330. Shrubby Sciatica Crefs with entire, wedge-shaped, blunt leaves; commonly called Tree Candy Tuft.

2. *IBERIS frutescens foliis linearibus acutis integerrimis.* *Lin. Hort. Cliff.* 330. Shrubby Sciatica Crefs, with narrow, pointed, whole leaves; commonly called perennial Candy Tuft.

3. *IBERIS foliis lanceolatis acuminatis, inferioribus serratis, superioribus integerrimis.* *Lin. Hort. Cliff.* 330. Sciatica Crefs with spear-shaped pointed leaves, the under ones being sawed, but the upper entire; commonly called Candy Tuft.

4. *IBERIS foliis linearibus supernè dilatatis serratis.* *Flor. Leyd.* 330. Sciatica Crefs with narrow leaves dilated at their top, and sawed.

5. *IBERIS foliis sinuatis, caule nudo simplici.* *Lin. Hort. Cliff.* 328. Sciatica Crefs with sinuated leaves, and a single naked stalk; or Rock Crefs.

6. *IBERIS foliis lanceolatis acutis subdentatis, floribus racemosis.* *Lin. Hort. Upsal.* 184. Sciatica Crefs with acute, spear-shaped, indented leaves, and flowers growing in bunches.

7. *IBERIS foliis subrotundis crenatis.* *Royen. Lin. Sp. Plant.* 649. Iberis with roundish crenated leaves.

8. *IBERIS frutescens, foliis linearibus acutis, corymbis hemisphæricis.* Shrubby Sciatica Crefs with narrow acute leaves, and hemispherical bunches of flowers.

The first sort here mentioned is a low shrubby plant, which seldom rises above a foot and a half high, having many slender diffused branches, which fall to the ground if they are not supported. These are well furnished with wedge-shaped leaves toward their extremity, which continue green all the year; in autumn the flowers are produced at the end of the shoots, which are white, and grow in an umbel. These continue long in beauty, and are succeeded by others, so that the plants are rarely destitute of flowers for near eight months, from the end of *October* to the beginning of *June*.

This plant is somewhat tender, therefore is generally preserved in green-houses in winter. But although it is commonly so treated, yet in moderate winters this plant will live in the open air, if it is planted in a warm situation, and on a dry soil; and if, in very hard frost, they are covered either with mats, reeds straw, or Pease haulm, they may be preserved very well, and the plants which grow in the full ground, will thrive better, and produce a greater number of flowers, than those which are kept in pots; but the soil in which these are planted, should not be over rich, nor too wet, for in either of these they will grow too vigorous in summer, so will be in greater danger of suffering by the frost in winter; but when they grow on a gravelly soil, or among lime rubbish, their shoots will be short, strong, and not so replete with moisture, so will better resist the cold.

This plant is propagated by cuttings, which, if planted during any of the summer months, and shaded from the sun, will be rooted in two months, and may afterward be either planted in pots, or into the borders where they are designed to stand.

There is a variety of this with variegated leaves, which is preserved in some of the gardens where persons delight in these striped leaved plants. This is not so hardy as the plain sort, therefore must be treated more tenderly in winter.

The second sort is a plant of humbler growth than the first; this seldom rises more than six inches high, nor do the branches grow woody, but are rather herbaceous; the leaves of this plant continue green through the year, and the flowers are of as long duration as those of the first sort, which renders it valuable. This rarely produces seeds in *England*, but is propagated by slips, which, in summer, easily take root, and the plants may be treated in the same manner as hath been directed for the first sort, but is hardier.

The third sort is a low annual plant, the seeds of which were formerly sown to make edgings for borders in the pleasure-garden, for which purpose all the low annual flowers are very improper, because they do not answer the intent: which is, to prevent the earth of the borders falling into the walks, which these plants never can do; and although they make a pretty appearance during their continuance in flower, which is seldom more than a fortnight or three weeks, yet after their flowers are past, they become very unsightly; therefore all these sorts of flowers should be sown in small patches in the borders of the flower-garden, where, if they are properly mixed with other flowers, they will have a very good effect, and by sowing of them at three or four different seasons, there may be a succession of them continued in flower till autumn.

There are two different varieties of this third sort, one with red, and the other hath white flowers, but the white is not common in the gardens, but the seeds of the sixth sort is generally sold for it, and is seldom distinguished but by those who are skilled in botany; the seeds should be sown thin in patches, and when the plants are grown pretty strong, they should be thinned, leaving but six or eight in each patch to flower; and by thus treating them, they will put out side branches, and flower much stronger, and continue longer in beauty than when they are left closer together; they will require no other culture but to keep them clean from weeds.

The fourth sort seldom grows so large as the third, and the flowers are much smaller, but have an agreeable odour. It grows naturally in *Helvetia*, and is preserved in botanick gardens for variety. It is annual, and requires the same treatment as the third.

The fifth sort grows on sandy and rocky places in several parts of *England*, so is rarely admitted into gardens. The leaves of this are small, and cut to the midrib into many jags; these spread on the ground, and between them arise a naked foot-stalk, two or three inches long, sustaining small umbels of white flowers. This is an annual plant, whose seeds should be sown in autumn, where the plants are designed to remain, and require no other care but to keep them clean from weeds.

The sixth sort is very like the third, but differs in the shape of the leaves. The flowers of this are white, so may be sown to make a variety with the red. It requires the same treatment.

The seventh sort grows naturally on the *Alps*; this is a perennial plant. The lower leaves which rise from the root, are round, fleshy, and crenated on their edges. The stalk rises four or five inches high, garnished with small oblong leaves, which half embrace the stalks with their base. The flowers terminate the stalk in a round compact umbel; they are of a purple colour.

It is propagated by seeds, which should be sown on a shady border in autumn, and when the plants are strong enough to remove, they should be transplanted on a shady border where they are designed to remain, and will require no other care but to keep them clean from weeds.

The eighth sort grows naturally in *Spain* and *Portugal*; this hath a great resemblance of the second, but the stalks do not spread so much; they grow erect, about seven or eight inches high, are ligneous and perennial. The leaves are very narrow, and seldom more than an inch long, standing thinly upon the stalks, having no foot-stalks. The flowers grow in hemispherical umbels on the top of the stalks, and are of a purple colour.

This sort may be propagated by cuttings, which should be treated in the same way as is before directed for the first sort, and some of the plants may be planted on a warm border in a dry soil, where they will endure the cold of our

ordinary winters very well; but it will be proper to have two or three plants in pots, which may be sheltered under a frame in winter, to preserve the kind, if, by severe frost, those in the open air should be destroyed.

IBISCUS. See *Hibiscus*.

ICACO. See *Chrysobalanus*.

ILEX. *Lin. Gen. Plant.* 158. The Holly tree.

The Characters are,

They have male, female, and hermaphrodite flowers on different plants, and often on the same tree. The male flowers have a small permanent empalement of one leaf, indented in four parts; they have but one petal, cut into four segments; they have four awl-shaped stamina. The female flowers have their empalements and petals the same as the male, but have no stamina; in their center is placed the roundish germen, which after-ward becomes a roundish berry with four cells, each containing a single hard seed.

The Species are,

1. ILEX *foliis oblongo-ovatis, undulatis, spinis acutis.* Holly tree with oblong oval leaves which are waved, and have acute spines; the common Holly.

2. ILEX *foliis ovatis, undulatis, marginibus aculeatis, paginis supernè spinosis.* Holly with oval waved leaves, whose borders are armed with strong thorns, and their upper surface prickly; commonly called Hedge hog Holly.

3. ILEX *foliis ovato-lanceolatis serratis.* *Hort. Cliff.* 40. Holly with oval, spear-shaped, sawed leaves; commonly called *Daboon* Holly.

There are several varieties of the common Holly with variegated leaves, which are propagated by the nursery-gardeners for sale, and some years past were in very great esteem, but at present are but little regarded; the old taste of filling gardens with thorn ever-greens being pretty well abolished; however, in the disposition of clumps, or other plantations of ever-green trees and shrubs, a few of the most lively colours may be admitted, which will have a good effect in the winter season, if they are properly disposed. As the different variegations of the leaves of Hollies, are by the nursery-gardeners distinguished by different titles, so I shall here mention the most beautiful of them, by the names they are generally known:

Painted-Lady Holly, *British* Holly, *Bradley's* best Holly, *Phyllis*, or Cream Holly, Milkmaid Holly, *Pritchett's* best Holly, Gold-edged Hedge-hog Holly, *Cheyney's* Holly, Glory of the West Holly, *Broaderick's* Holly, *Partridge's* Holly, *Herefordshire* white Holly, *Blind's* Cream Holly, *Longstaff's* Holly, *Eales's* Holly, Silver-edged Hedge-hog Holly.

All these varieties are propagated, by budding or grafting them upon stocks of the common green Holly: there is also a variety of the common Holly with smooth leaves, but this is frequently found intermixed with the prickly-leaved on the same tree, and often on the same branches: there are both sorts of leaves.

The common Holly grows naturally in woods and forests in many parts of *England*, where it rises from twenty to thirty feet high, and sometimes more, but their ordinary height is not above twenty-five feet: the stem by age becomes large, and is covered with a grayish smooth bark; and those trees which are not lopped or browsed by cattle, are commonly furnished with branches the greatest part of their length, so form a sort of cone; the branches are garnished with oblong oval leaves, of a lucid green on their upper surface, but are pale on their under, having a strong midrib: the edges are indented and waved, with sharp thorns terminating each of the points, so that some of the thorns are raised upward, and others are bent downward, and being very stiff renders them troublesome to handle.

The leaves are placed alternate on every side of the branches, and from the base of their foot-stalks come out the flowers in clusters, standing on very short foot-stalks; each of these sustain five, six, or more flowers. In some plants I have observed the flowers were wholly male, and produced no berries; in others I have observed female and hermaphrodite flowers, but upon some large old trees growing on *Windsor* forest, I have observed all three upon the same trees. The flowers are of a dirty white, and appear in *May*; these are succeeded by roundish berries, which turn to a beautiful red about *Michaelmas*, but continue on the trees, if they are not destroyed, till after *Christmas*, before they fall away.

The second sort grows naturally in *Canada*. The leaves of this sort are not so long as those of the common Holly, and their edges are armed with stronger thorns standing closer together; the upper surface of the leaves is set very close with short prickles, from whence the gardeners have given it the title of Hedge hog Holly. This sort is usually propagated in the nurseries, by budding or grafting it upon the common Holly, but I have raised it from the berries, and found the plants to be the same as those from whence the seeds were taken, so make no doubt of its being a distinct species.

There are two varieties of this with variegated leaves, one of which is yellow, and the other white. There is also a variety of the common Holly with yellow berries, which is also accidental, and is generally found on those plants which have variegated leaves, and but seldom on plain Hollies.

The common Holly is a very beautiful tree in winter, therefore deserves a place in all plantations of ever-green trees and shrubs, where its shining leaves and red berries make a fine variety; and if a few of the best variegated kinds are properly intermixed, they will enliven the scene. The Holly was also formerly planted for hedges, and is a very proper plant for that purpose.

The Holly is propagated by seeds, which never come up the first year, but lie in the ground as the Haws do; therefore the berries should be buried in the ground one year, and then taken up and sown at *Michaelmas* upon a bed exposed only to the morning sun; the following spring the plants will appear, which must be kept clean from weeds; and if the spring should prove dry, it will be of great service to the plants, if they are watered once a week; but they must not have it oftener, nor in too great quantity, for too much moisture is very injurious to these plants when young.

In this seed-bed the plants may remain two years, and then should be transplanted in the autumn, into beds at about six inches asunder, where they may stand two years longer; during which time they must be constantly kept clean from weeds, and if the plants have thriven well, they will be strong enough to transplant where they are designed to remain; for when they are transplanted at that age, there will be less danger of their failing, and they will grow to a larger size, than those which are removed when they are much larger; but if the ground is not ready to receive them at that time, they should be transplanted into a nursery in rows at two feet distance, and one foot asunder in the rows, in which place the plants may remain two years longer; and if they are designed to be grafted or budded with any of the variegated kinds, that should be performed after the plants have grown one year in this nursery; but the plants so budded or grafted, should continue two years after in the nursery, that they may make good shoots before they are removed; though the plain ones should not stand longer than two years in the nursery, because when

they are older they do not transplant so well. The best time for removing Hollies is in the autumn, especially in dry land, but where the soil is cold or moist, they may be transplanted with great safety in the spring; if the plants are not too old, or have not stood long unremoved, for if they have, it is great odds of their growing when removed.

The *Daboon* Holly grows naturally in *Carolina*, of which there are two sorts, one with spear-shaped, the other with linear leaves. This rises with an upright branching stem to the height of eighteen or twenty feet; the bark of the old stems is of a brown colour, but that of the branches or younger stalks is green and smooth, garnished with spear-shaped leaves, which are more than four inches long, and one and a quarter broad in the broadest part, of a light green and thick consistence; the upper part of the leaves are sawed on their edges, each serrature ending in a small sharp spine. The flowers come out in thick clusters from the side of the stalks, they are white, and shaped like those of the common Holly, but are smaller; these are succeeded by small, roundish, red berries in its native country, which make a fine appearance in winter, but they have not as yet perfected fruit in *England*, so far as I can learn.

Dr. *Linnæus* supposes this plant and the ever-green Cassine to be the same, but they are undoubtedly distinct plants; he may probably have been led into this mistake, by receiving seeds of both sorts mixed together from *America*, which I have more than once done; but whoever sees the two plants growing, cannot doubt of their being different.

This sort is tender while young, so requires protection in the winter till the plants are grown strong and woody, when they may be planted in the full ground in a warm situation, where they will endure the cold of our ordinary winters pretty well: but in severe frost they should be protected, otherwise the cold will destroy them.

This is propagated from seeds, in like manner as the common sort; the seeds of it will lie as long in the ground, so the berries should be buried in the ground a year, and then taken up and sown in pots filled with light earth, and placed under a frame in winter; in the spring the pots should be plunged into a hot-bed, which will bring up the plants; these should be preserved in pots while young, and sheltered in winter under a common frame till they have obtained strength, when they may be turned out of the pots and planted in the full ground, in a warm situation.

IMPATIENS. Rivin. Ord. 4. Lin. Gen. Plant. 899. Female Balsamine.

The Characters are,

The flower has a two-leaved small empalement. It hath five petals which are unequal, and shaped like a lip flower. It hath a nectarium in the bottom of the flower, shaped like a hood or cowl, which is oblique to the mouth rising on the outside, whose base ends in a tail or spur, and five short stamina, which are incurved. In the bottom is situated an oval sharp pointed germen, which after-ward becomes a capsule with one cell, opening with an elasticity in five valves which twist spirally, and contain several roundish seeds fixed to a column.

The Species are,

1. IMPATIENS *pedunculis multifloris solitariis, foliis ovatis, geniculis caulinis tumetibus*. Flor. Suec. 722. Impatiens with foot-stalks sustaining many single flowers, oval leaves, and stalks having swelling joints; Yellow Balsamine, or Touch me not.

2. IMPATIENS *pedunculis unifloris aggregatis, foliis lanceolatis, nectariis floris brevioribus*. Hort. Upsal. 276. Impatiens with

with foot-stalks sustaining single flowers, which arise in clusters, spear-shaped leaves, and nectariums which are shorter than the flower; the female Balsamine.

3. *IMPATIENS pedunculis trifloris solitariis, foliis angustolanceolatis*. Flor. Zeyl. 315. Impatiens with three flowers on a foot-stalk, and narrow spear-shaped leaves; upright or female Balsamine of *Ceylon*, with a narrow Peach leaf.

The first sort grows naturally in several parts of *Westmoreland* and *Yorkshire*, but is frequently introduced into gardens by way of curiosity. It is an annual plant, which rises about two or three feet high, with an upright succulent stalk, whose joints are swollen, garnished with oval smooth leaves, which stand alternate on every side the stalk. The flowers come out from the wings of the stalks, upon long slender foot-stalks, which branch into several other smaller, each sustaining one yellow flower, composed of five petals, which in front are shaped like the lip or grinning flowers, but at their base have a long tail like the flowers of *Indian Cress*; these are succeeded by taper pods, which, when ripe, burst open upon being touched, and twist spirally like a screw, casting out the seeds with great elasticity. If the seeds of this plant are permitted to scatter, they generally succeed better than when they are sown; for unless they are sown in the autumn soon after they are ripe, they very rarely grow. The plants require no care but to keep them clean from weeds, and thin them where they are too close. This delights in a shady situation and a moist soil. There is a variety of this with red flowers, which came from *North America*, which only differs in the colour of the flowers, and is equally hardy.

The second sort is the female Balsamine, of which there are several varieties; the common sort has been long an inhabitant in the *English* gardens; of this there is the white, the red, and striped flowered, and likewise the single and double flowering. The common single sort is so hardy as to rise in the full ground, and where the seeds scatter the plants will come up the following spring, but these do not come to flower so early as those which are raised upon a hot bed; however, they generally are stronger plants, and continue much longer in the autumn in flower than the others, so are an ornament to the garden, at such times when there is a greater scarcity of flowers.

There are two varieties, if not distinct species, with double variegated flowers; one of them grows naturally in the *East*, and the other in the *West-Indies*; that which comes from the *East-Indies*, by the title of *Immortal Eagle Flower*, is a most beautiful plant; the flowers are twice the size of those of the common sort, and are very double; they are in some scarlet and white variegated, and purple and white in others; and the plants producing plenty of the flowers, render them very valuable: if the seeds of these are carefully saved, the kinds may always be preserved. I have raised some plants from foreign seeds, whose flowers were so very double as to lose their male parts, so did not produce any seeds.

The seeds of these plants should be sown on a moderate hot-bed in the spring, and when the plants are come up about an inch high, they should be transplanted on another moderate hot-bed at about four inches distance, observing to shade them from the sun till they have taken new root; after which they should have a large share of free air, to prevent their drawing up tall and weak: they will require to be often refreshed with water, but it should not be given to them in too great plenty; for as their stems are very succulent, so they are apt to rot with much moisture. When the plants are grown so large as to touch each other, they should be carefully taken up with balls of earth to their roots, and each planted into a separate pot filled with light rich earth, and plunged into a very moderate hot-bed,

covered with a deep frame, to admit the plants to grow, shading them from the sun until they have taken fresh root; then they should have a large share of air admitted to them, and by degrees hardened, so as to bear the open air, into which part of the plants may be removed in *July*, placing them in a warm sheltered situation, where, if the season proves favourable, they will flower and make a fine appearance; but it will be proper to keep part of the plants either in a glass-case or a deep frame, in order to get good seeds, because those in the open air will not ripen their seeds unless the summer proves very warm; and the plants in shelter must have a good share of free air every day, otherwise they will grow pale and sickly; nor should they have too much of the sun in the middle of the day, in very hot weather, for that occasions their leaves hanging, and their requiring water, which is often very hurtful; therefore if the glasses are shaded in the middle of the day for three or four hours, the plants will thrive better, and continue longer in beauty than when they are exposed to the great heat. Those who are curious to preserve these plants in perfection, pull off all the single and plain coloured flowers from the plants which they preserve for seeds, leaving only those flowers which are double and of good colours; where this is carefully done, they may be continued without the least degeneracy.

The sort which grows in the *West-Indies*, is there called *Cockspur*. This hath single or semi-double flowers, which are as large as the last mentioned sort, but I never saw any of them more than half double, and only with white and red stripes: the plants are apt to grow to a very large size before they produce any flowers, so that it is late in the autumn before they begin to flower, and sometimes in bad seasons they will scarce have any flowers, and but rarely ripen their seeds here, so that few persons care to cultivate this sort, especially if they can have the other.

The third sort here mentioned grows naturally in *Ceylon*, and in many parts of *India*. This hath very narrow spear-shaped leaves, which are sawed on their edges; the foot-stalks sustain each three flowers, which are smaller than those of the common sort, so are not worthy of a place in gardens, except for the sake of variety. This is a tender plant, and requires the same treatment as the *Immortal Eagle Flower*.

IMPERATORIA. *Lin. Gen. Plant.* 321. *Masterwort*.

The *Characters* are,

It hath an umbellated flower; the principal umbel is plain, and has no involucre, but the small ones have. The principal umbel is uniform; the flowers have five heart-shaped inflexed petals. They have five hairy stamina. The germen is situated under the petals, which after-ward becomes a roundish compressed fruit divided in two parts, containing two oval bordered seeds.

We have but one *Species* of this genus, *viz.*

IMPERATORIA. *Hort. Cliff.* 103. *Masterwort*.

This plant grows naturally on the *Austrian* and *Styrian Alps*, and other mountainous places in *Italy*; the root is as thick as a man's thumb, running obliquely in the ground; it is fleshy, aromack, and has a strong acrid taste, biting the tongue and mouth like *Pellitory of Spain*; the leaves arise immediately from the root; they have long foot-stalks, dividing into three very short ones at the top, each sustaining a trilobate leaf, indented on the border; the foot-stalks are deeply channelled, and when broken emit a rank odour. The flower-stalks rise about two feet high, divided into two or three branches, each being terminated by a pretty large umbel of white flowers, whose petals are split; these are succeeded by oval compressed seeds, somewhat like those of *Dill*, but larger.

This plant is cultivated in gardens to supply the markets. It may be propagated either by seeds, or by parting the

roots; if it is propagated by seeds, they should be sown in autumn soon after they are ripe, on a bed or border, in a shady situation. In the spring the plants will appear, when they should be carefully weeded. Toward the beginning of May, if the plants come up too close together, they should be thinned, leaving them about six inches asunder, planting those which are drawn up into another bed about the same distance apart every way, being careful to water them duly, if the season should prove dry, until they have taken root; after which time these plants (as also those remaining in the seed-beds) will require no other culture but to keep them clear from weeds till the following autumn, when the plants should be transplanted where they are designed to remain, which should be in a rich moist soil, and a shady situation, for they delight in shade and moisture; so that where these are wanting, the plants will require a constant supply of water in dry weather. The distance which these plants should be placed, must not be less than two feet every way, for where they like their situation they will spread and increase much. When these plants are rooted, they will require no other culture, but to keep them clear from weeds; and in the spring before they shoot, the ground should be every year gently dug between the plants; in doing of which, great care should be had not to cut or bruise their roots. These plants, with this management, will continue several years, and will produce seeds in plenty.

If these plants are propagated by offsets, their roots should be parted at *Michaelmas*, and planted in a shady situation, at the same distance as has been directed for the seedling plants.

The roots of this plant are used in medicine, and are greatly recommended for their virtue in contagious distempers or the bites of venomous creatures; they are alexipharmick and sudrifick; by some they are recommended for cholicks and asthmas, for the cramp, and all cold diseases of the nerves.

INARCHING is a method of grafting, which is commonly called *grafting by approach*. This method of grafting is used, when the stock intended to graft on, and the tree from which the graft is to be taken, stand so near (or can be brought so near) that they may be joined together. The method of performing it is as follows: Take the branch you would inarch, and having fitted it to that part of the stock where you intend to join it, pare away the rind and wood on one side about three inches in length. After the same manner cut the stock or branch in the place where the graft is to be united, so that the rind of both may join equally together, that the sap may meet; then cut a little tongue upwards in the graft, and make a slit in the stock downward to admit it; so that when they are joined, the tongue will prevent their slipping, and the graft will more closely unite with the stock. Having thus placed them exactly together, they must be tied with some bass, or other soft bandage; then cover the place with grafting clay, to prevent the air from entering to dry the wound, or the wet from getting in to rot the stock: you should also fix a stake into the ground to which that part of the stock, as also the graft, should be fastened, to prevent the wind from breaking them asunder, which is often the case when this precaution is not observed.

In this manner they are to remain about four months, in which time they will be sufficiently united, and the graft may then be cut from the mother tree, observing to slope it off close to the stock; and if at this time you cover the joined parts with fresh grafting clay, it will be of great service to the graft.

INDIGO. See Anil.

INGA. Plum. Nov. Gen. 13. tab. 19.

The Characters are,

The flower has a permanent empalement, divided into five parts.

at the top. It hath one funnel-shaped petal, cut into five fringed segments at the brim, out of which arise a great number of stamina, which are three times the length of the tube. At the bottom of the tube is situated an oblong germen, which afterward becomes a fleshy pod, including several irregular seeds.

The Species are,

1. *INGA foliis pinnatis, petiolo articulato marginato, leguminibus latis carnosis & undulatis.* Inga with winged leaves, whose foot-stalk is bordered and jointed, and broad, fleshy, waved pods.

2. *INGA foliis pinnatis, petiolo articulato marginato leguminibus tenuissimis lanuginosis.* Inga with winged leaves, whose foot-stalk is jointed and bordered, and very narrow woolly pods.

The first sort grows naturally on the north side of the island of *Jamaica*, and on the *Spanish main*. This rises with a woody stalk fifteen or sixteen feet high, covered with a white bark, sending out many crooked irregular branches, which hang to the ground, garnished with winged leaves, composed of three or four pair of oblong oval lobes, placed opposite on a midrib, which has a border or wing on each side between the lobes, of a lucid green on their upper side. The flowers come out in spikes toward the end of the branches, each standing in a distinct empalement, divided into five segments at the top, having a great number of very long purple stamina; the flowers are succeeded by long fleshy pods three quarters of an inch broad, filled with a sweet pulp, in which the seeds are lodged; this pulp is frequently eaten by the negroes.

The second sort grows plentifully at *La Vera Cruz*. This seldom rises more than eight or ten feet high, the branches are covered with a brown down, as are the under side of the leaves; the lobes are not so obtuse as those of the other sort. The flowers come out from the wings of the branches in small spikes; they are of a purplish colour within, but of an herbaceous colour without, with long purple stamina, and are succeeded by long, narrow, downy pods, containing several irregular seeds.

These plants are propagated by seeds, which should be sown early in the spring in pots, and plunged into a hot-bed of tanners bark. When the plants are come up two inches high, they should be carefully transplanted into separate pots, and plunged into the hot-bed again, being careful to shade them from the sun until they have taken new root; after which time they must be treated in the same way as other tender exotick plants during the summer. At *Michaelmas* they must be removed into the stove, and plunged into the tan in the warmest part of the bed. During the winter season they must be kept very warm, and have but little water in cold weather; in the summer they will require to be oftener watered, and in hot weather they should have a large share of fresh air; but they must not be removed out of the stove, for they are too tender to endure the open air of this country, in the warmest part of the year.

INOCULATING, or Budding. This is commonly practised upon all sorts of stone fruit in particular, such as Peaches, Nectarines, Cherries, Plums, &c. as also upon Oranges and Jasmines, and is preferable to any sort of grafting for most sorts of tender fruit. The method of performing it is as follows: You must be provided with a sharp penknife, having a flat haft (the use of which is to raise the bark of the stock to admit the bud) and some sound bass mat, which should be soaked in water to increase its strength, and make it more pliable; then having taken off the cuttings from the trees you would propagate, you should choose a smooth part of the stock about five or six inches above the surface of the ground, if designed for dwarfs, but if for standards they should be budded six feet above ground; then with your knife make an horizontal cut cross the rind

of the stock, and from the middle of that cut make a slit downwards about two inches in length, so that it may be in the form of a T; but you must be careful not to cut too deep, lest you wound the stock: then having cut off the leaf from the bud, leaving the foot-stalk remaining, you should make a cross cut about half an inch below the eye, and with your knife slit off the bud, with part of the wood to it, in form of an escutcheon: this done, you must with your knife pull off that part of the wood which was taken with the bud, observing whether the eye of the bud be left to it, or not (for all those buds which lose their eyes in stripping, should be thrown away, being good for nothing :) then having gently raised the bark of the stock where the cross incision was made, with the flat haft of your penknife cleave the bark to the wood, and thrust the bud therein, observing to place it smooth between the rind and the wood of the stock, cutting off any part of the rind belonging to the bud, which may be too long for the slit made in the stock; and so having exactly fitted the bud to the stock, you must tie them closely round with bass mat, beginning at the under part of the slit, and so proceed to the top, taking care that you do not bind round the eye of the bud, which should be left open.

When your buds have been inoculated three weeks or a month, you will see which of them have taken; those of them which appear shrivelled and black being dead, but those which remain fresh and plump, you may depend are joined; at this time you should loosen the bandage, which, if not done in time, will pinch the stock, and greatly injure, if not destroy, the bud.

The *March* following you must cut off the stock about three inches above the bud, sloping it that the wet may pass off, and not enter the stock; to this part of the stock left above the bud, it is very proper to fasten the shoot which the bud makes in summer, to secure it from being blown out; but this part of the stock must continue on no longer than one year, after which it must be cut off close above the bud, that the stock may be covered thereby.

The time for inoculating is, from the middle of *June* until the middle of *August*, according to the forwardness of the season, and the particular sorts of trees to be increased; which may be easily known, by trying the buds whether they will come off well from the wood. But the most general rule is, when you observe the buds formed at the extremity of the same year's shoots, which is a sign of their having finished their spring growth.

INTYBUS. See Cichorium.

INULA. *Lin. Gen. Plant.* 860. Elecampane.

The Characters are,

It hath a radiated compound flower, with an imbricated empalement. The disk, or middle of the flower, is composed of hermaphrodite florets; the border, or ray of female half florets, stretched out like a tongue. The hermaphrodite florets are funnel-shaped, and cut into five parts at the top; these have five short slender stamina, which coalesce at the top; they have one long germen, crowned with down. The female half florets have narrow, entire, tongue-shaped petals, no stamina, but a long crowned germen with a hairy style. The germen in both flowers become a single, narrow, four-cornered seed, crowned with a down, sitting on a naked receptacle.

The Species are,

1. INULA foliis ovatis, rugosis, subtus tomentosus, calycum squamis ovatis. *Aman. Acad.* 1. p. 410. Elecampane with oval rough leaves, woolly on their under side, and the scales of the empalement oval; called Elecampane.

2. INULA foliis dentatis hirsutis, radicalibus ovatis, caulinis lanceolatis amplexicaulibus, caule paucifloro. *Lin. Sp. Plant.* 881. Inula with hairy indented leaves, those at the bottom oval, but the upper are spear-shaped, embracing the stalks, with few flowers.

3. INULA foliis lanceolatis recurvis serrato ciliatis, floribus solitariis, ramis angulatis. *Aman. Acad.* 1. p. 410. Inula with spear-shaped recurved leaves, which are sawed, hairy flowers growing singly, and angular branches.

4. INULA foliis lanceolatis recurvis, subdentatis, scabris, floribus subfasciculatis. *Lin. Sp. Plant.* 883. Inula with spear-shaped recurved leaves, which are rough and indented, and flowers growing in clusters.

5. INULA foliis linearibus carnosus tricuspidatis. *Lin. Sp. Plant.* 883. Inula with narrow fleshy leaves ending in three points; called Golden Samphire.

6. INULA foliis lanceolatis pubescentibus integerrimis, caule unifloro. *Lin. Sp. Plant.* 884. Inula with soft, hairy, spear-shaped, entire leaves, and one flower on a stalk.

7. INULA foliis oblongis, integris, hirsutis, caule piloso, corymbofo, floribus confertis. *Lin. Sp. Plant.* 881. Inula with oblong, entire, rough leaves, a hairy stalk divided by a corymbus, and flowers growing in clusters.

8. INULA foliis lanceolatis, serratis, subamplexicaulibus, subtus villosis, caule ramosa erecto. *Lin. Sp. Plant.* 882. Inula with spear-shaped sawed leaves embracing the stalk, hairy on their under side, and an erect branching stalk.

9. INULA foliis lanceolatis semiamplexicaulibus hispida, caulibus subunifloris teretibus. *Lin. Sp. Plant.* 883. Inula with spear-shaped prickly leaves half embracing the stalk, which is taper, and has but one flower.

10. INULA foliis ovatis, hirsutis, semiamplexicaulibus, caule ramoso piloso, squamis calycinis lanceolatis. Inula with oval hairy leaves half embracing the stalk, which is branching and hairy, and spear-shaped scales to the empalement.

11. INULA foliis ovato-lanceolatis denticulatis sessilibus, caule piloso erecto corymbofo. Inula with oval, spear-shaped, indented leaves, fitting close to the stalk, and an upright hairy stalk, terminating in a corymbus.

12. INULA foliis linearibus carnosus tricuspidatis, caule fruticoso. Inula with narrow, fleshy, three-pointed leaves, and a shrubby stalk.

13. INULA caule erecto hispido, foliis lanceolatis asperis, floribus alaribus solitariis sessilibus, terminalibus umbellatis. Inula with an erect prickly stalk, spear-shaped rough leaves, flowers proceeding singly from the sides of the stalks, fitting close, and terminating in an umbel.

The first sort grows naturally in several parts of *England*, but it is cultivated in gardens for the roots, which are used in medicine, and are accounted carminative, sudorifick, and alexipharmick, of great service in shortness of breath, coughs, stuffing of the lungs, and infectious distempers.

It hath a perennial root, which is thick, branching, and of a strong odour. The lower leaves are eight or nine inches long, and four broad in the middle, rough on their upper side, but downy on their under. The stalks rise about four feet high, and divide toward the top into several smaller branches, garnished with oblong oval leaves, indented on their edges, ending in acute points. The flowers terminate the stalks, each branch ending with one large, yellow, radiated flower, sitting in a scaly empalement, whose scales are oval, and placed like scales on fishes over each other. The flowers are succeeded by narrow four-cornered seeds crowned with down.

This sort may be propagated by seeds, which should be sown in autumn, soon after they are ripe, for if they are kept till the spring they seldom grow; but where they are permitted to scatter, the plants will come up the following spring without any care, and may be either transplanted the following autumn, or if they are designed to remain they should be hoed out to the distance of ten inches, or a foot each way, and constantly kept clean from weeds; these roots will be fit for use the second year.

But most people propagate this by offsets, which, if taken from the old roots, with a bud or eye to each, will take root very easily; the best time for this is the autumn, as soon as the leaves begin to decay; these should be planted in rows about a foot asunder, and nine or ten inches distance in the rows; the spring following the ground must be kept clean from weeds, and if in autumn it is slightly dug, it will promote the growth of the roots, which will be fit for use after two years growth; the young roots are preferable to those which are old and stringy. It loves a gentle loamy soil, not too dry.

The second sort hath a perennial root, from which arise several stalks about two feet high. The leaves at bottom are oval, indented, and hairy; those above embrace the stalks with their base. The stalks are divided into several branches, garnished with a few scattering yellow flowers. The root has a very sweet odour when broken.

The third sort hath a perennial root, from which arises many spear-shaped, smooth, recurved leaves. The stalks are angular and rise near two feet high, branching at the top into several foot-stalks, each sustaining one yellow radiated flower.

The fourth sort rises with an upright stalk, between three and four feet high, with spear-shaped leaves, which turn backward, indented on their edges, and rough on their upper side. The flowers are collected in close bunches on the upper part of the stalks; they are small and yellow. It grows on the *Alps*, and other mountainous parts of *Europe*.

The fifth sort grows naturally on the sea coasts in many parts of *England*. This rises with an upright stalk a foot and a half high, garnished with fleshy succulent leaves, which come out in clusters. The flowers are yellow, and come out at the top of the stalks in small umbels. The young branches of this plant are frequently sold in the *London* markets for *Samphire*, but this is a great abuse, because this plant has none of the warm aromack taste of the true *Samphire*.

The sixth sort grows naturally in *Germany*. This rises with upright stalks a foot and a half high, garnished with spear-shaped leaves, covered with soft hairs. The stalks do each support one large yellow flower.

The seventh sort has a perennial root. This grows naturally in *Hungary*. The leaves are oblong and hairy. The stalks branch at the top in form of a corymbus. The flowers are small, yellow, and in close clusters.

The eighth sort grows naturally in *Austria*, *Bohemia*, and other parts of *Germany*. This hath a perennial root; the stalk rises two feet high, garnished with spear-shaped woolly leaves, which closely embrace the stalks with their base. The upper part of the stalk divides into two or three erect branches, or foot-stalks, each sustaining one pretty large, deep yellow flower.

The ninth sort grows naturally in the south of *France*, *Spain*, and *Italy*. This hath a perennial root, from whence arise several stalks about one foot high; the lower leaves are spear-shaped and prickly, the upper embrace the stalks, which divide into several branches, each being terminated by one yellow flower.

The tenth sort hath a perennial root; the stalk rises about a foot high, dividing into many branches, garnished by oval hairy leaves, which half embrace the stalks with their base; each of the branches is terminated by one large yellow flower, whose empalement is composed of oval scales.

The eleventh sort grows naturally in *Hungary*. This rises with single upright stalks two feet high, garnished with oval spear-shaped leaves, slightly indented on the edges, which sit close to the stalks, and divide in form of a corymbus at the top. The flowers are pretty large, and of a pale yellow colour.

The twelfth sort grows naturally in the *Canary Islands*. This hath several shrubby stalks near four feet high, which divide into smaller branches, garnished with clusters of narrow fleshy leaves, divided into three parts at their points. The flowers come out on the top of the stalks; they are small, and of a pale yellow colour.

The second, third, fourth, sixth, seventh, eighth, ninth, tenth, and eleventh sorts, are abiding plants, which will thrive and flower in the open air in *England*; they may be all propagated by parting of their roots. The best time for doing of this is in autumn, when the plants should be removed; these may be intermixed with other flowering plants in the borders of large gardens, where they will make an agreeable variety during their continuance in flower. As these roots multiply pretty fast, they should be allowed room to spread, therefore should not be planted nearer than two feet from other plants; and if they are removed every third year, it will be often enough, provided the ground between them be dug every winter, and in summer, if they are kept clean from weeds, they will require no other care.

The twelfth sort will not live abroad in the open air in *England*, during the winter season, so must be removed into shelter in autumn, but should have as much free air as possible at all times, when the weather is mild, otherwise it is apt to draw up weak. This is easily propagated by cuttings any time in summer, which, if planted in a shady border, will take root in a short time.

The thirteenth sort was sent me from *Maryland*, where it grows naturally. This rises with a strong stalk about a foot and a half high, closely set with prickly hairs, and garnished with rough spear-shaped leaves; toward the upper part of the stalk there are single flowers coming from the wings at each joint, and the stalk is terminated by a cluster of small yellow flowers, disposed in form of an umbel.

JOHNSONIA. Dale.

The Characters are,

The flower hath an empalement of one leaf, cut at the brim into short segments. It hath one tubulous petal, divided into four parts at the brim, and four slender stamina, which are longer than the petal. In the center is situated a roundish germen, which afterward becomes a smooth globular berry, inclosing four hard oblong seeds.

We have but one Species of this genus, viz:

JOHNSONIA floribus verticillatis sessilibus, foliis ovato-lanceolatis oppositis, caule fruticoso. Dale. Shrubby Johnsonia with oval spear-shaped leaves sitting close to the stalks, placed opposite, and flowers growing in whorls.

This shrub grows plentifully in the woods near *Charleston* in *South Carolina*. It rises from four to six feet high, sending out many branches from the side, which are woolly when young, like those of the *Wayfaring tree*, garnished with oval spear-shaped leaves, placed opposite, standing on pretty long foot-stalks. The flowers come out in whorls round the stalks, sitting very close to the branches; they are small, tubulous, cut into four obtuse segments at the top, which expand, and are of a deep purple colour; these are succeeded by soft succulent berries, which turn first to a bright red colour, but afterward change to a deep purple when ripe, and inclose four hard oblong seeds.

The seeds of this plant were sent by Mr. *Catesby*, from *Carolina*, in 1724, and many of the plants were then raised in several curious gardens in *England*; most, if not all, of them were afterward planted in the open air, where they flourished very well for several years, and several of the plants produced flowers for some years, but were killed in the severe frost 1740; but the young plants which were raised from Dr. Dale's seeds the year before, which were only sheltered under a frame, were saved.

This plant rises easily from seeds, if they are sown in a moderate hot-bed; the best way is to sow the seeds in pots, and plunge them into a tan-bed, and when the plants come up, and have obtained some strength, they should be gradually inured to the open air, into which they should be removed in *June*, and placed in a sheltered situation, where they may remain till autumn. These young plants should be placed under a frame before the early frost comes on, for a small frost in autumn will kill the tender part of their shoots, which often causes their stalks to decay most part of their length before the spring. During the winter season they should be screened from frost, but in mild weather they must enjoy the free air. The following spring, just before the plants shoot, they should be carefully turned out of the pots, so as not to break their roots; and part of them may be planted in small pots, and the others into a nursery-bed in a warm situation, at about four or five inches asunder; those in the pots should be plunged into a moderate hot-bed, which will forward their taking fresh root, but afterward must be hardened to bear the open air as before; these plants in pots should be sheltered under a frame in winter three or four years, till they have obtained strength, then they may be turned out of the pots, and planted in a warm situation, where they will live in the open air in common winters, but in severe frost they are in danger of being killed, if they are not sheltered.

Those plants in the beds should also be covered with mats, or straw, in frosty weather, and after they have obtained strength, they may be transplanted into a warm situation, as the other.

JONQUIL. See Narcissus.

IPOMOEA. *Lin. Gen. Plant.* 199. Quamoclit, or Scarlet Convolvulus.

The Characters are,

The flower hath a small permanent empalment, cut into five parts at the top. The petal is funnel-shaped, having a long cylindrical tube, whose brim is five-pointed, spreading open flat. It hath five awl-shaped stamina. In the bottom of the tube is situated a round germen, which afterward becomes a roundish capsule with three cells, inclosing three oblong seeds.

The Species are,

1. IPOMOEA foliis pinnatifidis linearibus, floribus solitariis. *Hort. Cliff.* 60. Ipomoea with very narrow many-pointed leaves, and solitary flowers.

2. IPOMOEA foliis cordatis acuminatis, basi angulatis, pedunculis multifloris. *Hort. Upsal.* 39. Ipomoea with heart-shaped pointed leaves, angular at the base, and many flowers on a stalk; commonly called Scarlet Convolvulus.

3. IPOMOEA foliis cordatis acutis integerrimis, floribus solitariis. *Prod. Leyd.* 430. Ipomoea with acute, heart-shaped, entire leaves, and solitary flowers.

4. IPOMOEA foliis cordatis integerrimis, floribus confertis, corollis indivisis. *Sauv. Monsp.* 114. Ipomoea with heart-shaped entire leaves; flowers growing in clusters, and undivided petals.

5. IPOMOEA foliis palmatis, lobis septenis lanceolatis integerrimis. *Hort. Upsal.* 39. Ipomoea with hand-shaped leaves, composed of seven spear-shaped entire lobes; called Spanish Harbour Vine.

6. IPOMOEA foliis trilobis cordatis, pedunculis trifloris. *Lin. Sp. Plant.* 161. Ipomoea with heart-shaped leaves having three lobes; and three flowers on a foot-stalk.

7. IPOMOEA foliis palmatis, floribus aggregatis. *Flor. Zeyl.* 79. Ipomoea with hand-shaped leaves, and flowers growing in clusters; called Tyger's Foot.

8. IPOMOEA foliis digitatis glabris, foliolis sessilibus, caule lævi. *Lin. Sp. Plant.* 162. Ipomoea with smooth hand-shaped leaves, whose lobes sit close, and a smooth stalk.

The first sort grows naturally in both *Indies*; in the *West-*

Indies it is called Sweet *William*, and by some *Indian Pink*. It rises with a twining stalk seven or eight feet high, sending out many slender twining branches, which twist about any neighbouring plants for support; the leaves are winged, being composed of several pair of very fine narrow lobes, not thicker than fine sewing thread; they are about an inch long, of a deep green, and sometimes are by pairs opposite, and at others they are alternate; the flowers come out singly from the side of the stalks, standing upon slender foot-stalks about one inch long; they are funnel-shaped, having a tube an inch long, which is narrow at bottom, but gradually widens to the top, and spreads open flat, with five corners or angles; they are of a most beautiful scarlet colour, so make a fine appearance. This is an annual plant in *England*, but whether it is so in its native place I cannot tell; for as the seeds fall to the ground, so there may be a succession of young plants come up among the old ones, which, if not carefully observed, may occasion the plants to be thought perennial.

This is a tender plant, so will not thrive in the open air in *England*. It is propagated by seeds, which should be sown on a hot-bed in the spring, and as the plants will soon appear, they should be each transplanted into a small pot, before they twine about each other, for then it will be difficult to disengage them without breaking their tops. When they are potted they should be plunged into a new hot-bed, and sticks placed down by each plant for their stalks to twine about; after they have taken new root, they should have a good share of air in warm weather, to prevent their drawing up weak; and when they are advanced too high to remain under the frame, they should be removed into the tan-bed in the stove, where they should have support, for their branches will extend to a considerable distance. In this place they will begin to flower in *June*, and there will be a succession of flowers till the end of *September*, and seeds will ripen very well in autumn.

The second sort grows naturally in *Carolina*, and the *Bahama Islands*. This is also an annual plant in *England*, but not so tender as the former. It hath a twining stalk, which rises five or six feet high, garnished with heart-shaped leaves, ending in acute points, divided into angles at their base; the flowers come out from the side of the branches, upon slender foot-stalks, which support three or four flowers of the same form and size as the former, but not so deep coloured. There is a variety of this with Orange-coloured flowers, but they do not differ in any other respect. If the seeds of this sort are sown on a warm border of light earth in the spring, the plants will come up, and in favourable seasons will flower and produce good seeds; but most people raise the plants on a very gentle hot-bed, and transplant them afterwards into the borders, by which method they are brought forward, so will perfect their seeds earlier.

The third sort is like the second, but the leaves have no angles, and the flowers are of a Rose colour, each foot-stalk sustaining one flower. This may be treated in the same manner as the second sort.

The fourth sort grows naturally in the *West-Indies*, where it twines about any neighbouring support, and rises ten or twelve feet high, garnished with large, heart-shaped, entire leaves; the flowers are blue, and come out from the side of the branches, upon slender foot-stalks in clusters; their brims are not angular as in the former species, but entire. This sort is propagated by seeds, which should be sown on a hot-bed in the spring, and the plants afterward treated in the same way as is before directed for the first sort, for it is too tender to thrive in the open air here.

The fifth sort is cultivated in most of the islands in the *West-Indies*, but is supposed to have been introduced there from the *Spanish* main. The plants rise to a very great height,

height, and send out many branches, so are planted to cover arbours for shade in the islands, from whence it had the appellation of *Spanish Arbour Vine*. The stalks of this plant are covered with a purple bark, they twine about any neighbouring support, sending out many side branches, so that one plant will cover an arbour of fifty feet long. The leaves are divided into seven lobes almost to the bottom; the flowers come out from the side of the stalks, they are large, funnel-shaped, of a bright yellow colour, and smell very sweet; these are succeeded by large roundish capsules with three cells, containing one large seed in each, which is of a dark colour.

This is a perennial plant, but too tender to thrive in the open air in *England*; the seeds of this must be sown upon a hot-bed in the spring, and when the plants come up they must be transplanted into separate pots, and plunged into a fresh hot-bed; but as they will soon grow too tall to stand under a frame, they should be removed into the bark-stove, where they should constantly remain. As these plants extend their shoots to a very great length, they require a tall stove, where they may have room to grow, without which they will never produce any flowers. I have had these plants several years, but have only seen one flower produced from them; for they grow so very large before they begin to have flowers, as that few of the stoves in *England* have height enough for their growth.

The sixth sort grows naturally in most of the islands in the *West-Indies*; this hath a twining stalk, which rises ten or twelve feet high, garnished with leaves divided into three lobes, which are heart-shaped; the foot-stalks arise from the side of the stalks, each sustaining three purple flowers. This is also tender, so the plants must be raised on a hot-bed in the spring, and afterwards planted in separate pots, plunging them into another hot-bed, where they may remain till they reach the glasses; then they should be removed into a glass-case where they may have room, and be screened from the cold, but should have a large share of free air admitted to them in warm weather; with this treatment the plants will flower and produce ripe seeds.

The seventh sort grow naturally in *India*; this rises with a twining hairy stalk four or five feet high, garnished with hairy hand-shaped leaves, divided to the bottom into several lobes; the flowers come out in clusters, inclosed in a five-cornered involucre; they are of a purplish colour but small, and open only in the evening, so make no figure. This is propagated by seeds, and requires the same treatment as the sixth sort.

The eighth sort grows naturally in the *West-Indies*; this hath a smooth twining stalk, which rises four or five feet high, garnished with hand-shaped leaves having five lobes, which sit close to the stalks; the flowers come out from the side of the stalks upon short foot-stalks, which sustain two or three purple flowers, which are succeeded by round tri-capsular seed-vessels, in each cell there is one brown seed.

This sort requires the same treatment as the two former, with which it will produce flowers and perfect its seeds in *England*.

IRIS. *Tourn. Inst. R. H.* 358. tab. 186, 187, 188. Flower-de-luce.

The Characters are,

The flowers are inclosed in *spathæ* (or sheaths) which are permanent; the flowers are divided into six parts, the three outer are oblong, obtuse, and reflexed, the three inner are erect, and end in acute points; they have three awl-shaped stamens, which lie upon the reflexed petals. Under the flower is situated an oblong germen, which afterward becomes an oblong angular capsule with three cells, filled with large seeds.

The Species are,

1. IRIS *corollis imberbibus, petalis interioribus stigmate mino-*

ribus, foliis ensiformibus. Hort. Cliff. 19. Iris with an unbearded flower, the inner petals smaller than the stigma, and sword-shaped leaves; or yellow Marsh Flower-de-luce.

2. IRIS *corollis barbatis, caule foliis longiore multifloro. Hort. Cliff.* 18. Iris with bearded flowers, the stalks longer than the leaves, with many flowers; or common German Flower-de-luce.

3. IRIS *corollis barbatis, scapo nudo longitudine foliorum multifloro. Prod. Leyd.* 17. Iris with a bearded flower, and a naked stalk the length of the leaves, with many flowers.

4. IRIS *corollis barbatis, caule subfolioso longitudine foliorum multifloro. Prod. Leyd.* 17. Iris with a bearded flower, and a leafy stalk the length of the leaves, with many flowers.

5. IRIS *corollis barbatis, caule foliis longiore unifloro. Hort. Cliff.* 18. Iris with a bearded flower, and a stalk longer than the leaves, having one flower; commonly called *Caledonian Iris*.

6. IRIS *corollis herbatis, caule foliis brevior multifloro. Hort. Upsal.* 17. Iris with a bearded flower, and a stalk shorter than the leaves, with many flowers.

7. IRIS *corollis barbatis, caule foliis brevior unifloro. Lin. Sp. Plant.* 38. Iris with a bearded flower, and a stalk shorter than the leaves, with one flower.

8. IRIS *corollis barbatis, caule foliis longiore multifloro.* Iris with a bearded flower, a stalk longer than the leaves with many flowers; called greater *Dalmatian Iris*.

9. IRIS *corollis barbatis, germinibus trigonis, foliis ensiformibus longissimis caule foliis longiore bifloro. Pluk.* 154. Iris with a bearded flower, a three-cornered germen, very long sword-shaped leaves, and a stalk longer than the leaves, with two flowers.

10. IRIS *corollis imberbibus, germinibus sexangularibus, caule ancipiti, foliis linearibus. Hort. Cliff.* 19. Iris with flowers having no beards, a six-cornered germen, a stalk alike on both sides, and narrow leaves.

11. IRIS *corollis imberbibus, caule foliis brevior trifloro, foliis lineari-ensiformibus.* Iris whose flowers are not bearded, the stalk shorter than the leaves, with three flowers, and narrow sword-shaped leaves.

12. IRIS *corollis imberbibus, caule foliis æqualibus multifloro.* Iris whose flowers have no beards, the stalks equal in length with the leaves, with many flowers.

13. IRIS *corollis imberbibus, caule foliis longiore multifloro, germinibus sexangularibus, foliis linearibus.* Iris whose flowers have no beards, the stalks longer than the leaves, with many flowers, a six-cornered germen, and very narrow leaves.

14. IRIS *corollis imberbibus, germinibus sexangularibus, caule tereti, foliis sublinearibus. Hort. Cliff.* 19. Iris whose flowers have no beards, with a six-cornered germen, a taper stalk, and very narrow leaves.

15. IRIS *corollis imberbibus, caule unifloro foliis brevioribus radice fibrosâ. Flor. Virg.* 10. Iris with an unbearded flower, a stalk shorter than the leaves, with one flower, and a fibrous root.

16. IRIS *corollis imberbibus, germinibus subtrigonis, caule tereti, foliis ensiformibus. Lin. Sp. Plant.* 39. Iris with an unbearded flower, a three-cornered germen, a taper stalk, and sword-shaped leaves.

17. IRIS *corollis imberbibus petalis internis longitudine stigmatibus, foliis ensiformibus. Hort. Cliff.* 19. Iris with an unbearded flower, the inner petals as long as the stigma, and sword-shaped leaves; called *Stinking Gladwyn*.

18. IRIS *corollis imberbibus, germinibus trigonis, caule tereti, foliis linearibus. Lin. Hort. Cliff.* 19. Iris with an unbearded flower, a three-cornered germen, a taper stalk, and narrow leaves.

19. IRIS *corollis imberbibus, foliis tetragonis. Vir. Cliff.* 6. Iris with an unbearded flower and four-cornered leaves; called *Hermodactyle*.

The first sort grows naturally in ditches and standing waters in most parts of *England*; this is titled in the *Pharmacopœia*, *Acorus adulterinus*, or *Pseudo acorus*, i. e. Bastard *Acorus*. The roots of this are pretty thick, fleshy, and spread near the surface of the ground; the leaves are sword-shaped, very long, of a deep green colour, and not so stiff as those of the garden *Iris*; the stalks rise three feet high, toward the top of which grow three or four flowers, one above another, shaped like the ordinary *Flower-de-luce*, but the three inner petals are shorter than the stigma.

This sort is not cultivated in gardens, but grows wild in standing waters; but being an officinal plant, it is here mentioned to introduce the other.

The second sort grows naturally in *Germany*; the roots of this are very thick, fleshy, and divided into joints, spreading just under the surface of the ground; the leaves arise in clusters embracing each other at their base, but spread afunder upward; they are a foot and a half long, and two inches broad, having sharp edges ending in points like swords; the stalks between these, which are a little longer than the leaves, divide into three branches, each of which produce two or three flowers one above another at distances, inclosed in sheaths; they have three large Violet-coloured petals which turn backward, called falls; these have beards near an inch long on their midrib toward their base, and have a short arched petal which cover the beard, with three broad erect petals of the same colour, called standards; the stamina lie upon the reflexed petals. Under each flower is situated an oblong germen, which turns to a large three-cornered capsule with three cells, filled with large compressed seeds.

There is a variety of this with blue standards and purple falls, which is titled, *Iris hortensis latifolia*, by *Caspar Bauhin*; and one with pale purple standards, another with white, and a third with a smaller flower, but these are accidental varieties which have come from seeds.

The third sort has broader leaves than the second, the flower-stalks have no leaves, but are equal in length with the leaves; they have three or four large, bright, purple flowers, which stand above each other, with purplish sheaths or hoods; the three bending petals or falls, are striped with white from the base to the end of the beard; the flowers are succeeded by large, blunt, triangular capsules with three cells, filled with compressed seeds.

The fourth sort grows naturally in *Hungary*; the leaves of this are like those of the second sort, but are of a darker green; the stalks rise as tall as the leaves, and toward the bottom are garnished with one leaf at each joint, whose base embrace the stalks; the upper part is naked, and branches into three, each having two or three flowers above each other; the three upright petals or standards are yellow, and the bending petals or falls are variegated with purple stripes.

The fifth sort grows naturally near *Constantinople*, and in other parts of the east. The leaves of this sort are not so broad as those of the second, and are of a grayish colour; the stalks rise two feet and a half high, supporting one very large flower; the three upright petals are almost as broad as a hand, but very thin, striped black and white; the three bending petals or falls are of a darker colour, from whence some gardeners have called it the Mourning *Iris*.

The sixth sort hath broad leaves like those of the second sort, but shorter; the stalks rise nine or ten inches high, branching into two or three at the top, each sustaining two deep purple flowers.

The seventh sort hath narrower and shorter leaves than the former; the stalks are shorter than the leaves, and support one flower on the top of a light purple colour. There are two or three varieties of this, which differ in the colour of their flowers.

The eighth sort hath the largest leaves of any of this genus, of a grayish colour and spread wide, embracing each other at the base, where they are purplish. The stalks rise four feet high, and divide into several branches, each supporting three or four flowers above each other at distances, covered with a thin sheath; the three bending petals or falls, of a faint purple inclining to blue, with purple veins running lengthways; the beard is yellow, and the three erect petals or standards are of a bright blue with some faint purple stripes, the flowers have an agreeable scent.

The seeds of the ninth sort were brought from *Carniola*, by the Right Rev. Dr. *Pococke*, Bishop of *Ossory*, who found the plants growing there naturally.

This plant hath a thick fleshy root, divided into many knots or tubers, which spread and multiply in the ground, putting out many strong, thick, fleshy fibres. From these roots arise clusters of flat sword-shaped leaves of a deep green colour, which are more than three feet long, and little more than one inch broad in the broadest part, ending in points; between these arise the flower-stalks, which grow four feet high, having very long spathæ or sheaths at each of the upper joints, which include the flowers. These stalks generally sustain two flowers, which are divided into nine leaves; three of these stand erect, which are white, and six turn down, and are joined together at their base, the lower spreading out into a broad, obtuse, reflexed fall, having a beard, which is of a bright yellow colour; the upper segment is arched over the lower, so as to form a sort of lip, which is reflexed backward; under these is situated an oblong three-cornered germen, which afterward becomes an oblong, swollen, three-cornered seed-vessel, ending in a long point, which opens into three longitudinal cells, in which the seeds are ranged; it is very hardy, and thrives well in the open air without any protection. The roots propagate very fast, when they are in a light moist soil, so that it will soon be common in *England* without waiting for plants from seeds.

The tenth sort grows naturally in *Austria*; this hath narrow, flat, Grass-like leaves about a foot long, of a light green colour; between these arise the stalks about six inches high, having two narrow green leaves, which are much longer than the stalks; these stalks sustain two or three flowers, which are smaller than any of the former species; the petals have no beards, but have a broad yellow line adorned with purple stripes; the three falls are of a light purple colour striped with blue, and have a convex ridge running longitudinally, the other are of a reddish purple variegated with violet; the flowers have a scent like fresh Plums.

The eleventh sort grows naturally near the sea, in the south of *France*, and in *Italy*. This hath narrow sword-shaped leaves more than a foot long, of a deep green colour; the stalks do not rise so tall as the leaves; they sustain at the top two or three flowers which stand near together, of a bright purple colour with very deep falls, the three standards are blue; the bending petals have no beards, but instead of that white broad stripes through the middle.

The twelfth sort hath narrower leaves than the former, but of the same deep green colour; the stalks do not rise higher than the leaves, and support two or three flowers, which have long permanent empalements standing erect, which cover the seed-vessel till the seeds are ripe; the flowers are smaller, and of a paler colour than those of the eleventh sort.

The thirteenth sort has very narrow, long, Grass-like leaves, of a light green; the stalks rise two feet and a half high, sustaining three or four flowers above each other, which have blue falls, and purple standards striped with pale blue lines.

The fourteenth sort grows naturally in *Germany*; the leaves are like those of the eleventh sort, which, when broken, have a disagreeable scent; but this is accidental, and not common to all the plants; the stalks of this are taper, and rise a little above the leaves, sustaining three or four flowers one above another, which have light blue standards, and purple variegated falls without beards; instead of which, they have a broad white line in the middle; these are succeeded by short thick capsules, which have scarce any angles, opening in three cells, which are filled with angular seeds.

The fifteenth sort grows naturally in *North America*; this hath tufted fibrous roots, from which arise many narrow sword-shaped leaves; from between these come out the stalks, which are shorter than the leaves, supporting one purple flower with blue standards.

The sixteenth sort grows also in *North America*; this hath broader sword-shaped leaves than the former, of a light green colour; the stalks rise a little above the leaves, and support two or three flowers one above another; the standards are of a light blue, the falls are purple variegated, with a broad white line instead of a beard through the middle.

The seventeenth sort grows naturally in moist places in many parts of *England*, so is seldom admitted into gardens. This hath thick, tufted, fibrous roots, the leaves are of a Grass green colour, sword-shaped, and when broken emit a strong odour, not much unlike that of hot roast beef at the first scent, but if smelt too close, becomes disagreeable. It is generally called Stinking Gladwyn in *England*; the stalks rise about the same height with the leaves, supporting two small flowers of a purple colour, variegated.

The eighteenth sort grows naturally in *Austria* and *Bohemia*; this hath narrow sword-shaped leaves near a foot and a half long, of a dark green colour; the flower-stalks rise above the leaves, and support two or three flowers with light blue standards, and deep blue falls, with a broad stripe of white, instead of the beard.

All these sorts are generally propagated by parting of their roots, which do most of them multiply fast enough. The best time to remove and part the roots is in autumn, that they may get good root before the spring, otherwise they will not flower strong the following summer. All those sorts which spread much at their roots, should be transplanted every other year, to keep them within bounds, otherwise they will spread so much as to become troublesome, especially if they are planted near other flowers; indeed the large growing kinds are most of them too spreading for the flower-garden, so are only fit to fill up the spaces between trees and shrubs in large plantations, where they will have a good effect during the time of their flowering.

The fifth, sixth, seventh, tenth, eleventh, and thirteenth sorts, grow in less compass, so may be admitted into large borders, or in clumps of flowers in the pleasure-garden, where they will add to the variety. The fifth sort should have a warmer situation, being a little tender, but all the other sorts will grow in almost any soil or situation, and may be propagated by seeds, which should be sown soon after they are ripe, then the plants will come up the following spring; but if the seeds are sown in the spring, they will lie a year in the ground before they vegetate; but as most of the sorts are so easily propagated by their roots, few people care to wait for seeding plants, unless of those sorts which are scarce.

The nineteenth sort grows naturally in the islands of the *Archipelago*; this hath a tuberous knobbed root, from which arise five or six long, narrow, four-cornered leaves, between which arise the stalk, which supports one flower, shaped like those of the Iris, but small, and of a dark purple colour. This is propagated by the roots, which send out off-

sets, which may be taken up, and transplanted when their leaves decay, but should not be kept too long out of the ground. If these are planted in a deep loose soil, the roots will run down, and be lost in a few years where they are not disturbed, so they should be annually transplanted, and have a shallow soil; they are hardy in respect to cold, and require no farther care but to keep them clean from weeds.

IRIS Persica. }

ISATIS. *Tourn. Inst. R. H. 211. tab. 100.* Woad.

The Characters are,

The empalement of the flower falls away; the flower hath four oblong petals, placed in form of a cross. It hath six stamina, four of which are as long as the petals, the other two are shorter, with an oblong compressed germen, which becomes an oblong compressed pod, with one cell, opening with two valves, inclosing one oval compressed seed in the center.

The Species are,

1. ISATIS foliis radicalibus oblongo-ovatis obtusis integerrimis, caulinis sagittatis filiculis oblongis. Woad with oblong, oval, blunt, entire leaves at bottom, but those on the stalks arrow-pointed, and oblong pods; or cultivated Woad.

2. ISATIS foliis radicalibus lanceolatis integerrimis, caulinis sagittatis, filiculis angustioribus. Woad with spear-shaped entire lower leaves, those on the stalks arrow-shaped, and narrower pods; wild narrow-leaved Woad.

3. ISATIS foliis radicalibus crenatis, caulinis sagittatis, filiculis angustioribus villosis. Woad with crenated lower leaves, those on the stalks arrow-pointed, and narrow hairy pods; smaller *Portugal* Woad.

The first sort is cultivated in several parts of *England*, for the purposes of dying, being used as a foundation for many of the dark colours.

This is a commodity well worth propagating in all places where the land is suitable for it, which must be a pretty strong soil, but not too moist.

The plant is biennial, in which it differs from most of the others sorts, which are annual. The lower leaves of this are of an oblong oval figure, and pretty thick consistence, and end in obtuse roundish points; they are entire on their edges, and of a lucid green. The stalks rise four feet high, dividing into several branches, garnished with arrow-shaped leaves, sitting close to the stalks; the branches are terminated by small yellow flowers, in very close clusters, which are composed of four small petals, placed in form of a cross, which are succeeded by pods shaped like a bird's tongue, which, when ripe, turn black, and open with two valves, having one cell, in which is situated a single seed.

The second sort has been supposed to be the same species as the first, and only differing by culture; but I have propagated both sorts more than thirty years, and have not found either of them alter.

The third sort grows naturally in *Portugal*; it is an annual plant, whose lower leaves are narrow and crenated, but those on the stalks are arrow-pointed; they are of a pale green, and much thinner than those of the other sorts. The flowers are small, of a sulphur colour, and the seed-vessels are narrow and hairy.

The two last sorts are not cultivated for use, so are only preserved in botanick gardens for the sake of variety; they are propagated by seeds as the first sort.

The first sort which is propagated for use, is sown upon fresh land which is in good heart, for which the cultivators of Woad pay a large rent; they generally chuse to have their land situated near great towns, where there is plenty of dressing, but they never stay long on the same spot, for the best ground will not admit of being sown with Woad more than twice, and if it is oftener repeated, the crop seldom pays the charges of culture, &c.

Those

Those who cultivate this commodity have gangs of people who have been bred to this employment, so that whole families travel about from place to place, where-ever their principal fixes on land for the purpose; but these people go on in one track, just as their predecessors taught them, nor have their principals deviated much from the practice of their ancestors, so that there is a large field for improvement, if any of the cultivators of Woad were persons of genius, and could be prevailed on to introduce the garden culture so far as it may be adapted to this plant; this I know from experience, having made numbers of trials on the culture of this plant, therefore I shall insert them here, for the benefit of those who may have ingenuity enough to strike out of the old beaten track.

As the goodness of Woad consists in the size and fatness of the leaves, the only method to obtain this, is by sowing the seed upon ground at a proper season, and allow the plants proper room to grow, as also to keep them clean from weeds, which, if permitted to grow, will rob the plants of their nourishment. The method practised by some of the most skilful kitchen-gardeners in the culture of Spinach, would be a great improvement to this plant, for some of them have improved the round-leaved Spinach so much by culture, as to have the leaves more than six times the size they were formerly, and their fatness has been in the same proportion, though sown upon the same land as formerly; which has been effected by thinning of the plants when young, and keeping the ground constantly clean from weeds; but to return to the culture of Woad.

After having made choice of a proper spot of land, which should not be too light and sandy, nor over stiff and moist, but rather a gentle hazel loam, whose parts will easily separate, the next is to plough this up just before winter, laying it in narrow high ridges, that the frost may penetrate through the ridges, to mellow and soften the clods; then in the spring plough it again crossway, laying it again in narrow ridges; after it has lain some time in this manner, and the weeds begin to grow, it should be well harrowed to destroy them; this should be twice repeated while the weeds are young, and if there are any roots of large perennial weeds, they must be harrowed out, and carried off the ground. In *June* the ground should be a third time ploughed, when the furrows should be narrow, and the ground stirred as deep as the plough will go, that the parts may be as well separated as possible, and when the weeds appear again, the ground should be well harrowed to destroy them. Toward the end of *July*, or the beginning of *August*, it should be ploughed the last time, when the land should be laid smooth, and when there is a prospect of showers, the ground must be harrowed to receive the seeds, which should be sown either in rows with the drill plough, or in broad-cast after the common method; but it will be proper to steep the seeds one night in water before they are sown, which will prepare them for vegetation; if the seeds are sown in drills, they will be covered by an instrument fixed to the plough for that purpose, but those which are sown broad-cast in the common way, must be well harrowed in. If the seeds are good, and the season favourable, the plants will appear in a fortnight, and in a month or five weeks after will be fit to hoe; for the sooner this is performed when the plants are distinguishable, the better they will thrive, and the weeds being then young, will be soon destroyed. The method of hoeing these plants, is the same as for Turneps, with this difference only, that these plants need not be thinned so much, for at the first hoeing, if they are separated to the distance of four inches, and at the last to six inches, it will be space enough for the growth of the plants; if this is carefully performed, and in dry weather, most of the weeds will be destroyed, but as some of them may escape in this

operation, and young weeds will arise, so the ground should be a second time hoed in *October*, always choosing a dry time for this work; at this second operation, the plants should be singled out to the distance they are to remain. After this the ground will be clean from weeds till the spring, when young weeds will come up, therefore about the end of *March* will be a good time to hoe the ground again, for while the weeds are young, it may be performed in less than half the time it would require if the weeds were permitted to grow large, and the sun and wind will much sooner kill them; this hoeing will also stir the surface of the ground, and greatly promote the growth of the plants; if this is performed in dry weather, the ground will be clean till the first crop of Woad is gathered, after which it must be again well cleaned; if this is carefully repeated, after the gathering each crop, the land will always lie clean, and the plants will thrive the better. The expence of the first hoeing will be about six shillings per acre, and for the after hoeings half that price will be sufficient, provided they are performed when the weeds are young, for if they are suffered to grow large, it will require more labour, nor can it be so well performed; therefore it is not only the best husbandry to do this work soon, but it will be found the cheapest method; for the same number of men will hoe a field of ten acres three times when it is done in time, as is required to hoe it twice only, because the weeds will have longer time to grow between the operations.

If the land, in which this seed is sown, should have been in culture before for other crops, so not in good heart, it will require dressing before it is sown, in which case rotten stable-dung is preferable to any other, but this should not be laid on till the last ploughing before the seeds are sown, and not spread till the land is ploughed, that the sun may not exhale the goodness of it, which in summer is soon lost when spread on the ground. The quantity should not be less than twenty loads to each acre, which will keep the ground in heart till the crop of Woad is spent.

The time for gathering of the crop is according to the season, but it should be performed as soon as the leaves are fully grown, while they are perfectly green, for when they begin to change pale, great part of their goodness is over, for the quantity will be less, and the quality greatly diminished.

If the land is good, and the crop well husbanded, it will produce three or four gatherings, but the two first are the best; these are commonly mixed together in the manufacturing of it, but the after crops are always kept separate, for if these are mixed with the other the whole will be of little value. The two first crops will sell from twenty-five to thirty pounds a ton, but the latter will not bring more than seven or eight pounds, and sometimes not so much. An acre of land will produce a ton of Woad, and in good seasons near a ton and a half.

When the planters intend to save the seeds, they cut three crops of the leaves, and then let the plants stand till the next year for seed; but if only one crop is cut, and that only of the outer leaves, letting all the middle leaves stand to nourish the stalks, the plants will grow stronger, and produce a much greater quantity of seeds.

These seeds are often kept two years, but it is always best to sow new seeds when they can be obtained. The seeds ripen in *August*, when the pods turn to a dark colour the seeds should be gathered; it is best done by reaping the stalks in the same manner as Wheat, spreading the stalks in rows upon the ground, and in four or five days the seeds will be fit to thresh out, provided the weather is dry; for if it lies long, the pods will open and let out the seeds.

There are some of the Woad planters, who feed down the leaves in winter with sheep, which is a very bad method,

thod, for all plants which are to remain for a future crop, should never be eaten by cattle, for that greatly weakens the plants, therefore those who eat down their Wheat in winter with sheep, are equally blameable.

ISOPYRUM. *Lin. Gen. Plant.* 621.

The Characters are,

The flower has no empalement. It hath five oval petals, and five short tubulous nectariums, situated within the petals. It hath a great number of short hairy stamina, and several oval germen, which afterward become so many recurved capsules with one cell, filled with small seeds.

The Species are,

1. ISOPYRUM *stipulis subulatis, petalis acutis.* Hort. Upsal. 157. Isopyrum with awl-shaped stipulæ, and acute petals.
2. ISOPYRUM *stipulis ovatis, petalis obtusis.* Lin. Sp. Plant. 557. Isopyrum with oval stipulæ, and obtuse petals.
3. ISOPYRUM *stipulis obsoleteis.* Lin. Sp. Plant. 557. Isopyrum with obsolete stipulæ.

The first sort grows naturally in Siberia; this is an annual plant, which seldom rises more than three or four inches high. The leaves are shaped like those of Fumitory. The stalk is naked to the top, where there is a circle of leaves just under the flowers. The flowers are small, of an herbaceous colour on their outside, but yellow within, having five acute petals, and as many honey glands, with a great number of stamina which are shorter than the petals, and several reflexed moon-shaped germen. The flowers are succeeded by many recurved seed-vessels with one cell, filled with small shining black seeds.

The seeds of this plant should be sown in a shady border soon after they are ripe, for when they are kept long out of the ground, they seldom grow the first year; therefore, when the seeds are permitted to scatter, they succeed very well, and require no other care but to keep them clean from weeds: as there is no great beauty in this plant, so a small patch or two of them in any shady part of the garden, by way of variety, will be sufficient.

The second and third sorts grow naturally about Verona. The second sort hath leaves very like those of the smallest meadow Rue. The stalks rise four or five inches, supporting a few small white flowers, with obtuse petals; these are succeeded by several recurved seed-vessels, containing many small seeds.

The third sort hath leaves like the second, but a little larger, and of a greener colour. The stalks rise about six inches high, supporting two or three small white flowers, shaped like those of the second sort, which are succeeded by recurved seed-vessels, filled with small seeds.

Both these plants delight in a moist shady situation; they are propagated by seeds in the same way as the first sort, but these will live two or three years.

ISORA. See Helicteres.

ITEA. *Lin. Gen. Plant.* 243.

The Characters are,

The empalement of the flower is small and permanent, ending in five acute points. The flower has five petals, which are inserted in the empalement. It hath five awl-shaped stamina inserted in the empalement, and an oval germen, which afterward becomes a long oval capsule, with the style at the top, having one cell filled with small seeds.

We have but one Species of this genus, viz.

ITEA. *Flor. Virg.* 143.

This shrub grows in several parts of North America, by the sides of rivers, and in other moist land, where it rises to the height of eight or ten feet, sending out many branches from the ground upward, garnished with spear-shaped leaves, placed alternately, and slightly sawed on their edges, of a light green. At the extremity of the same year's shoots, are produced fine spikes of white flowers, three or

four inches long, standing erect; when these shrubs are in vigour, they will be entirely covered with these spikes of flowers, so that they make a fine appearance at their season of flowering, which is in July.

This shrub thrives well in the open air in England, the cold never injuring it; but upon dry gravelly ground, it is very apt to die in the summer, in a dry season. It is propagated by layers, but these should be made of young shoots of the same year, for the old branches do not put out roots very kindly. The shoots should be laid down in the autumn, and will be rooted in one year.

JUDAICA ARBOR. See Cercis.

JUGLANS. *Lin. Gen. Plant.* 950. Walnut.

The Characters are,

It hath male and female flowers at distances on the same tree. The male flowers are disposed in an oblong cylindrical katkin; each scale has one flower, with one petal, divided into six equal parts; in the center is situated many short stamina. The female flowers grow in small clusters, sitting close to the branches; these have short, erect, four-pointed empalements, sitting on the germen, and an acute erect petal, divided into four parts. Under the empalement sits a large oval germen, which afterward becomes a large oval dry berry, with one cell, inclosing a large oval nut with netted furrows.

The Species are,

1. JUGLANS *foliolis ovalibus glabris subserratis subæqualibus.* Hort. Cliff. 449. Walnut with oval lobes, which are smooth, sawed, and equal.
2. JUGLANS *foliolis lanceolatis acutè serratis, intermediis majoribus.* Black Virginia Walnut.
3. JUGLANS *foliolis cordato-lanceolatis infernè nervosis, pediculis foliorum pubescentibus.* Black Virginia Walnut, with an oblong fruit very deeply furrowed.
4. JUGLANS *foliolis lanceolatis serratis, exterioribus latioribus.* Lin. Sp. Plant. 997: White Virginia Walnut; or Hickery nut.
5. JUGLANS *foliolis cuneiformibus serratis, exterioribus majoribus.* White Walnut with a smaller fruit, and a smooth bark.
6. JUGLANS *foliolis lanceolatis serratis glabris subæqualibus.* White Walnut with an oval compressed fruit, a sweet kernel, and a scaly bark; commonly called Shagbark in America.

There are several varieties of the common Walnut, which are distinguished by the following titles: the large Walnut, the thin-shelled Walnut, the French Walnut, the late-ripe Walnut, and the double Walnut, but these do all of them vary when raised by seeds, so that the nuts from the same tree will produce plants, whose fruit will differ, therefore there can be no dependence upon the trees which are raised from nuts, till they have produced fruit; so that those persons who plant the trees for their fruit, should make choice of them in the nurseries when they have their fruit upon them, otherwise they may be deceived by having such as they would not choose.

The second sort is commonly called Black Virginia Walnut; this grows to a large size in North America. The leaves of this sort are composed of five or six pair of spear-shaped lobes, which end in acute points, and are sawed on their edges; the lower pair of lobes are the least, the other gradually increase in their size to the top, where the pair at the top, and the single lobe which terminates the leaf, are smaller; these leaves, when bruised, emit a strong aromatic flavour, as do also the outer cover of the nuts, which are rough, and rounder than those of the common Walnut. The shell of the nut is very hard, thick, and the kernel small, but very sweet.

The third sort grows naturally in North America, where the trees grow to a large size. The leaves of this sort are composed

composed of seven or eight pair of long heart-shaped lobes, broad at their base, where they are divided into two round ears, but terminate in acute points; they are rougher, and of a deeper green than those of the second sort, and have nothing of the aromattick scent which they have. The fruit is very long. The shell is deeply furrowed, and hard. The kernel is small, but well flavoured.

The fourth sort is very common in most parts of *North America*, where it is called Hickery nut. The leaves of this sort are composed of two or three pair of oblong lobes, terminated by an odd one; these are of a light green, sawed on their edges; the lower pair of lobes are the smallest, and the upper the largest. The fruit is shaped like the common Walnut, but the shell is not furrowed, and is of a light colour.

The fifth sort is not so large as the fourth. The leaves are composed of two pair of lobes, terminated by an odd one; these are narrow at their base, but broad and rounded at their ends; they are sawed on their edges, and of a light green. The nuts are small, and have a very hard smooth shell.

The sixth sort grows naturally in *North America*, where it rises to a middling stature. The leaves of this sort are composed of three pair of smooth spear-shaped lobes, of a dark green colour, sawed on their edges, ending in acute points. The fruit is oval, the shell white, hard, and smooth; the kernel small, but very sweet. The young shoots of the tree are covered with a very smooth brownish bark, but the stems and older branches have a rough scaly bark, from whence it had the appellation of Shagbark, in *America*.

The common Walnut is propagated in many parts of *England* for the fruit, and formerly the trees were propagated for their wood, which was in very great esteem, till the quantity of Mahogany, and other useful woods which have been of late years imported into *England*, have almost banished the use of Walnut.

The trees are propagated by planting of their nuts, which, as was before observed, seldom produce the same sort of fruit as was sown; so that the only way to have the desired sort, is to sow the nuts of the best kinds; and if this is done in a nursery, the trees should be transplanted out when they have had three or four years growth, to the place where they are designed to remain, for these trees do not bear transplanting when they are of a large size; therefore there may be a good number of the trees planted, which need not be put at more than six feet apart, which will be distance enough for them to grow till they produce fruit, when those whose fruit are of the desired kind may remain, and the others cut up, to allow them room to grow; by this method a sufficient number of the trees may be generally found among them to remain, which will thrive and flourish greatly when they have room; but as many people do not care to wait so long for the fruit, so the next best method is to make choice of some young trees in the nurseries when they have their fruit upon them; but though these trees will grow and bear fruit, yet they will never be so large or so long lived, as those which are planted young.

All the sorts of Walnuts which are propagated for timber, should be sown in the places where they are to remain; for the roots of these trees always incline downward, which being stopped or broken, prevent their aspiring upward, so that they afterwards divaricate into branches, and become low spreading trees; but such as are propagated for fruit, are greatly mended by transplanting; for hereby they are rendered more fruitful, and their fruit are generally larger and fairer; it being a common observation, that downright roots greatly encourage the luxuriant growth of

timber in all sorts of trees, but such trees as have their roots spreading near the surface of the ground, are always the most fruitful.

The nuts should be preserved in their outer covers in dry sand until *February*, when they should be planted in lines, at the distance you intend them to remain; but in the rows they may be placed pretty close, for fear the nuts should miscarry; and the young trees, where they are too thick, may be removed, after they have grown two or three years, leaving the remainder at the distance they are to stand.

In transplanting these trees, you should always observe never to prune either their roots or large branches, both which are very injurious to them; nor should you be too busy in lopping or pruning the branches of these trees while growing, for it often causes them to decay; but when there is a necessity of cutting any of their branches off, it should be done early in *September*, that the wound may heal over before the cold increases; and the branches should always be cut off quite close to the trunk, otherwise the stump which is left will decay, and rot the body of the tree.

The best season for transplanting these trees is as soon as the leaves begin to decay, at which time if they are carefully taken up, and their branches preserved entire, there will be little danger of their succeeding, although they are eight or ten years old; though, as was before observed, these trees will not grow so large, or continue so long, as those which are removed young.

This tree delights in a firm, rich, loamy soil, or such as is inclinable to chalk or marl; and will thrive very well in stony ground, and on chalky hills, as may be seen by those large plantations near *Leatherhead*, *Godstone*, and *Carshalton* in *Surry*, where are great numbers of these trees planted upon the downs, which annually produce large quantities of fruit, to the great advantage of their owners; one of which I have been told, farms the fruit of his trees, to those who supply the markets for 30*l.* per annum.

The distance these trees should be placed, ought not to be less than forty feet, especially if regard be had to their fruit; though when they are only designed for timber, if they stand near, it promotes their upright growth. The black *Virginia* Walnut is much more inclinable to grow upright than the common sort, and the wood being generally of a more beautiful grain, renders it preferable to that, and better worth cultivating. I have seen some of this wood which hath been beautifully veined with black and white, which, when polished, has appeared at a distance like veined marble. This wood was some years past greatly esteemed by the cabinet-makers for inlaying, for tables, and cabinets, and is a durable wood for those purposes, being less infected with insects of any kind, than most others of *English* growth (which may proceed from its extraordinary bitterness;) but it is not proper for buildings of strength, it being of a brittle nature, and exceeding subject to break very short, though it commonly gives notice thereof, by its cracking some time before it breaks.

The general opinion, that the beating down this fruit improves the trees, I do not believe, since in the doing of this, the younger branches are generally broken and destroyed; but as it would be exceeding troublesome to gather it by hand, so in beating it off, great care should be taken that it be not done with violence, for the reason before assigned. In order to preserve the fruit, it should remain upon the trees till it is thoroughly ripe, and drops from the trees, then laid in heaps for two or three days, when their husks will easily part from the shells: then dried well in the sun, and laid up in a dry place, where mice or other vermin cannot come to them, where they will remain

good four or five months; but there are some persons who put their Walnuts into an oven gently heated, where they let them remain four or five hours to dry, and then put them up in oil jars, or any other close vessel, mixing them with dry sand, by which method they will keep good six months. The putting of them in the oven is to dry the germ, and prevent their sprouting; but if the oven be too hot it will cause them to shrink, therefore great care must be had to that.

All the other sorts are propagated in the same way as the common Walnut, but as few of the sorts produce fruit in *England*, so their nuts must be procured from *North America*; which should be gathered when fully ripe, and put up in dry sand, to preserve them in their passage to *England*: when they arrive here, the sooner they are planted, the greater chance there will be of their succeeding; when the plants come up, they should be kept clean from weeds; and if they shoot late in the autumn, and their tops are full of sap, they should be covered with mats, to prevent the early frost from pinching their tender shoots, which often causes them to die down a considerable length before spring; but if they are screened from these early frosts, the shoots will become firmer and better able to resist the cold. Some of these sorts are tender while young, so require a little care the two first winters, but afterward will be hardy enough to resist the greatest cold of this country.

The black *Virginia* Walnut is full as hardy as the common sort; there are some large trees of this kind in the *Chelsea* garden, which have produced great quantities of fruit upward of forty years; the nuts have generally ripened so well there as to grow, but their kernels are small, so are of little value.

These trees all require the same culture as the common Walnut, but they grow best in a soft loamy soil not too dry, and where there is a depth of soil for their roots to run down. The Hickery when young, is very tough and pliable, so the sticks of it are much esteemed; but the wood when grown large, is very brittle, so not of any great use. The black *Virginia* Walnut is the most valuable wood of all the sorts; some of the trees are beautifully veined, and will take a good polish, but others have very little beauty, which is the case of many other sorts of wood.

JUJUBE. See *Ziziphus*.

JULIANS, or ROCKETS. See *Hesperis*.

JULY FLOWER. See *Dianthus*.

JUNCUS. *Tourn. Inst. R. H.* 246. *tab.* 127. *Rusii*.

The Characters are,

It hath a chaff opening with two valves, an empalement with six oblong pointed leaves; the flower hath no petals, but the coloured empalement is by some taken for petals. It hath six short hairy stamina, and a three-cornered germen, which afterward becomes a three-cornered capsule with one cell, opening with three valves, inclosing roundish seeds.

The Species are,

1. JUNCUS culmo subnudo tereti mucronato, paniculâ terminali, involucro diphylo spinoso. *Lin. Sp. Plant.* 325. Prickly large Sea Rush.

2. JUNCUS culmo nudo, apice membranaceo incurvo, paniculâ laterali. *Lin. Sp. Plant.* 326. Common hard Rush.

3. JUNCUS culmo nudo striato, paniculâ laterali. *Flor. Leyd.* 44. Larger common soft Rush, with a spreading panicle.

4. JUNCUS culmo nudo striato, capitulo laterali. *Prod. Leyd.* 44. Soft Rush, with a more compact panicle.

There are many other species of this genus which grow naturally in *England*, and are very troublesome weeds in many pastures, so are not worthy of being enumerated here; for those here mentioned, is only to point out a method of destroying them.

The first and second sorts grow on the sea-shores, where-

they are frequently watered by the salt water. These two sorts are planted with great care on the banks of the sea in *Holland*, in order to prevent the water from washing away the earth; which being very loose, would be in danger of removing every tide, if it were not for the roots of these Rushes, which fasten themselves very deep in the ground, and mat themselves near the surface, so as to hold the earth closely together. Therefore, whenever the roots of these Rushes are destroyed, the inhabitants immediately repair them to prevent farther damage. In the summer time, when the Rushes are fully grown, the inhabitants cut them, and tie them up into bundles, which are dried, and afterward carried into the larger towns and cities, where they are wrought into baskets, and several other useful things, which are frequently sent into *England*. These sorts do not grow so strong in *England*, as they do on the *Maeße*, and some other places in *Holland*, where I have seen them upward of four feet high.

The third and fourth sorts grow on moist, strong, uncultivated lands in most parts of *England*, and consume the herbage where they are suffered to remain. The best method of destroying these Rushes is, to fork them up clean by the roots in *July*, and after having let them lie a fortnight or three weeks to dry, lay them in heaps, and burn them gently; and the ashes which these afford, will be tolerable manure for the land; but in order to prevent their growing again, and to make the pasture good, the land should be drained, otherwise there will be no destroying these Rushes entirely; but after it is well drained, if the roots are annually drawn up, and the ground kept duly rolled, they may be subdued.

JUNIPERUS. *Tourn. Inst. R. H.* 588. *tab.* 361. Juniper.

The Characters are,

It hath male and female flowers in different plants, and sometimes at separate distances on the same plant. The male flowers have a conical katkin; the flowers are placed by threes opposite, and terminated by a single one; the scales are broad, lying on each other, and fixed to the column by a very short foot-stalk. The flower has no petal, but three stamina, joined in one body below. The female flowers have a small three-pointed empalement, sitting upon the germen; they have three stiff, acute, permanent petals; the germen sitting below the empalement, afterward becomes a roundish berry, inclosing three stony seeds which are oblong, angular on one side, but convex on the other.

The Species are,

1. JUNIPERUS foliis ternis patentibus mucronatis. *Lin. Sp. Plant.* 1040. The common English Juniper.

2. JUNIPERUS foliis ternis patentibus, longioribus acutioribusque, ramis erectioribus. The tree, or Swedish Juniper.

3. JUNIPERUS foliis ternis omnibus patentibus. Cedar of *Virginia*, or red Cedar.

4. JUNIPERUS foliis ternis basi aduatis, junioribus imbricatis, senioribus patulis. *Hort. Cliff.* 464. Commonly called Carolina Cedar.

5. JUNIPERUS foliis inferioribus ternis patentibus, superioribus quadrifariam imbricatis. Commonly called Cedar of *Bermudas*.

6. JUNIPERUS foliis ternis patentibus, subulatis acutis. Great Juniper with blue berries.

7. JUNIPERUS foliis inferioribus ternis brevioribus patentibus, superioribus imbricatis acutis. Greater Juniper, or Cedar with a Cypress leaf and yellowish fruit.

8. JUNIPERUS foliis undique imbricatis ovatis obtusis. *Flor. Leyd.* 90. Middle Juniper, or Cedar with a Cypress leaf and larger berries.

9. JUNIPERUS foliis omnibus quadrifariam imbricatis. Greatest Juniper, with a Cypress leaf; commonly called *Jamaica* berry-bearing Cedar.

10. JUNIPERUS foliis oppositis erectis decurrentibus, ramis patulis. Common Savin.

11. JUNIPERUS foliis oppositis patulis, decurrentibus, ramis erectioribus. Upright berry-bearing Savin.

12. JUNIPERUS foliis undique imbricatis obtusis, ramis teretibus. Greater Juniper with a brownish berry.

13. JUNIPERUS foliis quadrisariam imbricatis acutis. Prod. Leyd. 90. Taller Spanish Cedar, with a very large black fruit.

The first sort grows naturally upon chalky lands, in many parts of *England*. This is a low shrub, seldom rising more than three feet high, sending out many spreading branches, covered with a brown bark, garnished with narrow awl-shaped leaves, ending in acute points, placed by threes round the branches, which are of a grayish colour, and continue through the year; the male flowers sometimes are situated at distances on the same plant with the female, at other times they are upon distinct plants: the female flowers are succeeded by roundish berries which are first green, but when ripe, are of a dark purple colour. The berries ripen in the autumn.

The wood, the berries, and the gum are used in medicine; the gum is titled sandaracha.

The second sort is known in the gardens by the title of *Swedish Juniper*; this is by many supposed to be only a variety of the first, but is undoubtedly a distinct species, for I have many years raised both sorts from the seeds, and have never found them alter. This rises to the height of ten or twelve feet, the branches grow more erect, the leaves are narrower, and end in more acute points; they are placed farther asunder on the branches, and the berries are larger. It grows naturally in *Sweden*, *Denmark*, and *Norway*.

The third sort grows naturally in most parts of *North America*, where it is called red Cedar, to distinguish it from a sort of Cypress, which is there called white Cedar. Of this there are two, if not three varieties, besides the species here enumerated; one of which has leaves in every part like those of the Savin, and upon being rubbed, emit a very strong ungrateful odour, and is commonly distinguished in *America*, by the title of Savin tree. There is another with leaves very like those of Cypress, but as these generally arise from the same seeds when they are sent from *America*, so they are only feminal variations.

The lower leaves of the fourth sort are like those of the *Swedish Juniper*, but the upper leaves are like those of the Cypress; and this difference is constant, when the seeds are carefully gathered from the same tree; but as most of those people who send over these seeds, are not very careful to distinguish the difference, so it often happens that the seeds of two or three sorts are mixed together, which has given occasion to people to imagine them but one; but all the leaves of the third are like those of the Juniper, so the gardeners call that the red *Virginia Cedar*, and this *Carolina Cedar*, though they grow naturally in *Virginia*.

The fifth sort is the *Bermudas Cedar*, whose wood has a very strong odour; it was formerly in great esteem for wainscoting of rooms, and also for furniture, but the odour being too powerful for many persons, has rendered it less valuable, so at present there is not much of it imported into *England*. These plants, while young, have acute-pointed leaves, which spread open, and are placed by threes round the branches; but as the trees advance, so their leaves alter, and the branches are four-cornered; the leaves are very short, and placed by fours round the branches, lying over each other like the scales of fish; the berries are produced toward the end of the branches, these are of a dark red colour, inclining to purple. As there are few of these trees of any great size in *England*, so I have not had an oppor-

tunity of examining their flowers, therefore do not know if they are on different plants; for although I have received very fine specimens from *Bermudas*, yet they were all with fruit on them almost fully grown, and not one with flowers: as these trees are commonly destroyed in *England* whenever there happens a severe winter, we have little hopes of seeing them in flower here.

The sixth sort grows naturally in *Isria*. This hath spreading branches growing thinly, garnished with awl-shaped acute pointed leaves, placed by threes, of a dark green, and not very close to each other; they grow horizontally, pointing outward; the berries are much larger than those of the common Juniper, and are blue when ripe.

The seventh sort grows naturally in *Portugal*. This sort grows with its branches in a pyramidal form, the lower ones are garnished with short, acute-pointed, grayish leaves, placed by threes, pointing outward; but those on the upper branches are of a dark green, lying over each other like the scales of fish, ending in acute points. The male flowers are produced at the extremity of the branches, they are situated in a loose, scaly, conical katkin, standing upon a short foot-stalk erect; the fruit is produced sometimes upon the same tree, at distances from the flowers, and at other times they are upon separate trees; the berries of this are of a pale yellow when ripe, and about the size of those of the common Juniper.

The eighth sort grows naturally in *Spain* and *Italy*. The branches of this sort grow erect, and are covered with a brown bark; the leaves are small, obtuse, and lie over each other like the scales of fish; the male flowers grow at the extremity of the branches in a conical katkin, and the fruit grows single from the side of the branches below the katkins on the same branch; the berries are large, oval, and, when ripe, are brown.

The ninth sort grows naturally in *Jamaica*, and also in the other islands of the *West-Indies*, where it rises to be one of the largest timber trees in those countries; the wood is frequently fetched from thence by the inhabitants of *North America*, for building of ships. This is generally confounded with the *Bermudas Cedar*, and taken from the same, but the specimens of it which were sent by the late Dr. *Houssoun*, prove them to be different trees; for the branches of this spread wide, the leaves are extremely small, and are every where lying imbricatum over each other; the bark is rugged, and splits off in strings, and is of a very dark colour; the berries are smaller than those of the *Bermudas Cedar*, and are of a light brown colour when ripe.

The tenth sort is the common Savin; this grows naturally in *Italy*, *Spain*, and the *Levant*, upon the mountains where it is cold. It sends out its branches horizontally, so seldom rises more than three or four feet high; the branches are garnished with very short acute-pointed leaves placed opposite, and their ends point upward. This sort very rarely produces either flower or seed, when it is transplanted into gardens; the berries are smaller than those of the common Juniper, but of the same colour, and a little compressed; the whole plant has a very rank strong odour when touched. The leaves of this are much used by the farriers for horses when they have worms, and Mr. *Roy* commends the juice of it mixed with milk, and sweetened with sugar, as an excellent medicine for children who are troubled with worms.

The eleventh sort has, by many, been supposed to be only an accidental variety of the former, but there is a manifest difference between them; for the branches of this grow more erect, the leaves are shorter, and end in acute points which spread outward. This will rise to the height of eight or ten feet, and produces great quantities of berries. I have propagated this sort from seeds, but have ne-

ver found it vary. It has been distinguished by most of the old botanists, by the title of berry-bearing Savin. It grows naturally on the *Alps*.

The twelfth sort grows naturally in *Spain*, *Portugal*, and the south of *France*, where it rises ten or twelve feet high, sending out small taper branches without angles, the whole length of the stem, garnished with small obtuse leaves, lying over each other like the scales of fish; the male flowers are situated at the end of the branches in conical scaly katkins, and the berries grow below from the side of the same branches. These are larger than those of the common Juniper, and when ripe are brown.

The thirteenth sort grows naturally in *Spain* and *Portugal*, where it rises from twenty-five to thirty feet high, sending out many branches which form a pyramid, garnished with acute-pointed leaves which lie over each other four ways, so as to make the branches four-cornered; the berries of this sort are very large, and black when ripe.

These plants are all propagated by seeds, which should be sown as soon as they are ripe, if they can be procured; for when they are kept out of the ground till spring, they will not come up until the second year. The hardy sorts may be sown on a border exposed to the east, sifting some earth over them about half an inch thick; toward the middle or latter end of *April*, some of the plants will appear above ground, though perhaps part of them may lie till the spring following before they come up, therefore should not be disturbed till after that time; for as these plants which come up the first season, will not make great progress while they are young, so they will not require moving till after two summers growth. The second autumn after sowing some beds must be prepared to transplant them into, which should be of fresh undunged soil, well dug and cleansed from all noxious weeds and roots; then in the beginning of *October*, which is the proper season for removing these plants, they should be raised up with a trowel, preserving as much earth as possible to their roots, and planted into the beds about five or six inches asunder each way, giving them some water to settle the earth to their roots; and if it should prove very dry weather, this should be repeated two or three times. As some of the seeds may yet remain in the ground, so the beds should not be disturbed too much in taking up the plants; for I have known a bed sown with these berries, which has supplied plants for three years drawing, some of the berries having lain two years in the ground before they sprouted; therefore the surface of the beds should be kept level, and constantly clean from weeds.

The plants may remain two years in the beds after planting, observing to keep them clear from weeds; in the spring the ground should be gently stirred between them, that their roots may with greater ease strike into it; after which time they should be transplanted, either into a nursery, at the distance of three feet row from row, and eighteen inches asunder in the rows, or into the places where they are to remain for good. The best season to transplant them (as I before observed) is in the beginning of *October*.

In order to have these trees aspire in height, their under branches should be taken off, especially where they are inclined to grow out strong; but they must not be kept too closely pruned, which would retard their growth; for all these ever-green trees do more or less abound with a resinous juice, which in hot weather is very apt to flow out from such places as are wounded; so that it will not be advisable to take off too many branches at once, which would make so many wounds, from which their sap in hot weather would flow in such plenty, as to render the trees weak and unhealthy.

The other sorts are also propagated by seeds, which must be procured from the countries where they grow naturally,

and sown as was directed for the other Junipers. When the plants come up they must be carefully weeded, and in dry weather should be refreshed with water, which will greatly forward their growth; the autumn following they should have a little rotten tan laid between them, to keep out the frost. In this bed the plants may remain till they have had two years growth, then they should be transplanted into other beds, and managed as was directed before for the other sorts.

In these beds they may remain two years, observing to keep them clear from weeds; and in winter lay a little fresh mulch upon the surface of the ground round their roots, which will prevent the frost from penetrating to them, and effectually preserve them; for while the plants are young, they are liable to be injured by very hard frosts; but when they have attained a greater strength, they will resist the severest of our cold.

After two years, they should either be removed into a nursery (as was directed for the common Juniper) or transplanted where they are designed to remain; observing always to take them up carefully, otherwise they are subject to fail upon transplanting; as also to mulch the ground, and water them as was before directed, until they have taken root; after which they will require no farther care, than only to keep the ground clear about their roots, and to prune up their side branches to make them aspire in height.

The timber of these trees is of excellent use in *America*, for building of vessels, wainscoting houses, and for making many sorts of utensils, it abounding with a bitter resin, which prevents its being destroyed by vermin, but it is very brittle, and so not proper for stubborn uses; but however, by increasing the number of our timber trees, we shall find many advantages, besides the pleasure their variety affords; for we may hereby have trees of very different kinds, which are adapted to grow in various soils and situations, whereby we shall never want proper trees for all the different soils in *England*, if proper care be taken in their choice; which would be a great improvement to many parts of this kingdom, which now lie unplanted, because the owner, perhaps, finds that neither Oaks or Elms will thrive there, so concludes, that no other sort will, which is a great mistake.

The *Bermudas* Cedar being a native of that island, and also of the *Bahama Islands*, is much tenderer than either of the former sorts, so is not likely to thrive well in this country; for although many of these plants have lived several years in the open air in *England*, yet whenever a severe winter happens, it either kills them, or so much defaces them, as that they do not recover their verdure in a year or two after.

The timber of this tree is of a brown colour, and very sweet; it is commonly known in *England* by the name of Cedar wood, though there are divers sorts of wood called by that name, which come from very different trees, especially in the *West-Indies*, where there are several trees of vastly different appearance and genera, which have that appellation; it is this wood which is used for pencils, as also to wainscot rooms, and make stair cases. In *America* they build ships with this wood, for they say, the worms do not eat the bottoms of the vessels built with this wood, as they do those built with Oak; so that the vessels built with Cedar are much preferable, especially for the use of the *West-India* seas, but they are not fit for ships of war, the wood being so brittle as to split to pieces with a cannon ball.

The *Jamaica* Juniper is more impatient of cold than the *Bermudas*, so will not live through the winter in the open air in *England*, so the plants must be preserved in pots, and housed in the winter; this is propagated by seeds, in the same way as the *Bermudas* Cedar, but if the pots are plunged into a moderate hot-bed the second spring after the

the seeds are sown, it will bring up the plants sooner, and they will have more time to get strength before winter.

The common Savin should not be neglected, because it is so very hardy as never to be injured by the severest frost; and as this spreads its branches near the ground, so if the plants are placed on the borders of woods, they will have a good effect in winter, by screening the nakedness of the ground from sight.

Most of these plants may be propagated by cuttings, if they are planted in the autumn, and the tender sorts screened in winter with a common frame; but the plants so raised, will not be so good as those which come from seeds.

JUSSIÆA. *Lin. Gen. Plant.* 478.

The Characters are,

It hath a small permanent empalement, divided into five parts, sitting upon the germen. The flower has five roundish petals, and ten short slender stamina. The oblong germen afterward becomes a thick oblong capsule, crowned by the empalement, which opens lengthways, and is filled with small seeds.

The Species are,

1. JUSSIÆA *erecta villosa, floribus tetrapetalis, octandriis, pedunculatis. Lin. Sp. Plant.* 388. Upright hairy Jussiaea, with flowers standing upon foot-stalks, having four petals and eight stamina.

2. JUSSIÆA *villosa, caule erecto ramoso, floribus, pentapetalis, decandriis sessilibus.* Hairy Jussiaea with an erect branching stalk, flowers having five petals, and ten stamina, which sit close to the stalk.

3. JUSSIÆA *erecta glabra, floribus tetrapetalis octandriis sessilibus. Flor. Zeyl.* 170. Smooth upright Jussiaea, with four petals, and eight stamina to the flowers, which sit close to the stalk.

4. JUSSIÆA *caule erecta ramoso glabro, floribus tetrapetalis octandriis sessilibus, foliis lanceolatis.* Jussiaea with an upright, branching, smooth stalk, flowers having four petals, and eight stamina sitting close to the stalk, and spear-shaped leaves.

5. JUSSIÆA *caule erecto simplici hirsuto, foliis lanceolatis, floribus pentapetalis aecandriis sessilibus.* Jussiaea with a single, upright, hairy stalk, spear-shaped leaves, flowers which have five petals, and ten stamina sitting close to the stalk.

The first sort grows naturally at *Campeachy*. This rises with a shrubby stalk three feet high, sending out several side branches, garnished with oblong hairy leaves, placed alternate. The flowers come out from the side of the stalks singly, upon short foot-stalks, having four small yellow petals, with eight stamina, sitting upon the germen, which afterward becomes an oblong seed-vessel, crowned by the four-leaved empalement, including many small seeds.

The second sort grows naturally in *Jamaica*. This rises with a hairy branching stalk two feet high, garnished with narrow spear-shaped leaves, placed alternate. The flowers come out toward the end of the branches singly from the wings of the leaves, sitting close to the stalk; they are composed of five pretty large yellow petals, and ten stamina, which sit upon a long germen, which afterward becomes the seed-vessel, crowned by the empalement, filled with small seeds.

The third sort grows naturally in *Jamaica*. This rises with a smooth erect stalk three feet high, garnished with long, narrow, smooth, spear-shaped leaves. The flowers are large and yellow, sitting close to the stalk, and are succeeded by long seed-vessels, shaped like those of the other sorts.

The fourth sort grows near *Carthage*. This hath a branching smooth stalk three feet high, garnished with spear-shaped leaves, standing upon short foot-stalks. The flowers are small, yellow, and are composed of four petals, and eight stamina; these sit very close to the stalk, and are succeeded by seed-vessels, shaped like those of the former sorts.

The fifth sort was sent me from *La Vera Cruz*. This rises with single, upright, red, hairy, channelled stalks three feet high. The leaves are spear-shaped, and placed alternate, standing nearer together than in any of the other sorts. The flowers come out from the wings of the leaves on the upper part of the stalk; they are composed of five large yellow petals, and ten stamina, sitting close to the stalks, and are succeeded by seed-vessels, which are one inch long, and shaped like those of the former sorts.

The first, second, and fourth sorts are annual plants, at least they are so in *England*; for if the plants are raised early in the spring, they will flower in *July*, and ripen their seed the beginning of *October*, and the plants soon after decay.

The third and fifth sorts will continue through the winter in the bark-stove; but these must be such plants as do not flower and seed the first year, for after they have perfected seeds, the following summer the plants decay.

All these sorts are propagated by seeds, which should be sown early in the spring, on a moderate hot-bed. When the plants come up, and are fit to remove, they should be each planted into a small separate pot, and plunged into a hot-bed of tanners bark, where they should be shaded from the sun till they have taken new root, after which they should have free air admitted to them every day, in proportion to the warmth of the season. When the roots of the plants have filled these small pots, the plants should be removed into others, a size larger; and if the plants are too tall to stand under the frames of the hot-bed, they should be removed into the bark-stove, where they may remain to flower and perfect their seeds; for when the plants rise early in the spring, and are brought forward in hot-beds, all the sorts will flower and perfect their seeds the same year.

JUSTICIA. *Houft. Nov. Gen. Lin. Gen. Plant.* 26.

The Characters are,

The flower hath one petal, which is divided into two lips, almost to the bottom, which are entire. The upper lip is raised archways, and the under is reflexed. It hath two awl-shaped stamina, situated under the upper lip, with an oblong germen, which afterward becomes an oblong capsule with two cells, which open with an elasticity, and cast out the roundish seeds.

The Species are,

1. JUSTICIA *foliis oblongo-ovatis hirsutis, sessilibus, floribus spicatis alaribus, caule fruticoso.* Justicia with oblong, oval, hairy leaves, sitting close to the stalks, and flowers growing in spikes proceeding from the side of the stalks, which are shrubby.

2. JUSTICIA *caule erecto ramoso hexangulati, foliis ovatis oppositis, bracteis cuneiformibus confertis.* Justicia with an erect branching stalk, having six angles, oval leaves placed opposite, and wedge-shaped small leaves (or bractæ) growing in clusters.

3. JUSTICIA *foliis ovato-lanceolatis, pediculatis, hirsutis, bracteis cordatis acuminatis, caule fruticoso.* Justicia with oval spear-shaped leaves growing on foot-stalks, heart-shaped acute-pointed bractæ, and a shrubby stalk.

4. JUSTICIA *arborea, foliis lanceolato-ovatis, bracteis ovatis persistentibus, corollarum galeâ concavâ. Flor. Zeyl.* 16. Tree Justicia with oval spear-shaped leaves, oval permanent bractæ, and a concave helmet to the flower; commonly called *Malabar Nut*.

5. JUSTICIA *fruticosa, foliis lanceolatis integerrimis, pedunculis trifloris ancipitibus, bracteis calyce brevioribus. Lin. Sp. Plant.* 15. Shrubby Justicia with entire spear-shaped leaves, foot-stalks having three flowers looking different ways, and a bractæ shorter than the empalement; commonly called *Snap Tree*.

6. JUSTICIA *spinosa, foliis oblongo ovatis emarginatis, caule fruticoso ramoso.* Prickly Justicia with oblong oval leaves, indented at their edges, and a shrubby branching stalk.

7. JUSTICIA

7. *JUSTICIA arborea, foliis lanceolato-ovatis sessilibus, subtus tomentosis, floribus spicatis congestis terminalibus.* Tree *Justicia* with spear-shaped oval leaves, woolly on their under side, sitting close to the stalks, and spikes of flowers growing in clusters at the ends of the branches.

8. *JUSTICIA arborea, foliis lanceolato-ovatis, bracteis ovatis deciduis mucronatis, corollarum galeâ reflexâ.* Flor. Zeyl. 17. Tree *Justicia* with spear-shaped oval leaves, oval-pointed bractæ, which fall off, and a reflexed helmet to the flowers.

The first sort grows naturally at *La Vera Cruz*. This rises with a shrubby brittle stalk five or six feet high, sending out many branches, garnished with oblong, oval, hairy leaves, placed opposite; from the wings of the leaves come out the spikes of flowers, which are reflexed like a scorpion's tail. The flowers are large, of a carmine colour, ranged on one side of the spikes; these are succeeded by short pods about half an inch long.

The second sort is a native of the same country. This is an annual plant, with an upright stalk with six angles, which rises from two to three feet high, dividing into many branches, garnished with oval leaves placed opposite. At each joint come out clusters of small wedge shaped leaves, which are termed bractæ. The flowers are produced in small spikes at the end of the branches, sitting very close among the leaves; they are of a beautiful carmine colour, of one petal, which has two lips. The upper lip is arched, bending over the lower, which is also a little reflexed, but both are entire. The flowers are succeeded by short wedge-shaped capsules, opening lengthways, inclosing two small oval seeds.

The third sort grows naturally at *Campeachy*. This rises with a hairy shrubby stalk four or five feet high, dividing into several branches, garnished with oval, spear-shaped, hairy leaves, standing upon foot-stalks, placed opposite. The flowers come out in loose clusters from the wings of the stalks, toward the end of the branches; they are of a pale red colour, shaped like those of the former sort.

These plants are propagated by seeds, which should be sown early in the spring in small pots, and plunged into a moderate hot-bed of tanners bark. The seeds of these plants frequently lie a year in the ground, so that the pots must not be disturbed, if the plants do not come up the same year; but in the winter should be kept in the stove, and the spring following plunged into a fresh hot-bed, which will bring up the plants if the seeds were good.

When the plants are about two inches high, they should be carefully taken up, and each transplanted into a separate small pot, and plunged into the hot-bed again, being careful to water and shade them until they have taken new root; after which time they should have air admitted to them every day, in proportion to the warmth of the season, and duly watered in hot weather.

As the plants advance in their growth, they should be shifted into larger pots; and as they are too tender to endure the open air in this country, so they should always remain in the hot-bed, being careful to let them have a due proportion of air in hot weather; and the annual sort should be brought forward as fast as possible in the spring, that the plants may flower early, otherwise they will not produce good seeds in *England*.

The first and third sorts should remain in the hot-bed during the summer season (provided there be room under the glasses, without being scorched;) but at *Michaelmas* they should be removed into the stove, and plunged into the bark-bed, where they must remain during the winter season. The following summer these plants will flower, and abide several years, but they rarely produce good seeds in *Europe*.

The fourth sort grows naturally in the island of *Ceylon*, but has been long in the *English* gardens, where it is commonly known by the title of *Malabar Nut*. This, though a native of so warm a country, is hardy enough to live in a good green house in *England*, without any artificial heat. It rises here with a strong woody stalk, to the height of twelve or fourteen feet, sending out many spreading branches, garnished with spear-shaped oval leaves six inches long and three inches broad, placed opposite. The flowers are produced on short spikes at the end of the branches, which are white, with some dark spots, but are not succeeded by any seeds in *England*.

This sort may be propagated by cuttings, which, if planted in pots in *June* or *July*, and plunged into a very moderate hot-bed, will take root, but they must be screened from the sun; and if the external air is excluded from them, they will succeed better than when it is admitted to them. It may also be propagated by laying down the young branches, which will take root in one year, and then should be put each into a separate pot, and placed in the shade till they have taken new root; then they may be removed to a sheltered situation during the summer, and in the autumn they must be housed, and treated in the same way as *Orange trees*, with only this difference, that these require more water.

The fifth sort grows naturally in *India*. This rises with a shrubby stalk from three to four feet high, sending out branches on every side from the bottom, so as to form a kind of pyramid, garnished with spear-shaped entire leaves, near two inches long, and one third of an inch broad; they are smooth, stiff, and of a deep green, standing opposite. At the base of the foot-stalks come out clusters of smaller leaves, of the same shape and texture. The flowers come out upon short foot-stalks from the side of the branches, each foot-stalk supporting one, two, or three white flowers, with long empalements, which are succeeded by oblong seed-vessels, which when ripe cast out their seeds with an elasticity, from whence it had the title of *Snap tree*.

This is propagated by cuttings during any of the summer months, which should be planted in pots, and plunged into a hot bed which has lost its great heat, and shaded from the sun. In about two months the cuttings will have taken root, then they must be gradually inured to bear the open air, into which they should be removed, placing them in a sheltered situation, where they may stay till autumn; but if they get root pretty early in the summer, it will be proper to separate them each into a single small pot, setting them in the shade till they have taken new root, after which they may be placed as before directed; but when it is late in the season before they take root, it will be better to let them remain in the same pots till the following spring. In winter these plants must be placed in a warm green-house, or in a moderate warm stove, for they are impatient of cold and damp, nor will they thrive in too much warmth; they will often require water in winter, but during that season it must be given them moderately; in summer they must be removed into the open air, but should have a warm sheltered situation, and in warm weather they must have plenty of water. This plant flowers at different seasons, but never produces fruit here.

The sixth sort grows naturally in *Jamaica*. This rises with many shrubby slender stalks, about five feet high, sending out branches on every side, which are covered with a whitish bark, garnished with small, oblong, oval leaves, coming out two on each side the stalk opposite, and under the leaves are placed at every joint two sharp thorns like those of the *Berberry*; the flowers come out singly from the wings of the leaves; they are small, and of a pale red colour, and shaped like those of the other sorts.

The seventh sort grows naturally at *Campeachy*. This rises with a strong woody stem twenty feet high, dividing into many crooked irregular branches, covered with a light brown bark, garnished with spear-shaped oval leaves, near four inches long and two broad, which are covered with a soft down on their under side. The flowers grow in spikes from the end of the branches, three, four, or five of these spikes arising from the same point, the middle spike being near three inches long, and the others about half that length. The flowers are small, white, and shaped like those of the other species.

The eighth sort grows naturally at *Malabar* and in *Ceylon*. This rises with a strong woody stem ten or twelve feet high, dividing into many branches, garnished with spear-shaped oval leaves five inches long, and two and a half broad, of a lucid green, placed opposite. The flowers grow in very long spikes from the end of the branches; they are of a greenish colour, with a shade of blue; the helmet of the flower is reflexed.

These three sorts are propagated by seeds, in the same manner as the three first, and the plants must be treated in the same way, especially while they are young; but afterward the eighth sort may be more hardily treated. This sort may also be propagated by cuttings, in the same manner as the fifth sort; and when the plants are two or three years old, they will thrive in a moderate degree of warmth in winter, and in the summer they may be placed abroad for two months in the warmest season of the year, but they should have a warm sheltered situation, and when the nights begin to grow cold, they must be removed into the stove, but they must have free air admitted to them at all times when the weather is warm. The other two sorts should constantly remain in the bark-stove, and require the same treatment as other tender plants from the warmest countries.

IXIA. *Lin. Gen. Plant.* 54.

The Characters are,

It hath oblong permanent spathæ (or sheaths) which inclose the germen; the flower has six petals which are equal, and three awl-shaped stamina. It hath an oval three-cornered germen, situated below the flower, with a single style; the germen afterward becomes an oval capsule with three cells, filled with roundish seeds.

The Species are,

1. IXIA *foliis ensiformibus, floribus remotis.* *Hort. Upsal.* 16. Ixia with sword-shaped leaves, and flowers standing distant.
2. IXIA *floribus capitatis, spathis laceris.* *Lin. Sp. Plant.* 36. Ixia with flowers growing in heads, and ragged sheaths.
3. IXIA *foliis gladiolatis, nervosis, hirsutis, floribus, spicatis terminalibus.* *Icon. tab.* 155. *fig.* 1. Ixia with sword-shaped, hairy, veined leaves, and flowers growing in spikes at the ends of the stalks.
4. IXIA *foliis lineari-gladiolatis, floribus alaribus & terminalibus.* *Icon. tab.* 155. *fig.* 2. Ixia with narrow sword-shaped leaves, and flowers proceeding from the sides and tops of the stalk.
5. IXIA *foliis gladiolatis glabris, floribus corymbosus terminalibus.* *Icon. tab.* 156. Ixia with smooth spear-shaped leaves, and flowers growing in a corymbus terminating the stalk.
6. IXIA *foliis lineari-ensiformibus axillis bulbiferis, floribus alternis staminibus lateralibus.* *Lin. Syst.* Ixia with narrow sword-shaped leaves, flowers placed alternate, and stalks bearing bulbs at the joints.
7. IXIA *foliis gladiolatis, floribus distantibus.* Ixia with sword shaped leaves, and flowers growing distant.
8. IXIA *foliis lineari gladiolatis, floribus spicatis sessilibus terminalibus.* Ixia with narrow sword-shaped leaves, and sessile flowers growing in spikes at the top of the stalk.
9. IXIA *foliis gladiolatis glabris, floribus remotis alternim sitis, petalis patentibus acuminatis.* Ixia with smooth sword-shaped

leaves, flowers placed distant alternately, and pointed petals which spread open.

The first sort grows naturally in *India*, and also at the *Cape of Good Hope*; the stalks rise to the height of three or four feet. It hath a pretty thick fleshy root, divided in knots or joints of a yellowish colour, sending out many fibres; the stalk is pretty thick, smooth, and jointed, garnished with sword-shaped leaves a foot long and one inch broad, with several longitudinal furrows, embracing the stalks with their base, ending in acute points; the upper part of the stalk divaricates into two smaller, with a foot-stalk arising between them, which supports one flower; the smaller branches divaricate again in the same manner into foot-stalks, which are two inches long, each sustaining one flower. At each of these joints is a permanent spatha or sheath embracing the stalk, ending in an acute point; the flowers are composed of six equal petals, of a yellow colour within, variegated with dark red spots; the outside is of an Orange colour. These appear in *July* and *August*, and in warm seasons are succeeded by seeds.

This sort may be propagated either by seeds or parting of the roots: if by seeds, they should be sown in pots soon after they are ripe, and plunged into an old hot-bed, under a frame to screen them from frost; and in the spring the plants will come up, when they should be inured to the open air by degrees, for in summer they must be wholly exposed thereto. The following autumn they must be separated; some of the plants may be planted in a warm border, where they will abide through the common winters very well, but in severe frosts they are often killed, unless they are covered with tan, or other covering to keep out the frost, therefore a few of the plants may be kept in pots, and sheltered under a frame in winter.

The stalks and leaves of this plant decay to the root in autumn, so that if the surface of the ground about the roots is covered two or three inches thick with tan, it will secure them from the danger of frost; and in the spring before the roots shoot, will be the best time to remove and part the roots; but this should not be done oftener than every third year, for when they are often parted, they will be weak, and will not flower so well.

The second sort grows naturally at the *Cape of Good Hope*. This is a low plant, which rises three or four inches high; the leaves are narrow and veined, the flowers are small, growing in a downy head on the top of the stalk, but they make little appearance, so are only kept for the sake of variety.

The third sort I raised from seeds, which were sent me from the *Cape of Good Hope*. This hath a bulbous root a little compressed, covered with a red skin, from which arise five or six sword-shaped leaves about three or four inches long, hairy, with several longitudinal furrows; these embrace each other at their base; between these come out the flower-stalk, which rises six or eight inches high, naked to the top, and terminated by a cluster of flowers, each having a spatha or hood, which dries and is permanent; the flowers are of a deep blue colour, and are succeeded by roundish, three-cornered, seed-vessels with three cells, filled with roundish seeds.

The fourth sort was raised from seeds in the *Chelsea* garden, which came with those of the former. This hath a small, round, bulbous root, from which arise four or five narrow, long, sword shaped leaves six or seven inches long; between these come out a very slender round stalk about ten inches long; from the side of which there comes out one or two clusters of flowers, standing upon short foot-stalks, and at the top of the stalk the flowers grow in a loose spike; they are of a pure white, and shaped like those of the other species.

The seeds of the fifth sort were sent me from the *Cape of Good Hope*. This has an oval bulbous root, which is a little compressed, from which come up three or four narrow, thin, sword-shaped leaves near a foot long; the flower-stalk rises a little above the leaves; it is very slender, naked, and terminated by a round cluster of flowers, composed of six pretty large, oblong, concave petals, of a deep yellow colour, each having a large black spot at the base. This flowers early in *May*, and the seeds ripen the latter end of *June*.

The sixth sort hath narrow sword-shaped leaves about six or seven inches long. The stalk rises near a foot and a half high, garnished with one leaf at each of the lower joints, of the same shape with the other but smaller; these embrace the stalk with their base, and stand erect; the upper part of the stalk is adorned with flowers composed of six oblong, oval, whitish petals, having a blue stripe on their outside, which are placed alternate on the stalk, which is bent at each joint where the flowers stand; the flowers have three short stamina, which are joined at their base, terminated by long, flat, erect summits; the germen is situated under the flower, supporting a long slender style, crowned by a trifid stigma; the germen afterward becomes a roundish capsule with three cells, filled with roundish small seeds. The stalks at each of the lower joints thrust out small bulbs, which, if planted, will grow and produce flowers.

The seventh sort hath shorter and broader leaves than the former. The stalk is slender and furrowed; at each of the lower joints is garnished with one leaf of the same shape, embracing the stalk with their base; the flowers come out toward the top of the stalk at two or three inches distance, each stalk supporting two or three sulphur-coloured flowers, which are each composed of six spear-shaped petals an inch and a half long, equal in their size and regular in position; they have a short permanent empalement, cut into two long and two shorter acute segments; these are succeeded by round capsules with three cells, filled with round seeds.

The eighth sort hath very small, round, bulbous roots, from which arise three or four long, slender, smooth, Grass-like leaves, of a dark green colour; between these come

out the stalk, which is very slender, rising a foot and a half high; at the top the flowers are collected in a spike sitting close to the stalk, each having a thin, dry, permanent spatha or sheath, which covers the capsule after the flower is fallen. The flowers are of a pure white, and shaped like those of the other species, but are smaller; they are succeeded by small, round, seed-vessels with three cells, each containing two or three round seeds.

The ninth sort hath a roundish, compressed, bulbous root, from which arise broad sword-shaped leaves a foot and a half long, of a deep Grass-green colour: the foot-stalk of the flower rises two feet high; the flowers are placed alternately at distances on the upper part of the stalk, each having an acute-pointed spatha or sheath, which is permanent, afterward covering the capsule. The flowers are much larger than those of the former sorts, of a bright red colour, having six equal petals, which spread open wide, and three awl-shaped stamina arising from the intervals of the petals standing erect, between which arises a single style of the same length as the stamina. After the flower is past, the germen, which is situated under the flower, becomes an oval capsule with three cells, including several round seeds. The roots of most, if not all these sorts, are frequently eaten by the inhabitants at the *Cape of Good Hope*, who greatly esteem them.

All the sorts multiply very fast by offsets, so that when once obtained, there will be no occasion to raise them from seeds; for the roots put out offsets in great plenty, most of which will flower the following season, whereas those from seeds are three or four years before they flower. These plants will not live through the winter in the full ground in *England*, so should be planted in pots, and placed under a frame in winter, where they may be protected from frost, but in mild weather should enjoy the free air; but they must be guarded from mice, who are very fond of these roots, and, if not prevented, will devour them. If a frame is made for these in the same manner as is directed for the *African Gladioluses*, and other bulbous roots which require no artificial heat, they will thrive and flower much better than when they are planted in pots.

K.

K A L

KALI. See Salsola.
KALMIA. *Lin. Gen. Plant.* 482.

The Characters are,

The flower has a small permanent empalement, and one petal cut into five segments, which spread open. It hath ten stamina which are the length of the petal, and decline in the middle. In the center is situated a roundish germen, which afterward becomes an oval or globular capsule with five cells, filled with very small seeds.

The Species are,

1. KALMIA foliis ovatis, corymbus terminalibus. Kalmia with oval leaves, and flowers growing in bunches terminating the branches.

K A L

2. KALMIA foliis lanceolatis corymbis lateralibus. *Lin. Gen. Nov.* 1079. Kalmia with spear-shaped leaves, and flowers growing in round bunches on the sides of the stalk.

The first sort grows in several parts of *North America*, where it rises from six to twelve feet high, dividing into many ligneous branches, covered with a dark gray bark; they are generally crooked and irregular, but are closely garnished with stiff leaves about three inches long and one broad, of a lucid green, standing upon slender foot-stalks; the flowers grow in loose bunches at the end of the branches, upon long foot-stalks; they are of one petal, with a short tube, which spreads open at the top, where it is cut into five

five angles; the flowers are of a bright red colour when they first open, but afterward fade to a blush or Peach-bloom colour; these are succeeded by roundish, compressed, seed-vessels crowned by the permanent style, divided into five cells, which are filled with small roundish seeds.

The leaves of this elegant plant are supposed to have a noxious quality, destroying sheep and oxen when they feed upon them, yet the deer eat them with impunity.

The second sort grows naturally in *Pensylvania*, where it rises four or five feet high, but in *England* I have not seen any, which were more than half that height.

The leaves of this sort are about two inches long, and half an inch broad in the middle; they are stiff, of a lucid green, and stand opposite; sometimes they are by pairs at each joint, and at others there are four, two on each side, standing upon very short foot-stalks; the flowers come out in clusters on every side the stalks; they are of a beautiful red colour, and shaped like those of the first sort, but smaller; they are succeeded by short, roundish, compressed capsules with five cells, crowned by the permanent style, and filled with very small seeds. This shrub, in its native country, continues flowering most part of summer.

Both these sorts multiply by their creeping roots in their native soil, and where they have stood unremoved a considerable time, they put out suckers in pretty great plenty; and as these plants, which come from suckers, are much more likely to produce others than those which are raised from seeds, and will flower much sooner, so the plants should not be removed, but encouraged to spread their roots, whereby they may be propagated; they love a moist, light, boggy soil, in which they will thrive and flower.

KARATAS, the Penguin or wild Ananas.

The Characters are,

It hath a tubulous bell-shaped flower, divided into three parts at the mouth, from whose calyx arises the pointal, fixed like a nail in the hinder part of the flower, which afterward becomes a fleshy almost conical fruit, divided by membranes into three cells, which are full of oblong seeds.

There is but one sort of this plant at present known, which is,

KARATAS *foliis altissimis, angustissimis & aculeatis. Plum. Nov. Gen.* The wild Ananas or Penguin.

Father *Plumier* has made a great mistake in the figure and description of the characters of this plant, and the *Caraguata*; for he has joined the flower of the *Caraguata* to the fruit of the *Karatas*, and *vice versa*; and this has led many persons into mistakes, who have joined the *Bromelia* and *Ananas* to this, making them of the same genus.

This plant is very common in the *West-Indies*, where the juice of its fruit is often put into punch, being of a sharp acid flavour. There is also a wine made of the juice of this fruit, which is very strong, but it will not keep good long, so is only for present use. This wine is very intoxicating, and heats the blood, therefore should be drank very sparingly.

In *England* this plant is preserved as a curiosity, for the fruit seldom arrives to any degree of perfection for use in this country, though it often produces fruit in *England*, which has ripened pretty well; but if it were to ripen as thoroughly here as in its native country, it will be little valued on account of its great austerity, which will often take the skin off from the mouths and throats of those people, who eat it incautiously.

This plant is propagated by seeds, for though there are often suckers sent forth from the old plants, yet they come out from between the leaves, and are so long, slender, and ill-shapen, that if they are planted they seldom make regular plants. These seeds should be sown early in the spring in small pots, and plunged into a hot-bed of tanners bark, where the plants will come up in six weeks. When the

plants are strong enough to transplant, they should be carefully taken up, each planted into a separate pot, and plunged into the hot-bed again; when the plants have taken new root, they should have air and water in proportion to the warmth of the season. In this bed the plants may remain till *Michaelmas*, then they should be removed into the stove, and plunged into the bark-bed, where they should be treated in the same manner as the *Ananas*.

The leaves of this plant are strongly armed with crooked spines, which renders it very troublesome to shift or handle them; for the spines catch hold of whatever approaches them by their crooked form, being some bent one way, and others the reverse, so that they catch both ways, and tear the skin or clothes of the persons who handle them, where there is not the greatest care taken to avoid them.

The fruit of this plant is produced in clusters, growing upon a stalk about three feet high, with a tuft of leaves growing on the top, so at first sight has the appearance of a Pine Apple; but, when closer viewed, they will be found to be a cluster of oblong fruit, each being about the size of a finger.

KETMIA. See *Hibiscus*.

KIGGELARIA. *Lin. Gen. Plant.* 1001.

The Characters are,

The male and female flowers are situated on different trees; the male flowers have five concave petals, which are shaped like a pitcher; each having a honey gland fastened to their base, and have ten small stamina. The female flowers have petals like the male, but no stamina. In the center is situated a roundish germen, which afterward becomes a rough globular fruit with a thick cover, having one cell, filled with angular seeds.

We have but one Species of this genus, viz.

KIGGELARIA. *Hort. Cliff.* 462. fol. 29.

This plant grows naturally at the *Cape of Good Hope*, where it rises to be a tree of middling stature; but as it will not live in the open air here, they cannot be expected to grow to a great magnitude in *England*. There are plants of it in the *Chelsea* garden upward of ten feet high, with strong woody stems and pretty large heads; the branches have a smooth bark, which is first green, but afterward changes to a purplish colour; the leaves are about three inches long and one broad, of a light green colour, sawed on their edges, and stand upon short foot-stalks alternately. The flowers come out in clusters from the side of the branches, hanging downward; they are of an herbaceous white colour. The male flowers fall away soon after their farina is shed, but the female flowers are succeeded by globular fruit about the size of common red Cherries, with a rough cover, of a thick consistence, opening in four parts at the top, to each of which adhere many small angular seeds. These fruits have grown to their full size in the *Chelsea* garden, but the seeds never came to maturity.

These plants are not very common in *Europe*, being very difficult to propagate; for when any of the young branches are laid down, very few of them take root, and those which do are two years before they put out roots; nor do the cuttings succeed much better, for very few of them will take root, when planted with the utmost care: the best time to plant the cuttings is in *May*, just before the plants begin to shoot; these should be planted in pots, and plunged into a very moderate hot-bed, covering them close with a glass, to exclude the air from them, and shade them every day from the sun; they should have very little water after their first planting. Those which do grow should be planted into separate small pots, and shaded till they have taken fresh root, then may be exposed to the air in a sheltered situation till autumn, when they must be removed into the greenhouse, and treated in the same manner as *Orange* trees, and other greenhouse plants.

KITCHEN-GARDEN. A good kitchen-garden is almost as necessary to a country seat, as a kitchen to the house; for without one, there is no way of being supplied with a great part of necessary food, the markets in the country being but poorly furnished with esculent herbs, and those only upon the market days, which are seldom oftener than once a week; so that unless a person has a garden of his own, there will be no such thing as procuring them fresh, in which their goodness consists; nor can any variety of these be had in the country markets, therefore whoever proposes to reside in the country should be careful to make choice of a proper spot of ground for this purpose; and the sooner that is made and planted, the produce of it will be earlier in perfection; for fruit trees and Asparagus require three years to grow, before any produce can be expected from them; so that the later the garden is made, the longer it will be before a supply of these things can be had for the table. And although the usefulness of this garden is acknowledged by almost every one, yet there are few who are careful to make a proper choice of soil and situation for such a garden: the modern taste, which is perhaps carried to as extravagant lengths, in laying open and throwing every obstruction down, as the former custom of inclosing within walls was ridiculous; so that now one frequently sees the kitchen-garden removed to a very great distance from the house and offices, which is attended with great inconveniencies; and often situated on a very bad soil, sometimes too moist, and at others without water, so that there is a great expence in building walls and making the garden, where there can be little hopes of success.

Nor will a kitchen garden be well attended to, when it is so situated as to be out of sight of the possessor, especially if the gardener has not a love and value for it, or if it lies at a great distance from the mansion-house, or the other parts of the garden, a great part of the labourer's time will be lost in going from one part to the other: therefore, before the general plan of the pleasure-garden is settled, a proper piece of ground should be chosen for this purpose, and the plan so adapted, as that the kitchen-garden may not become offensive to the sight, which may be effected by proper plantations of shrubs to screen the walls; and through these shrubs may be contrived some winding walks, which will have as good an effect as those which are now commonly made in gardens for pleasure only. In the choice of the situation, if it does not shut out any material prospect, there can be no objection to the placing it at a reasonable distance from the house or offices; for as particular things may be wanted for the kitchen, which were not thought of at the time when directions were given to the gardener what to bring in, so if the garden is situated at a great distance from the house, it will be found very inconvenient to send thither as often as things are wanting: therefore it should be contrived as near the stables as possible, for the conveniency of carrying the dung thither; which, if at a great distance, will add to the expence of the garden.

As to the figure of the ground, that is of no great moment, since in the distribution of the quarters all irregularities may be hid; though if you are at full liberty, an exact square or an oblong is preferable to any other figure.

The great thing to be considered is, to make choice of a good soil, not too wet nor over dry, but of a middling quality; nor should it be too strong or stubborn, but of a pliable nature, and easy to work; and if the place where you intend to make the kitchen-garden should not be level, but high in one part and low in another, I would by no means advise the levelling it; for by this situation you will have an advantage which could not be obtained on a per-

fect level, which is, the having one part of dry ground for early crops, and the low part for late crops, whereby the kitchen may be the better supplied throughout the season with the various sorts of herbs, roots, &c. And in very dry seasons, when in the upper part of the garden the crops will greatly suffer with drought, then the lower part will succeed, and so *vice versâ*; but I would by no means direct the choosing a very low moist spot of ground for this purpose; for although in such soils garden herbs are commonly more vigorous and large in the summer season, yet they are seldom so well tasted or wholesome as those which grow upon a moderate soil; and especially since in this garden your choice fruits should be planted, it would be wrong to make choice of a very wet soil for this purpose.

This garden should be fully exposed to the sun, and by no means overshadowed with trees, buildings, &c. which are very injurious to fruit trees; but if it be defended from the north wind by a distant plantation, it will greatly preserve the early crops in the spring. But these plantations should not be too near nor very large, for I have generally found where kitchen-gardens are placed near woods or large plantations, they have been much more troubled with blights in the spring than those which have been more exposed.

The quantity of ground necessary for a kitchen-garden, must be proportioned to the largeness of the family, or the quantity of herbs desired: for a small family, one acre and a half of ground may be sufficient; but for a large family there should not be less than four or five acres; because, when the ground is regularly laid out, and planted with espaliers of fruit trees, this quantity will be found little enough, notwithstanding what some persons have said on this head.

This ground must be walled round, and if it can be conveniently contrived, so as to plant both sides of the wall's which have good aspects, it will be a great addition to the quantity of wall fruit: and those slips of ground which are without side of the walls, will be very useful for planting of Gooseberries, Currants, Strawberries, and some sorts of kitchen plants, so that they may be rendered equally useful with any of the quarters within the walls; but these slips should not be too narrow, lest the hedge, pale, or plantation of shrubs which inclose them, should shade the borders where the fruit trees stand: the least width of these slips should be twenty-five or thirty feet, but if they are double that it will be yet better, the slips will be more useful, and the fruit trees will have a larger scope of good ground for their roots to run. The walls should be built about ten or twelve feet high, which will be sufficient height for most sorts of fruit.

The soil of this garden should be at least two feet deep; but if deeper it will be still better, otherwise there will not be depth enough for many sorts of esculent roots, as Carrots, Parsneps, Beets, &c. which run down pretty deep in the ground, and most other sorts of esculent plants delight in a deep soil; and many plants, whose roots appear short, yet if their fibres, by which they receive their nourishment, are traced, they will be found to extend to a considerable depth in the ground; so that when these are stopped by meeting with gravel, chalk, clay, &c. the plants will soon shew it, by their colour and stunted growth.

In the distribution of this garden, next the south and other good aspected walls, the borders should be at least eight or ten feet broad, whereby the roots of the fruit trees will have greater liberty than in such places where the borders are not above three or four feet wide; and upon these borders you may sow many sorts of early crops, if exposed to the south; and upon those exposed to the north, you may have some late crops; but I would by no means advise the planting any sort of deep rooting plants too near the fruit trees,

trees, especially Pease and Beans; though for the advantage of the walls, to preserve them in winter, and to bring them forward in the spring, the gardeners in general are too apt to make use of those borders, which are near the best aspect walls, to the great prejudice of their fruit trees; but for these purposes it is much better to have some Reed hedges fixed in some of the warmest quarters, close to which you should sow and plant early Pease, Beans, &c. where they will thrive as well as if planted near a wall, and hereby the fruit trees will be entirely freed from such troublesome plants.

The walks of this garden should be also proportioned to the size of the ground, which in a small garden should be six feet, but in a large one the middle walks should be ten or twelve; on each side of the walk should be allowed a border four or five feet wide between the espalier and the walk, whereby the distance between the two espaliers will be greater, and these borders being kept constantly worked and manured, will be of great advantage to the roots of the trees; in these borders may be sown some small Sallad, or any other herbs, which do not continue long or root deep, so that the ground will not be lost.

The breadth of these middle walks, which I have here assigned them, may by many persons be thought too great; but my reason for this is to allow proper room between the espaliers, that they may not shade each other, or their roots interfere and rob each other of their nourishment; but where the walks are not required of this breadth, it is only enlarging of the borders on each side, and so reducing the walks to the breadth desired.

The walks of these gardens should not be gravelled, for as there will be constantly an occasion to wheel manure, water, &c. upon them, they would soon be defaced, and rendered unsightly; nor should they be laid with turf, for in green walks, when they are wheeled upon or much trodden, the turf is soon destroyed, and those places where they are much used, become very unsightly also, therefore the best walks for a kitchen-garden are those which are laid with a binding sand; but where the soil is strong and apt to detain the wet, there should be some narrow underground drains made by the side of the walks, to carry off the wet, otherwise there will be no using of the walks in bad weather; and where the ground is wet, some lime rubbish, flints, chalk, or any such material as can be procured with the least expence, should be laid at the bottom of them; and if neither of these can be had, a bed of heath or furze should be laid, and the coat of sand laid over it, by which the sand will be kept drier, and the walks will be sound and good in all seasons. These sand walks are by much the easiest kept of any, for when either weeds or moss begin to grow, it is but scuffling them over with a Dutch hoe in dry weather, and raking them over a day or two after, and they will be as clean as when first laid; or if the walks are covered with the dust taken from the great roads, it will bind and make a firm walk.

The best figure for the quarters to be disposed, is a square or an oblong, where the ground is adapted to such a figure; otherwise they may be triangular, or of any other shape, which will best suit the ground.

When the garden is laid out in the shape intended, if the soil is strong, and subject to detain moisture, or is naturally wet, there should always be underground drains made, to carry off the wet from every quarter of the garden, for otherwise most sorts of kitchen plants will suffer greatly by moisture in winter; and if the roots of the fruit trees get into the wet, they will never produce good fruit, so that there cannot be too much care taken to let off all superfluous moisture from the kitchen-garden.

In one of these quarters, which is situated nearest to the

itables, and best defended from the cold winds, or if either of the slips without the garden wall, which is well exposed to the sun, lies convenient, and is of a proper width, that should be preferred for a place to make hot-beds for early Cucumbers, Melons, &c. The reasons for my giving the preference to one of these slips, is, first, there will be no dirt or litter carried over the walks of the kitchen-garden in winter and spring, when the weather is generally wet, so that the walks will not be rendered unsightly; secondly, the view of the hot-beds will be excluded from sight; and lastly, the convenience of carrying the dung into these slips, for by making of a gate in the hedge or pale, wide enough for a small cart to enter, it may be done with much less trouble than that of barrowing it through the garden; and where there can be a slip long enough to contain a sufficient number of beds for two or three years, it will be of great use, because by the shifting of the beds annually, they will succeed much better than when they are continued for a number of years on the same spot of ground; and as it will be absolutely necessary to fence this Melon ground round with a Reed hedge, it may be so contrived as to move away in pannels, and then that hedge, which was on the upper side the first year, being carried down to a proper distance below that which was the lower hedge, and which may remain, there will be no occasion to remove more than one of the cross hedges in a year; therefore I am persuaded, whoever will make trial of this method, will find it the most eligible.

The most important points of general culture consist in well digging, keeping clean, and manuring the soil, and giving proper distance to the trees and plants, according to their different growths (which is constantly exhibited in their several articles in this book). The dunghills should also be kept always clear from weeds, for it will be to little purpose to keep the garden clean, if this is not observed; for if the seeds of weeds are suffered to scatter upon the dung, they will be brought into the garden, whereby there will be a constant supply of weeds yearly introduced, to the no small damage of your plants, and a perpetual labour occasioned to extirpate them again. Another thing which is absolutely necessary to be observed, is, to carry off all the refuse leaves of Cabbages, the stalks of Beans, and haulm of Pease, as soon as they have done beating, for the ill scent which most people complain of in kitchen-gardens, is wholly occasioned by these things being suffered to rot upon the ground; therefore when the Cabbages are cut, all the leaves should be carried out of the garden while they are fresh, at which time they may be very useful for feeding of hogs, or other animals, and this will always keep the garden neat, and free from ill scents. As for all other necessary directions, they will be found in the articles of the several sorts of kitchen plants, which renders it needless to be repeated in this place.

KLEINIA. See Cacalia.

KNAUTIA. *Lin. Gen. Plant.* 109.

The Characters are,

It hath several floscular flowers inclosed in one common cylindrical empalement, which have their petals ranged so as to appear like a regular flower, but each separate floscule is irregular; in the bottom of each floret is situated the germen, attended by four stamina, which germen after-ward changes to a single, oblong, naked seed.

There is but one Species of this plant at present known, viz.

KNAUTIA. *Lin. Hort. Cliff.* This plant is very near akin to the Scabious, under which genus it has been ranged by several botanists, but the appearance of the flower at first sight being like a Lychnis, Dr. Boerhaave separated it from the Scabious, and gave it the title of *Lychni Scabiosa*, which being

being a compound name, Dr. *Linnaeus* has altered to this of *Knautia*.

This is an annual plant; the seeds of it were brought from the *Archipelago*, where it is a native; but when it is allowed to scatter its seeds in a garden, it will propagate itself in as great plenty as if it were a native of *England*; and these autumnal plants, which arise from the scattered seeds, will grow much stronger than those which are sown in the spring. All the culture this plant requires is, to keep it clear from weeds, for it will thrive on almost any soil, or in any situation.

KOEMPFERIA. *Lin. Gen. Plant.* 7.

The Characters are,

It hath a single spathe of one leaf; the flower hath one petal, with a slender tube, divided in six parts; three of them are alternately spear-shaped and equal; the other are oval, and at bottom cut into two parts which are vertically heart-shaped. It hath one stamen, which is membranaceous. It hath a round germen supporting a style the length of the tube, which afterward becomes a roundish three-cornered capsule with three cells, filled with seeds.

We have but one Species of this genus in *England*, viz.

KOEMPFERIA *foliis ovatis sessilibus. Flor. Zeyl.* 80. *Koempferia* with oval leaves sitting close to the root; called *Galangale*.

This plant is a native of the *East-Indies*, where the root is greatly used in medicine as a sudorifick, and it is reckoned carminative. It hath much the scent of green *Ginger*, when taken out of the ground; the roots are divided into several fleshy tubers, which are sometimes jointed, and grow about four or five inches long; the leaves are oval, about four inches long and two broad, without foot-stalks, growing close to the root, and seem as if set on by pairs; between these leaves the flowers are produced singly, having no foot-stalks, but are closely embraced by the leaves; the flowers are white, having a bright purple bottom, but are not succeeded by fruit in *England*.

It is a native of hot countries, so will not bear the open air in *England*, but requires a warm stove to preserve it through the winter; the leaves decay in the autumn, therefore the plants should not have too much wet while they are in an inactive state. If these plants are placed in the bark-stove, and treated in the same manner as is directed for the *Ginger*, they will thrive, and produce plenty of flowers every summer. It is propagated by parting of the roots; the best time for this is in the spring, just before they begin to put out their leaves.

L ABLAB. See *Phaseolus* and *Dolichos*.
LABRUM VENERIS. See *Dipsacus*.
LABURNUM. See *Cytisus*.

LACRYMA JOBI. See *Coix*.

LACTUCA. *Tourn. Inst. R. H.* 473. *tab.* 267. *Lettuce*.

The Characters are,

The flowers are composed of several hermaphrodite florets, inclosed in a scaly oblong empalement. The florets have one petal, which is stretched out on one side like a tongue; these have five short hairy stamina. The germen afterward becomes one oblong pointed seed, crowned with a single down.

It would be to little purpose to mention in this place the several sorts of *Lettuce* that are to be found in botanick writers, many of which are plants of no use, and are never cultivated but in botanick gardens for variety, and some of them are found wild in many parts of *England*. I shall therefore pass over those, and only mention here the several sorts which are commonly cultivated in the kitchen-garden for use: 1. Common, or garden *Lettuce*. 2. *Cabbage Lettuce*. 3. *Cilicia Lettuce*. 4. *Dutch brown Lettuce*. 5. *Aleppo Lettuce*. 6. *Imperial Lettuce*. 7. *Green capuchin Lettuce*. 8. *Versailles*, or upright white *Cos Lettuce*. 9. *Black Cos*. 10. *Red Cos*. 11. *Red capuchin Lettuce*. 12. *Roman Lettuce*. 13. *Prince Lettuce*. 14. *Royal Lettuce*. 15. *Egyptian Cos Lettuce*.

The first of these sorts is commonly sown for cutting very young, to mix with other small *Sallad* herbs, and is only different from the second sort, in being a degeneracy therefrom, or otherwise the second is an improvement by frequent cultivation from the first; for if the seeds are saved from such plants of the second sort as did not cabbage

L A C

closely, the plants produced from that seed will all degenerate to the first sort, which is by the gardeners called *Lapped Lettuce*, to distinguish it from the other, which they call *Cabbage Lettuce*. The seeds of the first, which are commonly saved from any of the plants, without having regard to their goodness, are generally sold at a very cheap rate (especially in dry seasons, when these plants always produce the greatest quantity of seeds,) though sometimes this seed is sold in the seed shops, and by persons who make a trade of selling seeds, for the *Cabbage Lettuce*, which is often the occasion of peoples being disappointed in their crop; so that this sort should never be cultivated but to be cut up very young, for which purpose this is the only good sort, and may be sown any time of the year, observing only in hot weather to sow it on shady borders, and in the spring and autumn upon warm borders, but in winter it should be sown under glasses, otherwise it is subject to be destroyed by severe frosts.

The *Cabbage Lettuce* may also be sown at different times of the year, in order to have a continuation of it through the whole season. The first crop is generally sown in *February*, which should be upon an open warm spot of ground, and when the plants are come up, they should be thinned out to the distance of ten inches each way, which may be done by hoeing them out, as is practised for *Turneps*, *Carrots*, *Onions*, &c. provided you have no occasion for the superfluous plants, otherwise they may be drawn up, and transplanted into another spot of good ground at the same distance, which, if done before the plants are too large, they will succeed very well, though they will not be so large as those which were left upon the spot where they were

were sown, but they will come somewhat later, which will be of service where people do not continue sowing every fortnight.

You must also observe in sowing the succeeding crops, as the season advances, to choose a shady moist situation, but not under the drip of trees, otherwise, in the heat of summer, they will run up to seed before they cabbage. In the middle of *August* you should sow the last crop, which is to stand over winter; the seeds should be sown thin upon a good light soil, in a warm situation; and when the plants are come up, they must be hoed out so as to stand singly, and cut down all the weeds to clear them. In the beginning of *October* they should be transplanted into warm borders, where, if the winter is not very severe, they will stand very well; but in order to be sure of a crop, it will be advisable to plant a few upon a bed pretty close, where they may be arched over with hoops, and in severe frosts they should be covered with mats and straw, or Pease haulm, to secure them from being destroyed; and in the spring of the year, they may be transplanted out into a warm rich soil, at the distance before-mentioned; but still those which grew under the wall, if they escaped the winter, and were suffered to remain, will cabbage sooner than those which are removed; but you must observe not to place them too close to the wall, which would occasion their growing up tall, and prevent their being large or hard.

In order to save good seeds of this kind, you should look over your Lettuces when they are in perfection, and such of them as are very hard, and grow low, should have sticks thrust into the ground, by the sides of as many of them as you intend for seed, to mark them from the rest; and you should carefully pull up all the rest from amongst them as soon as they begin to run up, if any happen to be left, lest when they are run up to flower, they should, by intermixing their farina with the flowers of the good ones, degenerate the seeds.

The *Cilicia*, imperial, royal, black, white, and red Cos Lettuces may be sown at the following times; the first season is the beginning of *February*, upon a gentle hot-bed covered with a frame: the second is the latter end of *February*, or the beginning of *March*, upon a warm border of light soil, in an open situation, *i. e.* not over shadowed with trees; when the plants come up on the hot-bed, they should have a great share of fresh air admitted to them, to prevent their drawing up weak, and when they have four or six leaves, they should be transplanted upon another hot-bed to bring them forward, but this bed may be arched over with hoops and covered with mats. When the plants are strong enough to plant out for good, they should be set at sixteen inches distance each way. Those which were sown on the warm border, should also be transplanted into another spot of ground, at the same distance as the former, observing if the season is dry, to water them till they have taken root; after which they must be carefully kept clean from weeds, which is the only culture they will require, except the black Cos Lettuce, which should be tied up when they are full grown (in the manner as was directed for the blanching of *Endive*.) to whiten their inner leaves, and render them crisp, otherwise they are seldom good for much, rarely cabbaging without this assistance.

When the Lettuces are in perfection, they should be looked over, and as many of the best of them as you intend for seed, should be marked (in the same manner as was before directed for the common Cabbage Lettuce,) being very careful not to suffer any ordinary ones to seed amongst or near them, as was before observed, which would prove more injurious to these sorts than to the common, as being more inclinable to degenerate with us, if they are not carefully preserved.

But to continue these sorts of Lettuce through the season, the seeds must be sown in *April*, *May*, and *June*, observing (as was before directed) to sow the late crops in a shady situation, otherwise they will run up to seed before they grow to any size; in the middle or latter end of *September* there should be some seeds sown of these sorts, to abide the winter, which plants should be transplanted either under glasses, or in a bed, which should be arched over with hoops, in order to be covered in the winter, otherwise in hard winters they are often destroyed; but these plants should have as much free air as possible when the weather is mild, only covering them in hard rains, or frosty weather, for if they are kept too closely covered in winter, they will be subject to mouldiness, which soon rots them.

In the spring these plants should be planted out into a rich light soil, allowing them at least eighteen inches distance each way, for if they are planted too close, they are very subject to grow tall, but seldom cabbage well; and from this crop, if they succeed well, it will be proper to save the seeds; though some plants should also be marked of that crop sown in the spring, because sometimes it happens, that the first may fail by a wet season, when the plants are full in flower, and the second crop may succeed, by having a more favourable season afterward; and if they should both succeed, there will be no harm in that, since the seeds will grow very well when two years old, and if well saved, at three, but this will not always happen.

The most valuable of all the sorts of Lettuce in *England*, are the *Egyptian* green Cos, and the white Cos, the *Cilicia* and red Cos. Though some people are very fond of the Royal and Imperial Lettuces, but they seldom sell so well in the *London* markets as the other, nor are so generally esteemed. Indeed of late years, since the white Cos has been commonly cultivated, it has obtained the preference of all the other sorts, until the *Egyptian* green and the red Cos was introduced, which are so much sweeter and tenderer than the white Cos, that they are by all good judges esteemed the best sorts of Lettuce yet known. These will endure the cold of our ordinary winters full as well as the white Cos; but at the season of their cabbaging, if there happens to be much wet, they are very subject to rot.

The brown *Dutch* and green capuchin Lettuces are very hardy, and may be sown at the same seasons as was directed for the common Cabbage Lettuce, and are very proper to plant under a wall or hedge, to stand the winter, where many times these will live, when most of the other sorts are destroyed, therefore they will prove very acceptable, at a time when few other sorts are to be had; they will also endure more heat and drought than most other sorts of Lettuce, which renders them very proper for late sowing, for it often happens, in very hot weather, that the other sorts of Lettuce will run up to seed in a few days after they are cabbaged, whereas these will abide near three weeks in good order, especially if care be taken to cut the forwardest first, leaving those that are not so hard cabbaged to the last. In saving of these seeds, the same care should be taken to preserve only such as are very large and well cabbaged, otherwise the seeds will degenerate, and be good for little.

If these sorts of Lettuce are planted upon a moderate hot-bed in autumn, and covered with a good frame, they may be cabbaged so well as to be fit for use in *February* and *March*, and may be continued till those in the open air are fit for use.

In saving seeds of all these sorts of Lettuce, you should observe never to let two sorts stand near each other; for by their farina mixing, they will both vary from their original, and partake of each other; there should also be a stake fixed down by the side of each, to which the stem should be fastened,

fastened, to prevent their being broken, or blown out of the ground by wind, to which the *Cilicia*, *Cos*, and the other large growing Lettuces, are very subject when they are in flower. When the seeds begin to ripen, such branches of the large growing Lettuces as ripen first, should be cut, and not wait to have the seed of the whole plant ripe together, which never happens; but, on the contrary, some branches will be ripe a fortnight or three weeks before others, and when they are cut, they must be spread upon a coarse cloth in a dry place, that the seeds may dry; after which they should be beat or rubbed out, and dried again, and then carefully hanged up where mice and other vermin cannot come at them, for if they do, they will soon eat them up.

LACTUCA AGNINI. See Valerianella.

LADY'S SLIPPER. See Cypripedium.

LADY'S SMOCK. See Cardamine.

LAGŒCIA, Bastard Cumin.

The Characters are,

It hath many flowers collected into a head, in one common empalement, composed of eight indented leaves. The flower consists of five horned petals, at the bottom of each flower is situated the germen, attended by five stamina; the germen afterward changes to an oval seed, crowned with the empalement.

There is but one Species of this plant, viz.

LAGŒCIA. *Lin. Hort. Cliff.* Bastard, or Wild Cumin.

We have no other *English* name for this plant, nor is this a very proper one, but as it has been titled by some of the ancient botanists *Cuminum sylvestre*, so it may be stiled wild, or Bastard Cumin in *English*.

This is an annual plant, which grows about a foot high. The leaves resemble those of the Honewort. The flowers, which are of a greenish yellow colour, are collected in spherical heads at the extremity of the shoots; but there being little beauty in the plant, it is rarely cultivated, except in botanick gardens. It grows plentifully about *Aix* in *Provence*, as also in most of the islands of the *Archipelago*. It is annual, and perishes soon after the seeds are ripe. The seeds of this plant should be sown in autumn, sown after they are ripe, or if they are permitted to scatter, the plants will come up, and require no other care but to clear them from weeds. When the seeds are sown in the spring, they commonly remain in the ground a year before they grow, and sometimes I have known them lie two or three years in the ground, so that if the plants do not come up the first year, they should not be disturbed.

LAGOPUS. See Trifolium.

LAMIUM. *Tourn. Inst. R. H.* 183. *tab.* 89. Dead Nettle, or Archangel.

The Characters are,

The flower hath a permanent empalement, which is cut into five equal segments at the top, which end in beards. The flower is of the lip kind, with one petal, swollen at the chaps and compressed; the upper lip is arched, obtuse, and entire; the under is heart-shaped, and indented at the end. It hath four awl shaped stamina, two of which are longer than the other. It hath a four cornered germen, which afterward becomes four three-cornered seeds, sitting in the open empalement.

The Species are,

1. LAMIUM *foliis cordatis obtusis petiolatis. Hort. Cliff.* 314. Purple stinking Archangel, or Dead Nettle.

2. LAMIUM *foliis cordatis acuminatis serratis petiolatis. Hort. Cliff.* 314. White Archangel, or Dead Nettle.

3. LAMIUM *foliis cordatis crenatis villosis, labio floris superiore crenato.* Hoary dead Nettle with a purplish flower, whose upper lip is crenated.

4. LAMIUM *foliis cordatis obtusis glabris, foralibus sessilibus, calicibus profunde incis.* Eastern dead Nettle, sometimes sweet scented, and sometimes stinking, with a large flower.

5. LAMIUM *foliis cordatis nervosis serratis, petiolis longioribus, caule erecto.* Mountain dead Nettle with a Balm leaf.

There are other species of this genus, as also some varieties of it, but as they are many of them weeds, so there are few who care to admit them into their gardens.

The first sort grows naturally in most parts of *England*, under hedges and by the side of highways; it is also a troublesome weed in gardens, but as it stands in most of the dispensaries as a medicinal plant, I have chosen to insert it. This is an annual plant, whose stalks seldom rise more than four or five inches high; the under leaves are heart-shaped, blunt, and stand upon pretty long foot-stalks, but the upper leaves sit nearer to the stalks; the flowers come out in whorls on the upper part of the stalk; they are of a pale purple colour, and are succeeded by four naked seeds sitting in the empalement; after the seeds are ripe the plant decays. It flowers from the middle of *March*, when the autumnal self-sown plants begin, which are succeeded by others, which continue in succession all the summer.

The second sort is commonly called Archangel; this is also used in medicine, for which I have enumerated it here. The roots of this sort are perennial, and creep much in the ground, so are difficult to extirpate, especially where they happen to grow under bushes and hedges, for the roots intermix with those of the bushes, and every small piece of them will grow and spread. The stalks of this rise much higher than those of the last, the flowers are larger, white, and grow in whorls round the stalks; these continue in succession most part of the summer.

The third sort grows naturally upon the mountains in *Italy*; this hath a perennial creeping root, from which arise many thick square stalks a foot high, garnished with heart-shaped leaves which are hairy, placed opposite, standing upon pretty long foot-stalks; the flowers come out in whorls at the joints of the stalk, they are large, of a pale purplish colour, and continue in succession most part of the summer; the flowers are succeeded by seeds, which ripen about six weeks after. This may be propagated by seeds, but as the roots spread greatly in the ground, so when once it is obtained, it will propagate fast enough without care.

The fourth sort grows naturally in the *Archipelago*; this is an annual plant, which, if permitted to scatter its seeds, the plants will come up in the autumn, and thrive better than when sown by hand. The plants during the winter make a pretty appearance, for the leaves are marked with white spots, somewhat like those of the autumnal Cyclamen; the stalks rise eight or nine inches high, garnished with smooth heart-shaped leaves placed opposite; these in dry weather have a musky scent, but in wet weather are fetid; the flowers are white, standing in whorls round the stalks. They appear in *April*, and the seeds ripen in *June*, then the plants decay; this requires no culture, but to keep the plants clear from weeds.

The fifth sort grows naturally in *Portugal*; this hath a perennial root; the stalk rises a foot and a half high, it is strong, square, and grows erect; the leaves are large, heart-shaped, and much veined; they are deeply sawed on their edges, and are placed opposite. The flowers come out in whorls round the stalks at every joint, they are very large, of a deep purple colour; those on the lower part of the stalks appear the beginning of *May*, which are succeeded by others above, so that there is a continuance of flowers almost two months on the same stalks. This plant very rarely produces good seeds in *England*, nor do the roots propagate very fast, so that it is not common in *England*.

The best time to remove and part these roots is in *October*, but they must not be transplanted oftener than every third year, if they are required to flower strongly, for the great beauty of this plant consists in the number of stalks, which are always proportional to the size of the roots, for small ones

ones will put one or two stalks only, whereas the large ones will have eight or ten. The roots are hardy, and will thrive best in a soft loamy soil.

LAMPSANA. See Lapsana.

LAND. Its Improvement.

1. By Inclosing.

Inclosing of lands, and dividing the same into several fields, for pasture or tillage, is one of the principal ways of improvement; first, by ascertaining to every man his just property, and thereby preventing an infinity of trespasses and injuries, that lands in common are subject unto, beside the disadvantage of being obliged to keep the same seasons with the other people who have land in the same field; so that the sowing, fallowing, and tilling the ground, must be equally performed by all the landholders; and when there happens a slothful negligent person, who has land intermixed with others, it is one of the greatest nuisances imaginable. Secondly, where land is properly inclosed, and the hedge-rows planted with timber trees, &c. it preserves the land warm, and defends and shelters it from the violent cold nipping winds, which, in severe winters, destroy much of the Corn, pulse, or whatever grows on the champain grounds. And where it is laid down for pasture, it yields much more Grass than the open fields, and the Grass will begin to grow much sooner in the spring. The hedges and trees also afford shelter for the cattle from the cold winds in winter, and shade for them in the great heats of summer. These hedges also afford the diligent husbandman plenty of fuel, as also plough-boot, cart-boot, &c. And where they are carefully planted and preserved, furnish him with mast for his swine; or where the hedge-rows are planted with fruit trees, there will be a supply of fruit for cyder, perry, &c. which in most parts of *England* are of no small advantage to the husbandman.

By this method of inclosing, there is also much more employment for the poor, and is therefore a good remedy against beggary; for in those open countries, where there are great downs, commons, heaths, and wastes, there is nothing but poverty and idleness to be seen amongst the generality of their inhabitants.

In inclosing of land, regard should be had to the nature of the soil, and what it is intended for, because Corn land should not be divided into small fields; for besides the loss of ground in hedges, &c. the Corn doth seldom thrive so well in small inclosures, as in more open land, especially where the trees are large in the hedge-rows. The Grass also in pasture is not so sweet near hedges, or under the drip of trees, as in an open exposure; so that where the inclosures are made too small, or the land over-planted with trees, the herbage will not be near so good, nor in so great plenty, as in larger fields; therefore, before a person begins to inclose, he should well consider how he may do it to the greatest advantage: as for instance, it is always necessary to have some smaller inclosures near the habitation, for the shelter of cattle, and the conveniency of shifting them from one field to another, as the season of the year may require; and hereby the habitation, barns, stables, and out-houses, will be better defended from strong winds, which often do great damage to those that are exposed to their fury. These small inclosures may be of several dimensions, some of them three, four, six, or eight acres in extent; but the larger divisions for Corn should not contain less than twenty or thirty acres or more, according to the size of the farm.

The usual method of inclosing land is, with a ditch and bank set with Quick. But in marsh land, where there is plenty of water, they content themselves with only a ditch, by the sides of which they usually plant Sallows or Poplars, which being quick of growth, in a few years afford shade to the cattle; and when they are lopped, produce a

considerable profit to their owners. In some counties the divisions of their lands is by dry walls made of flat stones, laid regularly one upon another, and laying the top course of stones in clay, to keep them together, the weight of which secures the under ones. But in some parts of *Suffex* and *Hampshire* they often lay the foundation of their banks with flat stones, which is of a considerable breadth at bottom; upon which they raise the bank of earth, and plant the hedge on the top, which in a few years makes a strong durable fence, especially if they are planted with Holly, as some of those in *Suffex* are.

I shall now mention the most proper plants for making of fences for the different soils and situations, so as to answer the expectation of the planter: and first, the white Thorn is esteemed the best for fencing, and will grow upon almost any soil and in any situation, but it succeeds best on a Hazle loam.

The next to the white is the black Thorn, which, though not so generally esteemed as the white, yet it will make an excellent fence, where proper care is taken in the planting and after management of it; and the loppings of this hedge make much the best bushes, and are of longer duration for dead hedges, than any other sort, and are very proper to mend gaps in fences. These hedges will be better, if the plants are raised from the stones of the fruit, which should be sown on the spot where they are to remain, than where the plants are taken from a nursery.

The Crab will also make a strong durable fence; this may be raised by sowing the kernels in the place where the hedge is designed, but then there should be great care taken of the plants while they are young, to keep them clear from weeds, as also to guard them from cattle. When these stocks have obtained strength, some of them may be grafted with Apples for cyder, where the fence is not exposed to a publick road; but the grafts should not be nearer than thirty-five or forty feet, lest they spoil the hedge, by their heads overgrowing and dripping on it.

The Holly is also an excellent plant for ever-green hedges, and would claim the preference to either of the former, were it not for the slowness of its growth while young, and the difficulty of transplanting the plants when grown to a moderate size. This will grow best in cold stony lands, where, if once it takes well, the hedges may be rendered so close and thick, as to keep out all sorts of animals, and will grow to a great height, and is of long duration.

The Alder will also make a good hedge, when planted on a moist soil, or on the side of rivers, or large ditches; and will preserve the bank from being washed away, where there are running streams; for they spread pretty much at bottom, and send forth suckers from their roots in great plenty.

Of late years the Furz has been propagated for hedges in several parts of *England*, and indeed will make a good fence on poor, sandy, or gravelly soils, where few other plants will grow. The best method of raising these hedges is, to sow the seed about the latter end of *March*, or the beginning of *April*, in the place where the hedge is designed; for the plants will not bear to be transplanted, unless it be done while they are young, and then there is great hazard of their taking.

Elder is sometimes planted for hedges, being very quick of growth; so that if sticks or truncheons about four or five feet long be thrust into a bank slopewise each way, so as to cross each other, and thereby form a sort of chequer work, it will make a fence for shelter in one year. But as this is a vigorous growing plant, it will never form a close fence; and the young shoots being very soft and pithy, are soon broken by cattle, or boys in their sport,

There are some other plants which have been recommended for fences, but those here enumerated are the only

useful for such purposes; wherefore I shall pass over the others, as not worthy of the care of the husbandman. And as to the farther directions for planting and preserving of hedges, with instructions for plashing or laying them, the reader is desired to turn to the articles of FENCES and HEDGES, where there are particular directions for these works exhibited, which I shall not here repeat.

The draining of land is also another great improvement to it; for though meadows and pastures, which are capable of being overflowed, produce a greater quantity of herbage than dry land, yet where the wet lies too long upon the ground, the Grass will be four and extremely coarse; and where there is not care taken in time to drain this land, it will produce little Grass, and soon be over-run with Rushes and Flags, so as to be of small value.

The best method for draining of these lands is, to cut several drains across the land, in those places where the water is subject to lodge; and from these cross drains to make a convenient number of other drains, to carry off the water to either ponds or rivers in the lower parts of the land. These drains need not be made very large, unless the ground be very low, and so situated as not to be near any river to which the water may be conveyed; in which case there should be large ditches dug at proper distances, in the lowest part of the ground, to contain the water, and the earth which comes out of the ditches should be equally spread on the land, to raise the surface. But where the water can be conveniently carried off, the best method is to make under-ground drains at proper distances, which may empty themselves into large ditches, which are designed to carry off the water. These sort of drains are the most convenient, and as they are hid from the sight, do not incommode the land, nor is there any ground lost where these are made.

The usual method of making these drains is to dig trenches, and fill the bottoms with stones, bricks, Rushes, or bushes, which are covered over with the earth, which was dug out of the trenches; but this is not the best method, because the water has not a free passage through these drains, so that whenever there is a flood, they are often stopped by the soil which the water frequently brings down with it. The best method I have yet found to make these drains is to dig trenches to a proper depth for carrying off the water, which for the principal drains should be three feet wide at their top, and sloped down for two feet in depth, where there should be a small bank left on each side, upon which the cross stakes or bearers should be laid, and below these banks there should be an open drain left; at least one foot deep, and nine or ten inches wide, that there may be room for the water to pass through: these larger drains should be at convenient distances, and smaller drains of about six or seven inches wide, and the hollow under the bushes eight or nine inches deep, should be cut across the ground, which should discharge the water into these larger drains. The number and situation of them must be in proportion to the wetness of the land, and the depth of earth above the bushes must also be proportioned to the intended use of the land; for if it is arable land to be ploughed, it must not be shallower than a foot or fourteen inches, that there may be sufficient depth for the plough, without disturbing the bushes, but for pasture-land nine inches will be full enough; for when the bushes lie too deep in strong land, they will have little effect, the ground above will bind so hard, as to detain the wet on the surface. When the drains are dug, there should be prepared a quantity of good brush wood, the larger sticks should be cut out to lengths of about sixteen or eighteen inches, which should be laid across upon the two side-banks of the drain, at about four inches distance; then cover these sticks with the smaller Brush-wood, Furz, Broom,

Heath, or any other kind of Brush, laying it lengthwise pretty close; on the top of these may be laid Rushes, Flags, &c. and then the earth laid on to cover the whole. These sort of drains will continue good for a great number of years, and are never liable to the inconveniencies of the other, for the water will find an easy passage through them under the bushes; and where there is plenty of Brush-wood, they are made at an easy expence; but in places where wood is scarce, it would be chargeable to make them: however; in this case, it would be a great advantage to these lands to plant a sufficient number of cuttings of Willow, or the black Poplar, on some of the moist places, which would furnish Brush-wood for these purposes in four or five years; and as the expence of planting these cuttings is trifling, there cannot be a greater advantage to an estate which wants draining, than to practise this method, which is in every person's power, since there is little expence attending it.

In countries where there is plenty of stone, that is the best material for making these under-ground drains; for when these are properly made, they will never want repairing.

The best time of the year for making these drains is about *Michaelmas*, before the heavy rains of autumn fall, because at this season the land is usually dry, so that the drains may be dug to a proper depth; for when the ground is wet, it will be very difficult to dig to any depth, because the water will drain in where-ever there is an opening in the ground.

As the draining of cold wet lands is a great improvement to them, so the floating or watering of dry loose land is not a less advantage to them. This may be easily effected where there are rivers, or reservoirs of water, which are situated above the level of the ground designed to be floated, by under-ground drains (made after the manner of those before directed for draining of land,) through which the water may be conveyed at proper seasons, and let out on the ground: in order to this, there must be good sluices made at the heads of the drains, so that the water may never get out, but at such times as is required; for if this be not taken care of, the water, instead of improving the land, will greatly damage it.

The time for drowning of land is usually from *November* to the end of *April*; but though this is the general practice, yet I cannot approve of it for many reasons. The first is, that by the wet lying continually on the ground in winter, the roots of the finer sort of Grass are rotted and destroyed; and by letting on of the water, at the season when the seeds of Docks, and other bad weeds, which commonly grow by river sides, are falling, these seeds are carried upon the land, where they remain and grow, and fill the ground with bad weeds, which is commonly the case with most of the water meadows in *England*, the Grass in general being destroyed; so that Rushes, Docks, and other trumpery, make up the burden of these lands; but if these meadows were judiciously managed, and never floated till *March* or *April*, the quantity of sweet good Grass would be thereby greatly increased, and the beautiful verdure of the meadows preserved.

Another great improvement of land is by burning of it, which for sour, heathy, and rushy land, be it either hot or cold, wet or dry, is a very great improvement; so that such lands will, in two or three years after burning, yield more, exclusive of the charges, than the inheritance was worth before; but this is not to be practised on rich fertile land, for as the fire destroys the acid juice, which occasions sterility in the poor land, so it will in like manner consume the good juices of the richer land, and thereby impoverish it, so that it hath been with great reason disused in deep rich countries.

It is also a very great improvement, where land is overgrown with Broom, Furz, &c. to stub them up by the roots; and when they are dry, lay them on heaps, and

Cover them with the parings of the earth, and burn them, and spread the ashes over the ground. By this method vast tracts of land, which at present produce little or nothing to their owners, might be made good at a small expence, so as to become good estates to the proprietors.

LANTANA. Lin. Gen. Plant. 683. American Viburnum.

The Characters are,

The empalement of the flower is cut into four segments. The flower is of an irregular shape, having a cylindrical tube spread open at the bottom, where it is divided into five parts. In the center of the flower is situated the germen, attended by four stamina, two being longer than the other. The germen afterward changes to a roundish fruit, opening into two cells, inclosing a roundish seed.

The Species are,

1. LANTANA foliis oppositis, caule aculeato ramoso, floribus capitato-umbellatis. Sweet, prickly, American Viburnum, with broad Nettle leaves, and carmine flowers.

2. LANTANA caule inermi, foliis lanceolatis dentatis alternis, floribus corymbosis. Smooth Lantana, with spear-shaped leaves placed alternate, and a smaller flower and fruit.

3. LANTANA caule ramoso lanuginoso, foliis orbiculatis crenatis, oppositis, floribus capitatis. Lantana with a hairy branching stalk, round crenated leaves placed opposite, and flowers collected in heads.

4. LANTANA foliis ternis, spicis oblongis imbricatis. Liu. Sp. Plant. 626. Lantana with leaves placed by threes round the stalk, and oblong imbricated spikes of flowers.

5. LANTANA caule aculeato, foliis oblongo-cordatis serratis oppositis, floribus corymbosis. Lantana with a prickly stalk, oblong, heart-shaped, sawed leaves placed opposite, and flowers growing in a corymbus.

6. LANTANA caule inermi, foliis ovato-lanceolatis, serratis, rugosis, floribus capitatis lanuginosis. Lantana with a smooth stalk, oval, spear-shaped, rough, sawed leaves, and flowers growing in woolly heads.

7. LANTANA foliis oblongo-ovatis acuminatis serratis rugosis alternis, floribus capitatis. Lantana with oblong, oval-pointed, sawed leaves, which are rough, and placed alternate, and flowers growing in heads.

8. LANTANA caule inermi, foliis ovatis serratis, floribus capitatis alaribus sessilibus. Lantana with a smooth stalk, oval sawed leaves, and flowers growing in heads, proceeding from the wings of the leaves, sitting close to the stalks.

9. LANTANA foliis alternis sessilibus, floribus solitariis. Hort. Cliff. 320. Lantana with alternate leaves sitting close to the stalks, and flowers growing singly; commonly called African Jasmine with an Ilex leaf.

The first sort is pretty common in the English gardens. This grows naturally in Jamaica, and most of the other islands in the West-Indies, where it is called wild Sage: It rises with a woody stalk three or four feet high, sending out many square branches, armed with short crooked spines. The leaves are hairy, spear-shaped, and placed opposite; toward the end of the branches the flowers come out from the wings of the stalks, two foot-stalks arising from the same joint, one on each side, and are terminated by roundish heads of flowers; those which are on the outside, and form the border, are first of a bright red, or scarlet colour; these change to a deep purple before they fall. Those flowers which are in the center, are of a bright yellow, but after some time fade to an Orange colour. The flowers are succeeded by roundish berries, which, when ripe, turn black, having a pulpy covering over a single hard seed.

The second sort grows naturally in Jamaica. This rises with a slender, smooth, shrubby stalk, about four feet high, dividing into many small branches, which are garnished with spear-shaped leaves, indented on their edges, hoary on their under side, and stand alternate upon short foot-stalks.

Toward the end of the branches the foot-stalks of the flowers arise alternately from the wings of the leaves, which support small heads of pale purple flowers, succeeded by small purple berries, each having one seed.

The third sort was sent me from La Vera Cruz, by the late Dr. Houstoun. This rises with a shrubby stalk about four feet high, dividing into several woolly branches. The leaves are oblong, and sawed on their edges, standing opposite. The foot-stalks of the flowers come out from the wings of the leaves, sustaining an oblong spike of purple flowers.

The fourth sort rises with a shrubby stalk about three feet high, covered with a gray woolly bark, garnished with oblong leaves, indented on their edges; they are placed opposite at bottom, but by threes on the upper part of the stalk. At the end of the branches arise the foot-stalks of the flowers, which sustain an oblong head of purple flowers, which come out of imbricated cups, and are succeeded by pretty large purple berries, containing one seed. This flowers at the same time with the former sorts, and is an annual plant.

The fifth sort was sent me from La Vera Cruz, by the late Dr. Houstoun. This rises with a prickly branching stalk four or five feet high, garnished with oblong heart-shaped leaves, which are sawed on their edges, and end in acute points. At the end of the branches the flowers come out in round bunches, standing upon slender foot-stalks. The flowers are yellow, and grow in looser bunches or heads, than those of the former sorts.

The sixth sort rises with a smooth branching stalk five or six feet high, covered with a dark brown bark. The branches are more divided than those of most other sorts, and are much more ligneous. The leaves are deeply sawed on their edges, their upper surface very rough, and many of them closely set with white prominent spots as if fludded; these are placed alternately on the branches. The flowers come out from the wings of the stalk, standing upon pretty long foot-stalks; they are white, and are collected in small woolly heads.

The seventh sort rises with a branching shrubby stalk about four feet high, covered with a dark brown bark, garnished with small, oblong, oval leaves, ending in acute points, standing alternately pretty close to the branches. The flowers come out at the end of the branches, upon short foot-stalks in close small heads; these are white, and make but little appearance.

The eighth sort was sent me from Campeachy. This hath a slender shrubby stalk, which rises three or four feet high, dividing into many slender branches, garnished with small, oval, sawed leaves, placed opposite; from the wings of the stalk, at every joint, come out the flowers; they are small, white, and are collected in close heads.

These plants are all of them easily propagated by cuttings, except the fourth, which is an annual plant, so can only be propagated by seeds. They may also be propagated by seeds, which several of the sorts produce in England. These seeds should be sown in pots, and plunged into a hot-bed of tan; the reason for my advising them to be sown in pots, is, because the seeds frequently remain long in the ground before they vegetate; therefore if the plants should not come up the same year, the pots should be placed in the stove in winter, and the following spring plunged into a new hot-bed, which will bring up the plants. When these are fit to remove, they should be each planted in a small pot, and plunged into another hot-bed, observing to shade them till they have taken new root; then they should have air admitted to them every day, in proportion to the warmth of the season, to prevent their being drawn up with weak stalks; afterward they must be treated in the same manner

as other plants from the same country, till they have obtained strength; then they may be removed into an airy glass-case, or a dry stove, where they may have a large share of air in warm weather, but protected from the cold. This is necessary for the young plants, which should not the first year be exposed to the open air, but afterward they may be placed abroad in the warmest part of summer, and in winter placed upon stands in the dry stove, where they will continue long in flower, and many of the sorts will ripen their seeds; but in winter they should be sparingly watered, for much moisture will rot their roots.

If they are propagated by cuttings, the best time for planting them is in *July*, after the plants have been exposed to the open air for about a month, by which time the shoots will be hardened so as to be out of danger of rotting with a little moisture. These cuttings should be planted in small pots, and plunged into a moderate hot-bed, and screened from the violence of the sun in the middle of the day; in about six weeks time these will be rooted, when they must be hardened gradually to bear the open air, and afterward treated as the old plants.

The last sort has been long in the *English* gardens, and is commonly called the *Ilex-leaved Jasmine*. This sort rises with a shrubby stalk five or six feet high, sending out many irregular branches, closely garnished with thin oval leaves ending in points, sawed on their edges, which embrace the branches with their base, and from the bosom of each leaf comes out one solitary white flower, which is cut at the top into five parts, and at first sight has the appearance of a *Jasmine* flower, but when closer viewed, the tube will be found curved in the same manner with those which *Dr. Linnæus* titles ringent flowers. The flowers are not succeeded by seeds in *England*, but the plants are easily propagated by cuttings, which, if planted upon an old hot-bed any time in *July*, and covered with a bell or hand-glass, and shaded from the sun, will put out roots in a month or five weeks; then they may be planted in pots, and placed in the shade till they have taken fresh root; after which they may be removed to a sheltered situation, where they may remain till the frosts come on. This plant was brought from the *Cape of Good Hope*, so is not very tender, therefore may be preserved in a good green-house in winter, but must have a large share of air in mild weather, otherwise it is apt to grow mouldy. In the summer it may be exposed in the open air, with other green-house plants, in a sheltered situation. There is a succession of flowers upon the plants most part of the year, and the leaves continuing green renders it worthy of a place in every collection of plants.

LAPATHUM. *See* Rumex.

LAPSANA. *Lin. Gen. Plant.* 823. Nipplewort.

The Characters are,

The flower is composed of several hermaphrodite florets, included in one common imbricated empalement. The florets have one tubulous petal, stretched out at the top, in shape of a tongue; these have each five short hairy stamina. The germen is situated at the bottom of the floret, which afterward becomes an oblong three-cornered seed, situated in the scale of the empalement.

The Species are,

1. LAPSANA calycibus fructibus angulatis, pedunculis tenuibus ramosissimis. *Hort. Cliff.* 334. Common Nipplewort.

2. LAPSANA calycibus fructibus undique patentibus, radiis subulatis, foliis lanceolatis indivisis. *Hort. Upsal.* 245. This is the *Rhagadiolus alter.* 511.

3. LAPSANA calycibus fructibus undique patentibus, radiis subulatis, foliis lyratis. *Hort. Upsal.* 245. *Rhagadiolus* with a Nipplewort leaf.

4. LAPSANA calycibus fructibus torulosis depressis obtusis sessilibus. *Lin. Sp. Plant.* 811. *Zacintha*, or watered Cichory.

The first sort is a common weed, which grows by the

side of foot-paths and hedges in most parts of *England*, so is not permitted to have room in gardens.

The second and third sorts grow naturally in *Portugal*. These are annual plants, of no beauty or use, but are preserved in botanick gardens for the sake of variety. If the seeds of these are permitted to scatter, the plants will come up without trouble, and two or three of them will be enough to leave to keep the sorts.

The fourth sort grows naturally in *Italy*. This is also an annual plant, of neither use or beauty, but is like the others kept for variety. If the seeds of this sort scatter in the autumn, the plants will come up better than if sown in the spring. The plants require no culture, but will thrive like weeds.

LARIX. *Tourn. Inst. R. H.* 586. *tab.* 353. The Larch tree.

The Characters are,

It hath male and female flowers, growing separate on the same tree. The male flowers are disposed in a scaly katkin. The female flowers are disposed in a conical shape, having no petals, but a small germen, which afterward becomes a nut with a membranous wing, inclosed in the scales of the cones.

The Species are,

1. LARIX foliis deciduis, conis ovatis obtusis. Larch tree with deciduous leaves, and oval obtuse cones.

2. LARIX foliis acutis perennantibus, conis obtusis. Cedar of *Libanus*.

The first sort grows naturally upon the *Alps* and *Apennines*, and of late years has been very much propagated in *England*. This tree is of quick growth, the trunk will rise to the height of fifty feet or more; the branches are slender, their ends generally hang downward, and are garnished with long narrow leaves, which arise in clusters from one point, which spread open above like the hairs of a painter's brush; they are of a light green, and fall away in autumn, like other deciduous trees. In the month of *April* the male flowers appear, which are disposed in form of small cones; the female flowers are collected into oval obtuse cones, which in some species have bright purple tops, and in others they are white: these differences are accidental; the cones are about one inch long, obtuse at their points, the scales are smooth, and lie over each other; under each scale there is generally lodged two seeds, which have wings.

There are two other varieties of this tree, one of which is a native of *America*, and the other of *Siberia*; these have different appearances from the common Larch tree, in their shoots and leaves, but it is doubtful if they are specifically different. The *American* sort thrives pretty well in several gardens in *England*, but the latter requires a colder climate, for they are very apt to die in summer here, especially if they are planted on a dry soil. This sort will often push out leaves by the end of *February* in mild seasons, and if there happens frost later in the year, the shoots are frequently killed, and their leaves drop off, so are sometimes naked till *June*, when the trees put out fresh shoots. The cones of this sort, which have been brought to *England*, seem to be in general larger than those of the common kind.

The common Larch is now very plenty in most of the nurseries in *England*, and of late years there has been great numbers of the trees planted; but those which have been planted in the worst soil and in bad situations, have thriven the best, for where trees of equal size have been planted in good garden earth at the same time, the others on the cold stiff land have in twelve years been twice the height of those planted in good ground, which is an encouragement to plant these trees, since they will thrive in the most exposed situations, provided they are planted in clumps near each other, and not single trees; nor should the plants, which are planted in very open exposed places, be taken from warm nurseries,

nurseries, but rather raised as near to the spot where they are to remain, as possible; nor should the plants be more than three or four years growth when planted, where they are designed to grow large; for though trees of greater size will remove very well, and grow several years as well as if they had not been transplanted, yet after twenty or thirty years growth they will frequently fail, where the young planted trees have continued very vigorous.

These trees are raised from seeds, which most years ripen well in *England*. The cones should be gathered about the end of *November*, and kept in a dry place till the spring, when they should be spread on a cloth and exposed to the sun, or laid before a fire, which will cause the scales of the cones to open, and emit their seeds. These seeds should be sown on a border exposed to the east, where the morning sun only comes on it; or if they are sown on a bed more exposed to the sun, they should be screened with mats in the middle of the day, for when the plants first appear above ground, they are very impatient of heat; and when the bed is much exposed to the sun, the surface of the ground will dry so fast as to require to have water very often, which frequently rots the tender roots of the plants. These young plants should be constantly kept clean from weeds, and if they have made good progress they may be transplanted the following autumn, otherwise they may remain in the seed-bed another year, especially if the plants are not too close together. When they are transplanted, it should be performed in the autumn, as soon as their leaves decay; they may be planted in beds at about six inches asunder each way, which will be distance enough for the growth of the plants the two following years, by which time they will be fit to transplant where they are to remain.

When the young trees are planted out for good, they need not be planted at more than eight or ten feet asunder, always planting them closer on exposed situations, than where they are more defended; after the trees are planted they will require no other care but to keep them clean from weeds for three or four years till they have obtained strength, when they will over-top the weeds, and prevent their growth; the ground between these trees should not be dug, for that I have found has greatly stopped their growth.

The *American* or black Larch, thrives pretty well upon moist land, but on dry ground will make but little progress. A few of these trees, by way of variety, may be allowed to have place in every collection of trees designed for pleasure, but for profit the common Larch is to be preferred.

In *Switzerland*, where these trees abound, and they have a scarcity of other wood, they build most of their houses with it; and great part of their furniture is also made of the wood, some of which is white, and some red, but the latter is most esteemed. The redness of the wood is supposed to be from the age of the trees, and is not from any difference between them. They frequently cut out the boards into shingles of a foot square, with which they cover their houses, instead of tiles or other covering; these are at first very white, but after they have been two or three years exposed become as black as charcoal; and all the joints are stopped by the resin, which the sun draws out from the pores of the wood, which is hardened by the air, and becomes a smooth shining varnish, which renders the houses so covered impenetrable to either wind or rain; but as this is very combustible, so the magistrates have made an order of police, that the houses so covered should be built at a distance from each other.

In most countries where this wood is in plenty, it is preferred to all the kinds of Fir for every purpose; and in many places there are ships built of this wood, which they say are durable; therefore this may be a very proper tree for planting upon some of the cold barren hills in many

parts of *England*, which at present produce nothing to their proprietors, and in one age may be large estates to their posterity, and a national advantage; which might be effected without a great expence, where the business is properly conducted.

From the Larch tree is extracted the *Venice turpentine*, which the inhabitants of the valley of *St. Martin*, near *Lucern*, make a considerable merchandize of. They collect this by boring holes in the trunk of the trees, at about two or three feet from the ground, into which they fix narrow troughs about twenty inches long; the end of these are hollowed like a ladle, and in the middle is a small hole bored for the turpentine to run into a receiver, which is placed below it; as the turpentine runs from the trees, it passes along the sloping gutter or trough to the ladle, and from thence runs through the hole into the receiver. The people who gather this visit the trees morning and evening, from the end of *May* to *September*, to collect the turpentine from out of the receivers.

The second sort is the Cedar of *Libanus*, which is a tree of antiquity; and what is remarkable, this tree is not found as a native in any other part of the world, so far as hath come to our knowledge.

The cones of this tree are frequently brought from the *Levant*, which, if preserved entire, will preserve their seeds good for several years. The time of their ripening is commonly in the spring, and so consequently are near one year old before we receive them; for which they are not the worse, but rather the better, the cones having discharged a great part of their resin by lying, and the seeds are much easier to get out of them than such as are fresh taken from the tree.

The best way to get the seeds out is, to split the cones, by driving a sharp piece of iron through the center lengthways, which will split the cone, then the seeds may be taken out with ease; these are fastened to a thin leafy substance called wings, like those of the Fir tree: but before the seeds are taken out, it will be proper to put the cones in water for twenty-four hours, which will render them easier to split, so that the seeds may be taken out with greater safety; for there will require care in the doing of it, otherwise many of the seeds will be spoiled, as they are very tender, and will bruise where there is any force employed to get them out.

These seeds should be sown in boxes or pots of light fresh earth, and treated as was directed for the Firs (to which I refer the reader) but only shall observe, that these require more shade in summer while young than the Firs.

When the plants come up, they must be guarded from the birds, otherwise they will pick off their tops; they must also be constantly kept clean from weeds, and not placed under the drip of trees. The plants may remain in these boxes or pots in which they were sown till the following spring, but it will be proper to place them under a frame in winter, or cover them with mats, for while they are young they are in danger of losing their tops, if they are pinched by frost. In the spring, before the plants begin to shoot, they should be carefully taken up and transplanted into beds at about four inches distance, closing the earth gently to their roots; these beds should be arched over with hoops, and covered with mats in the heat of the day, to shade the plants from the sun till they have taken new root; and if the nights prove frosty, it will be proper to keep the mats over them in the night, but in cloudy or moist weather they must be always open. After the plants are well rooted, they will require no other care but to keep them clean from weeds, unless the season should prove very dry, in which case it will be proper to give them some water once a week; but it must be in small quantities, for

too much wet is often very injurious to them, so that it will be better to screen them from the sun in hot weather, to prevent the earth from drying too fast, or cover the surface of the ground with moss to keep it cool, than to water the plants often,

In these beds the plants may stand two years, then they should be either transplanted to the places where they are designed to remain, or to a nursery, where they may grow two years more; but the younger these plants are when they are planted out for good, the better the trees will thrive, and the longer they will continue.

When these plants begin to shoot strong, the leading shoot is very subject to incline to one side; therefore, in order to have them strait, their shoots must be supported with stakes, to keep the leaders strait, until they are grown to the height they are designed, otherwise their branches will extend on every side, and prevent their upright growth.

It is matter of surprize to me, that this tree hath not been more cultivated in *England* formerly, for till within a few years past there were but few here; for as it grows naturally upon the coldest parts of mount *Libanus*, where the snow continues most part of the year, so there can be no fear of its being hurt by frost in *England*. That these trees are of quick growth, is evident from four of them now growing in the physick garden at *Chelsea*, which (as I have been credibly informed) were planted there in the year 1683, at which time they were not above three feet high; two of which trees are at this time (*viz.* 1762) near twelve feet in girt, at two feet above ground, and their branches extend more than thirty feet on every side their trunks.

The soil in which these trees are planted, is a lean hungry sand, mixed with gravel, with about two feet surface. They stand at four corners of a pond, which is bricked up within two feet of their trunks, so that their roots have no room to spread on one side, and consequently are cramped in their growth; but whether their standing so near the water may not have been advantageous to them, I cannot say; but sure I am, if their roots had had full scope in the ground, they would have made a greater progress. I have also observed, that lopping or cutting of these trees is very injurious to them (more perhaps than to any other of the resinous trees) in retarding their growth; for two of the four trees above-mentioned, being unadvisedly planted near a green-house, when they began to grow large, had their branches lopped, to let the rays of the sun into the house, whereby they have been so much checked, as at present they are little more than half the size of the other two.

What we find mentioned in scripture of the lofty Cedars, can be no ways applicable to the common growth of this tree; since, from the experience we have of those now growing in *England*, as also from the testimony of several travellers, who have visited those few remaining trees on mount *Libanus*, they are not inclined to grow very lofty, but on the contrary extend their branches very far; to which the allusion made by the Psalmist agrees very well, when he is describing the flourishing state of a people, and says, *They shall spread their branches like the Cedar tree.*

Rauwolf, in his *Travels*, says, there were not at that time (*i. e.* anno 1574) upon mount *Libanus* more than twenty-six trees remaining, twenty-four of which stood in a circle; and the other two, which stood at a small distance, had their branches almost consumed with age; nor could he find any younger trees coming up to succeed them, though he looked about diligently for some. These trees (he says) were growing at the foot of a small hill, on the top of the mountains, and amongst the snow. These having very large branches, commonly bend the tree to one side, but are extended to a great length, and in so delicate and pleasant order, as if they were trimmed and made even with

great diligence, by which they are easily distinguished at a great distance from Fir trees. The leaves (continues he) are very like to those of the Larch tree, growing close together in little bunches, upon small brown shoots.

Maundrel, in his *Travels*, says, there were but sixteen large trees remaining, when he visited the mountains, some of which were of a prodigious bulk, but that there were many more young trees of a smaller size; he measured one of the largest, and found it to be twelve yards six inches in girt, and yet found, and thirty-seven yards in the spread of its boughs. At about five or six yards from the ground it was divided into five limbs, each of which was equal to a great tree. What *Maundrel* hath related, was confirmed to me by a worthy gentleman of my acquaintance, who was there in the year 1720, with this difference only, *viz.* in the dimensions of the branches of the largest tree, which he assured me he measured, and found to be twenty-two yards diameter. Now, whether Mr. *Maundrel* meant thirty-seven yards in circumference of the spreading branches, or the diameter of them, cannot be determined by his words, yet neither of them well agrees with my friend's account.

The wood of this famous tree is accounted proof against all putrefaction of animal bodies; the saw-dust of it is thought to be one of the secrets used by those mountebanks, who pretend to have the embalming mystery. This wood is also said to yield an oil, which is famous for preserving books and writings; and the wood is thought by my Lord *Bacon*, to continue above a thousand years sound. It is also recorded, that in the temple of *Apollo* and *Utica*, there was found timber of near two thousand years old. And the statute of the goddess, in the famous *Ephesian* temple, was said to be of this material also, as was most of the timber work of that glorious structure.

This sort of timber is very dry and subject to split, nor does it well endure to be fastened with nails, from which it usually shrinks, therefore pins of the same wood are much preferable to any other.

LARKSPUR. See Delphinium.

LASERPITIUM. *Tourn. Inst. R. H.* 324. *tab.* 172. Laserwort.

The Characters are,

It hath an umbellated flower, composed of many small umbels. The general umbel is uniform; the flowers have five equal heart-shaped petals, and five stamina. The roundish germen is situated under the flower, which afterward becomes an oblong fruit with eight longitudinal wings or membranes, resembling the fiers of a water mill.

The Species are,

1. LASERPITIUM *foliolis oblongo-cordatis, inciso-serratis, umbellâ maximâ.* Laserwort with oblong heart-shaped lobes, which are cut like a saw, and a very large umbel.

2. LASERPITIUM *foliolis cordatis inciso-serratis.* Hort. Cliff. 96. Laserwort with heart-shaped lobes cut like a saw.

3. LASERPITIUM *foliolis ovatis obtusis acutè serratis.* Laserwort with oval obtuse lobes, sharply sawed.

4. LASERPITIUM *foliolis cuneiformibus furcatis.* Lin. Sp. Plant. 248. Laserwort with wedge-shaped forked lobes.

5. LASERPITIUM *foliolis lanceolatis integerrimis sessilibus.* Hort. Cliff. 96. Laserwort with spear-shaped entire leaves, fitting close to the branches.

6. LASERPITIUM *foliolis trifidis acutis.* Laserwort with acute trifid lobes.

7. LASERPITIUM *foliolis trifidis obtusis, umbellis partialibus contractis.* Laserwort with obtuse trifid leaves, and the small umbels contracted.

8. LASERPITIUM *foliolis lanceolatis integerrimis extimis coalitis.* Hort. Cliff. 96. Laserwort with entire spear-shaped lobes, whose outer ones coalesce.

9. *LASERPITIUM foliolis pinnatifidis, caule anguloso.* Laserwort with wing-pointed lobes, and an angular stalk.

There are some other varieties, if not distinct species of this plant; some of which have been put down as distinct species, which differ only in the colour of their flowers, therefore should not be regarded as such; but the number of species has been greatly lessened by some late writers, who have erred as much in lessening, as those before them had done in multiplying of the species.

These plants grow naturally in the south of France, in Italy, and Germany, and are preserved in botanick gardens for the sake of variety; but as they have no great beauty, so are seldom cultivated in other gardens; they require much room, for their roots extend far every way, and the leaves of many sorts will spread three feet, when the plants are strong; their flower-stalks rise four or five feet high, and their umbels of flowers are very large; they have all of them perennial roots but annual stalks. They flower in June, and the seeds ripen in September.

It is generally supposed, that the *Silphium* of the antients was procured from one species of this genus, but from which of them we are at present ignorant. All the species, if wounded, drop a very acrid juice, which turns to a resinous gummy substance, very acrimonious. This was externally applied by the antients to take away black and blue spots that came by bruises and blows, as also to take away excrescences; it was also by some of the antients prescribed in internal medicines, but others have cautioned people not to make use of it this way, from the effects which they mention to have seen produced from the violence of its acrimony.

All these plants are extreme hardy, so will thrive in most soils and situations; they are propagated by seed, which if sown in autumn, the plants will come up the following spring, but when they are sown in the spring, the seeds commonly remain in the ground a whole year. The plants should be transplanted the following autumn where they are designed to remain, for they send out long deep roots, which are frequently broken by transplanting, if they are large; when the plants are removed, they should be planted three feet asunder. The roots will continue many years, and require no other culture, but to clear them from weeds, and to dig between the roots every spring.

LATHYRUS. *Tourn. Inst. R. H.* 394. *tab.* 216, 217. Chichling Vetch.

The Characters are,

The flower is of the butterfly kind. The standard is heart-shaped, and reflexed at the point. The wings are oblong and blunt; the keel is half round, and the size of the wings. It hath ten stamina, nine of them joined, and one separate. It hath an oblong, narrow, compressed germer, which afterward becomes a long compressed pod, ending in a point, having two valves, filled with roundish seeds.

The Species are,

1. *LATHYRUS pedunculis unifloris, cirrhis diphyllis, leguminibus compressis dorso bimarginatis.* *Hort. Cliff.* 367. Chichling Vetch with one flower upon a foot-stalk, tendrils having two leaves, and oval compressed pods with two borders on their back part.

2. *LATHYRUS pedunculis unifloris, cirrhis diphyllis, leguminibus ovatis compressis, dorso canaliculatis.* *Lin. Sp. Plant.* 730. Cultivated Chichling Vetch with a purple flower.

3. *LATHYRUS pedunculis unifloris, cirrhis diphyllis, leguminibus teretibus.* Chichling Vetch with one flower upon a foot-stalk, a two-leaved tendril, and a taper pod.

4. *LATHYRUS pedunculis unifloris, cirrhis tetraphyllis, stipulis dentatis.* *Flor. Leyd. Prod.* 363. Chichling Vetch with one flower upon a foot-stalk, a four-leaved tendril, and indented stipulæ.

5. *LATHYRUS pedunculis unifloris, cirrhis polyphyllis, stipulis lanceolatis.* *Hort. Cliff.* 368. Chichling Vetch with one flower upon a foot-stalk, a many-leaved tendril, and spear-shaped stipulæ.

6. *LATHYRUS pedunculis bifloris, cirrhis polyphyllis, foliolis alternis.* *Hort. Cliff.* 368. Spanish Chichling Vetch with a variable flower, and jointed pod.

7. *LATHYRUS pedunculis bifloris, cirrhis diphyllis, foliis ovato-oblongis, leguminibus hirsutis.* *Hort. Cliff.* 368. The sweet-scented Pea.

8. *LATHYRUS pedunculis bifloris, cirrhis diphyllis, foliolis lineari-lanceolatis, leguminibus hirsutis, seminibus scabris.* *Flor. Leyd. Prod.* 363. Narrow-leaved Chichling Vetch with a hairy pod.

9. *LATHYRUS pedunculis bifloris, cirrhis diphyllis, foliolis alternis lanceolatis.* *Flor. Leyd. Prod.* 363. Chichling Vetch of Tangier, with a bitter Vetch pod, and a large red flower.

10. *LATHYRUS pedunculis bifloris, cirrhis diphyllis, foliolis lineari-lanceolatis, internodiis membranaceis.* Yellow broad-leaved Chichling Vetch.

11. *LATHYRUS pedunculis multifloris, cirrhis diphyllis, foliolis ovalibus, internodiis nudis.* *Hort. Cliff.* 367. Creeping field Chichling Vetch with a tuberous root.

12. *LATHYRUS pedunculis multifloris, cirrhis diphyllis, foliolis lanceolatis, cirrhis simplicissimis.* *Hort. Cliff.* 367. Yellow wild Chichling Vetch of the woods.

13. *LATHYRUS pedunculis multifloris, cirrhis diphyllis tetraphyllisque, foliolis lanceolatis.* *It. W. Goth.* 75. Greater Chichling Vetch of Narbonne with narrow leaves.

14. *LATHYRUS pedunculis multifloris, cirrhis diphyllis foliolis lanceolato-linearibus acuminatis, internodiis membranaceis.* Greater wild Chichling Vetch with a smaller flower, and longer pointed leaves.

15. *LATHYRUS pedunculis multifloris, cirrhis diphyllis, foliolis lanceolatis, internodiis membranaceis.* *Hort. Cliff.* 367. Broad-leaved Chichling Vetch, commonly called Everlasting Pea.

16. *LATHYRUS pedunculis multifloris, cirrhis diphyllis foliolis ovato-lanceolatis, internodiis membranaceis.* Smaller broad-leaved Chichling Vetch with a larger flower; or large red flowering Everlasting Pea.

17. *LATHYRUS pedunculis multifloris, cirrhis polyphyllis, stipulis ovatis, basi acutis.* *Hort. Upsal.* 217. Chichling Vetch with many flowers on a foot-stalk, a many-leaved tendril, and oval stipulæ acute at the base.

18. *LATHYRUS pedunculis unifloris, foliis simplicibus, stipulis subulatis.* *Lin. Sp. Plant.* 729. Nissolia, or crimson Grass Vetch.

19. *LATHYRUS pedunculis unifloris calyce longioribus, cirrhis diphyllis simplicissimis.* *Lin. Sp. Plant.* 729. Chichling Vetch with single flowers upon a foot-stalk, which are longer than the empalement, and a two-leaved single tendril.

20. *LATHYRUS pedunculis bifloris, foliis reniformibus simplicissimis subtus venosis.* Chichling Vetch with two flowers upon a foot-stalk, and kidney-shaped single leaves, which are veined on their under side.

The first sort grows naturally in France, Spain, and Italy; it is an annual plant, with a climbing stalk about two feet high. The leaves come out at each joint alternate: they are composed of two long narrow lobes, with a tendril, or clasper, rising between, which fasten to any support near. The flowers come singly upon foot-stalks at each joint; they are blue, and shaped like those of the Pea; these are succeeded by oval compressed pods, with a double membrane, or wing, running longitudinally on the back. It is seldom cultivated, unless in botanick gardens for the sake of variety.

The second sort is cultivated in some countries for the seeds, which are used for feeding of poultry; this grows wild,

wild in *Italy* and *Spain*. It does not rise so high as the first sort. The leaves are longer, the pods are near twice the length of those, and are channelled on their back side; this is cultivated in the same manner as Vetches, or Tare.

The third sort was sent me from *Verona*, where it grows naturally; this is an annual plant, which seldom rises more than six or eight inches high. The two lobes of the leaves are small, and end with clasps. The flowers are of a bright scarlet, and are succeeded by taper pods, filled with roundish seeds.

The fourth sort grows naturally in *Bavaria*; this is also an annual plant. The stalk rises from two or three feet high, garnished with leaves at each joint, which are composed of four oval lobes, ending with clasps. At the base of the foot-stalk are two small appendages (called stipulæ) which are sharply indented on their edges. The flowers are small, blue, and sit close to the stalk, standing singly; these are succeeded by compressed pods an inch long, containing three or four roundish seeds.

The fifth sort grows naturally about *Paris*; this is an annual plant, with a slender stalk, about two feet high, garnished with leaves, composed of several narrow lobes placed alternate along the midrib, which ends in clasps. The flowers are blue, and come out singly upon pretty long foot-stalks.

The sixth sort grows naturally in *Spain* and *Italy*; it is an annual plant, with a climbing stalk, which rises three feet high, garnished with leaves, composed of several spear-shaped lobes, placed alternate along the midrib, which is terminated by very long clasps. The foot-stalks of the flowers are five or six inches long, upon which stand two flowers one above the other, shaped like those of the Pea. The standard, which is large, is of a bright red colour, but the keel and wings are white. The flowers are succeeded by pretty long jointed pods, filled with roundish seeds.

The seventh sort is commonly known by the title of Sweet Pea; this grows naturally in *Ceylon*, but is hardy enough to thrive in the open air in *England*. It is an annual plant with a climbing stalk, which rises from three to four feet high, garnished with leaves, composed of two large oval lobes, whose midrib is terminated by long clasps. The foot-stalks which come out at the joints, sustain two large flowers, with dark purple standards, but the keel and wings of a light blue colour. The flowers have a strong sweet odour, and are succeeded by oblong inflated pods, which are hairy, containing four or five roundish seeds in each.

There are two other varieties of this, one of which has a Pink-coloured standard with a white keel, and the wings of a pale blush colour; this is commonly called painted Lady Pea. The flowers of the other are all white, which are the only differences between them.

The eighth sort grows naturally in *Essex*. I have found it in places, which were spread over with Brambles, near *Hockereel*; this hath a perennial root, sending out three or four weak stalks, which are near two feet long, garnished with leaves composed of two oblong lobes, whose midrib is terminated by clasps. The foot-stalks sustain two purple flowers, which are succeeded by rough hairy pods, little more than one inch long, containing three or four roundish seeds.

The ninth sort was originally brought from *Tangier* to *England*; this is an annual plant, whose stalk rises four or five feet high, garnished with leaves composed of two oval veined lobes, whose midrib ends with clasps. The foot-stalks are short, and sustain two large flowers with purple standards, whose wings and keel are of a bright red; these

are succeeded by long jointed pods, containing several roundish seeds. This is sometimes titled by the gardeners Scarlet Lupine.

The tenth sort is an annual plant, which grows naturally about *Montpelier*; I have also received the seeds from *Siberia*; this rises with a climbing stalk five or six feet high, which has two membranes, or wings running along from joint to joint. The leaves are composed of two long narrow lobes, whose midrib ends with clasps. The flowers stand upon long foot-stalks, each sustaining two pale yellow flowers, which are succeeded by long taper pods, containing several roundish seeds.

The eleventh sort grows naturally amongst the Corn in the south of *France*, and in *Italy*, but is cultivated in the *Dutch* gardens for the roots, which are there sold in the markets, and are commonly eaten; this hath an irregular tuberous-root, about as big as those of the Pignut, covered with a brown skin; these shoot up several weak trailing stalks, garnished with leaves composed of two oval lobes, ending with clasps. The foot-stalks of the flowers are weak, about three inches long, each sustaining two deep red flowers, which are seldom succeeded by pods, but the roots increase plentifully in the ground. This sort will grow in most soils, but will thrive best on light ground.

The twelfth sort grows naturally in the banks and under thickets, in most parts of *England*; this hath a perennial creeping root, whereby it propagates so fast as to be a very troublesome weed, so should not be admitted into gardens.

The thirteenth sort grows naturally by the side of hedges, and in thickets, in several parts of *England*; this hath a perennial creeping root, which sends out many climbing stalks, which rise five or six feet high, garnished with leaves, which have sometimes two, and at others four long narrow lobes, terminated by clasps. The foot-stalks sustain several small flowers, with pale standards and blue wings and keels; these are succeeded by long taper pods, containing several roundish seeds.

The fourteenth sort I found growing naturally in a thicket near *Wimbleton*, in *Surry*, the seeds of which I brought to the *Chelsea* garden, where the plants have flourished many years, and continued their difference without variation. The stalks of this sort rise six or seven feet high, and have a membrane running along on each side between the joints. The leaves are composed of two narrow spear-shaped lobes, with long acute points. The foot-stalks are very long, and sustain several small Pea blossom flowers, with pale purple standards, but the keel and wings are of a deep blue colour; these are succeeded by long taper pods, like those of the former sort.

The fifteenth sort has been found growing naturally in some parts of *England*, but is frequently cultivated in gardens for ornament. It hath a perennial root, from which arise several thick climbing stalks, from six to eight feet high, which have membranaceous wings on each side, between the joints. The leaves are composed of two spear-shaped lobes, and the midrib is terminated by clasps. The foot-stalks are eight or nine inches long, and sustain several large red flowers, which are succeeded by long taper pods, containing several roundish seeds.

The sixteenth sort differs from the last in the stalks, being much shorter and stronger. The leaves are broader, and of a deeper green. The flowers are larger, and of a brighter red colour, so make a much better appearance; these differences are lasting from seeds, for I have raised many plants from seeds within thirty years past, and have always found them to be the same as the parent plant.

The seventeenth sort grows naturally in *Siberia*; this hath a perennial root and an annual stalk, which is garnished with

with leaves, composed of six or eight pair of oblong acute lobes. The flowers are blue, and many of them stand upon each foot-stalk; these are succeeded by pods, shaped like those of the Pea. It flowers in *July*, and the seeds ripen in autumn.

The eighteenth sort grows naturally in moist meadows in many parts of *England*; this rises with an upright stalk one foot high, garnished with long narrow single leaves at each joint. The foot-stalks come out from the joints toward the upper part of the stalk; they are slender, some having but one, and others have two bright red flowers on their tops.

The nineteenth sort grows naturally in *Syria*; this is an annual plant with a trailing stalk, garnished with leaves, composed of two lobes, whose midrib is terminated by a single tendril. The foot-stalk supports one flower of a pale purple colour, and when the flowers decay, the germen is thrust into the ground, where the pods are formed, and the seeds ripen.

The twentieth sort was discovered by the late *Dr. Houstoun*, growing naturally at *La Vera Cruz*; this is an annual plant with a trailing stalk a foot long, garnished with a single kidney-shaped leaf at each joint. The flowers grow two together upon very short foot-stalks; they are small, and of a deep yellow colour; these are succeeded by short taper pods, including three or four small roundish seeds.

This sort is tender, so the seeds should be sown upon a hot-bed in the spring, and when the plants are fit to remove they should be each planted into a small pot filled with light earth, and plunged into a tan-bed, where they should constantly remain, treating them in the same manner as other tender plants from warm countries; if they are brought forward in the spring, they will flower in *July*, and their seeds will ripen in autumn.

The other sorts are preserved in some curious gardens for the variety of their flowers. These may all of them be propagated by sowing their seeds either in spring or autumn, but those which are sowed in autumn should have a light soil and a warm situation, where the plants will abide the winter, and come to flower early the following spring, and their seeds will ripen in *July*; but those which are sown in the spring, should have an open exposure, and may be planted upon almost any soil, for they are not very tender plants, nor do they require much culture: these sorts should all of them be sown where they are designed to remain, for they seldom succeed when they are transplanted; so that where they are sown for ornament, there should be six or eight seeds sown in a small patch, in different parts of the borders of the flower-garden, and when the plants come up, they should be carefully kept clear from weeds; but when they are grown two or three inches high, there should be some sticks put down by them to support them, otherwise they will trail on the ground, and become unsightly; besides, they will trail on whatever plants grow near them.

LAVANDULA. *Tourn. Inst. R. H.* 198. tab. 93. Lavender.

The Characters are.

The flower is of the lip kind, with one petal, having a cylindrical tube spreading above; the upper lip is bifid and open, the under lip is cut into three equal segments. It hath four short stamina, two of which are shorter than the other. It hath a germen divided in four parts, which afterward turns to four oval seeds, sitting in the emplacement.

The Species are,

1. LAVANDULA *foliis lanceolatis integris, spicis nudis.* Hort. Cliff. 303. Broad-leaved Lavender.
2. LAVANDULA *foliis lanceolato-linearibus, spicis nudis.* Narrow-leaved Lavender.
3. LAVANDULA *foliis duplicato-pinnatifidis.* Vir. Cliff. 56. Cut-leaved Lavender.

4. LAVANDULA *foliis duplicato-pinnatifidis hirsutis, spicis fasciculatis.* Canary Lavender, with a longer, narrower, and more elegant cut leaf.

The first sort is cultivated in several of the *English* gardens, and has been generally known by the title of Spike, or Lavender Spike; the leaves of this sort are much shorter, and broader than those of the common Lavender; the branches are shorter, more compact, and fuller of leaves. This sort doth not often produce flowers, but when it does, the flower-stalks are garnished with leaves very different from those on the other branches, approaching nearer to those of the common sort, but are broader; the stalks grow taller, the spikes of flowers are larger, the flowers are smaller, and are in looser spikes.

The second sort is the common Lavender, which is so well known as to require no description. Both these sorts flower in *July*, at which time the spikes of the second sort are gathered for use; there is a variety of this with white flowers.

These are propagated by slips, the best season for which is in *March*; they should be planted in a shady situation, or at least shaded with mats until they have taken root; after which they may be exposed to the sun, and when they have obtained strength, may be removed to the places where they are designed to remain. These plants will abide the longest in a dry, gravelly, or stony soil, in which they will endure our severest winters; though they will grow much faster in the summer, if they are planted upon a rich, light, moist soil, but then they are generally destroyed in winter, nor are the plants half so strong scented, or fit for medicinal uses, as those which grow upon the most barren rocky soil.

The third sort grows naturally in *Andalusia*; this is an annual plant, which rises with an upright branching stalk near three feet high; the stalks are woolly, garnished with hoary leaves growing opposite, which are cut into many divisions to the midrib; these segments are again divided on their borders toward the top, into three obtuse segments, so that they end in many points. The foot-stalk of the flower is naked, having four corners or angles, and is terminated by a close spike of flowers about one inch long; the spike has the rows of flowers twisted spirally: under this spike there are commonly two small ones proceeding from the side of the stalk, at about an inch distance from the middle spike. There are two varieties of this, one with blue, and the other with white flowers.

This sort is sown every spring on borders or beds, and when the plants come up, they may be transplanted into other borders of the flower-garden, or into pots, where they are designed to flower, and will require no farther care, but to keep them clean from weeds. These are pretty plants to place in large borders, amongst other plants, for variety, but they are never used in *England*. If the seeds of this sort are permitted to scatter, the plants will come up the following spring without care, and may be treated in the manner before directed.

The fourth sort grows naturally in the *Canary Islands*. This rises with an upright branching square stalk four feet high, garnished with leaves which are longer, and cut into narrower segments than those of the third sort. They are of a lighter green, and hairy, the naked flower-stalk is also longer, and terminated with a cluster of spikes of blue flowers. The flowers are smaller than those of the common Lavender, but are of the same shape.

This sort is tenderer than either of the former, so the seeds must be sown on a moderate hot bed in the spring; and when the plants are fit to remove, they should be each planted into a separate small pot, and plunged into another hot-bed, to bring the plants forward; in the beginning of *June* they should be inured to the open air, into which

they should be placed in a sheltered situation toward the end of that month; in *July* the plants will flower, and if the autumn proves warm, the seeds will ripen in *September*; but when they do not perfect seeds in the open air, the plants may be removed into a glass case where the seeds will ripen.

LAVATERA. *Tourn. Art. Gal.* 1706. tab. 3.

The Characters are,

The flower has a double permanent empalement; the outer is of one leaf, and trifid; the inner is of one leaf, and quinquesid. The flower hath five petals, which are joined at their base. It has many stamina, which are joined in a column below, but above are loose. It has an orbicular germen, crowned by many bristly stigmas. The empalement afterward becomes a fruit with several capsules, covered in front by a hollow shield, each capsule having one kidney-shaped seed.

The Species are,

1. LAVATERA foliis infimis cordato-orbiculatis, caulinis trilobis acuminatis glabris, pedunculis unifloris, caule herbaceo. Common Lavatera with the leaf and appearance of Marsh-mallow.

2. LAVATERA foliis infimis cordato-angulatis, superne sagittatis, pedunculis unifloris, caule herbaceo hirsuto. African Lavatera with a beautiful flower.

3. LAVATERA foliis glabris, caule scabro herbaceo, pedunculis unifloris, fructibus orbiculo testis. Hort. Upsal. 203. Mallow with a variable leaf.

4. LAVATERA caule herbaceo, fructibus denudatis, calycibus incis. Hort. Upsal. 203. Lavatera with an herbaceous stalk, naked fruit, and a cut empalement.

5. LAVATERA caule arboreo, foliis septemangularibus tomentosis plicatis, pedunculis confertis unifloris axillaribus. Hort. Upsal. 202. Lavatera; or Tree Mallow, with a small flower.

6. LAVATERA caule fruticoso, foliis subcordatis subtrilobis rotundatis crenatis stipulis cordatis, pedunculis unifloris. Lin. Sp. Plant. 691. Shrubby Marshmallow with a rounder hoary leaf.

7. LAVATERA caule fruticoso, foliis quinquelobatis hastatis. Hort. Upsal. 202. Shrubby Marshmallow with an acute leaf, and a small flower.

8. LAVATERA caule fruticoso, foliis orbiculatis crenatis tomentosis, pedunculis confertis unifloris axillaribus. Lavatera; or Spanish shrubby Marshmallow with a rounder leaf.

9. LAVATERA caule fruticoso, foliis quinquelobatis acutis crenatis tomentosis, racemis terminalibus. Shrubby Althæa with a Briony leaf.

The first sort grows naturally in *Syria*; it is an annual plant, with an erect, branching, herbaceous stalk, rising two or three feet high; the under leaves are orbicularly heart-shaped, smooth, and stand upon long foot-stalks, the upper are divided into three acute lobes; the flowers come out upon long foot-stalks from the wings of the leaves, they are very large, and spread open like those of the Marsh-mallow, and are of a pale red or Rose colour.

There is a variety of this with white flowers, which has accidentally risen from seeds.

The second sort grows naturally at the *Cape of Good Hope*. This differs from the first in the shape of the leaves, the lower having angles, and the upper being arrow-pointed; the stalks are hairy, the flowers larger, and of a brighter red colour.

This sort is annual, and flowers at the same time with the former, and the seeds are ripe in the autumn.

The third sort grows naturally in *Spain* and *Sicily*; this is an annual plant, which rises with slender herbaceous stalks three or four feet high, covered with a brown bark; the lower leaves are roundish, the upper are angular, and some are arrow-pointed. The flowers are not half so large

as those of either of the former, and of a pale red colour.

The fourth sort hath a perennial root: it rises four or five feet high, and is woolly, garnished with angular heart-shaped leaves, standing upon long foot-stalks. The flowers come out from the wings of the stalk toward the top, sitting close to the stalks at every joint; they are of a purplish colour, and shaped like those of the Marshmallow, but are larger. It grows naturally in *Austria* and *Bobemia*.

The fifth sort is commonly called Mallow tree; this rises with a very strong thick stalk, to the height of eight or ten feet, dividing into many branches, garnished with soft woolly leaves that are plaited, and the edges cut into several angles. The flowers are produced in clusters at the wings of the leaves, each standing upon a separate foot-stalk; they are of a purple colour, and shaped like those of the common Mallow, and are succeeded by seeds of the same form.

The sixth sort rises with a shrubby stalk seven or eight feet high, sending out several long branches, garnished with woolly leaves, differing greatly in size and shape, the lower being partly heart-shaped at their base, but divide into five roundish lobes; the upper, which are small, have three lobes which are indented on their edges. The flowers come out from the wings of the stalk, three or four at each joint, upon very short foot-stalks; they are of a light purple colour, and shaped like those of Marshmallow.

The seventh sort is a shrub which grows to the same size as the sixth, and differs from it in the shape of the leaves, which are divided into three or five acute-pointed lobes; the flowers are smaller, but of the same shape and colour. This grows naturally in the south of *France*.

The eighth sort rises with a shrubby stalk six or eight feet high, sending out many branches, garnished with roundish, crenated, woolly leaves, standing upon long foot-stalks; the foot-stalks of the flowers come out in clusters from the wings of the leaves, each sustaining one large pale blue flower, of the same shape with those of the other species.

The ninth sort rises with a shrubby stalk six or seven feet high, sending out several shrubby branches, garnished with woolly leaves, divided into five lobes, which end in acute points; the lower part of the branches are adorned with a single flower at each joint, sitting close to the stalk, but the branches are terminated by loose spikes of flowers, which are of a pale blue colour, and shaped like those of the former.

The five last mentioned sorts, though they have shrubby stalks, yet are but of short duration here, seldom continuing longer than two years, unless when they happen to grow upon dry rubbish, where they make but little progress, their stalks and branches being firmer, are better able to resist the cold; for when they are in good ground, they are very vigorous and full of sap, so are killed by the frost in common winters.

All the shrubby sorts are easily propagated by seeds, which should be sown in the spring, upon a bed of light earth; and when the plants are about three or four inches high, they should be transplanted to the places where they are designed to remain; for as they shoot out long fleshy roots which have but few fibres, so they do not succeed well if they are transplanted after they are grown large. If the seeds of these plants are permitted to scatter on the ground, the plants will come up the following spring; and when they happen to fall into dry rubbish, and are permitted to grow therein, they will be short, strong, woody, and produce a greater number of flowers than those plants which are more luxuriant. As these plants continue a long time in flower, so a few plants of each sort may be allowed a place in all gardens where there is room.

The three first sorts are annual plants: the season for sowing their seeds is in *March*, in the places where they are designed to remain, which should be in the middle of the borders in the flower-garden; for, if the soil be good, they will grow two or three feet high; when the plants are come up two inches high, they should be thinned if they are too near; after which they will require no other care but to clear them from weeds, and to fasten them to stakes, to prevent their being injured by strong winds.

The two first sorts are very ornamental plants in a garden, when placed among other annuals, either in pots or borders.

The fourth sort hath a perennial root, which abides several years, but the stalks decay in the autumn, and new ones arise in the spring. This is propagated by seeds, which should be sown upon a bed of light earth in the spring, and when the plants are fit to remove, they should be either transplanted to the places where they are to remain, or into pots where they may stand to get more strength, before they are planted in the full ground. After the plants are well rooted, they will require no other care, but to keep them clear from weeds; and if the winter should prove very severe, it will be proper to cover the ground about them with old tanners bark, to keep out the frost; but they will endure the cold of our ordinary winters very well, and will produce their flowers and ripen their seeds annually.

LAUREOLA. See *Daphne*.

LAUROCERASUS. See *Padus*.

LAURUS. *Tourn. Inst. R. H.* 597. *tab.* 367. The Bay tree.

The Characters are,

It is male and female in different plants; the male flowers have no empalement. They have nine stamina which are shorter than the petal, standing by threes, terminated by slender summits. The female flowers have no empalements; they have one petal, which is cut into six segments at the top. In the bottom is situated an oval germen. There are two globular glands, standing upon very short foot-stalks, fixed to the base of the petal. The germen afterward becomes an oval berry with one cell, inclosing one seed of the same form.

The Species are,

1. LAURUS foliis lanceolatis venosis perennantibus, floribus quadrifidis diœciis. *Hort. Cliff.* 105. The common broad-leaved Bay.

2. LAURUS foliis lanceolatis venosis perennantibus, marginibus undatis. Common Bay tree with waved leaves.

3. LAURUS foliis lineari-lanceolatis venosis perennantibus, floribus quinquefidis diœciis. Narrow-leaved Bay tree.

4. LAURUS foliis lanceolatis perennantibus venosis planis, ramulis tuberculatis cicatricibus, floribus racemosis. *Hort. Cliff.* 154. The Indian Bay.

5. LAURUS foliis lanceolatis perennantibus marginibus reflexis transversè venosis, floribus racemosis. Carolina Bay tree with pointed leaves, and blue berries sitting upon long red foot-stalks.

6. LAURUS foliis ovato-lanceolatis obtusis integris annuis. The American Benjamin tree.

7. LAURUS foliis integris trilobisque. *Hort. Cliff.* 154. The Sassafras.

8. LAURUS foliis trinerviis lanceolato-ovatis, nervis supra basin unitis. *Lin Mat. Med.* 192. The Camphire tree.

The first sort is the broad-leaved Bay, which grows naturally in *Asia*. This is not quite so hardy as the common Bay tree, though it will live in the open air in *England* through our common winters, if it is planted in a warm situation; but severe frosts will kill it, therefore many people shelter the plants in green-houses every winter.

The second is the common Bay; of this there are plants with plain leaves, and others which are waved on their edges, but they seem to be the same species, for the berries

of one have produced a mixture of both sorts; but this is undoubtedly a different species from the first and third sorts.

The third sort hath very long narrow leaves, which are not so thick as those of the two former, and are of a lighter green; the branches are covered with a purplish bark, and the male flowers come out in small clusters from the wings of the leaves, sitting close to the branches. This sort is too tender to thrive in the open air in *England*, so the plants are generally kept in pots or tubs, and housed in winter.

The fourth sort grows naturally at *Madeira* and the *Canary Islands*, from whence it was formerly brought to *Portugal*, where it has been propagated in so great plenty, as to appear now as if it was a native of that country. In the year 1620, this plant was raised in the *Farnesian* garden, from berries which were brought from *India*, and was supposed to be a bastard sort of Cinnamon. This grows to the height of thirty or forty feet in temperate countries, but it is too tender to thrive in the open air in *England*, so the plants are kept in pots or tubs, and removed into the green-house in winter.

The leaves of this sort are larger than those of the common Laurel; they are thick, smooth, and of a light green, the foot-stalks inclining to red; the branches are regularly disposed on every side, and the male flowers are disposed in long bunches; they are of a whitish green colour; the berries are much larger than those of the other sorts. It is called by some the Royal Bay, and by others the *Portugal Bay*.

The fifth sort grows naturally in *Carolina*, where it is called Red Bay; it also is found in other parts of *America*, but not in so great plenty. In some situations near the sea, this rises with a large strait-trunk to a considerable height, but in the inland parts of the country do not grow so large. The wood of this tree is much esteemed, being of a fine grain, so is of excellent use for cabinets, &c.

The leaves of this sort are much longer than those of the common Bay, and are a little woolly on their under side, their edges are a little reflexed; the veins run transversely from the midrib to the sides, and the male flowers come out in long bunches from the wings of the leaves. The female trees produce their flowers in loose bunches, standing upon pretty long foot-stalks which are red; these are succeeded by blue berries sitting in red cups.

This sort is also too tender to thrive in the open air in *England*, for although some plants have lived abroad in a mild winter, which were planted in a warm situation, yet the first sharp winter has destroyed them; so that these plants must be kept in pots or tubs, and housed in winter like the former.

These five sorts may be propagated by layers, and the common sort is generally propagated by suckers, but those plants never keep to one stem, but generally send out a great number of suckers from their roots, and form a thicket, but do not advance in height; therefore the best way to have good plants, is to raise them from the berries, for the plants which come from seeds always grow larger than the others, and do not put out suckers from their roots, so may be trained up with regular stems. The best way is to sow the berries in pots, and plunge them into a moderate hot-bed, which will bring up the plants much sooner than if they were sown in the full ground, so they will have a longer time to get strength before winter; but the plants must not be forced with heat, therefore they should be inured to bear the open air the beginning of *June*, into which they should be removed, where they may remain till autumn; then the pots should be placed under a common frame, that the plants may be protected from hard frost, but in mild weather may enjoy the free air; for while the plants are so young, they are in danger of suffering in hard frost, even the common sort of Bay. The spring following, those

plants which will not live in the open air, should be each transplanted into separate pots; but the common sort may be planted in nursery-beds six inches asunder each way, where they may grow two years, by which time they will be fit to plant where they are designed to grow. The other sorts, which require protection, should be planted in pots, and placed in a sheltered situation till autumn, when they should be placed in the green-house.

The common Bay will make a variety in all ever-green plantations, and as it will grow under the shade of other trees, where they are not too close, so it is very proper to plant in the borders of woods, where it will have a good effect in winter.

The sixth sort grows naturally in *North America*, where it rises to the height of eight or ten feet, dividing into many branches, garnished with oval spear-shaped leaves, smooth on their upper surface, but with many transverse veins on their under side; these leaves fall off in the autumn, like other deciduous trees. The flowers I have but once seen, those were all male, and of a white herbaceous colour, but if I remember right they had but six stamina in each.

The Sassafras tree is also very common in most parts of *North America*, where it spreads greatly by its creeping roots, so as to fill the ground with suckers where-ever they are permitted to grow, but in *England* this shrub is with difficulty propagated. In *America* it is only a shrub, seldom rising more than eight or ten feet high; the branches are garnished with leaves of different shapes and sizes, some of them are oval and entire, about four inches long and three broad; others are deeply divided into three lobes; these are six inches long, and as much in breadth from the extremity of the two outside lobes; they are placed alternately upon pretty long foot-stalks, and are of a lucid green; the flowers appear in the spring just below the leaves, upon slender foot-stalks, each sustaining three or four small yellow flowers, which have five oval concave petals, and eight stamina in the male flowers, which are upon different plants from the female; these have an oval germen, that afterward becomes an oval berry, which when ripe is blue.

The Camphire tree grows naturally in *Japan*, and in several parts of *India*, where it rises to a tree of middling stature, dividing into many small branches, garnished with oval spear-shaped leaves, smooth on their upper side, having three longitudinal veins which unite above the base; if these are bruised, they emit a strong odour of Camphire, as also the branches when broken. These have male and female flowers on different trees; I have only seen those of the male, which has flowered plentifully in *England*; those were small, and composed of five concave yellow petals, very like those of the Sassafras tree, which were produced by threes or fours upon each foot-stalk in like manner.

The Sassafras tree is commonly propagated by the berries, which are brought from *America*; but these berries generally lie in the ground a whole year, and sometimes two or three years before they grow, when they are sown in the spring; therefore the surest method of obtaining the plants will be, to get the berries put into a tub of earth soon after they are ripe, and sent over in the earth; and as soon as they arrive, to sow the berries on a bed of light ground, putting them two inches into the earth; and if the spring should prove dry, the bed must be frequently watered, and shaded from the great heat of the sun in the middle of the day. With this management many of the plants will come up the first season; but as a great many of the berries will lie in the ground till the next spring, so the bed should not be disturbed, but wait until the season after, to see what will come up: the first winter after the plants come up, they should be protected from the frost, especially in the autumn; for the first early frost at that season is apt to

pinch the shoots of these plants, which are tender and full of sap, and do them more injury than the severe frost of the winter; for when the extreme part of the shoots are killed, it generally affects the whole plant.

When the plants have grown a year in the seed-bed, they may be transplanted into a nursery, where they may stand one or two years to get strength, and may then be transplanted into the places where they are to remain for good.

There have been some of the plants propagated by layers, but these are commonly two, and sometimes three years before they put out roots; and if they are not duly watered in dry weather, they rarely take root; so that it is uncertain whether one in three of these layers do succeed, which makes these plants very scarce in *England* at present.

The *Benjamin* tree, as it is falsely called, may be propagated in the same manner as the Sassafras, by sowing of the berries: these generally lie long in the ground, so that unless they are brought over in earth, in the same way as before directed, they often fail, or at least remain long in the ground; but this shrub is now frequently propagated by layers in *England*, which put out roots pretty freely, when the young shoots are chosen for to make layers.

The Camphire tree is very near akin to the Cinnamon tree, from which it differs in the leaves, those of the Cinnamon tree having three ribs running longitudinally from the foot-stalk to the point, which are remarkably large; whereas the ribs of the leaves of this tree are small, and extend toward the sides, and unite before they meet the foot-stalks; the leaves have a smooth shining surface: they have male and female flowers in different trees, so that there is a necessity for both sexes to stand near each other, in order to have good seeds.

In *Europe* this tree is propagated by layers, which are two years, and sometimes longer, before they take root, so that the plants are very scarce; and as all those which I have seen flower are male trees, so there can be no hopes of procuring seeds from them here; but if the berries of this, and also of the Cinnamon tree, were procured from the places of their growth, and planted in tubs of earth, as hath been directed for the Sassafras tree, there may be a number of these plants procured in *England*: and if they were sent to the *British* colonies in *America*, they might be there cultivated, so as to become a publick advantage; especially the Cinnamon tree, which will grow as well in some of our islands in the *West-Indies*, as it doth in the native places of its growth; and in a few years the trees might be had in plenty, for they propagate easily by the berries. The *Portuguese* brought some of the Cinnamon trees from the *East-Indies*, and planted them on the island of *Princes*, on the coast of *Africa*, where they now abound, having spread over a great part of the island; there is also one of the trees growing at the *Madeiras*, and I am credibly informed there are many trees in the *Brazils*.

The Camphire tree does not require any artificial heat in winter, so that if they are placed in a dry green-house, they will thrive very well. During the winter season they must be sparingly watered, and in the summer they should be placed in a warm situation, where they may be defended from strong winds, and not too much exposed to the direct rays of the sun; and during this season, they must be frequently refreshed with water.

They may be propagated by cuttings, which should be planted in pots, and plunged into a moderate hot-bed, covering them close with a hand-glass, and shading them in the heat of the day.

LAURUS ALEXANDRIA. See Ruscus.

LAURUS TINUS. See Tinus.

LAWSONIA. *Linn. Gen. Plant.* 443. *Henna Ludw.* 143.

The Characters are,

The flower is composed of four oval spear-shaped petals, which spread open, and eight slender stamina. It hath a roundish germen, which afterward becomes a globular capsule, ending in a point, having four cells, filled with angular seeds.

The Species are,

1. LAWSONIA ramis imermibus. Flor. Zeyl. 134. Broad-leaved Egyptian Privet, called *Albenna*, or *Henna*, by the Arabians.

2. LAWSONIA ramis spinosis. Flor. Zeyl. 135. Lawsonia with prickly branches.

The first sort grows naturally in *India*, *Egypt*, and other warm countries, where it rises with a shrubby stalk eight or ten feet high. The branches come out opposite; these are slender, covered with a whitish yellow bark, and are garnished with oblong small leaves, of a pale green, ending in acute points, placed opposite. The flowers are produced in loose bunches at the end of the branches; they are of a gray or dirty white colour, and are composed of four small petals which turn backward at the top. The flowers are succeeded by roundish capsules, with four cells, filled with angular seeds.

The leaves of this shrub are much used by the *Egyptian* women to colour their nails yellow, which they esteem an ornament.

The second sort grows naturally in both *Indies*, from whence I have received specimens of it.

This rises with a woody trunk eighteen feet high or more. The wood is hard and close, covered with a light gray bark. The branches come out alternate, and are garnished with oblong oval leaves, which stand without order; at the joints where the leaves are placed come out single, strong, sharp thorns. The flowers are produced in loose bunches from the side of the branches; they are of a pale yellow colour, and of a disagreeable scent; they have four petals, which spread open; between each of these are situated two pretty strong stamina, terminated by roundish summits. After the flowers are past, the germen becomes a roundish capsule with four cells, including many angular seeds.

These plants are both propagated by seeds, which should be sown on a hot-bed early in the spring, that the plants may have time to get strength before winter. When the plants are fit to remove, they should be each planted in a small pot, and plunged into a hot-bed of tanners bark, where they must be screened from the sun till they have taken new root, then their treatment should be the same as that of the Coffee tree, with this difference only, not to keep it too warm, nor give them so much water, but especially in the winter, during which season it should be given to them very sparingly, for by over watering these plants I have known many of them destroyed; these plants are too tender to thrive in the open air in *England*, so they must be placed in a moderate stove in autumn, but in the warmest part of summer they may be put in the open air in a sheltered situation.

LAYERS. Many trees may be propagated by layers, which do not produce seeds here, so are not easily increased by any other method, and a great number of plants are this way increased.

Laying of Trees.

The young branches of the former year's shoots of trees should be chosen to make layers, because these are generally more inclined to put out roots than the older wood. When these are produced near the ground, they may with greater facility be layed. These shoots should be divested of their side branches, if they have any; and those sorts of trees which put out roots with difficulty, should have a slit made upward at a joint, in that part which is to lie in the ground; or a piece of wire twisted close round the branch

at the same place, which will check the mounting sap, and cause them to put out roots; the ground should be well dug, and the clods broken; then the shoots should be layed five or six inches under the surface, driving down a peg to each to prevent their rising, leaving the end of the shoots five or six inches above ground in an erect position.

The season for laying hardy trees, that shed their leaves, is in *October*, but for such as are tender in *March*; but for ever-greens, *July* or *August* are good seasons.

However, the summer is the best time for small plants, because such plants being but short lived draw root the quicker.

If you would lay young trees from a high standard, the boughs of which cannot be bent down to the ground, then you must make use of Osier baskets, boxes, or pots, filled with fine sifted mould, mixed with a little rotten Willow dust, which will keep moisture to assist the layer in taking root; this basket, box, &c. must be set upon a post, or tressel, &c. and the bough must be laid according to the former way of laying, covering the surface with moss to prevent the earth from drying.

The harder the wood of the tree is, the younger should be the shoots, for such will take root best; but if the wood be soft, the older boughs will take root the best, and are less liable to rot.

There are many kinds of trees and plants which will not put out roots from their woody branches, though laid down with the utmost care, yet if the young shoots of the same year are laid in *July*, they will often put out roots very freely, so that when any plants are found difficult to propagate by layers in the common way, they should be tried at this season; but as these shoots will be soft and herbaceous, they must not have too much wet, for that will cause them to rot, therefore it will be a better method to cover the surface of the ground over the layers with moss, which will prevent the ground from drying too fast, so that a little water now and then will be sufficient.

LEAVES. A leaf is defined to be a part of a plant extended into length and breadth, in such a manner as to have one side distinguishable from the other; they are properly the most extreme part of a branch, and the ornament of the twigs, and consist of a very glutinous matter, being furnished every where with veins and nerves; one of their offices is, to subtilize and give more spirit to the abundance of nourishing sap, and to convey it to the little buds.

If the surface of leaves are altered, by reversing the branches of trees on which they grow, the plants are stopped in their growth, until the foot-stalks are turned, and the leaves recover their former position. This shews how necessary it is to support all those weak shoots of plants, which are naturally disposed for upright growth, which either twine about the neighbouring trees for support, or that put out claspers, by which they take hold of whatever trees or plants grow near them, and are thereby supported; and, on the contrary, how absurd is that practice of tying up the shoots of those plants which are naturally disposed to trail upon the ground, for in both these cases nature is reversed, and consequently the growth of both sorts of plants is greatly retarded.

This is one of the great functions for which the leaves of trees and plants are designed; but, besides this, there are others of equal importance to the well-being of plants and fruits; the first is that of the foot-stalks and leaves nourishing and preparing the buds of the future shoots, which are always formed at the base of these foot-stalks, and during the continuance of the leaves in perfect health, these buds increase in their magnitude, and, in the deciduous trees, are brought to maturity before the foot-stalks separate from the buds in autumn; but if by accident the leaves are blighted,

blighted, or if the entire surface of the leaves are cut off, and the foot-stalks are left remaining, the buds will decay for want of that proper nourishment which is conveyed to them from the leaves; so that whenever trees are divested of their leaves, or those leaves are cut, or otherwise impaired, though it may in either case happen when the buds may be nearly formed, yet if it is before the foot-stalks separate naturally from the branches, the future shoots will be weakened in proportion to the time when this is done; therefore from all the experiments which have been made in order to know how serviceable the leaves of trees and plants are to their well-being, it has been found, that where the plants have been divested of their leaves, or their leaves have been eaten or cut, during their growth, the plants have been remarkably weakened thereby. This should teach us not to pull, or cut off the leaves of trees, or plants, on any account, while they retain their verdure, and are in health; and this shews how absurd that common practice is; of feeding down Wheat in the winter and spring with sheep; for by so doing, the stalks are rendered very weak, and the ears are in proportion shorter, nor are the grains of Corn so plump and well nourished, as that which is not fed down upon the same ground; this is a fact which I can assert from many years experience. It is very evident, that Grass which is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the species of Grass is the same with that on the richest pastures; so that although this may be a desirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this should be avoided.

Another principal use of the leaves is to throw off by transpiration, what is unnecessary for the growth of the plants, answering to the discharge made by sweat in animal bodies; for as plants receive and transpire much more, in equal time, than large animals, so it appears how necessary the leaves are to preserve the plants in perfect health; for it has been found by the most exact calculations, made from repeated experiments, that a plant of the Sun flower receives and perspires, in twenty-four hours, seventeen times more than a man.

I shall beg leave to mention a few, out of the many experiments which have been made by *Mons. Bonnet*, of *Geneva*, to prove that most leaves imbibe the moisture of the air on their under surface, and not from their upper; they are as follow:

He gathered the leaves of sixteen sorts of herbaceous plants when fully grown; of each he put several leaves upon the surface of water in glass vases, some were posited with their upper surface, and others with their under surface upon the water; these were adjusted exactly to the surface of the water, with great care not to let any moisture reach their opposite surfaces, and the same care was taken to prevent their foot-stalks from receiving any moisture. The glasses in which these leaves were thus placed, were kept in a closet, where the air was very temperate; and as the water in the glasses evaporated, there was from time to time a supply of fresh, which was added with a syringe, so that the leaves were not disturbed. The leaves were taken from the following plants; the Plantain, the Mullein, the Wake Robin, the great Mallow, the Nettle, the Marvel of *Peru*, the Kidney-bean, the Sun-flower, the Cabbage, the Balm, the Cockscorn, the purple-leaved Amaranth, Spinach, and the smaller Mallow.

Six of these sorts he found continued green a long time, and these were with different surfaces upon the water; they were of the following sorts, the Wake Robin, the Kidney-bean, the Sun-flower, the Cabbage, the Spinach, and small Mallow; among the others the following sorts were found to draw the moisture better with their upper surface than

their under, the Plantain, the Mullein, the great Mallow, the Nettle, the Cockscorn, and the purple Amaranth.

The leaves of the Nettle, whose under surface was upon the water, were decayed in three weeks, whereas those whose upper surface was next the water continued two months.

The leaves of Mullein, whose under surface was next the water, did not continue fresh more than five or six days, but those whose upper surface was next the water lasted five weeks.

The leaves of the purple Amaranth, whose upper surface was next the water, continued fresh three months, whereas those whose under surface was next the water were decayed in a week.

The leaves of the Marvel of *Peru* and the Balm, appeared to have the advantage, whose under surfaces were next the water.

The leaves of Wake Robin and of the Cockscorn, whose foot-stalks only were put into the water, continued fresh a longer time, than those which were placed with either surface next the water.

The leaves of the great Mallow, the Nettle, the Sun-flower, the Marvel of *Peru*, and Spinach, whose foot-stalks were plunged into the water, continued fresh a shorter time, than those which had either of their surfaces next the water.

The leaves of the Mullein, of Plantain, and Amaranth, which received the water at their foot-stalk, continued fresh much longer than those whose under surfaces was next the water.

It is not difficult to explain the reason of this fact, for the orifices of the sap-vessels in the foot-stalk, are much larger than those of either surface, so that the moisture insinuates in greater quantities and with more ease, the first than by the second way.

After this the same gentleman made experiments on the leaves of sixteen sorts of trees and shrubs of the following sorts, the Lilac, the Pear tree, the Vine, the Aspen, the Laurel, the Cherry tree, the Plum tree, the Horse Chestnut, the White Mulberry, the Lime tree, the Poplar, the Apricot, the Walnut, the Filbert, the Oak, and the Creeper.

Among these species he found that the Lilac and the Aspen imbibed the moisture on their upper surface, equally with the under surface; but in all the other sorts, the under surface imbibed it in much greater quantities than the opposite. The difference was very remarkable in the leaves of the White Mulberry, for those whose upper surface was laid upon the water, faded in five days, whereas the other, whose under surface was next the water, preserved their verdure near six months.

The Vine, the Poplar, and Walnut tree, are very remarkable instances, how little disposed the upper surfaces of the leaves of ligneous plants are to imbibe the moisture; for those of these three sorts, whose upper surfaces were applied to the water, decayed almost as soon as those which had no nourishment.

In all the experiments made by this curious gentleman upon the various leaves of trees and herbs, it is remarkable, that all those leaves, which imbibed their moisture by their upper surface, were such as had that surface covered either with hairs or down; and on the contrary, where the under surface was garnished with either hairs or down, the moisture was imbibed by that surface. He likewise mentions many experiments made by himself, and also by *Mons. du Hamel de Monceau*, of the Royal Academy of Sciences at *Paris*, in rubbing the leaves over with varnish, oil, wax, and honey, to see the effect of these upon various leaves, some of which were rubbed over on both surfaces, others only upon one; some only a part of the surface, others the edges of the leaves.

leaves were rubbed over, and in some only the foot-stalks of the leaves were rubbed with these. They likewise anointed the trunks of some trees and shrubs, and left the leaves and branches in their natural state.

The result of these experiments was, that where the leaves were anointed on both surfaces with varnish, they decayed presently; and where they were anointed with the other things, in proportion as those were most penetrating, so the leaves continued a shorter time than the others; and where one surface only was anointed, they continued much longer than those which were anointed on both; and where the pedicle only was anointed, they continued still longer; but the anointing of the trunks made no sensible alteration, excepting in very hot weather; when they both imagine, that the anointing them was of service, by hindering the too great transpiration which might weaken the trees; for they observed, that those trees which were varnished, suffered less from the violent heat, than the trees which were left in their natural state.

Mons. Bonnet also observed, that those leaves which were varnished, that the tender parts of the leaves were destroyed by it, and the tough fibres only were left remaining.

We may therefore reasonably conclude, that one great use of leaves is what has been long suspected by many, viz. to perform, in some measure, the same office for the support of the vegetable life, as the lungs of animals do for the support of animal life; plants, very probably, drawing through their leaves some part of their nourishment from the air.

LEDUM. *Lin. Gen. Plant.* 483. Marsh Cistus, or wild Rosemary.

The Characters are,

The empalement of the flower is indented in five parts. It hath five oval concave petals, and ten slender stamina, and a roundish germen, which afterward becomes a capsule with five cells, opening at the base in five parts, filled with small, narrow, acute-pointed seeds.

We have but one Species of this genus, viz.

LEDUM *foliis linearibus subtus hirsutis, floribus corymbosis. Flor. Suec.* 341. Ledum with very narrow leaves, hairy on their under side, and flowers growing in a corymbus.

This plant grows naturally upon mosses and bogs in many parts of *Yorkshire*, *Cheshire*, and *Lancashire*, where it rises with a slender shrubby stalk about two feet high, dividing into many slender branches, garnished with narrow leaves not much unlike those of Heath. The flowers are produced in small clusters at the end of the branches, which are shaped like those of the Strawberry tree, but spread open wider at the top. These are of a reddish colour, and in the natural places of their growth are succeeded by seed-vessels filled with small seeds, which ripen in autumn.

It is with great difficulty this plant is kept in a garden, for as it naturally grows upon bogs, so unless the plants have some such soil and a shady situation, they will not thrive. The plants must be procured from the places of their growth, and taken up with good roots, otherwise they will not live.

LEEK. See Porrum.

LEMON TREE. See Limon.

LENS. See Ervum.

LENS PALUSTRIS, Duck Meat. This is a very common plant, growing upon standing waters in most parts of *England*; where, if it is not disturbed, it will soon cover the whole surface.

LENTISCUS. See Pistacia.

LEONTICE. *Lin. Gen. Plant.* 381. Lion's Leaf.

The Characters are,

The flower has six acute petals, and six nectariums which are fixed by small foot-stalks to the base of the petals. It has six

stamina. In the center is placed an oval germen, which afterward becomes a globular, swollen, succulent berry, with one cell, inclosing two or three globular seeds.

The Species are,

1. LEONTICE *foliis pinnatis, petiolo communi simplici. Hort. Cliff.* 122. Lion's Leaf, with winged leaves having one common single foot-stalk.

2. LEONTICE *foliis decompositis, petiolo communi trifido. Hort. Cliff.* 122. Lion's Leaf with decomposed leaves, and a common trifid foot-stalk.

These plants both grow naturally in the islands of the *Archipelago*, and also in the Corn-fields about *Aleppo*, where they flower soon after *Christmas*. They have large tuberous roots, about the size of those of *Cyclamen*, covered with a dark brown bark; the leaves arise upon slender foot-stalks immediately from their roots, which grow about six inches high; that of the first sort is single, having many small *folioli* ranged along the midrib, but the foot-stalks of the second sort are branched into three smaller; upon each of these are ranged several *folioli* or small leaves, in the same form as the winged leaves. The flowers set upon naked foot-stalks; those of the first sort sustain many yellow flowers, but the flowers of the second are smaller, and of a paler colour. These in their native country appear soon after *Christmas*, but in *England* they do not flower till the beginning of *April*, and are never succeeded by seeds here.

Both these plants are propagated by seeds, which require to be sown soon after they are ripe, otherwise they seldom succeed; but as they are brought from distant countries, they should be preserved in sand to be sent to *England*. I received a few of these seeds from the duke *D'Ayen*, which were sent him from *Aleppo* put up in sand, and these came up better than any of those which came over dry; for of several parcels of these seeds which I have sown of both kinds, I have not had more than two plants arise.

The plants are very difficult to preserve in *England*, for the roots will not thrive in pots; and when they are planted in the full ground, the frost frequently destroys them in winter, especially while the roots are young. Of late years the winters have proved so very unfavourable, as to kill all the young roots which I had raised in the *Chelsea* garden; but before the severe winter in 1740, I had some of the roots which were planted in a south-west-border, that flowered several years, and without any shelter survived the winters; but although I covered many of those roots which I had lately raised, yet I could not preserve them.

The leaves of these plants decay about *Midsummer*, and the roots remain in an unactive state till the following spring, at which time the flowers and leaves come up nearly at the same time.

LEONTODON. *Lin. Gen. Plant.* 817. Dandelion.

There are four or five species of this genus, which grow naturally in the fields, so are not cultivated in gardens; but some people in the spring gather the roots out of the fields, and blanch them in their gardens for a Sallad herb; however, as they are not cultivated, I shall forbear saying any thing more of them, than that they are very bad weeds both in gardens and fields, so should be rooted out before their seeds are ripe, otherwise they will spread to a great distance, as they have down adhering to them, by which they are waisted about by the wind.

LEONTOPODIUM. See Plantago.

LEONURUS. *Tourn. Inst. R. H.* 187. tab. 87. Lion's Tail.

The Characters are,

The flowers have one petal of the lip kind; the upper lip is cylindrical, hairy, and entire; the lower lip is reflexed, and cut into three parts. It hath four stamina, two of which are shorter than the other. In the bottom of the tube are situated four germen,

men, which after-ward become four oblong angular seeds, sitting in the empalement.

The Species are,

1. *LEONURUS foliis lanceolatis, obtusè ferratis.* Hort. Cliff. 312. Lion's Tail with spear-shaped leaves, which are bluntly sawed.

2. *LEONURUS foliis ovatis, calycibus decagonis, septem dentatis, inæqualibus.* Hort. Cliff. 312. Lion's Tail with oval leaves, an empalement having ten corners, and seven unequal indentures.

The first sort is a native of *Ethiopia*. This rises with a shrubby stalk seven or eight feet high, sending out several four-cornered branches, garnished with oblong narrow leaves, acutely indented on their edges, hairy on their upper side, and veined on their under, standing opposite. The flowers are produced in whorls, each of the branches having two or three of these whorls toward their ends; they are of the lip kind, shaped somewhat like those of the dead Nettle, but are much longer and covered with short hairs; they are of a golden scarlet colour, so make a fine appearance. The flowers commonly appear in *October* and *November*, and sometimes continue till the middle of *December*, but are not succeeded by seeds here.

There is a variety of this with variegated leaves, which is by some admired; but as this seldom produces so large whorls of flowers as the plain sort, is not generally esteemed.

The second sort is a native of the *Cape of Good Hope*, from whence I have two or three times received the seeds.

This rises with a square shrubby stalk about three feet high, sending out several four-cornered branches, garnished with oval crenated leaves, rough on their upper side like the dead Nettle, but veined on the under, placed opposite. The flowers come out in whorls round the branches, in like manner as the former, but are not so long nor so deep coloured; they appear at the same season with the first, and continue as long in beauty.

Both these sorts are propagated by cuttings. If the cuttings are planted the beginning of *July*, after the plants have been exposed to the open air long enough to harden the shoots, they will take root very freely. They should be planted in a loamy border to an east aspect, and if they are covered closely with a bell or hand-glass to exclude the air, and shaded from the sun, it will forward their putting out roots; but when they begin to shoot, the glasses should be raised to admit the free air, to prevent their drawing up weak, and by degrees they must be exposed to the open air. As soon as they have taken good root, they must be taken up, and each planted in a separate pot filled with soft loamy earth, and placed in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain till *October*, when they must be removed into the green-house, and after-ward treated as the Myrtle, and other hardy green-house plants, observing to water the first sort plentifully.

LEPIDIDIUM. Tourn. Inst. R. H. 215. tab. 133. Dittander, or Pepperwort.

The Characters are,

The flower has four oval petals placed in form of a cross, and six awl-shaped stamina, two of which are shorter than the other. In the center is situated a heart-shaped germen, which after-ward turns to a spear-shaped seed-vessel with two cells, divided by an intermediate partition, containing oblong seeds.

The Species are,

1. *LEPIDIDIUM foliis ovato-lanceolatis integris serratis.* Hort. Cliff. 330. Broad-leaved or common Dittander.

2. *LEPIDIDIUM foliis lanceolatis amplexicaulibus dentatis.* Hort. Cliff. 331. Dittander with spear-shaped indented leaves, which embrace the stalks.

3. *LEPIDIDIUM foliis lineari-lanceolatis subdentatis amplexicaulibus radice reptatrice.* Low Dittander of *Aleppo* with less hoary leaves.

4. *LEPIDIDIUM floribus diandris tetrapetalis, foliis inferioribus lanceolatis serratis, superioribus linearibus integerrimis.* Flor. Leyd. Prod. 334. Dittander with flowers having four petals and two stamina, whose under leaves are spear-shaped and sawed, and the upper narrow and entire.

5. *LEPIDIDIUM foliis caulinis pinnato-multifidis, ramiferis cordatis, amplexicaulibus integris.* Hort. Cliff. 331. The true Mithridate Mustard of *Dioscorides*.

6. *LEPIDIDIUM floribus subtriandris tetrapetalis, foliis linearibus pinnatis.* Lin. Gen. Plant. 645. Dittander with flowers having four petals, and sometimes three stamina, and very narrow winged leaves.

7. *LEPIDIDIUM foliis lyratis crispis.* Lin. Sp. Plant. 644. Dittander with curled lyre-shaped leaves.

The first sort grows naturally in moist places in many parts of *England*, so is seldom cultivated in gardens. It hath small white creeping roots, by which it multiplies very fast, so as to render it difficult to eradicate, after it has grown long in any place; the lower leaves are oval, spear-shaped, sawed on the edges, standing upon long foot-stalks. The stalks are smooth, rise two feet high, and send out many side branches; the leaves upon the stalks are longer, narrower, and more acute-pointed than the lower. The flowers grow in close bunches toward the top of the branches, coming out from the side; they are small, and composed of four small white petals. The seeds ripen in the autumn. The whole plant has a hot biting taste like Pepper, and the leaves have been often used by the country people to give a relish to their viands instead of Pepper; from whence it had the appellation, of poor Man's Pepper.

This plant is easily propagated, for every piece of the root will grow and multiply where-ever it is planted, so will become troublesome to root out after growing for some time in a garden.

The second sort grows naturally in *Austria* and *Italy*; this hath a fleshy fibrous root, from which arise several weak stalks about a foot and a half high, garnished with spear-shaped hoary leaves, deeply cut in upon the edges, which embrace the stalks with their base; the flowers are small, white, and grow in loose bunches at the end of the branches.

This is a perennial plant, which propagates very fast by its roots, and is seldom admitted into gardens.

The third sort grows naturally about *Aleppo*; this hath creeping roots, which extend to a great distance, so will soon spread over a large piece of ground. The leaves of this are longer and narrower than those of the former, and are less hoary; the flowers grow in loose bunches at the end of the branches; they are small, white, and like those of the first. This is a hardy perennial plant, which propagates by its creeping roots in as great plenty as either of the former.

The fourth sort grows naturally in the south of *France*, *Italy*, and *Sicily*. This hath a long fleshy root, which runs deep into the ground, sending out many oblong sawed leaves, which spread on the ground; the stalks are slender, stiff, and rise about two feet high, garnished with very narrow entire leaves. The flowers come out in close clusters at the end of the branches, they are white, and appear in *June* and *July*, and the seeds ripen in autumn. If these seeds are permitted to scatter, the plants will come up early in the spring, and require no other care but to keep them clean from weeds; the roots will abide several years if they are in a dry soil.

The fifth sort grows naturally in *Persia* and *Syria*; this is supposed to be the true Mithridate Mustard of *Dioscorides*. It is an annual plant, whose lower leaves are finely cut into many winged segments; the stalks rise a foot high, dividing at the top into slender branches, garnished with heart-shaped intire leaves, which embrace the stalks with their

their base. The flowers grow in long loose spikes from the end of the branches; they are small, yellow, and appear in *June* and *July*; the seeds ripen in *September*, soon after which the plant decays.

The seeds of this plant should be sown in the autumn, for those which are sown in the spring, seldom flower the same year, and are often killed by the frost in winter; whereas those which are sown in the autumn, or the plants that rise from scattered seeds, will always flower about *Midsummer*, and their seeds ripen the *September* following. The plants require no other care but to thin them to a proper distance, and keep them clean from weeds.

The sixth sort is an annual plant, which grows naturally in *Virginia*, and in most of the islands of the *West-Indies*, where the inhabitants gather the leaves, and eat them in their Sallads as we do the garden Cress.

The lower leaves of this sort are long and sawed on their edges, of a light green, with a biting taste like Cress. The stalk rises a foot and a half high, sending out a great number of small side branches, garnished with narrow leaves regularly sawed on their edges, so as to resemble winged leaves; these sit close to the branches. The flowers are produced at the end of the branches in loose spikes, they are small, white, and are succeeded by roundish or heart-shaped compressed seed-vessels, which have a border round them. This sort is easily propagated by seeds, which may be sown upon an open bed in *April*, where the plants are designed to remain, and when they come up, they will require no other care, but to thin them where they are too close, and keep them constantly clean from weeds; or if the seeds are permitted to scatter in the autumn, the plants will come up very well, and may be treated in the same way as the other.

The seventh sort grows naturally in *Asia*. This is a biennial plant, the lower leaves which spread on the ground, are indented on both sides, and are in shape of a lyre; the stalks rise a foot high, and divide into a great number of slender branches, garnished with small oblong leaves, which are cut, and a little curled on their edges; the stalks and leaves are of a gray colour, inclining toward hoariness. The flowers are produced in clusters at the end of the branches; they are white, and are succeeded by roundish bordered seed-vessels which are compressed, and have two cells each, containing two small oblong seeds, which are ripe in the autumn.

This sort may be propagated by seeds, in the same manner as the former; or if the seeds are permitted to scatter in the autumn, the plants will come up without care, and should be treated in the same way as the former sort; but this does not flower till the second year, so the plants should be left farther asunder.

LEPIDOCARPODENDRON. See Protea.

LETTUCE. See Lactuca.

LEUCANTHEMUM. See Anthemis.

LEUCOJUM. *Lin. Gen. Plant.* 363. Snowdrop.

The Characters are,

It hath an obtuse compressed spatha. The flower is of the spreading bell-shape, cut into six parts. It hath six short bristly stamina. The roundish germen is situated under the flower, which afterward becomes a turbinated capsule with three cells, opening with three valves, filled with roundish seeds.

The Species are,

1. LEUCOJUM *spathâ uniflorâ, stylo clavato. Lin. Sp. Plant.* 289. Early great Snowdrop.

2. LEUCOJUM *spathâ multiflorâ, stylo filiformi. Læf. Lin. Sp. Plant.* 289. Snowdrop with many flowers in a sheath, and a thread-like style.

The first sort grows naturally in *Switzerland* and *Germany*, as also upon the mountains near *Turin*. This hath

an oblong bulbous root, shaped like that of the Daffodil, but smaller; the leaves are flat, of a deep green, four or five in number, considerably broader than those of the small Snowdrop; between these arise an angular stalk near a foot high, which is naked, hollow, and channelled; toward the top comes out a sheath which is whitish, opening on the side, out of which come one, or sometimes two white flowers, hanging upon slender foot-stalks; these have but one petal, which is cut into six parts almost to the bottom. They are much larger than those of the small Snowdrop, and the ends of the segments of the petal are tipped with green, where they are of a thicker substance than in any other part. These flowers appear in *March*, soon after those of the small sort; they have an agreeable scent, not much unlike that of the flowers of Hawthorn; after the flower is past, the germen which is situated below the flower, swells to a Pear-shaped capsule with three cells, inclosing several oblong seeds.

The leaves of this sort decay toward the end of *May*, after which time the roots may be taken up and transplanted, for they should not be long kept out of the ground. It is propagated here by offsets, which the roots put out pretty plentifully when they are in a situation agreeable for them, and are not too often removed. They should have a soft, gentle, loamy soil, and an exposure to the east; the roots should be planted six inches asunder, and four or five inches deep, and must not be transplanted oftener than every third year.

The second sort is generally known by the title of late, or tall Snowdrop; this grows naturally in the meadows near *Pisa* in *Italy*, in *Hungary*, and also near *Montpelier*.

The root of this sort is near as large as that of the common Daffodil, and is very like it in shape; the leaves are also not unlike those of the Daffodil, and are more in number than those of the other sort; they are green, and keel-shaped at the bottom, where they fold over each other, and embrace the stalk, which rises a foot and a half high, and at the top is situated a spatha (or sheath) which opens on one side, and lets out three or four flowers, which hang downward, upon pretty long foot-stalks; these are cut into six oval concave segments almost to the bottom, and are of a clear white, with a large green tip to each segment, which is of a thicker consistence than any other part of the petal; within are situated six awl-shaped stamina, with oblong yellow summits, standing erect round a very slender style, crowned by an obtuse stigma. These flowers appear the latter end of *April* or beginning of *May*, and are succeeded by large triangular seed-vessels, having three cells, each containing two rows of seeds.

This sort is generally propagated in *England* by offsets, for the plants raised by seeds will not come to flower in less than four years; and as the roots put out offsets in plenty, so that is the more expeditious method. These roots may be treated in the same way as the first sort, and should have a soft loamy soil, and be exposed only to the morning sun, where they will flower stronger and continue longer in beauty, than when they are in an open situation, though they will thrive almost in any soil.

LEUCOJUM INCANUM. } See Cheiranthus.

LEUCOJUM LUTEUM. }

LEUCOJUM BULBOSUM. See Galanthus.

LICHEN, Liverwort.

There being two sorts of this plant, which are sometimes used in medicine, and one of those being accounted a sovereign remedy for the bite of mad dogs, I thought it would not be improper to mention them here, though they are plants which cannot be propagated by any method, except by paring up the turf of Grass whereon they grow, and laying it down in some moist shady place, where, if the turf takes root and thrives, these plants will spread and do well.

The two Sorts are,

1. LICHEN *petraeus latifolius*, *sive hepatica fontana*. C. B. P. Common broad-leaved Liverwort.
2. LICHEN *terrestris cinereus*. Raii Syn. Ash-coloured ground Liverwort.

The first sort grows on the sides of wells, and in moist shady places, not only on the ground, but on stones, bricks, or wood. Of this there are several varieties, which are distinguished by the curious in botany; but as most of them are plants of no use, I shall not enumerate them.

The second sort (which is used to cure the bite of mad dogs) grows on commons, and open heaths, where the Grass is short, in most parts of England, especially on declivities, and on the sides of pits. This spreads on the surface of the ground, and, when in perfection, is of an Ash colour, but as it grows old, it alters, and becomes of a dark colour. This is often carried into gardens with the turf which is laid for walks and slopes, and where the soil is moist and cool, it will spread, and be difficult to destroy, so that it renders the Grass unsightly; but this is the only method yet known to have it grow in gardens, where it is desired.

This is esteemed a sovereign remedy for the bite of mad dogs, and hath been for many years used with great success.

It was communicated to the Royal Society by Mr. *George Dampier*, whose uncle had long used this plant, to cure the bite of mad dogs, on men and animals, with infallible success. The method of taking it he has delivered as followeth: "Take of the herb, and dry it either in an oven, by the fire, or in the sun; then powder it, and pass it through a fine sieve; mix this with an equal quantity of powdered Pepper. The common dose of this mixture is four scruples, which may be taken in warm milk, beer, ale, or broth." He also advises, that the part bitten be well washed, as also the clothes of the person who is bit, lest any of the snivel, or drivel, of the mad dog should remain. If the person bitten be full grown, he advises, that he be blooded before the medicine is taken, and to use the remedy as soon after the bite as possible, as also to repeat the dose two or three several mornings fasting.

LIGUSTICUM. *Tourn. Inst. R. H. 323. tab. 171.*

The Characters are,

It hath an umbellated flower. The general umbel is composed of several smaller. The general umbel has an involucre of seven unequal leaves. The flower hath five equal petals, which are inflexed at their points. It hath five hairy stamina. The germen, which is situated under the flower, afterward turns to an oblong fruit, divided into two parts, which is angular and channelled, containing two oblong smooth seeds.

The Species are,

1. LIGUSTICUM *foliis multiplicibus, foliolis supernè incisis*. Hort. Cliff. 97. Common Lovage.
2. LIGUSTICUM *foliis biternatis*. Lin. Sp. Plant. 250. Scotch Lovage with a Small leaf.
3. LIGUSTICUM *foliis bipinnatis, foliolis confluentibus incisis integerrimis*. Lovage with double winged leaves, whose lobes run together, and have entire segments.
4. LIGUSTICUM *foliis pinnatifidis, foliolis linearibus planis*. Lovage of the Pyrenees, with a shining Fennel leaf.
5. LIGUSTICUM *foliis multiplicato pinnatis, foliolis pinnatim incisis*. Lin. Syst. 258. Broad leaved, stinking, bastard Hemlock.

The first sort is the common Lovage of the shops, which was formerly cultivated in the kitchen-gardens as an esculent herb, but has been long disused as such in England. It grows naturally upon the *Appennines*, and also near the river *Liguria*, not far from *Genoa*. It hath a strong perennial root, composed of many strong fleshy fibres, covered with a brown skin, of a strong aromack smell and taste. The leaves are large, winged, and composed of many large lobes shaped like those of Smallage, but of a deeper green.

The lobes toward the top are cut into acute segments. The stalks rise to the height of six or seven feet; they are large, channelled, and divide into several branches, each being terminated by a large umbel of yellow flowers, which are succeeded by oblong striated seeds.

This is easily propagated by seeds, which should be sown in autumn soon after they are ripe, for when they are kept out of the ground till spring, they seldom grow the first year; when the plants come up, they may be transplanted into a moist rich border, at about three feet distance from each other, and after they have taken new root, they will require no other care but to keep them clean from weeds. The roots will abide many years, and where the seeds are permitted to scatter, the plants will come up without care.

The second sort grows naturally near the sea in many parts of *Scotland*; this hath a perennial root, but of much less size than the former; the leaves are composed of broader and shorter lobes, each leaf having two or three trifoliate leaves, whose lobes are indented on their edges. The stalk rises about a foot high, sustaining a small umbel of yellow flowers on the top, shaped like those of the former; these are succeeded by oblong channelled seeds, which ripen in autumn. This plant may be cultivated in the same manner as the former.

The third sort grows naturally on the *Alps*; this is a perennial plant. The stalks rise about two feet high, and at every joint are bent alternate, first to one side, then to the opposite; at each joint they are garnished with doubly winged leaves, composed of small lobes, which run into each other, and just above each leaf comes out a side branch; these, as also the principal stalks, are terminated by umbels of white flowers, which are succeeded by oblong channelled seeds, which ripen in autumn.

The fourth sort grows naturally on the *Pyrenean* mountains; this hath a biennial root. The leaves are doubly winged. The lobes are very narrow, and finely divided. The stalks are strong, and rise a foot and a half high, garnished with shining winged leaves, and are terminated by pretty large umbels of yellowish flowers.

The fifth sort grows naturally on the *Peloponnesian* mountains; this hath a very thick fleshy root, like that of Parsnep. The leaves are large, composed of many winged leaves, whose lobes are cut into acute points; these are of a deep green, and, when bruised, emit a foetid odour. The stalks rise four or five feet high; they are very large and hollow, like those of Hemlock, and sustain at their top large umbels of yellowish flowers, in shape of a corymbus; these are succeeded by oblong channelled seeds, which ripen in autumn.

This has by some persons been thought to be the Hemlock of the ancients, their conjectures being founded upon the plant, answering in many particulars the description of *Cicuta*, and also from the poisonous quality of it, together with its foetid scent; and as this grows naturally in many parts of *Asia*, so they have been induced to believe it might be the same plant.

LIGUSTRUM. *Tourn. Inst. R. H. 596. tab. 367. Privet.*

The Characters are.

The flower hath one funnel-shaped petal, cut into four oval segments at the top, which spread open. It hath two stamina which stand opposite, and a roundish germen, which afterward turns to a smooth round berry with one cell, inclosing two oblong seeds, flat on one side, but convex on the other.

The Species are,

1. LIGUSTRUM *foliis lanceolato-ovatis obtusis*. The common Privet.
2. LIGUSTRUM *foliis lanceolatis acutis*. Privet with spear-shaped leaves; commonly called the *Italian* ever-green Privet.
3. LIGUSTRUM *foliis lanceolatis lucidis perennantibus, fructibus ovatis lateralibus*. *Carolina* blue-berried Bay.

The first sort grows common in the hedges in most parts of *England*, where it rises fifteen or sixteen feet high, with a woody stem covered with a smooth gray bark, sending out many lateral branches, garnished with spear-shaped leaves, ending with obtuse points, and are of a dark green. The flowers are white, and are produced in thick spikes at the end of the branches, having a tubular petal cut at the top in four parts, which spread open. These are succeeded by small round black berries, which ripen in the autumn. The leaves of this sort frequently remain green till after *Christmas*. There are two varieties of this, one with white, and the other hath yellow variegated leaves; but to preserve these varieties, they should be planted in poor land, for if they are in a rich soil, they will grow vigorous, and soon become plain.

The second sort grows naturally in *Italy*; this rises with a stronger stem than the former, the branches are less pliable, and grow more erect; their bark is of a lighter colour, the leaves are much larger, and end in acute points, and are also of a brighter green; they continue in verdure till they are thrust off by the young leaves in the spring. The flowers of this are rather larger than those of the common sort, and are seldom succeeded by berries in this country.

Both these sorts are cultivated in the nurseries near *London*, to furnish the small gardens and balconies in the city, the first being one of the few plants which will thrive in the smoke of *London*; but although they will live some years in the close part of the town, yet they seldom produce flowers after the first year, unless it is in some open places, where there is free air.

The *Italian* Privet is now generally preferred to the common sort, for planting in gardens, the leaves being larger, and continuing green all the year, renders it more valuable; and being so hardy as to resist the greatest cold in this country, it may be planted in any situation where the common sort will thrive. I have frequently planted it under the dropping of large trees, where I find it will thrive better than most other shrubs.

I cannot but think this sort, which is the most common in *Italy*, is the *Ligustrum* mentioned by *Virgil* in the second *Eclogue*: and my reason for it is, that as the flowers of this shrub are of a pure white, but fall off very soon, they are by no means proper to gather for garlands, &c. and the berries being of a fine black colour, and continuing long upon the plants, make a fine appearance. To confirm that these berries were gathered for use, we find in several authors of undoubted credit, that they were used in dyeing, as also that the best ink was made of these berries.

Besides, is it not much more reasonable to suppose, that *Virgil* would rather draw his comparison from the flowers and fruit of the same plant, when he is warning the youth not to trust to his beauty, than to mention two different plants, as has been generally supposed? for here are the white flowers of the Privet appearing early in the spring, which is an allusion to youth; but these are of short duration, soon falling away; whereas the berries, which may be applied to mature age, are of long continuance, and are gathered for use.

These plants are easily propagated by laying down their tender shoots in autumn, which in one year's time will be rooted enough to transplant; then they may be removed to the places where they are designed to remain, or planted in a nursery for two years, where they may be trained for the purposes designed.

They may also be propagated by cuttings, which if planted in the autumn on a shady border and in a loamy soil, will take root very freely, and may be afterward treated in the same way as the layers.

But the strongest and best plants, are those which are raised from seeds; indeed, this is a much more tedious method than the other, so is seldom practised, for the seeds generally lie a year in the ground before they vegetate; therefore, whoever would propagate the plants in this method, should gather the berries and put them in a pot with sand between them, and bury the pots in the ground, as is practised for Holly berries and Haws, and after they have laid a year in the ground, take them up and sow them on a border exposed to the east, where the plants will come up the following spring, and these will make great progress after they have gotten some strength, and will grow upright, and not send out suckers like the other.

Formerly these plants were greatly in use for hedges, but since so many other plants of greater beauty have been introduced, they have been almost rejected.

The two variegated kinds may be propagated by budding, or inarching them upon the plain sort, as also by laying down their branches; but as they seldom shoot so fast, as to produce many branches proper for layers, the other method is chiefly used. The silver striped sort is somewhat tenderer than the plain.

The third sort grows naturally in *Carolina* and some other parts of *North America*, where the inhabitants have given it the title of blue berried Bay. The seeds of this have been brought to *England* for several years past, and many of the plants have been raised in the gardens near *London*, but as they have not yet produced any flowers here, so we cannot be certain of its proper genus. Mr. *Catesby* has given a figure, and added a short description of it in his history of *Carolina*, under the title of *Ligustrum*, but neither his figure or description is clear enough to determine its genus; but as it cannot be a Bay, the flowers being all hermaphrodite, and ranged in long bunches, so I have added it to the genus of *Ligustrum*, until its true genus is ascertained.

Mr. *Catesby* in his description of this shrub, says it rises to the height of sixteen feet, the stem or trunk six inches diameter in its native soil; in *England* there are plants six feet high, but their stems are not large; the leaves are almost as large as those of the common Bay, of a lucid green, smooth and entire. These continue through the year. The plants which have been planted in the open air here, are generally placed against walls to a good aspect, where some of them have remained four or five years. These have much outgrown any of the plants which have been kept in pots and housed in winter, so that I would recommend their being planted in the full ground in a warm situation, for the great danger is of their tender shoots being hurt by the early frosts in autumn, especially if the plants make vigorous shoots; for those being repleat with moisture, are frequently nipped in the autumn, and when their extreme parts are killed, the disease descends lower in winter: therefore if their tops are sheltered in autumn to screen them from those early frosts, the plants may be preserved in the full ground.

This is propagated by the berries, which are brought to *England*; they should be sown in pots plunged into a moderate hot-bed, which will bring up the plants much better than if they are sown in the full ground: but the plants when up, must not be drawn up weak, to prevent which they should have plenty of air in warm weather, and screened from the sun in the heat of day. The following spring the plants should be each planted in a separate small pot, and plunged into a moderate hot-bed to forward their taking new roots, after which they should be gradually inured to bear the open air. For two or three years, while the plants are young, they should be sheltered in winter, then they may be planted in the full ground. It may also be propagated by layers; and the cuttings, if they are planted in the spring, and carefully managed, will take root.

LILAC. See Syringa.

LILIASTRUM. See Hemerocallis.

LILIO-ASPHODELUS. See Hemerocallis and Crinum.

LILIO-FRITILLARIA. See Fritillaria.

LILIO-HYACINTHUS. See Scilla.

LILIO-NARCISSUS. See Amaryllis.

LILIUM. Tourn. Inst. R. H. 369. tab. 191. The Lily.

The Characters are,

The flower has no empalement; it hath six petals reflexed at their points; each petal has a narrow longitudinal nectarium at their base. It hath six stamina which are erect, with a cylindrical oblong germen, which afterward becomes an oblong capsule, having three cells which are filled with flat seeds lying above each other, in a double order.

The Species are,

1. LILIUM foliis sparsis, corollis campanulatis erectis, intus glabris. Common white Lily with an erect flower.

2. LILIUM foliis sparsis, corollis campanulatis cernuis, petalis basi angustioribus. White foreign Lily with hanging flowers.

3. LILIUM foliis sparsis, corollis campanulatis erectis, intus scabris. Hort. Cliff. 120. Greater Lily with a purple Saffron-coloured flower; commonly called Orange Lily.

4. LILIUM humile, foliis linearibus sparsis, corollis campanulatis erectis, caule bulbifero. Smaller bulb-bearing Lily, by some called the fiery Lily.

5. LILIUM foliis sparsis subulatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. Narrow-leaved red Lily, or Martagon.

6. LILIUM foliis linearibus sparsis, pedunculis longissimis. Lily with short grassy leaves; commonly called Martagon of Pompony.

7. LILIUM foliis sparsis lanceolatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. Lily of Byzantium with a carmine flower; commonly called the scarlet Martagon.

8. LILIUM foliis sparsis lanceolatis, floribus pyramidalis reflexis, corollis revolutis. The great yellow Martagon.

9. LILIUM foliis verticillatis, floribus reflexis, corollis revolutis. Hort. Cliff. 120. Mountain Lily with reflexed flowers; commonly called purple Martagon.

10. LILIUM foliis verticillatis hirsutis, floribus reflexis corollis revolutis. Another Lily with reflexed hairy flowers; commonly called the red Martagon.

11. LILIUM foliis verticillatis, floribus reflexis, corollis campanulatis. Lin. Sp. Plant. 303. Martagon of Canada with spotted flowers.

12. LILIUM foliis verticillatis, floribus erectis, corollis campanulatis. Amern. Acad. 2. p. 348. Lily with leaves growing in whorls, and an erect bell-shaped flower.

13. LILIUM foliis verticillatis brevibus, corollis campanulatis, unguibus petalorum angustioribus, floribus erectis. Icon. tab. 165. Lily with very short leaves growing in whorls, and bell-shaped flowers, whose petals are very narrow at their base.

There is a greater variety of Martagons than are here mentioned, but as they are supposed to be only accidental arising from culture, so I thought it would be to little purpose to insert them here, therefore I shall only give their common titles hereafter.

The common white Lily is so well known as to need no description; this grows naturally in *Palesine* and *Syria*, but has been long cultivated in all the gardens of *Europe*. It is so hardy that no frost ever injure the roots, and it propagates so fast by offsets from the roots, that it becomes so common as to be little regarded, though there is great beauty in the flowers, which have an agreeable odour. Of this sort there are the following varieties:

The white Lily striped with purple.

The white Lily with variegated leaves.

The white Lily with double flowers.

These are varieties which have accidentally risen from culture; the sort with variegated flowers, has not been in *England* much more than forty years, but is now very common in most of the gardens, and is by some persons esteemed for the variety of its purple stripes; but as the pure white of the flower is stained by the purple, so as to appear of a dull colour, many prefer the common white Lily to this.

The sort with variegated leaves is chiefly valued for its appearance in winter and spring, for as the leaves come up early in the autumn which spread themselves on the ground, and being finely edged with broad yellow stripes, they make a pretty appearance during the winter and spring months. The flowers are the same as those of the common sort, but appear earlier in summer, which may be occasioned by the roots being weaker than those of the plain sort, for all variegated plants are weaker than those which are plain.

The white Lily with double flowers, is less valuable than either of the other, because their flowers rarely open well, unless they are covered with glasses to shelter them from the rain and dew, so often rot without expanding. These flowers have none of the agreeable odour which the single sort is valued for, even when they open the fairest; for as by the multiplicity of petals in the flowers, the parts of generation are destroyed, so there is a want of the fecundating powder from whence the odour is sent out.

The white Lily with dependent flowers was originally brought from *Constantinople*. This is by some supposed to be only a variety of the common sort, but is undoubtedly a distinct species; the stalk is much slenderer than the common, the leaves are narrower and fewer in number; the flowers are not quite so large, and the petals are more contracted at their base; these always hang downward, whereas those of the common sort grow erect. The stalks of this kind, sometimes are very broad and flat, and appear as if two or three were joined together; when this happens, they sustain from sixty to a hundred flowers, and sometimes more; this has occasioned many to think it a different sort, who have mentioned this with broad stalks and many flowers as a distinct species, though it is accidental, for the same root scarce ever produces the same two years.

These sorts are easily propagated by offsets, which the roots send out in so great plenty, as to make it necessary to take them off every other, or at most every third year, to prevent their weakening the principal roots. The time for removing of the roots is at the end of *August*, soon after the stalks decay, for if they are left longer in the ground, they will soon put out new fibres and leaves, when it will be improper to remove them, because that will prevent their flowering the following summer. They will thrive in almost any soil or situation, and as they grow tall and spread, so they must be allowed room; therefore in small gardens they take up too much space, but in large borders they are very ornamental.

The common Orange or red Lily is as well known in the *English* gardens, as the white Lily, and has been as long cultivated here. This grows naturally in *Austria*, and some parts of *Italy*. It multiplies very fast by offsets from the roots, and is now so common, as to be almost rejected; however, in large gardens these should not be wanting, for they make a good appearance when in flower, if they are properly disposed. Of this sort there are the following varieties:

The Orang Lily with double flowers.

The Orange Lily with variegated leaves.

The smaller Orange Lily.

These varieties have been obtained by culture, and are preserved in the gardens of florists. They all flower in

June and July, and their stalks decay in September, when the roots may be transplanted, and their offsets taken off, which should be done once in two or three years, otherwise their bunches will be too large, and the flower-stalks weak. This doth not put out new roots till toward spring, so that the roots may be transplanted any time after the stalks decay till November. It will thrive in any soil or situation, but will be strongest in a soft gentle loam not too moist.

The bulb-bearing fiery Lily, seldom rises much more than half the height of the former; the leaves are narrower, the flowers are smaller, and of a brighter flame colour; they are fewer in number, and stand more erect. These come out a month before the common sort, and the stalks put out bulbs at every joint, which, if taken off when the stalks decay, and planted, will produce plants, so that it may be propagated in plenty. There are several varieties of this, which are mentioned as distinct species, but are supposed to have been produced by culture. These are,

The greater broad-leaved bulb-bearing Lily.

The many flowered bulb-bearing Lily.

The small bulb-bearing Lily.

The hoary bulb-bearing Lily.

All these sorts of Lilies will thrive under the shade of trees, so may be introduced in plantations, and on the borders of woods, where they will have a good effect during the time they are in flower.

There is also a great variety of the Martagon Lily; these differ from the common Lilies, in having their petals reflexed backward in form of a Turk's turban, from whence many give them the title of Turk's Cap. In the gardens of the florists, particularly those in Holland, they make a great variety of these flowers, amounting to the number of thirty or upward; but in the English gardens, I have not observed more than a third of that number, and most of these are accidental, for those before enumerated are all that I think may be supposed specifically different. However, for the sake of such as are curious in collecting these sorts of flowers, I shall here mention those varieties which are to be found in the English gardens.

The common Martagon with double flowers.

The white Martagon.

The double white Martagon.

The white spotted Martagon.

The imperial Martagon.

The early scarlet Martagon.

The Constantinople vermilion Martagon.

The common Martagon with red flowers, which is the fifth sort before enumerated, has very narrow leaves, growing without order. The stalk rises near three feet high, sustaining at the top eight or ten bright red flowers, which stand at a distance from each other.

The sixth sort is called Martagon of Pompony. The stalks of this rise higher than those of the former, the leaves are shorter and set closer upon the stalks; each of these stalks sustain from fifteen to thirty flowers, of a very bright red approaching to scarlet. The foot-stalks of the flowers are very long, so that the head of flowers spreads out very wide; these hang downward, but their petals are reflexed quite back.

The seventh sort is commonly known by the title of scarlet Martagon. This rises with a stalk from three to four feet high; the leaves are much broader than those of the former sorts, and appear as if they were edged with white; they are placed very close upon the stalks, but without any order. The flowers are produced at the top of the stalk; they are of a bright scarlet, and are seldom more than five or six in number. This flowers late in July, and in cool seasons will continue in beauty great part of August.

The eighth sort rises with a strong stalk from four to five

feet high, garnished with leaves as broad as those of the last mentioned, which stand without order; the flowers are produced in form of a pyramid, on the upper part of the stalk. When the roots of this kind are strong, they produce forty or fifty flowers upon each stalk; they are large, of a yellow colour, spotted with dark spots, so make a fine appearance; but the flowers have such a disagreeable strong scent, that few persons can endure to be near them, which has occasioned their being thrown out of most English gardens.

The ninth sort is frequently called the purple Martagon, though in most of the old gardens it is known simply by the title of Turk's Cap. This rises with a strong stalk from three to four feet high, garnished by pretty broad leaves, which stand in whorls round the stalk, at certain distances. The flowers are of a dark purplish colour, with some spots of black; they are produced in loose spikes on the top of the stalks.

The tenth sort is very like the former, but the leaves are narrower; the whorls stand farther asunder, the leaves and stalks are somewhat hairy, and the buds of the flowers are covered with a soft down; the flowers are of a brighter colour with few spots, and come out earlier in the summer, though the stalks appear much later above ground.

The eleventh sort is commonly called the Canada Martagon, as it was first brought to Europe from thence, but it grows naturally in most parts of North America. The stalks rise from four to five feet high, garnished with oblong pointed leaves, placed in whorls round the stalk. The flowers are of a yellow colour, spotted with black, which are shaped like those of the Orange Lily; the petals are not turned backward, like those of the other sorts of Martagon.

The twelfth sort grows naturally in North America, and is also mentioned to grow at Campschatski. The flowers are shaped like those of the Canada Martagon, growing erect, but the petals of this are oval, not narrowed at their base as are those, and sit close to the foot-stalk; the flowers are of a deeper colour, and not so much spotted as those of the other sort.

The thirteenth sort grows naturally near Pennsylvania. The root of this is smaller than those of the other sorts, in the spring it sends out one upright stalk a foot and a half high; the leaves come out in whorls round the stalks; they are short, and have obtuse points. The stalk is terminated by two flowers which stand erect, upon short separate foot-stalks; they are shaped like the flowers of the bulb-bearing fiery Lily, but the petals are narrower at their base. The flowers are of a bright purple colour, marked with several dark spots toward their base.

All the sorts of Lilies may be propagated by offsets from the roots, which some of the sorts produce in plenty; but there are others which send out very few, which occasions their present scarcity. The roots of all the sorts of Martagon may be safely taken up when their stalks decay, and if there is a necessity for keeping the roots out of the ground, if they are wrapped in dry moss, they will keep perfectly well for two months, so that if their roots are to be transported to a distant place, this precaution of wrapping them up is necessary; but where they are to be planted in the same garden, there will be no occasion for this, especially if they are not kept too long out of the ground; for if the place is ready to receive the roots, they should be planted the beginning of October; so if the roots are put in a dry cool place, they will keep very good without any farther care; but if the ground is not ready to receive them till later in the year, then it will be proper to cover the roots with dry sand, or wrap them in moss to exclude the air, which, if they are much exposed to, will cause their scales to shrink, which weakens the roots, and is sometimes the occasion of their rotting.

These

These roots should be planted five or six inches deep in the ground, especially if the soil is light and dry; but where the ground is moist, it will be proper to raise the borders in which these are to be planted, five or six inches above the level of the surface of the ground; for if the water rises so high in winter as to come near the roots, it will cause them to rot; and where the soil is naturally stiff and subject to bind, there should be a good quantity of sea-coal ashes or rough sand, well mixed in the border, to separate the parts, and prevent the ground from binding in the spring, otherwise the roots will not send up very strong stalks, nor will they make so good increase.

As the *Canada*, *Pompony*, and the last sort of Martagons, are somewhat tenderer than the others, so if in very severe winters the surface of the ground over them is covered with old tanners bark or sea-coal ashes, it will be a good way to secure them from being injured by the frost; and in the spring the covering may be removed, before the roots shoot up their stalks.

The roots of all kinds of Martagons must never be transplanted after they have made shoots, for that will so much weaken them (if it does not entirely kill them) as not to be recovered in less than two or three years, as I have experienced to my cost; for being obliged to remove a fine collection of these roots early in the spring, I lost a great part of them, and the others were long recovering their strength.

All the sorts of Lilies and Martagons may also be propagated by sowing their seeds, by which method some new varieties may be obtained, provided the seeds are saved from the best sorts, especially the Martagons, which are more inclinable to vary than the other Lilies. The manner of sowing them being the same as for Tulips, the reader is desired to turn to that article for directions.

LILIUM CONVALLIUM. See Convallaria.

LILIUM PERSICUM. See Fritillaria.

LILIUM SUPERBUM. See Gloriosa.

LIME TREE. See Tilia.

LIMODORUM. *Lin. Gen. Plant.* Bastard Hellebore.

The Characters are,

The flowers have no empalment, but a spathe (or sheath) situated below them. The flower has five oval petals, which are dissimilar, so has much the appearance of a Butterfly flower. Within the petals is situated a concave nectarium, which is as long as the petals. It hath two stamina, which are as long as the petals, and a column-shaped germen, situated under the flower, which afterward turns to a capsule of the same form, opening with three valves, having one cell, in which are lodged four or five roundish seeds.

We have but one Species of this genus at present in England, viz.

1. LIMODORUM *foliis longis angustis acuminatis, pedunculis longissimis.* Limodorum with long narrow leaves ending in acute points, and a very long foot-stalk to the flower.

This plant grows naturally in *Jamaica*; it also grows in the *French* islands of *America*, and in the *Bahama Islands*; from several of these places I have received the roots.

The root of this plant is shaped like those of the Saffron, but the outer cover is of a darker brown colour; from this comes out three or four leaves, according to the size and strength of the root, which are nine or ten inches long, and near three quarters of an inch broad in the middle, being contracted toward both ends, terminating with long acute points; they have five longitudinal furrows, like the first leaves of young Palms; these leaves come out in the spring, and frequently decay the following winter, but when the plants are kept in a warm stove, they are seldom destitute of leaves. The flower-stalk arises immediately from the root, on one side of the leaves; this is naked,

smooth, and of a purplish colour toward the top. It is near a foot and a half high, terminated by a loose spike of purplish red flowers, composed of five or six petals; the two upper are connected together, forming a sort of helmet, the two side petals expand like the wings of a Butterfly flower, and the lower form a sort of keel. In the center of the petals is situated a column-shaped germen, which rises from their base, supporting a slender style, to which adhere two stamina; after the flowers are faded, the germen becomes a three-cornered column, which becomes a capsule with one cell, opening with three valves, containing several roundish seeds.

There are several other species of this genus mentioned by father *Plumier*, but I have not seen one more besides than this here mentioned, which had oval obtuse leaves, furrowed in the same manner as the leaves of this sort, but were of a thicker consistence; the flowers of this I have not yet seen. The root was sent me from *Maryland*, where it grew naturally in a thicket.

The sort here described is too tender to thrive in the open air in *England*; and although with care it may be preserved in a warm green-house, yet it seldom flowers in such a situation; so that to have it in perfection, it is necessary to keep it in the tan-bed in the stove in winter, and if in summer the pots are plunged in a tan-bed under a deep frame, the plants will thrive and flower as strong as in their native soil.

It is propagated by offsets from the root, which are sent out pretty freely when the plants are in vigour; these should be taken off, and the roots transplanted, when they are the most destitute of leaves,

LIMON. *Tourn. Inst. R. H.* 621. The Limon tree.

The Characters are,

The flower is composed of five oblong thick petals, which spread open; these sit in a small empalment of one leaf. It hath about ten or twelve stamina, which are joined in three or four bodies, and an oval germen, which afterward becomes an oval fruit, with a fleshy rind, inclosing a thin pulpy fruit with several cells, each having two hard seeds.

The Species are,

1. LIMON *foliis ovato-lanceolatis acuminatis, subserratis.* Limon tree with oval, spear-shaped, acute-pointed leaves, which are a little sawed; or common Limon.

2. LIMON *foliis ovatis integris, ramis subspinosis.* The Lime tree.

3. LIMON *foliis ovato-lanceolatis subserratis, fructu conglomerato.* Limon with oval spear-shaped leaves, which are somewhat sawed, and fruit growing in clusters.

There are great varieties of this fruit, which are preserved in some of the *Italian* gardens, and in both the *Indies* there are several which have not yet been introduced to the *European* gardens; but these, like Apples and Pears, may be multiplied without end from seeds, therefore I shall only mention the most remarkable varieties which are to be found in the *English* gardens at present, as it would be to little purpose to enumerate all those which are mentioned in the foreign catalogues.

The Limon tree with variegated leaves.

The sweet Limon.

The Pear-shaped Limon.

The imperial Limon.

The Limon called Adam's Apple.

The furrowed Limon.

The childing Limon.

The Limon with double flowers.

The common Limon and the sweet Limon are brought to *England* from *Spain* and *Portugal* in great plenty, but the fruit of the latter are not much esteemed. The Lime is not often brought to *England*, nor is that fruit much cultivated

in *Europe*, but in the *West-Indies* it is preferred to the Limon, the juice being reckoned wholesomer, and the acid is more agreeable to the palate; there are several varieties of this fruit in the *West-Indies*, some of which have a sweet juice, but those are not greatly esteemed; and as the inhabitants of those islands do not propagate these fruits by grafting or budding, being contented with sowing their seeds, so there is no doubt but a great variety of them may be found by any person who is curious in distinguishing them.

The Pear-shaped Limon is a small fruit, with very little juice, so is not much propagated any where; the curious who have room and convenience for keeping many of these trees, preserve a plant or two of this sort for the sake of variety.

The fruit of the imperial Limon is sometimes brought to *England* from *Italy*, but I do not remember to have seen any of this sort imported from *Spain* or *Portugal*, so that I suppose they are not much propagated in either of those countries; for the inhabitants of both those fine countries are so very incurious, especially in horticulture, as to truit almost entirely to nature, therefore the products of their gardens are inferior both in numbers and quality to the gardens in many other parts of *Europe*, where the climate is much less favourable for these productions. And in the article we are now upon, there are many strong instances of the slothfulness or incuriosity of the *Portuguese* particularly, for they had many of the most curious sorts of Orange, Limon, and Citron trees, brought from the *Indies* to *Portugal* formerly, which seemed to thrive almost as well there as in their native soil, and yet they have not been propagated; there are a few trees of these sorts still remaining in some neglected gardens near *Lisbon*, almost unnoticed by the inhabitants. As there are also several curious trees and plants, which were formerly introduced from both *Indies*, some of which thrive and produce fruit amidst the wild bushes and weeds, with which those gardens are spread over.

All the sorts of Limons are propagated by budding or inarching them either on stocks of Limons or Citrons, produced from seeds; but they will not so readily unite on Orange stocks, for which reason the Citrons are preferable to either Oranges or Limons for stocks, as they readily join with either sort, and being of quicker growth, cause the buds of the other sorts to shoot much stronger than if they were on stocks of their own kind. The method of raising these stocks, and the manner of budding them, being already exhibited under the article of *AURANTIUM*, it would be superfluous to repeat it here.

The culture of the Limon being the same with that of the Orange tree, it would be also needless to repeat it here; therefore I shall only observe, that the common Limons are somewhat hardier than the Oranges, and will bring their fruit to maturity with us better than they will do, and require to have a greater share of fresh air in winter.

LIMONIUM. *Tourn. Inst. R. H.* 341. tab. 177.

The Characters are,

The flowers have an imbricated perianthium, and are funnel-shaped, composed of five petals. It hath five awl-shaped stamens, crowned by prostrate summits, and a small germen, crowned by pointed stigmas. The empalement of the flower afterward becomes a capsule, shut close at the neck, but expanded above where the seeds are lodged.

The Species are,

1. LIMONIUM foliis ovato-lanceolatis, caule tereti nudo paniculato. Common great Sea Lavender.
2. LIMONIUM foliis oblongo-ovatis, caule paniculato patulo, spicis florum brevioribus. Sea Lavender with oblong oval leaves, a spreading paniculated stalk, and shorter spikes of flowers.
3. LIMONIUM foliis ovatis obtusis, petiolis decurrentibus,

caule paniculato, spicis florum erectioribus. Sea Lavender with oval obtuse leaves, running foot-stalks, a paniculated stalk, and more upright spikes of flowers.

4. LIMONIUM foliis lanceolatis, caule humile patulo, spicis florum tenuioribus. Sea Lavender with spear-shaped leaves, a low spreading stalk, and slender spikes of flowers.

5. LIMONIUM foliis lineari-lanceolatis, caule ramoso patulo, floribus distantibus uno versu dispositis. Sea Lavender with narrow spear-shaped leaves, a branching spreading stalk, and flowers ranged thinly on one side the stalk.

6. LIMONIUM foliis radicalibus alternatim pinnato-sinuatis, caulinis ternis triquetris subulatis, decurrentibus. Sea Lavender with the lower leaves alternately situated like wings, those upon the stalks three-cornered, awl-shaped, and running along the foot-stalk.

7. LIMONIUM caule fruticoso patulo, foliis lineari lanceolatis crassis, floribus solitariis distantibus. Sea Lavender with a spreading shrubby stalk, narrow, thick, spear-shaped leaves, and flowers growing singly at a distance from each other.

8. LIMONIUM foliis cuneiformibus, caule erecto paniculato, ramis inferioribus sterilibus nudis. Sea Lavender with wedge-shaped leaves, an upright paniculated stalk, and the under branches sterile and naked.

9. LIMONIUM caule nudo paniculato, foliis spatulatis retusis. Sea Lavender with a paniculated naked stalk, and spatula-shaped blunt leaves.

10. LIMONIUM caule nudo paniculato, tereti, foliis tuberculatis. Sea Lavender with a naked, taper, paniculated stalk, and leaves set with tubercles.

11. LIMONIUM caule erecto fruticoso, foliis lineari-lanceolatis obtusis, floribus alternis. Sea Lavender with an upright shrubby stalk, narrow spear-shaped leaves, ending in obtuse points, and flowers ranged alternately.

The first sort grows naturally in the marshes, which are flowed by the sea in several parts of *England*. The roots of this plant are thick, of a reddish colour, and an astringent taste, sending out many strong fibres, from which comes out several oval, spear-shaped, smooth leaves, of a pretty thick consistence. The stalk is naked, and rises upward of a foot high, divided into many small branches at the top, terminated by slender spikes of pale blue flowers, ranged on one side the stalk, coming out of narrow covers like sheaths.

The second sort grows naturally in the south of *France* on the sea coast. The leaves of this are of an oblong oval form, smooth, entire, and of a deep green. The stalk rises fifteen or sixteen inches high, dividing into several spreading branches, terminated by short spikes of pale blue flowers, ranged on one side the foot-stalk. This sort seldom flowers till the end of *August*, so never produces any good seeds in *England*.

The third sort grows naturally in *Narbonne* and *Provence*. This hath small, oval, obtuse leaves, standing on pretty long foot-stalks, which are bordered or winged. The stalk rises a foot and a half high, sending out branches alternately on each side, so as to form a loose kind of pyramid, and are terminated with spikes of pale blue flowers, which are erect.

The fourth sort grows naturally in *England*. It was first discovered on the sea banks near *Walden* in *Essex*, afterward near *Walden* in the same county, and since at the mouth of the river that runs from *Chichester* in *Suffex*. The leaves of this sort are spear-shaped, about three inches long, and one broad in the middle, lessening gradually to both ends. The stalk rises four or five inches high, dividing into many spreading branches, which are very thick set with short spikes of pale blue flowers.

The fifth sort was discovered by *Dr. Tournefort* in the *Levant*. The leaves of this sort are about four inches long, and

and three quarters of an inch broad in the middle, diminishing gradually to both ends. The stalks rise about five or six inches high, dividing into several spreading branches, which are terminated by short spikes of pale blue flowers, ranged on one side the foot-stalk. This sort flowers late in *August*, so never ripens seeds here.

The sixth sort grows naturally in *Sicily* and *Palestine*. This is a biennial plant. The lower leaves, which spread on the ground, are indented almost to the middle rib; these indentures are alternate and blunt. The stalks rise a foot and a half high, dividing upward into several branches, garnished at each joint with three narrow leaves sitting close to the stalks, from whose base proceeds a leafy membrane, or wing, which runs along on both sides the stalk. The stalks are terminated by panicles of flowers, which sit upon winged foot-stalks, each sustaining three or four flowers of a light blue colour, which continue long without fading.

The seventh sort grows naturally in *Sicily*. This hath a shrubby stalk, which rises about two feet high, dividing into several ligneous branches, which spread out on every side; the lower part of these are closely garnished with gray leaves, like those of the sea Purslain, of as thick consistence. The branches are terminated by panicles of blue flowers, which come out singly at a distance from each other, having long tubes, but divide into five segments upward, which spread open.

The eighth sort grows naturally in *Sicily*, and was found so growing on the border of the sea in *Norfolk*, by Mr. *Henry Scott*, a gardener. The lower leaves of this sort are narrow at their base, but enlarge upward, and are rounded at the top, in shape of a wedge. The stalks are slender and stiff, rising from seven to fourteen inches high, sending out many slender side branches; all those which proceed from the lower part of the stalk are barren, having no flowers, but toward the top they have short panicles of whitish flowers, which are small, and sit three or four together upon one foot-stalk.

The ninth sort grows naturally near the sea, about *Marseilles* and *Leghorn*. This hath many thick fleshy leaves, which are shaped like a spatula, growing near the root, which are smooth, of a grayish colour, and spread on the ground. The stalks are naked, and rise about six inches high, dividing toward the top into many small branches, which are terminated by short crooked panicles of small flowers, of a pale red colour.

The tenth sort grows naturally about *Montepelier* and in *Italy*. This is an annual plant, with long narrow leaves, which are set with rough tubercles like the leaves of *Viper Bugloss*. The stalks rise about eight inches high, dividing into two or three small branches, which are terminated by reflexed short spikes of pale blue flowers, which come out late in *August*, so the seeds are seldom perfected in *England*.

The eleventh sort grows naturally in *Egypt*. This rises with an upright shrubby stalk to the height of eight or ten feet, divided into many branches, which are garnished with narrow spear-shaped leaves, placed without order, of a thick consistence, and of a gray colour, sitting close to the branches. The flowers are produced at the end of the branches in loose panicles, standing alternate on each side the stalk; they have pretty long tubes, which enlarge upward, where they are cut into five obtuse segments, which spread open; they are of a bright sky blue, but fade to a purple before they fall off.

The first, second, third, fourth, and fifth sorts are abiding plants, which will thrive in the open air in *England*. These plants may be transplanted at almost any time of the year, provided they are carefully taken up, preserving some earth to their roots. These plants do not propagate very fast in

gardens, and unless they are planted in a moist shady border, do seldom flower well; the best way to have them succeed, is to keep the plants in pots, and in summer to place them in a shady situation; but in winter they may be removed to a place where they may enjoy the sun.

The sixth sort is a biennial plant, which rarely perfects seeds in *England*; so that unless fresh seeds can be procured from warm countries, where they ripen well, it will be very difficult to continue the sort. If the seeds can be obtained time enough to sow them in the autumn, the plants will come up the following spring, but when they are sown in the spring, they seldom grow the same year. The seeds should be sown on a border of loamy earth, but not stiff or moist, exposed to the south-east. When the plants come up, they must be kept clean from weeds, and if they are too close, some of them should be carefully taken out as soon as they are fit to remove, and planted in small pots, placing them in the shade till they have taken new root; then they may be placed where they may enjoy the morning sun till autumn, when they should be put into a hot-bed frame, where they may be screened from hard frost, but enjoy the free air in mild weather; those plants which are left in the border where they were sown, should be covered with mats in hard frost; for though they will often live through the winter in mild seasons, yet hard frost will always destroy them. The following summer the plants will flower, and if the season proves warm and dry, they will sometimes ripen seeds.

The seventh and eleventh sorts are shrubby plants, which are too tender to live through the winter in the open air in *England*, so the plants must be removed into shelter in the autumn, but they only require protection from hard frost: these plants may be placed with *Myrtles*, *Oleanders*, and other hardy green-house plants, where they often continue in flower great part of winter, and make a pretty variety. These sorts are easily propagated by cuttings, which, if planted in *July* on a shady border, and duly watered, will take root in six or seven weeks, when they should be taken up and planted in pots filled with light loamy earth, placing them in the shade till they have taken root; then they may be exposed till *October*, at which time they must be removed into shelter.

LINARIA. *Tourn. Inst. R. H. 168. tab. 76.* Toad-flax.

The Characters are,

The flower hath one petal, and is of the ringent kind, having an oblong swelling tube, with two lips above, and the chaps stout. The upper lip is bifid and reflexed on the sides, the lower lip is trifid and obtuse. It hath an oblong nectarium, prominent behind, and four stamina which are included in the upper lip, two of which are shorter than the other, and a roundish germen, which afterward turns to a roundish obtuse capsule with two cells, filled with small seeds.

The Species are,

1. LINARIA foliis lanceolato-linearibus confertis, caule erecto, spicis terminalibus sessilibus. Common yellow Toad-flax with a larger flower.

2. LINARIA foliis ternis ovatis. Toad-flax with oval leaves placed by threes.

3. LINARIA foliis quaternis lanceolatis, caule erecto ramoso, floribus pedunculatis. Toad-flax with spear-shaped leaves placed by fours, an upright branching stalk, and flowers upon foot-stalks.

4. LINARIA foliis subquaternis linearibus, caule diffuso, floribus racemosis. Toad-flax with linear leaves placed by fours on the lower part of the stalk, a diffused stalk and branching flowers.

5. LINARIA foliis lanceolato-linearibus sparsis, caule florifero erecto spicato. Toad-flax with spear-shaped linear leaves, and the flower-stalks erect and spiked.

6. LINARIA

6. *LINARIA foliis linearibus confertis, caule erecto ramoso, floribus spicatis terminalibus.* Toad-flax with linear leaves in clusters, an erect branching stalk, and flowers in spikes terminating the stalks.

7. *LINARIA foliis inferioribus quinque linearibus.* Toad-flax with linear leaves, placed by fives at the lower part of the stalks.

8. *LINARIA foliis lanceolatis sparsis, inferioribus oppositis, nectariis subulatis, floribus subsessilibus.* Toad-flax with spear-shaped sparsed leaves, which on the lower part of the stalk are opposite, awl-shaped nectariums, and flowers sitting almost close.

9. *LINARIA foliis linearibus confertis, caule nitido paniculato, pedunculis spicatis nudis.* Toad-flax with linear leaves in clusters, a shining paniculated stalk, and flowers in spikes on naked foot-stalks.

10. *LINARIA foliis lanceolatis hirtis alternis, floribus spicatis, foliolo calycino supremo maximo.* Toad-flax with alternate, hairy, spear-shaped leaves, flowers in spikes, and the upper leaf of the empalement very large.

11. *LINARIA foliis caulibus linearibus sparsis, radicalibus rotundis.* Toad-flax with linear leaves placed sparsedly on the stalks, and the lower leaves round.

12. *LINARIA foliis lineari-lanceolatis alternis, floribus racemosis, calycibus corollâ longioribus.* Toad-flax with linear spear-shaped leaves placed alternate, branching flowers, and empalements longer than the petals.

13. *LINARIA foliis lanceolatis alternis, caule suffruticoso.* Toad-flax with spear-shaped alternate leaves, and an under-shrub stalk.

14. *LINARIA foliis lanceolatis acuminatis, paniculâ virgatâ.* Toad-flax with spear-shaped acute-pointed leaves, and a rod-like panicle.

15. *LINARIA foliis ovatis alternis, caule flaccido procumbente.* Toad-flax with oval leaves placed alternate, and a weak trailing stalk; called Fluellin.

16. *LINARIA foliis hastatis alternis, caule flaccido procumbente.* Toad-flax with arrow-pointed leaves placed alternate, and a weak trailing stalk.

17. *LINARIA foliis cordatis quinquelobatis alternis glabris.* Toad-flax with heart-shaped leaves having five lobes, which are alternate and smooth; or common Cymbalaria.

The first of these plants grow in great plenty upon the sides of dry banks in most parts of *England*, and is rarely permitted a place in gardens, for it is a very troublesome plant to keep within bounds. This is one of the species mentioned in the catalogue of simples at the end of the College Dispensatory, to be used in medicine.

The second sort grows naturally about *Valencia* and in *Sicily*. This is an annual plant, which rises with an upright branching stalk a foot and a half high, garnished with oval, smooth, gray leaves, placed often by threes, and sometimes by pairs opposite; the flowers grow in short spikes at the top of the stalks; they are yellow, and shaped like those of the common sort, but have not so long tubes.

There is a variety of this whose flowers have a purple standard and spur, which makes a pretty appearance in a garden.

These are propagated by seeds, which should be sown in the spring, on the borders of the flower-garden where they are designed to remain, and when the plants come up, they should be thinned where they are too close, and kept clean from weeds, which is all the culture they require.

The third sort rises with upright stalks two feet high, garnished with spear-shaped smooth leaves, placed sometimes by fours round the stalk, and at others by pairs opposite; the stalks are terminated by large purple flowers with long spurs, standing upon foot-stalks; it seldom ripens seeds in *England*. This grows naturally in *Portugal* and *Spain*.

This is tenderer than the last, so should have a warm situation, otherwise the plants will be destroyed in winter. It is propagated by seeds in the same manner as the former, but it is advisable always to keep some of these plants in pots, that they may be removed into shelter in winter.

The fourth sort grows naturally about *Verona*. This is a perennial plant, from whose roots arise several diffused stalks about eight inches long, garnished with narrow, short, gray leaves, placed by fours round the stalks at bottom, but upward they are opposite; the stalks are terminated by short branching tufts of pale yellow flowers, with golden chaps.

The fifth sort grows naturally in the south of *France* and in *Italy*. This hath a perennial root, sending out many stalks; those of them which support the flowers are erect, but the other are weaker, and hang loosely on every side the plants; they are garnished with long, narrow, spear-shaped, gray leaves, placed sparsedly. The stalks are terminated by long loose spikes of blue flowers, which appear in *June*, *July*, and *August*, and the seeds ripen in the autumn.

The sixth sort grows naturally about *Henley* in *Oxfordshire*, and also in some parts of *Hertfordshire*. This hath a perennial creeping root, from which arise many stalks two feet high, garnished with narrow leaves, growing in clusters toward the bottom, but upward they are sometimes by pairs, and at others single. The flowers are of a pale blue, produced in loose spikes at the end of the stalks.

The seventh sort grows naturally in *Sicily*. This is an annual plant, from whose root arises many slender stalks about a foot high; their lower part are garnished with five very narrow leaves at each joint, but upward they are sometimes by pairs, and others they are single: the stalks are garnished with small yellow flowers, coming out single, and are shaped like those of the other species. The flowers appear in *July*, and the seeds ripen in the autumn. There are two varieties of this, one with a deep yellow, the other a sulphur-coloured flower.

This is propagated by seeds in the same manner as the second sort, or if the seeds are permitted to scatter, the plants will come up without care, and if they are kept clean from weeds, will produce their flowers early in the summer.

The eighth sort grows naturally on the rocks about *Gibraltar*, from whence the late *Sir Charles Wager* brought the seeds. This has a perennial root, sending out many slender succulent stalks, which are weak, and hang near the ground, garnished with short, narrow, spear-shaped leaves, of a gray colour and succulent, standing without order. The flowers are produced at the end of the stalks in small bunches; they are yellow, marked with purple stripes, and the chaps of the flower, as also the spur, are of a dark purple colour. They appear in *June* and *July*, but do not produce seeds in *England*.

This plant is easily propagated by planting cuttings in any of the summer months, which, if watered and shaded, will soon take root, and may afterwards be planted in pots filled with fresh, light, undunged earth, in which they will succeed much better than in a richer soil. These must be removed into shelter in winter, where they must have as much free air as possible in mild weather, and be only protected from severe cold; so that if the pots are placed under a hot-bed frame, it will be better than in a green-house, where they are apt to draw too much, which will cause them to decay.

The ninth sort grows naturally in *Wales*, particularly near *Pemryn*. This hath a perennial root, from which arise many branching stalks two feet high, garnished with very narrow leaves, growing in clusters, of a grayish colour. The flowers are produced in loose spikes at the end of the branches; they are of a pale blue colour, and smell sweet.

The seeds ripen in the autumn, which, if permitted to scatter, will furnish a supply of young plants without any further care.

The tenth sort grows naturally in *Spain*; the seeds of it were sent me by Dr. *Hortega* from *Madrid*. This is an annual plant, which rises with a single stalk about a foot and a half high, garnished with hairy spear-shaped leaves, sitting close to the stalk, placed alternate. The flowers grow on the top of the stalks in loose spikes; they are of a pale yellow colour, with a few deep stripes, and the chaps are of a gold colour; the upper segment of the empalement is much larger than the lower.

The seeds of this sort should be sown in the spring, upon a border of light earth, where the plants are designed to remain; and when the plants come up, they must be treated in the same way as those of the second sort.

The eleventh sort grows naturally in *France*. This is an annual plant, whose bottom leaves are round; the stalks are slender, branching, and rise a foot high, garnished with very narrow leaves at each joint. The flowers are produced in loose spikes at the end of the branches; they are of a bright blue colour; the seeds ripen in the autumn, at which time they should be sown; for those which are sown in the spring, frequently lie in the ground till the spring following, before the plants appear. When the plants come up, they must be thinned where they are too close, and kept clean from weeds, which is all the culture they require.

The twelfth sort grows naturally in *Sicily*. This is an annual plant, which rises with a branching stalk two feet high, garnished with very narrow spear-shaped leaves placed alternately. The flowers are produced singly all along the branches; they are small, white, and have very long tails or spurs. This flowers in *July*, and the seeds ripen in the autumn. If the seeds of this sort are permitted to scatter, the plants will come up without care, and require no other culture but to keep them clean from weeds.

The thirteenth sort grows naturally in *Crete*, and also in *Dalmatia*. This rises with a strong ligneous stalk three feet high, garnished with smooth spear-shaped leaves placed alternate, sitting close to the stalk. The flowers are produced at the end of the branches in short loose spikes; they are of a deep yellow colour, and much larger than those of the common sort, standing upon short foot-stalks. It is propagated by seeds, which should be sown early in the spring, upon a border of light earth; and when the plants come up, and are fit to remove, some of them should be planted in pots, to be sheltered under a common frame in winter. As these plants only require to be protected from hard frost, so in mild winters they will live abroad without shelter, if they are upon a dry soil; therefore a part of the plants may be planted on a warm border of poor sandy soil, where they will live through our common winters very well; and those plants which grow in rubbish and are stunted, will endure much more cold than the others.

The fourteenth sort grows naturally in *Siberia*. This is a biennial plant, which rises with an upright branching stalk, from three to four feet high, garnished with spear-shaped leaves, ending in acute points, of a grayish colour, placed alternate. The flowers are produced at the end of the branches in loose panicles; they are of a bright yellow colour, shaped like those of the other sorts. This flowers in *June* and *July*, and the seeds ripen in autumn, which, if permitted to scatter, the plants will come up the following spring, and require no other care but to thin them where they are too close, and keep them clear from weeds.

The fifteenth sort is frequently called *Fluellin*, and is sometimes used in medicine; it grows naturally amongst *Wheat* and *Rye* in several parts of *England*. It is an annual plant, with weak, trailing, hairy stalks, which spread

on the ground, garnished with oval leaves, placed alternately; at each joint comes out one flower, shaped like those of the other species. The upper lip is yellow, and the under is purple.

The sixteenth sort differs from the fifteenth, in nothing but the shape of the leaves, which in this are shaped like the point of an arrow, and those of the other are oval; this is more commonly found in *England* than the other.

The seventeenth sort was brought from *Italy* to *England*, where it now grows in as great plenty in the neighbourhood of *London*, as if it was in its native country, growing from the joints of walls, where-ever the seeds happen to scatter. It is a perennial plant, which will thrive in any soil or situation, so that where it is once established, it will be difficult to root out, for the seeds will get into any joints of walls, or the decayed parts of pales, as also in the hollow of trees, where they grow and propagate plentifully; for the stalks put out roots at their joints, so spread themselves to a great distance.

LINGUA CERVINA, Hart's Tongue.

These plants commonly grow out from the joints of old walls and buildings, where they are moist and shady, and also upon shady moist banks, but are seldom cultivated in gardens. There is a very great variety of these plants, both in the *East* and *West-Indies*, but there are very few species of them in *Europe*; all the hardy sorts may be propagated by parting their roots, and should have a moist soil and shady situation.

LINUM. *Tourn. Inst. R. H.* 339. *tab.* 176. Flax.

The Characters are,

The flower has five large oblong petals, which spread open. It hath five awl-shaped erect stamina. In the center is situated an oval germen, which afterward turns to a globular capsule with ten cells, opening with five valves; in each cell is lodged one oval, plain, smooth seed.

The Species are,

1. LINUM *calycibus capsulisque mucronatis, petalis crenatis, foliis lanceolatis alternis, caule subsolitario.* *Lin. Sp. Plant.* 277. Common manured Flax.

2. LINUM *calycibus capsulisque mucronatis, petalis emarginatis, foliis lanceolatis alternis, caule ramoso.* Low manured Flax with a larger flower.

3. LINUM *calycibus acuminatis, foliis lanceolatis sparsis striatis scabris acuminatis, caule tereti basi ramoso.* *Lin. Sp. Plant.* 278. Wild blue Flax with an acute leaf.

4. LINUM *calycibus acuminatis, foliis sparsis linearibus setaceis retrorsum scabris.* *Lin. Sp. Plant.* 278. Narrow-leaved wild Flax, with a pale purplish, or flesh-coloured flower.

5. LINUM *calycibus capsulisque acuminatis, caule subnudo scabro, foliis acuminatis.* Greater blue perennial Flax with larger heads.

6. LINUM *calycibus capsulisque obtusis, foliis alternis lanceolatis acutis, caulibus ramocissimis.* *Plant.* 166. Flax with obtuse empalements and capsules, alternate spear-shaped, acute leaves, and very branching stalks; commonly called *Siberian* perennial Flax.

7. LINUM *calycibus acutis, foliis lineari-lanceolatis sparsis, caule paniculato.* Flax with acute empalements, linear spear-shaped leaves placed without order, and a paniculated stalk.

8. LINUM *calycibus patulis acuminatis, foliis linearibus alternis, caule ramoso.* Flax with spreading acute-pointed empalements, linear alternate leaves, and a branching stalk.

9. LINUM *calycibus hirsutis acuminatis sessilibus alternis, caule corymbofo.* *Lin. Sp. Plant.* 277. Broad-leaved, hairy, wild Flax, with a blue flower.

10. LINUM *calycibus foliisque lanceolatis striatis mucronatis, margine scabris.* *Lin. Sp. Plant.* 279. Flax with spear-shaped leaves and empalements, which end in acute points, and have rough edges; or the *Passerini Lobellii.* *J. B.* 3. p. 454.

11. LINUM

11. LINUM *calycibus acutis, petalis integris, foliis inferioribus linearibus fasciculatis, superioribus alternis, caule suffruticoso.* Wild Flax with a shrubby stalk and acute leaves.

12. LINUM *foliis lanceolatis alternis, floribus alternis sessilibus, caule simplici.* Yellow Flax with single flowers growing from the joints.

13. LINUM *foliis oppositis ovato-lanceolatis, caule dichotomo, corollis acutis.* Hort. Cliff 372. Meadow Flax with small flowers; commonly called Mountain Flax.

14. LINUM *calycibus ovatis acutis muticis, foliis lanceolatis inferioribus oppositis.* Lin. Sp. Plant. 280. Yellow maritime Flax.

The first sort is the Flax which is cultivated in most parts of Europe, but particularly in the northern parts. This is an annual plant, which usually rises with a slender unbranched stalk a foot and a half high, garnished with narrow spear-shaped leaves, placed alternate, ending in acute points, of a gray colour. The flowers are produced on the top of the stalks, each stalk sustaining four or five blue flowers, composed of five petals, which are narrow at their base, but broad at the top, where they are slightly crenated. The flowers appear in June and July, and are succeeded by roundish capsules, which have ten cells, opening with five valves, which are terminated by acute points; each cell contains one smooth flattish seed, of a brown colour. The seeds ripen in September, and the plants soon after perish.

When this plant is cultivated in the fields after the usual method, it seldom rises higher than is before-mentioned, nor do the stalks branch out; but when they are allowed more room, they will rise between two and three feet high, and put out two or three side branches toward the top, especially if the soil is pretty good where it is sown.

The second sort differs from the first, in having stronger and shorter stalks branching out much more. The leaves are broader, the flowers are larger, and the petals are indented at their extremities. The seed-vessels are also much larger, and the foot-stalks are longer.

The third sort grows naturally in the south of France, in Italy, and Spain. This rises from a foot to eighteen inches high, branching out almost to the bottom into many long slender branches, garnished with narrow spear-shaped leaves. The flowers are produced at the end of the branches, almost in form of an umbel; they are smaller than those of the manured sort, and are of a paler blue colour.

The fourth sort grows naturally about Vienna and in Hungary. This seldom rises more than a foot high, with a slender stalk, which divides into three or four naked foot-stalks at the top, each sustaining two or three flowers, which are of a pale blue colour.

The fifth sort grows naturally in some parts of England. This hath a perennial root, from which arise three or four stalks, garnished with a few short narrow leaves toward their base, but upward have scarce any. The flowers are blue, and are produced at the end of the stalks, which are succeeded by pretty large round seed-vessels, ending in acute points. The roots will continue three or four years.

The sixth sort grows naturally in Siberia. It hath a perennial root, from which arise several strong stalks, in number proportional to the size of the root, and in height according to the goodness of the soil where it grows; for in rich moist ground they will rise near five feet high, but in middling ground about three feet; these divide into several branches upward, garnished with narrow spear-shaped leaves, placed alternate. The flowers are produced at the end of the branches, forming a kind of umbel; they are large, and of a fine blue colour. These appear in June, and are succeeded by obtuse seed-vessels, which ripen in September.

The seventh sort grows naturally in Spain. This hath a biennial root, from which come out several trailing stalks,

which never rise much from the ground, but between these come out upright stalks, which rise upward of two feet high, garnished with pretty long narrow spear-shaped leaves, placed without order. The flowers grow in a sort of panicle toward the upper part of the branches; they are like those of the common sort, and are of the same colour.

The eighth sort I received from Istria. This hath a biennial root, from which arise two or three stalks, which divide into several branches, garnished with short, narrow, acute-pointed leaves, placed alternately. The flowers come out from the side of the branches, standing upon long foot-stalks. They are of the same size and colour as the common Flax, and appear at the same season. The seeds ripen in the autumn, and the roots abide two years.

The ninth sort grows naturally in Hungary and Austria. This hath a perennial root, from which arise several strong stalks two feet high, dividing into several branches, garnished with broader leaves than the other species, which are hairy. The flowers grow along the stalks alternately; they are large, and of a deep blue colour, appearing at the same time with the common sort, and the seeds ripen in the autumn.

The tenth sort grows naturally in Germany and the south of France, amongst the Corn. This is an annual plant, rising with an upright stalk a foot and a half high, garnished with spear-shaped, acute-pointed leaves, which are rough on their edges, placed alternately. The stalks divide into several branches, each sustaining two or three yellow flowers, which appear in July, but unless the autumn proves favourable, the seeds never ripen in England.

The eleventh sort grows naturally in Spain. This hath a shrubby stalk, which rises a foot high, sending out several branches, garnished with very narrow leaves, coming out in clusters. The flowers are produced at the end of the branches, standing erect, upon long slender foot-stalks. The petals of the flower are large, entire, and white, but before the flowers open they are of a pale yellow colour. These flowers appear in July, but unless the autumn proves favourable, the seeds do not ripen in England.

The twelfth sort grows naturally upon the Alps. This hath a perennial root, from which arise two or three slender stiff stalks, which divide into two or three smaller, garnished with spear-shaped leaves, placed alternately. The flowers come out singly at the joints; they are yellow, and appear about the same time with the common sort, and the seeds ripen in the autumn.

The thirteenth sort grows common in many parts of England, upon dry barren hills. It is commonly called *Linum catharticum*, or purging Flax, and also mountain Flax. This rises with several branching slender stalks about seven or eight inches high, garnished with small, oval, spear-shaped leaves placed opposite. The flowers are small and white, standing upon pretty long foot-stalks. They appear in July, and are succeeded by small round capsules, containing small flat seeds, which ripen in the autumn.

The fourteenth sort grows naturally about Montpellier. This rises with upright stalks two feet high, the lower part of which are garnished with spear-shaped leaves placed opposite, but on the upper part they are alternate. The stalks divide into several branches terminated with yellow flowers, about the size of those of common Flax, which are succeeded by small oval capsules, containing smaller seeds than those of the common Flax.

The first sort is that which is cultivated for use in divers parts of Europe, and is reckoned an excellent commodity; the right tilling and ordering of which, is esteemed a good piece of husbandry.

The ground in which this is to be sown, should be as clean from weeds as possible; in order to have it so, it

should be fallowed two winters and one summer, observing to harrow it well between each ploughing, particularly in summer, to destroy the young weeds soon after they appear, that the smallest of them may not stand to ripen their seed; this will also break the clods, and separate their parts so, as that they will fall to pieces on being stirred. If the land should require dung, that should not be laid on till the last ploughing, but this dung should be such as is clear from the seeds of weeds. Just before the season for sowing of the Flax seed, the land must be well ploughed, laid flat and even, upon which the seeds should be sown about the latter end of *March*, when the weather is mild and warm.

The common way is to sow the seed in broad-cast, and to allow from two to three bushels of seeds to one acre of land; but from many repeated trials, I have found it is a much better method to sow the seeds in drills, at about ten inches distance from each other, by which half the quantity of seed which is usually sown, will produce a greater crop; and when the Flax is thus sown, the ground may be easily hoed between the rows to destroy the weeds, which, if twice repeated in dry weather, will keep the ground clean till the Flax is ripe: this may be performed at half the expence which the hand weeding will cost, and will not tread down the plants, nor harden the ground, which by the other method is always done; for it is absolutely necessary to keep the Flax clean from weeds, otherwise they will overbear and spoil the crop.

There are some people who recommend the feeding of sheep with Flax, when it is a good height; and say, they will eat away the weeds and Grass, and do the Flax good; and if they should lie in it, and beat it down or flatten it, it will rise again the next rain: but this is a very wrong practice, for if the sheep gnaw or eat the Flax, the plants will shoot up very weak stalks, which never come to half the size they would have done, if not cropped; and as to the sheep destroying the weeds, they never are so nice distinguishers, for if they like the crop better than the weeds, they will devour that, and leave the weeds untouched.

Toward the latter end of *August* the Flax will begin to ripen, when you must be careful that it grow not over ripe; therefore you must pull it up as soon as the heads begin to change brown and hang downwards, otherwise the seeds will soon scatter and be lost, so that the pluckers must be nimble, and tie it up in handfuls, setting them upright till they be perfectly dry, and then house them. If the Flax be pulled when it first begins to flower, it will be whiter than if it stand till the seed is ripe, but then the seed will be lost; but the thread will be stronger when the Flax is left till the seed is ripe, provided it does not stand too long, but the colour of it will not be so good.

The *Siberian* perennial Flax has been made trial of, and answers very well for making of common strong linen, but the thread spun from this is not so fine or white as that which is produced from the common sort; but as the roots of this sort will continue many years, so there will be a great saving in the culture, as it will require no other care but to keep it constantly clean from weeds; which cannot be well done, unless the seeds are sown in rows, that the ground may be constantly kept hoed to destroy the weeds when young, for if they are suffered to grow large, it will be difficult to get the ground clean, and they will weaken the roots. This sort must have the stalks cut off close to the ground when ripe, and tied up in small bundles, managing them afterward in the same way as the common sort.

The eighth sort which I received from *Istria*, produced

the finest thread; it grows taller than the common Flax, and having a biennial root, it may be worthy of trial to see how it will thrive in the open fields, for in gardens it lives through the winter without receiving the least injury from the frost. In order to make trial of its goodness, I gave a parcel of the stalks of this, as also of the *Spanish* and the *Siberian* perennial Flax, to a person who is well skilled in watering, breaking, and dressing of Flax, who prepared them, and assured me, that the *Istrian* Flax was by much the finest of the three, and equal in goodness to any he had seen.

The other sorts which are here mentioned, are preserved in gardens for the sake of variety, but none of them are used, except the mountain Flax, which is esteemed a good purger in dropical disorders, and has of late years been often prescribed.

They are all of them propagated by seeds, which may be sown in the spring, in the places where they are to remain, and will require no other culture, but to keep the plants clean from weeds. The annual sorts will flower and perfect their seeds the same year, but the roots of the perennial sorts will continue several years, putting out fresh stalks every spring. The shrubby sorts will live through the winter in the open air, provided it is in a dry soil and a warm situation, but these rarely produce seeds in *England*.

LINUM UMBILICATUM. See Cynoglossum.

LIPPIA. *Houft. Gen. Nov. Lin. Gen. Plant.* 699.

The Characters are,

The flower hath one petal, which is of the ringent kind. It hath four short stamina, two of which are a little longer than the other, and an oval germen, which afterward turns to a compressed capsule with one cell, opening with two valves, which appear like the scales of the empalement, inclosing two seeds which are joined.

We know but one Species of this plant at present, viz.

LIPPIA *arborescens, foliis conjugatis oblongis, capitulis squamosis & rotundis. Houft.* Tree Lippia, with oblong leaves growing by pairs, having round scaly heads.

This plant, in the country of its native growth, commonly rises to the height of sixteen or eighteen feet, it has a rough bark; the branches come out opposite, as do also the leaves, which are oblong, pointed, and a little sawed on their edges. From the wings of the leaves come out the foot-stalks, which sustain many round scaly heads, about the size of a large gray Pea, in which are many small yellow flowers appearing between the scales, which are succeeded by seed-vessels.

This plant will not thrive in this climate, unless it is preserved in a warm stove, so should be treated in the same manner as other shrubby plants, which are natives of warm countries; which is, to keep them always in the stove, plunged in the bark-bed, observing to give them a large share of air in warm weather, and frequently refresh them with water; but in winter they must be watered more sparingly, and kept in a moderate degree of warmth, otherwise they will not live through the winter, especially while they are young; but when they have acquired strength, they may be preserved with a less share of warmth.

LIQUIDAMBER. *Lin. Gen. Plant.* 955. Liquidamber, sweet Gum, or Storax tree.

The Characters are,

It hath male and female flowers on the same tree; the male flowers are disposed in long, loose, conical katkins; these have four-leaved empalements, no petals, but a great number of short stamina joined in one body. The female flowers are situated at the base of the male spike, collected in a globe; these have a double empalement. They have no petals, but an oblong germen fastened

to the empalement, which afterward turns to a roundish capsule of one cell, with two valves at the top, which are collected in a ligneous globe, containing many oblong acute-pointed seeds.

The Species are,

1. LIQUIDAMBER *foliis quinquelobatis serratis*. Liquidamber with sawed leaves having five lobes; or Maple-leaved Storax tree.

2. LIQUIDAMBER *foliis quinquelobatis, sinuatis obtusis*. Liquidamber with leaves having five lobes, which are sinuated and obtuse.

The first sort has by some writers been ranged with the Maple, but on no other account, except from the similitude of the leaves; for in flower and fruit it is very different from the Maple, and most other genera: nor has it any affinity to the Storax tree, but the gum which issues from this tree being transparent, and having a great fragrancy, has by some ignorant persons been taken for that.

It grows plentifully in *Virginia*, and several other parts of *North America*, where it rises with a strait naked stem to the height of fifteen or sixteen feet, and branches out regularly to the height of forty feet or upward, forming a pyramidal head. The leaves are angular, and shaped somewhat like those of the lesser Maple, having five lobes, but are of a dark green colour; a strong, sweet, glutinous substance exudes through the pores of the leaves in warm weather, which renders them clammy to the touch.

The flowers are generally produced early in the spring of the year, before the leaves are expanded, which are of a Saffron colour, and grow in spikes from the extremity of the branches; after these are past, the fruit swells to the size of a Walnut, being perfectly round, having many protuberances, each having a small hole and a short tail, which extends half an inch.

This is commonly propagated by layers in *England*, but those plants which are raised from seeds, grow to be much fairer trees.

The seeds of this tree commonly remain in the ground a whole year before the plants come up, unless they are sown in the autumn; so that the surest way to raise them is, to sow the seeds in boxes or pots of light earth, which may be placed in a shady situation during the first summer, and in autumn they may be removed where they may have more sun; but if the winter should prove severe, it will be proper to cover them with Peas haulm, or other light covering, which should be taken off constantly in mild weather. The following spring if these boxes or pots are placed upon a moderate hot-bed; it will bring up the plants early; so that they will have time to get strength before winter; the first and second winters, it will be proper to screen the plants from severe frost, but afterward they will bear the cold very well.

The seeds of the second sort were sent by Mr. *Peyssonel* from the *Levant*. The leaves of this sort differ from those of the first, in having their lobes shorter and deeply sinuated on their borders; they end in blunt points, and are not serrated; but as I have not seen the fruit of this, so I do not know how it differs from the other.

LIRIODENDUM. See Tulipifera.

LITHOSPERMUM. *Tourn. Inst. R. H. 137. tab. 55.* Gromwell, Gromill, or Graymill.

The Characters are,

The flower hath one petal, with a cylindrical tube divided into five obtuse points at the brim; the chaps are perforated. It hath five short stamina, which are shut up in the chaps of the petal; and hath four germen, which afterward turn to so many oval, hard, smooth, acute pointed seeds, sitting in the spreading empalement.

The Species are,

1. LITHOSPERMUM *seminibus lævibus, corollis calycem vix superantibus, foliis lanceolatis*, Hort. Cliff. 46. Greater upright Gromwell.

2. LITHOSPERMUM *seminibus rugosis, corollis vix calycem superantibus*. Hort. Cliff. 46. Field Gromwell with a red root.

3. LITHOSPERMUM *seminibus lævibus, corollis calycem multoties superantibus*. Hort. Cliff. 46. Smaller, creeping; broad-leaved Gromwell.

4. LITHOSPERMUM *foliis subovalibus nervosis, corollis acuminatis*. Lin. Sp. Plant. 132. Broad-leaved Gromwell of *Virginia*, with a longer whitish flower.

5. LITHOSPERMUM *villifum, caulibus procumbentibus simplicissimis*. Mat. Med. Lin. 58. Alkanet.

The first sort grows naturally upon banks, and in dry fields in many parts of *England*, so is seldom admitted into gardens. This hath a perennial root, from which arise upright stalks two feet high, garnished with spear-shaped, rough, hairy leaves, placed alternate, sitting close to the stalks. The flowers come out singly at every joint of the small branches; they are white, of one petal, cut into four parts at the top, and stand within the empalement; these are each succeeded by four hard white shining seeds, which ripen in the empalement.

The second sort is an annual plant, which grows among winter Corn in many parts of *England*. This rises with a slender branching stalk a foot and a half high, garnished with narrow, spear-shaped, rough leaves placed alternately. The flowers are produced singly on the upper parts of the stalks, they are small, white, and are succeeded by four rough seeds, which ripen in the empalement.

The third sort grows naturally in woods in many parts of *England*; this hath a perennial root, from which come out two or three trailing stalks scarce a foot long, garnished with narrow, spear shaped leaves, placed alternately. The flowers terminate the stalks, they are white, and the petals are much longer than the empalements.

The fourth sort grows naturally in *North America*; this hath a biennial root, from which arise several very hairy stalks about a foot and a half high, garnished with oval, rough, hairy, veined leaves, sitting close to the stalks alternately. The flowers grow in short reflexed spikes at the end of the branches; these are white, their petals being longer than the empalement, ending in acute points.

The fifth grows naturally in the south of *France*, and also in the *Levant*. This hath a biennial red root, which runs deep in the ground, from which comes a single trailing stalk a foot long, which is pretty closely set with hairs, and garnished with rough prickly leaves placed alternately. The flowers are produced in short reflexed spikes at the end of the stalk; standing in hairy empalements; they are of a reddish purple colour, but as they decay change to a deep purple.

This sort stands in the list of medicinal plants, but at present is rarely used: the bark of the root gives a fine purple tincture, for which it is sometimes used, but the colour is not permanent.

These may be cultivated by sowing their seeds soon after they are ripe, in a bed of fresh earth, allowing them at least a foot distance, keeping them clean from weeds, and they will thrive in almost any soil or situation.

LOBELIA. *Plum. Nov. Gen. 21. tab. 31.*

The Characters are,

The flower has one petal, which is tubulous, ringent, and cut into five parts at the brim. It hath five awl-shaped stamina the length of the tube, and a pointed germen under the petal, which afterward becomes an oval fleshy berry with two cells, each containing a single seed.

We have but one Species of this genus, viz.

LOBELIA *frutescens, foliis ovali oblongis integerrimis*. Flor. Zeyl. 313. Shrubby Lobelia with oblong, oval, entire leaves.

This

This plant rises with a succulent stalk, five or six feet high, garnished with oval, oblong, succulent leaves, placed alternately, which sit close to the stalk. The flowers are produced upon long foot-stalks, and sustain two or three white flowers of one petal, cut into five acute segments at the brim; these are succeeded by oval berries as large as Bullace, containing a stone with two cells, in each of these is lodged a single seed.

This plant grows naturally in many of the islands of the *West-Indies*. It is propagated by seed, which must be procured from the countries of its natural growth; these should be sown in pots, and plunged into a hot-bed of tanners bark, where the plants will come up in about five or six weeks, provided the bed is kept warm, and the earth often watered. When the plants are about two inches high, they should be carefully taken out of the pots in which they were sown, and each planted in a separate small pot, and then plunged into the hot-bed again, observing to shade them in the heat of the day until they have taken new root. In this hot-bed the plants may remain until the middle or latter end of *September*, when they must be removed into the stove, and plunged into the tan-bed, and afterward treated in the same way as other tender exotic plants, which require a stove to preserve them through the winter.

LOBUS ECHINATUS. See *Guilandina*.

LONCHITIS, Rough Spleenwort.

The Characters are,

The leaves are like those of the Fern, but the pinnulae are eared at their base; the fruit also is like that of the Fern.

The Species are,

1. LONCHITIS aspera. Ger. Rough Spleenwort.
2. LONCHITIS aspera major. Ger. Emac. Greater rough Spleenwort.

The first of these plants is very common in shady woods, by the sides of small rivulets in divers parts of *England*; but the second sort is not quite so common, and has been brought into several curious botanick gardens from the mountains in *Wales*. There are also great variety of these plants in *America*, which at present are strangers in the *European* gardens; they are seldom cultivated but in botanick gardens, for the sake of variety, where they must have a moist soil and shady situation.

LONICERA. *Lin. Gen. Plant. Tourn. Inst. R. H.* 609. tab. 379. Upright Honeyfuckle.

The Characters are,

The flower has one petal, with an oblong tube, cut into five parts at the brim, and five awl-shaped stamina. Under the petal is situated a roundish germen, which afterward turns to two berries, which join at their base.

The Species are,

1. LONICERA pedunculis bifloris baccis distinctis, foliis integerrimis pubescentibus. *Prod. Leyd.* 238. Dwarf Cherry with twin red fruit; commonly called Fly Honeyfuckle.
2. LONICERA pedunculis bifloris, baccis coadunatis didymis. *Lin. Sp. Plant.* 174. Dwarf Alpine Cherry with a red twin fruit, marked with two points; commonly called red-berried upright Honeyfuckle.
3. LONICERA pedunculis bifloris, baccis coadunatis globosis, stylis indivisis. *Lin. Sp. Plant.* 174. Mountain Dwarf Cherry with a single blue fruit; commonly called single, blue-berried, upright Honeyfuckle.
4. LONICERA pedunculis bifloris, baccis distinctis, foliis serratis. *Prod. Leyd.* 238. Alpine Dwarf Cherry with a black twin fruit; called black-berried upright Honeyfuckle.
5. LONICERA pedunculis bifloris, baccis distinctis, foliis cordatis obtusis. *Hort. Upsal.* 42. Dwarf Cherry with a twin red fruit, and smooth heart-shaped leaves.
6. LONICERA pedunculis bifloris, baccis distinctis, foliis oblongis glabris. *Lin. Sp. Plant.* 174. Pyrenan Dwarf Cherry; called Xylosteum.

7. LONICERA capitulis lateralibus pedunculatis, foliis petiolatis. *Lin. Sp. Plant.* 175. Commonly called shrubby St. Peterwort.

The first sort has been many years cultivated in the *English* gardens under the title of Fly Honeyfuckle. It grows naturally upon the *Alps*, and in other cold parts of *Europe*. It rises with a strong woody stalk six or eight feet high, covered with a whitish bark, divided into many branches, garnished with oblong, entire, downy, oval leaves, placed opposite. The flowers come out from the side of the branches opposite, standing upon slender foot-stalks, each sustaining two irregular white flowers, which are succeeded by two red clammy berries, which are joined at their base.

The second sort grows naturally on the *Alps*; this hath a short, thick, woody stem, which divides near the root into many strong woody branches, which grow erect, garnished with spear-shaped entire leaves, placed opposite. The flowers stand upon very long slender foot-stalks, which come out opposite on each side the branches, at the base of the leaves; they are red on their outside, but pale within, shaped like those of the former sort, but are larger, and are commonly succeeded by two oval red berries, joined at their base, which have two punctures. Sometimes there is but one berry succeeding each flower, which is frequently as large as a *Kentish* Cherry; this I believe has led some to suppose it was a distinct species, as I thought myself, when I saw all the fruit upon some of the shrubs were single, but, the following years, I found they had twin fruit like the others.

The third sort grows naturally upon the *Apennines*; this is a shrub of humbler growth than either of the former, seldom rising more than four or five feet high. The branches are slender, covered with a smooth purplish bark. The joints are farther asunder, the leaves come out opposite. The foot-stalks of the flowers are very short, each sustaining two white flowers, shaped like those of the former sorts; these are succeeded by blue berries, which are single and distinct.

The fourth sort grows naturally on the *Alps* and *Helvetian* mountains; this shrub is very like the former, but the branches are slenderer. The leaves are a little sawed on their edges. The flowers have two berries succeeding them, in which consists their difference.

The fifth sort grows naturally in *Tartary*; this shrub grows about the same height with the two former, to which this has a great resemblance in its branches, but the leaves of this are heart-shaped, and the berries are red, growing sometimes single, at others double, and frequently there are three joined together, which are about the same size with the former.

The sixth sort grows naturally on the *Pyrenean* mountains, and also in *Canada*. This seldom rises more than three or four feet high, dividing into several irregular branches, garnished with oblong smooth leaves, placed opposite. The flowers come out from the side of the branches, upon slender foot-stalks, each sustaining two white flowers, which are cut into five segments almost to the bottom, and are succeeded by berries as the other sorts.

The seventh sort grows naturally in *North America*; this hath a shrubby stalk, which rises six or seven feet high, sending out many slender branches, garnished with oval hairy leaves, placed opposite, having very short foot-stalks. The flowers are produced in whorls round the stalk; they are of an herbaceous colour. The fruit, which is hollow, and shaped like a pottage pot, ripens in the winter.

These shrubs are now propagated in the nursery-gardens near *London* for sale, and are commonly intermixed with other flowering shrubs for the sake of variety; but as there

is little beauty in their flowers, a few of them only should be admitted, to set off those which are preferable; they are all of them very hardy plants, so will thrive in a cold situation, better than in a warm one; they love a moist light soil, in which they will thrive, and produce a greater quantity of fruit than in dry ground.

They may be propagated either by seeds, or cuttings. The seeds commonly lie in the ground a year before they vegetate, but require no particular culture; if they are sown in autumn, many of them will grow the following spring. The cuttings should be planted in autumn in a shady border, where they will put out roots the following spring, and in the following autumn they may be removed into a nursery, to grow two years to get strength, after which they should be transplanted where they are designed to remain.

LORANTHUS. *Vaill. Act. R. Sc. 1702. Lin. Gen. Plant. 400.*

The Characters are,

The flower is tubulous, and cut into five narrow segments, almost to the bottom, which are reflexed. It hath four stamina. The germen which is situated below the empolment, afterward becomes an oval pulpy fruit with one cell, including several compressed seeds.

There is but one Species of this genus at present known, viz.

LORANTHUS. *Lin. Sp. Plant. 331.* Branching Loranthus with a scarlet flower, and black berries.

This plant was discovered by father Plumier, in the French islands in America, and was afterward found growing naturally at La Vera Cruz, by the late Dr. Housloun: it rises with a shrubby stalk eight or ten feet high, dividing into several branches, garnished with oblong entire leaves, which have three longitudinal nerves. The flowers are produced at the end of the branches in small clusters, and are of a scarlet colour, cut into five narrow segments almost to the bottom; these are succeeded by oval berries, with a pulp covering a hard shell with one cell, inclosing several compressed seeds.

This plant is propagated by seeds, which should be sown as soon as they are ripe, for if they are kept out of the ground long, they often miscarry; or if they do grow, it is not till the year after, so that those seeds which come from America, very seldom grow the first year; therefore they should be sown in pots, and kept in a moderate hot-bed the first summer, and in autumn removed into the stove, where, if the pots are plunged in the tan-bed between the plants, and the earth kept moist, in the spring they may be taken out, and plunged into a moderate fresh hot-bed, which will bring up the plants, which must be planted in separate small pots, and kept in the bark-stove, treating them in the same way as other tender plants from the same country.

LOTUS. *Tourn. Inst. R. H. 402.* Birds-foot Trefoil.

The Characters are,

The flower is of the butterfly kind. The standard is roundish, and reflexed backward. The wings are broad, and shorter than the standard, closing together at the top. The keel is closed on the upper side, and convex on the under. It hath ten stamina, nine joined and one separate, with an oblong taper germen, which afterward becomes a close cylindrical pod with one cell, opening with two valves, having many transverse partitions, in each of these is lodged one roundish seed.

The Species are,

1. LOTUS capitulis depressis, caulibus decumbentibus, leguminibus cylindricis. *Lin. Sp. Plant. 775.* Lesser smooth corniculated Birds-foot Trefoil.

2. LOTUS leguminibus subbinatis linearibus striatis erectis, caule erecto, pedunculis alternis. *Lin. Sp. Plant. 774.* Smaller, five-leaved, hairy Birds-foot Trefoil, with very narrow pods.

3. LOTUS capitulis depressis, caulibus decumbentibus, foliis linearibus glabris, leguminibus linearibus. Birds-foot Trefoil with depressed heads, trailing stalks, smooth linear leaves, and very narrow pods.

4. LOTUS capitulis subglobosis, caule erecto, leguminibus rectis glabris. *Hort. Upsal. 221.* Tallest hairy Birds-foot Trefoil with a glomerated flower.

5. LOTUS capitulis dimidiatis, caule fruticoso, foliis nitidis. *Hort. Cliff. 372.* Silvery Birds-foot Trefoil of Crete.

6. LOTUS capitulis hirsutis, caule erecto hirsuto, leguminibus ovatis. *Hort. Upsal. 220.* Birds-foot Trefoil with hairy heads, an erect hairy stalk, and oval pods.

7. LOTUS capitulis subglobosis hirsutis, caule erecto ramoso, hirsuto, foliis tomentosis. Birds-foot Trefoil with globular heads which are hairy, an upright, branching, hairy stalk, and woolly leaves.

8. LOTUS leguminibus subquinatis arcuatis compressis, caulibus diffusis. *Hort. Cliff. 372.* Birds foot Trefoil with five arched compressed pods, and diffused stalks.

9. LOTUS leguminibus subbinatis linearibus compressis nudentibus. *Hort. Cliff. 372.* Birds-foot Trefoil with two narrow, compressed, nodding pods.

10. LOTUS leguminibus solitariis erectis teretibus terminalibus, caule erecto. *Sauv. Monsp. 189.* Yellow meadow Birds-foot Trefoil.

11. LOTUS leguminibus solitariis gibbis incurvis. *Hort. Cliff. 370.* Birds-foot Trefoil with single, convex, incurved pods.

12. LOTUS leguminibus solitariis membranaceo-quadrangulatis, bracteis lanceolatis. *Flor. Suec. 610.* Yellow maritime Birds-foot Trefoil with a smooth leaf.

13. LOTUS leguminibus conjugatis membranaceo-quadrangulis, bracteis oblongo-ovatis. *Lin. Sp. Plant. 774.* Yellow Birds-foot Trefoil with angular pods.

14. LOTUS leguminibus solitariis membranaceo-quadrangulatis, bracteis ovatis. *Hort. Upsal. 220.* Red Birds-foot Trefoil with angular pods; commonly called winged Pea.

15. LOTUS capitulis dimidiatis, caule diffuso ramosissimo, foliis tomentosis. *Prod. Leyd. 387.* Podded, yellow, maritime Birds-foot Trefoil, with the appearance of Cytisus.

16. LOTUS leguminibus subternatis, caule herbaceo erecto, foliis linearibus. *Hort. Cliff. 372.* Narrow-leaved Birds-foot Trefoil of St. James's island, with a yellow purplish flower.

17. LOTUS capitulis aphyllis, foliis sessilibus quinatis. *Lin. Sp. Plant. 776.* Dorycnium of Montpellier.

The first, second, and third sorts grow naturally in many parts of England, so are rarely admitted into gardens. When these grow in moist land and a shady situation, they send out stalks near two feet long, but upon dry chalky and gravelly ground, their stalks are not more than three or four inches, and lie flat upon the ground. I have always observed in those pastures where these plants have grown, that the cattle of all sorts have avoided eating them, but the Grass all round them has been eaten very bare. I have cut the plants when young, and given it to various kinds of animals, but could never get them to eat it; and yet the seeds of these have been gathered and sold by some quacks in husbandry, under the title of Lady's Finger Grass, to be sown as an improvement to land for pasture.

The roots of these are perennial, so are difficult to get out when they have had long possession of the land, for they produce great quantities of seeds, which is cast about by the elasticity of the pods when ripe, to a considerable distance.

The fourth sort grows naturally in the south of France, in Italy and Sicily; this has by some been supposed the Cytisus of Virgil, but without foundation; it hath a strong perennial

perennial root, from which arise many upright strong stalks from five to six feet high, garnished at every joint by a trifoliate leaf, whose lobes are wedge-shaped; at the base of the foot-stalk are placed two heart-shaped lobes sitting close to the branch; the leaves are hairy on their under side; the flowers are produced at the end of the branches almost in globular heads, sitting close to the foot-stalk: they are of a pale flesh colour, and are succeeded by smooth straight pods almost an inch long, which change to a brown colour when ripe, and contain several roundish seeds. It is rarely cultivated but in botanick gardens for variety, but if any person has an inclination to cultivate this plant for feeding of cattle, it may be done in the same way as the Lucern, for which there is full directions in the article *MEDICAGO*.

The fifth sort grows naturally in *Syria* and *Crete*; this rises with slender stalks which require support, from three to four feet high, sending out a few side branches, garnished at each joint with neat, shining, silvery, leaves which are trifoliate, and have two appendages at the base of their foot-stalks. The foot-stalks of the flowers, which are from two to three inches long, arise from the side of the branches, and sustain heads of yellow flowers, which part in the middle, each head containing four or six flowers, which are succeeded by long taper pods filled with roundish seeds, which ripen in the autumn.

This sort has a perennial stalk, but is too tender to live in the open air in *England*, except the winter proves very mild, so is kept in pots and removed into the green-house in autumn, and treated like other hardy exotic plants, which only require protection from frost. It is propagated by seeds, which, if sown on a bed of light earth in *April*, the plants will come up in about a month after, and in another month will be fit to remove, when they should be each put into a separate small pot, placing them in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain till autumn.

It may be also propagated by cuttings, which may be planted during any of the summer months, upon a bed of light earth, covering them close with a bell or hand-glass, and screening them from the sun; in about five or six weeks they will have taken root, when they must be inured to bear the open air, and soon after may be planted in pots, and treated in the same way as the seedling plants.

The sixth sort grows naturally in the south of *France* and *Italy*; this hath a perennial hairy stalk, which rises three feet high, and divides into several branches, garnished with hoary trifoliate leaves, having two appendages at the base of the stalk; the flowers are collected into heads sitting upon pretty long foot-stalks, which come out of the side of the stalks. They are of a dirty white colour, with a few marks of pale red, and are succeeded by short thick pods of a Chestnut colour, containing several roundish seeds which ripen in the autumn. This is propagated by seeds in the same way as the last sort; the plants will live in the open air in moderate winters, but it will be proper to keep one or two plants in pots to be sheltered, lest those abroad should be destroyed by severe frost.

The seventh sort grows naturally in *Sicily*; this rises with an upright woody stalk near three feet high, garnished with leaves like the sixth, but much whiter, covered with a short woolly down; the flowers grow in close heads like the last, they are whiter, and are succeeded by short pods, which contain many yellow seeds. This is too tender to live in the open air in *England* through the winter, so the plants must be kept in pots and housed in autumn. It is propagated in the same way as the fifth sort, and requires the same culture.

The eighth sort grows naturally in *Sicily*; this is an annual plant, which sends out from the root many stiff stalks

from one to two feet high, garnished with trifoliate leaves, having two appendages at their base; the foot-stalks of the flower rise from the wings of the stalks, which are terminated by a cluster of yellow flowers, succeeded by flat pods two inches long, bent like an arch, and have many joints, separating the cells in which the seeds are lodged.

This is propagated by seeds, which should be sown early in *April*, upon an open bed or border exposed to the sun, where the plants are to remain: when they come up they must be thinned, leaving them near two feet asunder, and kept clean from weeds, which is all the culture they require.

The ninth sort grows naturally in *Spain* and *Portugal*; this is an annual plant like the former, but doth not branch so much, the small leaves are rounder and smoother; the foot-stalks are shorter, and seldom sustain more than two flowers, these are succeeded by two very narrow pods, which hang downward.

The tenth sort grows naturally in the south of *France*; this hath a perennial root, from which is sent out several hairy stalks near a foot long, garnished with trifoliate hairy leaves standing upon short foot-stalks, with two appendages at the base of the foot-stalk; the flowers stand upon pretty long foot-stalks singly, which rise from the end of the branches. The flowers are yellow, standing erect, and are succeeded by taper erect pods an inch and a half long. It is propagated by seeds, which should be sown where the plants are to remain, and must be treated as the two former sorts, but the roots of this will continue several years.

The eleventh sort grows naturally in *Sicily* and *Crete*, where the pods are eaten by the poorer inhabitants when they are young. It also grows about *Nice*. This is an annual plant, from whose roots come out several trailing stalks a foot long, garnished at each joint with trifoliate roundish leaves having appendages. The flowers stand singly upon long foot-stalks, which arise from the side of the branches; they are yellow, small, and are succeeded by single pods which are thick, and arched with a deep furrow on the outside. In cold summers the seeds will not ripen here. This must have the same culture as the annual sorts before-mentioned.

The twelfth sort grows near the borders of the sea in *France*, *Spain*, and *Italy*; this hath a perennial root, sending out many slender stalks about a foot and a half long, which trail upon the ground, garnished with trifoliate leaves, which are smooth, and have two appendages to the base of the foot-stalk. The flowers stand singly upon very long foot-stalks, arising from the wings of the stalk; they are yellow, and are succeeded by single pods near two inches long, having four leafy membranes running longitudinally at the four corners. It is propagated by seed in the same way as the tenth sort.

The thirteenth sort grows naturally in the south of *France* and in *Italy*; this is an annual plant, from whose roots are sent forth several branching stalks a foot long, garnished with trifoliate leaves, whose lobes are acute-pointed, and have two oblong oval appendages at the base of their foot-stalks; the foot-stalks of the flowers arise from the wings of the branches, each sustaining two yellow flowers, which are succeeded by taper pods, having four leafy membranes running longitudinally their length. It is propagated by seeds, in the same way as the annual sorts before-mentioned.

The fourteenth sort grows naturally in *Sicily*, but has been long cultivated in the *English* gardens; it was formerly cultivated as an esculent plant. The green pods of it were dressed and eaten as Peas, which the inhabitants of some of the northern counties still continue, but they are very coarse, so not agreeable to the taste of those who have been accustomed to better fare.

It is an annual plant, which is cultivated in the flower-gardens near *London* for ornament. This sends out from the root several decumbent stalks about a foot long, garnished with trifoliate oval leaves, with two appendages at the base of their foot-stalks; from each joint arise alternately the foot-stalks of the flowers, each sustaining one large red flower at the top, with three leaves just under the flower. After the flower fades, the germen becomes a swelling taper pod, having four leafy membranes or wings running longitudinally.

The seeds of this sort are commonly sown in patches, five or six seeds being sown near each other, in the borders of the pleasure-garden, where they are designed to remain. If the seeds do all grow, some of the plants may be pulled up, leaving only two or three in each patch; afterward they will require no other care but to keep them clean from weeds.

The fifteenth sort grows near the borders of the sea, in the south of *France* and *Spain*. This is a perennial plant, sending out from the root many stalks, garnished with roundish trifoliate leaves with two appendages, covered with a woolly down; the flowers stand upon short foot-stalks, four or six growing in a divided head; they are yellow, and are succeeded by taper pods filled with roundish seeds. This is propagated by seeds, which should be sown in the spring in the place where the plants are to remain, and must be treated in the same manner as the hardy perennial sorts before-mentioned.

The sixteenth sort grows naturally in the island of *St. James*. This has a slender stalk, which is woody, rising from two to three feet high, sending out many slender herbaceous branches, garnished with narrow gray leaves, which are sometimes trifoliate, and at others there are five narrow lobes to each; these sit close to the branches. The flowers are produced from the side of the stalks towards their end, upon very slender foot-stalks, each sustaining four or five flowers collected in a head of a yellowish deep purple colour, which are succeeded by taper slender pods little more than an inch long, containing five or six small roundish seeds. It is too tender to live abroad in *England*, so the plants must be kept in pots, and in the winter placed in a warm airy glass-case, but in the summer they should be placed abroad in a sheltered situation. It may be easily propagated by cuttings during the summer season, in the same way as the fifth sort, and also by seeds; but the plants which have been two or three times propagated by cuttings, seldom are fruitful.

The seventeenth sort grows naturally about *Montpelier*. It rises with weak shrubby stalks three or four feet high, sending out many slender branches, which are thinly garnished with small hoary leaves, composed of five lobes in form of a hand, which sit close to the branches. The flowers are produced at the extremity of the branches in small heads; they are very small, so make no great appearance, and are succeeded by short pods, containing two or three small round seeds. This shrub will live in the open air, if it is planted in a dry soil and a warm situation. It is propagated by seeds, which will come up in any common border.

LOTUS ARBOR. See *Celtis*.

LOVE-APPLE. See *Lycopersicon*.

LUDVIGIA. *Lin. Gen. Plant.* 142.

The Characters are,

The flower consists of four spear-shaped petals, which are equal. In the center of the flower is situated four stamina. The germen, which sits under the flower, afterward becomes a four-cornered fruit, crowned with the empalement, and has four cells, which are full of small seeds.

We have but one Species of this genus in the *English* gardens at present, which is,

LUDVIGIA foliis alternis lanceolatis. *Lin. Sp. Plant.* 118. Ludvigia with alternate spear-shaped leaves.

We have no *English* name for this plant, but it is very near akin to the *Onagra*, or *Tree Primrose*.

This plant grows naturally in *South America*. It is annual, and rises with an upright branching stalk a foot high, garnished with spear-shaped leaves placed alternate. The flowers come out singly at the foot-stalks of the leaves; they are composed of four small yellow petals, standing upon short foot-stalks, and are succeeded by roundish seed-vessels with four leafy membranes; they open in four cells, including many small seeds.

The plants must be raised in a hot-bed in the spring, and treated in the same manner as hath been directed for the *Amaranthus*; for if they are not brought forward in the spring, they seldom produce good seeds in *England*.

LUFFA. See *Momordica*.

LUNARIA. *Tourn. Inst. R. H.* 218. tab. Gen. 105. Sattin-flower, or *Honesty*.

The Characters are,

The flower has four petals, placed in form of a cross, which are entire. It hath six awl-shaped stamina; four of these are the length of the empalement, the other two are shorter; and an oblong oval germen, which afterward becomes an erect, plain, compressed, elliptical pod, sitting upon a small foot-stalk, terminated by the style, having two cells opening with two valves, which are parallel, inclosing several compressed kidney-shaped seeds, which are bordered, sitting in the middle of the pod.

The Species are,

1. LUNARIA filiculis oblongis. *Lin. Sp. Plant.* 653. Sattin-flower with oblong pods.

2. LUNARIA filiculis subrotundis. *Lin. Sp. Plant.* 653. Sattin-flower with a rounder pod.

3. LUNARIA foliis supra decompositis, foliolis trifidis, filiculis oblongis pendulis. Moonwort with leaves decomposed, whose lobes are trifid, and oblong hanging pods.

4. LUNARIA perennis, filiculis oblongis, foliis lanceolatis incanis. Perennial Moonwort with oblong pods, and spear-shaped hoary leaves.

The first sort grows naturally in *Hungary*, *Isiria*, and *Austria*. It is a biennial plant, which perishes soon after the seeds are ripe; it rises with a branching stalk from two to three feet high, covered with a reddish hairy bark, sending out branches on every side from the ground upward, garnished with heart-shaped leaves placed alternately, ending in acute points. The flowers terminate the branches in clusters; they are composed of four purplish heart-shaped petals, placed in form of a cross. These are succeeded by large, flat, roundish pods with two cells, inclosing two rows of flat kidney-shaped seeds, which have a border round them. These pods, when ripe, turn to a clear white or fawn colour, and are transparent.

This is propagated by seeds, which should be sown in the autumn, for those which are sown in the spring often miscarry, or lie a long time in the ground. The plants will grow in almost any soil, but love a shady situation. They require no other culture, but to keep them clean from weeds. If the seeds are permitted to scatter, the plants will rise without any further care; and if they are left unre-moved, they will grow much larger than those which are transplanted.

The second sort grows naturally upon the mountains in *Italy*. This hath stalks and leaves very like the first, but the flowers are rather larger, and of a lighter purple colour; but the principal difference is in the pods of this being longer and narrower than those of the other; it requires the same culture.

The third sort is an annual plant, which grows naturally in *Egypt*. This rises with a smooth branching stalk a foot high, garnished with winged leaves, composed of several pair of lobes ranged along the midrib, terminated by an

odd one; these lobes are of unequal sizes, and vary in their form; some of them are almost entire, and others are cut at their extremities into three parts; they are smooth, and of a lucid green. The flowers stand upon pretty long slender foot-stalks, which come out from the side, and at the end of the branches, in loose small clusters; they are of a purple colour, and are succeeded by oblong compressed pods, which hang downward.

This is propagated by seeds, which should be sown upon an open border where the plants are to remain; if they are sown soon after they are ripe, the plants will come up in the autumn, and live through the winter without shelter, and these will flower early the following summer. When the plants come up, they will require no other care, but to keep them clean from weeds, and thin them where they are too close. If the seeds are permitted to scatter in the autumn, the plants will rise without care, and may be treated in the same way.

The fourth sort grows naturally in the *Archipelago*. This is biennial; the stalks rise a foot high, covered with a white hairy bark, garnished with spear-shaped hoary leaves fitting close to the branches. The branches are terminated by loose spikes of yellow flowers, which are succeeded by oblong flat pods, containing flat kidney-shaped seeds, which ripen in the autumn.

This sort is propagated by seeds, which, if sown in the autumn, will succeed better than in the spring; they should be sown on a warm border and a dry poor soil, otherwise they will not live through the winter, but in a rubbishing soil the plants will do best.

LUPINUS. *Tourn. Inst. R. H.* 392. *tab.* 213. Lupine.

The Characters are,

The flower is of the butterfly kind; the standard is roundish, heart-shaped, the sides reflexed and compressed. The wings are nearly oval, and close at their base; the keel is narrow, falcated, and ends in a point. It hath ten stamina joined at their base in two bodies, but are distinct above. In the center is situated a hairy compressed germen, which after-ward becomes a large, oblong, thick-shelled pod with one cell, ending with an acute point, including several roundish compressed seeds.

The Species are,

1. LUPINUS *calycibus semiverticillatis appendiculatis, labio superiore bifido, inferiore subtridentato. Hort. Cliff.* 499. Wild Lupine, with a purple flower and a round variegated seed; commonly called the lesser blue Lupine

2. LUPINUS *calycibus alternis appendiculatis, labio superiore bipartito integro. Lin. Sp. Plant.* 721. Narrow-leaved, taller, blue Lupine.

3. LUPINUS *calycibus verticillatis appendiculatis, labio superiore bipartito, inferiore tridentato. Hort. Cliff.* 499. The common yellow Lupine.

4. LUPINUS *calycibus verticillatis appendiculatis, labio superiore inferioreque integris. Hort. Cliff.* 499. Foreign, greater, hairy Lupine, with a large blue flower; commonly called the great blue Lupine.

5. LUPINUS *calycibus alternis inappendiculatis, labio superiore integro, inferiore tridentato. Hort. Cliff.* 499. Garden or manured Lupine, with a white flower.

6. LUPINUS *calycibus alternis inappendiculatis, labio superiore emarginato, inferiore integro. Lin. Sp. Plant.* 721. Smaller, perennial, creeping, blue Lupine of *Virginia*.

The first sort grows naturally among the Corn in the south of *France* and *Italy*, and in great abundance in *Sicily*. This is an annual plant, which rises with a firm, strait, channelled stalk near three feet high, divided toward the top into several branches, garnished with hand-shaped leaves, composed of five, six, or seven oblong lobes, which join in one center at their base. The flowers are produced in spikes at the end of the branches, standing half round the stalk in

a sort of whorl; they are of a light blue colour, and are succeeded by strait taper pods with one cell, inclosing a row of roundish seeds.

It is propagated in the borders of the pleasure-garden for ornament, by sowing the seeds in *April* in the places where they are to remain; and when the plants come up, they should be thinned where they are too close, and kept clean from weeds, which is all the culture they require.

The second sort has much the appearance of the first, but the stalks rise higher; the leaves have more lobes, and stand upon longer foot-stalks; the lobes are blunt-pointed, and the seeds are variegated. This requires the same culture as the first, and flowers at the same time.

The third sort is the common yellow Lupine; this grows naturally in *Sicily*. It rises about a foot high, with a branching stalk, garnished with hand-shaped leaves, composed of nine narrow hairy lobes, which join at their base to the foot-stalks. The flowers are yellow, and are produced in loose spikes at the end of the branches, standing in whorls round the stalks. These are succeeded by flattish hairy pods about two inches long, inclosing four or five roundish seeds, a little compressed on their side. This sort flowers at the same time as the former; but to have a succession of the flowers, the seeds are sown at different times, *viz.* in *April*, *May*, and *June*, but those only which are first sown, will ripen their seeds. It may be cultivated in the same manner as the two former, and is equally hardy.

The fourth sort is supposed to be a native of *India*. It is an annual plant, which rises with a strong, firm, channelled stalk, from three to four feet high, covered with a soft brownish down, dividing upward into several strong branches, garnished with hand-shaped leaves, composed of nine, ten, or eleven wedge shaped hairy lobes, which are narrow at their base, where they join the foot stalk. The flowers are placed in whorls round the stalks above each other, forming a loose spike at the end of the branches; they are large, and of a beautiful blue colour, but have no scent. The pods of this sort are large, almost an inch broad and three inches long, inclosing three large roundish seeds compressed on their sides, very rough, and of a purplish brown colour. There is a variety of this with flesh coloured flowers, which is commonly called the Rose Lupine; it differs from the blue only in the colour of the flower, but this difference is permanent, for neither of the sorts vary.

This is generally late in the ripening of the seeds, so that unless the autumn proves warm and dry, they do not ripen well in *England*; therefore the best way to have good seeds, is to sow them in *September*, close to a warm wall on dry ground, where they will live through our ordinary winters; and these plants will flower early the following summer, so there will be time for the seeds to ripen before the rains fall in the autumn, which frequently causes the seeds to rot which are not ripe.

The fifth sort grows naturally in the *Levant*, but is cultivated in some parts of *Italy*, as other pulse for food. This hath a thick upright stalk about two feet high, which divides toward the top into smaller branches, garnished with hand-shaped leaves, composed of seven or eight narrow, oblong, hairy lobes, which join at their base, of a dark grayish colour, with a silvery down. The flowers are produced in loose spikes at the end of the branches; they are white, and sit close to the stalk, and are succeeded by hairy strait pods about three inches long, a little compressed on the sides, which contain five or six flattish white seeds, having a little cavity like a navel, in that part which is fixed to the pod. This is an annual plant, which is cultivated for ornament in the pleasure-garden. The seeds must be sown in the places where the plants are to remain, and may be treated in the same way as the first sort.

The sixth sort grows naturally in *Virginia*, and other of the northern parts of *America*. It hath a perennial creeping root, from which arise several erect channelled stalks a foot and a half high, garnished with hand-shaped leaves, composed of ten or eleven spear-shaped lobes, which join at their base. The flowers grow in long loose spikes, which terminate the stalks, and are placed without order on every side the stalk; they are of a pale blue colour, and are succeeded by pods, having three or four seeds, which ripen in *August*, and are soon scattered if they be not gathered; for after a little moisture, the sun causes the pods to open with an elasticity, and cast out the seeds to a distance. This sort is propagated by seeds as the former; which should be sown where the plants are to remain; for although the root is perennial, yet it runs so deep into the ground, as that it cannot be taken up entire; and if the root is cut or broken, the plant never thrives well after. I have traced some of the roots of this plant, which have been three feet deep in the ground in one year from seed; they also spread out far on every side, so that they must have room, therefore the young plants should not be left nearer than three feet asunder.

LUPULUS. *Tourn. Inst. R. H. 535. tab. 309.* The Hop.

The Characters are,

It has male and female flowers upon different plants. The male flower hath no petal, but has five short hairy stamina. The female flowers have neither petal or stamina, but a small germen situated in the center, which afterward turns to a roundish seed covered with a thick skin, inclosed in the base of the empalement.

We have but one Species of this genus, viz.

LUPULUS mas & femina. C. B. P. 298. Male and female Hop.

The male Hop grows wild by the side of hedges and upon banks, in many parts of *England*. The young shoots of these plants are often gathered by the poor people, and boiled as an esculent herb; but these must be taken very young, otherwise they are tough and stringy. This is easily distinguished by the flowers, which are small, and hang in long loose bunches from the side of the stalks, abounding with farina on their summits, and have no Hops succeeding to the flowers.

The female Hop is the sort which is cultivated for use; of this sort, the people who cultivate them reckon three different varieties: as first, the long and square Garlick Hop, the long white Hop, and the oval Hop, all which are indifferently cultivated in *England*.

There being the greatest plantation of Hops in *Kent* of any county in *England*, it is very probable, that their method of planting and ordering them should be the best.

As for the choice of their Hop-grounds, they esteem the richest and strongest grounds as the most proper; and if it be rocky within two or three feet of the surface, the Hops will prosper well; but they will by no means thrive on a stiff clay, or spongy wet land.

The *Kentish* planters account new land best for Hops; they plant their Hop-gardens with Apple trees at a large distance, and with Cherry trees between; and when the land hath done its best for Hops, which they reckon it will in about ten years, the trees may begin to bear. The Cherry trees last about thirty years, and by that time the Apple trees are large, they cut down the Cherry trees.

As to the situation of a Hop-ground, one that inclines to the south or west is the most eligible, but if it be exposed to the north-east or south-west winds, there should be a shelter of some trees at a distance, because the north-east winds are apt to nip the tender shoots in the spring, and the south-west winds frequently break and blow down the poles at the latter end of the summer, and very much endanger the Hops.

Hops require to be planted in a situation so open, as that the

air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middles of large plantations, while the outsides remain unhurt.

As for the preparation of the ground for planting, it should, the autumn before, be ploughed and harrowed even, and then lay upon it in heaps a good quantity of fresh rich earth, or well rotted dung and earth mixed together, sufficient to put half a bushel in every hole to plant the Hops in, unless the natural ground be very fresh and good.

The hills where the Hops are to be planted, should be ten feet asunder, that the air may freely pass between them; for in close plantations, they are very subject to what the Hop-planters call the fire-blast.

If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares checquerwise; but if the ground is so small, that it may be done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants, as to the kind of Hop; for if the Hop-garden be planted with a mixture of several sorts of Hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner.

The two best sorts are the white and the gray bind; the latter is a large square Hop, more hardy, and is the more plentiful bearer, and ripens later than the former.

There is also another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer and a less plentiful bearer, but it has this advantage, it comes first to market.

But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this conveniency, that they may be picked successively as they become ripe.

If there be a sort of Hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the Hops are tied, cutting off the tops, and burying them in the hill; or when the Hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting Hops, the *Kentish* planters best approve the months of *October* and *March*, both which sometimes succeed very well; but the sets are not to be had in *October*, unless from some ground that is to be destroyed; and likewise there is some danger that the sets may be rotted, if the winter prove very wet; therefore the most usual time of procuring them is in *March*, when the Hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping, the tops meeting at the center; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it.

The ground being thus planted, all that is to be done more that summer, is to keep the hills clear from weeds, and to dig up the ground about the month of *May*, and to raise a small hill round about the plants; in *June* you must twist the young binds or branches together into a bunch or knot; for if they are tied up to small poles the first year, in order to have a few Hops from them, it will not countervail the weakening of the plants.

A mixture of compost or dung being prepared for your Hop-ground, the best time for laying it on, if the weather prove dry, is about *Michaelmas*, that the wheels of the dung-

cart may not injure the Hops, nor furrow the ground: if this be not done then, you must be obliged to wait till the frost has hardened the ground, so as to bear the dung-cart; and this is also the time to carry on your new poles, to recruit those that are decayed, and to be cast out every year.

If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require, will be forty loads to an acre, reckoning about thirty bushels to the load.

If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or a third; for there is no occasion to dung the ground after this manner, oftener than once in three years.

Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about *November*, or in the spring; which last some account the best time, when the Hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to be very well rotted and fine.

As to the dressing of the Hops, when the Hop-ground is dug in *February* or *March*, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it.

About the end of *February*, if the Hops were planted the spring before, or if the ground be weak, they ought to be dressed in dry weather; but else, if the ground be strong and in perfection, the middle of *March* will be a good time; and the latter end of *March*, if it be apt to produce over-rank binds, may be soon enough.

Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds the last year; and also all the young suckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low that was left highest the preceding year. By pursuing this method, you may expect to have stronger buds, and also keep the hill in good order.

In dressing those Hops that have been planted the year before, you ought to cut off both the dead tops, and the young suckers, which have sprung up from the sets, and also to cover the stocks with fine earth a finger's length in thickness.

About the middle of *April* the Hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hills as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a space between two poles ought to be left open to the south, to admit the sun beams.

The poles ought to be in length sixteen or twenty feet, more or less, according as the ground is in strength; and great care is to be taken not to overpole a young or weak ground, for that will draw the stock too much, and weaken it. If a ground be overpoled, you are not to expect a good crop from it; for the branches, which bear the Hops, will grow very little, till the binds have over-reached the poles, which they cannot do when the poles are too long. Two small poles are sufficient for a ground that is young.

If you wait till the sprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largest poles; but if you stay till they are so long as to fall into the alleys, it will be in-

jurious to them, because they will entangle one with another, and will not clasp about the pole readily.

Maple or Aspen poles are accounted the best for Hops, on which they are thought to prosper best, because of their warmth; or else, because the climbing of the Hop is furthered by means of the roughness of the bark. But for lastingness, Ashen or Willow poles are preferable; but Chestnut poles are the most durable of all.

If after the Hops are grown up, you find any of them have been under-poled, taller poles may be placed near those that are too short, to receive the binds from them.

As to the tying of Hops, the buds that do not clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered Rushes, but not so close as to hinder them from climbing up the pole.

This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground be young, then none of these useless binds should be plucked up, but should be wrapt up together in the middle of the hill.

When the binds are grown beyond the reach of your hands, if they forsake the poles, you should make use of a stand-ladder in tying them up.

Towards the latter end of *May*, when you have made an end of tying them, the ground must have the summer dressing: this is done by casting up with the spade some fine earth into every hill; and a month after this is done, you must hoe the alleys with a *Dutch* hoe, and make the hills up to a convenient bigness.

When the Hops blow, you should observe if there be any wild barren hills among them, and mark them, by driving a sharpened stick into every such hill, that they may be digged up and replanted.

Hops, as well as other vegetables, are liable to distempers and disasters, and among the rest to the fen.

The Rev. Dr. *Hales*, in his excellent treatise of *Vegetable Staticks*, treating of Hops, gives us the following account of the state of Hops in *Kent*, in the year 1725, that he received from Mr. *Austen* of *Canterbury*, which is as follows:

In mid *April* not half the shoots appeared above ground, so that the planters knew not how to pole them to the best advantage.

This defect of the shoot, upon opening the hills, was found to be owing to the multitude and variety of vermin that lay preying upon the roots; the increase of which, was imputed to the long and almost uninterrupted series of dry weather for three months before. Towards the end of *April*, many of the Hop vines were infested with flies.

About the 20th of *May* there was a very unequal appearance, some vines being run seven feet, others not above three or four; some just tied to the poles, and some not visible; and this disproportionate inequality in their size, continued through the whole time of their growth.

The flies now appeared upon the leaves of the forwardest vines, but not in such numbers here, as they did in most other places. About the middle of *June* the flies increased, yet not so as to endanger the crop; but in distant plantations they were exceedingly multiplied, so as to swarm towards the end of the month.

June the 27th some specks of fen appeared. From this day to the 9th of *July* was very dry weather. At this time, when it was said that the Hops in most parts of the kingdom looked black and sickly, and seemed past recovery, ours held it out pretty well, in the opinion of the most skilful planters.

The great leaves were indeed discoloured, and a little withered, and the fen was somewhat increased. From the 9th of *July* to the 23d, the fen increased a great deal; but the flies and lice decreased, it raining much daily. In a week more the fen, which seemed to be almost at a stand, was considerably increased, especially in those grounds where it first appeared.

About the middle of *August* the vines had done growing both in stem and branch, and the forwardest began to be in the Hop, the rest in bloom; the fen continued spreading where it was not before perceived; and not only the leaves, but many of the burs were also tainted with it.

About the 20th of *August* some of the Hops were infected with the fen, and whole branches corrupted by it. Half the plantations had pretty well escaped hitherto, and from this time the fen increased but little; but several days wind and rain the following week so distorted them, that many of them began to dwindle, and at last came to nothing; and of those that then remained in bloom, some never turned to Hops; and of the rest which did, many of them were so small, that they very little exceeded the bigness of a good thriving bur.

We did not begin to pick till the 8th of *September*, which is eighteen days later than we began the year before; the crop was little above two hundred on an acre round, and not good. The best Hops sold this year at *Way-hill*, for 16*l.* the hundred.

About the middle of *July* Hops begin to blow, and will be ready to gather about *Bartholomew Tide*. A judgment may be made of their ripeness, by their strong scent, their hardness, and the brownish colour of their seed.

When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage, by breaking the branches, and bruising and discolouring the Hops; and it is very well known that Hops, being picked green and bright, will sell for a third part more than those which are discoloured and brown.

The most convenient way of picking them is into a long square frame of wood, called a bin, with a cloth hanging on tenter-hooks within it, to receive the Hops as they are picked.

The frame is composed of four pieces of wood joined together, supported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this serves to lay the poles upon, which are to be picked.

This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and six or eight persons may work at it, three or four on each side.

It will be best to begin to pick the Hops on the east or north side of your ground, if you can do it conveniently; this will prevent the south-west wind from breaking into the garden.

Having made choice of a plot of the ground containing eleven hills square, place the bin upon the hill, which is in the center, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole Hop-ground is finished.

When the poles are drawn up to be picked, you must take great care not to cut the binds too near the hills, especially when the Hops are green, because it will make the sap to flow excessively.

The Hops must be picked very clean, *i. e.* free from leaves and stalks; and, as there shall be occasion, two or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln, in order to be dried; for if they should

be long in the bin or bag, they will be apt to heat, and be discoloured.

If the weather be hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the Hops are dry; this will save some expence in firing, and preserve their colour better when they are dried.

The best method of drying Hops is with charcoal on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for the making it, since every carpenter or bricklayer, in those countries where Hops grow, or malt is made, knows how to build them.

The kiln ought to be square, and may be of ten, twelve, fourteen, or sixteen feet over at the top, where the Hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and the breadth of the kiln, and the beguels of the steddle where the fire is kept, *viz.* if the kiln be twelve feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionable in other dimensions.

The Hops must be spread even upon the oast a foot thick or more, if the depth of the curb will allow it, but care is to be taken not to overload the oast, if the Hops be green or wet.

The oast ought to be first warmed with a fire before the Hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the Hops; nor must it be suffered to sink or slacken, but rather be increased till the Hops be nearer dried, lest the moisture or sweat, which the fire has raised, fall back or discolour them. When they have lain about nine hours, they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried, by the brittleness of the stalks, and the easy falling off of the Hop leaves.

It is found by experience, that the turning of Hops, though it be after the most easy and best manner, is not only an injury or waste to the Hops, but also an expence of fuel and time, because they require as much fuel, and as long a time to dry a small quantity, by turning them, as a large one.

Now this may be prevented, by having a cover, (to be let down and raised at pleasure) to the upper bed whereon the Hops lie.

This cover may also be tinned, by nailing single tin plates over the face of it, so that when the Hops begin to dry, and are ready to burn, *i. e.* when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the Hops (like a reverberatory), which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every Hop be equally dried.

As soon as the Hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen, for if they are bagged immediately, they will powder, but if they lie awhile (and the longer they lie the better, provided they be covered close with blankets to secure them from the air,) they may be bagged with more safety, as not being liable to be broken to powder in treading, and this will make them bear treading the better, and the harder they are trodden the better they will keep.

The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a hop-bag (which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of Hops, they tie a handful of Hops in each lower corner of the bag, to serve as handles

to it, and they fasten the mouth of the hole, so placed that the hoop may rest upon the edges of the hole.

Then he that is to tread the Hops down into the bag, treads the Hops on every side, another person continually putting them in as he treads them, till the bag is full, which being well filled and trodden, they unrip the fastening of the bag to the hoops, and let it down, and close up the mouth of the bag, tying up a handful of Hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, they will keep good several years; but care must be taken, that they be neither destroyed nor spoiled by the mice making their nests in them.

The crop of Hops being thus bestowed, you are to provide for another, first by taking care of the poles against another year, which are best to be laid up in a shed, having first stripped off the haulm from them; but if you have not that conveniency, set up three poles in the form of a triangle, or six poles (as you please) wide at bottom; and having set them into the ground, with an iron picker, and bound them together at the top, set the rest of your poles about them; and being thus disposed, none but those on the outside will be subject to the injuries of the weather, for all the inner poles will be kept dry, unless at the top; whereas, if they were on the ground, they would receive more damage in a fortnight, than by their standing all the rest of the year.

In the winter time provide your soil and manure for the Hop-ground against the following spring.

If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your Hop-hills; but if it be new dung, then let it be mixed as before, till the spring come twelvemonths, for new dung is very injurious to Hops.

Dung of all sorts was formerly more commonly made use of than it is now, especially when rotted, and turned to mould, and they who have no other manure must use it; which, if they do, cows or hogs-dung, or human ordure mixed with mud, may be a proper compost, because Hops delight most in a manure that is cool and moist.

LUTEOLA. See Reseda.

LYCHNIDEA. See Phlox.

LYCHNIS. *Turn. Inst. R. H. 333. tab. 175.* Champion.

The Characters are,

The flower hath five petals, whose tails are the length of the empalement. It hath ten stamina, which are alternately ranged, and fastened to the tails of the petals. In the center is situated an almost oval germen. The empalement afterward becomes an oval capsule with one cell, opening with five valves, filled with roundish seeds.

The Species are,

1. LYCHNIS *floribus fasciculatis fastigiatis.* Hort. Cliff. 174. Greater hairy Champion with a scarlet flower.
2. LYCHNIS *petalis integris.* Lin. Sp. Plant. 436. Champion with entire petals; commonly called the Single Catchfly.
3. LYCHNIS *floribus dioicis.* Hort. Cliff. 171. Champion with male and female flowers on different plants; frequently called Bachelors Button.
4. LYCHNIS *floribus dioicis, calycibus inflatis hirsutis.* Wild Champion with a single white flower.
5. LYCHNIS *petalis quadrifidis, fructu subrotundo.* Hort. Cliff. 174. Champion with quadrifid petals, and a roundish fruit; commonly called Ragged Robin.
6. LYCHNIS *petalis bifidis corymbosis.* Lin. Sp. Plant. 436. Champion with bifid petals, and flowers growing in a corymbus.
7. LYCHNIS *petalis bifidis, caule dichotomo, foliis subhirsutis.* Lin. Sp. Plant. 437. Champion with bifid petals, a stalk divided by pairs, and leaves which are somewhat hairy.

8. LYCHNIS *caule erecto, calycibus striatis acutis, petalis dissectis.* Fig. Plant. Plat. 170. Champion with an erect stalk, striped acute empalements, and petals cut into many parts.

The first sort here mentioned is commonly known by the title of scarlet Lychnis; of which there is one with double flowers, which is most esteemed for the size of the flowers and multiplicity of the petals; as also for the duration of the flowers, which continue much longer in beauty than the single flowers, so that the latter is not much cultivated at present, though the flowers of this are very beautiful; and as the plants are so easily propagated by seed, they may soon be had in greater plenty than those with double flowers, which do not produce seeds. Of the single sort there are three varieties, the deep scarlet, the flesh colour, and the white, but the first is the most beautiful.

This is easily propagated by seeds, which should be sown on a border exposed to the east, in the middle of *March*. The plants will appear in *April*, and by the end of *June* they will be fit to remove, when there should be a bed of common earth prepared to receive them, into which they should be planted at about four inches apart, observing to water and shade them till they have taken root; after which time they will require no other care but to keep them clean from weeds till the following autumn, when they should be transplanted into the borders of the pleasure-garden where they are to continue. The summer following these plants will flower and produce ripe seed, but the roots will abide several years, and continue to flower.

The sort with double flowers is a valuable plant; the flowers are very double, and of a beautiful scarlet colour. This hath a perennial root, from which arise two, three, or four stalks, according to the strength of the roots, which in rich moist land grow upwards of four feet high; the stalks are strong, erect, and hairy, garnished the whole length with spear-shaped leaves, embracing the stalks; these are placed opposite. The flowers are produced in close clusters sitting upon the top of the stalk; the flowers are double, and of a bright scarlet colour. They appear the latter end of *June*, and in moderate seasons continue near a month in beauty. This was originally produced from the seeds of the single sort, and is propagated by slips from the roots in autumn; but as this is a slow method of increasing the plants, so the best way to have them in plenty is to cut off the stalks in *June*, before the flowers appear, which may be cut into small lengths, each of which should have three joints; these cuttings should be planted on an east border of soft loamy earth, putting two of the joints into the ground, leaving one eye just level with the surface; these must be watered, and then covered close with bell or hand-glasses, so as to exclude the outward air, and shaded with mats when the sun shines hot upon them. The cuttings so managed will put out roots in six weeks or two months, when they must be exposed to the open air. These will make good plants by autumn, when they may be transplanted into the borders of the pleasure-garden, where they will flower the following summer.

I have not seen any double flowers of the two other varieties, but have been informed that there are of both the white and the flesh colour with double flowers in some of the *French* gardens. These make a variety, but are not so beautiful as the scarlet, so are not much esteemed.

The second sort is commonly called Red German Catchfly. This hath been found growing naturally upon the rocks in *Edinburgh* park, and in some places in *Wales*. It was formerly cultivated in flower-gardens for ornament; but since this sort with double flowers hath been produced, the single has been almost banished out of the gardens. This hath long narrow Grass like leaves, which come out from the

root without order, sitting close to the ground; between these come up strait single stalks, which in good ground rise a foot and a half high; at each joint of the stalk come out two leaves opposite, of the same form as the lower, but decrease in their size upward; under each pair of leaves, for an inch in length, there sweats out of the stalk a glutinous liquor, which is almost as clammy as birdlime; so that the flies, which happen to light upon these places, are fastened to the stalk where they die, from whence it had the title of Catchfly. The stalk is terminated by a cluster of purple flowers, and from the two upper joints come out on each side the stalk a cluster of the same flowers, so that the whole form a sort of loose spike. These appear in the beginning of *May*, and are succeeded by roundish seed-vessels, which are full of small angular seeds, ripening in *July*.

It may be propagated in plenty by parting of the roots in autumn, at which time every slip will grow; or if the seeds are sown in the same manner as is directed for the first sort, the plants may be raised in plenty. This delights in a light moist soil, and a shady situation.

The double flowering of this sort was accidentally obtained from the seeds of the single. This has not been known much more than forty years in the *English* gardens, but it is now so common as to have excluded that with single flowers; it differs only from that in having very double flowers. As this never produces seeds, so it can only be propagated by parting and slipping of the roots; the best time for this is in autumn, at which time every slip will grow. If this is performed in *September*, the slips will have taken good root before the frost, and will flower well the following summer; but if they are expected to flower strong, the roots must not be divided into small slips, though for multiplying of the plants it matters not how small the slips are. These should be planted on a border exposed to the morning sun, and shaded when the sun is warm, till they have taken root. If the slips are planted in the beginning of *September*, they will be rooted strong enough to plant in the borders of the flower-garden, by the middle or latter end of *October*. The roots of this sort multiply so fast, as to make it necessary to transplant and part them every year; for when they are let remain longer, they are very apt to rot. This requires the same soil and situation as the former.

The third sort grows naturally by the side of ditches, and in moist pastures in many parts of *England*, so is seldom admitted into gardens. It hath a perennial root, from which arise many branching diffused stalks, from two to three feet high, garnished with oval acute-pointed leaves, placed by pairs at each joint, and are terminated by clusters of purple flowers, which appear in *April* and *May*. The male flowers grow upon separate plants from the female. The latter produces seeds which ripen in *July*; the stalks decay in autumn, but the roots continue several years.

There is a variety of this with double flowers, which is cultivated in gardens, by the title of Red Bachelors Button. This is an ornamental plant, and continues long in flower. It is propagated by slips, which should be planted the beginning of *August* in a shady border of loamy earth, where they will take root in about six weeks or two months, and may then be transplanted into the borders of the flower-garden. These roots should be annually transplanted, otherwise they frequently rot; and young plants must be propagated by slips, to supply the decay of the old roots, which are not of very long duration. This thrives best in a soft loamy soil, and in a shady situation, where they have only the morning sun.

The fourth sort is very common upon dry banks on the side of roads, in most parts of *England*, so is not admitted into gardens. There is a variety of this with purple flowers, which I find is by some supposed to be the same as the

third, but is very different, for the stalks of this are branched out much more; the leaves are longer and more veined, and the flowers of this stand singly upon pretty long foot-stalks, so are not produced in clusters like those of the third. This is also very hairy, and the empalement of the flowers is swollen like inflated bladders. This flowers near a month after the other, but the male and female flowers grow upon different plants, as in the former.

There is a variety of this with double flowers, which is propagated in gardens by the title of double white Bachelors Button, and is an ornamental plant in the flower-garden, though being white it doth not make so good an appearance as the other; however, it adds to the variety. This is propagated in the same way as the double sort before-mentioned, but the plants will thrive in a drier soil, and a more open exposure than that.

The fifth sort grows very common in moist meadows, and by the side of rivers in most parts of *England*, where it is intermixed with the Grass. This rises with upright unbranched stalks near a foot and a half high, garnished with narrow spear-shaped leaves, placed opposite at each joint. The stalks are slender, channelled, and are terminated by six or seven purple flowers, upon pretty long foot-stalks which branch out. The empalement of the flower is striped with purple, and the petals of the flowers are deeply jagged in four narrow segments, which appear as if torn; from whence the country people have given it the appellation of Ragged Robin. This sort is never kept in gardens, but there is a variety of it with double flowers, which is propagated by the gardeners for ornament. It only differs from the single in the multiplicity of the petals, and produces no seeds, so is propagated by slips in the same manner as the second sort. It is commonly known by the title of Double Ragged Robin.

The sixth sort grows naturally on the *Alps*, in *Lapland*, and the other cold parts of *Europe*. This is a perennial plant, which delights in a moist soil. The stalks of this are erect, half a foot high, garnished with narrow spear-shaped leaves, placed opposite like the former sort, but are a little shorter and broader. The flowers are produced in a corymbus on the top of the stalk, sitting close together; they are of a purple colour, and the petals are cut in the middle. It is propagated by seeds, and also by parting of the roots; it must have a moist soil and a shady situation, otherwise the plants will not thrive. The time for transplanting the plants and parting the roots, is the same as for the second sort.

The seventh sort grows naturally in *Siberia*. This hath a perennial root, from which arise many narrow leaves sitting close to the ground. The stalks rise a foot high, dividing into branches by pairs. The flowers grow out from the division of the branches, as also at the top of the stalks. They are composed of five white petals, which are divided in the middle, and are succeeded by roundish capsules filled with small angular seeds. This requires the same treatment as the former sort.

The eighth sort was brought from *Portugal* to *England*, and is probably a variety of one with single flowers, which grows naturally in that country, but is different from any we have in *England*. It approaches nearest to the Double Ragged Robin, but is different from that. It hath a perennial root, from which arise many oblong narrow leaves sitting close to the ground. From these come out upright stalks about nine inches high, which divide upwards by pairs; and from the middle of each division comes out a slender foot stalk two inches long, sustaining one double purple flower at the top, whose petals are very much jagged at their points; the empalements of the flowers are marked with deep purple stripes. From the side of the stalks there are also foot-stalks come out at the wings, which for the most

most part sustain but one flower, though sometimes they have two; these flowers being very double, are never succeeded by seeds. It is propagated by slips in the same manner as the third and fourth sorts, but coming from a warm country, it is impatient of much cold, and requires a particular treatment, for it does not thrive well in pots, nor will it live through the winter in open borders; so that the only situation in which I have seen it thrive, was where it was planted as close as possible to a south wall, in dry undunged earth; for in rich or moist ground the roots presently rot, as they also do when they are watered. If they are planted in brick rubbish, they will still do better. I was favoured with this plant by *John Browning, Esq;* of *Lincoln's-Inn*, who received it from *Portugal*.

The other *Species* of *LYCHNIS* are now ranged under the following genera, *viz.*

AGROSTEMMA, *CUCULABUS*, *SAPONARIA*, and *SILENE*, to which articles the reader is desired to turn for those which are not here enumerated.

LYCIUM. *Lin. Gen. Plant.* 232. Boxthorn.

The *Characters* are,

The flower is funnel-shaped, of one petal, with an incurved tube, whose brim is cut into five obtuse segments. It has five awl-shaped stamina. In the center is situated a roundish germen, which afterward becomes a roundish berry with two cells, inclosing kidney-shaped seeds fastened to the middle partition.

The *Species* are,

1. *LYCIUM foliis lineari-longioribus, tubo florum longiori, segmentis obtusis.* Boxthorn with longer linear leaves, a longer tube to the flower, and obtuse segments.

2. *LYCIUM foliis lineari-brevioribus, tubo florum breviori, segmentis ovalibus patentissimis.* Boxthorn with shorter linear leaves, a shorter tube to the flower, and oval segments spreading open.

3. *LYCIUM foliis cuneiformibus.* *Vir. Cliff.* 14. Boxthorn with wedge-shaped leaves.

4. *LYCIUM foliis lanceolatis crassiusculis, calycibus trifidis.* *Lin. Sp. Plant.* 192. Boxthorn with spear-shaped thick leaves, and trifid empalements.

5. *LYCIUM foliis ovato-lanceolatis, ramis diffusis, floribus solitariis patentibus alaribus, stylo longiori.* Boxthorn with oval spear-shaped leaves, diffused branches, and single spreading flowers proceeding from the sides of the branches, with a longer style.

6. *LYCIUM foliis lanceolatis acutis.* Boxthorn with spear-shaped acute leaves.

7. *LYCIUM foliis oblongo-ovatis, crassiusculis, confertis, spinis robustioribus.* Boxthorn with oblong, oval, thick leaves growing in clusters, and stronger spines.

8. *LYCIUM foliis lineari-lanceolatis confertis, calycibus brevibus acutis.* Boxthorn with linear spear-shaped leaves growing in clusters, and short acute empalements.

9. *LYCIUM inermis, foliis lanceolatis, alternis, perennantibus.* Smooth Boxthorn, with spear-shaped ever-green leaves placed alternate.

10. *LYCIUM foliis cordato-ovatis, sessilibus, oppositis perennantibus, spinis crassis bigeminis, floribus confertis.* *Lycium* with oval heart-shaped leaves placed opposite, which are ever-green, and sit close to the stalks, with thick double spines, and flowers growing in clusters.

The first sort grows naturally in *Spain*, *Portugal*, and at the *Cape of Good Hope*. This rises with irregular shrubby stalks ten or twelve feet high, sending out several crooked knotty branches, covered with a whitish bark, armed with long sharp spines, upon which grow many clusters of narrow leaves; these thorns often put out one or two smaller on their sides, which have some clusters of smaller leaves upon them; the branches are garnished with very narrow leaves an inch and a half long, and at the base of these

come out clusters of shorter and narrower leaves. The flowers come out from the side of the branches, standing upon short foot-stalks; they are funnel-shaped, of one petal, with a long incurved tube, cut into five obtuse segments at the brim, of a dull purple colour, and have five stamina, almost as long as the tube, with erect summits. In the center is situated a roundish germen, supporting a style which is longer than the stamina, crowned by a bifid stigma. The germen afterward turns to a roundish fleshy berry, of a yellowish colour when ripe, inclosing several hard seeds.

It may be propagated either by seeds, cuttings, or layers. If by seeds, they should be sown in the autumn soon after they are ripe, for if they are kept out of the ground till spring, they seldom come up the first year. If the seeds are sown in pots, the pots should be plunged into some old tan in the winter, and in very severe frost covered with Peas haulm or straw, but in mild weather should be open to receive the wet; in the spring the pots should be plunged into a moderate hot-bed, which will soon bring up the plants; these must be inured to bear the open air as soon as the danger of the frost is over, and when they are three inches high, they may be shaken out of the pots, and each planted in a small separate pot, and placed in the shade till they have taken new root, when they may be removed to a sheltered situation, where they may remain till the autumn; then they should be either removed into the green-house, or placed under a hot-bed frame to shelter them from hard frost; for these plants are too tender to live in the open air in *England*, so they must be kept in pots, and treated in the same way as *Myrtles*, and other hardy green-house plants; but when the plants are grown strong, there may be a few of them planted in the full ground in a warm situation, where they will live in moderate winters, but in hard frosts they are commonly destroyed. If the cuttings of these plants are planted in a shady border in *July*, and duly watered, they will take root, and may then be treated in the same way as the seedling plants.

The second sort came from the *Cape of Good Hope*. This hath an irregular shrubby stalk like the former, but seldom rises more than four or five feet high; the large leaves are shorter and a little broader than those of the first, but the tufts of small leaves are narrower; the tube of the flower is shorter, the brim is deeper, cut into oval segments which spread open; the empalement is shorter and cut into acute segments; the flowers and fruit are also smaller.

The third sort grows naturally in the hedges in the south of *France*, in *Spain*, and *Italy*. This hath many irregular shrubby stalks, which rise eight or nine feet high, sending out several irregular branches, covered with a white bark, armed with pretty strong thorns; the leaves are narrow at bottom, growing broader upward, and are of a pale green colour. The flowers come out from the side of the branches, they are of a purplish white colour and small, so make no great appearance.

It may be propagated by cuttings or layers, in the same manner as the first sort. The plants will live abroad in a sheltered warm situation, but in very hard frost they should be covered with straw or litter, otherwise the branches will be killed, and sometimes the roots are destroyed where they have not some cover.

The fourth sort was brought from *Africa* by the late *Dr. Shaw*, where it grows naturally. This hath a shrubby stalk which rises seven or eight feet high, sending out several irregular branches, which are armed with strong spines, and garnished with short, thick, spear-shaped, oval leaves, which stand without order. The flowers come out from the side of the branches, they are small and white, so make little appearance. It may be propagated by cuttings in the same

same way as the first sort, but is too tender to live in the open air in winter in this country, so the plants must be kept in pots, and removed into the green-house in autumn, and treated in the same way as other hardy kinds of green-house plants.

The fifth sort grows naturally in *China*. This has weak, irregular, diffused branches, which rise to a great height, but require support, otherwise they will trail upon the ground: I have measured some of these branches, which in one year has been upward of twelve feet long; the lower leaves are more than four inches long, and three broad in the middle, of a light green, and a thin consistence; as the shoots advance in length, so the size of the leaves diminish. The flowers come out singly at the joints toward the upper part of the branches, standing upon short slender foot-stalks; they are of a dull purple colour with short tubes; the brims are spread open broader than either of the former sorts, and the style is considerably longer than the tube of the flower. The plant is very hardy, and retains its leaves till *November* before they decay. It propagates fast enough by its creeping roots, which send out suckers at a great distance, and the cuttings thrust into the ground will take root as freely as Willows.

The sixth sort grows naturally in *China*. This rises with a shrubby stalk to a considerable height, sending out many irregular branches covered with a very white bark, and armed with a few short spines; the leaves are about three inches long, and one broad in the middle. The flowers of this sort appear in *June* and *July*, which are succeeded by small round berries, which are as red as coral. This sort is propagated by cuttings, which should be planted in the spring before they begin to shoot, in a border exposed to the morning sun, where they will take root very freely; but these should not be removed till the autumn, when they may be planted to cover high walls, for the branches are too weak to support themselves; and as the leaves continue green as long as most of the deciduous plants, so they are proper plants for such purposes, for they may be trained to a great height.

The seventh sort was brought me from the *Cape of Good Hope*. This rises with shrubby branching stalks seven or eight feet high, which are armed with long strong thorns, that have several clusters of leaves upon them; the branches are garnished with small, oblong, oval leaves, which are placed without order; sometimes they come out in small clusters from one point, at others they are single; these are of a light green, and a pretty thick consistence. The plants have not as yet flowered here, so I can give no account of them, but by the fruit, which I received entire, I make no doubt of its belonging to this genus.

This sort is pretty hardy, for it has lived abroad two winters, where it was planted against a south-east wall. It may be propagated either by layers or cuttings, in the same manner as the first; and when the plants have obtained strength, they may be planted in a warm situation, where they will live with very little shelter.

The eighth sort has much the appearance of the first, but the branches are not so strongly armed with thorns; the leaves are broader and of a lighter green, standing in clusters at every joint. The flowers are smaller, of a deeper purple colour, and have much shorter empalements, which are cut into acute segments. It flowers at the same time with the first sort, but does not produce any seeds in this country. It is not so hardy as the former sort, so requires protection from very hard frost; therefore the plants should be kept in pots, and housed in the winter, treating them in the same way as other hardy green-house plants.

The ninth sort has been long an inhabitant of the *Chelsea* garden; it was raised from seeds which came from *China*,

and was for many years taken for the Tea tree, till it produced some flowers, which discovered its true genus. This rises with a strong woody stalk six or seven feet high, sending out many branches, which are covered with a brown bark and are smooth, having no thorns; they are garnished with spear-shaped leaves about three inches long, and near three quarters of an inch broad, placed alternately on the branches, standing upon short foot stalks; they are of a deep green, and continue all the year. The flowers are white, and of the same shape with the others of this genus, but there has not been any seeds as yet produced in *England*.

This plant will live in the open air, if it is planted in a warm situation and a dry soil; but it is of slow growth, seldom shooting more than three or four inches in a season; it is also difficult to propagate, for the branches which are laid down, will not take root in less than two years, and cuttings are with difficulty made to grow.

The tenth sort grows naturally at the *Cape of Good Hope*, from whence the seeds were sent to *Holland* a few years past, where the plants were raised. This is a low shrubby plant, which sends out branches from the ground upward, which are covered with a dark green bark, and are armed with short strong thorns, which come out by pairs, and sometimes there are double pairs upon the same foot-stalk; these are situated just below the leaves, and where there are four, two of them point upward, and the other two downward. The leaves are heart-shaped, not much larger than those of the Box tree, of the same consistence and colour, terminating in acute points; they are placed opposite, upon very short foot-stalks, standing pretty close together; these continue green all the year. The flowers come out from the side of the branches, upon short slender foot-stalks, each supporting five or six small white flowers, which grow in a cluster at the top; these have very short empalements, and pretty long tubes, divided at the brim into five acute segments. These flowers have an agreeable odour, and are succeeded by oval scarlet berries, each containing two seeds.

This sort may be propagated by cuttings in the same manner as the first sort, which, if planted in *July*, and shaded from the sun, will take root very freely; then they should be planted into separate small pots, and placed in the shade till they have taken new root, after which they may be treated in the same manner as the eighth sort. This plant has not as yet been planted in the full ground in *England*, but it lives through the winter under a common frame.

The other species which were included in this genus, are now removed to *Celastrus*.

LYCOPERSICON. *Tourn. Inst. R. H. 150. tab. 63.*
Love Apples, or Tomatas.

The Characters are,

The flower has one wheel-shaped petal, with a very short tube, and a large five-cornered brim which spreads open and is plaited. It hath five small stamina which close together. It hath a roundish germen, which afterward becomes a roundish fleshy fruit or berry, divided into several cells, inclosing many flat seeds.

The Species are,

1. LYCOPERSICON caule inermi herbaceo, foliis pinnatis incisis, fructu rotundo glabro. Love Apple with an herbaceous unarmed stalk, pinnated cut leaves, and a smooth round fruit.

2. LYCOPERSICON caule herbaceo, hirsutissimo, foliis pinnatis, incisis, fructu compresso sulcato. Love Apple with a very hairy herbaceous stalk, winged cut leaves, and a compressed furrowed fruit; commonly called Tomatas by the Spaniards.

3. LYCOPERSICON caule inermi, herbaceo, erecto, foliis ovatis dentato-angulatis, subspinosis, fructu subrotundo sulcato. Love Apple with an herbaceous, erect; unarmed stalk, oval,

angular, indented leaves, with a few spines, and a roundish furrowed fruit.

4. *LYCOPERSICON caule inermi herbaceo, foliis inæqualiter pinnatis, foliolis obtuse-dentatis, racemis reflexis.* Love Apple with an herbaceous unarmed stalk, leaves unequally winged, whose lobes are bluntly indented, and reflexed spikes.

5. *LYCOPERSICON caule inermi herbaceo, foliis pinnatis, incis, undatis, stylo longiore persistente.* Love Apple with an unarmed herbaceous stalk, winged cut leaves which are waved, and a longer permanent style to the flower.

6. *LYCOPERSICON caule herbaceo, procumbente, foliis pinnatifidis, glabris, floribus solitariis alaribus.* Love Apple with an herbaceous trailing stalk, wing-pointed smooth leaves, and flowers growing singly from the wings of the stalk.

7. *LYCOPERSICON caule inermi herbaceo, foliis pinnatis integerrimis.* Love Apple with an unarmed herbaceous stalk, and winged leaves which are entire; commonly called Potatoe, by the *Indians* Batatas.

The first sort here mentioned, is supposed to be the *Lycopersicon* of *Galen*. This is an annual plant, with an herbaceous, branching, hairy stalk, which will rise to the height of five or six feet if supported, otherwise the branches will fall to the ground; garnished with winged leaves of a very rank disagreeable odour, composed of four or five pair of lobes terminated by an odd one; these are cut on their edges, and end in acute points. The flowers come out from the side of the branches, upon pretty long foot-stalks, each sustaining several yellow flowers, ranged in a single long bunch, which are succeeded by round, smooth, pulpy fruit, about the size of a large Cherry. There are two varieties of this, one with yellow, and the other with red fruit. This is the sort which is used in medicine.

The second sort is very like the first, excepting the shape and size of the fruit, which differ greatly; for those of the second sort are very large, compressed at both ends, and deeply furrowed on the sides. This never varies to the other, nor that to this, so that it is undoubtedly a distinct species. This is the sort which is commonly cultivated for soups, the *Portuguese* and *Spaniards* use them also in many of their sauces, by whom the fruit are called Tomatas.

The third sort is annual; this rises with an erect herbaceous stalk a foot and a half high, dividing into several branches, garnished with oval angular leaves, placed alternately upon pretty long foot-stalks, which have one or two short spines upon the midrib of the leaves. The flowers are white, and come out singly from the side of the branches, which are succeeded by red striated fruit, firmer than those of the other sorts, and about the size of Cherries.

The fourth sort is somewhat like the first, but the leaves are unequally winged, having some smaller lobes placed between the large ones; the lobes of this are shorter, broader, and not cut like those of the first, but have some obtuse indentures toward the base. These have not that rank disagreeable odour which the two first have; the fruit of it is not so large as those of the first, but they are round, smooth, and are very late before they ripen here; so that unless the plants are raised early in the spring, they will not produce ripe fruit in *England*.

The fifth sort is annual; this hath a very branching herbaceous stalk, spreading out into many divisions, and is not so hairy as the two first; the leaves are composed of a greater number of lobes, which are much shorter and more indented on their edges, where they are a little waved. The flowers stand upon very long foot-stalks, which branch out, and support a large number of flowers at the top; these have a longer style than those of the other species, which is permanent, remaining on the top of the fruit. This is also late in ripening the fruit, so that unless the

plants are raised early in the spring, the fruit will not ripen in *England*.

The sixth sort was raised by Mr. *James Gordon*, gardener at *Mile End*, who gave me some of the seeds, but from what country it came I could not learn. This hath very weak, trailing, smooth stalks, not more than a foot long, garnished with smooth leaves, standing by pairs opposite, which are regularly cut on the sides almost to the midrib, in form of a winged leaf; these segments are also indented on their edges, and at their points. The flowers, which are of a pale yellow colour, come out on the side of the stalks singly, and have large spreading empalements, which are deeply cut at the brim into many acute segments which spread open. The flowers are succeeded by small roundish berries a little compressed at the top, of an herbaceous yellow colour when ripe.

All these sorts are propagated by sowing their seeds on a moderate hot-bed in *March*, and when the plants are come up two inches high, they should be transplanted into another moderate hot-bed, at about four inches distance from each other, observing to shade them until they have taken root; after which they must have a large share of fresh air, for if they are too much drawn while young, they seldom do well afterwards.

In *May* these plants should be transplanted, either into pots or borders near walls, pales, or hedges, to which their branches may be fastened to support them from trailing on the ground, which they otherwise will do, and then the fruit will not ripen; so that where these plants are cultivated for the sake of their fruit, they should be planted to a warm aspect, and the branches regularly fastened as they extend, that the fruit may have the advantage of the sun's warmth to forward them, otherwise it will be late in the season before they are ripe, and they are unfit for use before; but when the plants are brought forward in the spring, and thus regularly trained to the south sun, the fruit will ripen by the latter end of *July*, and there will be a succession of it till the frost kills the plants.

The third sort is never used either in the kitchen or for medicine, but the plants are preserved for the sake of variety, especially by those persons who are lovers of botany. This sort is propagated by seeds, which should be sown upon a hot bed in the spring, and the plants afterward treated in the same manner as hath been directed for the *CAPSICUM*, with whose culture this plant will thrive, and produce plenty of fruit annually.

The seventh sort is the common Potatoe, which is a plant so well known now, as to need no description. Of this there are two varieties, one with a red and the other with a white root; that whose roots are red, have purplish flowers, but the white root has white flowers; these are supposed to be only accidental variations, and not distinct species.

The common name of Potatoe, seems to be only a corruption of the *Indian* name Batatas. This plant has been much propagated in *England* within thirty years past, for although it was introduced from *America* about the year 1623, yet it was but little cultivated in *England* till of late; the roots being despised by the rich, and deemed only proper food for the meaner sort of persons; however, they are now esteemed by most people, and the quantity of them which are cultivated near *London*, I believe, exceeds that of any other part of *Europe*.

This is generally propagated by its roots, which multiply greatly, if planted in a proper soil. The common way is, either to plant the small roots or offsets entire, or to cut the larger roots into pieces, preserving a bud or eye to each; but neither of these methods is what I would recommend, for when the smaller offsets are planted, they generally produce

produce a great number of roots, but these are always small; and the cuttings of the larger roots do frequently rot, especially if wet weather happens soon after they are planted; therefore what I would recommend is, to make choice of the fairest roots for this purpose, and to allow them a larger space of ground, both between the rows, as also in the rows, plant from plant; by which method I have observed, the roots have been in general large the following autumn.

The soil in which this plant thrives best, is a light sandy loam, not too dry or over moist; this ground should be well ploughed two or three times, in order to break and divide the parts; and the deeper it is ploughed, the better the roots will thrive. In the spring, just before the last ploughing, there should be a good quantity of rotten dung spread on the ground, which should be ploughed in the beginning of *March*, if the season proves mild, otherwise it had better be deferred until the middle or latter end of that month; for if it should prove hard frost after the roots are planted, they may be greatly injured, if not destroyed thereby; but the sooner they are planted in the spring, after the danger of frost is over, the better it will be, especially in dry land. In the last ploughing, the ground should be laid even, and then the furrows should be drawn at three feet distance from each other, and about seven or eight inches deep. In the bottom of this furrow the roots should be laid, at about one foot and a half asunder; then the furrow should be covered in with the earth, and the same continued through the whole field or parcel of land, intended to be planted.

After all is finished, the land may remain in the same state till near the time when the shoots are expected to appear above ground, when the ground should be well harrowed over both ways, which will break the clods, and make the surface very smooth; and by doing of it so late, it will destroy the young weeds, which, by this time, will begin to make their appearance; and this will save the expence of one hoeing, as also stir the upper surface of the ground, which, if much wet has fallen after the planting, is often bound into a hard crust, which retards the appearance of the shoots.

As I have allotted the rows of Potatoes at three feet distance, it was in order to introduce the hoe plough between them, which will greatly improve these roots; for by twice stirring and breaking of the ground between these plants, it will not only destroy the weeds, but also loosen the ground, whereby every shower of rain will penetrate the ground to the roots, and greatly improve their growth; but these operations should be performed early in the season, before the stems or branches of the plants begin to fall, and trail upon the ground, because after that, it will be impossible to do it without injuring of the shoots.

If these ploughings are carefully performed, it will prevent the growth of weeds, till the haulm of the plants cover the ground, so that afterward there will be little danger of weeds growing so as to injure the crop; but as the plough can only go between the rows, it will be necessary to make use of a hoe to stir the ground, and destroy the weeds in the rows between the plants; and if this is carefully performed in dry weather, after the two ploughings, it will be sufficient to keep the ground clean until the Potatoes are fit to take up.

In places where dung is scarce, many persons scatter it only in the furrows, where the roots are planted; but this is a very poor method, because when the Potatoes begin to push out their roots, they soon extend beyond the width of these furrows, and the new roots are commonly formed at a distance from the old, so will be out of the reach of this dung, and consequently will receive little benefit from it. And as most of the farmers covet to have a crop of Wheat

after the Potatoes are taken off the ground, so the land will not be so thoroughly dressed in every part, nor so proper for this crop, as when the dung is equally spread, and ploughed in all over the land, nor will the crop of Potatoes be so good. I have always observed, where this method of planting the Potatoes has been practised, the land has produced a fine crop of Wheat afterward, and there has scarce one shoot of the Potatoe appeared among the Wheat, which I attribute to the farmers planting only the largest roots; for when they have forked them out of the ground the following autumn, there have been six, eight, or ten large roots produced from each, and often many more, and scarce any very small roots; whereas, in such places where the small roots have been planted, there has been a vast number of very small roots produced; many of which were so small, as not to be discovered when the roots were taken up; so have grown the following season, and have greatly injured whatever crop was on the ground.

The haulm of these Potatoes is generally killed by the first frost in the autumn, then the roots should be taken up soon after, and may be laid up in dry sand in any sheltered place, where they may be kept dry, and secure from frost. Indeed the people who cultivate these roots near *London*, do not wait for the decaying of the haulm, but begin to take up part of them as soon as their roots are grown to a proper size for the market; and so keep taking up from time to time, as they have vent for them. There are others likewise, who do not take them up so soon as the haulm decays, but let them remain much longer in the ground; in which there is no hurt done, provided they are taken up before hard frost sets in, which would destroy them, unless where the ground is wanted for other crops: in which case, the sooner they are taken up the better, after the haulm is decayed. When these roots are laid up, they should have a good quantity of sand or dry earth laid between them, to prevent their heating; nor should they be laid in too large heaps, for the same reason.

LYCOPUS, Water Horehound.

This plant grows in great plenty on moist soils by the sides of ditches, in most parts of *England*, but is never cultivated in gardens, so that it would be needless to say any thing more of it in this place.

LYSIMACHIA. *Tourn. Inst. R. H. 141. tab. 59.*
Loostrife.

The Characters are,

The flower is of one petal, cut into five oblong segments, which spread open. It hath five awl-shaped stamina, and a roundish germen, which afterward turns to a globular capsule with one cell, opening with ten valves, and filled with small angular seeds.

The Species are,

1. LYSIMACHIA *paniculata*, racemis terminalibus. *Lin. Sp. Plant.* 146. Greater yellow Loostrife.

2. LYSIMACHIA *racemis lateralibus pedunculatis*. *Lin. Sp. Plant.* 147. Two-leaved Loostrife with yellow globular flowers.

3. LYSIMACHIA *spicis terminalibus patulis, lanceolatis staminibus corollâ longioribus*. *Lin. Sp. Plant.* 147. Narrow-leaved Eastern Loostrife, with a purple flower.

4. LYSIMACHIA *racemis simplicibus terminalibus, petalis obtusis, staminibus corollâ brevioribus*. *Lin. Sp. Plant.* 146. Loostrife with spikes of flowers terminating the stalks, obtuse petals to the flower, and stamina shorter than the petal.

5. LYSIMACHIA *petiolis ciliatis, floribus cernuis*. *Lin. Sp. Plant.* 147. Loostrife with hairy foot-stalks and nodding flowers.

6. LYSIMACHIA *racemis simplicibus terminalibus, petalis obtusis, staminibus corollâ longioribus*. Willow-leaved Loostrife, with a spike of white flowers terminating the stalk.

7. *LYSIMACHIA foliis subcordatis, floribus solitariis, caule repente.* Vir. Cliff. 13. Great Yellow Moneywort.

8. *LYSIMACHIA foliis ovatis acutiusculis, pedunculis folio longioribus, caule repente.* Lin. Sp. Plant. 148. Smaller Moneywort with a purplish flower.

9. *LYSIMACHIA foliis ovatis acutis, floribus solitariis, caule procumbente.* Hort. Cliff. 52. Yellow Pimpernel of the woods.

10. *LYSIMACHIA foliis subquaternis, pedunculis verticillatis unifloris.* Lin. Sp. Plant. 147. Smaller yellow Loostrife, with leaves marked with black spots.

The first sort grows by the side of ditches and rivers in many parts of *England*, so is not often admitted into gardens, because the roots creep far in the ground, whereby it becomes often a troublesome plant. It rises with upright stalks from two to three feet high, garnished with smooth spear-shaped leaves, placed sometimes by pairs, at others there are three, and frequently four of these leaves placed round the stalk at each joint. The upper part of the stalk divides into several foot-stalks, which sustain yellow flowers growing in a panicle; these have one petal which is deeply cut into five segments, spreading open, and are succeeded by roundish seed-vessels, filled with small seeds.

The second sort grows naturally in the northern parts of *England*. This hath a perennial creeping root, which sends up several erect stalks a foot and a half high, garnished at every joint by two pretty long narrow leaves placed opposite. The foot-stalks of the flowers come out opposite on each side of the stalks, sustaining at their top a globular or oval thyrse of yellow flowers, whose stamina are much longer than the petals. This is seldom kept in gardens for the same reason as the former.

The third sort is a biennial plant, which was discovered by Dr. *Journesfort* in the *Levant*. This rises with an upright stalk about a foot high, garnished with spear-shaped leaves, ending in acute points, placed opposite; they are smooth, and of a lucid green. The flowers are purple, and grow in a loose spike, terminating the stalks.

It is propagated by seeds, which should be sown in autumn soon after they are ripe, and from those the plants will come up the following spring; but if the seeds are kept out of the ground till spring, they will not vegetate till the year after. When the plants come up, they must be kept clean till autumn, then they may be planted into the borders of the pleasure-garden, where they will flower and produce ripe seeds the following summer.

The fourth sort is an annual plant, which grows naturally in the *Levant*. This hath a shorter stalk than the former. The lower leaves are broader, the spikes of flowers are shorter, and of a pale purple colour. The seeds of this sort should be sown in the autumn, where the plants are to remain; when they come up they will require no other culture, but to keep them clean from weeds, and if they are too close they should be thinned to the distance of four or five inches, which is all the culture they will require.

The fifth sort grows naturally in *Canada*. This has a perennial creeping root, sending up erect stalks about two feet high, garnished with oblong smooth leaves, placed opposite, which are veined on their under side, and end in acute points. The flowers are produced from the wings of the stalks, each sitting upon a long slender foot-stalk, three or four arising from the short branches, which come out on each side the stalk. The flowers are like those of the first sort, but smaller.

This sort spreads and propagates by roots, in as great plenty as the first, and is equally hardy, so requires no other culture.

The sixth sort grows naturally in *Spain*. This hath a perennial root, from which arise several upright stalks three feet high, garnished with narrow, smooth, spear-shaped

leaves, which stand opposite. The flowers are white, and are produced in a long, close, upright spike, at the top of the stalk; they are cut into five oval segments, which spread open; the stamina stand out longer than the petal.

This is the finest species of this genus; and as the roots of it do not spread like those of the other, so deserves a place in the pleasure-garden, where it is a very ornamental plant for shady borders. It loves a moist soil and a shady situation, where it will continue long in beauty. It may be propagated by parting of the roots in autumn, but by this method it increases slowly, so that the only way to have it in plenty is by sowing of the seeds; these should be sown upon an east-aspected border in autumn, soon after they are ripe, then the plants will come up the following spring. When the plants come up, they should be kept clean from weeds, and if they are too close, some of them may be drawn out and transplanted on a shady border, which will give the remaining plants room to grow till autumn, when they may be transplanted into the borders where they are designed to flower.

The seventh sort is commonly called Moneywort, or Herb Two-pence. This is a perennial plant, which grows naturally in moist shady places in most parts of *England*, so is not cultivated in gardens.

The eighth sort is a small trailing plant, which grows upon bogs in most parts of *England*. The stalks seldom are more than three or four inches long, and are terminated by three or four small flowers, of a bright purple colour, growing in a bunch.

The ninth sort is a perennial plant with trailing stalks, which grows naturally in moist woods in most parts of *England*, so is not cultivated in gardens.

The tenth sort grows naturally among Rushes and Reeds, by the river's side in *Holland*. This hath a perennial creeping root like the first. The stalks rise a foot high, garnished by spear-shaped leaves, placed sometimes by pairs, at others by threes, and often four at each joint, surrounding the stalk. The flowers also come out at each joint, four of them standing round the stalk in whorls, which are yellow. It may be treated in the same manner as the first sort, and is equally hardy.

LYSIMACHIA GALERICULATA. See *Scutellaria*.

LYSIMACHIA NON PAPPOSA. See *Cenothera*.

LYSIMACHIA SILIQUOSA. See *Epilobium*.

LYTHRUM. Lin. Gen. Plant. 532. Willow Herb, or purple Loostrife.

The Characters are.

The flower hath six oblong blunt petals, which spread open, whose tails are inserted in the indentures of the empalement, and ten slender stamina. In the center is situated an oblong germen, which after-ward turns to an oblong acute capsule with two cells, filled with small seeds.

The Species are,

1. *LYTHRUM foliis oppositis cordato-lanceolatis, floribus spicatis dodecandriis.* Lin. Sp. Plant. 446. Common purple Willow Herb with oblong leaves.

2. *LYTHRUM foliis cordato-ovatis, floribus verticillato-spicatis tomentosis.* Purple Willow Herb with roundish leaves.

3. *LYTHRUM foliis alternis linearibus, floribus hexandriis.* Hort. Upsal. 118. Willow Herb with a narrow Hyssop leaf.

4. *LYTHRUM foliis oblongo-ovatis inferne oppositis, supernè alternis, floribus hexandris.* Spanish Willow Herb with a Hyssop leaf, and oblong, deep, blue flowers.

The first sort grows naturally by the side of rivers and ditches in most parts of *England*. It has a perennial root, from which come forth several upright angular stalks, which rise from three to four feet high, garnished with oblong leaves, placed sometimes by pairs; at others there are three leaves at each joint, standing round the stalk. The flowers are

are purple, and are produced in a long spike at the top of the stalk, which make a fine appearance. Although this plant is despised, because it grows common, yet it merits a place in gardens better than many other which are propagated with care, because they are more rare. It is easily cultivated by parting of the roots in autumn, and should be planted in a moist soil, where it will thrive and flower without any other care than the keeping it clean from weeds.

There is a variety of this with an hexangular stalk, and generally with three leaves at each joint, but this is only accidental, for the roots of this, when removed into a garden, come to the common sort.

The second sort is like the first, but has oval, heart-shaped, downy leaves, placed by threes round the stalk. The flowers are produced in long spikes at the top of the stalks, disposed in thick whorls, with spaces between each; they are of a fine purple colour, and appear at the same time with the former.

The third sort grows naturally on moist bogs in many parts of *England*, so is seldom admitted into gardens.

The fourth sort grows naturally in *Spain* and *Portugal*, from both which countries I have received the seeds. The root of this is perennial. The stalks are slender, not more than nine or ten inches long, spreading out on every side. The lower part of the stalks are garnished with oblong oval leaves, placed opposite. On the upper part of the stalks the leaves are narrower, and placed alternate. The flowers come out singly from the side of the stalks at each joint; they are larger than those of the common sort, and of a deeper purple colour, so make a fine appearance in *July*, when they are in beauty.

This sort has never produced any seeds in *England*, and the severe winter in 1740, killed all the plants here, since which time I have not seen any of the plants in the *English* gardens.

M.

M A G

MACALEB. See *Cerasus*.

MADDER. See *Rubia*.

MMAGNOLIA. *Plum. Nov. Gen. 38. tab. 7. Lin. Gen. Plant. 610.* The Laurel-leaved Tulip tree.

The Characters are,

The flower is composed of eight or ten oblong, concave, blunt leaves. It hath a great number of short stamina, which are inserted into the germen, and many oblong oval germina, fastened to the receptacle, supporting recurved contorted styles, with hairy stigmas. The germen afterward becomes oval cones, with imbricated capsules, having one cell, opening with two valves, inclosing one kidney-shaped seed, hanging by a slender thread from the scale of the cone.

The Species are,

1. *MAGNOLIA foliis ovato-lanceolatis subtus glaucis annuis.* Magnolia with oval spear-shaped leaves, which are gray on their under side, and annual; commonly called Small Magnolia.

2. *MAGNOLIA foliis lanceolatis persistentibus, caule erecto arboreo: Fig. Plant. tab. 172.* Magnolia with spear-shaped leaves, which are ever-green, and an erect tree-like stalk; commonly called Greater Magnolia.

3. *MAGNOLIA foliis lanceolatis amplissimis annuis, petalis exterioribus dependentibus.* Magnolia with very large spear-shaped leaves, which are annual, and the outer petals of the flower declining; commonly called Umbrella tree.

4. *MAGNOLIA foliis ovato-lanceolatis acuminatis annuis, petalis obtusis.* Magnolia with oval, spear-shaped, pointed leaves, which are annual, and obtuse petals to the flower.

The first sort grows pretty common in *Virginia* and *Carolina*, and other parts of *North America*. In moist places this grows from seven or eight to fifteen or sixteen feet high, with a slender stem. The wood is white and spongy, the bark is smooth and white; the branches are garnished with thick smooth leaves, resembling those of the Bay, but are of an oval shape, smooth on their edges, and white underneath. The flowers are produced at the extremity of the

M A G

branches, which are white, and composed of six concave petals, and have an agreeable sweet scent. After these are past, the fruit increases in size to be as large as a Walnut with its cover, but of a conical shape, having many cells round the outside; in each of which is lodged a flat seed, about the size of a small Kidney Bean. The fruit is at first green, afterward red, and when ripe of a brown colour. The seeds when ripe are discharged from their cells, and hang by a slender thread.

When these trees are transplanted from the places of their growth into dry ground, they make handfomer trees, and produce a great number of flowers. This is to be understood of *America*, for in *Europe* they do not thrive so well in a dry soil, as in a moist loamy land.

The second sort grows in *Florida* and *South Carolina*, where it rises to the height of eighty feet or more, with a strait trunk upward of two feet diameter, having a regular head. The leaves of this tree resemble those of the common Laurel, but are much larger, and of a lucid green on their upper side, and in some trees are of a russet or buff colour on their under side. These leaves continue all the year, so that this is one of the most beautiful ever green trees yet known. The flowers are produced at the end of the branches, composed of eight or ten petals, which are narrow at their base, but broad at their extremity, where they are rounded, and a little waved; they are of a purple white colour. In the center is situated a great number of stamina and styles, fastened to one common receptaculum; the flowers are succeeded by oblong scaly cones. These trees, in their native places of growth, begin to produce their flowers in *May*, which are succeeded by others, so that the woods are perfumed with their odour for a long time; but those which have flowered in *England*, seldom begin till the middle of *June*, and do not continue long in beauty. There are many large plants of this sort in the gardens of his Grace the Duke of *Richmond*, at *Goodwood* in *Suffex*, which have produced flowers several years; and in the nursery of Mr.

Christopher

Christopher Gray, near *Fulham*, there is one very handsome plant, which has lived in the open air many years, and has also flowered several years.

As this sort is a native of a warm country, it is a little impatient of cold, especially while young, therefore the plants should be kept in pots, and sheltered in winter for some years, until they have acquired strength, when they may be shaken out of the pots, and planted in the full ground; but they must be planted in a warm situation, where they may be defended from the strong winds, and screened from the north and east, otherwise they will not live abroad.

The third sort grows in *Carolina* pretty frequent, but in *Virginia* it is pretty rare. This usually grows from sixteen to twenty feet high, with a slender trunk, the wood is soft and spongy; the leaves of this tree are remarkably large, and are produced in horizontal circles, somewhat resembling an Umbrella, from whence the inhabitants of those countries have given it this name. The flowers are composed of ten or eleven white petals, which hang down without any order; the fruit is very like that of the former sort, but longer; the leaves of this sort drop off at the beginning of winter.

This tree is as yet very rare in *Europe*, but as it is propagated from seeds, we may hope to have it in greater plenty soon, if we can obtain good seeds from *Carolina*, for it is rarely met with in *Virginia*.

The fourth sort is also very rare in *England*. There are but few of the plants at present here, nor is it very common in any of the habitable parts of *America*; some of these trees have been discovered by Mr. *John Bartram*, growing on the north branch of *Susquehannab* river. The leaves of this tree are near eight inches long and five broad; ending in a point. The flowers come out early in the spring, which are composed of twelve white petals, and are shaped like those of the second sort; the fruit of this tree is longer than those of the other species, but in other respects agrees with them. The wood of this tree is of a fine grain, and an Orange colour.

All these sorts are propagated by seeds, which must be procured from the places of their natural growth; these should be put up in sand, and sent over to *England*, as soon as possible, for if they are kept long out of the ground, they very rarely grow; therefore the seeds should be sown as soon as possible, when they arrive here.

Some years past I received a good quantity of these seeds from *Carolina*, which I sowed in pots as soon as I received them, and plunged the pots into a moderate hot-bed, and with this management I raised a great number of plants; but from the seeds which have been lately brought over, there have been but few plants produced; whether the seeds were not perfectly ripe when they were gathered, or from what other cause this has happened, I cannot say, but it is certain the fault must be in the seeds, because they have been differently sown and managed by the several persons who received them, and the success was nearly alike everywhere.

There have been several plants of the first and second sorts raised from layers, and some from cuttings; but these do not thrive so well as those which come from seeds, nor will they grow to near the size of those, so that it is much the best way to procure their seeds from *America*, and propagate them that way.

The first sort frequently comes up well from seeds, but the young plants are very difficult to keep the two first years; for if they are exposed much to the sun, their leaves change yellow, and the plants decay, so the best way is to keep the pots plunged in a moderate hot-bed, and shade them every day from the sun with mats, giving them air

in plenty when the weather is warm, and frequently refresh them with water; during the winter season they must be screened from frost, and in mild weather they must enjoy the free air, to prevent their growing mouldy; they should have but little wet after their leaves are fallen. With this management the plants may be trained up, and when they have acquired strength, they may be planted in the open air, where they will thrive and flower, if they have a sheltered situation.

The second sort is not so difficult to train up; but in order to get them forward, it will be proper, when they are removed out of the seed-pots, to plant them each into a separate small pot, and plunge them into a gentle hot-bed of tanners bark, observing to shade them from the sun, and admit proper air to them; but at *Midsummer* they should be inured to the open air gradually, and then placed in a sheltered situation, where they may remain till autumn; but on the first approach of frost, they should be removed under shelter, otherwise the early frosts will pinch their tender shoots, which often occasions their dying downward after. When the plants have got strength, some of them may be turned out of the pots, and planted in the full ground, in a warm sheltered situation; but part of them should be kept in pots, and sheltered in the winter, to preserve them, lest by severe frost the other should be killed.

If the plants make good progress, they will be strong enough to plant in the full ground in about six or seven years. The time for removing or shifting these plants is in *March*, before they begin to shoot, which may sometimes happen to be too soon to turn them out of the pots into the full ground, especially if the season proves late; but as there will be no danger in removing them out of the pots, the ball of earth being preserved to their roots, so it is best to defer this till the month of *April*; but it will be necessary to harden those plants which are intended to be planted out, by exposing them to the air as much as possible, for this will keep the plants backward, and prevent their shooting; for if they make shoots in the green-house, those will be too tender to bear the sun, until they are by degrees hardened to it, and the least frost will greatly pinch them, and such often happen very late in the spring.

The two or three winters after these are planted out, it will be necessary to lay some mulch on the surface of the ground about their roots, as also to throw some mats over their heads, especially at the beginning of the morning frosts in autumn, for the reasons before given; but they should never be too closely covered up, lest the shoots should grow mouldy, for that will certainly kill the leading buds of every shoot, and prove to the full as injurious to them as the frost. As the plants get strength, they will be better able to endure the cold of our climate, though it will be proper to lay some mulch about their roots every winter, and in very severe frost to cover their heads and stems.

It is the second sort which requires the most care, being much tenderer than any of the other sorts, for they will endure the cold very well, without much care, after they have acquired strength; for as these lose their leaves in the winter, the frost will not have so much force upon them as the second sort, whose leaves are frequently tender toward the end of the shoots, especially when they grow freely, or shoot late in the autumn.

MALLOW. See Malva.

MALLOW Tree. See Lavatera.

MALOPE. Bastard Mallow.

The Characters are,

The flower is shaped like that of the Mallow, and hath a double empalement, the outer being composed of three, and the inner is of one leaf, cut into five segments; the flower is of one petal, divided into five parts to the bottom. In the center is situated the column, having a great number of stamina and styles joined closely to it. The germen afterward becomes a fruit composed of many cells, which are collected into a head, in each of which is lodged a single seed.

We have but one Species of this plant, viz.

MALOPE foliis ovatis crenatis glabris. Lin. Hort. Cliff. 347. Bastard Mallow with oval smooth leaves, which are notched.

The whole plant has greatly the appearance of the Mallow, but differs from it, in having the cells collected into a button, somewhat like a Blackberry; the branches spread, and lie flat upon the ground, extending themselves a foot or more each way. The flowers are produced singly upon long foot-stalks, from the setting on of the leaves, which are in snape and colour like those of the Mallow.

This is propagated by seeds, which should be sown upon a warm border in August, where the plants will come up before winter, which should be planted in small pots, and sheltered under a hot-bed frame, for they are too tender to live in the open air in winter; but in summer they should be placed with other hardy foreign plants in a sheltered situation, where in warm seasons they will produce seeds.

MALPIGHIA. Plum. Nov. Gen. 46. tab. 36. Barbadoes Cherry.

The Characters are,

The flower has five kidney-shaped petals, which are concave, and spread open, and ten awl-shaped stamina, and two mellow glands adhering to the empalement. It has a small roundish germen, supporting three slender styles. The germen afterward turns to a large, furrowed, globular berry, with one cell, inclosing three rough, stony, angular seeds.

The Species are,

1. MALPIGHIA foliis ovatis integerrimis glabris, pedunculis umbellatis. Hort. Cliff. 169. Malpighia with smooth, oval, entire leaves, and umbellated foot-stalks; commonly called Barbadoes Cherry.

2. MALPIGHIA foliis ovato-lanceolatis, acuminatis, glabris, pedunculis umbellatis. Malpighia with the appearance of the Pomegranate tree.

3. MALPIGHIA foliis lanceolatis subtus incanis, pedunculis umbellatis alaribus. Malpighia with spear-shaped leaves, hoary on their under side, and umbellated foot-stalks proceeding from the wings of the stalk.

4. MALPIGHIA foliis cordato-lanceolatis, setis decumbentibus rigidis, pedunculis unifloris aggregatis. Broad-leaved Malpighia, with spines growing on the under side of the leaf.

5. MALPIGHIA foliis ovatis acutis glabris, pedunculis umbellatis alaribus terminalibusque. Malpighia with oval, smooth, acute-pointed leaves, and umbellated foot-stalks proceeding from the sides and ends of the branches.

6. MALPIGHIA foliis lineari lanceolatis, setis decumbentibus rigidis, pedunculis unifloris aggregatis. Malpighia with linear spear-shaped leaves, rigid declining bristles, and foot-stalks having one flower, proceeding from the sides of the branches in clusters.

7. MALPIGHIA foliis lanceolatis dentato-spinosis subtus hispida. Lin. Sp. Plant. 426. Malpighia with spear-shaped leaves, indented and prickly, whose under sides are set with spiny hairs.

8. MALPIGHIA foliis subovatis dentato-spinosis, pedunculis unifloris. Malpighia with leaves nearly oval, indented and prickly, and foot-stalks with one flower.

The first sort is commonly cultivated in the West-Indies for the sake of the fruit; this usually grows to the height of sixteen or eighteen feet, having a slender stem, covered with a light brown bark. The leaves are placed opposite to each other; they are oval, smooth, ending in acute points, and continue green all the year. The flowers are produced in bunches upon pretty long foot-stalks, which come out from the side of the branches; they are composed of five petals, which are of a Rose colour, joined at their base. The flowers are succeeded by red fruit, shaped like those of the small wild Cherry, of the same size, each inclosing four angular furrowed stones, surrounded by a thin pulp, which has an agreeable acid flavour.

The second sort grows naturally in Jamaica. This rises with a shrubby stalk ten or twelve feet high, dividing into several slender spreading branches, covered with a light brown bark, garnished with oval, spear-shaped, smooth leaves placed opposite, ending in acute points. The flowers are produced in umbels at the end of the branches, standing upon short foot-stalks; they are of a pale Rose colour, composed of five obtuse, concave, indented petals, having long narrow tails. In the center is situated the roundish germen, supporting three styles, attended by ten stamina which spread asunder. The germen afterward turns to a roundish pulpy berry with many furrows, red when ripe, inclosing three or four hard angular seeds.

The third sort grows naturally at Campeachy. This rises with a strong woody stalk eighteen or twenty feet high; dividing into many branches, covered with a brown spotted bark, garnished with spear-shaped leaves placed opposite, which are hoary on their under side. The flowers come out in umbels from the side of the branches; they are of a Rose colour, and are succeeded by oval channelled fruit, like those of the former sort.

The fourth sort grows naturally in Jamaica. This rises with a woody stalk from fifteen to eighteen feet high, dividing into many strong branches, which are furrowed and covered with a brown bark. The leaves are from three to four inches long, and one broad at their base, where they are rounded in form of a heart, lessening gradually to the point; these are covered on their under sides with stinging bristly hairs so closely, as to render it very troublesome to handle them, for these fasten themselves into the flesh, and are difficult to get out again. The flowers are produced in umbels from the side of the branches; they are of a light purple colour, and shaped like those of the other species, and are succeeded by oval furrowed fruit, like those of the former sort. This is called in the West-Indies Couhage, or Cowitch Cherry.

The fifth sort grows naturally at Cartagena in New Spain. This rises with a shrubby stalk about ten feet high, covered with a light brown spotted bark, branching out regularly on every side; the leaves are oval, smooth, and end in acute points, standing opposite, of a light green on their upper side, but paler on their under. The flowers come out from the side of the stalks in small umbels, standing erect; the foot-stalks of the umbels are scarce an inch long, and come out alternately from the side of the branches. The flowers are of a pale blush colour, shaped like those of the former sorts, which are succeeded by roundish furrowed berries with a red skin, covering three hard angular seeds.

The sixth sort grows in the island Barbuda. This rises with a shrubby stalk seven or eight feet high, covered with a bright purplish bark, which is spotted and furrowed, dividing toward the top into several smaller branches, garnished with narrow spear-shaped leaves, of a lucid green on their upper side, but of a russet brown on their under, where they are closely armed with stinging bristles, which fasten themselves into the flesh on clothes of those who touch them.

The

The flowers are produced from the side of the branches in clusters; they are of a pale purple colour, of the same form as the other species, and are succeeded by small, oval, furrowed fruit, of a dark purple colour when ripe.

The seventh sort grows naturally in the island of *Cuba*. This rises with a shrubby stalk to the height of seven or eight feet, sending out branches the whole length, covered with a gray bark, and garnished with narrow prickly leaves like those of the Holly, which have many stinging bristles on their under side. The flowers are of a pale blush colour, and are produced in small clusters from the side of the branches. The fruit is more pointed than those of the common sort, and turns to a dark purple colour when ripe.

The eighth sort grows naturally near the *Havannah*. This is a very low shrub, seldom rising more than two or three feet high; the stalk is thick and woody, covered with a rough gray bark, garnished with lucid green leaves, which appear as if cut at their ends, where they are hollowed in, and the two corners rise like horns ending in a sharp thorn, as do also the indentures on the sides. The flowers come out from the side of the branches, upon foot-stalks an inch long, each sustaining one small, pale, blush flower, of the same form with those of the other species; the fruit is small, conical, and furrowed, changing to a purple red colour when ripe.

The fruit of most of the species here mentioned, are promiscuously gathered and eaten by the inhabitants of the countries where they grow; but the first sort is that which is cultivated in some of the islands for its fruit, though it is but indifferent; the pulp which surrounds the stone is very thin, but has a pleasant acid flavour, which renders it agreeable to the inhabitants of those warm countries, where, to supply the want of those Cherries which are cultivated in *Europe*, they are obliged to eat the fruit of these shrubs.

These plants are preserved in the gardens of those persons who are so curious in botanical studies, as to erect hot-houses for maintaining foreign plants; and where there are such conveniencies, these plants deserve a place, because they retain their leaves all the year, and commonly continue flowering from *December* to the end of *March*, when they make a fine appearance at a season, when there is a scarcity of other flowers, and many times they produce ripe fruit here. Those sorts whose leaves are armed with stinging bristles, like the Cowitch, are the least worthy of a place in stoves, because they are so troublesome to handle, nor do their flowers make so good an appearance as many of the other sorts.

As these plants are natives of the warmest parts of *America*, so they will not live through the winter in *England*, unless they are preserved in a warm stove; but when the plants have obtained strength, they may be exposed in the open air in a warm situation, from the middle or latter end of *June*, till the beginning of *October*, provided the weather continues so long mild; and the plants so treated, will flower much better than those which are constantly kept in a stove.

They are all propagated by seeds, which must be sown upon a good hot-bed; and when the plants are fit to transplant, they must be each put into a separate small pot, and plunged into a hot-bed of tanners bark, and must be treated in the same manner as hath been directed for other tender plants of the same country; the two first winters it will be proper to keep them in the bark-bed in the stove; but afterward they may be placed upon stands in the dry stove in winter, where they may be kept in a temperate warmth, in which they will thrive much better than in a greater heat; these must be watered two or three times a week, when they are placed in the dry stove, but it must not be given to them in large quantities.

MALVA. *Tourn. Inst. R. H. 94. tab. 23. Mallows.*

The Characters are,

The flower has a double empalement; the outer is composed of three, the inner is of one leaf, cut into five broad segments at the brim. The flower is of one petal. It has a great number of stamina which coalesce at bottom in a cylinder, but spread open above. In the center is situated an orbicular germen supporting a short cylindrical style, with many bristly stigmas. The empalement afterward turns to several capsules, which are joined in an orbicular depressed head fastened to the column, opening on their inside, each containing one kidney-shaped seed.

The Species are,

1. MALVA caule erecto herbaceo, foliis lobatis obtusis, pedunculis petiolisque pilosis. *Lin. Sp. Plant. 689.* Wild Mallow with a sinuated leaf.

2. MALVA caule repente, foliis cordato-orbiculatis obsolete quinquelobatis. *Hort. Cliff. 347.* Common Mallow with a small flower and a round leaf.

3. MALVA annua, caule erecto herbaceo, foliis lobatis obtusis crenatis. Annual Mallow with an erect herbaceous stalk, and obtuse lobed leaves which are crenated.

4. MALVA caule erecto, foliis angulatis, floribus axillaribus glomeratis. *Vir. Cliff. 356.* Curled or furbelowed Mallow.

5. MALVA annua, caule erecto herbaceo simplici, foliis suborbiculatis obsolete quinquelobatis, floribus confertis alaribus sessilibus. Upright, annual, China Mallow, with very small white flowers.

6. MALVA caule erecto ramoso hirsuto, foliis angulatis, floribus alaribus pedunculis brevioribus. Tallest annual Mallow of *Crete*, with small flowers growing in umbels on the sides of the stalk.

7. MALVA caule erecto herbaceo, foliis lobatis, spicis secundis axillaribus. *Lin. Sp. Plant. 688.* Mallow with an erect herbaceous stalk, leaves having lobes, and spikes of flowers proceeding from the sides of the stalks.

8. MALVA caule erecto, foliis multipartitis scabriusculis. *Hort. Cliff. 347.* Narrow-leaved, curled, Vervain Mallow.

9. MALVA caule erecto, foliis trilobatis obtusis dentatis glabris. Common, greater, Vervain Mallow.

10. MALVA caule erecto hirsuto, foliis trilobatis dentatis subtus tomentosis. Mallow with an erect hairy stalk, and indented leaves having three lobes, which are downy on their under side.

11. MALVA foliis radicalibus reniformibus incisissimis, caulibus quinque partitis pinnato multifidis. *Hort. Upsal. 202.* Round, cut-leaved, Vervain Mallow.

12. MALVA foliis palmatis dentatis, corollis calyce minoribus. *Lin. Sp. Plant. 690.* Egyptian Vervain Mallow with a Crane's-bill leaf.

13. MALVA foliis quinquelobatis incisissimis, calycibus acutis bipidibus, pedunculis longissimis. Maritime Vervain Mallow of *Provence*, with a Crane's-bill leaf.

14. MALVA foliis subcordatis laciniatis hirsutis, caule arborescente. African shrubby Mallow with a red flower.

15. MALVA foliis cordatis crenatis, floribus lateralibus solitariis, terminalibus spicatis. *Prod. Leyd. 359.* Low American Marshmallow, with a yellow spiked flower.

The two first sorts are found wild in most parts of *England*, so are rarely cultivated in gardens. The first is the sort commonly used in medicine, with which the markets are supplied by the herb-folks, who gather it in the fields.

The third sort was discovered by *Dr. Tournefort* in the *Levant*. This is an annual plant, with an erect stalk; the flowers are larger than those of the common sort, and are of a soft red colour.

The fourth sort is annual. This rises with an upright stalk four or five feet high; the leaves are curled on their edges, for which variety it is preserved in gardens.

The fifth sort was formerly sent from *China* as a pot-herb, and hath been cultivated in some curious gardens in *England*; though it is not likely to obtain here as an esculent plant, since we have many others which are preferable to it for that purpose. This is an annual plant, which will propagate itself fast enough, provided it be permitted to scatter its seeds.

The sixth sort was discovered by Dr. *Tournefort*, in the island of *Candia*. This will become a weed, if suffered to scatter the seeds.

The seventh sort grows naturally in *Peru*. This is an annual plant, rising with an upright branching stalk two feet high, garnished with broad hairy leaves, having three lobes. The flowers grow in spikes from the wings of the stalks of a pale blue, set very closely on the spikes, and are succeeded by seeds, which, if permitted to scatter, will come up plentifully the following spring without care.

The eighth sort is a biennial plant, which grows naturally in pastures in many parts of *England*, so is seldom admitted into gardens. The stalks of this are a foot and a half long, and frequently incline toward the ground. The leaves are finely cut into narrow segments almost to the midrib, and these segments are deeply indented. The flowers are shaped like those of the common Mallow, and are of a Rose colour.

The ninth sort is the common Vervain Mallow, which is mentioned in the catalogue of medicinal plants. This is found growing naturally in some of the midland counties in *England*, but not near *London*. It is a biennial plant, the stalks rise higher than those of the former; the leaves are cut into three obtuse lobes, which are indented. The flowers are larger than those of the former, but appear at the same time, and the seeds ripen in autumn.

The tenth sort differs from the ninth, in having hairy stalks, and the under side of the leaves being downy. This grows naturally about *Paris*.

The eleventh sort is a biennial plant, which grows naturally in *France* and *Italy*. The lower leaves of this are rounded and eared somewhat like a kidney in shape, and are cut on their edges; but those on the stalks are divided into five parts, which end with many wing-shaped points; the stalks of this are shorter than those of the other sorts.

The twelfth sort grows naturally in *Egypt*. This is an annual plant, whose stalks are smooth a foot long, and decline toward the ground. The leaves stand upon pretty long foot-stalks, shaped like a hand, having five divisions which join at their base to the foot-stalk. The flowers come out single from the wings of the stalk, and at the top in clusters; they have pretty large acute empalements, they are small, and of a pale blue colour. These appear in *June*, and the seeds ripen in autumn.

The thirteenth sort grows naturally in the south of *France*. This is an annual plant, which has some resemblance of the former, but the stalks are longer and more branched; the leaves are cut into five obtuse lobes almost to the bottom, and are deeply cut on their side. The flowers stand upon very long foot-stalks; the empalement of the flower is large, prickly, and acute-pointed; the flowers are blue, and larger than those of the other sort. It flowers and ripens its seeds about the same time with that.

The fourteenth sort grows naturally at the *Cape of Good Hope*. This rises with a woody stalk ten or twelve feet high, sending out branches from the side; the stalks and branches are closely covered with hairs, and are garnished with hairy leaves, which are indented on the sides, so as to have the appearance of a trilobate leaf. The flowers come out from the side of the branches, upon foot-stalks an inch long; they are of a deep red colour, and shaped like those of the common Mallow, but are smaller. This plant

continues flowering great part of the year, which renders it valuable.

There are two other varieties of this plant, which have been mentioned by some authors as distinct species. The first is, *Alcea Africana frutescens, grossulariæ folio ampliore, unguibus florum atro-rubentibus. AÆ. Phil. 1729.* Shrubby African Vervain Mallow, with a larger Gooseberry leaf, and the bottoms of the flower of a dark red. The other is, *Alcea Africana frutescens, folio grossulariæ flore parvo rubro. Boerb. Ind. alt. 1. 272.* Shrubby African Vervain Mallow, with a Gooseberry leaf, and a small red flower. The leaves of the last appear very different from either of the other, being deeply divided into three lobes, which are also deeply indented, so that any person, upon seeing it, would suppose it to be a different species; but I have frequently raised all these, with some other intermediate varieties, from the seeds of one plant.

This sort is easily propagated by seeds, which, if sown on a common border in the spring, the plants will come up; but as it is too tender to live abroad in the winter, so when the plants are three or four inches high, they should be each planted into a separate pot, placing them in the shade till they have taken fresh root; then they may be removed to a sheltered situation, intermixing them with other hardy exotick plants, where they may remain till the frost comes on, when they should be removed into the greenhouse, and afterward treated in the same way as the hardy plants from the same country, always allowing them plenty of free air in mild weather.

The fifteenth sort grows naturally in most of the islands in the *West-Indies*. This is an annual plant, which rises about a foot high, sending out a few, short, woolly branches from the side, garnished with heart-shaped woolly leaves, which are notched on their edges, standing alternately upon pretty long foot-stalks. The flowers terminate the stalks in a close spike; they are small, and of a pale yellow colour. The seeds ripen in autumn.

This is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a new hot-bed, shading them until they have taken fresh root; then they must have free air admitted to them, in proportion to the warmth of the season, and the latter end of *June* they may be placed in the open air in a sheltered situation, where they will flower and produce ripe seeds.

There are some other sorts of Mallows, which are natives of this country, but as they are plants of no great beauty or use, it is needless to mention them in this place.

MALVA ROSEA. See *Alcea*.

MALUS, the Apple tree.

The Species are,

The branches spread, and are more depressed than those of the Pear tree. The flower consists of five leaves, which expand in form of a Rose. The fruit is hollowed about the foot-stalk, it is, for the most part, roundish and umbilicated at the top; is fleshy, and divided into five cells or partitions, in each of which is lodged one oblong seed.

The Species are,

1. *MALUS foliis ovatis serratis, caule arborco.* Wild Apple with a very four fruit, commonly called Crab.

2. *MALUS foliis serrato-angulosis.* Wild Crab of *Virginia*, with a sweet-scented flower.

3. *MALUS foliis ovatis serratis, caule fruticoso.* Dwarf Apple, commonly called Paradise Apple.

Of the first sort there are two varieties of fruit, one is white, and the other purple toward the sun, but these are accidental variations. There is also a variety of this with variegated leaves, which has been propagated in some of

the nurseries near *London*; but when the trees grow vigorous, their leaves soon become plain.

The second sort grows naturally in most parts of *North America*; where the inhabitants plant them for stocks to graft other sorts of Apples upon; the leaves of this are longer and narrower than any of the other sorts, and are cut into acute angles on their sides. The flowers of this have a fragrant odour, which perfumes the *American* woods at the time they appear.

The third sort is undoubtedly a distinct species from all the others, for it never rises to any height; the branches are weak, scarce able to support themselves, and this difference is permanent when raised from seeds.

There is a sort of Apple called the Fig Apple, which is common to *England* and *North America*, but the fruit is not greatly esteemed; however, as some persons are fond of variety, so I have mentioned it. The varieties of *French* Apples are,

Pomme de Rambour. The Rambour is a very large fruit, of a fine red next the sun, and striped with a pale or yellowish green. This ripens very early, commonly about the end of *August*, and soon grows meally, therefore is not esteemed in *England*.

Pomme de Courpendu, the hanging Body. This is a very large Apple, of an oblong figure, having some irregular risings or angles, which run from the base to the crown; it is of a red cast on the side toward the sun, but pale on the other side; the foot-stalk is long and slender, so that the fruit is always hanging downward, which occasioned the *French* gardeners to give it this name.

The *Rennette-blanche*, or White Renette, or *French Renette*. This is a large fine fruit, of a pale green, and a roundish figure, having some small gray spots; the juice is sugary, and it is good for eating or baking; it will keep till after *Christmas* good.

The *Rennette-grise*: This is a middle sized fruit, shaped like the Golden Renette, but is of a deep gray colour on the side next the sun, but on the other side intermixed with yellow; it is a very juicy good Apple, of a quick flavour. It ripens in *October*, and will not keep long.

Pomme d'Api. This is a small hard fruit, of a bright purple colour on the side next the sun, and of a yellowish green on the other side; it is a very firm fruit, but hath not much flavour, so is only preserved by some persons by way of curiosity. It keeps a long time sound, and makes a variety in a dish of fruit.

Le Calville d'Automne, the Autumn Calville. This is a large fruit of an oblong figure, of a fine red colour toward the sun. The juice is vinous, and much esteemed by the *French*.

Fenouillet ou Pomme d'Anis, the Fennel, or Anise Apple. This is a middle sized fruit, a little longer than a Golden Pippin, of a grayish colour. The pulp is tender, and has a spicy taste like Anise-seed; the wood and the leaves are whitish.

Pomme violette, the Violet Apple. This is a pretty large fruit, of a pale green, striped with deep red to the sun. The juice is sugary.

The Crab, which is the first sort here mentioned, has been generally esteemed as the best stock for grafting Apples upon, being very hardy, and of long duration; but of late years there have been few persons who have been curious enough to raise these stocks, having commonly sown the kernels of all sorts of Cyder Apples for stocks without distinction, as these are much easier to procure than the other; so the gardeners generally call all those Crabs, which are produced from the kernel, and have not been grafted: but were the kernels of the Crabs sown, I should prefer those for stocks, because they are never so luxuriant in their

growth, as those from Apple kernels, and they will continue longer sound; besides, these will preserve some of the best sorts of Apples in their true size, colour, and flavour; whereas the other free stocks produce larger fruit, which are not so well tasted, nor will they keep so long.

The Paradise Apple some years ago was much esteemed for stocks to graft or bud upon, but these are not of long duration; nor will the trees grafted upon them ever grow to any size, unless they are planted so low as that the cyon may strike its root into the ground, when it will be equal to no stock, for the graft will draw its nourishment from the ground, so that it is only by way of curiosity, or for very small gardens, that these stocks are proper, since there can never be expected any considerable quantity of fruit from such trees.

There is another Apple which is called the *Dutch Paradise* Apple, much cultivated in the nurseries for grafting Apples upon, in order to have them dwarfs; and these will not decay or canker as the other, nor do they stint the grafts near so much, so are generally preferred for planting espaliers or dwarfs, being easily kept within the compass usually allotted to these trees.

Some persons have also made use of Codlin stocks to graft Apples upon, in order to make them dwarf; but the fruit which are upon these stocks, are not so firm, nor do they last so long, therefore the winter fruits should never be grafted upon these stocks:

The *Virginian Crab* tree with sweet flowers, is preserved by such persons as are curious in collecting great variety of trees; it may be propagated by budding or grafting it upon the common Crab or Apple tree; but it is somewhat tender while young, wherefore it should be planted in a warm situation, otherwise it will be subject to suffer by an extreme hard winter. The flowers of this tree are said to be exceeding sweet in *Virginia*, where it grows in the woods in great plenty; but I could not observe much scent in some of them which have flowered in *England*, so that I am in doubt whether the sort at present in the gardens is the same with that of *Virginia*.

The Fig Apple is supposed by many persons to be produced without a previous flower. But this opinion is rejected by more curious observers, who affirm there is a small flower precedes the fruit, which is very fugacious, seldom continuing above a day or two.

The other sorts which are above-mentioned, are what have been introduced from *France*; but there are not above two or three of them, which are much esteemed in *England*, viz. the *French Renette*, the *Rennette-grise*, and the Violet Apple; the other being early fruit, which do not keep long, and their flesh is generally meally, so that they do not deserve to be propagated, as we have many better fruits in *England*; which I shall next mention.

The first Apple which is brought to the *London* markets, is the Codlin. This fruit is so well known in *England*, that it is needless to describe it.

The next is the *Margaret* Apple: this fruit is not so long, as the Codlin, of a middling size; the side next the sun changes to a faint red when ripe, the other side is of a pale green; the fruit is firm, of a quick pleasant taste, but doth not keep long.

The Summer Pearmain is an oblong fruit, striped with red next the sun; the flesh is soft, and in a short time is meally, so that it is not greatly esteemed.

The *Kentish* Fill Basket is a species of Codlin, of a large size, longer shaped than the Codlin. This ripens a little later in the season, and is generally used for baking, &c.

The Transparent Apple: This was brought to *England* about the year 1724, and was esteemed a curiosity; it came from *Petersburgh*, where it is affirmed to be so transparent,

as that the kernels may be perfectly seen, when the Apple is held to the light; but in this country it is a meally intrepid fruit, so is not worth propagating.

Loan's Pearmain. This is a beautiful fruit to the sight, of a middling size; the side next the sun is of a fine red, striped with the same colour on the other; the flesh is vinous, but as it soon grows meally, it is not greatly esteemed.

The Quince Apple. This is a small fruit, seldom larger than the Golden Pippin, but is longer, and in shape like the Quince, especially toward the stalk; the side next the sun is of a russet colour, on the other side inclining to yellow. This is an excellent Apple for about three weeks in *September*, but it will not keep much longer.

The Golden Renette is a fruit so well known in *England*, as to need no description. This ripens about *Michaelmas*, and for about a month is a very good fruit, either for eating raw or baking.

The Aromatick Pippin is also a very good Apple. It is about the size of a Nonpareil, but a little longer; the side next the sun is of a bright russet colour; the flesh is breaking, and hath an aromatick flavour. It ripens in *October*.

The Hertfordshire Pearmain, by some called the *Winter Pearmain*. This is a good sized fruit, rather long than round, of a fine red next the sun, and striped with the same colour on the other side; the flesh is juicy, and stews well, but is not esteemed for eating by any nice palates. This is fit for use in *November* and *December*.

The Kentish Pippin is a large handsome fruit, of an oblong figure; the skin is of a pale green colour; the flesh is breaking, and full of juice, which is of a quick acid flavour. This is a very good kitchen fruit, and will keep till *February*.

The Holland Pippin is larger than the former; the fruit is somewhat longer, the skin of a darker green, and the flesh firm and juicy. This is a very good kitchen fruit, and will keep late in the season.

The Monstrous Renette is a very large Apple, of an oblong shape, turning red toward the sun, but of a dark green on the other side; the flesh is apt to be meally, so it is not much valued by those who are curious, and only preserved for the magnitude of the fruit.

The Embroidered Apple is a pretty large fruit, somewhat shaped like the Pearmain, but the stripes of red are very broad, from whence the gardeners have given it this title. It is a middling fruit, and is commonly used as a kitchen Apple, though there are many better.

The Royal Russet, by some called the *Leather Coat Russet*, on account of the deep russet colour of the skin. This is a large fair fruit, of an oblong figure, broad toward the base; the flesh is inclinable to yellow. This is one of the best kitchen Apples we have, and is a very great bearer; the trees grow large and handsome, and the fruit is in use from *October* till *April*, and is also a pleasant fruit to eat.

Wheeler's Russet is an Apple of a middling size, flat and round; the stalk is slender, the side next the sun of a light russet colour, the other side inclining to a pale yellow when ripe; the flesh is firm, and the juice has a very quick acid flavour; but it is an excellent kitchen fruit, and will keep a long time.

Pile's Russet is not quite so large as the former, but is of an oval figure, of a russet colour to the sun, and of a dark green on the other side. It is a very firm fruit, of a sharp acid flavour, but is much esteemed for baking, and will keep sound till *April*, or later, if they are well preserved.

The Nonpareil is a fruit pretty generally known in *England*, though there is another Apple which is frequently sold in the markets for it, which is what the *French* call *Haute-bonne*. This is a larger fairer fruit than the Nonpareil, more inclining to yellow; the russet colour brighter, and it is earlier ripe, and sooner gone: this is not so flat as

the true Nonpareil, nor is the juice so sharp, though it is good Apple in its season; but the Nonpareil is seldom ripe before *Christmas*, and where they are well preserved, they will keep till *May* perfectly sound. This is justly esteemed one of the best Apples that have been yet known.

The Golden Pippin is a fruit peculiar to *England*. There are few countries abroad where this succeeds well, nor do they produce so good fruit in many parts of *England*, as were to be wished. This is in some measure owing to their being grafted on free stocks, which enlarges the fruit, but renders it less valuable, because the flesh is not so firm, nor the flavour so quick, and it is apt to be dry and meally; therefore this should always be grafted upon the Crab stock, which will not canker like the others: and though the fruit will not be so fair to the sight, yet it will be better flavoured.

There are yet a great variety of Apples, which, being inferior to those here mentioned, I have omitted, as those which are here enumerated will be sufficient to furnish the table and the kitchen, during the whole season of these fruits; so that where these sorts are to be had, no person of taste will eat the other.

I shall here mention some of the Apples which are chiefly preferred for the making of cyder, though there are, in every cyder country, new sorts frequently obtained from the kernels; but those hereafter mentioned, have for some years been in the greatest esteem.

The Red-streak.

Devonshire Royal Wilding.

The Whitfour.

Hertfordshire Under Leaf.

John Apple, or Deux-annes.

Everlasting Hanger.

Gennet Moyle.

All the sorts of Apples are propagated by grafting or budding upon the stocks of the same kind, for they will not take upon any other sort of fruit tree. In the nurseries there are three sorts of stocks generally used, to graft Apples upon; the first are called free stocks, which are raised from the kernels of all sorts of Apples indifferently, and by some these are also termed Crab stocks; for all those trees which are produced from the seeds, before they are grafted, are termed Crabs without any distinction; but, as I before observed, I should always prefer such stocks as are raised from the kernels of Crabs, where they are pressed for verjuice; and I find several of the old writers on this subject of the same mind. *Mr. Austen*, who wrote a hundred years ago, says, *The stock which he accounts best for Apple grafts, is the Crab, which is better than sweeter Apple trees to graft on, because they are usually free from canker, and will become very large trees, and I conceive will last longer than stocks of sweeter Apples, and will make fruits more strong and hardy to endure frosts.* It is very certain, that by frequent grafting some sorts of Apples upon free stocks, the fruits have been rendered larger, but less firm, poignant, and of shorter duration.

The second sort of stocks is the *Dutch Creeper* before-mentioned; these are designed to stint the growth of the trees, and keep them within compass for dwarfs or espaliers.

The third sort is the *Paradise Apple*, which is a very low shrub, so only proper for trees which are kept in pots, by way of curiosity, for these do not continue long.

Some persons have made use of *Codlin* stocks for grafting of Apples, in order to stint their growth; but as these are commonly propagated by suckers, I would by no means advise the using of them; nor would I choose to raise the *Codlin* trees from suckers, but rather graft them upon Crab stocks, which will cause the fruit to be firmer, last longer, and have a sharper flavour. The trees so propagated will

ast much longer sound, and never put out suckers, as the Codlins always do, which, if not constantly taken off, will weaken the trees, and cause them to canker; and it is not only from the roots, but from the knots of their stems, there are generally a great number of strong shoots produced, which fill the trees with uselefs shoots, and render them un-fighly, and the fruit small and crumpled.

The method of raising stocks from the kernels of Crabs, or Apples, is, to procure them where they are pressed for verjuice or cyder, and after they are cleared of the pulp, they may be sown upon a bed of light earth, covering them over about half an inch thick with the same light earth; these may be sown in *November* or *December*, where the ground is dry, but in wet ground, it will be better to defer it till *February*; but then the seeds should be preserved in dry sand, and kept out of the reach of vermin, for if mice or rats can get to them, they will devour the seeds; there should also be care taken of the seeds, when they are sown, to protect them from these vermin, by setting traps to take them, &c. In the spring, when the plants begin to appear, they must be constantly kept clear from weeds, which, if suffered to grow, will soon over-top the plants, and spoil their growth; if these thrive well, some of them will be fit to transplant into the nursery the *October* following, for the sooner these seedling plants are removed from the seed-bed, the less danger there will be of their shooting down tap roots, which in fruit trees should always be prevented. The ground where these young stocks are to be planted, should be carefully digged, and cleansed from the roots of all bad weeds, and laid level; then the stocks should be planted in rows three feet asunder, and the plants one foot distance in the rows, closing the earth pretty fast to their roots; when the stocks are transplanted out of the seed-bed, the first autumn after sowing, they must not be headed, but such as are inclined to shoot downward, the tap root must be shortened, in order to force out horizontal roots: if the ground is pretty good in which these stocks are planted, and the weeds constantly cleared away, the stocks will make great progress, so that those which are intended for dwarfs, may be grafted the spring twelve months after they are planted out of the seed-bed; but those which are designed for standards will require two or three years more growth, before they will be fit to graft, by which time they will be upward of six feet high. The other necessary work to be observed in the culture of these trees, while they remain in the nursery, being exhibited under the article of NURSERY, I shall not repeat it in this place.

I shall next treat of the manner of planting such of these

trees as are designed for espaliers in the kitchen-garden, where, if there is an extent of ground, it will be proper to plant, not only such sorts as are for the use of the table, but also a quantity of trees to supply the kitchen; but where the kitchen-garden is small, the latter must be supplied from standard trees, either from the orchard, or wherever they are planted; but as many of these kitchen Apples are large, and hang late in the autumn upon the trees, they will be much more exposed to the strong winds, on standard trees, than in espaliers, whereby many of the fruit will be blown down before they are ripe, and others bruised, so as to prevent their keeping; therefore where it can be done, I should always prefer the planting them in espaliers.

The distance which I should choose to allow these trees, should not be less than twenty-five, or thirty feet, for such sorts as are of moderate growth (if upon Crab or free stocks) but the larger growing sorts should not be allowed less room than thirty-five feet, which will be found full near enough, if the ground is good, and the trees properly trained; for as the branches of these trees should not be shortened, but trained at their full length, so in a few years they will be found to meet. Indeed, at the first planting, the distance will appear so great, to those persons who have not observed the vigorous growth of these trees, that they will suppose they never can extend their branches so far, as to cover the espalier; but if these persons will but observe the growth of standard trees of the same kinds, and see how wide their branches are extended on every side, they may be soon convinced, that as these espalier trees are allowed to spread but on two sides, they will of course make more progress, as the whole nourishment of the root will be employed in these side branches, than where there is a greater number of branches on every side of the tree, which are to be supplied with the same nourishment.

The next thing to be observed is the making choice of such sorts of fruits as grow nearly alike, to plant in the same espalier. This is of great consequence, because of the distance they are to be placed, otherwise those sorts which make the largest shoots, may be allowed less room to spread than those of smaller growth; besides, when all the trees in one espalier are nearly equal in growth, they will have a better appearance than when some are tall, and others short; but for the better instruction of those persons who are not conversant in these things, I shall divide the sorts of Apples into three classes, according to their different growths.

Largest growing tree.

All the sorts of Pearmains.
Kentish Pippin.
Holland Pippin.
 Monstrous Renette.
 Royal Ruffet.
Wheeler's Ruffet.
Pile's Ruffet.
 Nonpareil.
 Violet Apple.

Middle growing tree.

Codlin.
 Margaret Apple.
 Golden Renette.
 Aromatick Pippin.
 Embroidered Apple.
 Renette Grise.

Smallest growing tree.

Quince Apple.
 Transparent Apple.
 Golden Pippin.
Pomme d'Api.
Fenouillet, or Anise Apple.

N. B. These are all supposed to be grafted on the same sort of stocks.

If these Apples are grafted upon Crab stocks, I would willingly place them at the following distance from each other, especially where the soil is good, *viz.* the largest growing trees at forty feet, the middle growing at thirty

feet, and the small growing at twenty feet, which, from constant experience, I find to be full near enough; for in many places, where I have planted the trees at twenty-four feet distance, the trees have grown so strong, as that in seven years

years their branches have met; and in some places where every other tree hath been taken up, the branches have almost joined in seven years after; therefore it will be much the better way to plant these trees at a proper distance at first, and between these to plant some Dwarf Cherries, Currants, or other sort of fruit, to bear for a few years, which may be cut away when the Apple trees have extended their branches to them; for when the Apple trees are planted nearer together, few persons care to cut down the trees when they are fruitful, so that they are obliged to use the knife, saw, and chisel, more than is proper for the future good of the trees; and many times, where persons are inclinable to take away part of their trees, the distances will be often so irregular (where there was not this consideration in planting,) as to render the espalier unsightly.

When the trees are upon the *Dutch* dwarf stock, the distance should be for the larger growing trees thirty feet; twenty-five, for those of middle growth; and the smallest twenty feet, which will be found full near, where the trees thrive well.

The next is the choice of the trees, which should not be more than two years growth from the graft, but those of one year should be preferred; be careful that their stocks are young, sound, and smooth, free from canker, which have not been cut down in the nursery; when they are taken up, all the small fibres should be entirely cut off from their roots, which, if left on, will turn mouldy and decay, so will obstruct the new fibres in their growth; the extreme parts of the roots must be shortened, and all bruised roots cut off; and if there are any misplaced roots, which cross each other, they should also be cut away. As to the pruning of the head of these trees, there need be nothing more done, than to cut off any branches, which are so situated, as that they cannot be trained to the line of the espalier; in the planting there must be care taken not to place their roots too deep in the ground, especially if the soil is moist, but rather raise them on a little hill, which will be necessary to allow for the raising of the borders afterward. The best season for planting these trees (in all soils which are not very moist) is, from *October*, to the middle, or latter end of *November*, according as the season continues mild; but so soon as the leaves fall, they may be removed with great safety. After the trees are planted, it will be proper to place down a stake to each tree, to which the branches should be fastened, to prevent the winds from shaking or loosening their roots, which will destroy the young fibres; for when these trees are planted pretty early in the autumn, they will very soon push out a great number of new fibres, which, being very tender, are soon broken, so the trees are greatly injured thereby. If the winter should prove severe, it will be proper to lay some rotten dung, tanners bark, or some sort of mulch, about their roots, to prevent the frost from penetrating of the ground, which might damage these tender fibres; but I would not advise the laying of this mulch before the frost begins, for if it is laid over the roots soon after the trees are planted (as is often practised), it will prevent the moisture entering the ground, and do much harm to the trees.

The following spring, before the trees begin to push, there should be two or three short stakes put down on each side of the tree, to which the branches should be fastened down as horizontally as possible, never cutting them down, as is by some practised, for there will be no danger of their putting out branches enough to furnish the espalier, if the trees are once well established in their new quarters.

In the pruning of these trees, the chief point is, never to shorten any of the branches, unless there is an absolute want of shoots to fill the places of the espalier; for where the knife is much used, it only multiplies useless shoots, and

prevents their fruiting; so that the best method to manage these trees is, to go over them three or four times in the growing season, and rub off all such shoots as are irregularly produced, and train the others down to the stakes, in the position they are to remain; if this is carefully performed in summer, there will be little left to be done in the winter, and by bending of their shoots from time to time, as they are produced, there will be no occasion to use force to bring them down, nor any danger of breaking the branches. The distance which these branches should be trained from each other, for the largest sorts of fruit, should be about seven or eight inches, and for the smaller, five or six. If these plain instructions are followed, it will save much unnecessary labour of pruning, and the trees will, at all times, make a handsome appearance; whereas when they are suffered to grow rude in summer, there will be much difficulty to bring down their shoots without breaking, especially if they are grown stubborn. All the sorts of Apples produce their fruit upon cursons, or spurs, so that these should never be cut off, for they will continue fruitful a great number of years.

The method of making the espaliers having been already exhibited under that article, I need not repeat it here, but only observe, that it will be best to defer making the espalier, till the trees have had three or four years growth, for before that time, the branches may be supported by a few upright stakes, so that there will be no necessity to make the espalier, until there are sufficient branches to furnish all the lower part.

I shall now treat of the method to plant orchards, so as to have them produce the greatest profit. And first, in the choice of the soil and situation for an orchard: the best is that on the ascent of gentle hills, facing the south, or south-east, but this ascent must not be too steep, lest the earth should be washed down by hasty rains. There are many persons who prefer low situations at the foot of hills, but I am thoroughly convinced from experience, that all bottoms where there are hills on every side, are very improper for this purpose; for the air is drawn down in strong currents, which, being pent in on every side, renders these bottoms much colder, than the open situations; and during the winter and spring, these bottoms are very damp, and unhealthy to all vegetables; therefore the gentle rise of a hill, fully exposed to the sun and air, is by much the best situation. As to the soil, a gentle hazel loam, which is easy to work, and that doth not detain the wet, is the best; if this happens to be three feet deep, it will be the better for the growth of the trees, for although these trees will grow upon very strong land, yet they are seldom so thriving, nor are their fruit so well flavoured, as those which grow on a gentle soil; and on the other hand, these trees will not do well upon a very dry gravel, or sand, therefore those soils should never be made choice of for orchards.

The ground intended to be planted should be well prepared the year before, by ploughing it thoroughly, and if some dung is laid upon it the year before, it will be of great service to the trees; if in the precedent spring a crop of Peas or Beans is planted on the ground (provided they are sown or planted in rows, at a proper distance, so as that the ground between them is horse-hoed), it will destroy the weeds, and loosen the ground, so that will be a good preparation for the trees, for the earth cannot be too much wrought, or pulverized for this purpose; these crops will be taken off the ground before the season for planting of these trees, which should be performed when the trees begin to shed their leaves.

In choosing of the trees, I would advise the taking such as are but of two years growth from the graft, and never to plant old trees, or such as are grafted upon old stocks; for

for it is losing of time to plant such, young trees being always more certain to grow, and make a much greater progress than those which are old. As to pruning of the roots, it must be done in the same manner as hath been already directed for the espalier trees; and in pruning their heads, little more is necessary than to cut such branches as are ill placed, or that cross each other, for I do not approve the heading of them down, as is by some often practised, to the loss of many of their trees.

The distance which these trees should be planted, where the soil is good, must be fifty or sixty feet; and where the soil is not so good, forty feet may be sufficient; but nothing can be of worse consequence, than the crowding trees too close together in orchards: for although there be some persons who may imagine this distance too great, yet I am sure, when they have thoroughly considered the advantages attending this practice, they will agree with me. Nor is it my own authority, for in many of the old writers on this subject, who have wrote from experience, there is often mention made of the necessity for allowing a proper distance to the fruit trees in orchards; particularly *Austen*, who says, *He should choose to prescribe the planting these trees fourteen or sixteen yards asunder; for both trees and fruits have many great advantages, if planted a good distance from one another.* One advantage he mentions is, *The sun refreshes every tree, the roots, body, and branches, with the blossoms and fruits; whereby trees bring forth more fruit, and those fairer and better.* Another advantage he mentions is, *That when trees are planted at a large distance, much profit may be made of the ground under and about these trees, by cultivating garden stuff, commodious as well for sale as housekeeping; as also Gooseberries, Raspberries, Currants, and Strawberries, may be there planted.* Again he says, *When trees have room to spread, they will grow very large and great; and the consequences of that will be, not only multitudes of fruits, but also long lasting, and these two are no small advantages.* For, says he, *men are mistaken, when they say, The more trees in an orchard, the more fruits; for one or two larger trees, which have room to spread, will bear more fruit than six or ten (it may be) of those that grow near together, and crowd one another.* Again he says, *Let men but observe, and take notice of some Apple trees, that grow a great distance from other trees, and have room enough to spread both their roots and branches, and they shall see, that one of those trees (being come to full growth) hath a larger head, and more boughs and branches, than (it may be) four, or six, or more, of those which grow near together, although of the same age.*

And Mr. *Lawson*, an ancient planter, advises to plant Apple trees twenty yards asunder. As the two authors above quoted have written the best upon this subject, and seem to have had more experience than any of the writers I have seen, I have made use of them as authorities to confirm what I have advanced; though the fact is so obvious to every person who will make the least reflection, that there needs no other proof.

When the trees are planted, they should be staked, to prevent their being shaken, or blown out of the ground by strong winds; but in doing of this, there should be particular care taken, to put either straw, haybands, or woollen cloth, between the trees and the stakes, to prevent the trees from being rubbed and bruised by the shaking against the stakes, for if their bark should be rubbed off, it will occasion such great wounds, as not to be healed over in several years, if they ever recover it.

If the winter should prove very severe, it will be proper to cover the surface of the ground about their roots with some mulch, to prevent the frost from penetrating the ground, which will injure the young fibres; but this mulch should not be laid on too soon, as hath been before mentioned, lest the moisture should be prevented from soaking

down to the roots of the trees, nor should it lie on too long in the spring, for the same reason: therefore where persons will be at the trouble to lay it on in frosty weather, and remove it again after the frost is over, that the wet in *February* may have free access to the roots of the trees; and if *March* should prove dry, with sharp north or east winds, which often happens, it will be proper to cover the ground again with the mulch, to prevent the winds from penetrating and drying the ground, which will be of singular service to the trees. But I am aware, that this will be objected to by many, on account of the trouble, which may appear to be great; but when it is considered, how much of this business may be done by a single person in a short time, it can have little force, and the benefit which the trees will receive by this management, will greatly recompense the trouble and expence.

As these trees must be constantly fenced from cattle, it will be the best way to keep the land in tillage, for by constant ploughing or digging of the ground, the roots of the trees will be encouraged, and they will make the more progress in their growth; but where this is done, whatever crops are sown or planted, should not be too near the trees, lest the nourishment should be drawn away from them; and if the ground is ploughed there must be care taken not to go too near the stems of the trees, whereby their roots would be injured, or the bark of their stems rubbed off; but it will be of great service to dig the ground about the trees, where the plough doth not come, every spring or autumn, for five or six years after planting, by which time their roots will have extended themselves to a greater distance.

It is a common practice in many parts of *England*, to lay the ground down for pasture, after the trees are grown pretty large in their orchards; but this is by no means advisable, for I have frequently seen trees of above twenty years growth, almost destroyed by horses, in the compass of one week; and if sheep are put into orchards, they will constantly rub their bodies against the stems of the trees, and their grease sticking to the bark, will stint their growth, and in time will spoil them; therefore wherever orchards are planted, it will be much the better method to keep the ground ploughed or dug annually, and such crops put on the ground, as will not draw too much nourishment from the trees.

In pruning of orchard trees nothing more should be done, but to cut out all those branches which cross each other, which, if left, would rub and tear off the bark from each other, as also decayed branches, but never shorten any of their shoots. If suckers, or shoots from their stems, should come out, they must be entirely taken off, and when any branches are broken by the wind, they should be cut off, either down to the division of the branch, or close to the stem from whence it was produced; the best time for this work is in *November*, for it should not be done in frosty weather, nor in the spring, when the sap begins to be in motion.

The best method to keep Apples for winter use is, to let them hang upon the trees, until there is danger of frost; to gather them in dry weather, and then lay them in large heaps to sweat for a month or six weeks; afterward look them over carefully, taking out all such as have appearance of decay, wiping all the sound fruit dry, and pack them up in large oil jars, which have been thoroughly scalded and dry, stopping them down close, to exclude the external air; if this is duly observed, the fruit will keep sound a long time, and their flesh will be plump, for when they are exposed to the air, their skins will shrink, and their pulp will be soft.

MAMMEA. Plum. Nov. Gen. 44. tab. 4. The Mammee tree.

The Characters are,

The flower has four large concave petals, which spread open. It hath many awl-shaped stamina, and in the center a roundish germen, which afterward turns to a large fleshy fruit, of a spherical figure, inclosing one, two, or three large, almost oval stones.

There is but one Species of this tree known, viz.

MAMMEA staminibus flore brevioribus. Lin. Sp. 512. Mammee with the stamina shorter than the flower.

This tree, in the *West-Indies*, grows to the height of sixty or seventy feet; the leaves are large and stiff, and continue green all the year; the fruit is as large as a man's fist; when ripe, it is of a yellowish green colour, and is very grateful to the taste. It grows in great plenty in the *Spanish West-Indies*, where the fruit is generally sold in their markets, and is esteemed one of the best fruits of the country. It also grows on the hills of *Jamaica*, and has been transplanted into most of the *Caribbee Islands*, where it thrives exceeding well.

In *England* there are few of these plants, but none of any size. The plants may be propagated by planting the stones, which are often brought from the *West-Indies* (but these stones should be fresh, otherwise they will not grow); these should be put into pots, and plunged into a hot-bed of tanners bark. In about two months the plants will appear above ground, after which, in warm weather, the glasses of the hot-bed should be raised to let in the fresh air. In three months after the roots of the plants will have filled the pots, when they should be carefully taken out of the pots, and the outer shell of the nut taken off with all possible care not to injure the roots of the plants; then they must be new potted, and plunged again into the bark-bed, observing to water and shade them until they have taken root, after which they should have air and water in proportion to the warmth of the season. In this bed they may remain till *Michaelmas*, when they must be removed into the bark-stove, where they must be constantly kept, and may be treated after the manner directed for the Coffee tree.

If, when the stones of this fruit are brought over, they are put into the tan-bed, under the bottom of any of the pots, they will sprout sooner than those which are planted in the earth.

MANCANILLA. See Hippomane.

MANDRAGORA. Tourn. Inst. R. H. 16. tab. 12. Mandrake.

The Characters are,

The flower hath one erect bell-shaped petal, which is a little larger than the empalement. It has five awl-shaped stamina, which are arched and hairy at their base. In the center is situated a roundish germen, which afterward turns to a large round berry with two cells, having a fleshy receptacle convex on each side, filled with kidney-shaped seeds.

We have but one Species of this genus at present in the *English* gardens, viz.

MANDRAGORA. Hort. Cliff. 51. Mandrake with a round fruit.

This plant grows naturally in *Spain*, *Portugal*, *Italy*, and the *Levant*, but is preserved here in the gardens of the curious. It hath a long taper root shaped like a Parsnep, which runs three or four feet deep in the ground; it is sometimes single, and at others divided into two or three branches, al-

most of the colour of Parsnep, but a little darker; from this arises a circle of leaves, which at first stand erect, but, when grown to their full size, spread open, and lie upon the ground; they are more than a foot in length, and four or five inches broad in the middle, of a dark green colour, and a fetid scent. These rise immediately from the crown of the root, without any foot-stalk; between them come out the flowers, each standing upon a separate foot-stalk about three inches long, which also arise immediately from the root; the flowers are five-cornered, of an herbaceous white colour; spreading open at the top like a Primrose, having five hairy stamina, with a globular germen in the center; supporting an awl-shaped style. The germen afterward turns to a globular soft berry lying upon the leaves, which, when fully grown, is as large as a nutmeg, of a yellowish-green colour when ripe, full of pulp, in which the kidney-shaped seeds are lodged. It flowers in *March*, and the seeds are ripe in *July*.

This plant is propagated by seeds, which should be sown upon a bed of light earth soon after they are ripe, for if they are kept until the spring, they seldom succeed well; but those which are sown in autumn will come up in the spring, when they should be carefully cleared from weeds. In this bed they should remain till the autumn, when they should be taken up very carefully, and transplanted into the places where they are to remain, which should be in a light deep soil; for their roots always run downward very deep; so that if the soil be wet, they are often rotted in winter; and if it be too near the gravel or chalk, they seldom thrive well; but if the soil is good and they are not disturbed, the plants will grow to a large size in a few years, and will produce great quantities of flowers and fruit, and will abide a great many years.

I have been informed by some persons of credit, that one of these roots will remain sound fifty or sixty years, and be as vigorous as a young plant. I know some plants myself, which are now above forty years old, and in great vigour, which may continue so many years longer, as there are no signs of their decay; but they should never be removed after their roots have arrived to any considerable size, which would break their lower fibres, and so stint the plants, as that if they live they will not recover their former strength in two or three years.

As to the feigned resemblance of a human form, which the roots of this plant are said to carry, it is all imposture, owing to the cunning of quacks and mountebanks, who deceive the populace and the ignorant with fictitious images shaped from the fresh roots of Briony and other plants: and what is reported as to the manner of rooting up this plant, by tying a dog thereto, to prevent the certain death of the person who should dare to attempt it, and the groans it emits upon the force offered, &c. is all a ridiculous fable: for I have taken up several large roots of this plant, some of which have been transplanted into other places, but could never observe any accident which attended it, nor was there any difference from that of other deep rooting plants.

MANIHOT. See Jatropha.

MAPLE. See Acer.

MARACQCK. See Passiflora.

MARANTA. Plum. Nov. Gen. 16. tab. 36. Indian Arrow-root.

The Characters are,

The flower hath one petal, which is of the grinning kind, with an oblong compressed tube, cut into six small segments, representing a lip flower. It has one membranaceous stamina, appearing like a segment of the petal, and a roundish germen situated under the flower, which afterward turns to a roundish three-cornered capsule with three valves, containing one hard rough seed.

The Species are,

1. *MARANTA segmentis petalorum dentatis*. Indian Arrow-root, with the segments of the flower indented.

2. *MARANTA segmentis petalorum integerrimis*. Indian Arrow-root, with the segments of the petals entire; called Indian Arrow-root.

The first sort was discovered by father Plumier in some of the French settlements in America; and the late Dr. William Houstoun, found the same sort growing in plenty near La Vera Cruz in New Spain.

This hath a thick, fleshy, creeping root, which is very full of knots, from which arise many smooth leaves, six or seven inches long and three broad in the middle, terminating in points, which arise immediately from the root; between these come out the stalks, which rise near two feet high, and divide upward into two or three smaller, garnished at each joint with one leaf of the same shape with the lower, but are smaller. The stalks are terminated by a loose spike of small white flowers, standing upon long foot-stalks. The flowers are cut into six narrow segments, which are indented on their edges, and sit upon the germen, which afterward turns to a roundish three-corned capsule, inclosing one hard rough seed.

The other sort was brought from some of the Spanish settlements in America, into the islands of Barbadoes and Jamaica, where it is cultivated in their gardens as a medicinal plant, being a sovereign remedy to cure the bite of wasps, and to extract the poison of the Manchineel tree. The Indians apply the root to expel the poison of their arrows, which they use with great success. They take up the roots, and after cleansing them from dirt, they mash them, and apply it as a poultice to the wounded part, which draws out the poison, and heals the wound. It will also stop a gangrene, if it be applied before it is gone too far, so that it is a very valuable plant.

This sort is very like the first, but the flowers are smaller, and the segments of the petals are entire, in which their principal difference consists.

These plants being natives of a warm country, are tender, therefore will not live in this climate, unless they are preserved in stoves. They propagate fast by their creeping roots, which should be parted the middle of March, just before they begin to push out new leaves, and planted in pots filled with light earth, then plunged into a moderate hot-bed of tanners bark, observing now and then to refresh them with water; but it must not be given to them in large quantities, for too much moisture will soon rot them, when they are in an unactive state. When the green leaves appear above ground, the plants will require frequently to be watered, and should have free air admitted to them every day, in proportion to the warmth of the season and the heat of the bed in which they are placed. Where they are constantly kept in the tan-bed, and have proper air and moisture, they will thrive, so as from a small root to fill the pots, in which they were planted, in one summer. About Michaelmas the first sort will begin to decay, and in a short time after the leaves will die to the ground, but the pots must be continued all the winter in the bark-bed, otherwise the roots will perish; for although they are in an unactive state, yet they will not keep from shrinking very long, when taken out of the ground; and if the pots are taken out of the tan, and placed in any dry part of the stove, the roots often shrivel and decay; but when they are continued in the tan, they should have but little water given to them when their leaves are decayed, lest it rot them.

MARJORAM. See Origanum.

MARLE is a kind of clay, which is become fatter, and of a more enriching quality, by a better fermentation, and by its having lain so deep in the earth as not

to have spent or weakened its fertilizing quality by any product.

Marles are of different qualities in different counties of England. There are reckoned to be four sorts of marles in Suffex, a gray, a blue, a yellow, and a red; of these the blue is accounted the best, the yellow the next, and the gray the next to that; and as for the red, that is the least valuable.

In Cheshire they reckon six sorts of marle:

1. The cowshut marle, which is of a brownish colour, with blue veins in it, and little lumps of chalk or lime stone; it is commonly found under clay, or low black land, seven or eight feet deep, and is very hard to dig.

2. Stone, slate, or flag marle, which is a kind of soft stone, or rather slate of a blue or bluish colour, that will easily dissolve with frost or rain. This is found near rivers, and the sides of hills, and is a very lasting sort of marle.

3. Peat marle, or delving marle, which is close, strong, and very fat, of a brown colour, and is found on the sides of hills, and in wet or boggy grounds, which have a light sand in them about two feet or a yard deep.

4. Clay marle; this resembles clay, and is pretty near akin to it, but is fatter, and sometimes mixed with chalk stones.

5. Steel marle, which lies commonly in the bottom of pits that are dug, and is of itself apt to break into cubical bits; this is sometimes under sandy land.

6. Paper marle, which resembles leaves or pieces of brown paper, but something of a lighter colour; this lies near coals.

The properties of any sorts of marles, and by which the goodness of them may be best known, are better judged of by their purity and uncompoundness, than their colour: as if it will break in pieces like dice, or into thin flakes, or is smooth like lead ore, and is without a mixture of gravel or sand; if it will shake like slate stones, and shatter after wet, or will turn to dust when it has been exposed to the sun; or will not hang and stick together when it is thoroughly dry, like tough clay; but is fat and tender, and will open the land it is laid on, and not bind; it may be taken for granted, that it will be beneficial to it.

Marles do not make so good an improvement of lands the first year as afterwards.

The quantity of marle ought to be in proportion to the depth of the earth, for over marling has often proved of worse consequence than under marling, especially where the land is strong; for by laying it in too great quantities, or often repeating the marling, the land has become so strong and bound so closely, as to detain the wet like a dish, so that the owners have been obliged to drain the ground at a great expence; but in sandy land there can be no danger in laying on a great quantity, or repeating it often, for it is one of the best dressings for such land.

MARRUBIASTRUM. See Sideritis.

MARRUBIUM. Tourn. Inst. R. H. 192. tab. 91. Horehound.

The Characters are,

The flower is of the lip kind, with a cylindrical tube, divided into two lips. It has four stamina which are under the upper lip, two of which are a little longer than the other. It hath a four-pointed germen, which afterward turns to four oblong seeds, sitting in the empalement.

The Species are,

1. *MARRUBIUM dentibus calycinis setaceis uncinatis*. Hort. Cliff. 312. Common white Horehound.

2. *MARRUBIUM foliis ovato-lanceolatis serratis, calycum denticulis setaceis*, Hort. Cliff. 311. Broad-leaved, foreign, white Horehound.

3. *MARRUBIUM foliis lanceolatis dentatis, verticillis minoribus, dentibus calycinis setaceis erectis.* Narrow-leaved, foreign, white Horehound.

4. *MARRUBIUM foliis cuneiformibus, verticillis involucri destitutis.* Hort. Cliff. 311. Horehound called Madwort, with leaves which are deeply cut.

5. *MARRUBIUM dentibus calycinis setaceis rectis villosis.* Hort. Cliff. 312. Low Spanish Horehound, with silver-coloured fattiny leaves.

6. *MARRUBIUM foliis subovatis lanatis supernè emarginato-crenatis, denticulis calycinis subulatis.* Hort. Cliff. 312. The whitest and most hairy Horehound.

7. *MARRUBIUM calycum limbis patentibus, denticulis acutis.* Hort. Cliff. 312. Round-leaved Spanish Horehound.

8. *MARRUBIUM foliis subovatis tomentosis supernè serratis, denticulis calycinis setaceis erectis.* Whitest round-leaved Horehound.

9. *MARRUBIUM calycum limbis planis villosis, foliis orbiculatis rugosis, caule herbaceo.* Spanish bastard Dittany, with rough-curved leaves.

10. *MARRUBIUM calycum limbis planis villosis, foliis cordatis rugosis incanis, caule suffruticoso.* Spanish bastard Dittany, with a very large hoary leaf.

11. *MARRUBIUM calycum limbis planis villosis, foliis cordatis, caule fruticoso.* Hort. Cliff. 312. Whorled, unfavoury, bastard Dittany.

12. *MARRUBIUM calycum limbis tubo longioribus membranaceis, angulis majoribus rotundatis.* Lin. Sp. Plant. 584. Bastard Dittany, with an empalement like *Molucca* Baum.

The first sort is the Prassium, or white Horehound of the shops. This grows naturally in many parts of *England*, so is seldom propagated in gardens. It hath a ligneous fibrous root, from which come out many square stalks two feet in length, garnished with hoary roundish leaves, indented on the edges, placed opposite. The flowers grow in very thick whorls round the stalks at each joint; they are small, white, and of the lip kind, standing in stiff hoary empalements, cut into ten parts at the top, which end in stiff bristles; these are succeeded by four oblong black seeds, fitting in the empalement.

The second sort grows naturally in *Italy* and *Sicily*. This rises with square stalks near three feet high, which branch much more than the first; the leaves are rounder, whiter, and stand farther asunder; the whorls of flowers are not so large, but the flowers have longer tubes.

The third sort grows naturally in *Spain* and *Portugal*. This rises with slender hoary stalks three feet high; the leaves are very hoary, much longer and narrower than those of the second; the whorls of flowers are smaller, the bristly indentures of the empalement are longer and erect; the whole plant has an agreeable flavour.

The fourth sort grows naturally in *Spain* and *Italy*. This is a biennial plant, whose stalks are about the same length as those of the first; the leaves are wedge-shaped, hoary, and obtusely indented; the whorls of flowers are small, and have no covers. The flowers stand looser in the whorls, and the cuts of the empalement end in very stiff prickles which spread open; the flowers are purple, and larger than those of the first sort.

The fifth sort grows naturally in *Spain*, and also in the islands of the *Archipelago*. The stalks of this are seldom above eight or nine inches long, covered with a soft hoary down; the leaves are small, roundish, very soft to the touch, and indented on the edges. The whorls of flowers are small, very downy and white.

The sixth sort grows naturally in *Spain*. This hath stalks about the same length as the first; the leaves are nearly oval, woolly, and crenated toward the top, and the empalement of the flowers are awl-shaped.

The seventh sort grows naturally in *Spain*. The stalks of this grow more erect than those of the common sort; the leaves are rounder and more sawed on the edges; the empalement of the flowers spread open, ending in acute segments. The flowers are like those of the common sort; the whole plant is very hoary.

The eighth sort grows naturally in the *Levant*. The stalks of this sort are very woolly; the leaves are almost oval, thick, and indented on their edges toward the top; their foot-stalks are broad, the whorls of flowers are large, and the indentures of the empalements end in stiff bristles; the whole plant is very white.

The ninth sort grows naturally in *Spain* and *Sicily*. This sends out many stiff roundish stalks, which rise more than two feet high, covered with a white cottony down; the leaves are almost round, rough on their upper side, and woolly on their under; the whorls of flowers are large, the borders of the empalement are flat and hairy; the tube of the flower is scarce so long as the empalement, so the two lips are but just visible.

The tenth sort grows naturally in *Spain*. The stalks of this are a little shrubby, and rise near three feet high, dividing into small branches; the leaves are heart-shaped and rough on their upper side, but hoary on their under; the whorls of flowers are large, the borders of the empalements flat and hairy; the tube of the flower is longer, and the flowers are larger than those of the former sort; they are of a pale purple colour, and their upper lips are erect.

The eleventh sort grows naturally in *Sicily*, and the islands of the *Archipelago*. This rises with a shrubby stalk two feet high, which divides into many branches, garnished with small heart-shaped leaves, fitting pretty close to the stalks; the whorls of flowers are not so large as those of the two former sorts. The rim of the empalements are flat. The flowers are white, and the whole plant is very hoary.

The twelfth sort grows naturally in *Crete*. This hath very woolly stalks, which rise two feet high, garnished with woolly heart-shaped leaves. The whorls of flowers are large, the borders of the empalements flat, and cut into many segments, which are membranaceous, angular, and rounded at the top. The flowers are small, of a pale purple colour, but scarce appear out of their empalements, and their upper lips are erect.

The fourth sort is supposed to be *Galen's* Madwort. This was by the ancients greatly recommended for its efficacy in curing of madness, and some few of the moderns have prescribed it in the same disorder, but at present it is seldom used.

All these plants are preserved in botanick gardens for the sake of variety, but there are not above two of the sorts which are cultivated in other gardens; these are the eleventh and twelfth sorts, whose stalks are shrubby, and the plants very hoary, so make a variety when intermixed with other plants; these very rarely produce seeds in *England*, so are propagated by cuttings, which, if planted in a shady border the middle of *April*, will take root very freely.

They are somewhat tender, so in very severe winters should be screened from the hard frosts, especially those plants which grow in good ground, and are luxuriant; their branches are more replete with juice, so very liable to suffer by cold; but when they are in a poor, dry, rubbishy soil, the shoots will be short, firm, and dry, so are seldom injured by the cold, and these plants will continue much longer than those in better ground.

The other sorts are easily propagated by seeds, which should be sown on a bed of dry earth in the spring; when the plants come up, they must be kept clean from weeds, and where they are too close they should be thinned, leaving them a foot and a half asunder, that their branches

may have room to spread, after this they require no other culture; they may also be propagated by cuttings in the same manner as the two other sorts.

MARRUBIUM NIGRUM. See Ballote.

MARTAGON. See Lilium.

MARTYNIA. *Houft. Gen. Nov. Martyn. Dec. 1. 42.*

The Characters are,

The flower hath one bell-shaped petal, and is of the ringent kind, with a swelling tube, at the base of which is situated a gibbous nectarium. It hath four slender incurved stamina, which are inflexed into each other, and an oblong germen situated under the flower. The empalement afterward turns to an oblong gibbous capsule, which divides into two parts, including a hard nut shaped like the body of a stag beetle, with two incurved strong horns at the end, having four cells, two of which are generally barren, the other two have one oblong seed in each.

The Species are;

1. MARTYNIA caule ramoso, foliis angulatis. *Lin. Sp. Plant.* 618. Martynia with a branching stalk, and angular leaves.
2. MARTYNIA caule simplici, foliis serratis. *Lin. Sp. Plant.* 618. Martynia with a single stalk, and sawed leaves.
3. MARTYNIA caule ramoso, foliis cordato-ovatis pilosis. *Plat. 286.* Martynia with a branching stalk, and oval, heart-shaped, hairy leaves.

The first sort was discovered by the late Dr. William Housoun, near La Vera Cruz, in New Spain.

This rises with a strong herbaceous stalk near three feet high, which divides upward into two or three large branches, garnished with oblong, oval, hairy, viscous leaves, cut into angles on their sides. The flowers are produced in short spikes, from the end of the branches; they are shaped like those of the common Foxglove, but are of a paler purple colour, and are succeeded by oblong oval capsules, which are thick, tough, and clammy; when ripe, divide into two parts, and drop off, leaving a large hard nut hanging on the plant, about the size and much of the same form as the stag beetle, with two strong crooked horns at the end. The nut has two deep longitudinal furrows on the sides, and several smaller crossing each other in the middle, and is so hard, that it is with difficulty cut open, without injuring of the seeds; within are four oblong cells, two of which have a single oblong seed in each, but the other two are abortive. If the plants are brought forward in the spring, they will begin to shew their flowers in July, which are first produced at the division of the branches, and afterward at the extremity of each branch, so there will be a succession of flowers on the same plant till the end of October, when the plants decay.

The second sort was discovered by Mr. Robert Millar, growing naturally about Carthagena, in New Spain. This hath a perennial root, and an annual stalk. The roots of this plant are thick, fleshy, and divided into scaly knots, somewhat like those of Toothwort, from which arise several single, fleshy, succulent stalks, about a foot high, of a purplish colour, garnished with oblong thick leaves, whose base fits close to the stalk; they are sawed on their edges, rough on their upper side, where they are of a dark green, but their under side is purplish. The stalk is terminated by a spike of blue flowers, which are bell-shaped, and do not spread open at the rim so much as the former sort; these are not succeeded by seeds in England.

The third sort grows naturally in the Mississippi. This is an annual plant, having a thick fleshy stalk about two feet high, which divides into three or four spreading branches, garnished with oval heart-shaped leaves, of a soft green, very viscous and hairy; the flowers terminate the branches in a loose thyrse; they are in shape like those of the first sort, but of a paler colour, and are succeeded by large oval fruit, having very thick covers like the outer shell of Wal-

nuts, with two long incurved horns at the end: the outer shell drops off when the fruit is ripe, leaving a hard fibrous nut hanging on the plant, which opens in the middle, having four cells, each containing two or three oval seeds.

The first and third sorts are annual, so are only propagated by seed, which should be sown in pots, and plunged into a hot-bed of tanners bark, where, if the seeds are intirely separated from their covers, the plants will appear in about a month, and will grow pretty fast, if the bed is warm; they should therefore be transplanted in a little time after they come up, each into a separate pot, and plunged into the hot-bed again, observing to water and shade them from the sun, until they have taken new root; then they should have a large share of fresh air admitted to them in warm weather, to prevent their drawing. With this management the plants will make great progress, so as to fill the pots with their roots in about a month's time, when they should be shifted into pots, about a foot diameter at the top, and plunged into the hot-bed in the bark-stove, where they should be allowed room, because they put out many side branches, and will grow three feet high or more, according to the warmth of the bed, and the care which is taken to supply them constantly with water. When these plants thrive well, they will send out many side branches, which will all of them produce small spikes of flowers; but it is only from the first spike of flowers that good seeds can be expected in this country, so that particular care should be taken, that none of those are pulled off or destroyed, because it is very difficult to obtain good seeds here, especially of the first sort: but the third sort is much more hardy, so will perfect its seeds here very well, especially if the plants are not too much drawn.

The nuts of the first sort are so hard, as to render it very difficult to get out the seeds without breaking them; and if the whole nut is put into the ground, the seeds do seldom grow. I have had some of the nuts lying in the ground two years, which after were taken up, and appeared as found and good as when they were first put in, and some of the seeds have grown after being kept four or five years above ground.

The second sort dies to the root every winter, and rises again the succeeding spring. This must be constantly preserved in the stove, and plunged into the bark-bed, otherwise it will not thrive in this country. During the winter season, when the plants are decayed, they should have but little water given them; about the middle of March, just before the plants begin to shoot, is the proper season to transplant and part the roots, when they should be planted into pots of a middle size, and plunged into the bark-bed, which should at this time be renewed with fresh tan. When the plants come up, they must be treated in the same way as other tender exoticks, which require the bark-stove.

MATRICARIA. *Tourn. Inst. R. H. 493. tab. 281.* Fe-verfew.

The Characters are,

It hath a compound flower. The ray or border is composed of female half florets, and the disk, which is hemispherical, of hermaphrodite florets. The female half florets are tongue-shaped, and indented in three parts at the end; these have a naked germen. The hermaphrodite florets are tubulous, funnel-shaped, and

cut into five parts at the brim; they have each five hairy short stamina, and an oblong naked germen. The germen of both turn to single, oblong, naked seeds.

The Species are,

1. *MATRICARIA foliis compositis planis, foliolis ovatis incisif, pedunculis ramosis.* Hort. Cliff. 416. Common, or Garden Feverfew.

2. *MATRICARIA receptaculis hemisphaericis, foliis bipinnatis subcarnosis, supra convexis, subtus carinatis.* Lin. Sp. Plant. 891. Feverfew; commonly called dwarf, perennial, maritime Chamomile, with short, thick, dark, green leaves.

The first sort is the common Feverfew, which is directed to be used in medicine. It grows naturally in lanes, and upon the side of banks, in many parts of England, but is frequently cultivated in the physick gardens to supply the markets. The stalks rise upward of two feet high; they are round, stiff, and striated; the leaves are composed of seven lobes, which are cut into many obtuse segments; the stalks and branches are terminated by the flowers, which are disposed almost in the form of loose umbels. The flowers are composed of several short rays, which are white like those of the Chamomile, surrounding a yellow disk composed of hermaphrodite florets, which form a hemisphere, and are inclosed in one common scaly empalement, which are succeeded by oblong, angular, naked seeds. The whole plant has a strong unpleasant odour.

The following varieties of this plant, are preserved in botanick gardens, many of which are pretty constant, if care is taken of saving the seeds; but where the seeds of these plants have been suffered to scatter, it will be almost impossible to preserve the varieties without mixture. I shall only just insert them here, for those who are curious in collecting the varieties.

1. Feverfew with very double flowers.
2. Feverfew with double flowers, whose borders or rays are plain, and the disk fistular.
3. Feverfew with very small rays.
4. Feverfew with very short fistular florets.
5. Feverfew with naked heads, having no rays or border.
6. Feverfew with naked sulphur-coloured heads.
7. Feverfew with elegant curled leaves.

These plants are propagated by their seeds, which should be sown either in spring or autumn; and when the plants are come up, they should be transplanted out into nursery-beds, at about six inches asunder, where they may remain till they have grown large, when they may be taken up, with a ball of earth to their roots, and planted in the middle of large borders, where they will flower, and produce ripe seeds.

When the different varieties of these plants are intermixed with other plants of the same growth in large gardens, they are ornamental. But as their roots seldom abide more than two years, fresh plants should be raised from seeds, to supply their places; for although they may be propagated by parting their roots either in spring or autumn, yet these seldom make so good plants as those obtained from seeds. When these plants grow from the joints of walls, or upon dry lime rubbish, they will continue much longer than in good ground.

The second sort grows naturally near the sea, in several parts of England. I have observed it upon the *Suffex* coast in great plenty, from whence I brought the plants, which were of no longer duration in the garden than two years, though in their native soil they may continue longer. The stalks of this plant branch out pretty much, and spread near the ground; they are garnished with dark green leaves, which are composed of many double wings, or pinnæ, like those of the common Chamomile, but are much thicker in substance; they have their edges turned backward, so are

convex on their upper surface, and concave on their under. The flowers are white, like those of the common Chamomile, and are disposed almost in the form of an umbel.

This plant is seldom cultivated but in botanick gardens for variety. It may be propagated by seeds, which may be sown either in autumn, soon after they are ripe, or in the spring, upon a bed of common earth, in almost any situation; and when the plants come up, they will require no other care, but to thin them where they are too close, and keep them clean from weeds.

MAUDLIN. See Achillea.

MAUROCENIA. Lin. Gen. Plant. edit. 2. 289. The Hottentot Cherry.

The Characters are,

The flower hath five oval petals, which spread open. It hath five stamina, which are situated between the petals. In the center is situated a roundish germen, crowned by a trifid stigma. The germen afterward turns to an oval berry, with one or two cells, each containing a single oval seed.

The Species are,

1. *MAUROCENIA foliis subovatis integerrimis, floribus confertis lateralibus.* Maurocencia with entire leaves, which are almost oval, and flowers growing in clusters on the sides of the branches; commonly called Hottentot Cherry.

2. *MAUROCENIA foliis obversè ovatis serratis, floribus corymbosis alaribus & terminalibus.* Maurocencia with obverse, oval, sawed leaves, and flowers growing in a corymbus at the sides and ends of the branches; commonly called Cape Phillyrea, and by the Dutch Leplehout.

3. *MAUROCENIA foliis ovatis nervosis integerrimis.* Maurocencia with oval veined leaves, which are entire; commonly called smaller Hottentot Cherry.

4. *MAUROCENIA foliis obversè ovatis emarginatis, floribus solitariis alaribus.* Maurocencia with obverse oval leaves, which are indented at the edges, and flowers growing singly from the sides of the branches.

The first three sorts grow naturally at the Cape of Good Hope; the first rises to a considerable height in that country. The stalk is strong, woody, and covered with a purplish bark, sending out many stiff branches, garnished with very thick leaves, almost oval, standing for the most part opposite, of a dark green colour, and entire. The flowers come out from the side of the old branches in clusters, three, four, or five standing upon one common foot-stalk; they are composed of five plain equal petals, ending in acute points, of a greenish yellow colour, changing to white. In the center is situated the oval germen, crowned by a trifid stigma, and between each petal is situated a stamina, terminated by obtuse summits. The germen afterward turns to an oval pulpy berry, some having but one, and others two cells; in each of these is lodged one oval seed.

The second sort hath a woody stalk, which in this country seldom rises more than eight or ten feet high, dividing into many branches, covered with a dark purplish bark, garnished with pretty stiff leaves, which are sawed on their edges, obversely oval, and stand opposite, of a light green, having short foot-stalks. The flowers are produced in roundish bunches from the side, and at the end of the branches; they are white, and have five small petals, between which are situated the stamina, terminated by obtuse summits. In the center is situated a roundish germen, crowned sometimes by a bifid, and at others by a trifid stigma.

The third sort rises with a woody stalk about the same height as the former, dividing into many branches, garnished with stiff, oval, entire leaves, of a light green colour, having three longitudinal veins; these are sometimes placed opposite, and at others they are alternate, having a strong margin or border surrounding them.

The fourth sort was discovered by the late Dr. *Houffouin*, growing naturally at the palisadoes in *Jamaica*. This rises with a woody stalk, from fifteen to twenty feet high, covered with a rough brown bark, which divides into many branches, garnished with stiff leaves, placed alternately, indented at the top, with a stiff reflexed border, of a gray colour on their upper side, but of a rusty iron colour on their under, standing upon short foot-stalks. The flowers come out singly along the side of the branches, which have five small white petals, ending in acute points, and five slender stamina, which are terminated by obtuse summits. In the center is situated a roundish germen, supporting a long bifid stigma, which is permanent. The germen afterward turns to a round berry, with one or two cells, each having one oblong seed.

The first sort is too tender to live abroad in *England*, but as it requires no artificial heat, so may be preserved through the winter in a good green-house, where it deserves a place for the beauty of its leaves, which are very thick, of a deep green, and differing in appearance from every other plant. It may be propagated by laying down those shoots which are produced near the ground, but they are long in putting out roots. The shoots should be twisted in the part which is laid, to facilitate their putting out roots: if these are laid down carefully in autumn, they will put out roots sufficient to remove by the following autumn; it may also be propagated by cuttings, but this is also a tedious method, as they are seldom rooted enough to transplant in less than two years. When this is practised, the young shoots of the former year should be cut off, with a small piece of the old wood at the bottom, and planted in pots filled with loamy earth, which must be plunged into a moderate hot-bed, covering the pots with hand-glasses, which should be close stopped down to exclude the external air; they should be pretty well watered at the time they are planted, but afterward they will require but little wet; the glasses over them should be covered with mats, to screen the cuttings from the sun during the heat of the day, but in the morning before the sun is too warm, and in the afternoon, when the sun is low, they should be uncovered, that the oblique rays of the sun may raise a gentle warmth under the glasses. With this care the cuttings will take root, but where this is wanting, they seldom succeed. When the cuttings or layers are rooted, they should be each planted in a separate small pot, and placed in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain during the summer season; and, before the frosts of the autumn, they must be removed into the green-house, and treated in the same way as the other plants of that country. When the plants have obtained strength, they will produce flowers and fruit, which in warm seasons will ripen perfectly; and if the seeds are sown, soon after they are ripe, in pots, and plunged into the tan-bed in the stove, the plants will come up the spring following, and may then be treated in the same manner as those which are propagated by cuttings and layers.

The second sort is not altogether so hardy as the first, so must have a warmer place in the green-house in winter, and should not be placed abroad quite so early in the spring, nor suffered to remain abroad so late in the autumn; but if the green-house is warm, the plants will require no additional heat. This may be propagated by layers and cuttings, in the same manner as the first, and requires the same care, for the cuttings are with difficulty made to root; nor will the branches which are laid put out roots in less than a year, and if these are not young shoots, they will not take root.

The third sort is yet more rare than either of the former, and is with greater difficulty propagated, for the layers and

cuttings are commonly two years before they get roots sufficient to remove; and as it never produces seeds here, so can be no other way propagated. This is also tenderer than either of the other sorts, so requires a moderate degree of heat in winter, for without some artificial warmth it will not live through the winters in *England*. In the middle of summer the plants may be placed abroad in a warm situation, but they must be removed into shelter early in the autumn, before the cold nights come on, otherwise they will receive a check, which they will not recover in winter.

The fourth sort is much more impatient of cold than either of the other, being a native of a warmer country. This is propagated in the same way as the other sorts, but when seeds can be obtained from *Jamaica*, the plants produced from those will be much the best; but as the seeds seldom come up the first year, so they should be sown in pots, and plunged into a moderate hot-bed of tanners bark, where they may remain all the summer; and in the autumn they should be removed into the bark-stove, and plunged into the tan-bed between the other pots of plants, in any vacant spaces; there they may remain till spring, when they should be taken out of the stove, and plunged into a fresh hot-bed, which will bring up the plants. When these are fit to remove, they should be each transplanted into a separate small pot, and plunged into a hot bed again, being careful to shade them from the sun, till they have taken new root; after which, they must be treated in the same manner as other tender plants from the same country.

All the sorts delight in a soft, gentle, loamy soil, not over stiff, so as to detain the wet; nor should the soil be too light, for in such they will not thrive. They retain their leaves all the year, so make a good appearance in the winter season, their leaves being remarkably stiff and of a fine green, especially the first sort, whose fruit ripen in winter, which when it is in plenty on the plants, affords an agreeable variety.

MAYS. See *Zea*.

MEADIA. *Catesb. Carol.* 3. p. 1.

The Characters are,

The flower hath a permanent empalement of one leaf, cut into five long segments, which are reflexed. The flower hath one petal, cut into five parts, whose limb is reflexed backward. It hath five short stamina sitting in the tube, connected at the top with a conical germen, terminated by an obtuse stigma. The empalement afterward becomes an oblong oval capsule with one cell, opening at the top, and filled with small seeds.

This genus of plants was so titled by Mr. *Mark Catesby*, F. R. S. in honour of the late Dr. *Mead*, who was a generous encourager of every useful branch of science.

We have but one Species of this genus, viz.

MEADIA. *Catesb. Hist. Carol. App.* 1. tab. 1. *Meadia*.

This plant grows naturally in *Virginia*, and other parts of *North America*, from whence many years ago it was sent by Mr. *Banister* to Dr. *Compton*, Lord Bishop of *London*, in whose curious garden I first saw this plant growing in the year 1709; after which it was for several years lost in *England*, till within a few years past, when it was again obtained from *America*, and has been since propagated in pretty great plenty. It hath a perennial root, from which comes out several long smooth leaves, which are six inches long, and two and a half broad; at first standing erect, but afterward they spread on the ground, (especially if the plants are much exposed to the sun). From between these leaves arise two, three, or four stalks, in proportion to the strength of the roots, eight or nine inches high; they are smooth, naked, and are terminated by an umbel of flowers, under which is situated the many-leaved involucre. Each flower is sustained by a pretty long slender foot stalk, which is recurved, so that the flower hangs downward. It has but one

one petal, which is deeply cut into five spear-shaped segments, which are reflexed backward like the flowers of Cyclamen or Sowbread; the stamina, which are five in number, are short, and sit in the tube of the flower, having five arrow-pointed summits, which are connected together round the style, forming a sort of beak. The flowers are purple, inclining to a Peach blossom colour, and have an oblong germen situated in the bottom of the tube, which afterward becomes an oval capsule inclosed by the empalement, with the permanent style on its apex, which, when ripe, opens at the top to let out the seeds, which are fastened round the style. This plant flowers the beginning of *May*, and the seeds ripen in *July*, soon after which the stalks and leaves decay, so that the roots remain inactive till the following spring.

It is propagated by offsets, which the roots put out freely when they are in a loose moist soil and a shady situation; the best time to remove the roots, and take away the offsets, is in *August*, after the leaves and stalks are decayed, that they may be fixed well in their new situation, before the frost comes on. It may also be propagated by seeds, which the plants generally produce in plenty; these should be sown in the autumn soon after they are ripe, either in a shady moist border, or in pots which should be placed in the shade; in the spring the plants will come up, and must then be kept clean from weeds, and if the season proves dry, they must be frequently refreshed with water; nor should they be exposed to the sun, for while the plants are young, they are very impatient of heat, so that I have known great numbers of them destroyed in two or three days, which were growing to the full sun. These young plants should not be transplanted till the leaves are decayed, then they may be carefully taken up and planted in a shady border, where the soil is loose and moist, at about eight inches distance from each other, which will be room enough for them to grow one year, by which time they will be strong enough to produce flowers, so may then be transplanted into some shady borders in the flower-garden, where they will appear very ornamental during the continuance of their flowers.

MEADOW SAFFRON. See Colchicum.

MEDEOLA. *Lin. Gen. Plant.* 411.

The Characters are,

The flower has no empalement; it hath six oblong oval petals, and six awl-shaped stamina, terminated by incumbent summits, and three horned germen terminating the style. The germen afterward turns to a roundish trifid berry with three cells, each containing one heart shaped seed.

The Species are;

1. MEDEOLA *foliis ovato-lanceolatis alternis, caule scandente.* Medeola with oval, spear-shaped, alternate leaves, and a climbing stalk; commonly called Climbing African Asparagus, with a Myrtle leaf.

2. MEDEOLA *foliis lanceolatis alternis, caule scandente.* Medeola with spear-shaped alternate leaves, and a climbing stalk; or narrow-leaved, climbing, African Asparagus.

3. MEDEOLA *foliis verticillatis, ramis aculeatis.* *Lin. Sp. Plant.* 339. Medeola with leaves growing in whorls and prickly branches.

4. MEDEOLA *foliis verticillatis, ramis inermibus.* *Lin. Sp. Plant.* 339. Medeola with leaves growing in whorls and smooth branches.

The first and second sorts grow naturally at the Cape of Good Hope. They have tuberose roots, composed of several dug or oblong knobs, which unite together at the top, from which arise two or three stiff stalks, which rise four or five feet high, if they meet with any neighbouring support, to which they can fasten, otherwise they fall to the ground: the first is garnished with oval spear-shaped leaves,

ending in acute points, placed alternately, sitting close to the stalks, of a light green on their under side, and dark on their upper; the leaves of the second are much longer and narrower, in which their difference consists. The flowers come out from the side of the stalks, sometimes singly, at others there are two upon a slender short foot-stalk; they have six oblong equal petals, of a dull white colour; within these sit six stamina, which are as long as the petals, terminated by incumbent summits. In the center is situated a germen with three horns, sitting upon a short style, and crowned by three thick recurved stigmas; the germen afterward turns to a roundish berry with three cells, each containing one heart-shaped seed.

Both these sorts propagate freely by offsets from the roots, so that when they are once obtained, there will be no necessity of sowing their seeds, which commonly lie a year in the ground; nor will the plants be strong enough to flower in less than two years more, whereas the offsets will flower the following spring. The time for transplanting and parting of the roots is in *July*, when their stalks are entirely decayed, for they begin to shoot toward the end of *August*, and keep growing all the winter. These roots should be planted in pots, and may remain in the open air till there is danger of frost, when they must be removed into shelter, for they are too tender to live through the winter in the open air; but if they are placed in a warm greenhouse, they will thrive and flower very well, but they seldom produce fruit unless they have some heat in winter; therefore where that is desired, the plants should be placed in a stove kept to a moderate degree of warmth.

The third sort grows naturally in the *West-Indies*. The late Dr. *Houssoun* found it near the *Havannah*, and Mr. *Robert Millar* gathered it in the isle of *Tobago*, where it was growing in plenty. This is a very low shrub, seldom rising more than three feet high in its native soil; the stalks are herbaceous like those of Butchers Broom, and divide upward into several branches, garnished with stiff leaves, ending in acute spines; they are like those of the Butchers Broom, but are longer and narrower; these stand in whorls round the stalks; there are nine, eleven, or more, at each joint. The flowers are produced just under the leaves, sometimes singly, at others there are two, which come out from the same joint; they are of an herbaceous white colour, having six oblong pointed petals, with six stamina not so long as the petals, and a roundish germen, which afterward turns to an oval berry with three cells, each having one heart-shaped seed.

This plant is tender, so will not thrive in this country, unless it is placed in a bark-stove. It is propagated by seeds, which should be sown in pots, and plunged into a bark bed, where they may remain all the summer, for the plants seldom come up the first year; in autumn they should be removed into the bark stove, where they may remain till the following spring, when they should be removed into a fresh hot-bed, which will bring up the plants; but as these are very slow in their growth, so they will not be fit to transplant till the following spring, when they may be each planted in a separate pot filled with light sandy earth, and plunged into a fresh hot-bed, shading them from the sun till they are new rooted; after which, they must be treated in the same way as other tender plants from the same country.

The fourth sort is a native of *North America*. It is by Dr. *Linnaeus* joined to this genus, in which I have followed him; though, if I remember rightly, the characters do not exactly agree with the other, for the flower is either polypetalous, or is cut into many segments, and has but five stamina; being some years since I saw the flowers, I cannot be very certain if I am right. This hath a small scaly root, from which

which arises a single stalk about eight inches high, garnished with one whorl of leaves at a small distance from the ground, and at the top there are two leaves standing opposite; between these come out three slender foot-stalks, which turn downward, each sustaining one small, pale, herbaceous flower, with a purple pointal.

This plant is hardy enough to live in the open air, but does not propagate fast here, as it produces no seeds, so can only be increased by offsets.

MEDICA. *Tourn. Inst. R. H.* 410. *tab.* 231. Medick, or *La Lucerne*.

The Characters are,

The flower is of the butterfly kind; the standard is oval, and entire; the two wings are oblong, oval, and fixed by an appendix to the keel; the keel is oblong, bifid, and reflexed toward the standard. It has ten stamina, nine of which are joined almost to their tops; the other is single, terminated by small summits. It hath an oblong compressed germen, which is recurved, sitting on a short style; this and the stamina are involved by the keel and standard. The germen afterward turns to a compressed moon-shaped pod, inclosing several kidney-shaped seeds.

The Species are,

1. MEDICA caule erecto herbaceo, foliis ternatis, foliolis lanceolatis supernè ferratis floribus spicatis alaribus. Greater upright Medick with purplish flowers; commonly called *La Lucerne*, and by the French, *Burgundy Hay*.

2. MEDICA caule herbaceo diffuso, foliis ternatis, foliolis lineari-lanceolatis, spicis brevioribus alaribus & terminalibus. Wild Medick with Saffron-coloured flowers.

3. MEDICA caule herbaceo procumbente, foliis ternatis, leguminibus ciliato-dentatis. Medick with an herbaceous trailing stalk, trifoliate leaves, and pods which have hairy indentures.

4. MEDICA caule herbaceo procumbente, foliis pinnatis, leguminibus ciliato-dentatis. Medick with a trailing herbaceous stalk, winged leaves, and pods having hairy indentures.

5. MEDICA caule herbaceo prostrato, foliis ternatis, foliolis cuneiformibus supernè ferratis, leguminibus margine integerrimis. Medick with a prostrate herbaceous stalk, trifoliate leaves, whose lobes are wedge-shaped, sawed at the top, and the borders of the pods entire.

6. MEDICA caule herbaceo prostrato, pedunculis racemosis, leguminibus lunatis. Medick with a prostrate herbaceous stalk, branching foot-stalks, and moon-shaped pods.

7. MEDICA caule herbaceo prostrato, foliis radicalibus integerrimis, caulibus pinnatis, leguminibus dentatis. Medick with a prostrate herbaceous stalk, the bottom leaves entire, those on the stalks winged, and indented pods.

8. MEDICA foliis ternatis, foliolis cuneiformibus, caule erecto arboreo. Medick with trifoliate leaves, whose lobes are wedge-shaped, and an erect tree-like stalk; or *Cytisus Virgilii*.

The first sort hath a perennial root and an annual stalk, which rises four feet high in good land, garnished with trifoliate leaves at each joint, whose lobes are spear-shaped, sawed toward their top. The flowers grow in spikes, which are from two to near three inches in length, standing upon naked foot-stalks, rising from the wings of the stalk; they are of the Pea bloom or butterfly kind, of a fine purple colour; these are succeeded by compressed moon-shaped pods, which contain several kidney-shaped seeds.

There are the following varieties of this plant:

One with Violet-coloured flowers.

Another with yellow flowers.

A third with yellow and Violet flowers mixed.

And a fourth with variegated flowers; but the first is the best for use.

This plant is supposed to have been brought originally from *Media*, and from thence had its name *Medica*; it is

by the Spaniards called *Alfafa*; by the French, *La Lucerne*, and *Grande Trèfle*; and by several botanick writers it is called *Fœnum Burgundiacum*, i. e. *Burgundian Hay*. But there is little room to doubt of this being the *Medica* of *Virgil*, *Columella*, *Palladius*, and other ancient writers of husbandry, who have not been wanting to extol the goodness of this fodder, and have given direction for the cultivation of it in those countries where they lived.

But notwithstanding it was so much commended by the ancients, and hath been cultivated to so good purpose by our neighbours in *France* and *Switzerland* for many years, it hath not as yet found so good reception in our country as could be wished, nor is it cultivated in any considerable quantity here; though it is evident, it will succeed as well in *England* as in either of the before-mentioned countries, being extremely hardy, and resisting the severest cold of our climate: as a proof of this, I must beg leave to mention, that the seeds which have happened to be scattered upon the ground in autumn, have come up, and the plants have endured the cold of a severe winter, and made very strong plants.

About the year 1650, the seeds of this plant were brought over from *France*, and sown in *England*; but whether for want of skill in its culture, whereby it did not succeed, or that the people were so fond of going on in their old beaten road, as not to try the experiment, was the occasion of its being entirely neglected in *England*, I cannot say, but it is very certain that it was neglected many years, so as to be almost forgotten. However, I hope, before I quit this article, to give such directions for its culture, as will encourage the people of *England* to make farther trial of this valuable plant, which grows in the greatest heat, and also in very cold countries, with this difference only, that in very hot countries, such as the *Spanish West-Indies*, &c. where it is the chief fodder for their cattle at this time, they cut it every week, whereas in cold countries it is seldom cut oftener than three or four times a year. It is very certain, that this plant will be of great service to the inhabitants of *Barbadoes*, *Jamaica*, and the other hot islands in the *West-Indies*, where one of the greatest things they want is fodder for their cattle; since by the account given of this plant by *Pere Feuillé*, it thrives exceedingly in the *Spanish West-Indies*, particularly about *Lima*, where they cut it every week, and bring it into the market to sell, and is there the only fodder cultivated.

The directions given by all those who have written of this plant, are very imperfect, and generally such as, if practised in this country, will be found entirely wrong; for most of them order the mixing of this seed with Oats or Barley (as is practised for Clover;) but in this way it seldom comes up well, and if it does, the plants will draw up so weak by growing amongst the Corn, as not to be recovered under a whole year, if ever it can be brought to its usual strength again.

Others have directed it to be sown upon a low, rich, moist soil, which is found to be the worst next to a clay, of any for this plant; in both which the roots will rot in winter, and in a year or two the whole crop will be destroyed.

But the soil in which this plant is found to succeed best in this country is, a light, dry, loose, sandy, deep land, which should be well ploughed and dressed, and the roots of all noxious weeds, such as Couch Grass, &c. destroyed, otherwise these will overgrow the plants while young, and prevent their progress.

The best time to sow the seed is about the middle of *April*, when the weather is settled and fair; for if you sow it when the ground is very wet, or in a rainy season, the seeds will burst and come to nothing (as is often the case with several of the leguminous plants;) therefore you should

always observe to sow it in a dry season; and if there happens some rain in about a week or ten days after it is sown, the plants will soon appear above ground.

But the method I should direct for the sowing these seeds, is as follows: After having well ploughed and harrowed the land very fine, you should make a drill quite across the ground almost half an inch deep, into which the seeds should be scattered very thin, covering them a quarter of an inch thick, or somewhat more, with the earth; then proceed to make another drill about a foot and a half from the former, sowing the seeds therein in the same manner as before, and so proceed through the whole spot of ground, allowing the same distance between row and row, and scatter the seeds very thin in the drills. In this manner, an acre of land will require about six pounds of seeds; for when it is sown thicker, if the seed grows well, the plants will be so close as to spoil each other in a year or two, the heads of them growing to a considerable size, as will also the roots provided they have room. I have measured the crown of one root, which was in my possession, eighteen inches diameter; from which I cut near four hundred shoots at one time, which is an extraordinary increase, and this upon a poor, dry, gravelly soil, which had not been dunged for many years, but the root was at least ten years old; so that if this crop be well cultivated, it will continue many years, and annually improve; for the roots generally run down very deep in the ground, provided the soil be dry; and although they should meet a hard gravel a foot below the surface, yet their roots would penetrate it, and make their way downward, as I have experienced, having taken up some of them, which were above a yard in length, and had run above two feet into a rock of gravel, which was so hard as not to be loosened without mattocks and crows of iron, and that with much difficulty.

The reason for directing this seed to be sown in rows is, that the plants may have room to grow; and for the better stirring the ground between them, to destroy the weeds, and encourage the growth of the plants, which may be very easily effected with a *Dutch* hoe, just after cutting the crop each time, which will cause the plants to shoot again in a very little time, and be much stronger than in such places where the ground cannot be stirred; when the plants first come up, the ground between should be hoed with a common hoe; and if in doing of this you cut up the plants where they are too thick, it will cause the remaining to be much stronger. This hoeing should be repeated two or three times while the plants are young, according as the weeds are produced, observing always to do it in dry weather, that the weeds may the better be destroyed; for if it be done in moist weather, they will root and grow again.

With this management the plants will grow to the height of two feet or more, by the beginning of *August*, when the flowers will begin to appear, at which time it should be cut, observing to do it in a dry season; if it is to be made Hay, it must be often turned, that it may soon dry, and be carried off the ground, for if it lie long upon the roots, it will prevent the shooting again. After the crop is taken off, you should stir the ground between the rows with a hoe, to kill the weeds, and loosen the surface, which will cause the plants to shoot again in a short time, so that by the middle or end of *September* there will be shoots four or five inches high, when you may turn in sheep upon it to feed it down, for it will not be fit to cut again the same season, nor should the shoots be suffered to remain upon the plants, which would decay when the frosty weather comes on, and fall upon the crown of the roots, and prevent their shooting early the succeeding spring. So that the best way is to feed it until *November*, when it will have done shooting for that season; but it should not

be fed by large cattle the first year, because the roots being young, would be in danger of being destroyed, either by their trampling upon them, or their pulling them out of the ground; but sheep will be of service to the roots by dunging the ground, provided they do not eat it too close, so as to endanger the crown of the roots.

The beginning of *February*, the ground between the rows should be again stirred with the hoe, to make it clean; but in doing of this you should be careful not to injure the crown of the roots, upon which the shoots will be coming out, for it is one of the earliest pabulum for cattle yet known. With this management, if the soil be warm, by the middle of *March* the shoots will be five or six inches high, when, if you are in want of fodder, you may feed it down till a week in *April*; after which it should be suffered to grow for a crop, which will be fit to cut the beginning of *June*, when you should observe to get it off the ground as soon as possible, and stir the ground again with a *Dutch* hoe, which will forward the plants shooting again; so that by the middle or latter end of *July*, there will be another crop fit to cut, which must be managed as before; after which it should be fed down again in autumn, and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you should turn in large cattle; but you must always observe not to suffer them to remain after the roots have done shooting, lest they should eat down the crown of the roots below the buds, which would considerably damage, if not destroy them.

In this manner you may continue constantly to have two crops to cut, and two feedings upon this plant; and in good seasons there may be three crops cut, and two feedings, which will be a great advantage to graziers, especially as this plant will grow upon dry barren soils, where Grass will come to little; and this will afford a good feed in dry summers, when Grass is often burnt up; for as it is an early plant in the spring, so it will be of great service when fodder falls short at that season, for it will be fit to feed at least a month before Grass or Clover.

The best places to procure the seed from, are *Switzerland*, and the northern parts of *France*, which succeed better with us than that which comes from a more southern climate; but this seed may be saved in *England* in great plenty, if a small quantity of ground stocked with the plants should be left uncut till the seeds are ripe, when it must be cut, and laid to dry in an open barn where the air may freely pass through, but defended from the wet, for if it be exposed thereto, it will shoot while it remains in the pod, whereby it will be spoiled. When it is quite dry, it must be threshed out, and cleansed from the husk, and preserved in a dry place till the season for sowing it. The seed saved in *England* is much preferable to any brought from abroad, as I have several times experienced, the plants produced from it having been much stronger than those produced from *French*, *Switzerland*, and *Turkey* seeds, which were sown at the same time, and on the same soil and situation.

I am inclinable to think that the reason of this plant not succeeding, when it has been sown in *England*, has either been occasioned by the sowing it with Corn, with which it will by no means thrive; or by sowing it at a wrong season, or in wet weather, whereby the seeds have rotted, and never come up, which hath discouraged their attempting it again; but however the success has been, I dare aver, that if the method of sowing and managing of this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other sort of fodder now cultivated in *England*, and will continue much longer; for if the ground be duly stirred after the cutting each crop, and the last crop fed, as hath been directed, the plants will continue in vigour forty or fifty years, or more, without renewing, as there

there are many large fields now in *France* much older, which are very vigorous. I have had some plants in my possession more than forty years old, in great perfection.

The hay of this plant should be kept in close barns, it being too tender to be kept in reeks open to the air as other hay; but it will remain good, if well dried before it be carried in, three years. The people abroad reckon an acre of this fodder sufficient to keep three horses all the year round.

And I have been assured by persons of undoubted credit, who have cultivated this plant in *England*, that three acres of it have fed ten cart horses from the end of *April* to the beginning of *October*, without any other food, though they have been constantly worked. Indeed the best use which can be made of this Grass is, to cut it, and give it green to the cattle; where this hath been daily practised, I have observed that by the time the field has been cut over, that part which was the first cut, hath been ready to cut again; so that there has been a constant supply in the same field, from the middle of *April* to the end of *October*; when the season has continued long mild, and when the summers have proved showery, I have known six crops cut in one season, but in the driest seasons there will be always three or four. When the plant begins to flower it should then be cut, for if it stands longer, the stalks will grow hard, and the under leaves will decay, so that the cattle will not so greedily devour it. Where there is a quantity of this cultivated, some of it should be cut before the flowers appear, otherwise there will be too much to cut within a proper time.

When this is made into Hay, it will require a great deal of making; for as the stalks are very succulent, it must be often turned, and exposed a fortnight or more before it will be fit to house, for this requires a longer time to make than Saint Foin, therefore, when it is cut, it should be carried to make upon some Grass ground, because the earth in the intervals of the rows will wash up, and mix with the Hay in every shower of rain, and by carrying it off as soon as it is cut, the plants will shoot up again soon; but it is not so profitable for Hay, as to cut green for all sorts of cattle, especially horses, which are extremely fond of it, and to them it will answer the purpose of both Hay and Corn, and they may be worked at the same time just as much as when they are fed with Corn, or dry food. If milch cows are fed with this plant cut green all the summer, they will give a greater quantity of milk than with any other food; and the milk, as also the butter, will be better flavoured, as I have frequently experienced: therefore every dairy farm, where there is proper land, should always have a good field sown with Lucerne, which will be found very advantageous to the possessor: for I have known twelve cows kept from *May* day to *October*, with less than two acres of this plant; whereby the Hay on the other land, has been wholly reserved for winter.

The second sort grows naturally in the south of *France*, in *Spain* and in *Italy*, and has been supposed only a variety of the first, but I have frequently cultivated this by seeds, and have never observed it to alter. The stalks of this are smaller, do not stand erect, and never rise so high; the leaves are not half so broad; the flowers are produced in short roundish spikes, and are of a Saffron colour. It hath a perennial root which will continue many years, but is seldom cultivated any where.

The third sort grows naturally in *Italy*; this is an annual plant, with several slender branching stalks a foot and a half long, which spread on the ground, garnished with trifoliate leaves, whose lobes are oval, spear-shaped, and entire. The flowers are produced singly upon slender foot-stalks, which proceed from the side of the branches; they are small,

of a yellow colour, and shaped like those of the former sort; these are succeeded by broad, flat, moon-shaped pods, whose borders are indented, and terminated by fine hairs; in each of these pods, is lodged four or five kidney-shaped seeds.

The fourth sort grows naturally in *Spain*; this is also an annual plant, whose stalks grow a foot and a half long, trailing on the ground, garnished with winged leaves, composed of two pair of small lobes, terminated by one large, oval, spear-shaped one. The flowers stand upon long slender foot-stalks, each sustaining four or five gold-coloured flowers at the top, which are succeeded by compressed moon-shaped pods, not half so large as those of the third sort, but have hairy indentures like those.

The fifth sort grows naturally on the borders of the sea in several parts of *Italy*; this is also an annual plant, with prostrate herbaceous stalks, about a foot long, garnished with trifoliate leaves, whose lobes are wedge-shaped and sawed toward the top. The flowers are produced upon slender foot-stalks, each sustaining five or six pale yellow flowers, which are succeeded by small, thick, moon-shaped pods, whose borders are entire, containing three or four small kidney-shaped seeds in each.

The sixth sort grows in most of the warm countries in *Europe*; this is a biennial plant, with a prostrate herbaceous stalk about a foot long, garnished with trifoliate leaves, whose lobes are oval and entire. The flowers stand upon branching foot-stalks, which come out toward the end of the branches, each sustaining many pale yellow flowers upon short separate foot-stalks, which are succeeded by moon-shaped pods, each containing four or five kidney-shaped seeds.

The seventh sort grows naturally in the *Archipelago*; this is an annual plant; the stalks are slender, about a foot long, branching out into smaller, garnished with winged hoary leaves; those on the lower part of the stalk, are composed of two pair of lobes, terminated by an odd one, but those on the upper part of the stalks are trifoliate. The flowers are produced at the end of the stalks, they are small, yellow, and shaped like those of the other sorts, and are succeeded by compressed moon-shaped pods, which are acutely indented on their borders, and contain three or four kidney-shaped seeds.

These annual sorts are preserved in the gardens of those who are curious in botany; the seeds of these should be sown on an open bed of fresh ground, in the place where the plants are to remain, because they do not bear transplanting well, unless when they are young. As the plants spread their branches on the ground, so they should not be sown nearer than two feet and a half asunder; when the plants come up, they will require no other care, but to keep them clean from weeds.

The eighth sort grows naturally in the islands of the *Archipelago*, in *Sicily*, and the warmest parts of *Italy*. This rises with a shrubby stalk to the height of six or seven feet, covered with a grayish bark, and divides into many branches, which, while young, are covered with a hoary down, garnished at each joint with trifoliate leaves; the lobes are small, spear-shaped, and hoary on their under side; these remain all the year. The flowers are produced on foot-stalks, which arise from the side of the branches, which are of a bright yellow, each foot stalk sustaining four or five flowers, which are succeeded by compressed moon-shaped pods, each containing three or four kidney-shaped seeds.

It flowers great part of the year, especially when the winters are favourable, or when the plants are sheltered in winter, they are seldom destitute of flowers; but those in the open air begin to flower in *April*, and continue in succession till *December*. Those flowers which appear early in summer,

summer, will have their seeds ripe in *August*, or the beginning of *September*, and the others will ripen in succession till the cold stops them.

This plant may be propagated by sowing the seeds, either upon a moderate hot-bed, or on a border of light earth, in the beginning of *April*; when the plants come up, they should be carefully cleaned from weeds; but they should remain undisturbed, if sown in the common ground, till *August* following; but if on a hot-bed, they should be transplanted about *Midsummer* into pots, placing them in the shade until they have taken root; after which they may be removed into a situation where they may be screened from strong winds, in which they may abide till the latter end of *October*, when they must be put under a frame, to shelter them from hard frosts, especially while they are young. In *April* following these plants may be shaken out of the pots, and placed in the full ground, where they are designed to remain, which should be in a light soil and a warm situation, in which they will endure the cold of our ordinary winters extremely well, and continue to produce flowers most part of the year, and retaining their leaves all the winter renders them the more valuable.

Those also which were sown in an open border may be transplanted in *August* following, in the same manner; but in doing of this, you must be careful to take them up with a ball of earth to their roots, if possible, as also to water and shade them until they have taken root; after which they will require little more care than to keep them clear from weeds, to prune off the luxuriant branches to keep them within due compass; but you should never prune them early in the spring, nor late in autumn, for if frost should happen soon after they are pruned, it will hurt the tender branches, and, many times, the whole plant is lost thereby.

These plants have been supposed tender, so were housed every autumn; but I have had large plants of this kind, which have remained in the open air in warm situations many years without any cover, and have been much stronger, and flowered better, than those which were housed; though, indeed, it will be proper to keep a plant or two in shelter, lest by a very severe winter (which sometimes happens in *England*) the plants abroad should be destroyed.

They may also be propagated by cuttings, which should be planted in *April*, upon a bed of light earth, and watered and shaded until they have taken root, after which they may be exposed to the open air, but they should remain in the same bed till *August* following before they are transplanted, by which time they will have made strong roots, so should be removed to the places where they are to remain, observing (as was before directed) to water and shade them until they have taken root; after which you may train them up with straight stems, by fastening them to sticks, otherwise they are apt to grow crooked and irregular; and when you have got their stems to the height you design them, they may then be reduced to regular heads, and, with pruning their irregular shoots every year, they may be kept in very good order.

This plant grows in great plenty in the kingdom of *Naples*, where the goats feed upon it, with whose milk the inhabitants make great quantities of cheese; it also grows in the islands of the *Archipelago*, where the *Turks* use the wood of these shrubs to make handles for their sabres, and the *Calogers* of *Patmos* make their beds of this wood.

This is by many people supposed to be the *Cytisus* of *Virgil*, *Columella*, and the old writers on husbandry, which they mention as an extraordinary plant, and worthy of cultivation for fodder, from whence several persons have recommended it as worthy of our care in *England*. But however useful this plant may be in *Crete*, *Sicily*, *Naples*, or those

warmer countries, yet I am persuaded it will never thrive in *England*, so as to be of any real advantage for that purpose; for in severe frost it is very subject to be destroyed, or at least so much damaged, as not to recover its former verdure before the middle, or latter end of *May*, and the shoots which are produced, will not bear cutting above once in a summer, and then will not be of any considerable length, the stems growing very woody, which renders the cutting of it very troublesome; so that, upon the whole, it can never answer the trouble and expence in cultivating it, nor is it worth the trial, since we have so many other plants preferable to it; though in hot, dry, rocky countries, where few other plants will thrive, this may be of great advantage, as it grows from the fissures of rocks, where there is not soil for cultivation, in such situations this plant will live many years, and thrive very well.

But however unfit this may be for such uses in *England*, yet for the beauty of its hoary leaves, which will abide all the year, together with its long continuance in flower, it deserves a place in every good garden, where being intermixed with shrubs of the same growth, it makes a very agreeable variety.

MEDICAGO. *Lin. Gen. Plant.* 805. Snail Trefoil.

The Characters are,

The flower is of the butterfly kind, having an oval erect standard, whose borders are reflexed. The wings are oblong, oval, and fixed to the keel by an appendix. The keel is oblong, bifid, obtuse, and reflexed. It hath ten stamina, nine of which are joined, and the other is single, and an oblong germen, which sits upon a short style, and is involved with the stamina by the keel, crowned by a very small stigma; it afterward turns to a pod, twisted into the form of a snail, inclosing many kidney-shaped seeds.

The Species are,

1. MEDICAGO *pedunculis racemosis, leguminibus cochleatis, spinosis, caule procumbente tomentoso.* *Hort. Cliff.* 378. Medicago with branching foot-stalks, snail-shaped prickly pods, and a trailing woolly stalk; or Sea Medick.

2. MEDICAGO *leguminibus cochleatis inermibus, stipulis dentatis, caule anguloso diffuso, foliis oblongo ovatis acute dentatis.* Snail Trefoil; commonly called Snails.

3. MEDICAGO *leguminibus tornatis inermibus, stipulis acute dentatis, foliis ferratis.* Snail Trefoil, with a smaller, turned, smooth fruit.

4. MEDICAGO *leguminibus cochleatis spinosissimis aculeis utrinque tendentibus.* Snail Trefoil with a large fruit, whose spines point upward and downward; commonly called Hedgehog.

5. MEDICAGO *leguminibus cochleatis spinosis, foliis acute dentatis tricuspisisque.* Snail-shaped Trefoil, with a round prickly capsule, and elegantly cut leaves.

There are many other species of this genus, which grow naturally in the warm parts of *Europe*, and are preserved in botanick gardens for the sake of variety; but as these are rarely cultivated in other gardens, so it would be beside my purpose to enumerate them here.

The first sort grows naturally on the borders of the *Mediterranean* sea; this is a perennial plant, with trailing woolly branches about a foot long, divided into small branches, garnished with trifoliate downy leaves at each joint. The flowers are produced from the side and at the ends of the branches, in small clusters; they are of a bright yellow colour, and are succeeded by small, round, snail-shaped fruit, which are downy, armed with a few short spines.

This plant is perennial, and may be propagated by seeds, which should be sown upon a warm border of dry soil in the spring, where the plants are designed to remain; when the plants come up, two or three of them may be transplanted into small pots to be sheltered in winter, because in

small, of a purplish colour, and are succeeded by small black fruit.

The thirteenth sort is a low shrub, seldom rising more than three feet high, dividing toward the bottom into slender branches, garnished with spear-shaped leaves, ending in acute points, of a dark green on their upper side, but of a hoary white on their under, having three longitudinal veins, and are placed opposite, upon short foot-stalks. The flowers are produced in loose bunches at the end of the branches, which are white, and are succeeded by small purple fruit.

The fourteenth sort hath a shrubby stalk eight or nine feet high, divided into many smooth slender branches, garnished with oval spear-shaped leaves; they are entire on their edges, and smooth on both sides, standing opposite, and have three longitudinal veins. The flowers are produced in loose panicles at the end of the branches, which are succeeded by very small purple fruit.

The fifteenth sort rises with several shrubby stalks five or six feet high, dividing into crooked branches, garnished with oval rough leaves, having five longitudinal veins, of a dark green on their upper side, but pale on their under, indented on their edges. The flowers are produced in very loose bunches, which come out from the side of the stalks, of an herbaceous colour, and are succeeded by small purplish fruit, filled with very small seeds.

The sixteenth sort rises with a shrubby stalk seven or eight feet high, divided into many smooth branches, garnished with smooth spear-shaped leaves, of a dark green colour, with three longitudinal veins; the edges of these leaves are closely set with bristly stinging hairs. The flowers are produced in loose bunches at the end of the branches, of a purplish colour, and are succeeded by very small black fruit.

All the sorts are natives of the warm parts of *America*, where there are many more species than are here enumerated. Most of these here mentioned, were found by the late Dr. *Houssoun*, growing naturally in *Jamaica*, from whence he sent many of their seeds to *Europe*, some of which succeeded; but most, if not all the plants which were raised from them, were lost in the severe winter in 1740, since which time they have not been recovered in *Europe*.

There is great beauty in the diversity of the leaves of these plants, many of them being very large, and most of them are of different colours on the two surfaces, their under side being either white, gold colour, or russet, and their upper of different shades of green, so that they make a fine appearance in the hot-house all the year; indeed, their flowers have no great beauty to recommend them, but yet for the singular beauty of their leaves, these plants deserve a place in all curious collections, as much as most other sorts.

There are very few of these plants at present in any of the *European* gardens, which may have been occasioned by the difficulty of bringing over growing plants from the *West-Indies*; and the seeds being small when they are taken out of the pulp, soon become dry, so rarely succeed. The best way to obtain these plants is, to have the entire fruits put up in dry sand, as soon as they are ripe, and forwarded by the soonest conveyance to *England*; these should be immediately taken out when they arrive, and the seeds sown in pots of light earth, and plunged into a moderate hot-bed of tanners bark. When the plants come up and are fit to remove, they must be each planted into a small pot, and plunged into the tan-bed; and afterward should be treated in the manner directed for the *ANNONA*, to which I shall desire the reader to turn, to avoid repetition.

MELIA. *Lin. Gen. Plant.* 473. The Bead tree.

The Characters are,

The flower hath five spear-shaped petals which spread open, and

a cylindrical nectarium of one leaf, indented at the brim in ten parts. It has ten small stamina inserted in the top of the nectarium, with a conical germen, which afterward turns to a soft globular fruit, including a roundish nut, having five rough furrows, and five cells, each containing one oblong seed.

The Species are,

1. MELIA *foliis bipinnatis*. *Flor. Zeyl.* 162. The Bead tree, or false Sycamore.

2. MELIA *foliis pinnatis*. *Hort. Cliff.* 161. Melia with winged leaves, or ever-green Bead tree.

The first sort grows naturally in *Syria*, from whence it was brought to *Spain* and *Portugal*, where it is now become as common almost, as if it were a native of those countries. This in warm countries grows to a large tree, spreading out many branches, garnished with winged leaves composed of three smaller wings, whose lobes are notched and indented on their edges, of a deep green on their upper side, but pale on the under. The flowers come out from the side of the branches in long loose bunches, composed of five long, narrow, spear-shaped petals, of a whitish blue colour, which are succeeded by oblong fruit as large as a small Cherry, green at first, but when ripe changes to a pale yellow, inclosing a nut with five deep furrows, having four or five cells, in each of which is lodged one oblong seed. The pulp which surrounds the nut, is said to have a deadly quality if eaten, and if mixed with grease and given to dogs it will kill them. The nuts are bored through, and strung by the *Roman* catholicks to serve as beads.

There has been of late years some of these plants introduced to the islands in the *West-Indies*, where I am informed they continue flowering, and produce their fruit most part of the year. The fruit I have received from thence by the title of *Indian Lilac*, from which I have raised many of the plants, which flower much stronger than those raised from *Portugal* seeds.

This sort is propagated by seeds, which should be sown in pots, and plunged into a hot-bed of tanners bark, where (if the seeds are fresh) they will come up in about two months time: in *June* they should be gradually inured to bear the open air, and soon after placed abroad in a well sheltered situation, that they may be hardened before winter. In *October* you should remove the pots under a hot-bed frame, where they may enjoy free open air when the weather is mild, and be covered in hard frost.

In *April* following, you may shake out your plants from the seed-pots and divide them, planting each into a separate small pot, plunging them into a moderate hot-bed, which will greatly promote their rooting, and increase their growth; but you should not draw them too much, but give them a large share of air, when the weather is good; and the beginning of *June*, you should remove them out into the open air as before; during the three or four winters, while the plants are young, they require shelter from hard frost; but when the plants are grown pretty large and woody, they may be planted in the open air. The best season for this is in *April*, at which time you should shake them out of the pots, being careful not to shake the earth from the roots, but only pare off with a knife the outside of the ball. They should have a dry soil and a warm situation, otherwise they will be liable to miscarry in severe frosty weather.

Some of these plants which were planted in an open exposure, have endured the cold of our ordinary winters very well; but when a severe frost happens, they are generally killed, or at least their shoots are destroyed to the main stem; therefore it is much more secure to plant them against good aspected walls, where they will live and produce their flowers annually, and in warm seasons they may have fruit.

The second sort grows naturally in *India*, where it becomes a large tree; the stem is thick, the wood of a pale yellow, and the bark of a dark purple colour and very bitter. The branches extend wide on every side, which are garnished with winged leaves, composed of five or six pair of oblong acute-pointed lobes, terminated by an odd one, and have a strong disagreeable odour. The flowers are produced in long branching panicles, which proceed from the side of the branches; they are small, white, and cut into five acute segments; these are succeeded by oval fruit the size of small Olives, which, when ripe, are yellow; the pulp which surrounds the nut is oily, acrid, and bitter; the nut is white, and shaped like that of the former. It grows in sandy land, both in *India* and the island of *Ceylon*, where it is always green, and produces flowers and fruit twice a year.

This sort is now very rare in *England*, and also in the *Dutch* gardens, where some years past it was more common; it is propagated by seeds in the same way as the other sort, but being much tenderer, the plants should be kept constantly in the tan-bed.

The first sort is commonly called, *Zizyphus alba*, in *Portugal* and *Spain*, and in *Italy*, *Pseudocymorus*. It was by most of the modern botanists titled, *Azederach*, but Dr. *Linnaeus* has altered it to this of *Melia*, which was by *Theophrastus* applied to a species of Ash.

MELIANTHUS. *Tourn. Inst. R. H.* 430. tab. 245. Honey Flower.

The Characters are,

The flower hath four narrow spear shaped petals, divided into two lips, connected on their sides, and a nectarium of one leaf, situated in the lower segment of the empalement, and fastened with it to the receptacle. It hath four erect stamina, the two under being somewhat shorter than the other. In the center is situated a four-cornered germen, which afterward becomes a quadrangular capsule with distended cells, divided by partitions in the center, each containing one almost globular seed.

The Species are,

1. MELIANTHUS *stipulis solitariis petiolo adnati*. Hort. Cliff. 492. African Honey Flower, or greater Melianthus.
2. MELIANTHUS *stipulis geminis distinctis*. Hort. Cliff. 492. Smaller, stinking, African Honey Flower.

These plants grow naturally at the *Cape of Good Hope*, from whence the first sort was brought to *Holland* in the year 1672; this hath a perennial root, which spreads much in light ground, from which arise many hollow soft stalks, six or seven feet high, garnished with large winged leaves, which embrace the stalks with their base, where they have a large single stipulæ fastened on the upper side of the foot-stalk, with two ears at the base, which also embrace the stalk: The leaves have four or five pair of very large lobes, terminated by an odd one, which are deeply jagged on their edges into acute segments; between the lobes runs a double leafy border, or wing, on the upper side of the midrib, so as to connect the base of the lobes together. The flowers are produced in pretty long spikes, which arise from the top of the stalks; they are of a chocolate colour, formed like the lip flower, but have four narrow petals, in which it differs from the lip flowers; these are succeeded by oblong four-cornered capsules, divided by a central partition into four cells, each containing one roundish seed.

This plant was formerly preserved in green-houses, and treated as a tender exotick, but with that management the plants were so much drawn in winter, as to prevent their flowering. But of late years they have been treated in a different way, most of them having been planted in the full ground in warm borders, where all those stalks which are not killed by frost, seldom fail to flower the spring following; so that the surest method to have them flower, is to cover

them with mats or reeds in frosty weather, to prevent their tops being killed by the cold; and if the plants grow in dry rubbish, they will not shoot so vigorous as in good ground, so will be less succulent, and therefore not so liable to suffer by frost.

This plant is easily propagated by taking off suckers or side shoots in spring, which, if they have good roots, there will be little danger of their growing, so should be planted where they are to remain, and will require no other care than is before-mentioned; they may be also be propagated by cuttings during any of the summer months, which, if watered and shaded, will take root very well, and may afterwards be transplanted where they are designed to remain.

The second sort rises with round, soft, ligneous stalks, five or six feet high, which send out two or three branches from their side, garnished with winged leaves like those of the former sort, but not half so large, and have two distinct stipulæ adhering to their foot-stalks; they are of a deep green on their upper side, and whitish on their under. The flowers come out from the side of the stalks in loose hanging bunches, each sustaining six or eight flowers, which are shaped like those of the first sort, but smaller; the lower part of the petals are green, their upper part are of a Saffron colour, and on the outside in the swelling part of the petals, is a blush of fine red; these have two long and two shorter stamina, which are terminated by yellow summits. The flowers are succeeded by four-cornered seed-vessels, which are shorter than those of the first sort, in which are lodged four oval seeds, in separate apartments.

This sort does not spread its roots so much as the first, so is not propagated with so great facility; but cuttings of this sort planted upon an old hot-bed, whose heat is over, and covered close with bell, or hand-glasses, to exclude the air, will take root pretty freely; these may be planted in pots, and sheltered in the winter under a common frame for a year or two, till they have obtained strength, then they may be planted in a warm border, and treated in the same way as the former sort, with which management I have seen them flower much better than any of those which have been treated more tenderly, and these plants have perfected their seeds in good seasons.

MELILOTUS. See *Trigonella*.

MELISSA. *Tourn. Inst. R. H.* 193. tab. 91. Baum.

The Characters are,

The flower is of the lip kind, having a cylindrical tube; the chaps are gaping, the upper lip is erect, forked, and indented at the end. The under lip is trifid. It hath four awl-shaped stamina, two of which are as long as the petal, the other are but half so long. It hath a quadrifid germen, which afterward turns to four naked seeds, sitting in the empalement.

The Species are,

1. MELISSA *racemis axillaribus verticillatis, pedicellis simplicibus*. Lin. Sp. Pl. 592. Garden, or common Baum.
2. MELISSA *floribus verticillatis sessilibus, foliis hirsutis*. Roman Baum, with soft hairy leaves and a strong smell.
3. MELISSA *pedunculis axillaribus dichotomis longitudine florum*. Lin. Sp. Plant. 592. Calamint with a large flower.
4. MELISSA *pedunculis axillaribus dichotomis longitudine foliorum*. Lin. Sp. Plant. 593. Common officinal Calamint of the Germans.
5. MELISSA *pedunculis axillaribus dichotomis folio longioribus, caule decumbente*. Lin. Sp. Plant. 593. Calamint with the scent of Pennyroyal.
6. MELISSA *racemis terminalibus, pedunculis solitariis brevissimis*. Lin. Sp. Plant. 593. Hoary Calamint with Basil leaves.
7. MELISSA *foliis ovatis glabris, floribus verticillatis sessilibus, pedunculis solitariis brevissimis*. Roman Calamint, with a Marjoram leaf, and the scent of Pennyroyal.

8. MELISSA

8. MELISSA fruticosa, ramis attenuatis virgatis, foliis sub-
tus tomentosis. Lin. Sp. Plant. 593. Shrubby Spanish Cala-
mint with a Marum leaf.

The first sort grows naturally on the mountains near *Geneva*, and in some parts of *Italy*, but is cultivated here in gardens, as a medicinal and culinary herb. It has a perennial root, the stalks are square, branching, and rises from two to three feet high, garnished with leaves set by pairs, indented about their edges, the lower ones standing upon pretty long foot-stalks. The flowers grow in loose bunches at the wings of the stalk, in whorls, standing upon single foot-stalks; they are of the lip kind, the upper lip stands erect, and is forked, the under lip is divided into three parts; the middle one is roundish, and indented at the top. The flowers are white, and the whole plant has a pleasant scent, somewhat like Lemons.

This plant is easily propagated by parting of the root; the best time for this is in *October*, that the offsets may have time to get root before the frosts come on. They should be planted two feet asunder in beds of common garden earth, in which they will soon spread and meet together; the only culture required is to keep the plants clean from weeds, and cut off the decayed stalks in autumn, stirring the ground between them.

The second sort grows naturally about *Rome*, and in several parts of *Italy*; this is very like the former. The stalks are slender, the leaves are much shorter than those of the former sort, and the whole plant is hairy, and of a strong disagreeable odour. It is seldom preserved, except in botanick gardens, but may be cultivated in the same way as the former.

The third sort grows naturally in the mountains of *Tuscany* and *Austria*, but is preserved in many *English* gardens for the sake of variety. It hath a perennial root, the stalks rise about a foot high, garnished at each joint with two leaves standing opposite, sawed on their edges, of a lucid green on their upper side, and whitish on their under: from the wings of the stalks come out single foot-stalks, which divide into two smaller, each of these sustain two flowers upon short separate foot-stalks. The flowers are large, of a purple colour, and shaped like those of the other species. This may be propagated and treated in the same way as the first sort.

The fourth sort is the common Calamint of the shops, which grows naturally in many parts of *England*, so is seldom kept in gardens.

The fifth sort is found in greater plenty than the fourth in *England*. The stalks of this are longer, and bend towards the ground. The leaves are larger, and more indented on their edges, and have a very strong scent like Pennyroyal. The whorls of flowers are set closer together than those of the fourth, but in other respects they agree.

The sixth sort grows naturally in the south of *France* and in *Italy*; this is not of so long duration as the former sorts, seldom continuing more than two or three years. The stalks are slender, a little ligneous, garnished with small, roundish, hoary leaves, placed opposite. The flowers are produced in whorls toward the upper part of the stalks, which are terminated by a loose spike; they are small and white, shaped like those of the other species, and are succeeded by seeds which ripen in autumn, and if they are permitted to scatter, there will be a sufficient supply of young plants.

The seventh sort grows naturally in *Italy*; this is a biennial plant, whose stalks are two feet long, declining toward the ground, garnished with roundish leaves, about the size of Marjoram. The flowers come out in close whorls on the upper part of the stalk, each standing on a short separate foot-stalk; they are large, and of a bright purple colour; this is propagated by seeds, which should be sown soon

after they are ripe, and then the plants will come up in the spring; but when the seeds are not sown till the spring, they seldom grow till the following year. The plants may also be propagated by cuttings, which, if planted in the summer, and shaded from the sun, will take root very freely. If these plants are planted on a warm border, they will live through the winter, but to preserve the species, a plant or two should be kept in pots, and sheltered under a frame in winter.

The eighth sort grows naturally in *Spain*; this hath slender shrubby stalks about nine inches long, which put out small side branches opposite, garnished with small, hoary, oval-pointed leaves, placed by pairs; these have much the appearance of the Marum Syriacum. The flowers grow in whorled spikes at the end of the stalks; they are small and white, and the seeds ripen in autumn. The whole plant has a strong scent of Pennyroyal; this is of as short duration as the seventh sort, and may be propagated either by seeds or cuttings in the same way, and the plants require the same treatment.

MELISSA TURCICA. See Dracocephalon.

MELO. Tourn. Inst. R. H. 104. tab. 32. Melon.

The Characters are,

It hath male and female flowers on the same plant. The male flowers have one petal, which is bell-shaped, fastened to the empalement, and cut into five segments at the brim. It hath three or four short stamina inserted in the empalement, joined together, two of which have bifid points. The female flowers have no stamina, or summits, but have a large oval germen situated below the flower, which afterward turns to an oval fruit with several cells, filled with oval, acute-pointed, compressed seeds, inclosed in a soft pulp.

There is a great variety of this fruit cultivated in the different parts of the world, and in this country there are too many of them propagated, which are of no value, especially by those who supply the markets, where their size is chiefly regarded; so that by endeavouring to augment their bulk, the fruit is rendered of no value: I shall therefore only mention a very few of the varieties, which are the most deserving of care, excluding the common Melons, as being unworthy the trouble and expence of cultivation.

The sort of Melon, which is in the greatest esteem among all the curious in every part of *Europe*, is the *Cantaleupe*, which is so called from a place about fourteen miles from *Rome*, where the pope has a country-seat, in which place this fruit has been long cultivated; but it was brought thither from that part of *Armenia*, which borders on *Persia*; where this fruit is in so great plenty, that a horse load is sold for a *French* crown. The flesh of this Melon, when in perfection, is delicious, and does not offend the most tender stomachs, so may be eaten with safety. The *Dutch* are so fond of this fruit, as to cultivate very few other sorts, and by way of pre-eminence, call it only by the appellation of *Cantaleupe*, and never join the title of Melon to it, which they apply indifferently to all the other sorts. The outer coat of this sort is very rough, full of knobs and protuberances like warts; it is of a middling size, rather round than long; the flesh is for the most part of an Orange colour, though there are some with a greenish flesh, but I have never met with any of that colour, so good as those of the other.

The *Romana* is by some much esteemed, and when the fruit is well conditioned, the plants in perfect health, and the season dry, it is a good Melon, and may be brought forwarder in the season than the *Cantaleupe*, therefore those who are desirous of early Melons, may cultivate this sort.

The *Succado* is also a good sort, and may be cultivated for early fruit, but these must give way to the *Cantaleupe*, when that is in season.

The Zatte is also a very good Melon, but very small. The fruit of this is seldom larger than an Orange; it is a little flattened at the two ends, and the outer coat is warted like the *Cantaleupe*, but there is so little flesh in one of these fruit, that they are scarce worthy the trouble of propagating.

The small *Portugal* Melon, which is by some called the *Dormer* Melon, is a pretty good fruit, and the plants generally produce them in plenty; so by many people this is preferred to most other, especially those who love a plenty, and are not so nice in distinguishing the quality. This may also be cultivated for an early crop.

But the best Melon for this purpose is the *Black Galloway*, which was brought from *Portugal* by Lord *Galloway* many years since, but of late years is rarely to be met with in *England*, it having been degenerated by growing among other sorts. The fruit of this sort will ripen in a shorter time from its first setting, than any other which I have yet seen; and when suffered to ripen naturally, is not a bad fruit.

The few varieties here mentioned, are sufficient to satisfy the curious, who may be fond of variety, for there are scarce any other which deserve the trouble; and indeed, those who have a true taste for this fruit, seldom cultivate any but the *Cantaleupe*; but as I before observed, where this fruit is desired early in the season, the *Cantaleupe* is not so proper as some of the other, therefore a few plants of one of the other sorts should be raised earlier in the spring, but it should be in a different part of the garden from the *Cantaleupe* Melons; for when two sorts of Melons grow near, they cannot be preserved perfectly right, therefore the *Dutch* and *German* gardeners are very careful in this respect; and in order to keep the sort in perfection, do not plant any other sort of Melon, Cucumber, or Gourd, near these, lest by the impregnation of the farina of those other, these fruit should be rendered bad; and in this particular I am convinced, from long experience, they are right; and from the not observing this, many persons who are lovers of this fruit, have gradually diminished their goodness, without knowing the cause, and have imputed it to the long cultivating from the seeds sowed in the same garden, believing it absolutely necessary to procure seeds from a distant place frequently, to preserve them good; indeed, where a person can securely depend on the care and skill of those he procures the seeds from, it is a very good method to exchange seeds now and then; but there are so few who are exact in making choice of the fruits from which they save the seeds, or careful enough to do it themselves, but often depend on others to clean the seed, that I should advise every one to do it himself, which is the sure way to have it good; for I have frequently been deceived myself, by depending on the fidelity and skill of others; nor could I procure any of these seeds from *Cantaleupe*, which were good, until my much honoured friend, the *Chevalier Rathgeb* sent me plentifully of it from thence; though I had often been supplied with seeds by persons who I thought could not be deceived in their choice, and who lived near the place of their growth.

Before I quit this head, I beg leave to caution all persons against depending upon seeds which are brought from abroad, either by those persons who import them for sale, or gentlemen who frequently bring or send over these seeds to their friends, for it seldom happens that any of these prove tolerable. I have been so often deceived by these myself, as to determine never to make trial of any of these seeds again, unless I receive them from a person who is skilful, and who eat of the fruit himself, of which he saved the seeds; for in *Italy*, *Spain*, *Portugal*, and many parts of *France*, the gardeners are very careless in the choice of all

their seeds, but of the Melons they are remarkably so; and as for those which come from *Constantinople*, *Aleppo*, and other parts of *Turkey*, I have rarely seen one Melon produced from those seeds, which was tolerable.

The seeds of Melons should not be sown until they are three years old, nor would I choose to sow them when they are more than six or seven; for although they will grow at ten or twelve years old, yet the fruit which are produced from those old seeds, are seldom so thick fleshed, as those which come from seeds which are fresher: it is the same of light seeds, which swim upon water, when they are taken out of the pulp, for I have made some trials of these, and have had them grow at three years old; but not one of the Melons produced on these plants was near so deep fleshed, as those which grew upon plants raised from heavy seeds, taken out of the same fruit, though they grew in the same bed, and were cultivated exactly in the same manner; nor was their flesh so firm, but rather inclining to be mealy; therefore I would not advise the sowing of these light seeds, nor those which are very old.

Having thus largely treated of the choice of the sorts, and of the seeds, I shall next proceed to the method of cultivating them, in order to obtain plenty of good fruit: the method which I am going to prescribe being very different from what has been constantly practised in *England*, will, I doubt not, be objected to by many; but it is what has been practised in all the good gardens in *Holland* and *Germany*, where the *Cantaleupe* Melon is produced in great plenty and perfection; and from several years experience, I have found this to be the only method in which these Melons can be cultivated with success; and I am likewise convinced, of its being the best way to obtain plenty of any other sort of Melon.

It is common to hear many persons valuing themselves upon having two or three early Melons, which, when brought to the table, are not better than a Pumpkin, and these are produced at a great expence with much trouble; and in order to have them ripe a little earlier, than they would naturally come, if suffered to grow to their full size, the stem upon which the fruit grows is commonly twisted, to prevent the nourishment entering the fruit, whereby the growth is checked; then the fruit is closely covered with the mowings of Grass-plats, laid of a sufficient depth to cause a fermentation, by which the fruit becomes coloured; but where this unnatural method is practised, the fruit hath little flesh, and that has neither moisture, firmness, or flavour; so that after four months attendance, with a great expence of dung, &c. there may perhaps be three or four brace of Melons produced, which are fitter for the dung-hill than the table. Therefore my advice is, never to attempt to have these fruit ripe earlier than the middle of *June*, which is generally soon enough for this climate; and from that time to the end of *September*, they may be had in plenty, if they are skilfully managed; and when the autumn has continued favourable, I have had them very good in the middle of *October*.

But in order to continue this fruit so long, the seeds must be sown at two different seasons; or if at three, it will be still better: the first should be sown the second week in *March*, if the season proves forward; but if it is otherwise, it will be better to defer it till the middle of that month, for the future success greatly depends on the raising the plants in strength; which cannot be so well effected, if the weather should prove so bad after the plants are come up, as that a sufficient quantity of fresh air cannot be admitted to them, therefore it is not adviseable to be too early in sowing the seeds.

These seeds may be sown on the upper side of a Cucumber-bed, where there are any; and if there are none, a
proper

proper quantity of new horse-dung must be provided, which must be thrown in a heap to ferment, and turned over, that it may acquire an equal heat, in the same manner as hath been directed for CUCUMBERS; and the plants must be raised and managed in the same manner as hath been directed for them, until they are planted where they are to remain for good; to which article the reader is desired to turn, to avoid repetition.

The second season for sowing of these seeds is the end of *March*; both these sowings must be understood to be planted under frames; for those which are designed for bell or hand-glasses, or to be covered with oil papers, should not be sown till ten or twelve days in *April*; for when these are sown earlier, if the plants are properly managed, they will extend their shoots to the sides of the glasses, before it will be safe to let them run out, for it often happens in this country, that we have sharp morning frosts in the middle of *May*; so that if the ends of these vines are then without the glasses, if they are not covered with mats, to guard them against the frost, they will be in danger of suffering greatly therefrom; and, on the other hand, if the plants have spread so much as to fill the glasses, and are not permitted to run out, they will be in equal danger of suffering by their confinement from the heat of the sun in the day time; therefore it is, that I should advise the putting of the seed in rather a little later for the glasses, than those which are to be covered with oil papers. Nor will the times here mentioned be found too late, for I have put the seeds of *Cantaleupe* Melons into a hot-bed the third of *May*, which were not transplanted, but remained where they were sown, and covered with oiled paper; and from this bed I cut a large crop of good fruit, which ripened about the latter end of *August*, and continued till the end of *October*. This I only mention, to shew what has and may be done, though it must not be always depended upon.

We next come to the making and preparing of the beds, or, as the gardeners term it, the ridges, into which the plants are to be put out to remain; these should always be placed in a warm situation, where they may be defended from all cold and strong winds, for the east and north winds are generally very troublesome in the spring of the year; so that if the place be exposed to these aspects, it will be difficult to admit a proper share of fresh air to the young plants; and if it is much exposed to the south-west winds, which often are very boisterous in summer and autumn, these will turn up and displace the vines, whereby they will suffer greatly; therefore the best position for these beds is, where they are open to the south, or a little inclining to the east, and sheltered at a distance by trees from the other points: this place should be inclosed with a good Reed fence, which is better for this purpose than any other inclosure, because the winds are deadened by the Reeds, and are not reverberated back again, as they are by walls, pales, or other close fences; but in making the inclosure, it should be extended to such distance every way from the beds, as not to obstruct the sun's rays during any part of the day; this should have a door wide enough to admit of wheelbarrows passing, to carry in dung, earth, &c. and should be kept locked, that no persons should be allowed to go in, but those who have business; for ignorant persons, having often curiosity to look into the beds, open the glasses and let the cold air to the plants, and frequently leave the glasses in part open; or sometimes when they are raised by the gardener to admit the fresh air, the tilts are thrown down, so that the air is excluded; all which are very injurious to the young plants, as is also the handling of the fruit after it is set; therefore none should be admitted, but when the person who is intrusted with the care of them is there.

The next thing is the preparation of the earth for these plants, in which the *Dutch* and *German* gardeners are very exact: the mixture which they generally prepare is of the following sorts; of Hazel loam, one third part; of the scouring of ditches or ponds a third part, and of very rotten dung a third part; these are mixed up at least one, and often two years, before they make use of it, frequently turning it over, to incorporate their parts and sweeten it; but the compost in which I find these plants succeed best in *England*, is two thirds of fresh gentle loam, and one third of rotten neats dung; if these are mixed together one year before it is wanted, so as to have the benefit of a winter's frost and summer's heat, observing to turn it over often, and never suffer weeds to grow upon it, this will be found equal to any other compost whatever.

As these plants succeed best when they are planted young, so before the plants appear there should be a quantity of new dung thrown in a heap, proportionable to the number of lights intended, allowing about fifteen good wheelbarrows full to each light; this must be two or three times turned over, to prepare it (as hath been directed for Cucumbers) and in a fortnight it will be fit for use, at which time the trench must be dug to receive the dung, where the bed is intended, which must be made rather wider than the frames, and in length proportional to the number of frames intended. As to the depth, that must be according as the soil is dry or wet; in a dry ground it should not be less than a foot, or a foot and a half deep; for the lower these beds are made, the better they will succeed, where there is no danger of their suffering by wet. In the well laying and mixing of the dung, the same care must be taken as hath been advised already for Cucumbers, which in every respect must be the same for these beds. When the bed is made, the frames should be placed over it to keep out wet; but there should be no earth laid upon it, till after it has been three or four days made, and is found of a proper temperature of heat; for many times these beds will heat so violently when they are first made, as to burn the earth, if covered with it; and when this happens, it is much the best way to take off this earth again, for the plants will never thrive in it.

As soon as the bed is found to be of a proper warmth, the earth should be laid upon it, which at first need not be more than two inches thick, except in the middle of each light, where the plants are to be placed, where there must be raised a hill eighteen inches high or more, terminating in a flat cone; in two or three days after the earth is put on the bed, it will be of a proper temperature to receive the plants; then in the evening you may transplant the plants, but always do it when there is little wind stirring: in taking up of the plants, their roots should be carefully raised with a trowel, so as to preserve all their fibres; for if these are broken off, the plants do not soon recover this; or if they do, they are generally weaker, and never make so good vines as those which are more carefully removed; for these plants are more nice and tender in transplanting than those of Cucumbers, especially the *Cantaleupe* Melon; which, if it is not planted out, soon after the third, (or what the gardeners call the rough) leaf is put out, they are long recovering their vigour; so that when it happens, that the beds cannot be ready for them in time, it will be a good method to plant each plant into a small pot while they are young, and these may be plunged into the hot bed where they were raised, or in a Cucumbe-bed where there is room, so that they may be brought forward; and when the bed is ready, they may be turned out of the pots, with the whole ball of earth to their roots, whereby they will receive no check in removing: and this latter method is what I should prefer to any other for the *Cantaleupe*, because there should

never be more than one plant left to grow in each light; therefore by this method there will be no necessity of planting more, as there will be no danger of their succeeding; whereas in the common way, most people plant two or more plants in each light, for fear one should miscarry. When the plants are placed on the top of the hills, they should be gently watered, which should be repeated once or twice after till the plants have taken good root, after which they seldom require more; for when they receive too much wet, they often canker at the root, and when that happens they never produce good fruit. When the plants have established themselves well in the new beds, there should be a greater quantity of earth laid on the bed, beginning round the hills where the plants grow, that their roots may have room to strike out; and as the earth is put in from time to time, it must be trodden or pressed down as close as possible, and at last it should be raised at least a foot and a half thick upon the dung all over the bed, observing also to raise the frames, that the glasses may not be too near the plants, lest the sun should scorch them.

When the plants have gotten four leaves, their tops should be pinched off with the finger and thumb, but not bruised or cut with a knife, because in either of these cases the wound will not so soon heal over: this pinching is to cause the plants to put out lateral branches, for these are what will produce the fruit; therefore when there are two or more of these lateral shoots produced, they must also be afterward pinched, to force out more, which must be practised often, that there may be a supply of what the gardeners call runners, to cover the bed. The management of these beds must be nearly the same as hath been directed for the Cucumbers, therefore I need not repeat it here; but shall only observe, that the Melons require a greater share of air than Cucumbers, and very little water; and when it is given to them, it should be at a distance from their stems.

If the plants have succeeded well, they will spread over the bed and reach to the frames in about six weeks, at which time the alleys between the beds should be dug out; or where there is but one bed, there should be a trench made on each side of about four feet wide, as low as the bottom of the bed, and hot dung wheeled in, to raise a lining to the same height as the dung of the bed, which should be trodden down close, and afterward covered with the same earth as was laid upon the bed, to the thickness of a foot and a half or more, treading it down as close as possible; this will add to the width of the bed, so much as to make it in the whole twelve feet broad, which is absolutely necessary; for the roots of the plants will extend themselves quite through it, so that if the extreme fibres are exposed to the air, it is common to see the vines decay, before the fruit is well grown; for where there is no addition made to the width of the bed, the roots will have reached the sides of the bed by the time that the fruit appears, and having no more room to extend themselves, their extremities are dried by the sun and air, which is soon discovered by the plants hanging their leaves in the heat of the day, which is soon after attended with a decay of many of those leaves, which are near the stem, and the plants from that time will gradually languish, so that the fruit cannot be supplied with nourishment, but when ripe will be found to have little flesh, that mealy and ill flavoured; whereas those plants which have sufficient breadth for their roots to run, and the earth laid of a proper depth and closely trod down, will remain in vigour until the frost destroys them; so that I have had a second crop of fruit on them, which have sometimes ripened well; but all the first were excellent, and of a larger size than these sorts usually grow: the leaves of these plants were very large, of a strong green, so that they

were in the utmost vigour; whereas, in most places where the *Cantaleupe* Melons have been raised in *England*, the beds have been no wider than they were first made, and perhaps not more than three inches thickness of earth upon them, so that the plants have decayed many times before they have ripened a single fruit; from whence people have imagined, that this sort of Melon was too tender for this climate, when their ill success was entirely owing to their not understanding their culture.

There is also another advantage attending this method of widening the beds, as above directed, which is that of adding a fresh warmth to the beds, by the hot dung which is buried on each side, which will cause the dung in the bed to renew its heat; and as the plants will by this time shew their fruit, this additional heat will be of great service in setting of the fruit, especially if the season should prove cold, as it sometimes happens in this country till the end of *May*. When the beds are made up in the manner here directed, and the vines have extended so far as to fill the frames, and want more room, the frames should be raised up with bricks about three inches high, to admit the shoots of the vines to run out from under them; for if the plants are strong, they will extend six or seven feet each way from their stems, especially if they are raised from new seeds; for which reason I caution every one to allow them room, and to put but one plant in each light; for when the vines are crowded, the fruit seldom will set well, but will drop off when they are as large as an egg; therefore the frames which are designed for Melons should not be made small, for the wider these are, the better will the plants thrive, and produce a greater plenty of fruit.

There is no part of gardening, in which the practitioners of this art differ more, than in the pruning and managing of these plants; nor are there any rules laid down in the several books in which the culture of Melons have been treated of, by which any person can be instructed; for there is such inconsistency in all their directions, and what is worse, the greatest part of them are absurd, so that whoever follows them can never hope to succeed; therefore I shall, in as few words as possible, give such plain directions, as I hope will be sufficient to instruct any person, who is the least conversant in these things.

I have before advised the pinching off the ends of the plants as soon as they have a joint, in order to get lateral shoots, which are by the gardeners called runners; and when these shoots or runners have two or three joints, to pinch off their tops also, to force out more runners, because it is from these that the fruit is to be produced; but after a sufficient number are put out, they should not be stopped again, but wait for the appearance of the fruit, which will soon come out in plenty; at which time the vines should be carefully looked over three times a week, to observe the fruit, and make choice of one upon each runner, which is situated nearest the stem, having the largest foot-stalk, and that appears to be the strongest fruit; then pinch off all the other fruit which may appear upon the same runner, also pinch off the end of the runner at the third joint above the fruit; this will stop the sap and set the fruit. There is also another method practised by some gardeners to set this fruit, which is the taking off some of the male flowers, whose farina is just ripe and fit for the purpose, laying them over the female flowers, which are situated on the crown of the young fruit, and with their nails gently strike the male flowers to shake the farina into the female flowers, whereby they are impregnated, and the fruit soon after will swell, and shew visible signs of their being perfectly set; so that where the plants are under frames, and the wind excluded from them, which is necessary to convey the farina from

the male to the female flowers, this practice may be very necessary; but when the fruit appears on the vines, the glasses should be constantly taken off at all times, when the weather is good, for where this is omitted, the fruit seldom sits in plenty. The taking off all the other fruit will prevent the nourishment being drawn away from the fruit intended to grow, which if they were all left on, the plant could not supply them with sufficient nourishment; so that when they come to be as large as the end of a man's thumb, they all drop off, and scarce one of them sets, which will be prevented by the method before directed: but there are some persons, who are so covetous of having a number of fruit, as not to suffer any to be taken off, whereby they generally fail in their expectation. My allowing but one fruit to be left upon each runner is, because if half of these stand, there will be full as many fruit as the plant can nourish; for if there are more than six or eight upon one plant, the fruit will be small, and not so well nourished; indeed I have sometimes seen fifteen or twenty Melons upon one plant, but these have generally been of the smaller kinds, which do not require so much nourishment as the *Cantaleupes*, whose skins are of a thick substance; so that where a greater number are left of them than the plants can well supply, their flesh will be remarkably thin.

As I before advised the stopping or pinching off the runners three joints above the fruit, so by this there will be fresh runners produced a little below the places where the others were pinched; therefore it is that I advise the careful looking over the vines so often, to stop these new runners soon after they come out, as also to pull off the young fruit which will appear; and this must be repeated as often as it is found necessary, which will be until those intended to stand are grown so large as to draw all the nourishment which the plants can supply, for then the plants will begin to abate of their vigour. These few directions, if properly made use of, is all the pruning which is necessary to be given them; but at the same time when this is practised, it may be necessary to give some water to the plants, but at a distance from their stems, which will be of service to set the fruit and cause it to swell; but this must be done with great caution.

When the plants have extended themselves from under the frames, if the weather should alter to cold, it may be necessary to cover the extremities of the vines every night with mats; for if these are injured, it will retard the growth of the fruit, and often prove very injurious to the plants: after this, what water is given to the plants should be in the alleys between the beds; for as the roots of the vines will by this time have extended themselves through into the alleys, so when the ground there is well moistened, the plants will receive the benefit of it; and by this method, the stems of the plants will be preserved dry, whereby they will continue sound; but these waterings should not be repeated oftener than once a week in very dry warm weather, but be sure to give as much air as possible to the plants, when the season is warm.

Having given full instructions for the management of those Melons which are raised under frames, I shall next proceed to treat of those which are raised under bell or hand-glasses. The plants for these must be raised in the same manner as hath been already directed, and about the latter end of *April*, if the season proves forward, will be a good time to make the beds; therefore a sufficient quantity of hot dung should be provided, in proportion to the intended number of glasses, allowing eight or nine good wheelbarrows of dung to each glass. Where there is but one bed, which is proposed to be extended in length, the trench should be dug out four feet wide, and the length accord-

ing to the number of glasses intended, which should not be placed nearer than four feet to each other; for when the plants are too near each other, the vines will intermix, and fill the bed so closely, as to prevent the fruit from setting: in digging of the trench, it should be so situated as to allow for the widening of the bed three or four feet on each side; the depth must be according as the soil is dry or wet; but, as was before observed, if the soil is so dry, as that there is no danger of the beds being hurt by the wet, the lower they are made in the ground the better: in the making of the beds, the same regard must be had to the well mixing and laying of the dung, as was before directed; and after the dung is laid, there should be a hill of earth raised, where each plant is to stand one foot and a half high; the other part of the bed need not as yet be covered more than four inches thick, which will be sufficient to keep the warmth of the dung from evaporating; then the glasses should be placed over the hills, and set down close, in order to warm the earth of the hills to receive the plants; and if the beds work kindly, they will be in a proper temperature to receive the plants, in two or three days after making; then the plants should be removed in the same manner as was before directed, and if they are in pots, so that there will be no danger of their growing, there should but one plant be put under each glass; if they are not in pots, there should be two, one of which may be afterward taken away, if they both grow. These plants must be watered at first planting, to settle the earth to their roots, and shaded every day, until they have taken new root; and if the nights prove cold, it will be proper to cover the glasses with mats, to preserve the warmth of the bed.

Where there are several of the beds intended, they should be placed at eight feet distance from each other, that there may be a proper space left between them, to be afterward filled up, for the roots of the vines to have room for extending themselves, for the reasons before given.

When the plants have taken good root in the beds, their tops must be pinched off; and their pruning, &c. must, from time to time, be the same as for those under the frames: in the day time, when the weather is warm, the glasses should be raised on the opposite side to the wind, to admit fresh air to the plants; for where this is not observed, they will draw up weak and sickly, therefore all possible care should be taken to prevent this; for if the runners have not proper strength, they can never supply the fruit with nourishment.

When the plants are grown so long as to reach the sides of the glasses, if the weather proves favourable, the glasses must be set up on three bricks, so as to raise them about two or three inches from the surface of the beds, to give room for the vines to run out from under them; but when this is done, the beds should be covered all over with earth to the depth of one foot and a half, and trod down as close as possible; and if the nights should prove cold, there should be a covering of mats put over the beds, to prevent the cold from injuring the tender shoots of the vines; but as the vines of the *Cantaleupe* Melons are impatient of wet, it will be necessary to arch the beds over with hoops, to support the mats, that they may be ready for covering at all times when they require it; which is the only sure method to have these Melons succeed in *England*, where the weather is so very uncertain and variable; for I have had some beds of these Melons in as fine order under these glasses as could be desired, which were totally destroyed by one day's heavy rain in *June*.

After the thickness of earth is laid upon the beds, if the weather should prove cold, it will be adviseable to dig trenches on each side of the beds, into which you should lay a suffi-

cient quantity of hot dung, to make it of the same thickness with the bed, after the manner before directed for the frames; or if there is a sufficient quantity of hot dung ready, the whole space between the beds may be dug out, and filled up with the dung, laying thereon the earth a foot and a half deep, treading it down close: this new dung will add a fresh warmth to the beds, and cause the plants to shew fruit soon after.

The watering of these plants must be done with great caution, and not given to their stems; the pinching of the runners must also be duly attended to, as also the pulling off all superfluous fruit, to encourage those which are designed to remain; and in short, every thing before directed for those under frames, must likewise be observed for these; and the further care is, to cover them in all hard rains and cold nights with mats; which, if performed with care, there will be little danger of their miscarrying, and these vines will remain vigorous until the cold in autumn destroys them.

There have been many persons, who of late years have raised their Melons under oiled paper, and in many places they have succeeded well; but where this is practised, there must be great care taken not to keep these coverings too close over them; for where that is done, the vines will draw very weak, and rarely set their fruit in any plenty; therefore where these coverings are proposed to be used, I should advise the bringing up of the plants under hand or bell-glasses, in the manner before directed, until they are grown far enough to be let out from under the glasses; and then, instead of the covering with mats, to put over the oiled paper; and if this covering is prudently managed, it will be the best that can be used. The best sort of paper for this purpose is that which is strong, and not of too dark colour; it should be done over with Linseed oil, which will dry soon. There should be a proportionable number of the sheets of this paper pasted together, as will spread to the dimensions of the frame to which it is to be fastened; and if this is fixed to the frame, before the oil is rubbed over it, so much the better; but this should be done so long before they are used, as that the oil may be thoroughly dry, and the stench gone off, otherwise it will hurt the plants.

There are some persons who make these frames of broad hoops, in imitation of the covers of waggons; but as these are cumbersome to move, and there are no conveniencies for admitting air to the plants, but by raising the whole frame on one side, so I prefer those made of pantile laths, framed like the ridge of a house; each slope having hinges, whereby any of the pannels may be raised at pleasure, to admit the air to the plants: but as descriptions of these things are not well comprehended by persons not so conversant with them, I shall exhibit a figure of one of these frames, to be added to the article of STOVES.

There are some few persons of quality in England, who have made the same conveniencies for their hot-beds, to raise the *Cantaloupe* Melons, as is in general practised by the *Dutch*; which is first to dig a trench in the ground ten feet wide, and in length proportional to the number of lights which are designed to cover the beds: this pit is boarded up with old ship planks, so as to make the depth full three feet and a half, or more, which pit they fill with tanners bark or dung mixed well together: then they have frames made six feet wide in the clear, which are placed in the middle of the hot-bed, whereby there will be two feet left on each side the frame within the planking, to allow room for the roots of the Melon plants to extend each way. Upon this hot-bed made with tanners bark and dung, they lay a foot and a half of good loamy earth for the plants to root into. By this method the dung, tan, and earth, is prevented from falling into the walks on the sides of the beds, so the walks

will be clean for to pass between them, which is an advantage. But as these ship-planks will not last long found, so I have made several of these trenches, the sides of which are bricked up, and the top of the wall covered with an Oak curb, to prevent the bricks from being displaced. These pits I find answer the purpose better than the other, and when their duration is considered, will be found as cheap as the other.

The further management of the Melons, after their fruit is set, is to keep pulling off all the superfluous fruit, and to pinch off all weak runners, which may draw away part of the nourishment from the fruit; as also to turn the fruit gently twice a week, that each side may have equal benefit of the sun and air; for when they are suffered to lie with the same side constantly to the ground, that side will become of a pale or whitish colour, as if it were blanched, for want of the advantages of the sun and air. The plants will require a little water in very dry weather, but this should be given them in the alleys, at a distance from the stems of the plants, and not oftener than once in a week or ten days, at which times the ground should be well soaked in the alleys. This will encourage the growth of fruit, and cause the flesh to be thick; but the great caution which is necessary to be observed, is not to over-water the plants, which is certain injury to them; also be sure to give as much free air as possible, at all times, when the weather will permit, for this is absolutely necessary to render the fruit good.

When the fruit is fully grown, they must be duly watched to cut them at a proper time; for if they are left a few hours too long upon the vines, they will lose much of their delicacy, therefore they should be looked over at least twice every day; and if those fruit which are intended for the table, are cut early in the morning, before the sun has warmed them, they will be much better flavoured; but if any should require to be cut afterward, they should be put into cold spring water, or ice, to cool them, before they are brought to the table; and those cut in the morning, should be kept in the coolest place till they are served up to table. The sign of this fruit's maturity is, that of its beginning to crack near the foot-stalk, and its beginning to smell, which never fail; for as these *Cantaloupe* Melons seldom change their colour until they are too ripe, that should never be waited for.

The directions here given for the management of the *Cantaloupe* Melons, will be found equally good for all the other sorts, as I have fully experienced; for in the common method of managing them, where the earth is laid but three or four inches thick, the plants are very apt to decay before the fruit is ripe; for their roots soon reach to the dung, and are extended to the sides of the bed, where their tender fibres are exposed to the air and sun, which causes the leaves of the plants to hang down in the heat of the day, so it is necessary to shade the plants with mats, to prevent their sudden death; for this drooping of the leaves occasions the watering of the plants often to keep them alive, which is also prejudicial to their roots; whereas, when the beds are made of a proper width, and earthed of a sufficient thickness, the plants will bear the strongest heat of the sun in this climate, without shewing the least want of moisture, or their leaves drooping, and they will continue in health till the autumn cold destroys them.

In saving of the seeds, I need not repeat here, that only such should be regarded which are taken from the firmest fruit, and those which have the highest flavour; and if these are taken out with the pulp entire, without displacing the seeds, and suffered to remain in the pulp two or three days before it is washed out, the better; and then to preserve only the heavy seeds, which sink in the water.

MELOCACTUS. } See Cactus.
MELOCARDUUS. }

MELOCHIA. See Corchorus.

MELON. See Melo.

MELONGENA. *Tourn. Inst. R. H. 151. tab. 65.* Mad Apple, by some called Egg Plant.

The Characters are,

The flower has but one petal, which is cut into five parts, and reflexed. It hath five awl-shaped stamina. In the center is situated an oblong germen, which afterward becomes an oval or oblong fruit with one cell, with a fleshy pulp, filled with compressed roundish seeds.

The Species are,

1. MELONGENA caule inermi herbaceo, foliis oblongo-ovatis tomentosis integris, fructu ovato. Mad Apple with an oblong Violet-coloured fruit.

2. MELONGENA caule inermi herbaceo, foliis oblongo-ovatis tomentosis, fructu tereti. Mad Apple with a taper Violet-coloured fruit.

3. MELONGENA caule inermi herbaceo, foliis oblongis sinuatis tomentosis, fructu incurvo. Mad Apple with an incurved fruit.

4. MELONGENA spinosa, foliis sinuato-lacinatis, fructu tereti, caule herbaceo. Apple-bearing Nightshade, with prickly leaves and fruit.

The first sort grows naturally in *Asia, Africa, and America*, where the fruit is commonly eaten by the inhabitants; it is cultivated in the gardens in *Spain* as an esculent fruit, by the title of *Barenkeena*; the *Turks*, who also eat the fruit, call it *Badinjan*, the *Italians* *Melanzana*, and the inhabitants of the *British* islands in *America* *Brown John*, or *Brown Jolly*. It is an annual plant, with an herbaceous stalk, which becomes ligneous, and rises from two to three feet high, sending out many side branches, garnished with oblong, oval, woolly leaves, whose borders are very slightly sinuated. The flowers come out singly from the side of the branches, which have a thick fleshy empalement, deeply cut into five acute segments, armed with strong prickles on the outside. The flowers have one petal, which is cut at the brim into five segments, which expand in form of a star, but are a little reflexed; they are blue, and the summits which are connected together in the bosom of the flower are yellow. The flowers are succeeded by oval fleshy fruit about the size and shape of a swan's egg, of a dark purple on one side, and white on the other.

There are the following varieties of this species; one with white fruit, called by some the *Egg Plant*; one with yellow fruit, and another with pale red fruit; all these varieties are generally constant, the seeds producing the same fruit as those from which they were taken, but as they only differ in colour, so I choose not to enumerate them as distinct species.

The second sort differs from the first in the shape of the fruit, which is commonly eight or nine inches long, taper and strait; in other respects they are the same, but as this never varies when propagated in gardens, so there can be no doubt of its being a distinct species. There are two varieties of this sort, one with a purplish fruit, and the other white, but the latter is the most common in *England*.

The third sort differs from the two former in the shape of the leaves, which are deeply sinuated on their borders. The fruit is oblong and incurved, of a yellowish colour, and larger at the end than in any other part.

The fourth sort grows naturally in *India*. This differs greatly from either of the former. The stalks and leaves are armed with very strong thorns; the leaves are larger, and deeply jagged on their sides. The flowers are larger, and of a deeper blue colour. The fruit is long, taper, and white.

These fruit are eaten by most of the inhabitants of the warm parts of the globe, and are esteemed a delicacy, but are supposed to have a property of provoking lust.

They are propagated by seeds, which should be sown upon a moderate hot-bed early in *March*; when the plants come up, they must be transplanted into another hot-bed about three or four inches asunder, observing to water and shade them until they have taken root; after which they must have a great share of air when the weather is warm, otherwise they will draw up very weak. They must also be frequently watered, without which they will make but very indifferent progress. When the plants are grown so strong as to fill the frame (which will be by the middle or end of *May*) you must transplant them out into a rich spot of ground, at two feet distance, or into the borders of the pleasure-garden at the same distance from other plants, observing to preserve as much earth to the roots as possible when you take them up, otherwise they are subject to miscarry. They must have water plentifully, until they have taken root; after which they will require but very little care, more than to keep them clear from weeds, and in very dry weather to give them some water.

These plants are only preserved as curiosities in the *English* gardens, the fruit being seldom eaten in this country, except by some *Italians* or *Spaniards*, who have been accustomed to eat them in their own countries.

MELOPEPO. See Cucurbita.

MELOTHRIA. *Lin. Gen. Plant. 48.*

The Characters are,

The flower is of one leaf, wheel-shaped. In the center of the flower is situated the germen, attended by three conical stamina, inserted in the tube of the flower. The germen afterward becomes an oval small berry, having three divisions, in which are lodged small flat seeds.

We have but one Species of this plant, viz.

MELOTHRIA. *Lin. Hort. Cliff. 490.* Smallest Cucumber, with a smooth, black, oval fruit.

This plant grows wild in the woods in *Carolina, Virginia*, and also in many of the islands in *America*; the vine spreads upon the ground, having angular leaves, resembling those of the Melon, but much smaller. These vines strike out roots at every joint, which fasten themselves into the ground, by which means their stalks extend to a great distance each way. The flowers are very small, in shape like those of the Melon, of a pale sulphur colour. The fruit in the *West-Indies* grows to the size of a Pea, of an oval figure, and changes black when ripe; these are by the inhabitants sometimes pickled when they are green.

In *England* the fruit are much smaller, and are so hidden by the leaves, as to render it difficult to find them. The plants will not grow in the open air here, but must be sown upon a hot-bed, and if they are permitted, will soon spread over the surface, when the fruit is ripe; if they scatter their seeds, the plants will come up where the earth happens to be used on a hot-bed again. This is preserved in some gardens for the sake of variety, but is of no use.

MENISPERMUM. *Tourn. Art. R. Par. 1705.* Moonseed.

The Characters are,

The flower has six oblong, oval, concave petals, and six stamina which are shorter than the petals, with three almost oval germen on the top of the styles, crowned by obtuse indented stigmas. The germen afterward turn to three oval berries with one cell, each inclosing one moon-shaped compressed seed.

The Species are,

1. MENISPERMUM foliis peltatis subrotundis angulatis. *Hort. Cliff. 140.* Climbing Moonseed of *Canada*, with a navel-shaped leaf.

2. *MENISPERMUM foliis cordatis peltatis lobatis. Flor. Virg.*
40. Moonseed with an Ivy leaf.

3. *MENISPERMUM foliis cordatis subtus villosis. Lin. Sp. Plant.* 340. Moonseed with heart-shaped leaves, which are hairy on their under side.

The first sort grows naturally in the woods of *Canada, Virginia*, and most parts of *North America*. It hath a thick ligneous root, from which are sent out many climbing stalks, which become ligneous, and rise to the height of twelve or fourteen feet, twisting themselves about the neighbouring plants for support, and are garnished with large, smooth, roundish leaves, whose foot-stalks are placed almost in the middle of them; on the upper side there is a hollow in that part of the leaf, resembling a navel. The flowers come out in loose bunches from the side of the stalks; they are of an herbaceous colour, small, and composed of six oblong oval petals, and six very short stamina, terminated by single summits; the three germen situated in the center, turn to so many channelled berries, each containing one compressed seed.

This sort may be easily propagated by laying down of the branches, which, if performed in autumn, they will have made good roots by that time twelve-month, when they may be separated from the old plant, and transplanted where they are designed to remain; these plants require support, for their branches are slender and weak. In the country, where it grows naturally, they climb up the trees to a considerable height; so that if these are planted near trees in wilderness quarters, where their stalks may have support, they will thrive better than in an open situation.

The second sort differs from the first in the shape of its leaves, which are angular; their foot-stalks join to the base of the leaves, so have no umbilical mark on their surface. The stalks of this become ligneous, and rise as high as those of the first sort; the flowers and berries do not differ from them. It is propagated after the same manner.

The third sort grows naturally in *Carolina*. This has by some been supposed the same with the second sort, but it differs from that in its roots, not becoming woody as those do. The stalks are also herbaceous; the leaves are entire and hairy, not more than half so large as those of the second, nor is the plant so hardy. This sort does not produce flowers in *England*, unless the season proves very warm.

This may be propagated by parting of the roots; the best time for doing this is in the spring, a little before the plants begin to shoot; these should be planted in a warm situation and a light soil, for in strong land, where the wet is detained in winter, the roots are apt to rot; therefore if they are planted close to a wall exposed to the south or west, their stalks may be fastened against the wall, to prevent their trailing upon the ground, and in this situation the plants will frequently flower, and by a little shelter in severe frost, their stalks may be preserved from injury.

MENTHA. Tourn. Inst. R. H. 188. tab. 89. Mint.

The Characters are,

It hath a lip flower of one petal. The mouth is cut into four almost equal segments, the upper being a little larger and indented. It hath four erect stamina, the two nearest being longest. In the bottom of the tube is situated a four-pointed germen, which afterward turns to four naked seeds sitting in the empalement.

The Species are,

1. *MENTHA floribus spicatis, foliis oblongis serratis. Hort. Upsal.* 168. Mint with spiked flowers; commonly called Spear Mint.

2. *MENTHA floribus spicatis, foliis longioribus glabris, superne minimè serratis.* Narrow-leaved, smooth-spiked Mint.

3. *MENTHA foliis lanceolatis serratis, subtus incanis, floribus spicatis hirsutissimis.* Mint with spear-shaped sawed leaves, which are hoary on their under side, and very hairy spiked flowers.

4. *MENTHA spicis confertis, foliis serratis tomentosiss sessilibus. Hort. Cliff.* 306. Wild Mint with a longer leaf.

5. *MENTHA spicis crassioribus, foliis ovato-lanceolatis serratis subtus tomentosiss petiolatis.* Hairy Water Mint with a thicker spike.

6. *MENTHA spicis crassioribus interruptis, foliis lanceolatis acute serratis.* Blackish hot Mint, with a taste like Pepper; commonly called Pepper Mint.

7. *MENTHA floribus spicatis, foliis cordatis dentatis undulatis sessilibus. Hort. Cliff.* 306. Danish or German curled Mint.

8. *MENTHA spicis confertis, foliis ovatis rugosis sessilibus.* Wild Mint with a rounder rough leaf, and a spiked flower having a strong scent.

9. *MENTHA spicis confertis interruptis, foliis oblongo-ovatis acuminatis dentatis sessilibus.* Round-leaved red Mint, smelling like an Orange; commonly called Orange Mint.

10. *MENTHA foliis oblongis dentatis, utrinque tomentosiss sessilibus, spicis tenuioribus.* Narrow-leaved wild Mint of *Aleppo*, which rarely flowers.

11. *MENTHA floribus capitatis, foliis ovatis serratis petiolatis, staminibus corollâ longioribus. Hort. Cliff.* 306. Greater, round-leaved, Water Mint.

12. *MENTHA floribus capitatis, foliis lanceolatis serratis subpetiolatis. Lin. Sp. Plant.* 576. Broad-leaved, blackish, hot Mint, or Pepper Mint.

13. *MENTHA floribus verticillatis, foliis ovatis acutis serratis, staminibus corollâ brevioribus. Lin. Sp. Plant.* 577. Whorled hairy Field Mint, or Calamint of the shops.

14. *MENTHA floribus verticillatis, foliis ovatis dentatis, staminibus corollâ longioribus.* Smallest Water Mint.

15. *MENTHA floribus verticillatis, foliis ovatis, marginibus ciliatis, staminibus corollam æquantibus.* Whorled Mint with a rounder leaf, smelling like Basil.

16. *MENTHA floribus verticillatis, foliis ovatis serratis hirsutis, staminibus corollâ longioribus.* Common, hairy, Water Mint, or Sifymbrium.

17. *MENTHA floribus verticillatis, foliis lanceolatis acutis serratis, rugosis, staminibus corollam æquantibus.* Whorled Mint with a longer acute-pointed leaf, and an aromatick scent.

18. *MENTHA floribus verticillatis, foliis oblongo-ovatis rugosis serratis, staminibus corollâ longioribus.* Curled Mint with whorled flowers, and a rounder leaf.

The first sort is what the gardeners cultivate to supply the markets, which is used both as a culinary herb, and for medicine. It is generally called Spear Mint, and by some Hart Mint, or *Roman Mint*. This is a plant so well known, as to need no description. There are two varieties of this, one with a curled, and the other has variegated leaves, but both these run from the common sort; these are by some preserved in their gardens for the sake of variety, therefore I have mentioned them here.

The second sort hath smoother and narrower leaves than the first, but in other respects it agrees with that, so that it is frequently cultivated in the gardens for use, without distinction.

The third sort grows naturally in moist places. The leaves of this are shorter, and broader in the middle than either of the former; the serratures on their edges are more acute, and their under sides are woolly. The scent of this sort is very like that of the Garden Mint.

The fourth sort hath longer and broader leaves than either of the former, which are woolly and white. The serratures on their edges are farther asunder; they are hairy, and very sharp pointed. The spikes of flowers are slender, hairy, several of them grow together at the top of the stalk. This is the *Mentastrum*, or wild Mint of the shops, and is an ingredient in the *Trochisci de Myrrha*.

The fifth sort grows naturally in several parts of *England*; it is titled Spiked Horse Mint, or Water Mint. The stalks of this are shorter than those of either of the former; the leaves are oval, spear-shaped, of a pale colour, sawed on their edges. The flowers grow in short thick spikes at the top of the stalks, their stamina being shorter than the petal.

The sixth sort grows naturally by the side of the river between *Mitcham* and *Croydon* in *Surry*. This hath smooth purple stalks; the leaves are smaller than those of common Mint, sawed on their edges, of a darker green colour than either of the former; their midrib and veins are purple, and a little hairy on their under side. The spikes of flowers are shorter and thicker than those of the common Mint, and are broken, or interrupted at the bottom. The whole plant has a hot biting taste like Pepper, and a pleasant scent.

The seventh sort was originally brought from *Denmark*, where it was thought to grow naturally, but Dr. *Linnaeus* fixes it as a native of *Siberia*. The stalks of this sort are hairy, and rise about the same height with the common. The leaves are heart-shaped, deeply indented on their edges, waved and curled, and fit close to the stalk; they are of a light green. The flowers are purple, growing in thick interrupted spikes at the top of the stalks; their empalements are cut almost to the bottom, and the style of the flower is bifid, standing out beyond the petal.

The eighth sort grows naturally in many parts of *England*. This rises with a strong hairy stalk, about the same height as the common Mint, garnished with oval rough leaves fitting close; they are of a dark green, and crenated on their edges. The spikes of flowers grow in clusters at the top of the stalks, which are short and close; their stamina are stretched out beyond the petal.

The ninth sort is commonly called Orange Mint, from its scent, which is somewhat like that of the rind of Orange. This rises with an upright smooth stalk about the same height with the common Mint, but does not branch out like that; the leaves are much broader than those of the common sort, the indentures on their edges are deep, and they end in acute points. The spikes of flowers grow in clusters on the top of the stalks, which are interrupted; their stamina are shorter than the petal. It is commonly cultivated in gardens for its pleasant scent.

The tenth sort grows naturally at *Aleppo*, but is hardy enough to thrive in the open air in *England*. This hath slender stalks, which are purple at bottom, but woolly upward, seldom branching, garnished with oblong indented leaves, which are downy on both sides, fitting close to the stalks. The spikes of flowers are single, and very slender, but do not often appear in *England*, but when they do it is late in the summer. It creeps much at the root, so the only way to obtain flowers, is to confine their roots in pots.

The eleventh sort grows naturally in ditches in most parts of *England*, and is commonly known by the name of Water Mint. This hath hairy stalks about a foot high, which branch toward the top, garnished with oval sawed leaves, standing upon pretty long foot-stalks. The flowers grow in roundish spikes at the end of the branches, of a purple colour, and their stamina are longer than the petal. The whole plant has a very strong scent, somewhat like that of Pennyroyal.

The twelfth sort grows naturally in ditches in several parts of *England*. The stalks of this are purple, smooth, and short; the leaves are small, spear-shaped, of a dark colour, and are slightly sawed on their edges. The flowers grow in roundish heads on the top of the stalks; their stamina are longer than the petal. This sort has a warm biting taste, but not quite so hot as the Pepper Mint before described, but is often used for it.

The thirteenth sort grows naturally in arable land in most parts of *England*, and is rarely admitted into gardens. This is the Water Calamint of the shops, but is now seldom used in medicine. The stalks of this sort rise about a foot high, are hairy, garnished with oval leaves, ending in acute points, sawed on their edges. The flowers grow in very thick whorls round the stalks; they are small, of a purple colour, and their stamina are shorter than the petal.

The fourteenth sort grows in watery places in many parts of *England*. This hath weak trailing stalks a foot and a half long, garnished with small oval leaves, which are indented on their edges, and stand upon pretty long foot-stalks. The flowers grow in thick whorls round the stalks, and their stamina are longer than the petal.

The fifteenth sort grows plentifully on the side of the road between *Bocking* and *Gosfield* in *Effex*. The stalks of this are much smaller, and not so long as those of the former; the leaves are shorter and rounder, and are very little indented on their edges, but have their borders set with hairs. The whorls of flowers are smaller, and the whole plant has the scent of Basil.

The sixteenth sort grows naturally in ditches in many parts of *England*. This hath hairy stalks a foot or more in height; the leaves are oval, sawed, and very hairy. The flowers grow in large whorls toward the top of the stalks, and their stamina are longer than the petals. This hath a pleasanter scent than the common Water Mint, so is called Sweet Water Mint, by way of distinction.

The seventeenth sort grows naturally by the side of the river *Medway*, between *Rocheester* and *Chatham*. This hath hairy stalks near two feet high, garnished with spear-shaped leaves, ending in acute points; the stalks are beset with whorls of flowers, almost their whole length, so that they have frequently ten or twelve whorls on each. The flowers are purplish, and their stamina are equal with the petals: this hath a very pleasant aromattick scent.

The eighteenth sort grows naturally in *Holland*, between *Leyden* and *Haerlem*. This hath purple smooth stalks, which rise about the same height as the common Mint, garnished with oblong oval leaves, which are rough and sawed on their edges, having very short foot-stalks. The flowers grow in whorls toward the top of the stalks; under each of these are placed two very small leaves, in which this differs from most of the other whorled Mints.

All the sorts of Mint are easily propagated by parting the roots in spring, or by planting cuttings during any of the summer months, but they should have a moist soil; and after the cuttings are planted, if the season should prove dry, they must be often watered, until they have taken root; after which they will require no farther care, but to keep them clear from weeds: they should be planted in beds about four feet wide, allowing a path two feet broad, to go between the beds to water, weed, and cut the plants. The distance they should be set is about five or six inches, or more, because they spread very much at their roots; for which reason, the beds should not stand longer than three years, for by that time the roots will be matted so closely, as to rot and decay each other, if permitted to stand longer. There are some people who are very fond of Mint fallad in winter and spring; in order to obtain which, they take up the roots before *Christmas*, and plant them upon a moderate hot-bed close together, covering them with fine earth about an inch thick, and cover the bed either with mats or frames of glass. In these beds the Mint will come up in a month's time, and be soon fit to cut for that purpose.

When the herb is cut for medicinal use, it should be done in a very dry season, just when it is in flower; for if it stand longer, it will not be near so handsome, nor so well

well tasted; and if it be cut when it is wet, it will change black and be little worth; this should be hung up to dry in a shady place, where it may remain until it be used.

MENTHA CATARIA. See Nepeta.

MENTZELIA. Plum. Nov. Gen. Plant. 40. tab. 6.

The Characters are,

The flower hath five petals a little longer than the empalement, and many erect bristly stamina. From the long cylindrical germen, which is situated under the flower, arises a bristly style. The germen afterward turns to a cylindrical long capsule with one cell, containing many small seeds.

We know but one Species of this genus, viz.

MENTZELIA. Hort. Cliff. 492. Plumier titles it *Mentzelia foliis & fructibus asperis*. Nov. Gen. Plant. 41. Mentzelia with prickly leaves and fruit.

This plant grows plentifully at *La Vera Cruz*.

The plant is annual, it rises with a slender, smooth, stiff stalk, a little woody, more than three feet high, branching out alternately at distances; the branches are distorted, and run into one another; these are garnished with leaves shaped like the point of a halbert, standing alternately upon short foot-stalks, covered with short hooked prickles, which fasten themselves into the clothes of those who rub against them. The flowers come out singly from the joints of the stalk, resting upon a cylindrical germen, which is near an inch in length, narrow at the base, but widens upward. Upon the top of it comes out the empalement, after the same manner as those of the *Onagra*; the flowers are of a pale yellow colour. In the middle arises a great number of stamina which are erect, terminated by single summits; from the germen arises a single style, crowned by a single stigma. The germen afterward turns to a long cylindrical capsule, armed with prickles as the leaves, which also fasten themselves to the clothes of those who rub against them; these have but one cell, which is filled with small seeds.

As this is an annual plant, which perishes soon after the seeds are ripe, so the seeds must be sown on a hot-bed early in the season, that the plants may be brought forward early in the spring, otherwise they will not produce ripe seed in this country. When the plants are come up about an inch high, they should be each transplanted into a separate pot, and plunged into a hot-bed of tanners bark, being careful to shade them from the sun until they have taken new root; then they must be treated in the same manner as other tender annual plants.

MENYANTHES, is the *Trifolium Palustre*, or Bog Bean.

This plant is common upon boggy places in divers parts of *England*; but as it is never cultivated in gardens, so I shall not trouble the reader with any further account of it.

MERCURIALIS. Tourn. Inst. R. H. 534. tab. 308.

The Characters are,

It is male and female in different plants; the male flowers have a spreading empalement, cut into three concave segments, but have no petals; they have nine or twelve erect hairy stamina. The female flowers have no petals, but have two awl-shaped, acute-pointed nectariums; to each of these there is a single broad germen, which afterward turns to a twin capsule shaped like a *scrotum*, having two cells, each containing one roundish seed.

The Species are,

1. MERCURIALIS caule brachiato, foliis glabris. Hort. Cliff. 461. Mercury with spiked and testiculated flowers, which are male and female.

2. MERCURIALIS caule simplicissimo, foliis scabris. Hort. Cliff. 461. Mountain Mercury, or Dog's Mercury, with spiked and testiculated flowers.

3. MERCURIALIS caule subfruticoso, foliis tomentosis. Hort. Cliff. 461. Shrubby hoary Mercury, having spiked and testiculated flowers.

The first sort is commonly called *French Mercury*, from whence it might have been brought into *England*; for although it is now become a weed in gardens and upon dung-hills, yet it is seldom found growing at a distance from habitations. This is an annual plant, with a branching stalk about a foot high, garnished with spear-shaped leaves, of a pale or yellowish green colour. The male plants have spikes of herbaceous flowers, growing on the top of the stalk; these fall off soon; but the female plants, which have testiculated flowers proceeding from the side of the stalks, are succeeded by seeds, which, if permitted to scatter, will produce plenty of plants of both sexes.

The second sort grows under hedges and in woods in most parts of *England*. This hath a perennial root, which creeps in the ground; the stalks are single and without branches, rising ten or twelve inches high, garnished with rough leaves, placed by pairs at each joint, of a dark green colour, indented on their edges; these have their male flowers growing in spikes upon different plants, from those which produce seeds.

The third sort grows naturally in the south of *France*, in *Spain*, and *Italy*. This rises with a shrubby branching stalk a foot and a half high, garnished with oval leaves placed by pairs, which are covered with a white down on both sides. The male flowers grow in short spikes from the side of the stalks, upon different plants from the fruit, which are testiculated and hoary. If the seeds of these are permitted to scatter, the plants will come up the following spring; and if the seeds are sown, it should be performed in the autumn, for those which are sown in the spring never grow the same year. This plant should have a warm situation and a dry rubbishy soil, in which it will live three or four years, but in hard frost these plants are frequently killed.

MESEMBRYANTHEMUM. Dill. Gen. 9. Hort. Elth. 179. Ficoides, or Fig Marygold.

The Characters are,

The flower hath one petal, which is cut into many linear segments almost to the bottom, and ranged in several series, but are joined together at their base; within these are ranged a great number of hairy stamina. Under the flower is situated an obtuse five-cornered germen, supporting sometimes five, and often ten or more styles. The germen afterward becomes a roundish fleshy fruit, having as many cells as there are styles, filled with small seeds.

The Species are,

1. MESEMBRYANTHEMUM foliis alternis teretiusculis obtusis ciliatis. Hort. Upsal. 129. Fig Marygold of *Naples* with a white flower, or *Egyptian Kali*.

2. MESEMBRYANTHEMUM foliis alternis ovatis obtusis undulatis. Hort. Cliff. 216. African Fig Marygold, with a waved Plantain leaf, marked with silvery spots; commonly called the *Diamond Ficoides*, or *Diamond Plant*.

3. MESEMBRYANTHEMUM foliis semiteretibus, floribus sessilibus axillaribus. Lin. Sp. Plant. 481. Fig Marygold of the *Cape*, with a taper leaf and a whitish flower.

4. MESEMBRYANTHEMUM foliis semicylindraccis, floribus quadrifidis. Lin. Sp. Plant. 481. Upright, ligneous, Fig Marygold of *Africa*, with a radiated flower, which is at first purple, afterward silvery, shut in the day, and opens at night.

5. MESEMBRYANTHEMUM foliis semiteretibus falcatis, caule arborecente. African Tree Fig Marygold, with a taper leaf, and a white flower opening at night, but shut in the day.

6. MESEMBRYANTHEMUM foliis subtrigonis, subulatis, caule erecto, corymbo trichotoma. Lin. Sp. Plant. 481. Upright African Fig Marygold, with a taper leaf, and white flowers growing in umbels.

7. MESEMBRYANTHEMUM *acaule, foliis subteretibus connatis, floribus octagynis. Lin. Sp. Plant. 481.* Low Fig Marygold of the Cape, with an Onion leaf, and a staminate flower.

8. MESEMBRYANTHEMUM *foliis lanceolatis planis crenulatis. Hort. Cliff. 217.* Trailing, African, Fig Marygold, with a Tripolium leaf and a silvery flower.

9. MESEMBRYANTHEMUM *acaule, foliis triquetris linearibus apice trifariam dentatis. Hort. Cliff. 218.* Dwarf Fig Marygold of the Cape, with a triangular leaf indented at the top, and a smaller purplish flower.

10. MESEMBRYANTHEMUM *acaule, foliis subulatis triquetris dorso supernè serratis.* Dwarf Mesembryanthemum, with awl-shaped three-cornered leaves, whose back part is sawed toward the top.

11. MESEMBRYANTHEMUM *caulescens, foliis deltoidibus triquetris dentatis. Hort. Cliff. 218.* African Fig Marygold, with a short, thick, gray, triangular leaf, with prickles on the three edges.

12. MESEMBRYANTHEMUM *caulescens, foliis deltoidibus, lateribus minimè dentatis.* African Fig Marygold, with very thick, short, triangular, gray leaves, having small indentures on their edges.

13. MESEMBRYANTHEMUM *acaule, foliis apice barbatis.* African Fig Marygold with a rough spotted leaf, whose point is armed with spines in form of a star.

14. MESEMBRYANTHEMUM *caulibus subfruticosis decumbentibus, foliis teretibus apice barbatis.* Shrubby Fig Marygold of the Cape, with a star-pointed tumid leaf, and a purple flower.

15. MESEMBRYANTHEMUM *caule hispido, foliis cylindricis deflexis. Lin. Sp. Plant. 482.* African, shrubby, Fig Marygold, having stalks adorned with silvery down, and long, small, taper leaves, spotted as it were with silvery drops, and a Violet-coloured flower.

16. MESEMBRYANTHEMUM *caule foliisque pubescentibus. Hort. Cliff. 217.* Mesembryanthemum, whose stalks and leaves are garnished with downy hairs.

17. MESEMBRYANTHEMUM *foliis subulatis subtus undique scabris. Hort. Cliff. 219.* African Fig Marygold, with a long, green, rough, triangular leaf, and a Violet-coloured flower.

18. MESEMBRYANTHEMUM *articulis caulinis terminatis in folia acuminata subtus dentata. Hort. Cliff. 218.* African Fig Marygold, with a short, perfoliated, triangular leaf, whose point is prickly; commonly called Buckhorn Ficoides.

19. MESEMBRYANTHEMUM *perfoliatum, foliis majoribus, apicibus triacanthis. Hort. Elth. 251.* Shrubby, perfoliate, African Fig Marygold, with a triangular, gray, spotted leaf, and a thin, white, ligneous bark; commonly called Stag-horn Ficoides.

20. MESEMBRYANTHEMUM *spinis ramosis. Hort. Cliff. 216.* African Fig Marygold with long spines, and smaller leaves arising from the wings of the large leaves.

21. MESEMBRYANTHEMUM *foliis subulatis papillofis, radice capitata. Hort. Cliff. 216.* African Fig Marygold, with a triangular recurved leaf, and umbellated flowers of a dark colour, which are purple on their outside.

22. MESEMBRYANTHEMUM *foliis subulatis semiteretibus glabris, internodio longioribus. Hort. Cliff. 216.* Low Fig Marygold of the Cape, with a taper leaf, and a scarlet flower.

23. MESEMBRYANTHEMUM *foliis subulatis subcylindraceis obsolete papillofis distinctis. Hort. Cliff. 220.* Upright, tree-like, African Fig Marygold, with a jointed stalk, and a green leaf.

24. MESEMBRYANTHEMUM *caule repente semicylindraceo, foliis semicylindricis lævibus connatis, apice triquetris. Hort. Cliff. 217.* Creeping, African, Fig Marygold, with a green triangular leaf, and deep purple-coloured flower.

25. MESEMBRYANTHEMUM *foliis acinaciformibus distinctis lævibus, ramis teretibus. Hort. Cliff. 219.* African Fig Marygold, with a triangular, cimeter-shaped, short leaf, and a pale purplish flower.

26. MESEMBRYANTHEMUM *foliis acinaciformibus connatis lævibus, caule decumbente.* Greater, trailing, African Fig Marygold, with a triangular cimeter-shaped leaf.

27. MESEMBRYANTHEMUM *falcatum majus, flore amplo luteo. Hort. Elth. 283.* Greater, trailing, African Fig Marygold, with a triangular leaf, and a large eatable fruit.

28. MESEMBRYANTHEMUM *foliis subtriquetris scabris, corollis bicoloribus. Lin. Sp. Plant. 485.* Shrubby Fig Marygold of the Cape, with a taper leaf, having punctures, and flowers with yellow and red petals.

29. MESEMBRYANTHEMUM *foliis subulatis triquetris, angulo carinali retrorsum serratis. Hort. Cliff. 218.* African Fig Marygold with a long triangular leaf, which is incurved, and a purple stalk.

30. MESEMBRYANTHEMUM *foliis subulatis subcylindraceis papillofis distinctis, caule scabro. Hort. Cliff. 220.* Fig Marygold of the Cape, with a silvery taper leaf, and flowers having many Orange-coloured petals.

31. MESEMBRYANTHEMUM *foliis linearibus obsolete triquetris distinctis, summis imbricatis, lævibus. Hort. Cliff. 220.* Shrubby Fig Marygold of the Cape, with taper gray leaves growing in clusters, and a white flower.

32. MESEMBRYANTHEMUM *acaule, foliis semicylindricis connatis externè tuberculatis. Hort. Cliff. 219.* African Fig Marygold, with a long, triangular, succulent leaf, and red stalks.

33. MESEMBRYANTHEMUM *foliis subcylindricis acutis connatis arcuatis lævibus. Hort. Cliff. 220.* African Tree Fig Marygold, with a taper gray leaf, having a thick purple top.

34. MESEMBRYANTHEMUM *foliis subulatis triquetris strictis acutis, punctis pellucidis obsolete sparsis. Hort. Cliff. 220.* African Fig Marygold with an erect ligneous stalk, a triangular, cimeter-shaped, rough leaf, and a large yellow flower.

35. MESEMBRYANTHEMUM *caulescens, foliis subulatis semicylindricis recurvis connatis longis. Hort. Cliff. 219.* African Fig Marygold with a long triangular leaf, having obtuse borders, and a large flower of a pale yellow within, and marked with a long red streak on the outside.

36. MESEMBRYANTHEMUM *caulibus procumbentibus, foliis subtriquetris angulis obtusioribus recurvis connatis, pedunculis brevioribus.* Trailing, African, Fig Marygold, with a longer, gray, triangular leaf, and a yellowish flower.

37. MESEMBRYANTHEMUM *foliis planis oppositis ovatis acuminatis connatis integerrimis.* Trailing, African, Fig Marygold, with plain leaves set by pairs, which are lucid, surround the stalk with their base, and a large, whitish, yellow flower.

38. MESEMBRYANTHEMUM *foliis planis congestis externè punctatis acuminatis integerrimis.* Trailing Fig Marygold of the Cape, with an Olive leaf, and a white flower of a Saffron colour in the middle.

39. MESEMBRYANTHEMUM *subacaule, foliis ciliato-dentatis. Lin. Hort. Cliff. 218.* Low Fig Marygold of the Cape, with a triangular leaf indented toward the top, and a yellow flower; commonly called Dogs Chap Ficoides.

40. MESEMBRYANTHEMUM *acaule, foliis crassis triquetris, margines laterales ciliato dentatis, pedunculis brevibus.* African Fig Marygold with a triangular, cimeter-shaped, short, thick leaf, whose borders have many large spines; commonly called Cats Chap Ficoides.

41. MESEMBRYANTHEMUM *foliis dolabriformibus. Hort. Cliff. 219.* Low Fig Marygold of the Cape, with leaves like a stag's horn, and a yellow flower opening at night.

42. MESEMBRYANTHEMUM *foliis difformibus*. *Prod. Leyd.*
287. African Fig Marygold with very broad, thick, shining, deformed leaves.

43. MESEMBRYANTHEMUM *acaule, foliis linguiformibus altero margine crassioribus*. *Hort. Cliff.* 219. African Fig Marygold without stalk, broad, thick, shining leaves growing by pairs, and a very large yellow flower.

44. MESEMBRYANTHEMUM *acaule, foliis linguiformibus latissimis, pedunculis brevioribus*. African Fig Marygold having no stalk, very broad, thick, shining leaves placed by pairs, and a large golden flower with a short foot-stalk.

45. MESEMBRYANTHEMUM *subacaule foliis subtriquetris glaucis integerrimis obtusioribus*. African Fig Marygold with a thick, triangular, succulent leaf.

46. MESEMBRYANTHEMUM *foliis alternis subulatis triquetris longissimis*. *Hort. Cliff.* 216. Fig Marygold of the Cape, with a Clove Gilliflower leaf, and a beautiful gold-coloured flower.

47. MESEMBRYANTHEMUM *foliis subulatis triquetris incurvis, ramis dependentibus*. African Fig Marygold with a long triangular leaf, of a gray colour, whose edges are obtuse.

These plants are most of them natives of the *Cape of Good Hope*, from whence their seeds were first brought to *Holland*, and the plants raised in many of their curious gardens, and have since been communicated to most parts of *Europe*.

Most of the plants of this genus have beautiful flowers, which appear at different seasons of the year; some of them flower early in the spring, others in summer, some in the autumn, and there are others which flower in winter; and many of them produce their flowers in such quantity, as that when they are expanded, the plants are entirely covered with them; they have all of them thick succulent leaves, but some of the species are much more so than others, and the figures of their leaves vary so much in the several species, that they afford an agreeable variety when they are not in flower.

All the sorts here mentioned are perennial plants, except the two first, which are annual. The perennial sorts are easily propagated by cuttings during any of the summer months; such of them as have shrubby stalks and branches, do very readily take root when planted in a bed of light soil, and covered either with mats or glasses, but when they are covered with the latter, they must be shaded every day when the sun is warm; the cuttings of the shrubby sorts, need not be cut from the plants more than four or five days before they are planted; during which time they should be laid in a dry room, not too much exposed to the sun, that the part which was separated from the old plants, may heal over and dry before they are planted, otherwise they are apt to rot. When the cuttings are taken from the old plants, they should be divested of their lower leaves, so far as may be necessary, to allow a naked stalk of sufficient length for planting.

When the cuttings are planted, it will be necessary to give them a little water to settle the ground about them, but it should be done with caution, for too much wet will spoil them; but if there should happen some gentle showers of rain, it will be proper to take off their covers, and let them receive it, but they should be screened from hard rains. The cuttings thus managed will put out good roots in about six weeks, when they should be carefully taken up, and each planted in a separate small pot filled with light sandy earth, and placed in a shady situation, giving them a little water to settle the earth to their roots; in this place they may remain about ten days, or a fortnight, by which time they will have taken good root, and may be removed to a sheltered place, where they may have more sun, in which they may remain till autumn: during the summer

months these may be watered two or three times a week, but it must not be given them in too great plenty; but as the sun declines in autumn, they should not have it so often; for if they are often supplied with it, the plants will grow luxuriant, their leaves and branches will be so replete with moisture, that the early frosts in the autumn will destroy them; whereas when they are kept dry, their growth will be stunted, so that they will be hardy enough to resist small frosts; but there must be care taken that they do not shoot their roots through the holes of the pots into the ground, for when they do the plants will grow very luxuriant; and when the pots are removed, and those roots are torn off, their leaves and branches will shrink, so will not recover it in a long time; to prevent which, the pots should be removed every month in summer, and where the roots are beginning to come through the pots, they should be cut off. The sorts which grow very freely, should be shifted three or four times in the summer, to pare off their roots, and keep them within compass; and these should never be planted in rich earth for the reasons before given, for if the earth is fresh, there will require no dung, or other compost, unless it is strong; in which case sea sand, or lime rubbish, will be a good mixture; the quantity of either must be in proportion to the stiffness of the ground, always being careful to render it so light, as that the wet may easily pass off.

We next proceed to treat of those sorts whose stalks and leaves are very succulent. The cuttings of these should be taken from the plants ten days or a fortnight before they are planted, that they may have time for their wounded part to heal over and dry; the lower leaves of these should also be stripped off, that their naked stalks may be of a sufficient length for planting. As these are mostly plants of humble growth, so if their stalks are divested of their leaves an inch and a half, it will be sufficient. The cuttings of these sorts require to be covered with glasses, to keep off the wet; they must also have less water than the other, but in other particulars will require the same treatment. The roots of these do not spread and extend so much as those of the other, so will not require to be shifted oftener than twice a year; they must also be kept in small pots, to confine their roots; the earth in which they are planted, should be rather light and not rich. During the summer season, they must not have too much wet, and in the winter they must have but little water. If these succulent sorts are placed in an open airy glass-case in winter, where they may have free air admitted to them in plenty in mild weather, and screened from the frost, they will thrive much better than when they are more tenderly treated.

The shrubby kinds may be sheltered in winter under a common frame, where, if they are protected from frost and wet, it is all they require; for the hardier these are treated, the greater quantity of flowers they will produce: some of the sorts are so hardy, as to live abroad when planted close to a good aspected wall, in a poor dry soil; so that where there is room to dispose them against a wall, and the border is raised with lime rubbish to prevent their rooting deep and growing luxuriant, they may be preserved through the winter with very little shelter, and these will flower much better than those under cover.

The first sort grows naturally in *Egypt*, where they cut up the plants, and burn them for pot-ash; and this is esteemed the best sort for making hard soap, and the best sort of glass.

This is an annual plant, which does not perfect seeds in *England*; for when it is placed in the stove, or kept in the hot-bed, their stalks grow long and slender, so are not productive of flowers; and those which are raised in hot beds, and afterward exposed in the open air, will flower pretty freely, but do not perfect their seeds. As this plant will

thrive in *South Carolina* as well as in its native soil, so it might turn to the advantage of that colony, and likewise become beneficial to the publick, if the inhabitants could be prevailed on to cultivate this plant.

The second sort is annual; it is propagated for the oddness of its leaves and stalks, which are closely covered over with pellucid pimples full of moisture, which when the sun shines on the plants, they reflect the light, and appear like small bubbles of ice; from whence some have called it the Ice Plant, and others have named it the Diamond Plant, or Diamond Ficoides.

This sort is propagated by seeds, which must be sown on a hot-bed early in the spring; and when the plants come up, they must be planted on a fresh hot-bed to bring them forward; after they have taken root in the hot-bed, they should have but little wet. When they are grown large enough to transplant again, they should be each planted into a small pot, filled with light fresh earth, and plunged into a hot-bed of tan, observing to shade them in the heat of the day until they have taken new root; then they should have plenty of fresh air admitted to them every day in warm weather, to prevent their drawing weak. In the latter end of *June*, some of the plants may be inured to bear the open air, and afterward they may be turned out of the pots, and planted into a warm border, where they will thrive and spread their branches to a great distance upon the ground; but these plants will not be very productive of flowers, therefore some of them must be continued in the small pots, and may at the same time, when the others are planted out, be removed into the stove or glass-case, placing them upon the shelves, that their roots may not get out from the bottom of the pots, so that they may be confined, which will cause them to flower plentifully, and from these good seeds may every year be obtained.

MESPILUS. *Tourn. Inst. R. H.* 641. *tab.* 410. The Medlar.

The Characters are,

The empalement of the flower is permanent. The flower is composed of five roundish concave petals, which are inserted in the empalement. The number of stamina are different in the several species, from ten to twenty or more; these are also inserted in the empalement. The germen is situated under the flower, and supports an uncertain number of styles from three to five; it afterward becomes a roundish or oval berry, carrying the empalement on its top, and inclosing four or five hard seeds.

The Species are,

1. MESPILUS *inermis, foliis lanceolatis dentatis acuminatis, subtus tomentosis, calycibus acuminatis.* Greater Medlar with a Bay tree leaf, and a smaller less substantial fruit.

2. MESPILUS *inermis, foliis lanceolatis integerrimis subtus tomentosis, calycibus acuminatis.* Hort. Cliff. 189. German Medlar, with a Bay tree leaf which is not sawed.

3. MESPILUS *inermis, foliis quinquefidis, subtus læviter villosis acutis.* Medlar with a cut Smallage leaf; commonly called L'Azarole.

4. MESPILUS *foliis obtusis bitrifidis serratis, ramis aculeatis.* Wild Medlar with a Smallage leaf and prickly branches; or common Hawthorn.

5. MESPILUS *inermis, foliis trilobatis obtusis glabris serratis, pedunculis trifloris.* Medlar with a cut Smallage leaf, and a yellowish white smaller fruit.

6. MESPILUS *spinosa, foliis lanceolato-ovatis crenatis, calycibus fructus obtusis.* Hort. Cliff. 189. Prickly Medlar, with spear-shaped, oval, crenated leaves; called Pyracantha.

7. MESPILUS *spinosa foliis ovatis acutis repando-angulatis serratis venosis.* Largest prickly Medlar of *Virginia*; called Cockspur Hawthorn.

8. MESPILUS *inermis foliis ovatis repando-angulatis serratis glabris.* Medlar without thorns, and oval, sawed, smooth leaves; commonly called Cockspur Haw without thorns.

9. MESPILUS *foliis lanceolato-ovatis crenatis glabris, ramis spinosis.* Medlar with spear-shaped, oval, crenated, smooth leaves and prickly branches; called *Virginia L'Azerole*.

10. MESPILUS *foliis lanceolatis serratis, spinis robustioribus, floribus corymbosis.* Fig. Pl. *tab.* 178. *fol.* 2. Medlar with spear-shaped sawed leaves, very strong spines, and flowers growing in round bunches.

11. MESPILUS *foliis cordato-ovatis acuminatis, acutè serratis, ramis spinosis.* Fig. Plant. *tab.* 179. Medlar with heart-shaped, oval, acute-pointed leaves, which are sharply sawed, and prickly branches.

12. MESPILUS *foliis oblongo-ovatis acuminatis, angulato-serratis glabris, ramis spinosis.* Medlar with oblong, oval, acute-pointed, smooth leaves, which are angularly sawed, and prickly branches; called Maple-leaved Hawthorn.

13. MESPILUS *foliis ovatis angulato-serratis glabris, ramis inermibus.* Medlar with oval smooth leaves which are angularly sawed, and smooth branches.

14. MESPILUS *inermis, foliis ovato-lanceolatis nervosis serratis subtus villosis.* Medlar without thorns, and oval, spear-shaped, veined, sawed leaves, which are hairy on their under side.

15. MESPILUS *foliis ovatis obtusis, supernè serratis, glabris, fructu ovato.* Medlar with oval, obtuse, smooth leaves, which are sawed toward their points, and an oval fruit; commonly called Pear-shaped Haw.

16. MESPILUS *inermis, foliis obverse ovatis, supernè denticulatis utrinque viridibus.* Medlar without spines, and obverse oval leaves, which are slightly indented toward their ends, and green on both sides.

17. MESPILUS *foliis lanceolato-ovatis serratis subtus villosis floribus solitariis, calycibus foliaceis, spinis longissimis tenuioribus.* Medlar with spear-shaped oval leaves which are sawed, and hairy on their under side, flowers growing singly with leafy empalements, and very long spines; commonly called Lord Islay's Haw.

18. MESPILUS *inermis, foliis ovalibus serratis, cauliculis hirsutis.* Lin. Sp. Plant. 478. Medlar without thorns, having oval sawed leaves, and hairy stalks; commonly called Ame-lanchier.

19. MESPILUS *foliis ovato-oblongis glabris serratis, caule inermi.* Lin. Sp. Plant. 478. Medlar with oval, oblong, smooth, sawed leaves, and branches without thorns.

20. MESPILUS *foliis ovatis integerrimis.* Hort. Cliff. 189. Medlar with oval entire leaves; commonly called Dwarf Quince.

21. MESPILUS *inermis, foliis ovalibus serratis glabris, floribus capitatis, bracteis deciduis linearibus.* Lin. Sp. Plant. 479. Medlar without thorns, having smooth, oval, sawed leaves, headed flowers, and linear bractæ which fall off.

22. MESPILUS *foliis ovatis crassis integerrimis, subtus tomentosis, floribus umbellatis axillaribus.* Medlar with oval, thick, entire leaves, which are woolly on their under side, and flowers growing in umbels from the wings of the stalk; or Dwarf Cherry of mount *Ida*.

The first sort grows naturally in *Sicily*, where it becomes a large tree. It rises with a straiter stem, and the branches grow more upright than those of the *Dutch Medlar*; the leaves are narrower and not sawn on their edges; the flowers are smaller than those of the *Dutch Medlar*; and the fruit is shaped like a Pear.

The second is generally called the *Dutch Medlar*; this never rises with an upright stalk, but sends out crooked deformed branches at a small height from the ground; the leaves of this are very large, entire, and downy on their under

under side. The flowers are very large, as are also the fruit, which are rounder, and approach nearer to the shape of an Apple. This being the largest fruit, is now generally cultivated in the gardens; but there is one with smaller fruit, which is called the *Nottingham Medlar*, of a much quicker and more poignant taste than this, which is supposed to be only a variety, so I have not enumerated it.

The third sort grows naturally in *Sicily*, and the islands of the *Archipelago*; of this there are several varieties, which differ in the form and size of their leaves, some being cut into five, others into six or seven lobes, which are sometimes sawed on their edges, and others are entire; some of them have oval large fruit, and others are smaller, rounder, and of different colours; some almost white, others yellow, and some are red. These fruit are cultivated for the table in most parts of *Italy*, where they are eaten in the autumn and winter, as the common Medlars are in *England*.

The fourth sort is the common Hawthorn, which is generally cultivated in *England* for fences to inclose fields, and is one of the best and most durable plants for that purpose, which we have in this country. There are several varieties of this, which differ in the size of their leaves, the manner in which they are cut, and the size and shape of their fruit; but those with the smallest leaves, are the best for close hedges, because their branches grow closer together.

There is also a variety of this with double flowers, which is an ornamental shrub for gardens, for which purpose it is propagated in the nurseries. The *Glastenbury Thorn* is also supposed to be only a variety of the common Hawthorn; but this was certainly brought to *England* from the east, for I have of late years raised many plants from Haws which came from *Aleppo*, and find them all prove to be what is here called *Glastenbury Thorn*; it differs from our common Hawthorn in putting out its leaves very early in the spring, and in flowering twice a year; for in mild seasons it often flowers in *November* and *December*, and again at the usual time with the common sort; but the stories which are told of its budding, blossoming, and fading, on *Christmas* day, are ridiculous, having no foundation.

These varieties are propagated by budding or grafting them on the common sort, especially the double flowering, which cannot be propagated any other way.

The fifth sort has much broader leaves than the common Hawthorn, which are divided into three obtuse lobes which are smooth, slightly sawed on their edges, and of a lucid green on their upper surface. The flowers are larger than those of the common sort, and each foot-stalk sustains three of them; the fruit is the shape and size of the common Haw, but is of a yellowish white colour; this came from *Italy*.

The sixth sort is most commonly known by the title of *Pyracantha*, or ever-green Hawthorn. This does not rise to a tree, for the stalk and branches are too slender and weak to stand without support, so the plants are generally planted against walls or buildings to cover them. It grows naturally in the hedges in the south of *France* and *Italy*. The flowers come from the side of the branches in large umbels, they are smaller than those of the common Hawthorn, and of a dirty white; these are succeeded by roundish umbilicated berries, of a fiery red colour, which ripen in the winter, and being intermixed with the ever-green leaves, make a fine appearance at that season of the year.

This is propagated by the seeds in the same manner as the common Hawthorn, or by laying down of the branches, which, if young, and laid in the autumn, will put out roots fit to remove in one year; but when the old wood is laid down, it seldom puts out roots in less than two or three years, if they ever do.

The seventh sort grows naturally in *North America*; this is called *Cockspur Hawthorn*, from the shape of its thorns, which are very strong, and bent downward like a cockspur. This hath a strong stem, which rises ten or twelve feet high, dividing into several branches, garnished with oval leaves, sawed on their edges, cut into acute angles, and of a light green on their upper side, but pale on their under. The flowers come out in large umbels, from the side, and at the extremity of the branches; they are much larger than those of the common Hawthorn, and have ten stamina in each, in the center there are five styles crowned by reflexed stigmas. The fruit are nearly as large as the common black Cherry, of a fine red colour when ripe, so make a good appearance at that season, as their flowers also do at the time when they appear. The fruit is good food for the deer, so it deserves to be propagated.

The eighth sort is very like the seventh, but the branches have no thorns on them; the leaves are a little deeper sawed on their edges, and not so deeply veined; this is a native of the same country, and grows to as large a size as the seventh.

The ninth sort is a native of *North America*, where it grows to be a tree of middling size. The young branches have a dark brown bark, and a few pretty strong thorns, which are thinly placed. The leaves are spear-shaped, of a lucid green, and indented on their edges. The flowers are as large as those of the former sorts, but the umbels are less; they have at least twenty stamina, terminated by small red summits, and but three styles, crowned by indented stigmas; the fruit of this is as large as that of the *Cockspur Hawthorn*, but a little oval-shaped, of a red colour, and ripens a little later in the year.

The tenth sort is also a native of *America*; it is of humbler growth than either of the three former; the branches have a dark brown smooth bark, and are armed with longer and stronger thorns than any of the other species. The branches shoot horizontally, and bend downward, so are often interwoven one in another; these are garnished with spear-shaped smooth leaves, sawed on their edges, of a lucid green. From the side of the branches come out flowers in roundish bunches; these have ten stamina in each flower; between these are situated three styles, crowned by obtuse stigmas; the fruit is large, roundish, and of a deep red colour when ripe. As this sort is armed with strong thorns, and the branches naturally intermix with each other, it will make one of the strongest fences, if properly managed, that can be planted.

The eleventh sort was raised in the *Chelsea* garden from seeds, which came from *North America*. This hath a strong stem about five feet high, covered with a rough bark, dividing into many spreading branches, which are armed with long slender thorns, and garnished with oval leaves, differing in their form, some being indented at their foot-stalks in form of a heart, and others are entire at that part; some of them end in very acute points, and others are obtuse; they are sharply sawed on their edges, of a light yellowish green on their upper side, and pale on their under, standing upon slender foot-stalks. The flowers come out in bunches from the side and at the end of the branches; they are about the size and shape of those of the common sort, having eight stamina in each; they have four styles in each, crowned by obtuse stigma; the fruit is of the same size, shape, and colour, as the common Hawthorn.

The twelfth sort was brought from *Virginia*, where it grows naturally. This rises to a tree of middling size, the branches are armed with a few slender thorns, and are garnished with oblong, oval, angular leaves, of a lucid green on their upper side, but pale on their under; some of the leaves are cut so deep on their sides, as almost to divide

them into lobes, but others are more entire. The flowers are produced in large umbels at the end of the branches, they are larger than those of the common Hawthorn, and have twenty stamina, and three short styles in each. The fruit are rather smaller than those of the common sort, and are of a very bright red colour, so make a fine appearance in the autumn, as the flowers do in summer; this sort is one of the latest in blossoming. The gardeners call it the Maple-leaved Haw.

The thirteenth sort grows naturally in *North America*; this rises to a middling height, with a pretty strong stem, dividing into many spreading branches, which have no thorns, but are garnished with oval leaves which are sharply sawed on their edges, and cut into many acute angles, of a light yellowish green, and smooth. The flowers come out at the end of the branches in close umbels, they are larger than those of the common sort, and have ten stamina and three styles in each. The fruit is larger than that of the common Hawthorn, and of the same colour.

The fourteenth sort was raised from seeds, which were brought from *North America*; this hath a strong upright stem, sending out many strong branches without thorns, which are garnished with oval spear-shaped leaves, sawed on their edges. The leaves run along the short foot-stalk to the bottom, like wings; they are of a dark green on their upper side, but pale and hairy on their under. The flowers come out in large umbels at the extremity of the branches; they have a great number of stamina in each, which are terminated by round red summits, and three styles crowned by obtuse stigmas. This sort flowers late in the summer, about the same time with the eleventh.

The fifteenth sort grows naturally in *North America*; this is a tree of middling growth. The branches are covered with a dark brown bark, and have no thorns, but are garnished with oval obtuse leaves, some of which are broad at the ends, others come more to a point; their upper parts are regularly sawed, and most of them draw to a point at the foot-stalk; they are of a yellowish green on both sides, and smooth. The flowers are produced in small bunches at the end of the branches, their empalements are cut into acute segments. The flowers are larger than those of the common sort, and have ten stamina in each, and five styles. The fruit is pretty large, almost shaped like an egg, and of an herbaceous yellow colour when ripe; it is by the gardeners called the Pear-shaped Haw.

The sixteenth sort is a native of *North America*; this is a tree of humble growth, seldom rising higher than the common Hawthorn. The branches are without spines, covered with a gray bark, and garnished with obverse oval leaves, which are rounded and sawed, some of the leaves being pointed, and others obtuse; they are of a bright green on both sides. The flowers are produced in large umbels at the end of the branches, and are about the size of those of the common sort; these have about twenty stamina, and five styles. The fruit is like that of the common Hawthorn.

The seventeenth sort was raised by his Grace the late Duke of *Argyle*, in his curious garden at *Whitton*, and is generally known by the title of Lord *Islay's* Hawthorn. The seeds of it were sent from *Virginia*, by Mr. *Banister*, and some of the plants were raised in the Bishop of *London's* garden at *Fulham* many years ago, which were afterward destroyed, with many other curious shrubs and trees: this is of humble growth, seldom rising more than six or seven feet high, sending out a great number of slender branches, armed with very long, slender, sharp thorns. The leaves are small, and sawed on their edges, with very short foot-stalks. The flowers are produced at the end of the branches, generally one coming out from between the leaves, but sometimes there are two or three, one below the other, at

the wings of the stalks; they have large leafy empalements, much longer than the petal. The flowers are small, sitting in the empalement; they have twelve or more stamina, and four styles in each. The fruit is smaller than that of the common Hawthorn, crowned by the leafy empalement, and is of an herbaceous yellow colour when ripe.

The eighteenth sort grows naturally in *Austria*, *Italy* and *France*, particularly near *Fontainebleau*; this rises with many slender stalks about three feet high, which put out small side branches, covered with a dark purple bark without thorns, which are closely garnished with oval leaves, slightly sawed on their edges; the small side branches which sustain the flowers, are very hairy and woolly, as are also the foot-stalks, and the under side of the leaves, but their upper sides are smooth and green. The flowers come out in bunches at the end of the shoots, which have five long narrow petals, and about ten stamina in each. These are succeeded by small fruit, which, when ripe, are black; the gardeners call this *New England Quince*; there is one of this kind which grows naturally in *North America*, but the leaves of that are wedge-shaped, and not sawed on the edges, so I take it to be a different species.

The nineteenth sort grows naturally in *Canada*; this is also a low shrub, seldom rising more than five feet high, dividing into several smooth branches, covered with a purplish bark. The leaves grow upon long slender foot-stalks; they are smooth on both sides, and a little sawed on their edges. The flowers come out in small bunches at the end of the branches; they are about the size of those of the common Hawthorn, and are succeeded by small fruit of a purplish colour when ripe.

The twentieth sort grows naturally on the *Pyrenean* mountains, and in other cold parts of *Europe*; this rises with a smooth shrubby stalk about four feet high, dividing into a few small branches, covered with a purple bark, garnished with oval intire leaves, with very short foot-stalks. The flowers come out from the side of the stalks, two or three together; they are small, of a purplish colour, and sit close to the stalks; these appear in *May*, and are succeeded by small roundish fruit, which are of a bright red colour when ripe.

The twenty-first sort grows naturally in the northern parts of *Europe*; this hath a smooth stalk, rising about four or five feet high, sending out slender branches, which are covered with a purplish bark, garnished with oval smooth leaves, sawed on their edges, with the teeth pointing upward; they have pretty long slender foot-stalks, and are of a yellowish green on both sides. The flowers come out from the wings of the stalk, four or five joined together in a close head, of a purplish colour; between the flowers come out long narrow bractea, which are purplish, and fall off as the flowers begin to decay. The fruit is small, and red when ripe.

The twenty-second sort grows naturally upon mount *Ida*, in *Crete*, where the poor shepherds feed upon the fruit when ripe; this hath a smooth stalk, covered with a brown bark, and rises eight or ten feet high, dividing into many smooth branches, which are garnished with oval leaves, two inches and a half long, and near two inches broad; of a thick substance, and a dark green on their upper side, but downy on their under, standing up short foot-stalks. The flowers come out from the side of the stalk; they are of a purple colour, the petals being but little longer than the empalement, which is woolly, and cut into five obtuse segments. The fruit is large, roundish, and of a fine red colour when ripe.

All these sorts are hardy enough to thrive in the open air in *England*, and several of them are very ornamental plants for gardens; and all the larger growing kinds are as proper for parks, where, during the season of their flowering, they will make a fine appearance; and again in autumn, when their

their fruit are ripe, they will afford an agreeable variety, and their fruit will be food for the deer and birds, so that if clumps of each sort are planted in different parts of the park, nothing can be more ornamental.

All the *American* kinds are usually propagated in the nurseries, by grafting or budding them upon the common White Thorn, but the plants so propagated will never grow to half the size of those which are propagated by seeds, so that where they are designed for parks and large plantations, those plants should always be chosen which have not been grafted or budded, but are upon their own roots, for several of the *American* sorts naturally grow twenty feet high, if they are not stunted by grafting; so that those sorts when grafted are only fit to intermix with shrubs for gardens, where they are not designed to grow large.

But there are many who object to this method of raising the plants from seeds, on account of their seeds not growing the first year, as also from the tediousness of the plants growth after; but where a person can furnish himself with the fruit in autumn, and take out their seeds soon after they are ripe, putting them into the ground immediately, the plants will come up the following spring; and if they are kept clean from weeds, and in very dry weather supplied with water, they will make great progress; but if these are planted in the places where they are to remain, after two years growth from seeds, they will succeed much better, than when the plants are of a greater age; but if they are planted in clumps in parks, the ground should be well trenched, and cleansed from the roots of all bad weeds; the places must also be securely fenced, otherwise the cattle will soon destroy them. The best time to transplant them is in autumn, when their leaves fall off; these should be constantly kept clean from weeds, and if the ground between the plants is dug every winter for the first seven years, it will encourage their growth, and by that time the plants will have made such progress, as to be strong enough to encounter and keep down the weeds, so that if they are cut twice in the summer, it will be sufficient; but the inclosure must not be taken away, till the stems are so large, and their bark so rough, as that the cattle will not eat it; their stems should also be trained up so high, as that their branches may be out of the reach of cattle, otherwise they will crop them, especially those which have no thorns.

If when these clumps are planted, the ground be inclosed with an Oak pale, in the same manner as that round parks, the fence will last as long as the trees will require any protection; but these pales should not be quite close, for if they are placed so near each other at bottom as to keep out hares, it will be sufficient; and upward, if they are not so close, there will be more air admitted to the plants, which will be of service to them, so that such pales may be chosen for these purposes, which are broader at one end than the other, and the broadest ends turned downward. The plants in these clumps need not be planted at a greater distance from each other than six feet, for by being so near together, they will draw one another up taller, than where they have more room to spread.

The sort with double flowers, can be no other way propagated than by grafting, or budding it upon the other sorts, so that where this sort is desired to grow large, it should be grafted or budded upon stocks of the Cockspur, or other large growing kind, upon which this will grow to a much larger size than upon the common White Thorn; or if they are budded upon the *Aria Theophrasti*, which grows to a large size, they will also be much improved.

All the sorts of *Mespilus* and *Cratægus* will take by budding or grafting upon each other; they will also take upon the Quince, or Pear stocks, and both these will take upon

the Medlars, so that these have great affinity with each other, and might be with more propriety brought together under the same genus, than the Pear and Apple, which will not take upon each other; but although the Pear will take upon the White Thorn, yet it is not advisable to make use of these stocks, because they generally cause the fruit to be small, and often to crack, and renders their flesh stony, so unless it is the very soft melting kinds of Pears which are upon these stocks, the fruit will not be good.

The common Hawthorn is usually propagated for fences; the best plants for this purpose, are those which are raised from seeds, and the younger these are planted, the better they will succeed; and where people have patience to raise their hedges from seeds in the places where they are to remain, the plants will be stronger, and of longer duration, than those which are transplanted; but there are few who have patience to practise this method. When the seeds of this sort are sown, it is the usual way to bury the Haws in the ground one year, and then take them up and sow them, because when the Haws are sown without being thus prepared, they do not grow the first year; but where persons are in haste to raise the plants, if they get the Haws as soon as they are ripe, and put them into a tub, or pot, and bury them in a heap of hot dung for a month or six weeks, in which time they will ferment, and the skin and pulp will rot; then take them out, and macerate them in water, to separate the seeds, and sow them immediately after, the plants will come up the first year, as I have experienced, and hereby a year will be saved. The after management of these plants, with the method of transplanting them, and training them up, having been already fully treated of under the article of HEDGES, I shall not repeat it here.

The five last mentioned sorts being plants of humble growth, are only proper for gardens, so are generally intermixed with other flowering shrubs to add to the variety; these are frequently propagated in the nurseries, by budding or grafting them upon the stocks of the White Thorn; but as the buds or grafts of these sorts do not keep pace in their growth with the stocks, so after a few years they will appear very unsightly, and many times they are blown out of the stocks, when the heads are grown so large as to stop the wind in its course, and thereby the plants are destroyed; so that these sorts should always be propagated by seeds, or by laying down of the young branches, which will take root in one year, when they are carefully laid, and sometimes the cuttings of these will take root, if they are planted in autumn, in a loamy soil; and these plants upon their own roots, will always thrive better, and continue longer, than those which are upon other stocks. The method of propagating these by seeds being the same as for the other species, it need not be repeated.

METHONICA. See *Gloriosa*.

MEUM. See *Athamanta*.

MEZEREON. See *Thymelæa*.

MICROPUS. *Lin. Gen. Plant.* 892. Bastard Cudweed.

The Characters are,

It hath hermaphrodite and female flowers, which are included in the same naked empalement. The female flowers are hid under the scales of the interior empalement, which have each a single oval seed succeeding them, included in the small leaves of the empalement, but have no down about them.

We have but one Species of this genus, viz.

MICROPUS. *Hort. Upsal.* 275. *Prod. Leyd.* 145. Portugal Bastard Cudweed.

This is an annual plant, which grows naturally in Portugal, near the sea. The root sends out several trailing stalks, about six or eight inches long, which are garnished with

with small, oval, silvery leaves, whose base embrace the stalks. The flowers come out from the wings of the stalks in small clusters; they are very small, white, and sit in a double empalement, the interior being so large, as to almost hide the flowers. It flowers in *June* and *July*, and the seeds ripen in autumn; this is frequently preserved in gardens, for the beauty of its silvery leaves; if the seeds are sown in autumn, or are permitted to scatter, the plants will come up in the spring, and will require no other care but to keep them clean from weeds, and thin them where they are too close. When the seeds of this plant are sown in the spring, they seldom grow the first year.

MILIUM. *Tourn. Inst. R. H. 514. tab. 298. Lin. Gen. Plant. 73.* Millet.

The Characters are,

It is of the *Corn; or Grass* tribe, with one flower in each chaff. The petal of the flower is bivalve, and smaller than the empalement. It hath three very short hairy stamina, and a roundish germen with two hairy styles. The germen afterward turns to a roundish seed, covered by the petal of the flower.

The Species are,

1. MILIUM paniculâ laxâ flaccidâ, foliorum vaginis pubescentibus. Millet with a loose hanging panicle, and the sheaths of the leaves hairy; Millet with a yellow seed.

2. MILIUM paniculâ sparsâ erectâ, glumis aristatis. Millet with a loose erect panicle, and bearded chaff.

The first sort grows naturally in *India*, but is now cultivated in many parts of *Europe*, as an esculent grain; this rises with a Reed-like stalk, three or four feet high, channelled; at every joint there is one Reed-like leaf, which is joined on the top of the sheath, which embraces and covers that joint of the stalk below the leaf; this sheath is closely covered with soft hairs, but the leaf which is expanded has none. The top of the stalk is terminated by a large loose panicle, which hangs on one side, having a chaffy flower, which is succeeded by a small round seed, which is often made into puddings, &c. There are two varieties of this, one with white, and the other hath black seeds, but do not differ in any other particular.

The second sort was discovered growing naturally at *La Vera Cruz*; this has a slender stalk than the former, which rises about three feet high. The sheaths which surround it have no hairs, but are channelled. The leaves are shorter than those of the former. The panicle stands erect, and the chaff has shorter awns, or beards.

The common Millet was originally brought from the eastern countries, where it is still greatly cultivated, from whence we are furnished annually with this grain, which is by many persons greatly esteemed for puddings, &c. This is seldom cultivated in *England*, but by way of curiosity in small gardens, or for feeding of poultry, where the seeds generally ripen very well.

They must be sown the beginning of *April*, upon a warm dry soil, but not too thick, because these plants divide into several branches, and should have much room; and when they come up, they should be cleared from weeds, after which they will, in a short time, get the better of them, and prevent their future growth. In *August* these seeds will ripen, when it must be cut down and beaten out, as is practised for other grain; but when it begins to ripen, if it be not protected from birds, they will soon devour it.

MILLEFOLIUM. See Achillea.

MILLERIA. *Houss. Gen. Nov. Martyn. Cent. 4. Lin. Gen. Plant. 881.*

The Characters are,

This hath a compound flower, included in a naked empalement, cut into three parts, and is permanent. It hath a large three-cornered germen, without down. The germen afterward turns to an oblong, three-cornered, obtuse seed, inclosed in the empalement.

The Species are,

1. MILLERIA foliis cordatis, pedunculis dichotomis. *Hort. Cliff. 426.* Milleria with heart-shaped leaves, and foot-stalks arising from the division of the stalks.

2. MILLERIA foliis infimis cordato-ovatis acutis rugosis, caulibus lanceolato-ovatis, acuminatis. Milleria whose lower leaves are oval, heart-shaped, acute-pointed, and rough, and the upper ones oval, spear-shaped, and pointed.

3. MILLERIA foliis ovatis, pedunculis simplicissimis. *Hort. Cliff. 425.* Milleria with oval leaves, and single foot-stalks.

4. MILLERIA foliis ovato-lanceolatis acuminatis trinerviis, pedunculis alaribus. Milleria with oval, spear-shaped, acute-pointed leaves, having three veins, and foot-stalks proceeding from the wings of the leaves.

5. MILLERIA foliis lanceolatis rugosis, floribus confertis axillaribus. Milleria with rough spear-shaped leaves, and flowers growing in clusters from the wings of the stalks.

The first sort was discovered by the late *Dr. William Houstoun*, at *Campeachy*, in the year 1731, who sent the seeds to *Europe*; and as the characters which distinguish this genus, are different from all the other genera of the class to which it belongs, so he constituted a new genus with this title.

This rises with an herbaceous branching stalk, from three to four or five feet high, garnished with large heart-shaped leaves, slightly sawed on their edges, having two veins on each side the midrib, which join to it near the base, but diverge from it toward the borders of the leaves. The leaves are of a light green, hairy, and stand opposite; their foot-stalks are about an inch long, and have a part of the leaf running on each side, like wings. The stalks divide by pairs upward, and the foot-stalks of the flowers come out at the divisions; these branch again by pairs, and terminate in loose spikes of yellow flowers, composed of four or five hermaphrodite florets, which are barren, and one female half floret, which is succeeded by a single, oblong, angular seed, wrapped in the empalement of the flower. It flowers in *July* and *August*, and the seeds ripen in autumn.

The second sort was discovered by *Mr. Robert Millar*, at *Campeachy*, in the year 1734; this approaches near to the first sort, but the stalks rise six or seven feet high, and branch out very wide. The leaves are seven inches long, and four inches and a half broad toward their base, ending in long acute points; they are deeper sawed on their edges, and have several large black spots scattered over them; their surface is rougher, and they are of a darker green than those of the first. The upper leaves are long, and spear-shaped; the foot-stalks of the flowers branch out wider, and the spikes of flowers are shorter than those of the first.

The third sort was discovered at *Campeachy*, by the late *Dr. Houstoun*; this is an annual plant, which rises with an herbaceous stalk about two feet high, branching out at a small distance from the root, into three or four slender stalks, which are naked almost to the top, where they have two oval spear-shaped leaves, placed opposite, which are about two inches long, and three quarters of an inch broad near their base, ending in points; they are hairy, and stand upon naked foot-stalks, having three longitudinal veins, and are slightly indented on their edges. The flowers come out at the foot stalks of the leaves, in small clusters; the common empalement is composed of three orbicular leaves, which are compressed together; in each of these are situated two or three hermaphrodite florets, which are barren, and one female half floret, which is fruitful, being succeeded by a roundish angular seed, inclosed in the empalement. This flowers and perfects seeds about the same time with the former.

The fourth sort was discovered by the late Mr. Robert Millar at *Campeachy*. This is an annual plant, which rises with an upright stalk three or four feet high, garnished the whole length with oval spear-shaped leaves near four inches long, and almost two broad near their base; they have three longitudinal veins, and toward the top there are two more which diverge from the midrib, but join again at the point. The upper side of the leaves are of a dark green and smooth, their under are of a pale green, and indented on their edges. The flowers grow from the wings of the leaves in small clusters, standing upon short foot-stalks; these have empalements like the former, but are much smaller, in each of which are situated two hermaphrodite florets which are barren, and one female half floret which is fruitful. This flowers and seeds later in the year than either of the former, so that unless the plants are brought forward in the spring, they will not ripen their seeds in *England*.

The fifth sort was discovered by the late Mr. Robert Millar at *Campeachy*. This rises with a pretty strong channelled stalk near four feet high, divided into branches by pairs; these are garnished with spear-shaped leaves about three inches long and one broad in the middle, ending in acute points; they are rough, and their edges are entire. The flowers come out at every joint the whole length of the branches, in very close clusters, each containing upward of twenty, so that the branches are almost covered with them; they have orbicular compressed empalements, which have borders to them, and are smaller than those of either of the two former. Their leaves are equal, and in each of the empalements are situated two hermaphrodite florets which are barren, and one half floret which is female and fruitful. This is also late in flowering, so that unless the plants are brought forward early in the spring, they will not ripen seeds in *England*.

The seeds of these plants should be sown early in the spring, on a moderate hot-bed; and when the plants are come up about two inches, they should be each transplanted into a separate pot, filled with light rich earth, and then plunged into a moderate hot-bed of tanners bark, being careful to shade them from the sun until they have taken root, as also to water them frequently. After the plants are rooted, they should have a large share of free air admitted to them; they must also be constantly watered every day in hot weather, for they are very thirsty plants. With this management the plants will, in a month after transplanting, rise to a considerable height; therefore they should be shifted into larger pots, and placed in the stove, plunging them into the bark-bed, where they may have room to grow, especially the first and second sorts, which usually grow high and branch out, where they are well managed. But the other sorts seldom rise above three or four feet high, and do not spread their branches very far, so these may be allowed less room.

In the middle of *July* these plants will begin to flower, and the seeds will be ripe about a month after; therefore they must be gathered when they begin to change of a dark brown colour, otherwise they will soon fall off, especially those of the two large kinds, which will drop on the least touch when they are ripe. These plants will continue flowering till *Michaelmas*, or later, if the season proves favourable; but when the cold of the autumn comes on, they will soon decay.

MIMOSA. *Tourn. Inst. R. H. 605. tab. 375. Lin. Gen. Plant. 597.* The Sensitive Plant.

The Characters are,

The empalement of the flower is small, indented in five parts at the top: the flowers are male and hermaphrodite, included in each head; the male flowers have ten, but the other have

seldom more than five. These have long hairy stamina, a short slender style, crowned by a truncated stigma. The germen afterward turns to a jointed pod with several transverse partitions, inclosing compressed roundish seeds.

The Species are,

1. MIMOSA *inermis, foliis bipinnatis, spicis cernuis, floribus decandris, inferioribus castratis apetalis. Flor. Zeyl. 505.* Smooth Sensitive Plant, with double winged leaves, nodding spikes of flowers, having ten stamina, and the lower without either stamina or petals; or the Sensitive Plant of *Jamaica*.

2. MIMOSA *inermis, foliis bipinnatis, spicarum floribus pentandris, inferioribus plenis. Hort. Upsal. 145.* Smooth Sensitive Plant with double winged leaves, the flowers of the spikes with five stamina, and the under ones double.

3. MIMOSA *inermis decumbens, foliis bipinnatis, spicis cernuis, floribus pentandris, inferioribus castratis. Hort. Upsal. 145.* Smooth Sensitive Plant with inclining stalks, double winged leaves, nodding spikes of flowers having five stamina, but the under ones without any; Spurious Sensitive Plant.

4. MIMOSA *aculeata, foliis pinnatis, caule procumbente villoso, siliquis articulatis.* Prickly Sensitive Plant with winged leaves, a hairy trailing stalk, and jointed pods.

5. MIMOSA *foliis subdigitatis pinnatis, caule aculeato hispido. Lin. Sp. Plant. 518.* Sensitive Plant with winged handed leaves, and a prickly hairy stalk.

6. MIMOSA *foliis subdigitatis pinnatis, caule aculeato decumbente, siliquis confertis, involucris hispidis.* Sensitive Plant with winged handed leaves, a prickly declining stalk, and small pods growing in clusters, with prickly coverings.

7. MIMOSA *aculeata, foliis bipinnatis, caule quadrangulo, aculeis recurvis, leguminibus quadrivalvibus. Lin. Sp. Plant. 522.* Prickly Sensitive Plant with double winged leaves, a four-cornered stalk, recurved spines, and pods having four valves.

8. MIMOSA *foliis conjugatis pinnatis, partialibus bijugis, intimis minimis, caule aculeato. Lin. Sp. Plant. 518.* Sensitive Plant with conjugated winged leaves, whose wings have two pair of lobes, the inner of which are the least, and a prickly stalk.

9. MIMOSA *caule fruticoso, foliis bipinnatis, aculeatis, aculeis geminis, siliquis radiatis hirsutis. Fig. Plant. tab. 183. fol. 3.* Sensitive Plant with a shrubby stalk, double winged prickly leaves, whose spines grow in pairs, and hairy radiated pods.

10. MIMOSA *caule inermi herbaceo repente, foliis conjugatis pinnatis, floribus globosis alaribus.* Sensitive Plant with a creeping, herbaceous, unarmed stalk, conjugated winged leaves, and globular flowers proceeding from the wings of the stalks.

The first sort grows naturally in most of the islands in the *West-Indies*; it has also been found growing in some warm moist spots, as far north as *Virginia*. This rises with upright branching stalks six or seven feet high, which become ligneous toward the root, but are not perennial (at least they are not so here in any situation, the plants always decaying in winter;) these are smooth, and garnished with double winged leaves, composed of four or five pair of long winged lobes, which have about twenty pair of small leaves ranged along the midrib; they are smooth, and rounded at their points, of a full green on their upper side, but pale on their under. These small leaves contract themselves together on their being touched, but the foot-stalks do not decline at the same time as those do which are titled Humble Plants; therefore this is called the Sensitive Plant simply, by way of distinction. The flowers are produced upon long foot-stalks, which come out from the wings of the leaves, and are disposed in globular heads which nod downward; they are yellow, and all those which are hermaphrodite have tubulous petals, with ten stamina in each, but

but the female flowers, situated round the border, have neither petals or stamina; the hermaphrodite flowers are succeeded by pods an inch and a half long, and a quarter of an inch broad, which change to a dark brown when ripe, inclosing three or four compressed, shining, black seeds.

The second sort was discovered by the late Dr. *Houftoun* at *La Vera Cruz*, growing in stagnant waters, where the stalks were very broad and flat, and floated on the surface, in the same way as the pond weeds do; but in those places where the water was dried up, the stalks grew upright and were round, which is always the case when the plants are cultivated in gardens, so that they might easily pass for different plants, to those who never saw them growing in both situations. When this sort is cultivated in gardens, it has great resemblance to the first, but the stalks of this never grow so erect, the wings of the leaves are longer, and stand more horizontal; the heads of flowers are much larger, the stamina are longer, and the flowers on the under side of the spike, which have no stamina, are double: the pods of this sort are shorter, and much broader than those of the first sort. This is also an annual plant in this country. It was since discovered by a friend of mine, growing naturally in a marshy spot of land in the island of *Barbuda*, from whence he sent me the seeds, with a large branch of the plant in a glass filled with a lixivium, which preserved it in the state it was gathered, with the flowers and pods upon it.

The third sort grows naturally in all the islands of the *West-Indies*, where it is titled the Slothful Sensitive Plant, because the leaves do not contract on their being touched. The stalks of this sort seldom rise more than two feet and a half high; they are smooth, and garnished with double-winged leaves, which are shorter, and the small leaves are much narrower than those of the two former sorts; the heads of flowers are smaller, and the pods are longer and narrower than those of the other. This sort will live through the winter in a moderate warm air.

The fourth sort was discovered by the late Dr. *Houftoun*, growing naturally at *La Vera Cruz*. This hath ligneous stalks, which decline to the ground, and send out several side branches, which are armed with short yellowish spines under the foot-stalks of the leaves, and are their whole length closely covered with bristly stinging hairs. It hath single winged leaves, whose base meet in a point, but spread above like the fingers of an open hand, closely garnished with small narrow lobes, set by pairs along the midrib. The flowers come out from the wings of the leaves upon pretty long foot-stalks; they are collected into globular heads, and are of a pale yellowish colour; these are succeeded by small jointed pods, containing two or three shining black seeds.

The fifth sort grows naturally at *Campeachy*. This hath ligneous declining stalks, which are armed with thorns, and covered with stinging bristly hairs; the leaves are composed of four wings, which join at their base, where they are inserted to the foot-stalk, spreading out like the fingers of an open hand: these wings are much shorter than those of the former, and the small leaves or lobes are broader. The flowers come out from the wings of the stalk upon long foot stalks, growing in oval heads; they are white, and are succeeded by small prickly pods. This is one of those species whose foot-stalks fall upon being touched.

The sixth sort is the most common of any in the islands of the *West-Indies*, as also in the *English* gardens; the seeds of this sort are frequently sold in the seed-shops, by the title of Humble Plant. The roots of this are composed of a great number of hairy fibres, which mat close together, from which come out several ligneous stalks, which naturally decline toward the ground, unless they are supported;

they are armed with short recurved spines, and garnished with winged leaves, composed of four, and sometimes five wings, whose base join at a point, where they are inserted to the foot-stalk, spreading upward like the fingers of a hand: these wings are shorter than those of the former sort, and the stalks are not hairy. The flowers come out from the wings of the stalks upon short foot-stalks; they are collected in small globular heads, are yellow, and are succeeded by short, flat, jointed pods, which have two or three orbicular, bordered, compressed seeds in each: these pods are in close clusters, almost covered with stinging hairy covers.

The seventh sort grows naturally at *La Vera Cruz*. This hath a perennial creeping root, which spreads and multiplies greatly in the sands, where it grows wild; the stalks are slender, and have four acute angles, armed with short recurved spines pretty closely; the leaves stand upon long prickly foot-stalks, which are thinly placed on the branches; they are composed of two pair of wings, standing about an inch asunder; the wings are short, and the small leaves are narrow, and not placed so close together, as in many of the other species. The foot-stalks of the flowers come out from the wings of the leaves, sustaining a small globular head of purple flowers; these are succeeded by four-cornered pods about two inches long, which have four cells; opening with four valves, containing several angular seeds in each.

This sort spreads so much at the root, as to render it not so productive of flowers and seeds, as most of the others; and the plants which are propagated by parting of the roots, are always weak, so that the best way is to propagate them by seeds, when they can be obtained. This is one of the sorts, whose foot-stalks fall on being touched.

The eighth sort grows naturally at *La Vera Cruz*. This rises with a slender ligneous stalk seven or eight feet high, armed with short recurved thorns. The leaves grow upon long foot-stalks which are prickly, each sustaining two pair of wings; the exterior pair have two lobes, which join at their base, and are rounded on their outside, but strait on their inner edges, very much shaped like a pair of those shears, used for shearing of sheep; these two outer pair of lobes are much larger than the inner. From the place where these are inserted to the stalk, come out small branches, which have three or four globular heads of pale purple flowers upon short foot-stalks, and the principal stalk has many of these heads of flowers on the upper part for more than a foot in length; and this, as also the branches, are terminated by the like heads of flowers, which are succeeded by broad, flat, jointed pods, which open with two valves, some having but one, others two, and some have three orbicular compressed seeds. The leaves of this sort move but slowly when they are touched, but the foot-stalks fall when they are pressed pretty hard.

The ninth sort was also found growing naturally at *La Vera Cruz*. This hath a shrubby erect stalk about five feet high, which is hairy, and armed with short, broad, strong, white thorns, standing on each side almost opposite, and at others alternately. The leaves are composed of five or six pair of wings, which are ranged opposite along a strong midrib, and between each pair are placed two short strong spines, pointing out each way. The small leaves which compose these wings are extremely narrow, and stand very close to each other. Toward the upper part of the stalk, the flowers are produced from the sides upon short foot-stalks; they are collected into globular heads, and are of a bright purple colour; the stalks are also terminated by smaller heads of the like flowers. These are succeeded by flat jointed pods about two inches long, and a quarter of an inch broad, which spread open like rays, there being commonly five or six of these joined together.

ther at their base to the foot-stalk. These pods separate at each articulation, leaving the two side membranes or borders standing, and the seeds which are compressed and square, drop out from the joints of the pods; these pods are hairy at first, but as they ripen become smooth.

This is a perennial plant, which may be preserved through the winter in a warm stove, by which method the seeds may be obtained, for they seldom flower the first year. The foot-stalks of this sort do not fall on being touched, but the small leaves on the wings close up.

The tenth sort grows naturally in *Jamaica*. This hath trailing herbaceous stalks, which put out roots at every joint, which fasten in the ground and spread to a great distance, as they will also do here, when placed in a bed of tanners bark. I have had a single plant in one summer, which has spread near three feet square, whose branches were closely joined, so as to cover the surface of the bed; but when they are thus permitted to grow, they seldom produce flowers. These stalks have no thorns, but are garnished with winged leaves, composed of two pair of short wings, whose small leaves or lobes are narrow; these stand upon short foot-stalks, which are smooth. The leaves of this sort contract and fall down upon the least touch, so that where the plant is extended to a distance, a person may draw any figure with a stick upon the leaves, which will be very visible till the leaves recover again. The flowers come out from the wings of the leaves, upon naked foot-stalks about an inch in length; they are of a pale yellowish colour, and are collected into small globular heads; these are succeeded by short, flat, jointed pods, containing three or four compressed roundish seeds.

These plants are all of them propagated by seeds, which should be sown early in the spring, upon a good hot-bed. If the seeds are good, the plants will appear in a fortnight or three weeks, when they will require to be treated with care, for they must not have much wet till they have acquired strength; nor should they be drawn too weak, so that fresh air should be admitted to them, at all times when the weather is temperate. In about a fortnight or three weeks after the plants come up, they will be fit to transplant, especially if the bed, in which they were sown, continues in a proper degree of heat; then there should be a fresh hot-bed prepared to receive them, which should be made a week before the plants are removed into it, that the violent heat may be abated before the earth is laid upon the dung, and the earth should have time to warm before the plants are planted into it. Then the plants must be carefully raised up from the bed to preserve the roots entire, and immediately planted in the new bed, at about three or four inches distance, pressing the earth gently to their roots; then they should be gently sprinkled over with water to settle the earth to their roots; after this they must be shaded from the sun till they have taken new root, and the glasses of the hot-bed should be covered every night, to keep up the heat of the bed. When the plants are established in their new bed, they must have frequent but gentle waterings; and every day they must have free air admitted to them, in proportion to the warmth of the season, to prevent their being drawn up weak; but they must be constantly kept in a moderate degree of heat, otherwise they will not thrive. In about a month after the plants will be strong enough to remove again, when they should be carefully taken up, preserving as much earth to their roots as possible, and each planted in a separate small pot, filled with good kitchen-garden earth, and plunged into a hot-bed of tan, carefully shading them from the sun till they have taken new root, then they must be treated in the same manner as other tender exotick plants from very warm countries.

The sorts which grow upright and tall, will soon rise high enough to reach the glasses of the hot-bed, especially if they thrive well; therefore they should be shifted into larger pots, and removed into the stove, and if they are plunged into the tan-bed there, it will greatly forward them. The first sort will often flower here, if the plants are raised early in the spring, and brought forward by their removal from one hot-bed to another, and two or three times I have had their seeds ripen, but this can only be expected in very warm seasons.

The perennial sorts will live through the winter, if they are preserved in a warm stove, and the following summer they will produce flowers and ripen their seeds. Some of these may be propagated by laying down their branches, which will put out roots, and then may be separated from the old plants; and I have sometimes propagated them by cuttings, but the plants which rise from seeds are preferable to either of these.

There is no particular management which these plants require, different from others of the same warm countries; the great care must be to keep them in a proper temperature of heat, and not to give them too much water, especially in cool weather; nor should they be kept too dry, for many of the sorts require frequent waterings, as they naturally grow in moist places. There should also be care taken that they do not root into the tan-bed, for they soon put out their roots through the holes at the bottom of the pots, which, when they strike into the tan, will cause the plants to grow very luxuriant; but when they are removed, and these roots are cut or broken off, the plants seldom survive it; therefore the pots should be frequently drawn out of the tan, and if any of the roots are beginning to get through the holes at bottom, they should be cut off close, to prevent their getting into the tan.

Some of those sorts, whose stalks spread near the ground, may be turned out of the pots in the middle or latter end of *June*, and planted in a very warm border, where, if they are covered with bell or hand-glasses, they will live through the summer; but these will not grow very large, and upon the approach of cold in autumn, they are soon destroyed; however, those who have not conveniency of stoves or tan-beds, may raise the plants on common hot-beds in the spring; and when they have acquired strength, they may be treated in this manner, whereby they will have the pleasure of these plants in summer, though not in so great perfection, as those which have the advantages before-mentioned: but when these plants are exposed to the open air in this country, they will not retain their sensibility on being touched.

It is not the light which causes them to expand, as some have affirmed, who have had no experience of these things; for in the longest days of summer, they are generally contracted by five or six in the evening, when the sun remains above the horizon two or three hours longer; and although the glasses of the stove, in which they are placed, is covered close with shutters to exclude the light in the middle of the day, yet if the air of the stove is warm, the leaves of the plants will continue fully expanded, as I have several times observed. Nor do these plants continue shut till the sun rises in the morning, for I have frequently found their leaves fully expanded by the break of day in the morning; so that it is plain the light is not the cause of their expansion, nor the want of it that of their contraction.

I have also observed, that those plants which are placed in the greatest warmth in winter, continue vigorous, and retain their faculty of contracting on being touched; but those which are in a moderate warmth, have little or no motion.

Some of the sorts are so susceptible of the touch, that the smallest drop of water falling on their leaves will cause them to contract, but others do not move without a much greater pressure.

The roots of all the sorts have a very strong disagreeable odour, almost like that of a common sewer. I have met with some accounts of these plants, in which it is mentioned, that the leaves and branches have a poisonous quality; and that the *Indians* extract a poison from them, which kills by slow degrees, and that the root of the plant is the only remedy to expel it; but how far this is true I cannot say, having never made any experiments on the qualities of these plants; but if these plants are endued with so deadly a quality as related, this sensibility in which they are endued, may be designed by Providence, to caution persons from being too free with it; and as many of them are strongly armed with thorns, so that is a guard against their being eaten by animals; for in all the enquiries which I have made of those persons who have resided in the countries where they naturally grow, I could never learn that any animal will browse upon them.

These plants are all of them natives of *America*, so were unknown to the other parts of the world till that was discovered, for I have not heard of any of them being found in any other country; and a few years ago I sent some of the seeds of these plants to *China*, which succeeded, and occasioned great admiration in all who saw the plants.

MIMULUS. *Lin. Gen. Plant.* 701. *Cynophyneium. Mitch.* 3.

The Characters are,

The flower hath an oblong permanent empalement; it is of the lip or rigent kind, whose brim is divided into two lips. The upper lip is erect, divided at the top in two parts; the lower lip is broad and trifid, the middle segment is the least; the palate is convex and bifid. It has four slender stamina, two longer than the other, and a conical germen, which afterward turns to an oval capsule with two cells, filled with small seeds.

We have but one Species of this genus, viz.

MIMULUS. *Hort. Upsal.* 176. tab. 2.

This plant grows naturally in *North America*, in moist ground. It has a perennial root, and an annual stalk, which is square, and rises a foot and a half high, garnished at each joint with two oblong smooth leaves. The lower part of the stalk sends out two or three short branches, and the upper part is adorned with two flowers at each joint, coming from the bosom of the leaves on each side the stalk; these have an oblong curved empalement with five angles, indented at the top in five parts, out of which arises the flower, with a long curved tube, spreading open at the top into two lips; the upper lip standing erect, which is slightly cut into two parts at the top; the under lip turns downward, and is cut into three slight segments. The flowers are of a Violet colour, but have no scent. These appear in *July*, and are succeeded by oblong capsules with two cells, filled with small seeds which ripen in the autumn.

This plant is very hardy in respect to cold, but should have a loamy soft soil, rather moist than dry, and not too much exposed to the sun. It may be propagated by parting of the roots in autumn, but they should not be divided too small; it may also be propagated by seeds, which should be sown in autumn, soon after they are ripe, for those which are sown in the spring, seldom grow the same year; these may be sown on a border exposed to the morning sun.

MINT. See *Mentha*.

MIRABILIS. *Lin. Gen. Plant.* 215. Marvel of Peru, or Four o'Clock Flower.

The Characters are,

The empalement of the flower has five, oval, small leaves. The flower has one funnel-shaped petal, with a long slender tube

sitting upon the nectarium. It hath five, slender, unequal stamina, which adhere to the petal, with a roundish germen within the nectarium, which afterward becomes an oval five-cornered nut, inclosing one seed.

The Species are,

1. MIRABILIS caule erecto, floribus amplioribus. Marvel of Peru with an erect stalk, and large flowers.

2. MIRABILIS caule erecto, geniculis tumentibus, parvo flore. Marvel of Peru with an erect stalk, having swelling joints, and a small flower.

3. MIRABILIS caule decumbente, villoso & viscoso; tubo floris longissimo, fructu rugoso. Marvel of Peru with a declining, hairy, viscous stalk, a very long tube to the flower, and a rough fruit.

The first sort is the Marvel of Peru, which has been many years cultivated in the *English* gardens for ornament; of this there are several varieties, which differ in the colour of their flowers; two of which always retains their difference, one of them has purple and white flowers, which are variable, some of them are plain purple, others are plain white, but most of them are variegated with the two colours, and all these varieties are sometimes upon the same plant, and at others on different plants; the other has red and yellow flowers, which are generally mixed in the same flowers, but are often with plain flowers of both colours on the same plant, intermixed with those which are variegated; but some plants have only plain flowers, and I have never found that the seeds of the purple and white sort ever produced the yellow and red, nor the latter ever vary to the former, and I have constantly cultivated both more than forty years; but although these do not change from one to the other, yet as there is no other difference between them than in the colour of their flowers, I have not enumerated them as distinct species.

The second sort is very common in all the islands of the *West-Indies*, where the inhabitants call it the Four o'Clock Flower, from the flowers opening at that time of the day. Of this sort I have never seen any with variable flowers; they are of a purplish red colour, and not much more than half the size of the other. The stalks of this sort have thick swollen joints; the leaves are smaller, and the fruit is very rough, so there can be no doubt of their being distinct species, for I have never seen any alteration in this from seed, and I have cultivated it more than thirty years. *Tournefort* was informed by father *Plumier*, that the root of this plant was the officinal jalap, upon which he constituted the genus, and gave that title to it; but the late Dr. *Houssoun* was fully informed in the *Spanish West-Indies* of the contrary, and brought over a drawing of the plant which was made by a *Spaniard* at *Halapa*, and he carried two or three of the plants to *Jamaica*, where he planted them in a garden, but after he left the island they were destroyed by hogs; however, he was fully satisfied of its being a *Convolvulus*; indeed the roots of Marvel of Peru are purgative, and when given in a double quantity for a dose, will answer the purpose of jalap.

The third sort was sent from *Mexico*, a few years since. The seeds of this were first sent me from *Paris*, by Dr. *Monier*, of the *Royal Academy of Sciences*, and afterward I had some sent me from *Madrid*, by Dr. *Hortega*. The stalks of this sort fall on the ground, if they are not supported; these grow about three feet long, and divide into several branches, which are garnished with heart-shaped leaves, placed opposite; these, as also the stalks, are hairy and viscous, sticking to the fingers of those that handle them. The flowers come out at the end of the branches; they are white, and have very long slender tubes, and a faint musky odour; these are like the other sorts, closely shut all the day, but expand every evening when the sun declines. The seeds

seeds of this sort are larger than those of any other species, and are as rough as those of the second sort.

The two varieties of the first sort are very ornamental plants in gardens, during the months of *July, August, and September*; and if the season continues mild, they often last till near the end of *October*. The flowers do not open till toward the evening, while the weather continues warm, but in moderate cool weather, when the sun is obscured, they continue open almost the whole day. The flowers are so plentifully produced at the ends of the branches, as that when they are open, the plants seem entirely covered with them, and there being some plain, and others variegated on the same plants, they make a fine appearance.

These plants are propagated by seeds, in the choice of which there should be care taken not to save any from those plants, whose flowers are plain; and those who are desirous of having only the variegated kinds, are careful to pull off all the plain flowers from those plants which they intend for seeds, to prevent their having any seeds; by this method they rarely have any plants with plain flowers.

The seeds should be sown upon a moderate hot-bed in *March*, and when the plants come up; they should have plenty of air admitted to them; when the weather is mild, to prevent their being drawn up weak; and when they are about two inches high, they should be transplanted on another very moderate hot-bed; or if they are each planted in a small pot filled with light earth, and plunged into a moderate hot-bed, it will be a more secure way, for then there will be no danger in shaking them out of the pots, when they are to be planted in the borders, so as to preserve all the earth to their roots; by this method they will not require to be shaded, whereas those which are to be transplanted from the second hot-bed to the borders, often rise with little earth to their roots, so must be carefully shaded, otherwise they often miscarry.

When they are in the second hot-bed, they should be shaded till they have taken fresh root, after which they must have plenty of free air, to prevent their being drawn up weak, and in *May* they must be gradually inured to bear the open air. The beginning of *June*, if the season is favourable, they should be transplanted into the borders of the pleasure-garden, giving them proper room; and after they have taken new root, they will require no further care. If the seeds are sown in a warm border, they will grow very well, but the plants will be late in the season before they flower.

As the seeds of these plants ripen very well every year, so there are not many who are at the trouble of preserving their roots; but if these are taken out of the ground in autumn, and laid in dry sand all the winter, secured from frost, and planted again in the spring, they will grow much larger, and flower earlier than the seedling plants; or if the roots are covered in winter with tanners bark, to keep out the frost, they may remain in the borders, provided the soil be dry. If the roots, which are taken out of the ground, are planted the following spring in large pots, and plunged into a hot-bed under a deep frame, they may be brought forward, and raised to the height of four or five feet, as I have frequently practised, and these plants have come early in the season to flower, so have been intermixed with other ornamental plants, to decorate halls and shady courts, where they have appeared very beautiful.

The other two species require the same treatment, but the second sort is not quite so hardy as the other two, so unless the plants are brought forward in the spring, they will not flower till very late, so their seeds will not ripen.

MISLETOE. See *Viscum*.

MITELLA. *Tourn. Inst. R. H. 241. tab. 126. Lin. Gen. Plant. 496. Bastard Americau Sanicle.*

The Characters are;

The flower has a bell-shaped empalement of one leaf. It hath five petals, which are inserted in the empalement, as are also the ten awl-shaped stamina, which are shorter than the petals. It hath a roundish bifid germen, with scarce any style. The empalement afterward becomes an oval capsule with one cell, opening with two valves, filled with small seeds.

The Species are,

1. MITELLA *scapo diphylla. Lin. Gen. Nov. 29.* Mitella with flower-stalks having two leaves.

2. MITELLA *scapo nudo. Amoen. Acad. 2. p. 252.* Mitella with a naked stalk.

The first sort grows naturally in the woods, in most parts of *North America*. It has a perennial root, from which come out many heart-shaped angular leaves, some of which are obtuse, and others end in acute points; they are indented on their edges, of a lucid green, and stand upon pretty long foot-stalks. The flower-stalks arise immediately from the root, having two or three angular leaves toward the bottom, and about the middle of the stalk come out two small leaves, with acute angles, placed opposite. The stalks rise eight or nine inches high, and are terminated by a loose spike of small whitish flowers, whose petals are fringed on their edges. These appear the beginning of *June*, and are succeeded by roundish capsules, filled with small seeds.

The second sort grows naturally in the northern parts of *Asia*. This is of humbler growth than the first, seldom rising more than five or six inches high. The leaves are not so angular as those of the first sort, and the flower-stalks are always naked, having no leaves. The spikes of flowers are shorter, and more compact.

Both these are propagated by parting of their roots; the best time for this is in autumn; they should be planted in a shady situation, and a soft loamy soil.

MITELLA MAXIMA. See *Bixa*.

MOLDAVICA. See *Dracocephalum*.

MOLLE. See *Schinus*.

MOLLUGO. *Lin. Gen. Plant. 99.*

The Characters are,

The empalement of the flower is composed of five oblong small leaves, coloured on their inside, and permanent. The flower has five oval petals shorter than the empalement, and three bristly stamina, which stand near the style, terminated by single summits, with an oval germen, having three furrows, supporting three very short styles. The germen afterward becomes an oval capsule with three cells, filled with small kidney-shaped seeds.

The Species are,

1. MOLLUGO *foliis verticillatis cuneiformibus acutis, caule subdiviso decumbente, pedunculis unifloris. Hort. Upsal. 24.* Mollugo with acute wedge-shaped leaves growing in whorls, a trailing divided stalk, and foot-stalks bearing a single flower.

2. MOLLUGO *foliis quaternis obovatis, paniculâ dichotomâ. Hort. Cliff. 28.* Mollugo with four leaves at each joint, which are almost oval, and a panicle arising at the division of the branches.

There are two or three other species of this genus, which are rarely admitted into gardens, so I have not enumerated them here.

Both these sorts are annual; the first is a native of warm countries, so is less hardy than the second; they are both trailing plants, whose stalks lye on the ground; the first spreads out eight or nine inches every way, and at each joint is garnished with six or seven small leaves spread out in form of a star. The flowers are small, like those of Chickweed, one standing upon each foot-stalk; these are succeeded by oval capsules, filled with small seeds, which, if permitted to scatter, the plants will come up the following

ing spring without any care ; but when the seeds happen to fall upon earth which is thrown upon a hot-bed, the plants will be forwarder and stronger than those in the open air. This is preserved in some gardens for the sake of variety, but has no great beauty.

The other sort has been already mentioned under the article *HERNIARIA*, but being ranged in this genus by Dr. *Linnaeus*, I have enumerated it here.

MOLUCCELLA. *Lin. Gen. Plant.* 543. *Molucca Balm*.

The Characters are,

The flower hath a large permanent empalement of one leaf, which is deeply indented at the brim, where it spreads open. The flower is of the lip kind, with a short tube. The upper lip is erect, concave, and entire. The under lip is trifid, the middle segment being longer than the other. It has four stamina situated under the upper lip, two of which are shorter than the other, and a germen with four parts, which afterward turns to four angular convex seeds, sitting in the empalement.

The Species are,

1. *MOLUCCELLA calycibus quinquedentatis, denticulis æqualibus*. *Prod. Leyd.* 314. *Molucca Balm*, with empalements indented in five equal parts ; or smooth *Molucca Balm*.

2. *MOLUCCELLA calycibus septemdentatis*. *Prod. Leyd.* 314. *Molucca Balm*, whose empalements are indented in seven parts ; or prickly *Molucca Balm*.

The first sort rises with a square stalk three feet high, spreading out into many smooth branches by pairs, garnished with roundish leaves, set opposite, which are deeply notched on their edges, standing upon long foot-stalks ; they are smooth, of a light green on both sides, and at the base of their foot-stalks the flowers come out in whorls ; these have very large spreading empalements, which are indented in five parts. The flowers are small, and being situated at the bottom of the large empalements, are not visible at a distance ; they are white, with a cast of purple, and shaped like those of the other lip flowers, having the upper lip entire, and hollowed like a spoon, and the under lip is cut into three segments, the middle one being the longest. After the flower is past, the germen turns to four club-shaped angular seeds inclosed in the empalement. It flowers in *July*, but unless the season proves warm and dry, the seeds do not ripen in *England*. The smell of this plant is to some persons very disagreeable, and to others very pleasant.

The second sort hath square smooth stalks, of a purplish colour, which do not rise so high as those of the former, but branch out in the same manner. The leaves are smaller, and stand upon shorter foot-stalks ; they are deeper, and more acutely indented on their edges. The empalements of the flowers are not so large, and cut into seven segments, each being terminated by an acute spine. The flowers are like those of the former species, as are also the seeds ; this is not so hardy as the first sort.

The first grows naturally in several parts of *Syria*, and the second is a native of the *Molucca Islands*, from whence this genus received its title. They are both annual plants, which decay soon after their seeds are ripe, and being natives of warm countries, they seldom perfect their seeds in *England*, when they are sown in the spring ; therefore the best way is to raise the plants in autumn, and plant them in small pots ; these should be placed under a hot-bed frame in winter, where they may have free air in mild weather, by taking off the glasses, but covered in frosty weather, observing to keep them pretty dry, otherwise they are very subject to rot, especially when they are closely covered in frosty weather. In the spring, the plants may be turned out of the pots, with all the earth about their roots, and planted in a warm border, defended from strong winds, giving them a little water to settle the earth to their roots ; after this they will require no other care, but to keep them

clean from weeds, and to support them with stakes, to prevent their being broken by the winds. The plants thus preserved through the winter, will flower the latter end of *June*, so from these good seeds may be expected.

MOLY. See *Allium*.

MOMORDICA. *Tourn. Inst. R. H.* 103. *tab.* 29, 30. *Lin. Gen. Plant.* 967. Male Balsam Apple.

The Characters are,

It hath male and female flowers upon the same plant. The male flowers have an open concave empalement of one leaf. It has three short awl-shaped stamina, which are compressed in a body, and have a reflexed line containing the farina. The female flowers have the same empalement and petal as the male, but sit upon the germen ; these have three short filaments without summits. The germen supports one taper trifid style, crowned by three oblong gibbous stigmas ; and afterward turns to an oblong fruit, opening with an elasticity, having three membranaceous cells, filled with compressed seeds.

The Species are,

1. *MOMORDICA pomis angulatis tuberculatis, foliis glabris patenti-palmatis*. *Hort. Cliff.* 451. Male Balsam Apple with angular warted fruit, and smooth open-handed leaves.

2. *MOMORDICA pomis angulatis tuberculatis, foliis villosis, longitudinaliter palmatis*. *Hort. Cliff.* 451. Male Balsam Apple with angular warted fruit, and hairy leaves, which are longitudinally hand-shaped.

3. *MOMORDICA pomis ovatis acuminatis tuberculatis, foliis glabris palmatis ferratis*. Male Balsam Apple, with an oval, acute-pointed, warted fruit, and smooth hand-shaped leaves, which are sawed.

4. *MOMORDICA pomis hispida, cirrhis nullis*. *Lin. Sp. Plant.* 1010. Male Balsam Apple with a prickly fruit, and no tendrils to the vines ; or Wild Cucumber, and Elaterium of *Boerhaave*.

The first sort grows naturally in *Asia*, the second and third in the island of *Ceylon* ; they are all annual plants, which perish soon after they have ripened their fruit ; these have trailing stalks, like those of the Cucumber and Melon, which extend four or five feet in length, sending out many side branches, with tendrils, by which they fasten themselves to any neighbouring plants, to secure themselves from being tost, and blown about by the winds, and are garnished with leaves shaped like those of the Vine. The leaves of the first and third sorts are smooth, and deeply cut into several segments, and are spread open like a hand ; but those of the second sort are extended more in length, and are hairy. The fruit of the first species is oval, ending in acute points, having several deep angles, which have sharp tubercles placed on their edges ; it changes to a red or purplish colour, when ripe, opening with an elasticity, and throwing out its seeds.

The fruit of the second sort is much longer than that of the first, and not so deeply channelled. The tubercles are scattered all over the surface, and are not sharp like those of the other ; this fruit is yellow when ripe, and casts out its seeds with an elasticity.

The fruit of the third sort is short and pointed like that of the first, but does not swell so large in the middle. The angles of this are not deep, and the whole surface is closely set with large tubercles ; this changes to a deep Orange colour, when ripe, and casts out its seeds in the like manner.

The fourth sort is commonly called Wild or Spurting Cucumber, from its casting out its seeds, together with the viscid juice in which the seeds are lodged, with a violent force, if touched when ripe ; and from hence it has sometimes the appellation of *Noli me tangere*, or Touch me not. This plant grows naturally in some of the warm parts of *Europe*, but in *England* it is cultivated in gardens for the fruit, which

which is used in medicine, or rather the *fæcula* of the juice of the fruit, which is the *Elaterium* of the shops.

This plant hath a large fleshy root, somewhat like that of Briony, from which come forth every spring, several thick, rough, trailing stalks, which divide into many branches, and extend every way two or three feet; these are garnished with thick, rough, almost heart-shaped leaves, of a gray colour, standing upon long foot-stalks. The flowers come out from the wings of the stalk, these are male and female, growing at different places on the same plant, like those of the common Cucumber, but they are much less, of a pale yellow colour, with a greenish bottom: the male flowers stand on short thick foot-stalks, but the female flowers sit upon the young fruit, which, after the flower is faded, grows of an oval form, an inch and a half long, swelling like a Cucumber, of a gray colour like the leaves, and covered over with short prickles. These do not change their colour when ripe, like most of the other fruit of this class, but if attempted to be gathered, they quit the foot-stalk, and cast out the seeds and juice with great violence; so that where any plants are growing, and the fruit permitted to stand till it is ripe, the seeds will be scattered all round to a great distance, and there will be plenty of the plants produced the following spring.

But when the fruit is designed for use, it should always be gathered before it is ripe, otherwise the greatest part of the juice will be lost, which is the only valuable part; for the juice which is expressed, with part of the parenchyma of the fruit, is not to be compared with the other for its virtues; for the *Elaterium* which is made from the clear juice of the fruit, is much whiter, and will retain its virtues much longer than that which is extracted by pressure.

The three first sorts are annual; their seeds must be sown on a hot-bed the beginning of *March*, and when the plants come up, they should be transplanted out into a fresh hot-bed, after the manner of Cucumbers or Melons, putting two plants of the same kind under each light, and the plants watered and shaded until they have taken root; after which they must be treated as Cucumbers, permitting their branches to extend upon the ground in the same manner, and observe to keep them clear from weeds.

With this management (provided you do not let them have too much wet, or expose them too much to the open air) they will produce their fruit in *July*, and their seeds will ripen in *August* and *September*, when you must observe to gather it as soon as you see the fruit open, otherwise it will be cast abroad, and with difficulty gathered up again.

These plants are preserved in curious gardens for the oddness of their fruit; but as they take up a great deal of room in the hot-beds, requiring frequent attendance, and being of little beauty or use, so they are not much cultivated in *England*, except in botanick gardens for variety.

There are some persons who put these plants in pots, and fasten them to stakes, to support the vines from trailing on the ground, and place the pots in stoves; where, when they are skilfully managed, they will produce their fruit tolerably well; and in this way they make a better appearance, than when the vines spread on the ground like Cucumbers and Melons. But when the plants spread on the ground, which is their natural way of growing, they thrive much better, and produce more fruit, than when they are supported; for though these plants have clasps, yet these are not formed for climbing, but merely to fasten themselves about any neighbouring support, to secure them from being raised by the wind and broken, which would often happen, where they grow in the open air and are fully exposed, were it not for this security.

The fourth sort is easily propagated by seeds, which (as was before mentioned) if permitted to scatter, there will be

a supply of plants come up the following spring; or if the seeds are sown upon a bed of light earth, the plants will come up in about a month after, and may be transplanted to an open spot of ground, in rows at three or four feet distance, and almost as far asunder in the rows; if these are carefully transplanted while young, there will be little hazard of their growing; and after they have taken new root, they will require no farther care, but to keep them clear from weeds. If the ground is dry in which these are planted, the roots will continue three or four years, unless the winter should prove very severe, which will sometimes kill them.

MONARDA. *Lin. Gen. Plant.* 34.

The Characters are,

The flower has a cylindrical empalement of one leaf, which is cut into five equal parts at the brim. The flower hath one petal, and is of the lip kind, divided at the top into two lips. The upper lip is narrow, entire, and erect; the under lip is broad, trifid and reflexed. It hath two bristly stamina the length of the upper lip. In the bottom of the tube is situated a four-pointed germen, supporting a slender style involved with the stamina; and crowned by an acute bifid stigma. The germen afterward turns to four naked seeds, inclosed in the empalement.

The Species are,

1. MONARDA *capitulis terminalibus, caule obtus-angulo.* *Hort. Upsal.* 12. Monarda with heads of flowers terminating the stalks, which have obtuse angles.

2. MONARDA *floribus capitatis sub-didynamis, caule acutangulo.* *Lin. Sp. Plant.* Monarda with headed flowers, whose stamina are almost in two bodies, and an acute angular stalk.

3. MONARDA *floribus verticillatis corollis punctatis.* *Hort. Upsal.* 12. Monarda with flowers growing in whorls, whose petals are spotted.

4. MONARDA *floribus capitatis, foliis lævibus serratis.* *Lin. Syst.* 853. Monarda with flowers growing in heads, and smooth sawed leaves.

5. MONARDA *floribus verticillatis, corollis involucre longioribus.* *Lin. Syst.* 853. Monarda with whorled flowers, whose corolla are longer than the empalement.

The first sort grows naturally in *Canada*, and many other parts of *North America*. It hath a perennial root. The stalks rise near three feet high, which are hairy, and have obtuse angles; these send out two or four small side branches toward the top, which, as also the principal stalk, are garnished with oblong leaves, broad at their base, but terminate in acute points; they are hairy, a little indented on their edges, and are placed by pairs. The stalk and branches are terminated by heads of purple flowers, which have a large involucre, composed of five acute-pointed leaves. The flowers have each two stamina which are longer than the petal, with a style of the same length. The flowers appear in *July*, and are succeeded by seeds which ripen in autumn.

The second sort also grows naturally in *North America*, where the inhabitants frequently use the leaves for tea, so it is commonly called *Oswego Tea*, by which title it was brought to *England*. This hath a perennial root. The stalks of this sort are smooth, having four acute angles; they rise about two feet high, and are garnished with smooth, oval, spear-shaped leaves, which are indented on their edges, and stand opposite; these, when bruised, emit a very grateful refreshing odour; the stalks send out toward their top, two or four small side branches, which are garnished with small leaves of the same shape with the other. The flowers are produced in large heads or whorls at the top of the stalk, and there is often a smaller whorl of flowers, growing round the stalk at a joint below the head; and out of the head arises a naked foot-stalk, sustaining a small head or whorl

whorl of flowers; the flowers are of a bright red colour; they have two lips, the upper lip is long, narrow, and entire, the under lip is cut into three parts; they have each two stamina, which are longer than the petal. This plant flowers in *July*, but in a moist season, or when the plants are in a moist soil, they will continue in flower till the middle or latter end of *September*.

Both these sorts may be propagated by parting of their roots; the first does not multiply so fast as the second, but as that produces plenty of seeds, so it may be easily propagated that way: if the seeds are sown in the autumn soon after they are ripe, the plants will come up the following spring; but if they are not sown till spring, the plants seldom rise till the next year. When the plants are come up, and are fit to remove, they should be transplanted into a shady border, at about nine inches distance, and when they have taken new root, they will require no other care but to keep them clean from weeds till the autumn, when they should be transplanted into the borders where they are to remain. The following summer they will flower and produce ripe seeds, but the roots will continue several years, and may be parted every other year to increase them. This loves a soft loamy soil, and a situation not too much exposed to the sun.

The second sort seldom ripens seeds in *England*, but it increases fast enough by its creeping roots, as also by slips or cuttings, which, if planted in a shady border in *May*, will take root, in the same manner as Mint or Balm; but as the roots multiply so fast, there is seldom occasion to use any other method to propagate them.

This sort loves a moist light soil, and in a situation where the plants have only the morning sun, they will continue longer in flower, than those which are exposed to the full sun. This is a very ornamental plant in gardens, and the scent of the leaves is very refreshing and agreeable to most people, and some are very fond of the tea made with the young leaves.

The third sort grows naturally in *North America*; this is seldom more than a biennial root, and probably in its native country may be an annual, for the roots perish after the plants have perfected their seeds. It hath square stalks which rise about two feet high, branching out from the bottom to the top, garnished with spear shaped leaves, which come out in clusters at each joint, where there are two larger leaves placed opposite, and several smaller come out on each side the stalk: the larger leaves are about two inches and a half long, and three quarters of an inch broad, and are slightly indented on their edges. Toward the upper part of the stalk the flowers come out in large whorls, having to each whorl an involucre, composed of ten or twelve small spear-shaped leaves, of a purplish red colour on their inside; the flowers are pretty large, of the same form with those of the other sorts, of a dirty yellow colour spotted with purple; these have each two long stamina situated under the upper lip, which are terminated by bifid compressed summits, and are succeeded by four naked seeds inclosed in the empalement. It flowers in *July*, and if the summer proves favourable, the seeds will ripen in the autumn.

This plant is propagated by seeds, which, if sown on a border of light earth exposed to the east, the plants will rise very freely; when they are fit to remove, they may be transplanted into a shady border, in the same manner as hath been directed for the first sort; and if they should shoot up stalks to flower, they should be cut down to strengthen the roots, that they may put out lateral buds; for when they are permitted to flower the first year, the roots seldom live through the winter, therefore they should be prevented: in the autumn the plants may be removed, and planted in the

open borders of the pleasure-garden, where they will flower the following summer; and if the season should prove dry, they should be duly watered, otherwise they will not be near so beautiful, nor will the plants produce good seeds.

The fourth sort approaches near to the first, but the leaves are smoother, and sawed on their edges; the flowers are almost white, but grow in heads in the same manner as the first. This is a perennial plant, and requires the same treatment as the first.

The fifth sort approaches near to the third, but has not a coloured involucre, nor are the flowers spotted, but the greatest difference between them is in the length of the corolla, which in this is longer than the involucre: It is a biennial, and requires the same treatment as the third.

MONBIN. See *Spondias*.

MONTIA. See *Heliocarpus*.

MOREA.

The Characters are,

The flower is very like those of the *Iris*, but it has six spear-shaped petals which spread open horizontally, three of which are alternately larger than the other, and three erect standards, so these have no falls as the *Irises* have. The spathe, number of stamina, and the seed-vessel, agrees very nearly to the *Iris*.

The title of this genus I have added in honour of *Robert More*, Esq; of *Shrewsbury*, who is an excellent botanist, and has a garden well stored with plants.

The Species are,

1. MOREA *spatha biflora*, caule planifolio, floribus minoribus. Fig. Pl. tab. 238. Morea with two flowers in each sheath, plain leaves on the stalk, and smaller flowers.

2. MOREA *spatha uniflora*, caule planifolio, floribus majoribus. Ibid. Morea with one flower in a sheath, plain leaves on the stalk, and larger flowers.

3. MOREA *spatha uniflora*, foliis gladiolatis, floribus alternis. Morea with one flower in a sheath, sword-shaped leaves, and flowers placed alternate.

These plants are natives of the *Cape of Good Hope*, from whence the seeds were brought. The two first have oblong bulbous roots, which early in the spring send out three or four long, narrow, plain leaves, which end in acute points. Toward the end of *March* the flower-stalk arises, which is garnished with two or three smaller leaves, of the same form with those at bottom, and is terminated with one or two spathæ or sheaths, which in those of the first sort is included two flowers, but those of the second have but one. The foot-stalk which sustains the flower is longer than the sheath; the six petals of the flower which spread horizontally, are of a pale blue colour, each having a yellow spot toward the bottom. The three standards which inclose the stamina are white; the flowers appear the latter end of *April*, but open only in the morning, shutting every day at noon. They continue in flower about a fortnight, then the germen, which is situated immediately under the flower, swells to a turgid three-cornered seed vessel, having three cells, filled with roundish seeds, which ripen the end of *June*.

There is but little difference in the colour of the flowers of the two first sorts, but those of the second are the biggest.

The third sort came by the *Dutch* title of *White Water Lily*. The root of this is composed of several fleshy fibres; the leaves are flat and shaped like those of *Iris* or *Flower-de-luce*, and are of a dark green colour. The stalk rises near two feet high, and is garnished at each joint with one small leaf shaped like those below, whose base embraces the stalk; the flower comes out of a smooth sharp-pointed sheath; it is composed of six oval spear-shaped petals, of a dirty white, shaded with a sky blue colour; these are equal in size, and spread open flat. In the center of these arise three forked petals standing erect, of a bluish purple colour;

four; these encompass the stamina and style, the stamina being connected at their base to their tails. The outer petals have a large sulphur-coloured spot in each. Each stalk produces several flowers, which are placed alternately. This sort flowers in *June*, and then the germen swell to a large, oblong, furrowed capsule with three cells, filled with roundish compressed seeds, which do not ripen till winter. The leaves of this sort remain green all the year.

These plants may be propagated by seeds, which should be sown in pots filled with light earth; those of the two first should be sown in *August*, and those of the third soon after they are ripe. The pots should be placed in a hot-bed frame in winter, to screen the seeds from frost. In the spring the plants will appear, when the glasses should be drawn off every day when the weather is mild, to prevent the plants being drawn up weak, and in *May* the pots should be placed abroad in a sheltered situation, where they may enjoy the morning sun, but screened from the great heat. If the season proves dry, the plants must be frequently refreshed with water, but it must not be given them in too great plenty. Toward the latter end of *June* the leaves of the two first sorts will decay, after which, if the roots are too close, they may be transplanted; but as they will be very small, six or seven of them may be planted in one small pot, and then placed on an east border, where they may have only the morning sun, and kept clean from weeds till autumn, when they must be placed into the frame to be screened from frost, but should be always exposed to the open air in mild weather; this should be repeated every winter, and in three years the plants will flower. The time for removing these bulbs is always soon after their stalks and leaves decay. In summer, when they are at rest, they must have very little water, and only require to be kept clean from weeds, and in winter they must be sheltered in a frame.

These may also be propagated by offsets which are produced from the old roots, which will flower the second year.

The third sort may be treated in the same way as the other, but as the leaves of this continue all the year, the best time to transplant them is in *September*, when the roots are in the most inactive state. This may be propagated by parting of the roots, in the same way as is practised for the flag-leaved Iris.

MORINA. *Tourn. Cor.* 48. tab. 480.

The Characters are,

It hath a double empalement, which is tubulous, bifid, of one leaf, and permanent. The flower hath one petal, with a long tube a little incurved. The top is divided into two lips; the upper lip is small and bifid, the under lip is cut into three equal obtuse segments, the middle one being extended beyond the other. It hath two bristly stamina. The globular germen is situated under the flower, supporting a slender style which is longer than the stamina, crowned by a target-shaped stigma; the germen afterward becomes a single seed, crowned by the empalement of the flower.

There is but one Species of this genus at present known, which is,

MORINA. *Hort. Cliff.* 14. Eastern Morina.

This plant was discovered by Dr. *Tournefort*, in his travels in the *Levant*, who gave it this name in honour of Dr. *Morin*, a physician at *Paris*.

It grows naturally near *Erzeron* in *Persia*, and was in the *English* gardens before the severe winter in 1740, which killed all the plants. The root of this plant is taper and thick, running deep into the ground, sending out several thick strong fibres as large as a finger; the stalk rises near three feet high; it is smooth, of a purplish colour toward the bottom, but hairy and green at the top, garnished at each joint by three or four prickly leaves like those of the

Carlina Thistle, of a lucid green on their upper side, armed on their edges with spines. The flowers come out from the wings of the leaves on each side the stalk; these have very long tubes, which are slender at the bottom, but are enlarged upward, and are a little incurved; the brim opens with two large lips, the upper lip is indented at the top and rounded, the lower lip is cut into three obtuse segments; under the upper lip are situated two bristly stamina, which are crooked, and crowned with yellow summits. These flowers appear in *July*, but I never had any seeds succeed from them. Some of the flowers are white, and others of a purplish red on the same plant.

This plant is propagated by seed, which should be sown soon after it is ripe in the autumn, otherwise the plants will not come up the following summer; for I have several times observed, where the seeds have been sown in the spring, they have remained in the ground fourteen or fifteen months before the plants have appeared. These seeds should be sown in the places where the plants are to remain, because they send forth tap roots, which run very deep into the ground; and when these are broken or injured in transplanting, the plants seldom thrive after. They may be sown in open beds or borders of fresh light earth, being careful to mark the places, that the ground may not be disturbed; for it frequently happens, that the seeds do not come up the first year, when they are sown in autumn; but when they are sown in the spring, they never come up the same year. The ground where the seeds are sown must be kept clear from weeds, which is all that is necessary to be done until the plants come up; where they are too close together, they should be thinned so as to leave them near eighteen inches apart; after which time they will require no other culture but to keep them constantly clear from weeds, and in the spring, just before the plants put out new leaves, to stir the ground gently between them, and lay a little fresh earth over the surface of the bed to encourage them.

In autumn these plants decay to the ground, and send forth new leaves the following spring; but it will be three years from the time of the plants first coming up to their flowering, though after that time they will flower every season; and the roots will continue many years, provided they are not disturbed or killed by very severe frost.

MORUS. *Tourn. Inst. R. H.* 589. tab. 363. The Mulberry tree.

The Characters are,

It hath male flowers growing at separate distances from the female, on the same tree. The male flowers are collected in long taper ropes or katkins; these have no petals, but have four long, awl-shaped, erect stamina. The female flowers are collected into roundish heads; these have no petals, but a heart-shaped germen, supporting two long, rough, reflexed styles, crowned by single stigmas. The empalement of these afterward become large, fleshy, succulent fruit, composed of several protuberances, in each of which is lodged one oval seed.

The Species are,

1. MORUS *foliis cordatis scabris*. *Hort. Cliff.* 441. Mulberry with rough heart-shaped leaves; or the common Mulberry.

2. MORUS *foliis palmatis hirsutis*. Mulberry with hand-shaped hairy leaves; smaller black Mulberry with elegant cut leaves.

3. MORUS *foliis cordatis subtus villosis, amentis cylindricis*: *Lin. Sp. Plant.* 986. Mulberry with heart-shaped leaves which are hairy on their under side, and cylindrical katkins.

4. MORUS *foliis oblique cordatis lewibus*. *Hort. Cliff.* 441. Mulberry with oblique, smooth, heart-shaped leaves; or Mulberry with a white fruit.

5. *MORUS foliis obliquè cordatis acuminatis hirsutis.* Mulberry with oblique, heart-shaped, acute-pointed, hairy leaves; or Fustick wood.

6. *MORUS foliis palmatis, fructibus hispidis.* Lin. Sp. Plant. 986. Mulberry with hand-shaped leaves and prickly fruit.

7. *MORUS foliis ovato-oblongis utrinque æqualibus, inæqualiter serratis.* Flor. Zeyl. 337. Mulberry with oval oblong leaves, which are equal on both sides, but unequally sawed.

The first sort is the common black Mulberry tree, which is cultivated for the delicacy of its fruit. This tree grows naturally in *Persia*, from whence it was first brought to the southern parts of *Europe*, but is now become common in every part of *Europe*, where the winters are not very severe: for in the northern parts of *Sweden*, these trees will not live in the open air; and in several parts of *Germany* they are planted against walls, and treated in the same way as Peach, and other tender fruits are here.

These trees are generally of both sexes, having male flowers or katkins, on the same tree with the fruit; but it often happens, that some of the trees which are raised from seeds, have only male flowers, and produce no fruit; so that those who plant these trees for their fruit, should never make choice of such as have been propagated by seeds, unless they have seen them produce fruit in the nursery. It is also the surest way to mark such trees as are fruitful in the nursery, at the time when their fruit is upon them, because those trees which are propagated by layers, are sometimes of the male sort; for I have several times observed, that some of the large branches of these trees have produced only katkins, when the other parts of the trees have been very fruitful; so that unless care is taken in the choice of the branches for making the layers, there is the same hazard as in seedling trees: nor should the shoots which come out near the roots of old trees be ever laid down, for these rarely produce fruit until they have been planted many years, although the trees from which these were produced might be very fruitful. I have observed some trees which produced only katkins for many years after they were planted, and afterward have become fruitful; the same I have observed in Walnut trees, and my honoured friend the Chevalier *Rathgeb*, has informed me, that he has observed the same in the Lentisk and Turpentine trees.

The old Mulberry trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; so that where there are any of these old trees, it is the best way to propagate from them, and to make choice of those branches which are most fruitful. The usual method of propagating these trees, is by laying down their branches, which will take root in one year, and are then separated from the old trees; but as the most fruitful branches are often so far from the ground as not to be layed, unless by raising of boxes or baskets of earth upon supports for this purpose, so the better way is to propagate them by cuttings, which, if rightly chosen and skilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a distance, and from the most fruitful branches. These cuttings should be the shoots of the former year, with one joint of the two years wood to their bottom; the cuttings should not be shortened, but planted their full length, leaving two or three buds above ground. The best season for planting them is in *March*, after the danger of hard frost is over; they should be planted in light rich earth, pressing the ground pretty close about them; and if they are covered with glasses, it will forward their putting out roots; but where there is not such conveniency, the ground about them should be covered with moss, to prevent its drying; and where this is carefully done, the cuttings will require but little water, and will succeed much better than with having much wet.

If the cuttings succeed well and make good shoots, they may be transplanted the following spring into a nursery where they should be regularly trained to stems, by fixing down stakes to each, to which the principal shoots should be fastened; and most of the lateral branches should be closely pruned off, leaving only two or three of the weakest to detain the sap, for the augmentation of the stem; for when they are quite divested of the side shoots, the sap is mounted to the top, so that the heads of the trees grow too fast for the stems, and become too weighty for their support. In about four years growth in the nursery, they will be fit to transplant where they are to remain; for these trees are transplanted with greater safety while young, than when they are of a large size.

I have two or three times made trial of planting the cuttings of Mulberries on a hot-bed, and have found them succeed extremely well. This I was led to, by observing some sticks of Mulberry trees which were cut for forks, and thrust into the hot-bed, to fasten down the vines of Cucumbers; which, although they had been cut from the tree a considerable time, yet many of them put out roots and shot out branches; so that where any person is in haste to propagate these trees, if the cuttings are planted on a hot-bed, they will take root much sooner than in the common ground.

This tree delights to grow in rich light earth, such as is in most of the old kitchen-gardens about *London*, where there is also a great depth of earth; for in some of those gardens there are trees of a very great age, which are very healthy and fruitful, and their fruit is larger and better flavoured, than those of the younger trees. I have never yet seen any of these trees which were planted in a very stiff soil, or on shallow ground either upon clay, chalk, or gravel, which have been healthy or fruitful, but their stems and branches are covered with moss, so that the little fruit which they sometimes produce are small, ill tasted, and late before they ripen.

If these trees are planted in a situation where they are defended from the strong south and north-west winds, it will preserve their fruit from being blown off; but this shelter whether it be trees or buildings, should be at such a distance, as not to keep off the sun; for where the fruit has not the benefit of his rays to dissipate the morning dews early, they will turn mouldy and rot upon the trees. There is never any occasion for pruning of these trees, more than to cut off any of the branches which may grow across another, so as to rub and wound their bark, by their motion occasioned by the wind; for their shoots should never be shortened, because the fruit is produced on the young wood.

The second sort grows naturally in *Sicily*, from whence I received a parcel of the seeds, and raised a good number of the plants; all of these were totally different in their leaves from the common Mulberry, so that I am certain of its being a distinct species. It is also a tree of humbler growth, but the fruit is small and has no flavour, so is not worth propagating; some of the trees produced fruit two or three years in the *Chelsea* garden.

The white Mulberry is commonly cultivated for its leaves to feed silk worms, in *France*, *Italy*, &c. though the *Persians* always make use of the common black Mulberry for that purpose; and I have been assured by a gentleman of honour, who has made trial of both sorts of leaves, that the worms fed with those of the black produce much better silk than those fed with the white; but he observes, that the leaves of the black sort should never be given to the worms, after they have eaten for some time of the white, lest the worms should burst, which is often the case when they are thus treated.

The trees which are designed to feed silk worms, should never be suffered to grow tall, but rather kept in a sort of hedge;

hedge; and instead of pulling off the leaves singly, they should be sheared off together with their young branches; which is much sooner done, and not so injurious to the tree.

This white sort may be propagated either from seeds or layers, as the black Mulberry, and is equally hardy; but the most expeditious method of raising these trees in quantity, is from the seeds, which may be procured in plenty from the south of *France* and *Italy*. The best way to sow these seeds in *England*, is to make a moderate hot-bed, which should be arched over with hoops, and covered with mats; upon this bed the seeds should be sown in the middle of *March*, and covered over with light earth about a quarter of an inch deep: in very dry weather the bed must be frequently watered, and in the heat of the day shaded with mats, and also covered in the nights when they are cold. With this management the plants will come up in five or six weeks, and as they are tender when they first appear, so they must be guarded against frosty mornings, which often happen in *May*. During the summer they must be kept clean from weeds, which is all the culture they require: but there must be care taken of them the first winter, especially to cover them in autumn, when the first frosts come, which will kill the tender plants to the ground, if they are not protected; the following *March* these plants should be transplanted into the nursery to get strength, where they may remain two or three years, and then should be removed where they are to continue.

There are two or three varieties of this tree, which differ in the shape and size of their leaves, and colour of their fruit; but as they are of no other use than for their leaves, the strongest shooting and that with the largest leaf should be preferred.

The third sort, which is the large-leaved *Virginian* Mulberry with black shoots, is more uncommon than either of the former. The leaves of this are somewhat like those of the common Mulberry tree, but are rougher and longer.

This tree is propagated only by seeds, for it will not take by grafting or budding, either on the black or white Mulberries, for it has often been tried on both, but without success. The seeds of this may be procured from *North America*. This is very hardy, and will endure the cold of our climate in the open air very well, and is coveted as a curiosity by such as delight in the variety of trees and shrubs.

The fifth sort is the tree whose wood is used by the dyers, and is better known by the title of Fustick, which is given to the wood, than by its fruit, which is of no estimation. This grows naturally in most of the islands in the *West-Indies*, but in much greater plenty at *Campeachy*, where it abounds. This wood is one of the commodities exported from *Jamaica*, where it grows in greater plenty than in any other of the *British* islands.

This tree, in the countries where it grows naturally, rises to the height of sixty feet and upward; it has a light brown bark, which hath some shallow furrows; the wood is firm, solid, and of a bright yellow colour. It sends out many branches on every side, covered with a white bark, garnished with leaves about four inches long, which are broad at their base, indented at the foot stalks, where they are rounded, but one side is broader than the other, so that they are oblique to the foot-stalk; these diminish gradually, and end in acute points; they are rough like those of the common Mulberry, of a dark green, and stand upon short foot-stalks. Toward the end of the young branches, come out short katkins of a pale herbaceous colour, and in other parts of the same branches the fruit is produced, growing upon short foot-stalks; they are as large as Nutmegs of a roundish form, full of protuberances like the common Mulberry, green within, and on the outside, of a luscious sweet taste when ripe.

It is too tender to thrive in this country, unless preserved in a warm stove. The seeds of this plant come up very freely on a hot-bed, and when the plants are fit to remove, they should be each planted in a separate small pot filled with fresh light earth, and plunged into a hot-bed of tanners bark, and shaded from the sun till they have taken new root; then they should be treated in the same way as other plants from those hot countries, always keeping them in the tan-bed in the stove, where they will make good progress. These plants retain their leaves all the year in the stove.

The sixth sort grows naturally in *China* and *Japan*, where the inhabitants make paper of the bark; they cultivate the trees for that purpose on the hills and mountains, much after the same manner as Osiers are cultivated here, cutting down the young shoots in autumn for their bark. There were several of these trees raised from seeds a few years past, in the gardens of the Right Hon. the Earl of *Northumberland*, who was so good as to favour me with one of the plants, which thrives very well in the open air, without any shelter, as many of the trees and plants of those countries will do, if they grow on the mountains. This plant makes very strong vigorous shoots, but seems not to be of tall growth, for it sends out many lateral branches from the root upward. The leaves are large, some of them are entire, others are deeply cut into three, and some into five lobes, in form of a hand, while the plants are young; they are of a dark green, and rough to the touch, but of a pale green, and somewhat hairy on the under side, falling off on the first approach of frost in autumn, as do those of the common Mulberry. The description which *Kaempfer* gives of the fruit is, that they are a little larger than Peas, surrounded with long purple hairs, are composed of acini, or protuberances, and when ripe change to a black purple colour, and are full of sweet juice.

This tree may be propagated by laying down of the branches, in the same way as is practised for the common Mulberry, or it may be multiplied by planting of the cuttings, in the same manner as before directed for the common sort.

The seventh sort grows naturally in *India*, where it becomes a large tree. It hath a soft, thick, yellowish bark, with a milky juice like the Fig tree, which is astringent. The branches come out on every side, which are garnished with oblong oval leaves, standing upon short foot-stalks; both sides of these leaves are equal, but their edges are unequally sawed; they are rough, of a dark green on their upper side, but pale on their under, standing alternately on the branches. The flowers come out in round heads at the foot-stalks of the leaves, on each side the branches; they are of an herbaceous white colour; the male flowers have four stamina; the female flowers are succeeded by roundish fruit, which are first green, afterwards white, and when ripe turn to a dark red colour.

The plants are too tender to live out of a stove in this country, for as I raised a good number of the plants, so when they had obtained strength, I placed some of them in different situations, where they were defended from the frost, but not any of them survived the winter, but those which were in the bark-stove, where they are constantly kept, and treated in the same manner as other tender plants, giving them but little water in winter; with which management the plants thrive, and retain their leaves all the year.

MOSCHATELLINA. See Adoxa.

MOSS. See Muscus.

MOTHERWORT. See Cardiaca.

MOULD, the goodness of which may be known by the sight, smell, and touch.

First, by the sight: those moulds that are of a bright Chestnut, or hazelly colour, are counted the best; of this

colour are the best loams, and also the best natural earth; and this will be the better yet, if it cuts like butter, and does not stick obstinately, but is short, tolerably light, breaking into small clods, is sweet, will be tempered without crusting or chapping, in dry weather, or turning to mortar in wet.

The next to that, the dark gray and russet moulds are accounted the best, but the clear tawny is by no means to be approved, and that of a yellowish red colour is accounted the worst of all; this is commonly found in wild and waste parts of the country, and, for the most part, produce nothing but Furz and Fern, according as their bottoms are more or less of a light and sandy, or of a spewy gravel, or clayey nature.

Secondly, by the smell: all lands that are good and wholesome, will, after rain, or breaking up by the spade, emit a good smell.

Thirdly, by the touch: by this means we may discover whether it consists of substances entirely arenaceous or clammy; or, according as it is expressed by Mr. Evelyn, whether it be tender, fatty, detersive, or slippery, or more harsh, gritty, porous, or friable.

That being always the best that is between the two extremes, and does not contain the two different qualities of soft and hard mixed, of moist and dry, of churlish and mild, that is, neither too unctuous or too lean, but such as will easily dissolve, of a just consistence, between sand and clay, and such as will not stick to the spade or fingers upon every flash of rain.

MULBERRY. See Morus.

MULLEIN. See Verbascum.

MUMMY, is a sort of grafting wax, made of one pound of common black pitch, and a quarter of a pound of common turpentine, put into an earthen pot, and set on the fire in the open air: in doing this, you ought to hold a cover in your hand, ready to cover it, in order to quench it, by putting it thereon, which is to be done several times, setting it on the fire again, that the nitrous and volatile parts may be evaporated. The way to know when it is enough, is by pouring a little of it upon a pewter plate, and if it be so it will coagulate presently; then this melted pitch is to be poured into another pot, and a little common wax is to be added to it, mixing them well together, and then to be kept for use.

MUNTINGIA. Plum. Gen. Nov. 41. tab. 6. Lin. Gen. Plant. 575.

The Characters are,

The empalement of the flower is cut into five segments. The flower hath five heart-shaped petals, inserted in the empalement, and spread open like a Rose. It has a great number of stamina. In the center is situated a roundish germen, having no style, but is crowned by a stigma divided into many parts. The germen afterward turns to a soft fruit, with one cell, crowned by the stigma, like a navel, and filled with small seeds.

The Species are,

1. MUNTINGIA foliis cordato-lanceolatis acuminatis subtus tomentosis, pedunculis unifloris. Muntingia with heart spear-shaped leaves, ending in acute points, woolly on their under side, and foot-stalks having one flower.

2. MUNTINGIA foliis lanceolatis scabris trinervis, floribus confertis axillaribus sessilibus. Muntingia with rough spear-shaped leaves, having three veins, and flowers growing in clusters from the wings of the stalk, sitting close.

3. MUNTINGIA foliis oblongo-ovatis acutis rugosis, floribus alaribus confertis pedunculatis. Muntingia with oblong, oval, acute, rough leaves, and flowers growing in clusters upon foot-stalks at the wings of the stalk.

The first sort is figured and described by Sir Hans Sloane, in his *History of Jamaica*, by the title of *Loti arboris folio*

angustiore, rubi flore, fructu polyspermo umbilicato. 2. p. 80.

This tree rises to the height of thirty feet or more, in its native soil, sending out many branches toward the top, which are garnished with oblong heart-shaped leaves, which end in acute points, are very woolly on their under side, but smooth above, of a lucid green, slightly sawed on their edges, and placed alternately. The flowers come out from the wings of the stalk, standing upon long foot-stalks; they are composed of five heart-shaped petals, which are white, and spread open, resembling those of the Bramble, having many stamina, about half the length of the petals, terminated by globular summits, and in the center is situated a roundish germen, crowned by a many-pointed stigma. The germen afterward turns to a pulpy umbilicated fruit, as large as the fruit of the Cockspur Hawthorn, and, when ripe, of a dark purple colour, inclosing many small, hard, angular seeds. This sort has produced flowers and fruit in *England*.

The second sort grows naturally in *Jamaica*. This seldom rises more than twelve or fourteen feet high, sending out many branches the whole length, which are covered with a dark brown bark, garnished with spear-shaped leaves, about two inches long, and half an inch broad; they are very rough, and their borders are reflexed, standing alternately pretty close together, on very short foot-stalks. The flowers come out at every leaf in clusters, sitting very close to the stalks; they are small, white, and shaped like those of the first, and are succeeded by small umbilicated fruit, of a yellowish colour when ripe.

The third sort grows in the *West-Indies*, where it rises from twelve to fifteen feet high, sending out many hairy branches, covered with a light brown bark, garnished with oval leaves, ending in acute points; they are rough, and a little hairy, have six veins, which come out from the midrib, two arising near the base, two more a little higher, and the other two near the point; these diverge toward the borders of the leaf, but meet again at the point; they are of a yellowish green. The flowers come out in small clusters from the side of the branches, standing upon short foot-stalks; they are small, of a yellowish colour, and shaped like those of the other sorts, and are succeeded by small Orange-coloured fruit.

These plants are propagated by seeds, which should be sown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark. The seeds will often remain in the ground a whole year before the plants will appear, in which case the pots must be kept constantly clear from weeds, and should remain in the hot-bed till after *Michaelmas*, when they may be removed into the stove, and plunged into the bark-bed, between other pots of tall plants, where there is not room for plants to stand, where they may remain. During the winter season, these pots should be now and then watered, when the earth appears dry, and in the beginning of *March* the pots should be removed out of the stove, and placed into a fresh bark-bed under frames, which will bring up the plants soon after.

When the plants are come up about two inches high, they should be carefully taken out of the pots, and each planted into a separate small pot filled with light rich earth, and then plunged into the hot-bed again, observing to shade them from the sun, until they have taken new root; after which time they should be duly watered, and in warm weather they must have a large share of fresh air. In this hot-bed the plants may remain till autumn, when the nights begin to be cold; at which time they should be removed into the stove, and plunged into the bark-bed. During the winter season, these plants must be kept warm, especially while they are young, and frequently refreshed with water; but it must not be given to them in large quantities, lest it rot the tender fibres of their roots. It will be proper to continue

continue these plants in the stove all the year, but in warm weather they should have a large share of air; but as the plants grow in strength, they will be more hardy, and may be more exposed in summer, and in winter will live in a dry stove, if kept in a moderate degree of heat.

MURUCUIA. See Passiflora.

MUSA. Plum. Nov. Gen. 24. tab. 34. Lin. Gen. Plant. 1010. The Plaintain tree.

The Characters are,

It hath male and hermaphrodite flowers upon the same stalk; these are produced on a single stalk (or spadix); the male flowers are situated on the upper part of the spike, and the hermaphrodite below; these are in bunches, each bunch having a sheath or cover, which falls off. The flowers are of the lip kind. The petals constitute the upper lip, and the nectarium the under; they have six awl-shaped stamina, five of which are situated in the petal, and the sixth in the nectarium; this is double the length of the other, terminated by a linear summit, the others have none. The germen is situated under the flower, which is long, having three obtuse angles supporting an erect cylindrical style, crowned by a roundish stigma. The germen afterward turns to an oblong, three-cornered, fleshy fruit, covered with a thick rind, divided into three parts.

The Species are,

1. MUSA *spadice nutante, fructu longiore triquetro*. Musa with a nodding spike, and a long three-cornered fruit; commonly called Plaintain tree.

2. MUSA *spadici nutante, fructu brevior obtuse-angulo*. Musa with a nodding spike, and a short fruit with obtuse angles; commonly called Banana.

The first sort is cultivated in all the islands of the *West-Indies*, where the fruit serves the negroes for bread, and some of the white people also prefer it to most other things, especially to the Yams, and Cassada bread.

This plant rises with a soft herbaceous stalk fifteen or twenty feet high; the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side; these are often six feet long, and near two feet broad, with a strong fleshy midrib, and a great number of transverse veins running from the midrib to the borders. The leaves are thin and tender, so that where they are exposed to the open air, they are generally torn by the wind, for as they are large, the wind has great power against them; these leaves come out from the center of the stalk, and are rolled up at their first appearance, but when they are advanced above the stalk, they expand and turn backward; as these leaves come up rolled in the manner before-mentioned, their advance upward is so quick, that their growth may almost be discerned by the naked eye; and if a fine line is drawn across, level with the top of the leaf, in an hour's time the leaf will be near an inch above it. When the plant is grown to its full height, the spike of flowers will appear in the center, which is often near four feet in length, and nods on one side. The flowers come out in bunches, those on the lower part of the spike being the largest, the others diminish in their size upward; each of these bunches is covered with a spathæ, or sheath, of a fine purple colour, which drops off when the flowers open. The upper part of the spike is made up of male or barren flowers, which are not succeeded by fruit, but fall off with their covers. The fruit of this is eight or nine inches long, and above an inch diameter, a little incurved, and has three angles; it is at first green, but when ripe of a pale yellow colour. The skin is tough, and within is a soft pulp of a luscious sweet flavour. The spikes of fruit are often so large, as to weigh upward of forty pounds.

The fruit of this sort is generally cut before it is ripe, and roasted in the embers, then is eaten instead of bread.

The leaves are used for napkins and table-cloths, and are food for hogs.

The second sort, which is commonly called Banana, differs from the first, in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste, so is generally eaten by way of desert, and seldom used in the same way as the Plaintain, therefore is not cultivated in such plenty.

Both these plants were carried to the *West-Indies*, from the *Canary Islands*, to which place it is believed they were carried from *Guinea*, where they grow naturally; they are also cultivated in *Egypt*, and in most other hot countries, where they grow to perfection in about ten months, from their first planting to the ripening of their fruit, when their stalks are cut down, and several suckers come up from the root; soon after which they will also produce fruit in ten months after, so that by cutting down the stalks at different times, there is a constant succession of fruit all the year.

In *Europe* there are some of these plants preserved in the gardens of curious persons, who have hot-houses capacious enough for their reception, in many of which they have ripened their fruit very well; but as they grow very tall, and their leaves are large, they require more room in the stove, than most people care to allow them; they are propagated by suckers, which come from the roots of those plants which have fruited; and many times the younger plants, when they are stunted in growth, will put out suckers; these should be carefully taken off, preserving some fibres to their roots, and planted in pots filled with light rich earth, and plunged into the tan-bed in the stove; they may be taken off any time in summer, and it is best to take them off when young, because if their roots are grown large, they do not put out new fibres so soon, and when the thick part of the root is cut in taking off, the plants often rot.

During the summer season these plants must be plentifully watered, for the surface of their leaves being large, there is a great consumption of moisture, by perspiration, in hot weather, but in the winter they must be watered more sparingly, though at that season they must be often refreshed, but it must not be given them in such quantities.

The pots in which these plants are placed, should be large, in proportion to the size of the plants, for their roots generally extend pretty far, and the earth should be rich and light. The degree of heat with which these plants thrive best, is much the same with the Anana, or Pine Apple, in which I have had many of these plants produce their fruit in perfection, and they were near twenty feet high.

The most sure method to have these plants fruit in *England* is, after they have grown for some time in pots, so as to have made good roots, to shake them out of the pots with the ball of earth to their roots, and plant them into the tan-bed in the stove, observing to lay a little old tan near their roots, for their fibres to strike into, and in a few months the roots of these plants will extend themselves many feet each way in the bark, and these plants will thrive a great deal faster than those which are confined in pots or tubs. When the bark-bed wants to be renewed with fresh tan, there should be great care taken of the roots of these plants, not to cut, or break them, as also to leave a large quantity of the old tan about them, because, if the new tan is laid too near them, it will scorch their roots, and injure them. If the plants push out their flower-stems in the spring, there will be hopes of their perfecting their fruit, but when they come out late in the year, the plants will sometimes decay before the fruit is ripe. The stoves in which these plants are placed, should be at least twenty feet in height, otherwise there will not be room for their leaves to expand; for when the plants are in vigour, the leaves are often eight feet in length, and

near three feet broad; so that if the stems grow to be fourteen feet to the division of the leaves, and the house is not twenty feet high, the leaves will be cramped, which will retard the growth of the plant; besides, when the leaves are bent against the glass, there will be danger of their breaking them, when they are growing vigorously; for I have had, in one night, the stems of such bent leaves force through the glass, and by the next morning advanced two or three inches above the glass.

I have seen some bunches of fruit of the first sort, which were upward of forty pounds weight, and perfectly ripe in *England*; but this is not so good a fruit, as to tempt any person to be at the expence of raising them in *England*: the second sort is preferred to the first, for the flavour of its fruit, in all those hot countries where these plants abound; the bunches of these are not near so large as those of the first sort, nor are the single fruit near so long; these change to a deeper yellow colour, as they ripen, but their taste is somewhat like that of mealy Figs. Some persons who have resided in the *West-Indies*, having eaten some of these fruit, which were produced in *England*, have thought them little inferior to those which grew in *America*; and I imagine, that the inhabitants of those countries would not esteem these fruits so much, had they variety of other sorts; but, for want of better, they eat many kinds of fruit, which would not be valued in *Europe*, could they be obtained in perfection.

MUSCARI. *Tourn. Inst. R. H.* 347. *tab.* 180. Musk, or Grape Hyacinth.

The Characters are,

The flower has no empalement. It hath one oval pitcher-shaped petal, which is reflexed at the brim. It hath three nectariums on the top of the germen, and six awl-shaped stamina, which are shorter than the petal, whose summits join together. In the center is situated a roundish three-cornered germen, supporting a single style, crowned by an obtuse stigma. The germen afterward turns to a roundish three-cornered capsule, having three cells filled with roundish seeds.

The Species are,

1. MUSCARI *corollis globosis uniformibus, foliis canaliculato-cylindricis*. Muscari with uniform globular petals, and cylindrical gutter-shaped leaves; commonly called Grape Hyacinth.

2. MUSCARI *corollis angulato-cylindricis, summis sterilibus longius pedicellatis*. Muscari with angular cylindrical petals, which on the top of the spike are barren, and have longer foot-stalks; commonly called Fair-haired Hyacinth.

3. MUSCARI *corollis ovatis*. Muscari with oval petals; commonly called Musk Hyacinth.

4. MUSCARI *floribus paniculatis monstrosis*. Muscari with monstrous flowers growing in panicles; called Feathered Hyacinth.

5. MUSCARI *paniculâ ramosâ, floribus monstrosis*. Muscari with a branching panicle, and monstrous flowers.

6. MUSCARI *corollis irregularibus sexpartitis*. *Lin. Sp. Plant.* 318. Muscari with irregular petals, which are cut into six parts.

The first sort grows naturally in the vineyards and arable fields, in *France*, *Italy*, and *Germany*, and where it is once planted in a garden, it is not easily rooted out again; for the roots multiply greatly, and if they are permitted to scatter the seeds, the ground will be filled with the roots: there are three varieties of this, one with blue, another with white, and a third with Ash-coloured flowers; it hath a small, round, bulbous root, from which come out many narrow gutter-shaped leaves; between these arise the flower-stalk, which is naked below, but toward the top garnished with a close spike of blue flowers, shaped like pitchers, sitting very close to the stalk; these smell like fresh starch, or the stones of

Plums which are fresh. They flower in *April*, and the seeds ripen the latter end of *June*.

The second sort grows naturally in *Spain* and *Portugal*, from whence I have received both roots and seeds. This hath a bulbous root, as large as a middling Onion, from which come out five or six leaves a foot long, and three quarters of an inch broad at their base, diminishing gradually to a point. The flower-stalk rises about a foot high, naked the lower half, but the upper is garnished with cylindrical, angular, purple flowers, standing upon foot-stalks half an inch long; these grow horizontally, but the stalk is terminated by a tuft of flowers, whose petals are oval, and have neither germen or style, so are barren. This sort flowers the latter end of *April*, or the beginning of *May*; there is a variety of this with white, and another with blue flowers, but the purple is the most common.

The third sort hath pretty large, oval, bulbous roots, from which arise several leaves, which are about eight or nine inches long, and half an inch broad, which end in obtuse points; these embrace each other at their base; out of the middle of these, the naked stalk which sustains the flowers arises, garnished at the top with small flowers growing in a spike; these have oval pitcher-shaped petals, which are reflexed at their brim, and are of an Ash-coloured purple, or obsolete colour, seeming as if faded, but have an agreeable musky scent; the stalks do not rise more than six inches high, so the flowers make no great appearance, but where they are in some quantity, they will perfume the air to a considerable distance. This sort flowers in *April*, and the seeds ripen in *July*.

Of this there are two varieties, one of which has the same coloured flowers with this here enumerated, on the lower part of the spike, but they are larger, and have more of the purple cast, but the flowers on the upper part of the spike are yellow, and have a very grateful odour. The *Dutch* gardeners title it *Tibcadi Muscari*. As this is supposed to be only a femal variety of the third, I have not enumerated it as distinct. There is another variety of this with very large yellow flowers, that has been lately raised from seeds in *Holland*, which the florists there sell for a guinea a root.

The fourth sort hath a large bulbous root, from which come out several plain leaves. The flower-stalks rise near a foot and a half high, and are terminated by panicles of flowers standing upon long foot-stalks, each sustaining three, four, or five flowers, whose petals are cut into slender filaments, like hairs; they are of a purplish blue colour, and have neither stamina or germen, so do never produce seeds. It flowers in *May*, and, after the flowers are past, the stalks and leaves decay to the root, and new ones arise the following spring.

The fifth sort has a round, solid, bulbous root, covered with a purple skin. The leaves are about the same length with those of the former sort, but are narrower, and their borders are incurved, so are formed gutter fashion. The stalks rise about a foot high, but are slender, so that unless they are supported, they decline toward the ground, especially when the flowers come out; these have two or three long narrow leaves; the stalks are naked to the panicle, which is much shorter than that of the former sort, but branches out wide on every side. The petals of the flowers are cut into finer filaments, which turn back, like the curls of hair; these have neither stamina or style, so never produce seeds; they are of a dark purple colour, and appear in *May*; in *July* the stalks and leaves decay to the root: this has been an old inhabitant in some of the *English* gardens, but from whence it originally came is not easy to trace.

The sixth sort grows naturally at the *Cape of Good Hope*. This hath a small, white, bulbous root, about the size of a Hazel

Hazel nut, from which comes out generally but two (though sometimes when the roots are strong) three leaves, which are five or six inches long, and one inch and a half broad in the middle, ending in obtuse points; these are of a lucid green, and have many spots or protuberances on their upper surface. The flower-stalk rises between them to the height of six or seven inches; it is round, smooth, and naked for three inches high, or more, and is terminated by a spike of flowers, which are of a pale sulphur colour; these have no foot-stalks; they have one petal, which is of an irregular figure, and cut at the top into six parts. The stamina are almost equal with the petal, and stand round the style, which is of the same length. The flowers appear in *March*, but are seldom succeeded by good seeds here.

The five first sorts are very hardy, so will thrive in the open air, and require no other culture than any other hardy, bulbous-rooted flowers, which is to take up their roots every second or third year, to separate their bulbs, for as some of the sorts multiply pretty fast, so when they are become large bunches, they do not flower so strong, as when they are single; the best time to take them out of the ground, is soon after their stalks and leaves are decayed; then they should be spread on a mat, in a dry shady room, for a fortnight to dry, after which they may be kept in boxes like other bulbous roots, till *Michaelmas*, when they may be planted again in the borders of the flower-garden, and treated in the same way as the common hardy kinds of Hyacinths.

The first sort should not be admitted into the flower-garden, because the roots will propagate so fast, as to become a troublesome weed there.

The second sort has but little beauty, so a few of these only should be allowed a place merely for the sake of variety: this is so hardy, as to thrive in any soil or situation.

The third sort merits a place for the extreme sweetness of its flowers, but especially that variety of it with yellow flowers, called Tibcady.

The fourth and fifth sorts may also be allowed to have place in the common borders of the pleasure-garden, where they will add to the variety, and are by no means to be despised.

They are all easily propagated by offsets, which most of their roots send out in pretty great plenty, so that there is little occasion for sowing of their seeds, unless it be to gain some new varieties.

The sixth sort is too tender to thrive in the open air in *England*, so the roots must be planted in small pots, filled with light rich earth, and in the autumn they should be placed under a hot-bed frame, where they may be protected from frost, but should have as much free air as possible in mild weather; for when these are placed in a green-house, their leaves are drawn long and narrow, and the flower-stalks are generally weak, so never flower so well as when they have plenty of free air. These flowers will continue a month where they are not drawn, but will decay in half that time in a green-house.

These roots should be transplanted in *July*, when their stalks and leaves are decayed; and should be placed in the open air during the summer season, but should have very little water when their leaves are decayed.

MUSCIPULA. See *Silene*.

MUSCOSE, MUSCOSUS, Mossy, or abounding with Moss.

MUSCOSITY, Mossiness.

MUSCUS, Moss.

These, though formerly supposed to be only excrescences produced from the earth, trees, &c. yet are no less perfect plants than those of greater magnitude, having roots, branches, flowers, and seeds, but yet cannot be propagated from the latter by any art.

The botanists distinguish these into several genera, under each of which are several species; but as they are plants of no use or beauty, it would be to no purpose to enumerate them in this place.

MUSHROOMS are, by many persons, supposed to be produced from the putrefaction of the dung, earth, &c. in which they are found; but notwithstanding this notion is pretty generally received amongst the unthinking part of mankind, yet by the curious naturalists they are esteemed perfect plants, though their flowers and seeds have not as yet been perfectly discovered. But since they may, and are annually propagated by the gardeners near *London*, and are (the esculent sort of them) greatly esteemed by most curious palates, I shall briefly set down the method practised by the gardeners who cultivate them for sale.

But first, it will not be improper to give a short description of the true eatable kind, since there are several unwholesome sorts, which have been by unskilful persons gathered for the table.

The true Champignon, or Mushroom, appears at first of a roundish form like a button; the upper part of which, as also the stalk, is very white, but being opened, the under part is of a livid flesh colour; but the fleshy part, when broken, is very white: when these are suffered to remain undisturbed, they will grow to a large size, and explicate themselves almost to a flatness, and the red part underneath will change to a dark colour.

In order to cultivate them, if you have no beds in your own, or in neighbouring gardens, which produce them, you should look abroad in rich pastures, during the months of *August* and *September*, until you find them (that being the season when they are naturally produced); then you should open the ground about the roots of the Mushrooms, where you will find the earth, very often, full of small white knobs, which are the offsets, or young Mushrooms; these should be carefully gathered, preserving them in lumps with the earth about them: but as this spawn cannot be found in the pasture, except at the season when the Mushrooms are naturally produced, you may probably find some in old dunghills, especially where there has been much litter amongst it, and the wet hath not penetrated it to rot it; as likewise by searching old hot-beds it may be often found, for this spawn has the appearance of a white mold, shooting out in long strings, by which it may be easily known, wherever it is met with: or this may be procured by mixing some long dung from the stable, which has not been thrown on a heap to ferment; which being mixed with strong earth, and put under cover to prevent wet getting to it, the more the air is excluded from it, the sooner the spawn will appear; but this must not be laid so close together as to heat, for that will destroy the spawn: in about two months after, the spawn will appear, especially if the heap is closely covered with old thatch, or such litter as hath lain long abroad, so as not to ferment, then the beds may be prepared to receive the spawn: these beds should be made of dung, in which there is good store of litter, but this should not be thrown on a heap to ferment; that dung which hath lain spread abroad for a month or longer, is best; these beds should be made on dry ground, and the dung laid upon the surface; the width of these beds at bottom should be about two feet and a half, or three feet, the length in proportion to the quantity of Mushrooms desired; then lay the dung about a foot thick, covering it about four inches with strong earth. Upon this lay more dung, about ten inches thick; then another layer of earth, still drawing in the sides of the bed, so as to form it like the ridge of a house, which may be done by three layers of dung and as many of earth. When the bed is finished, it should be covered with litter or old thatch, to keep out wet, as also

to prevent its drying; in this situation it may remain eight or ten days, by which time the bed will be in a proper temperature of warmth to receive the spawn; for there should be only a moderate warmth in it, great heat destroying the spawn, as will also wet; therefore when the spawn is found, it should always be kept dry until it is used, for the drier it is, the better it will take in the bed; for I had a parcel of this spawn, which had lain near the oven of a stove upward of four months, and was become so dry, that I despaired of its success; but I never have yet seen any which produced so soon, nor in so great quantity as this.

The bed being in a proper temperature for the spawn, the covering of litter should be taken off, and the sides of the bed smoothed; then a covering of light rich earth, about an inch thick, should be laid all over the bed, but this should not be wet; upon this the spawn should be thrust, laying the lumps two or three inches asunder; then gently cover this with the same light earth, above half an inch thick, and put the covering of litter over the bed, laying it so thick as to keep out wet, and prevent the bed from drying: when these beds are made in the spring or autumn, as the weather is in those seasons temperate, so the spawn will then take much sooner, and the Mushrooms will appear perhaps in a month after making; but those beds which are made in summer, when the season is hot, or in winter, when the weather is cold, are much longer before they produce.

The great skill in managing of these beds is, that of keeping them in a proper temperature of moisture, never suffering them to receive too much wet: during the summer season, the beds may be uncovered to receive gentle showers of rain at proper times; and in long dry seasons the beds should be now and then gently watered, but by no means suffer much wet to come to them; during the winter season they must be kept as dry possible, and so closely covered as to keep out cold. In frosty or very cold weather, if some warm litter shaken out of a dung heap is laid on, it will promote the growth of the Mushrooms; but this must not be laid next the bed, but a covering of dry litter between the bed and this warm litter; and as often as the litter is found to decay, it should be renewed with fresh; and as the cold increases, the covering should be laid so much thicker. If these things are observed, there may be plenty of Mushrooms produced all the year; and these produced in beds, are much better for the table than any of those which are gathered in the fields.

A bed thus managed, if the spawn takes kindly, will continue good for several months, and produce great quantities of Mushrooms; from these beds when they are destroyed, you should take the spawn for a fresh supply, which may be laid up in a dry place until the proper season of using it; which should not be sooner than five or six weeks, that the spawn may have time to dry before it is put into the bed, otherwise it will not succeed well.

Sometimes it happens, that beds thus made do not produce any Mushrooms till they have lain five or six months, so that these beds should not be destroyed, though they should not at first answer expectation; for I have frequently known these to have produced great quantities of Mushrooms afterward, and have continued a long time in perfection.

MUSTARD. See Sinapis.

MYAGRUM. *Tourn. Inst. R. H.* 211. tab. 99. Gold of Pleasure.

The Characters are,

The empalement of the flower is composed of four oblong coloured leaves. The flower hath four roundish obtuse petals, placed in form of a cross. It hath six stamina the length of the petals, four of which are a little longer than the other. In the

center is situated an oval germen, which afterward becomes a turbinated, heart-shaped, little pod, having two valves, with the rigid style in the top, inclosing roundish seeds.

The Species are,

1. MYAGRUM *filiculis ovatis, pedunculatis polyspermis.* Hort. Cliff. 328. Myagrums with oval pods having foot-stalks, inclosing one seed; commonly called Gold of Pleasure.

2. MYAGRUM *filiculis cordatis pedunculatis polyspermis, foliis denticulatis obtusis.* Myagrums with heart-shaped pods standing upon foot-stalks, having many seeds and indented leaves.

3. MYAGRUM *filiculis globosis compressis punctato-rugosis.* Hort. Cliff. 328. Myagrums with globular, compressed, small pods, having rough punctures; or Field Charlock with an acute-eared leaf.

4. MYAGRUM *filiculis biarticulatis dispermis, foliis extrorsum sinuatis denticulatis.* Hort. Upsal. 182. Myagrums with short pods, having two joints and two seeds, whose outer leaves are sinuated and indented.

5. MYAGRUM *filiculis cordatis subsessilibus, foliis amplexicaulis.* Hort. Upsal. 182. Myagrums with small heart-shaped pods sitting close to the stalk, and the leaves embracing it.

The first sort grows naturally in Corn fields in the south of France and Italy; I have also found it growing in the Corn in Easthampsted Park, the seat of the late William Trumbull, Esq; but it is not common in this country. It is an annual plant with an upright stalk, about a foot and a half high, sending out two or four side branches, which grow erect; they are smooth, and have a fungous pith; the lower leaves are of a pale or yellowish green, and are eared at their base; those upon the stalks diminish in their size all the way up, are entire, and almost embrace the stalks with their base. The flowers grow in loose spikes at the end of the branches, standing upon short foot-stalks an inch long; they are composed of four small yellowish petals, placed in form of a cross; these are succeeded by oval capsules, which are bordered and crowned at the top with the style of the flower, having two cells, which are filled with red seeds.

The second sort is also an annual plant, and differs from the first in having a taller stalk; the leaves are much longer, narrower, and are regularly indented on their edges, ending in obtuse points. The flowers are larger, but of the same form and colour; the capsules are much larger, and are shaped like a heart. Both these plants flower in June and July, and their seeds ripen in September.

The third sort grows naturally on the borders of arable fields, in the south of France and Italy. This is an annual plant, whose lower leaves are five or six inches long; they are hairy and succulent; their base is eared, and they end in acute points. The stalks rise a foot and a half high, they are brittle and hairy, branching out toward the top like the two former, and are terminated by short loose spikes of small pale flowers, which are succeeded by small, rough, roundish capsules, compressed at the top. It flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally amongst the Corn, in France and Germany. This is also an annual plant, the lower leaves are large, jagged, and hairy; the stalks branch out from the bottom, and are garnished with hairy leaves, unequally jagged. The stalks are terminated by very long loose spikes of yellow flowers, which are succeeded by short pods with two joints, each including one roundish seed. It flowers about the same time with the former.

The fifth sort grows naturally in the south of France and Italy; this hath a smooth branching stalk upward of two feet high; the lower leaves are five or six inches long, smooth, succulent, and a little indented; the upper leaves almost

almost embrace the stalks with their base. The flowers are produced in long loose spikes, which are yellow, and sit close to the stalk; these are succeeded by heart-shaped compressed pods, divided into two cells by a longitudinal partition, each containing one roundish seed. It flowers at the same time with the former.

If the seeds of all these plants are permitted to scatter in the autumn, the plants will rise without any care, and only require to be thinned and kept clean from weeds. These autumnal plants will always ripen their seeds, whereas those which are sown in the spring sometimes fail.

MYOSURUS, Moustail.

This plant is very near akin to the *Ranunculus*, under which genus it is ranged by some botanists; the flowers are extremely small, and are succeeded by long slender spikes of seeds, resembling the tail of a mouse, from whence it had the name. It grows wild upon moist grounds in divers parts of *England*, where it flowers the latter end of *April*, and the seeds ripen a month after, when the plants decay, being annual.

MYRICA. *Lin. Gen. Plant.* 981. The Candleberry Myrtle, Gale, or Sweet Willow.

The Characters are,

The male flowers are upon different plants from the female; the male flowers are produced in a loose, oblong, oval katkin, imbricated on every side; under each scale is situated one moon-shaped flower, having no petal, but hath four or six short slender stamina, terminated by large twin summits, whose lobes are bifid. The female flowers have neither petal or stamina, but an oval germen supporting two slender styles, crowned by single stigmas. The germen afterward becomes a berry with one cell, inclosing a single seed.

The Species are,

1. MYRICA foliis lanceolatis subserratis, caule fruticoso. *Lin. Sp. Plant.* 1024. Myrica with spear-shaped sawed leaves, and a shrubby stalk; sweet Willow, Dutch Myrtle, or Gale.

2. MYRICA foliis lanceolatis integerrimis, caule fruticoso. Myrica with entire spear-shaped leaves, and a shrubby stalk; commonly called Candleberry Myrtle.

3. MYRICA foliis ovato-lanceolatis serratis, caule fruticoso. Myrica with spear-shaped sawed leaves, and a shrubby stalk; or *Carolina* Candleberry tree, with broader leaves which are more sawed.

4. MYRICA foliis oblongis alternatim sinuatis. *Hort. Cliff.* 450. Myrica with oblong leaves, which are alternately sinuated; or *Maryland* Gale with a Spleenwort leaf.

5. MYRICA foliis oblongis oppositè sinuatis glabris. Myrica with oblong smooth leaves, which are oppositely sinuated.

6. MYRICA foliis oblongis oppositè sinuatis hirsutis. Myrica with oblong hairy leaves, which are oppositely sinuated.

7. MYRICA foliis subcordatis serratis sessilibus. *Hort. Cliff.* 456. Myrica with sawed leaves which are almost heart-shaped, and sit close to the stalk.

The first sort grows naturally upon bogs in many parts of *England*, particularly in the northern and western counties, as also in *Windsor Park*, and near *Tunbridge Wells*. This rises with many shrubby stalks near four feet high, which divide into several slender branches, garnished with stiff spear-shaped leaves, of a light or yellowish green, smooth, and a little sawed at their points, and emit a fragrant odour when bruised. The male flowers or katkins, are produced from the side of the branches, growing upon separate plants from the female, which are succeeded by clusters of small berries, each having a single seed. It flowers in *July*, and the seeds ripen in autumn.

The leaves of this shrub has been by some persons gathered and used for tea, but it is generally supposed to be hurtful to the brain; but from this use of it, a learned physician a few years since, wrote a treatise to prove this

to be the true tea, in which he has only shewn his want of knowledge in these things.

It grows naturally in bogs, so cannot be made to thrive on dry land, for which reason it is seldom preserved in gardens.

The second sort grows naturally in *North America*, where the inhabitants get a sort of green wax from the berries which they make into candles. The method of collecting and preparing of this, is described by Mr. *Catesby*, in his *History of Carolina*.

This grows naturally on bogs and swampy lands, where it rises with many strong shrubby stalks seven or eight feet high, sending out several branches, which are garnished with stiff spear-shaped leaves, having scarce any foot-stalks, of a yellowish lucid green on their upper side, but paler on their under; these have a very grateful odour when bruised. The katkins come out upon different plants from the berries, these are about an inch long, standing erect. The female flowers come out on the side of the branches in longish bunches, which are succeeded by small roundish berries, covered with a sort of meal. This shrub delights in a moist soft soil, in which it thrives exceeding well, and lives in the open air without any protection.

The third sort grows naturally in *Carolina*; this doth not rise so high as the former, the branches are not so strong, and they have a grayish bark; the leaves are shorter, broader, and are sawed on their edges, but in other respects is like the second sort; the berries of this also is collected for the same purpose.

These sorts are propagated by seeds, which should be sown in the autumn, and then the plants will come up the following spring; but if the seeds are kept out of the ground till the spring, they seldom grow till the year after. These plants will require water in dry weather, and should be screened from frosts while young, but when they have obtained strength, they will resist the cold of this country very well in the open air.

The fourth sort grows naturally in *Philadelphia*, from whence many of the plants have been brought to *England*; and those which have been planted on a moist soil, have thriven very well; some of these creep at their roots, and send up suckers plentifully, in the same manner as in their native soil.

This rises with slender shrubby stalks near three feet high, which are hairy, and divide into several slender branches, which are garnished with leaves alternately indented almost to the midrib, and have a great resemblance to those of Spleenwort; they are of a dark green, hairy on their under side, and sit close to the stalks. The male flowers or katkins, come out on the side of the branches between the leaves, these are oval and stand erect. I have not seen any of these plants in fruit, so I can give no description of it.

This sort will propagate by suckers sent out from the roots, where it is planted in a loose moist soil, and endures the cold full as well as the two former sorts.

The fifth and sixth sorts grow naturally at the *Cape of Good Hope*; these only differ from each other, in one having very smooth shining leaves, and those of the other are hairy. I do not know if they are really different species, but as I received them from *Holland* as such, and the plants still retaining their difference, so I have enumerated them both.

These rise with shrubby slender stalks about four feet high, which divide into smaller branches, closely garnished with indented leaves; in one sort they are smooth and shining, and in the other they are hairy, and of a darker green; they sit close to the branches, and end in obtuse points which are indented: between the leaves come out some oval katkins

katkins which drop off, but the fruitful plants produce berries like the former sorts. These retain their leaves all the year, but are too tender to live through the winter in the open air in *England*, so must be placed in the green-house in winter. They are propagated by layers, but as they do not take root very freely, so the plants are not very common in *Europe* at present; for I do not find the cuttings of these plants will take root, having made several trials of them in all the different methods; nor have the *Dutch* gardeners had better success, so that the plants are as scarce there as in *England*.

When the layers are taken off from the old plants, they should be each put into a separate small pot, filled with soft, rich, loamy earth; and if they are placed under a common frame, shading them from the sun in the middle of the day, it will forward their taking new root; then they may be placed in a sheltered situation during the summer, and in the autumn removed into the green-house, and treated in the same way as other plants from the same country. The best season for laying down the branches, I have observed to be in *July*, and by the same time the following year, they have been fit to remove.

The seventh sort is a native of the *Cape of Good Hope*; this hath a weak shrubby stalk, which rises five or six feet high, sending out many long slender branches, which are closely garnished their whole length with small heart-shaped leaves, which sit close on the branches, and are slightly indented and waved on their edges. The flowers come out between the leaves in roundish bunches; these are male in all the plants I have yet seen; they have an uncertain number of stamina, and are all included in one common scaly involucre or cover. These flowers appear in *July*, but make no great appearance; the leaves of this sort continue all the year.

This is propagated in the same way as the two former sorts, and is difficult to increase, so is not common in the *European* gardens. It requires the same treatment as the two former sorts.

MYRRHIS. See *Chærophyllum*, *Scandix*, *Sison*.

MYRTUS. *Tourn. Inst. R. H.* 640. *tab.* 409. Myrtle.

The Characters are,

The empalement of the flower is of one leaf, cut into five points. The flower has five large oval petals which are inserted in the empalement, and a great number of small stamina which are also inserted in the empalement, terminated by small summits. The germen is situated under the flower, supporting a slender style, crowned by an obtuse stigma, which afterward turns to an oval berry with three cells, crowned by the empalement, each cell containing one or two kidney-shaped seeds.

The Species are,

1. MYRTUS *foliis ovatis, pedunculis longioribus*. Myrtle with oval leaves, and longer foot stalks to the flowers; or common broad-leaved Myrtle.

2. MYRTUS *foliis lanceolatis acuminatis*. Myrtle with spear-shaped acute-pointed leaves; or broad-leaved *Dutch* Myrtle.

3. MYRTUS *foliis lanceolato-ovatis acutis*. Myrtle with spear-shaped, oval, acute-pointed leaves.

4. MYRTUS *foliis ovato-lanceolatis confertis*. Myrtle with oval spear-shaped leaves growing in clusters; commonly called Orange-leaved Myrtle.

5. MYRTUS *foliis ovato-lanceolatis acutis, ramis erectioribus*. Myrtle with oval, acute-pointed, spear-shaped leaves, and erect branches; called upright Myrtle.

6. MYRTUS *foliis ovatis, baccis rotundioribus*. Myrtle with oval leaves and rounder berries; called the Box-leaved Myrtle.

7. MYRTUS *foliis lineari-lanceolatis acuminatis*. Myrtle with linear, spear-shaped, acute-pointed leaves; commonly called Rosemary-leaved Myrtle.

8. MYRTUS *pedunculis multifloris, foliis ovatis subpetiolatis*. *Lin. Sp. Plani.* 472. Myrtle with many flowers on each foot-stalk, and oval leaves having short foot-stalks.

The first sort is the common broad-leaved Myrtle, which is one of the hardiest kinds we have. The leaves of this are an inch and a half long, and one inch broad, of a lucid green, standing upon short foot-stalks. The flowers are larger than those of the other sorts, and come out from the side of the branches, on pretty long foot-stalks; these are succeeded by oval berries of a dark purple colour, inclosing three or four hard kidney-shaped seeds. It flowers in *July* and *August*, and the berries ripen in winter. This sort is by some called the flowering Myrtle, because it generally has a greater quantity of flowers, and those are larger than of any other sort.

The second sort has leaves much less than those of the former, and are more pointed, standing closer together on the branches. The flowers are smaller, and have shorter foot-stalks than those of the first sort; this flowers a little later in the summer, and seldom ripens its berries here.

The double flowering Myrtle I take to be a variety of this, for the leaves and growth of the plant, the size of the flowers, and the time of flowering, agree better with this than any of the other sorts.

The third sort grows naturally in the south of *France* and in *Italy*; the leaves of this are much smaller than those of the second, ending in acute points, of a dull green, and set pretty close on the branches. The flowers are smaller than either of the former, and come out from the wings of the leaves toward the end of the branches; the berries are small and oval.

The fourth sort hath a stronger stalk and branches than either of the former sorts, and rises to a greater height; the leaves are oval, spear-shaped, and are placed in clusters round the branches; these are of a dark green. The flowers are of a middling size, and come out sparingly from between the leaves; the berries are oval, and smaller than those of the first sort, but seldom ripen in *England*. The gardeners call this the Orange-leaved Myrtle, and by some it is stiled the Bay-leaved Myrtle. This sort is not so hardy as the former.

The fifth sort is the common *Italian* Myrtle; this hath oval spear-shaped leaves, ending in acute points; the branches of this grow more erect than those of either of the former sorts, as do also the leaves, from whence it is called by the gardeners upright Myrtle. The flowers of this sort are not large, and the petals are marked with purple at their points, while they remain closed; the berries are small, oval, and of a purple colour. There is a variety of this with white berries, in which it only differs from it; and I believe the Nutmeg Myrtle is only a variety of this, for I have raised several of the plants from seed, many of which were so like the *Italian* Myrtle, as not to be distinguished from it.

The sixth sort is commonly called the Box-leaved Myrtle; the leaves of this are oval, small, and sit close on the branches; they are of a lucid green, ending in obtuse points; the branches are weak, and frequently hang downward, when they are permitted to grow without shortening, and have a grayish bark. The flowers are small, and come late in the summer, the berries are small and round.

The seventh sort is called the Rosemary-leaved Myrtle, and by some it is called the Thyme-leaved Myrtle. The branches of this grow pretty erect; the leaves are placed close on the branches; they are small, narrow, and end in acute points; they are of a lucid green, and have a fragrant odour when bruised. The flowers of this are small, and come late in the season, and are but seldom succeeded by berries here.

There are some other varieties of these Myrtles, which are propagated in the gardens for sale; but as their difference has been occasioned by culture, so it would be multiplying their titles to little purpose. Those which are here enumerated, I believe to be really distinct; for I have raised most of them from seeds, and have not found them change from one to another, though there has been other small variations among the plants.

The eighth sort is a native of the island of *Ceylon*; this is much tenderer than either of the former sorts, so cannot be kept through the winter in *England*, without some artificial heat. This hath a strong upright stalk, covered with a smooth gray bark, dividing upward into many slender stiff branches, garnished with oval leaves placed opposite, of a lucid green, and have very short foot-stalks. The flowers come out at the end of the branches, several of them being sustained upon one common foot-stalk, which branches out, and each flower stands on a very slender distinct foot-stalk; they are very like the flowers of *Italian Myrtle*, but always appear in *December* and *January*, and are never succeeded by berries here.

As there are several varieties of the common sorts of Myrtle cultivated in the gardens for sale, I shall just mention the titles by which they are known, that the curious may be informed how many there are:

Two sorts of Nutmeg Myrtles, one with a broader leaf than the other.

The Bird's Nest Myrtle, the Striped Nutmeg Myrtle, the Striped upright Myrtle, the Striped Rosemary-leaved Myrtle, the Striped Box-leaved Myrtle, and the Striped broad-leaved Myrtle.

These plants may all be propagated from cuttings, the best season for which is in the beginning of *July*, when you should make choice of some of the fraittest and most vigorous young shoots, which should be about six or eight inches long; and the leaves on the lower part must be stripped off about two or three inches high, and the part twisted which is to be placed in the ground; then having filled a parcel of pots (in proportion to the quantity of cuttings designed) with light rich earth, you should plant the cuttings therein, at about two inches distance from each other, observing to close the earth fast about them, and give them some water to settle it to the cuttings; then place the pots under a common hot-bed frame, plunging them either into some old dung, or tanners bark, which will prevent the earth from drying too fast; but you must carefully shade them with mats in the heat of the day, and give them air in proportion to the warmth of the season, not forgetting to water them every two or three days, as you shall find the earth in the pots require it. With this management, in about six weeks, the cuttings will be rooted, and begin to shoot, when you must inure them to the open air by degrees, into which they should be removed towards the latter end of *August*, or the beginning of *September*, placing them in a situation, where they may be sheltered from cold winds; in which place they may remain till the middle, or latter end of *October*, when the pots should be removed into the green-house, but should be placed in the coolest part thereof, that they may have air given to them, whenever the weather is mild, for they require only to be protected from severe cold, except the Orange-leaved, and the striped Nutmeg Myrtles, which are somewhat tenderer than the rest, and should have a warmer situation.

If these pots are placed under a common hot-bed frame in winter, where they may be screened from frost, and have the free air in mild weather, the young plants will succeed better than in a green-house, provided they do not receive too much wet, and are not kept closely covered, which will occasion their growing mouldy, and dropping their leaves.

The spring following these plants should be taken out of the pots very carefully, preserving a ball of earth to the roots of each of them, and every one should be placed into a separate small pot filled with rich light earth, observing to water them well to settle the earth to their roots, and place them under a frame until they have taken root, after which they should be inured to the open air, and in *May* they must be placed abroad for the summer, in a sheltered situation, where they may be defended from strong winds.

During the summer season, they will require to be plentifully watered, especially those in small pots, which in that season soon dry; therefore you should observe to place them where they should receive the morning sun; for when they are too much exposed to the sun in the heat of the day, the moisture contained in the earth of these small pots will soon be exhaled, and the plants greatly retarded in their growth thereby.

In *August* following you should shift them into pots a size larger, filling them up with the like rich earth, and observe to trim the roots which were matted to the side of the pots, as also to loosen the earth from the outside of the ball with your hands, some of which should be taken off, that the roots may the easier find passage into the fresh earth; then you must water them well, and place the pots in a situation where they may be defended from strong winds; and at this time you may trim the plants, in order to reduce them to a regular figure; such of them as are inclinable to make crooked stems, you should thrust down a slender strait stick, close by them, to which their stems should be fastened, so as to bring them upright.

If care be taken to train them thus while they are young, the stems afterward, when they have acquired strength, will continue strait without any support, and their branches may be pruned, so as to form either balls or pyramids, which for such plants as are preserved in the green-house, and require to be kept in small compass, is the best method to have them handsome; but then these sheered plants will not produce flowers, for which reason that sort with double flowers should not be clipped, because the chief beauty of that consists in its flowers; but it will be necessary to suffer a plant or two of each kind to grow rude, for the use of their branches in nosegays, &c. for it will greatly deface those which have been constantly sheered to cut off their branches.

As these plants advance in stature, they should annually be removed into larger pots, according to the size of their roots; but you must be careful not to put them into pots too large, which will cause them to shoot weak, and many times prove the destruction of them; therefore when they are taken out of the former pots, the earth about their roots should be pared off, and that within side the ball must be gently loosened, that the roots may not be closely confined; and then place them into the same pots again, provided they are not too small, filling up the sides and bottom of them with fresh rich earth, and giving them plenty of water to settle the earth to their roots, which should be frequently repeated, for they require to be often watered both in winter and summer, but in hot weather they must have it in plenty.

The best season for shifting these plants is either in *April* or *August*, for if it be done much sooner in the spring, the plants are then in a slow growing state, and so not capable to strike out fresh roots again very soon; and if it be done later in autumn, the cold weather coming on will prevent their taking root; nor is it advisable to do it in the great heat of summer, because they will require to be very often watered, and also to be placed in the shade, otherwise they will be liable to droop for a considerable time; and that being the season when these plants should be placed amongst

other exoticks, to adorn the several parts of the garden, these plants, being then removed, could not be exposed until they have taken root again, which, at that time (if the season be hot and dry) will be three weeks, or a month.

In *October*, when the nights begin to be frosty, you should remove the plants into the green-house; but if the weather proves favourable in autumn (as it often happens), they may remain abroad until the beginning of *November*, for if they are carried into the green-house too soon, and the autumn should prove warm, they will make fresh shoots at that season, which will be weak, and often grow mouldy in winter, if the weather should be so severe, as to require the windows to be kept closely shut, whereby they will be greatly defaced; for which reason they should always be kept as long abroad as the season will permit, and removed out again in the spring, before they begin to shoot out; and during the winter season that they are in the green-house, they should have as much free air as possible when the weather is mild.

The three first mentioned sorts I have planted abroad in warm situations, upon a dry soil, where they have endured the cold of our winters for several years very well, with only being covered in very hard frosts with two or three mats, and the surface of the ground about their roots covered with a little mulch to prevent the frost from entering the ground; but in *Cornwall* and *Devonshire*, where the winters are more favourable than in most other parts of *England*, there are large hedges of Myrtle, which have been planted several years, and are very thriving and vigorous, some of which are upward of six feet high; and I believe, if the double flowering kind were planted abroad, it would endure the cold as well as any of the others, it being a native of the southern parts of *France*. This, and the Orange-leaved kind, are the most difficult to take root from cuttings; but if they are planted toward the latter end of *June*, making choice of only such shoots as are tender, and the pots are plunged into an old bed of tanners bark which has lost most of its heat, and the glasses shaded every day, they will take root extremely well, as I have more than once experienced. The Orange-leaved sort, and those with variegated leaves, are somewhat tenderer than the ordinary sorts, and should be housed a little sooner in autumn, and placed farther from the windows of the green-house.

The eighth sort is at present rare in *Europe*, and in very few gardens. This was by *Dr. Linnæus* separated from the Myrtles in the former editions of his works, and had the title of Myrsine applied to it; but in his *Species of Plants*, he has joined it to this genus again, to which, according to his system, it properly belongs; for the number of petals, stamina, and style, do agree with those of the Myrtle, but it differs in fructification, this having but one seed in each fruit, and the Myrtle has four or five.

This plant is with difficulty propagated, which occasions its present scarcity, for as it does not produce ripe seeds in *Europe*, it can only be increased by layers or cuttings. By the former method the layers are commonly two years before they take root, and the cuttings frequently fail, though the latter is preferred, when performed at a proper season, and in a right method; the best time to plant the cuttings is in *May*; in the choice of them, it should be the shoots of the former year, with a small piece of the two years wood at bottom; these should be planted in a soft loamy earth, and covered with bell or hand-glasses to exclude the air; which will be of great service to promote the cuttings putting out roots, and if they are covered with the glasses of the hot-bed above them, it will be yet better: the cuttings should be shaded from the sun, in the heat of the day, and gently refreshed with water, but they should by no means have the glasses moved; so the water given to them must be over the whole, which will soak in and moisten the earth under the glasses; in about five or six weeks they will have taken root, when they should be gradually inured to bear the open air, into which it will be proper to remove them about the middle of *July*, that they may be strengthened before winter. In *August* they should be carefully taken up, and each planted in a small pot filled with light earth from a kitchen garden, and placed in a shady situation till they have taken fresh root; then they should be placed in a sheltered situation, where they may remain till the end of *September*, and then be removed into the stove.

This plant will not live through the winter in *England* in a green-house, but if it is placed in a moderate degree of warmth, it will flower well in winter; and in *July*, *August*, and *September*, the plants should be placed abroad in a sheltered situation.

MYRTUS BRABANTICA. See Myrica.

N.

N A P

NAPPELLUS. See Aconitum.
NAPUS. See Brassica and Rapa.
NAPÆA. *Lin. Gen. Plant.* 748.

The Characters are,

It hath male and hermaphrodite flowers in distinct plants. The male flowers have pitcher-shaped empalements of one leaf. The flowers have five oblong petals, which are connected at their base; they have many hairy stamina, which are joined at the bottom into a sort of cylindrical column. The hermaphrodite flowers have the like empalement, petals, and stamina, as the

N A P

male, and have a conical germen, supporting a cylindrical style, divided at the top into ten parts, crowned by single stigmas. The germen afterward turns to an oval fruit, inclosed in the empalement, divided into ten cells, each containing one kidney-shaped seed.

The Species are,

1. NAPÆA pedunculis involucretis angulatis, foliis scabris floribus dioicis. *Lin. Sp.* Napæa with angular foot-stalks, rough leaves, and male flowers upon different plants from the fruitful.

2. NAPÆA

2. *NAPÆA foliis trilobatis, lobis acuminatis inæqualiter serratis, pedunculis nudis trifloris.* Napæa with leaves having three acute-pointed lobes, which are unequally sawed, and naked foot-stalks with three flowers.

Both sorts have perennial roots, which are composed of many thick fleshy fibres, which strike deep into the ground, and are connected at the top into large heads; the leaves of the first sort are rough, hairy, and are deeply cut into six or seven lobes, which are irregularly indented on their edges, each lobe having a strong midrib, which all meet in a center at the foot-stalk. The foot-stalks are large and long, arising immediately from the root, and spread out on every side. The stalks rise seven or eight feet high, and divide into smaller branches; they are hairy, and garnished at each joint with one leaf, of the same form as those below, but diminish in their size toward the top, where they seldom have more than three lobes; at the upper part of the stalk, come out from the side at each joint, a long foot-stalk, sustaining several white flowers, which are tubulous at bottom, where the segments of the petal are connected, but they spread open above, and are divided into five obtuse segments; in the center arises the column, to which their stamina are joined at their base, but spread open above, and in the hermaphrodite flowers the style is connected to the same column. The hermaphrodite flowers are succeeded by compressed orbicular fruit, inclosed in the empalement, and divided into ten cells, each containing a kidney-shaped seed, but the male plants are barren. It flowers in *July*, and the seeds ripen in autumn, soon after which the stalks decay, but the roots will live many years.

The roots of the second sort frequently creep in the ground, to some distance from the old plant; the stalks rise about four feet high, and are garnished with smooth leaves, placed alternately, standing upon long slender foot-stalks; they are deeply cut into three lobes, which end in acute points, and are irregularly sawed on their edges. At the base of the leaf comes out the foot-stalk of the flower, which is about three inches long, dividing at the top into three smaller, each sustaining one white flower of the same form with those of the first sort, but are smaller, and the column of stamina is longer, their summits standing out beyond the petal; these plants have some male and hermaphrodite flowers on the same plants.

Both these plants grow naturally in *Virginia*, and other parts of *North America*; from the bark of these plants might be procured a sort of hemp, which many of the malvaceous tribe afford; and in some of the sorts which grow naturally in *India*, the fibres of the bark are so fine, as to spin into very fine threads, of which there might be woven very fine cloth.

These plants are easily propagated by seeds, which, if sown on a bed of common earth in the spring, the plants will rise very freely, and will require no other care, but to keep them clear from weeds till autumn, when they may be transplanted into the places where they are to remain; they delight in a rich moist soil, in which they will grow very luxuriantly, so they must be allowed room. The second sort may be propagated by its creeping roots, which may be parted in autumn; but as these plants have no great beauty, so one or two of each sort in a garden, for the sake of variety, will be enough.

NARCISSO LEUCOIUM. See *Galanthus*.

NARCISSUS. *Tourn. Inst. R. H.* 353. *tab.* 185. The Daffodil.

The Characters are,

The flowers are included in an oblong compressed spathe (or sheath), which tears open on the side, and withers. The

flowers have a cylindrical funnel shaped empalement of one leaf, which is spread open at the brim; they have six oval petals on the outside of the nectarium, which are inserted above their base, and six awl-shaped stamina fixed to the tube of the nectarium, terminated by oblong summits; they have a three-cornered, roundish, obtuse germen, situated below the flower, which afterward turns to an obtuse, roundish, three-cornered capsule, with three cells filled with globular seeds.

The Species are,

1. *NARCISSUS spathâ uniflorâ, nectarii limbo campanulato erecto, petalo æquale.* *Lin. Sp. Plant.* 289. Daffodil with one flower in each sheath, whose nectarium is erect, bell-shaped, and equal with the petals; or common *English Daffodil*.

2. *NARCISSUS spathâ uniflorâ, nectarii limbo rotato brevissimo.* *Hort. Upsal.* 74. Daffodil with one flower in a sheath, having a very short wheel-shaped nectarium.

3. *NARCISSUS spathâ uniflorâ, nectarii limbo campanulato erecto, petalo dimidio brevior.* Daffodil with one flower in a sheath, having an erect bell-shaped empalement, half the length of the petal; or the *Incomparable Daffodil*.

4. *NARCISSUS spathâ biflorâ, nectarii campanulato, brevissimo, floribus nutantibus.* Daffodil with two flowers in a sheath, a short bell-shaped nectarium, and nodding flowers; called *Primrose Peerless*.

5. *NARCISSUS spathâ uniflorâ, nectario campanulato brevissimo, petalis reflexis.* Daffodil with one flower in a sheath, having a very short bell-shaped nectarium, and reflexed petals.

6. *NARCISSUS spathâ uniflorâ, nectario turbinato maximo, genitalibus declinatis.* *Lin. Sp. Plant.* 289. Daffodil with one flower in a sheath, having a very large turbinated nectarium, and declined stamina; commonly called the *Hoop Petticoat Narcissus*.

7. *NARCISSUS spathâ uniflorâ, nectario brevissimo sexpartito.* *Læf. Lin. Sp. Plant.* 290. Daffodil with one flower in a sheath, having a very short nectarium, which is cut into six parts; or small autumnal Daffodil.

8. *NARCISSUS spathâ multiflorâ, nectario campanulato, foliis planis.* *Hort. Upsal.* 74. Daffodil with many flowers in a sheath, having a bell-shaped nectarium, and plain leaves; commonly called *Polyanthus Narcissus*.

9. *NARCISSUS spathâ multiflorâ, nectario campanulato brevi, foliis subulatis.* *Hort. Upsal.* 75. Daffodil with many flowers in a sheath, a short bell-shaped nectarium, and awl-shaped leaves; called *Jonquil*.

The sorts here enumerated, are all the real species which I have met with in the *English* gardens, though there is a great variety of each species, which differ so much from one another, as to render it very difficult to ascertain the species to which they belong; in order to find out as well as I could, from what species many of those varieties have been raised, I endeavoured to degenerate as many of the double flowering, and others of the best kinds, so far as I could, by which I have observed several changes, and shall here mention, under each species, the varieties I have observed.

The first sort is the common *English Daffodil*, which grows naturally by the borders of woods, and fields, in many parts of *England*; this hath a large bulbous root, from which comes out five or six flat leaves, about a foot long, and an inch broad, of a grayish colour, a little hollowed in the middle, like the keel of a boat. The stalk rises a foot and a half high, having two sharp longitudinal angles; at the top comes out a single flower, inclosed in a thin spathe (or sheath), which is torn open on one side, to make way for the flower to come out, and then withers and remains on the top of the stalk. The flower is of one petal, or

leaf, being connected at the base, but is cut into six parts almost to the bottom, which expand; in the middle of this is situated a bell-shaped nectarium, called by the gardeners a cup, which is equal in length to the petal, and stands erect. The flower nods on one side the stalk. The petal is of a pale brimstone colour, and the nectarium yellow. It flowers the beginning of *April*, and after the flowers are past, the germen turns to a roundish capsule, with three cells, filled with roundish black seeds, which ripen in *July*. This sort propagates very fast by offsets from the root.

The *Varieties* of this are,

One with white petals, and a pale yellow colour.

One with yellow petals, and a golden cup.

The common, double, yellow Daffodil.

Another double Daffodil with three or four cups within each other.

And, I believe, *John Tradescant's* Daffodil may be referred to this species.

The second sort grows naturally in the south of *France*, and in *Italy*; this has a smaller and rounder bulbous root than the former. The leaves are longer, narrower, and flatter than those of that sort. The stalks do not rise higher than the leaves, which are of a gray colour; at the top of the stalk comes out one flower from the sheath, which nods on one side. The petal of this is cut into six segments, which are rounded at their points; they are of a snow white, and spread open flat. In the center is situated a very short nectarium or cup, which is fringed on the border with a bright purple circle. The flowers have an agreeable odour. This flowers in *May*, but seldom produces seeds, however it increases fast enough by offsets.

The double white Narcissus is the only variety of this which I have observed, though there is mentioned in some books several other.

The third sort grows naturally in *Spain* and *Portugal*, from whence I have received the roots. The bulbs of this sort are very like those of the first. The leaves are longer, of a darker green, and the flower-stalks rise higher. The segments of the petal are rounder, and spread open, flatter than those of the first sort. The nectarium or cup, in the middle, is about half the length of the petal, and is edged with a gold-coloured fringe. It flowers in *April*, but seldom produces seeds here. This sort sports and varies more than any of the other: the following variations I have traced in the same roots.

The roots of these, the first year, produced very double flowers, of the sort which is commonly called the Incomparable Daffodil. The six outer segments of the petal were longer than either of the others, and white; the middle was very full of shorter petals, some of which were white, others yellow, and collected into a globular figure: some of these roots, the following year, produced flowers less double than before, with no white petals in them, but the larger petals were of a sulphur colour, and the others yellow; from this they afterward degenerated to half double flowers, and at last to single flowers, with a cup half the length of the petal, in which manner they have continued to flower many years; so that we may conclude, that those varieties were first obtained from the seeds of this single flower.

The fourth sort grows naturally in the south of *France* and in *Italy*, and has been found growing in the fields in some parts of *England*, but it is likely to have been from some roots which have been thrown out of gardens with rubbish. The roots of this sort are not so large as those of the first, and are rounder; the leaves are long, of a gray colour, and smoother than those of the first; the flower-stalks are of the same length with the leaves, and have commonly but one flower in a sheath, but sometimes when

the roots are strong they have two. The flower nods downward, the segments of the petal are a little waved on their edges, the nectarium or cup is short, and bordered with yellow; it flowers in *May*. The scent of these flowers is not very agreeable, and as they are not very beautiful, so they are seldom cultivated in gardens, since the finer sorts have been plenty. There is no variety of this, so far as I have been able to trace, for I could never observe any variation in their flowers.

The fifth sort has some resemblance of the fourth, but the flowers are whiter; the segments of the petal are reflexed, and the border of the nectarium or cup is of a gold yellow colour; this has some affinity to the second sort.

The sixth sort grows naturally in *Portugal*, from whence I have received the roots. The bulbs of this kind are small, the leaves are very narrow, having some resemblance to those of the Rush, but are a little compressed, and have a longitudinal furrow on one side; these are seldom more than eight or nine inches long. The flower-stalk is slender, taper, and about six inches long, sustaining at the top one flower, which is at first inclosed in a sheath; the petal is scarce half an inch long, and is cut into six acute segments; the nectarium or cup is more than two inches long, very broad at the brim, lessening gradually to the base, being somewhat formed like the ladies hoop-petticoats, from whence the flower is so called. It flowers in *April*, but does not produce seeds here. There are no varieties of this sort.

The seventh sort grows naturally in *Spain*. This hath a small bulbous root; the leaves are but few in number, and are narrow; the stalk is jointed, and rises about nine inches high, sustaining at the top one flower, which at first is inclosed in the spatha (or sheath); the flower is cut into six narrow segments, which are white; the nectarium or cup is yellow. It flowers late in the autumn, and the roots are tender, so are often killed by hard frosts in *England*, which renders it scarce here.

The eighth sort grows naturally in *Portugal*, and in the islands of the *Archipelago*; of this there are a greater variety than of all the other species, for as the flowers are very ornamental, and come early in the spring, so the florists in *Holland*, *Flanders*, and *France*, have taken great pains in cultivating and improving them; so that at present the catalogues printed by the *Dutch* florists, contain more than thirty varieties, the principal of which are these hereafter mentioned.

These have yellow petals, with Orange, yellow, or sulphur-coloured cups or nectariums.

The Great Algiers.	The Most Beautiful.
The Ladies Nofegay.	The Golden Star.
The Greater Bell.	The Mignon.
The Golden Royal.	The Zeylander.
The Golden Scepter.	The Madouse.
The Triumphant.	The Golden Sun.

The following have white petals, with yellow or sulphur-coloured cups or nectariums.

The Archdutchefs.	The Greater Bozelman.
The Triumphant Nofegay.	The Czarina.
The New Dorothy.	The Grand Monarque.
The Passe Bozelman.	The Czar of Muscovy.
The Superb.	The Surpassante.

There are some with white petals and white cups, but these are not so much esteemed as the others, though there are two or three varieties with large bunches of small white flowers, which have a very agreeable odour, so are as valuable as any of the other, and comes later to flower than most

most of the other sorts. There is also one with very double flowers, whose outer petals are white, and those in the middle are some white, and others are of an Orange colour, which have a very agreeable scent, and is the earliest in flowering; it is generally called the *Cyprus Narcissus*, and seems to be a distinct species from the others. This, like most other double flowers, never produces any seeds, so is only propagated by offsets, and is the most beautiful of all the *Narcissuses*, when blown upon glasses of water in a room; but when it is planted in the ground, if the bed in which they are planted is not covered with mats in frosty weather, to prevent their flower-buds from being destroyed, they seldom flower; for the leaves begin to shoot early in the autumn, and the flower-buds appear about *Christmas*, which are tender; so that if hard frost happen when they are coming out of the ground, it generally kills them; but if they are properly screened from frost, they will flower in *February*, and in mild seasons often in *January*.

The ninth sort is the *Jonquil*, a flower so well known as to need no description; of this there is the great and small *Jonquil* with single flowers, and the common sort with double flowers, which is most esteemed.

I shall first treat of the method for raising of the fine sorts of *Polyanthus Narcissus* from seeds, which is the way to obtain new varieties.

The not practising this has occasioned our sending abroad annually for great quantities of flower-roots, which were for many years kept up to a high price, on account of the great demand for them in *England*; whereas, if we were as industrious to propagate them as our neighbours, we might soon vie with them, if not outdo them, in most sorts of flowers, as may be seen, by the vast variety of *Carnations*, *Auriculas*, *Rununculas*, &c. which have been produced from seeds in *England* within a few years past, and exceed most of those kinds in any part of *Europe*.

You must first be very careful in saving your seeds, to gather none but from such flowers as have good properties, and particularly from such only as have many flowers upon a stalk, that flower tall, and have beautiful cups to their flowers; from such you may expect to have good flowers produced, provided the roots are not intermixed with ordinary kinds, which by the mixing of the farina will greatly degenerate the best sort of flowers; and if you sow ordinary seed, it is only putting yourself to trouble and expence to no purpose, since from such seeds there can be no hopes of procuring any valuable flowers.

Having provided yourself with good seeds, you must procure either some shallow cases or flat pans, made on purpose for the raising of seedlings, which should have holes in their bottoms, to let the moisture pass off; these must be filled with fresh light earth about the beginning of *August* (this being the season for sowing the seeds of most bulbous-rooted flowers); the earth in these must be levelled very even; then sow the seeds thereon pretty thick, covering them over with fine, sifted, light earth, about half an inch thick, and place the cases or pans in a situation where they may have only the morning sun till about ten o'clock, where they should remain until the beginning of *October*, when they must be removed into a warmer situation, placing them upon bricks, that the air may freely pass under the cases, which will preserve them from being too moist.

They should also be exposed to the full sun in winter, but screened from the north and east winds; and if the frost should be severe, they must be covered either with mats, *Peas haulm*, or some light covering, otherwise there will be danger of their being destroyed: in this situation they may remain until the beginning of *April*, by which time the plants will be up, when you must carefully clear them from weeds; and if the season should prove dry, they must

be frequently watered: the cases should also now be removed into their former shady position, or shaded in the middle of the day, for the heat of the noon-day sun will be too great for the young plants.

The latter end of *June*, when the leaves of the plants are decayed, you should take off the upper surface of the earth in the cases (which by that time will have contracted a mossiness, and, if suffered to remain, will greatly injure the young roots), observing not to take it so deep as to touch the roots; then sift some fresh light earth over the surface, about half an inch thick, which will greatly strengthen the roots; the same should also be repeated in *October*, when the cases are moved again into the sun.

During the summer season, if the weather should prove very wet, and the earth in the case appear very moist, you must remove them into the sun till the earth be dry again; for if the roots receive much wet, during the time they are unactive, it very often rots them while young; therefore you must never give them any water after their leaves are decayed, but only place them in the shade, as was before directed.

Thus you should manage them the two first seasons, till their leaves are decayed the second summer after sowing; when their leaves are decayed you should carefully take up the roots, which may be done by sifting the earth in the cases through a fine sieve, whereby the roots will be easily separated from the earth; then having prepared a bed of good, fresh, light earth, in proportion to the quantity of your roots, you should plant them therein, at about three inches distance every way, and about three inches deep in the ground.

These beds should be raised above the level of the ground, in proportion to the moisture of the soil, which if dry, three inches will be enough; but if it be wet, they must be raised six or eight inches high, and laid a little rounding, to shoot off the wet.

If these beds are made in *August*, which is the best time to transplant the roots, the weeds will soon appear very thick; therefore you should clean the surface of the ground to destroy them, being very careful not to disturb any of the roots; and this should be repeated as often as may be found necessary, by the growth of the weeds, observing always to do it in dry weather, that they may be effectually destroyed; and toward the latter end of *October*, after having entirely cleared the beds from weeds, you should sift a little rich light earth over them, about an inch thick; the goodness of which will be washed down to the roots by the winter's rain, which will greatly encourage their shooting in the spring.

If the cold should be very severe in winter, you should cover the beds, either with old tan or sea-coal ashes, or in want of these with *Peas haulm*, or some such light covering, to prevent the frost from penetrating the ground to the roots, which might greatly injure them while they are so young.

In the spring, when the plants begin to appear above ground, you must gently stir the surface of the ground, clearing it from weeds, &c. in doing of which, you should be very careful not to injure the roots; and if the season should prove dry, you should now and then gently refresh them with water, which will strengthen them.

When their leaves are decayed, you should clear the beds from weeds, and sift a little earth over them (as was before directed, which must also be repeated in *October* in like manner; but the roots should not remain longer in these beds than two years, by which time they will have grown so large as to require more room, therefore they should be taken up as soon as their leaves are decayed, and planted into fresh beds, which should be dug deep, and a little very rotten

ro ten dung buried in the bottom, for the fibres of the roots to strike into. Then the roots should be planted at six inches distance, and the same depth in the ground. In the autumn, before the frost comes on, if some rotten tan is laid over the beds, it will keep out the frost, and greatly encourage the roots; and if the winter should prove severe, it will be proper to lay a greater thickness of tan over the beds, and also in the alleys, to keep out frost, or to cover them over with Straw or Peas haulm, otherwise they may be all destroyed by the cold. In the spring these coverings should be removed, as soon as the danger of hard frosts is over, and the beds must be kept clean from weeds the following summer: at *Michaelmas* they should have some fresh earth laid over the beds, and covered again with tan; and so every year continued till the roots flower, which is generally in five years from seed, when you should mark all such as promise well, which should be taken up as soon as their leaves decay, and planted at a greater distance in new prepared beds; but those which do not flower, or those you do not greatly esteem, should be permitted to remain in the same bed; therefore, in taking up those roots which you marked, you must be careful not to disturb the roots of those left, and also to level the earth again, and sit some fresh earth over the beds (as before) to encourage the roots; for it often happens in the seedlings of these flowers, that at their first time of blowing, their flowers seldom appear half so beautiful as they do the second year; for which reason none of them should be rejected until they have flowered twice, that so you may be assured of their worth.

Thus having laid down directions for the sowing and managing these roots, until they are strong enough to flower, I shall proceed to give some instructions for planting and managing the roots afterwards, so as to cause them to produce large fair flowers.

All the sorts of Narcissus, which produce many flowers upon a stalk, should have a situation defended from cold and strong winds, otherwise they will be subject to be injured by the cold in a severe winter, and their stems broken down when in flower; for notwithstanding their stalks are generally pretty strong, yet the number of flowers upon each renders their heads weighty, especially after rain, which lodges in the flowers, and, if succeeded by strong winds, very often destroys their beauty, if they are exposed thereto; so that a border under a hedge, which is open to the south-east, is preferable to any other position for these flowers.

The morning sun rising upon them, will dry off the moisture which had lodged upon them the preceding night, and cause them to expand fairer than when they are planted in a shady situation; and if they are too much exposed to the afternoon sun, they will be hurried out of their beauty very soon; and the strong winds usually coming from the west and south-west points, they will be exposed to the fury of them, which is frequently very injurious to them.

Having made choice of a proper situation, you must then proceed to prepare the earth necessary to plant them in; for if the natural soil of the place be very strong or poor, it will be proper to make the border of new earth, removing the former soil away about three feet deep. The best earth for these flowers is a fresh light Hazel loam, mixed with a little very rotten neats dung: this should be well mixed together, and often turned over, in order to sweeten it; then having removed away the old earth to the fore-mentioned depth, you should put a layer of rotten dung or tan, in the bottom, about four or five inches thick, upon which you must lay some of the prepared earth about eighteen or twenty inches thick, making it exactly level; then having marked out by line the exact distances at which the roots are to be planted (which should not be less than six or eight inches square), you must place the roots accordingly, ob-

erving to set them upright; then you must cover them over with the before-mentioned earth about eight inches deep, being very careful in doing of it, not to displace the roots: when this is done, you must make the surface of the border even, and make up the side strait, which will appear handsome.

The best time for planting these roots is in *September*, for if they are kept too long out of the ground, it will cause their flowers to be very weak. You should also observe the nature of the soil where they are planted, and whether the situation be wet or dry, according to which you should adapt the fresh earth, and order the beds; for if the soil be very strong, and the situation moist, you should then make choice of a light earth, and raise the beds six or eight inches, or a foot, above the level of the ground, otherwise the roots will be in danger of perishing by too much wet; but if the situation be dry, and the soil naturally light, you should then allow the earth to be a little stronger, and the beds should not be raised above three or four inches high; for if they are made too high, the roots will suffer very much, if the spring should prove dry, nor would the flowers be near so fair. As also in very severe winters, those beds which are raised much above the level of the ground, will be more exposed to the cold than those which are lower, unless the alleys are filled up with rotten tan or litter.

During the summer, the only culture these flowers require is, to keep them free from weeds; and when their leaves are entirely decayed, they should be raked off, and the beds made clean, but by no means cut off their leaves till they are quite decayed, as is by some practised, for that greatly weakens the roots.

Toward the middle of *October*, if the weeds have grown upon the beds, you should in a dry day gently hoe the surface of the ground to destroy them, observing to rake it over smooth again; and before the frosts come on, the beds should be covered over two inches thick with rotten tan, to keep out the frost; after which they will require no farther care till the spring, when their leaves will appear above ground; at which time you should gently stir the surface of the earth with a small trowel, being very careful not to injure the leaves of the plants, and rake it smooth with your hands, clearing off all weeds, &c. which, if suffered to remain at that season, will soon grow so fast, as to appear unsightly, and will exhaust the nourishment from the earth. With this management these roots will flower very strong, some of which will appear in *March*, and the others in *April*, which, if suffered to remain, will continue in beauty a full month, and are, at that season, very great ornaments to a flower-garden.

After the flowers are past and the leaves decayed, you should stir the surface of the ground, to prevent the weeds from growing; and if at the same time you lay a little very rotten dung over the surface of the beds, the rain will wash down the salts thereof, which will greatly encourage the roots the succeeding year.

During the summer season they will require no farther care, but to keep them clear from weeds till *October*, when the surface of the beds should be again stirred, raking off all weeds, &c. and laying some good fresh earth over the beds about an inch deep, which will make good the loss sustained by weeding, &c. and in the spring you must manage as was directed for the preceding year.

These roots should not be transplanted oftener than every third year, if they are expected to flower strong and make a great increase, because the first year after removing they never flower so strong as they do the second and third; nor will the roots increase so fast, when they are often transplanted; but if you let them remain longer than three years unremoved, the number of offsets, which by that time will

will be produced, will weaken the large bulbs, and cause them to produce very weak flowers; therefore, at the time of transplanting them, all the small offsets should be taken off, and planted in a nursery-bed by themselves, but the large bulbs may be planted again for flowering. If you plant them in the same bed where they grew before, you must take out all the earth two feet deep, and fill it up again with fresh, in the manner before directed, which will be equal to removing them into another place: this is the constant practice of the gardeners in *Holland*, who have but little room to change their roots; therefore they every year remove the earth of their beds and put in fresh, so that the same place is constantly occupied by the like flowers. But those people take up their roots every year, for as they cultivate them for sale, the rounder their roots are, the more valuable they will be: the way to have them so is, to take their offsets from them annually, for when the roots are left two or three years unremoved, the offsets will have grown large, and these pressing against each other, will cause their sides to be flatted; so that where the roots are propagated for sale, they should be annually taken up as soon as their leaves decay, and the large bulbs may be kept out of the ground till the middle or end of *October*, but the offsets should be planted the beginning of *September* or sooner, that they may get strength, so as to become blowing roots the following year; but where they are designed for ornament, they should not be removed oftener than every third year, for then the roots will be in large bunches, and a number of stalks with flowers coming from each bunch, they will make a much better appearance than where a single stalk rises from each root, which will be the case when the roots are annually removed.

The common sorts of *Daffodil* are generally planted in large borders of the pleasure-garden, where, being intermixed with other bulbous-rooted flowers, they afford an agreeable variety in their seasons of flowering. These roots are very hardy, and will thrive in almost any soil or situation, which renders them very proper for rural gardens, where, being planted under the shade of trees, they will thrive for several years without transplanting, and produce annually in the spring great quantities of flowers, which will make a good appearance before the trees come out in leaf.

The *Jonquils* should be planted in beds or borders, separate from other roots, because these require to be transplanted at least every year, otherwise their roots are apt to grow long and slender, and seldom flower well after, which is also the case, if they are continued many years in the same soil; wherefore the roots should be often removed from one part of the garden to another, or at least the earth should be often renewed, which is the most probable method to preserve these flowers in perfection.

The soil in which these flowers succeed best, is an *Hazel loam*, neither too light nor over stiff; it must be fresh, and free from roots of trees or noxious weeds, but should not be dunged; for it is very remarkable, that where the ground is made rich, they seldom continue good very long, but are subject to shoot downwards, and form long slender roots.

These flowers are greatly esteemed by many people for their strong sweet scent, though there be very few ladies that can bear the smell of them; so powerful is it, that many times it overcomes their spirits, especially if confined in a room; for which reason, they should never be planted too close to a habitation, lest they become offensive, nor should the flowers be placed in such rooms where company is entertained.

NASTURTIUM. *Tourn. Inst. R. H.* 213. tab. 102. Crefs.

The Characters are,

The flower hath a four-leaved empalement. It has four petals

placed like a cross, and six awl-shaped stamina, four of which are the same length of the empalement, and two are shorter. In the center is situated a heart shaped germen, which afterward turns to a heart-shaped short capsule, with acute borders, having two cells, each containing one or two oval seeds.

The Species are,

1. *NASTURTIUM foliis oblongis multifidis, caule erecto*. Crefs with oblong leaves ending in many points, and an erect stalk; or common Garden Crefs.

2. *NASTURTIUM foliis radicalibus incis, caulinis oblongis integerrimis, caule erecto ramofo*. Crefs with lower leaves divided, but those on the stalks oblong and entire, and an erect branching stalk; or broad-leaved Garden Crefs.

3. *NASTURTIUM foliis pinnatifidis, caulibus procumbentibus*. Crefs with leaves ending in many points, and trailing stalks; Swines Crefs.

There are some other species of this genus, but as they are seldom cultivated in gardens, so I shall not enumerate them here.

The common Crefs is a plant so well known, as to need no description; there is a variety of this, whose lower leaves are much curled on their edges; this was formerly cultivated in greater plenty than at present. Whether this is a distinct species, or only a variety, I cannot determine, though for some years I found it retained its difference.

The broad-leaved sort, I think, is a distinct plant; the lower leaves are very broad, and cut into three or five lobes. The stalks rise much higher, and branch out more than those of the common sort, and the branches grow more upright; this was formerly more cultivated than at present.

The first sort is commonly cultivated in gardens as a salad herb, and is chiefly esteemed in the winter and spring, it being one of the warm kind. During the winter season, it must be sown upon a gentle hot-bed, and covered with either mats or glasses, to preserve it from great rains or frost, both which are equally destructive at that season: in the spring it may be sown in warm borders, where, if it be defended from cold winds, it will thrive very well; but if you would continue it in summer, you must sow it upon shady borders, and repeat sowing every third day, otherwise it will be too large for use, for at that season it grows very fast.

The curled sort is preserved in some gardens for curiosity sake, and to garnish dishes, but the common sort is equally as good for use. This should be sown somewhat thinner than the common sort, and when the plants come up, they should be drawn out, so as to leave the remaining ones half an inch asunder, whereby they will have room to expand their leaves.

In order to preserve the variety with curled leaves distinct, you must carefully separate all such plants as appear inclined to degenerate from their kinds, leaving only such as have their leaves very much curled, being very careful not to intermix them together. When the seeds are ripe, the plants should be drawn up, and spread upon a cloth two or three days to dry; after which the seeds should be beaten out, and preserved in a dry place for use.

NASTURTIUM INDICUM. See *Tropæolum*.

NECTARINE [properly so called of *Nectar*, the poetical drink of the gods] *Nectarine*.

This fruit should have been placed under the article of *PEACHES*, to which it properly belongs, differing from them in nothing more than in having a smooth rind, and the flesh being firmer. These the *French* distinguish by the name of *Brugnon*, as they do those *Peaches* which adhere to the stone, by the name of *Pavies*, retaining the name of *Pêche* to only such as part from the stone; but since the writers in gardening have distinguished this fruit by the name of *Nectarine* from the *Peaches*, so I shall follow their example, lest by endeavouring to rectify their mistakes, I should

render

render myself less intelligible to the reader. I shall therefore mention the several varieties of this fruit which come to my knowledge :

1. *Fairchild's Early Nectarine*. This is one of the earliest ripe Nectarines we have ; it is a small round fruit, about the size of the Nutmeg Peach, of a beautiful red colour, and well flavoured ; it ripens the end of *July*.

2. *Etruge Nectarine*. The tree has sawed leaves ; the flowers are small ; it is a middle-sized fruit, of a dark red or purple colour next the sun, but of a pale yellow or greenish colour towards the wall ; it parts from the stone, and has a soft melting juice : this ripens in the beginning of *August*.

3. *Newington Nectarine*. The tree has sawed leaves ; the flowers are large and open ; it is a fair large fruit (when planted on a good soil), of a beautiful red colour next the sun, but of a bright yellow towards the wall ; it has an excellent rich juice ; the pulp adheres closely to the stone, where it is of a deep red colour : this ripens the latter end of *August*, and is the best flavoured of all the sorts.

4. *Scarlet Nectarine* is somewhat less than the last, of a fine red or scarlet colour next the sun, but loses itself in paler red towards the wall : this ripens in the end of *August*.

5. *Brugnon or Italian Nectarine* has smooth leaves ; the flowers are small ; it is a fair large fruit, of a deep red colour next the sun, but of a soft yellow towards the wall ; the pulp is firm, of a rich flavour, and closely adheres to the stone, where it is very red : this ripens in the end of *August*.

6. *Roman Red Nectarine* has smooth leaves and large flowers ; it is a large fair fruit, of a deep red or purple colour towards the sun, but has a yellowish cast next the wall ; the flesh is firm, of an excellent flavour, closely adhering to the stone, where it is very red : this ripens in the end of *August*.

7. *Murry Nectarine* is a middle-sized fruit, of a dirty red colour on the side next the sun, but of a yellowish green towards the wall ; the pulp is tolerably well flavoured : this ripens the beginning of *September*.

8. *Golden Nectarine* is a fair handsome fruit, of a soft red colour next the sun, but of a bright yellow next the wall ; the pulp is very yellow, of a rich flavour, and closely adheres to the stone, where it is of a faint red colour : this ripens the middle of *September*.

9. *Temple's Nectarine* is a middle-sized fruit, of a soft red colour next the sun, but of a yellowish green toward the wall ; the pulp is melting, of a white colour towards the stone, from which it parts, and has a fine poignant flavour : this ripens the end of *September*.

9. *Peterborough, or late green Nectarine*, is a middle-sized fruit, of a pale green colour on the outside next the sun, but of a whitish green towards the wall ; the flesh is firm, and, in a good season, well flavoured : this ripens the middle of *October*.

There are some persons who pretend to have more sorts than I have here set down, but I much doubt whether they are different from those here mentioned, there being so near a resemblance between the fruits of this kind, that it requires a very close attention to distinguish them well, especially if the trees grow in different soils and aspects, which many times alters the same fruit so much, as hardly to be distinguished by persons who are very conversant with them ; therefore, in order to be thoroughly acquainted with their differences, it is necessary to consider the shape and size of their leaves, the size of their flowers, their manner of shooting, &c. which is many times very helpful in knowing of these fruits.

The culture of this fruit differing in nothing from that of the Peach, I shall forbear mentioning any thing on that head in this place, to avoid repetition, but refer the reader to the article of *PERSICA*, where there is an ample account of their planting, pruning, &c.

NEPETA. *Lin. Gen. Plant.* 629. Catmint, or Nep.

The Characters are,

The empalement of the flower is cylindrical, indented into five acute parts at the top, The flower is of the lip kind, with one petal, having an incurved cylindrical tube, gaping at the top. The upper lip is erect, roundish, and indented at the point. The under lip is large, concave, entire, and sawed on the edge. It hath four awl-shaped stamina, situated under the upper lip, two of which are shorter than the other. In the bottom of the tube is situated the quadrifid germen, which afterward turns to four oval seeds, sitting in the empalement.

The Species are,

1. *NEPETA floribus spicatis, verticillis subpedicellatis, foliis petiolatis cordatis dentato-serratis. Lin. Sp. Plant.* 570. Catmint with spiked flowers, whose whorls have very short foot-stalks, and heart-shaped leaves growing on foot-stalks, which are indented like the teeth of a saw ; or common Greater Catmint.

2. *NEPETA floribus spicatis, spicis interruptis, verticillis pedicellatis, foliis subcordatis serratis petiolatis.* Catmint with spikes of flowers, which have interrupted whorls standing on foot-stalks, and sawed leaves almost heart-shaped ; or Smaller common Catmint.

3. *NEPETA floribus spicatis, verticillis subsessilibus, foliis cordato-oblongis serratis sessilibus.* Catmint with spiked flowers, whose whorls grow almost close to the stalks, and oblong, sawed, heart-shaped leaves, sitting close ; or Greater narrow-leaved Catmint.

4. *NEPETA foliis linearibus, profundè dentatis, inferioribus petiolatis, supernè sessilibus, verticillis pedicellatis longioribus.* Catmint with linear leaves, which are deeply indented, the lower ones standing upon foot-stalks, the upper ones sitting close, and whorls of flowers standing upon very long foot-stalks ; or Smaller narrow-leaved Catmint.

5. *NEPETA floribus paniculatis, foliis oblongo-cordatis acutis serratis sessilibus.* Catmint with paniced flowers, and oblong, heart-shaped, acute, sawed leaves, sitting close to the stalks ; or Smaller Catmint with a *Turkey Balm* leaf.

6. *NEPETA floribus sessilibus verticillato-spicatis, bracteis lanceolatis longitudine calycis, foliis petiolatis. Lin. Sp. Plant.* 571. Catmint whose flowers grow in whorled spikes, sitting close to the stalk, with spear-shaped bractæ the length of the empalement, and leaves growing upon foot-stalks ; or Smaller *Alpine* Catmint.

7. *NEPETA verticillis pedunculatis corymbosis, foliis petiolatis cordato-oblongis dentatis. Lin. Sp. Plant.* 570. Catmint with roundish whorls standing upon foot-stalks, and oblong, heart-shaped, indented leaves.

8. *NEPETA floribus spicatis sessilibus, bracteis ovatis coloratis, verticilla excipientibus, foliis sessilibus. Hort. Cliff.* 311. Catmint with spiked flowers sitting close to the stalks, oval-coloured bractæ receiving the whorls, and leaves sitting close to the stalks.

9. *NEPETA floribus sessilibus verticillato-spicatis, verticillis tomento obvolutis. Hort. Cliff.* 311. Catmint with flowers growing in whorled spikes, sitting close to the stalk, and the whorls covered with down.

10. *NEPETA foliis lanceolatis, capitulis terminalibus, staminibus flore longioribus. Lin. Sp. Plant.* 571. Catmint with spear-shaped leaves, stalks terminated by flowers growing in heads, and stamina longer than the flower.

11. *NEPETA floribus spicatis, verticillis crassioribus, foliis cordatis obtusè dentatis petiolatis.* Catmint with spiked flowers, whose whorls are very thick, and heart-shaped leaves, which are obtusely indented, and stand upon foot-stalks.

12. *NEPETA floribus verticillatis, bracteis ovatis hirsutis, foliis cordato-ovatis crenatis, caule procumbente.* Catmint with whorled flowers, having oval hairy bractæ, oval heart-shaped leaves, which are crenated, and a trailing stalk.

The

The first fort is the common Nep or Catmint, which grows naturally on the side of banks and hedges, in many parts of *England*. This has a perennial root, from which arise many square branching stalks, about two feet high, garnished at each joint by two heart-shaped leaves, standing opposite, upon pretty long foot-stalks; they are sawed on their edges, and hoary on their under side. The flowers grow in spikes at the top of the stalks, and below the spikes are two or three whorls of flowers, which have very short foot-stalks. The flowers are white, and have two lips; the upper lip stands erect, the lower is a little reflexed, and indented at the point; these are each succeeded by four oval black seeds, which ripen in the empalement.

The whole plant has a strong scent between Mint and Pennyroyal. It is called Catmint, because cats are very fond of it, especially when it is withered, for then they will roll themselves on it, and tear it to pieces, chewing it in their mouths with great pleasure. Mr. Ray mentions his having transplanted some of the plants of this sort, from the fields into his garden, which were soon destroyed by the cats, but the plants which came up from seeds in his garden escaped; which verifies the old proverb, *viz. If you set it the cats will eat it, if you sow it the cats will not know it*. I have frequently made trial of this, and have always found it true; for I have transplanted one of the plants from another part of the garden, within two feet of some plants which came up from seeds, the latter has remained unhurt, when the former has been torn to pieces and destroyed by the cats; but I have always observed, where there is a large quantity of the herb growing together, they will not meddle with it. This flowers in *June* and *July*, and the seeds ripen in autumn. It is used in medicine.

The second fort grows naturally in *Italy*, and the south of *France*. The stalks of this are slenderer, their joints farther asunder, the leaves are narrower, and the whole plant whiter than the first.

The stalks of the third fort do not branch so much as either of the former; they are slenderer, and their joints farther asunder; the leaves are small, narrow, and almost heart-shaped, sawed on their edges, hoary, and stand upon short foot-stalks. The spikes of flowers are more broken, or interrupted, than those of the second, and the whorls stand upon foot-stalks. It grows naturally in *Italy*.

The fourth fort hath slender stalks, which branch out near the ground. The joints are far asunder; the leaves are very narrow, and deeply sawed on their edges. The whorls of flowers come out from the wings of the stalk; those on the lower part have long foot-stalks, but these shorten upward, and the stalks are terminated by close whorls.

The fifth fort grows naturally in *Sicily*. This rises with a strong four-cornered stalk near three feet high; the lower joints are four or five inches asunder. The leaves are long, narrow, and heart-shaped, deeply sawed on their edges, and set pretty close to the stalk. The flowers grow in panicles along the stalks, and are of a pale purplish colour. It flowers about the same time with the other forts.

The sixth fort grows naturally upon the *Alps*; the stalks of this seldom rise more than a foot and a half high, sending out very few branches. The whorls of flowers, which form the spike, are distant from each other, and set close to the stalk. The leaves are short, oval, heart-shaped, and stand upon foot-stalks; the plant is hoary, and strong scented.

The seventh fort grows naturally in *Spain*; the stalks of this rise about two feet high, and have a few slender branches coming out from their sides. The leaves are heart-shaped, and indented on their edges. The flowers grow in roundish whorls upon foot-stalks, and are blue; there is also a variety of this with white flowers.

The eighth fort grows naturally in *Portugal*. This has a thick knobbed root, from which comes out one or two stalks, which often decline to the ground. The leaves are oblong, crenated on their edges, sit close to the stalks, and are of a deep green. The upper part of the stalk, for more than a foot in length, is garnished with whorls of flowers, the lower being two inches asunder, but are nearer all the way upward; these sit very close to the stalks, and are guarded by oval, small, coloured leaves or bractæ. The flowers are blue, and shaped like those of the other species; there is one of this fort with an erect stalk, which is the only difference between them.

The ninth fort grows naturally in *Sicily*. The stalks of this grow about two feet high; the branches come out toward the bottom; the leaves are heart-shaped, obtuse, and but little indented, standing upon pretty long foot-stalks. The stalks are terminated by long spikes of whorled flowers, which are separated, and sit close to them; these are wrapped in a hoary down. The flowers are white, and appear in *July*.

The tenth fort grows naturally in *North America*. This hath a perennial root, from which arise several four-cornered stalks two feet high, which are garnished with hairy leaves, somewhat like those of Marjoram, but are larger. The flowers grow in whorls round the stalks, and also at the extremity of the stalk, in a large roundish whorl or head; they are of a pale flesh colour, and their stamina is longer than the petal. It flowers in *July*.

The eleventh fort grows naturally in the *Levant*. The stalks of this are strong, and rise near three feet high. The leaves are heart-shaped, and have blunt indentures on their edges, standing upon short foot-stalks. The flowers grow in whorled spikes at the top of the stalks; the whorls are very thick, and set close together, terminating in an obtuse point. The flowers are of a pale flesh colour; the whole plant is hoary, and has a strong scent.

The twelfth fort grows naturally among the rocks in *Candia*, where it is used as Water Germander by the inhabitants; this hath four-cornered stalks a foot long, which trail upon the ground, sending out some slender branches from the side. The leaves are very like those of the round-leaved Mentastrum, sitting close to the stalk. The flowers grow in thick roundish whorls, which sit close to the stalk, and are surrounded by oval hairy leaves or bractæ. The flowers are white, and just peep out of their empalements. The roots of this fort seldom continue longer than two years, but as the seeds ripen well, so if they are permitted to scatter, the plants will come up the following spring.

All the forts are very hardy, so are not injured by frost; they are easily propagated by seeds, for if they are permitted to fall, the plants will rise without trouble; or if the seeds are sown, either in the spring or autumn, the plants will come up, and require no other culture, but to thin them where they are too close, and keep them clean from weeds. If these plants are sown upon a poor dry soil, they will not grow too rank, but will continue much longer, and appear handsomer than in rich ground, where they grow too luxuriant, and have not so strong a scent.

NERIUM. *Lin. Gen. Plant.* 262. The Oleander, or Rose Bay.

The Characters are,

The empalement of the flower is permanent, and cut into five acute segments. The flower has one funnel-shaped petal cut into five broad obtuse segments, which are oblique. It hath a nectarium terminating the tube, which is torn into hairy segments. It hath five short awl-shaped stamina within the tube. It hath an oblong germen, which is bisid, with scarce any style, crowned by single stigmas. The germen afterward turns to two long, taper, acute-pointed pods, filled with oblong seeds, lying over each other like the scales of fish, and crowned with down.

The Species are,

1. *NERIUM foliis linearilanceolatis rigidis sæpius ternis erectis*. Oleander, or Rose Bay, with linear, spear-shaped, rigid leaves, which are erect, and often placed by threes round the stalk; or Oleander with red flowers.

2. *NERIUM foliis linearibus rigidis*. Oleander, or Rose Bay, with linear rigid leaves; or *Indian Rose Bay*, with single sweet-scented flowers.

3. *NERIUM foliis lanceolatis longioribus, flaccidis*. Rose Bay with longer, spear-shaped, flaccid leaves; commonly called the Double Oleander.

The first sort grows naturally in *Greece*, and in several parts near the *Mediterranean* sea, generally by the sides of rivers and brooks: there are two varieties of this, one with white, the other with red flowers, but seem to have no other difference, so may properly be placed together as one species, though that with white flowers is rarely found growing wild in any place, but the island of *Crete*.

This rises with several stalks, to the height of eight or ten feet. The branches come out by threes, round the principal stalks, and have a smooth bark, which in the red flowering is of a purplish colour, but the white sort hath a light green bark. The leaves for the most part stand by threes round the stalks, upon very short foot-stalks, and point upward, of a dark green, very stiff, and end in acute points. The flowers come out at the end of the branches in large loose bunches, which are in one of a bright purple, or crimson colour, and in the other they are of a dirty white; they have short tubes, which spread open at the top, where they are deeply cut into five obtuse segments, which are twisted at bottom, so are oblique to the tube. At the mouth of the tube the torn capillary nectarium is situated, and within the tube are the five stamina, with the germen at bottom, which afterward turns to a brown, taper, double pod, about four inches long, which opens longitudinally on one side, and is filled with oblong seeds, crowned with long hairy down, lying over each other like the scales of fish. This plant flowers in *July* and *August*, and in warm seasons they are succeeded by pods, but the seeds seldom ripen well here.

When the summers are warm and dry, these plants make a fine appearance, for then they open and flower in great plenty; but, in cold moist seasons, the flowers often decay without expanding, and the sort with white flowers, is more tender than the red; so that unless the weather is warm and dry at the time the flowers appear, they rot, and make no figure, unless they are placed under glasses to screen them.

The second sort grows naturally in *India*; this rises with shrubby stalks six or seven feet high, which are covered with a brown bark, garnished with stiff leaves, from three to four inches long, and not more than a quarter of an inch broad; they are of a light green, and their edges are reflexed; these are placed sometimes by pairs opposite, at others they are alternate, and sometimes by threes round the branches. The flowers are produced in loose bunches at the end of the branches; they are of a pale red, and have an agreeable musky scent. It flowers at the same time with the former, but the flowers seldom open here in the open air, so that unless the plants are placed in an airy glass-case, where they are defended from wet and cold, they will not flower.

The third sort grows naturally in both *Indies*; this plant was first introduced to the *British* islands in *America*, from the *Spanish Main*, and is called by the inhabitants of those islands *South Sea Rose*; the beauty and sweetness of its flowers engaged the inhabitants of the islands to cultivate the plants, so that in many places they were planted to form hedges; but the cattle browsing upon them, when there was scarcity of food, were many of them killed, which has occasioned their being destroyed in all places exposed to

cattle, so that now they are only preserved in gardens, where they make a fine appearance great part of the year; for in those warm countries, they are seldom destitute of flowers: this has been by some persons, who have only a superficial knowledge of plants, thought only a variety of the common sort, but those who have cultivated both, know better; for the first will live through the winter in *England*, if planted in a warm situation, but this is too tender to thrive in *England*, unless preserved in a warm greenhouse; nor will the plants flower without the assistance of a glass-case in summer. The third sort was not known here till the middle of the last century, being a stranger in *Europe*, but the former has been in the *English* gardens near two centuries: nor has the seeds of the first ever produced plants of the third sort, notwithstanding it has been positively asserted by persons of no skill.

The leaves of this sort are six inches long, and one inch broad in the middle, of a much thinner texture than those of the first, and their ends are generally reflexed; they are of a light green, and irregularly placed on the branches; sometimes they are by pairs, at others alternate, and sometimes by threes round the branches. The flowers are produced in very large bunches at the end of the branches, standing upon very long foot-stalks; they have three or four series of petals within each other, so are more or less double. The flowers are much larger than those of the common sort, and smell like the flowers of Hawthorn. The plain flowers are of a soft red, or Peach colour; but in most they are beautifully variegated with a deeper red, and make a fine appearance. Their usual time of flowering is in *July* and *August*, but if they are placed in a warm stove, they will continue to *Michaelmas*. As the flowers of this are double, they are not succeeded by seeds, and at present we are unacquainted with the single flowering of this kind, for the second is undoubtedly a distinct species.

All the species of the Rose Bay, are supposed to have a poisonous quality; the young branches, when cut or broken, have a milky sap or juice, and the larger branches, when burnt, emit a very disagreeable odour, so there is great reason to believe the plants have some noxious quality; but this genus of plants has been confounded by many of the writers on botany, with the *Chamærhododendros* of *Tournefort*, and many of the noxious qualities with which the latter abounds, have been applied to the *Nerium*, but particularly that of the honey, about *Trebisond*, which is reckoned very unwholesome; which has been supposed to be occasioned by the bees sucking it from the flowers of the *Nerium*, whereas it is from the flowers of the *Chamærhododendros*, as *Tournefort* has fully informed us; but the affinity of their names in the *Greek* language, has occasioned these two plants to be often confounded.

These plants are generally propagated by layers in this country, for although they will take root from cuttings, yet that being an uncertain method, the other is generally pursued; and as the plants are very apt to produce suckers, or shoots from their roots, those are best adapted for laying, for the old branches will not put out roots; when these are laid down, they should be slit at a joint, in the same manner as is practised in laying of Carnations, which will greatly facilitate their taking root; if these branches are laid down in autumn, and are properly supplied with water, they will have taken root by that time twelvemonth, when they should be carefully raised up with a trowel, and if they have taken good root, they should be cut off from the old plant, and each planted in a separate small pot, filled with soft loamy earth; those of the common sort will require no other care, but to be placed in a shady situation, and gently watered as the season may require, till they have taken new root; but the two other species should be plunged into a very moderate

rate hot-bed, to forward their taking root, observing to shade them from the sun in the heat of the day; after the common sort has taken new root, the plants may be placed in a sheltered situation with other hardy exoticks, where they may remain till the end of *October*, when they should either be removed into the green-house, or placed under a hot-bed frame, where they may be protected from frost in winter, but enjoy the free air at all times, when the weather is mild.

This sort is so hardy as to live abroad in mild winters, if planted in a warm situation; but as they are liable to be destroyed in severe frost, the best way is to keep the plants in pots, or if they are very large, in tubs, that they may be sheltered in winter, and in the summer removed abroad, placing them in a warm sheltered situation. In the winter they may be placed with Myrtles, and other of the hardier kinds of exotick plants, in a place where they may have as much free air as possible, in mild weather, but screened from severe frost; for if these are kept too warm in winter, they will not flower strong, and when the air is excluded from them, the ends of their shoots will become mouldy, so that the hardier they are treated, provided they are not exposed to hard frosts, the better they will thrive.

The other two sorts require a different treatment, otherwise they will not make any appearance; therefore the young plants when they have taken new root, should be gradually inured to bear the open air, into which they should be removed in *July*, where they may remain till *October*, provided the weather continues mild; but during this time, they should be placed in a sheltered situation; and upon the first approach of frost, they should be removed into shelter, for if their leaves are injured by frost, they will change to a pale yellow, and will not recover their usual colour till the following summer. These sorts may be preserved in a good green-house through the winter, and the plants will be stronger than those which are more tenderly treated; but in *May*, when the flower-buds begin to appear, the plants should be placed in a open glass-case, where they may be defended from the inclemency of the weather; but when it is warm weather, the air should at all times be admitted to them in plenty. With this management the flowers will expand, and continue long in beauty; and during that time, there are few plants which are equal to them, either to the eye or nose, for their scent is very like that of the flowers of the White Thorn; and the bunches of flowers will be very large, if the plants are strong.

NICOTIANA. *Tourn. Inst. R. H.* 117. *tab.* 41. Tobacco.

The Characters are,

The empalement of the flower is permanent, of one leaf, cut into five acute segments. The flower has one funnel-shaped petal, with a long tube spread open at the brim, ending in five acute points. It hath five awl-shaped stamina which are the length of the tube, a little inclined and terminated by oblong summits, and an oval germen supporting a slender style, crowned by an indented stigma. The germen afterward turns to an oval capsule, having two cells which open at the top, and are filled with rough seeds fastened to the partition.

The Species are,

1. NICOTIANA *foliis ovato-lanceolatis rugosis, semi-amplexicaulibus.* Tobacco with oval, spear-shaped, rough leaves, which half embrace the stalks.

2. NICOTIANA *foliis lanceolatis sessilibus.* Tobacco with spear-shaped leaves sitting close to the stalks; or broad-leaved Tobacco.

3. NICOTIANA *foliis lanceolatis acutis, sessilibus, calycibus acutis, tubo floris longissimo.* *Plat.* 185. Tobacco with acute spear-shaped leaves sitting close to the stalks, sharp-pointed empalements, and a very long tube to the flower; or narrow-leaved Tobacco.

4. NICOTIANA *foliis lineari-lanceolatis acuminatis, semi-*

amplexicaulibus, caule fruticoso. Tobacco with linear, spear-shaped, acute-pointed leaves, half embracing the stalks, and a shrubby stalk.

5. NICOTIANA *foliis ovatis acuminatis semiamplexicaulibus, capsulis ovatis obtusis.* Tobacco with oval acute-pointed leaves, half embracing the stalk, and oval obtuse seed-vessels.

6. NICOTIANA *foliis ovato-lanceolatis sessilibus, caule fruticoso perenni.* Tobacco with oval spear-shaped leaves sitting close to the stalks, and a shrubby perennial stalk.

7. NICOTIANA *foliis ovatis Hort. Cliff.* 56. Tobacco with oval leaves; commonly called *English Tobacco*.

8. NICOTIANA *foliis ovatis rugosis petiolulatis.* Tobacco with oval rough leaves having foot-stalks.

9. NICOTIANA *foliis cordatis, floribus paniculatis, tubis clavatis.* *Lin. Sp. Plant.* 180. Tobacco with heart-shaped leaves, paniculated flowers, and club-shaped tubes.

10. NICOTIANA *foliis cordatis, corollis racemosis subringentibus, calycibus inæqualibus.* *Lin. Sp. Plant.* 181. Tobacco with heart-shaped leaves, branching ringent petals, and unequal empalements.

11. NICOTIANA *foliis ovato-lanceolatis obtusis rugosis calycibus brevissimis.* *Plat.* 185. Tobacco with oval, spear-shaped, obtuse, rough leaves, and a very short empalement.

The first sort is the most common Tobacco which is sown in *England*, and which has been generally taken for the broad-leaved Tobacco of *Caspar Bauhin*, and others, but is greatly different from it. The leaves of this sort are more than a foot and a half long, and a foot broad, the surface very rough and glutinous: when these plants are in a rich moist soil, they will grow more than ten feet high; the base of the leaves half embrace the stalks; the upper part of the stalk divides into smaller branches, which are terminated by loose bunches of flowers standing erect; they have pretty long tubes, and are of a pale purplish colour. It flowers in *July* and *August*, and the seeds ripen in the autumn. This is the sort of Tobacco which is commonly brought to the markets in pots, to adorn the shops and balconies of *London*, and by some is called *Oroonoko Tobacco*.

The second sort is the broad-leaved Tobacco of *Caspar Bauhin*; the stalks of this seldom rise more than five or six feet high, and divide into more branches than the first. The leaves are about ten inches long and three and a half broad, smooth, and end in acute points, fitting close to the stalks; the flowers of this are rather larger, and of a brighter purple colour than those of the first. It flowers and perfects seeds at the same time; this is by some called sweet-scented Tobacco.

The third sort rises with an upright branching stalk, four or five feet high; the lower leaves are a foot long, and three or four inches broad; those on the stalks are much narrower, lessening to the top, and end in very acute points, fitting close to the stalks; they are very glutinous. The flowers grow in loose bunches at the top of the stalks, they have long tubes, and are of a bright purple or red colour. These appear at the same time with the former sorts, and their seeds ripen in the autumn.

The fourth sort rises with very branching stalks about five feet high; the leaves on the lower part of the stalks are a foot and a half long, broad at the base where they half embrace the stalks, and are about three inches broad in the middle, terminating in long acute points; the stalks divide into many smaller branches, which are terminated by loose bunches of flowers of a bright purple colour, and are succeeded by acute-pointed seed-vessels. This flowers about the same time with the former, but if the plants are placed in a warm green-house, they will live through the winter. The seeds of this sort were sent me for *Brazi* Tobacco.

The fifth sort grows naturally in the woods in the island of *Tobago*, from whence the seeds were sent me by the late Mr. *Robert Millar*. This rises about five feet high; the stalk does not branch so much as those of the former; the leaves are large and oval, about fifteen inches long and two broad in the middle, but diminish gradually in their size to the top of the stalk, and with their base half embrace it. The flowers grow in closer bunches than those of the former, and are white; these are succeeded by short, oval, obtuse seed-vessels. It flowers and perfects seeds about the same time with the former.

The sixth sort grows naturally at *Senegal* in *Africa*, from whence the seeds were sent by Mr. *Adanson*, to the royal garden at *Paris*. This rises about four or five feet high; the lower leaves are nine inches long, and four broad in the middle; they are smooth, and sit close to the stalks; the upper leaves are of the same form, but gradually diminish toward the top in their size. The flowers are collected in pretty close bunches, they are of a pale purple colour, and are succeeded by oblong seed-vessels, inclosed in acute five-pointed empalements. The stalks of this sort are perennial, and put out shoots from their joints; if the plants are sheltered in winter, they will live two or three years.

The seventh sort is commonly called *English Tobacco*, from its having been the first which was introduced here, and being much more hardy than the other sorts. The seeds ripen very freely, and scattering in the autumn, the plants have come up without care, wherever any of the plants have been suffered to seed, so that it has been a weed in many places; but it came originally from *America*, by the title of *Petum*. *Dodonæus*, *Tabernemontanus*, and others, have titled it *Hyoscyamus luteus*, from the affinity there is between this plant and the Henbane; but the flowers of this are tubulous, and not ringent, as are those of the Henbane; nor do the seed-vessels of this open with a lid on the top, as that of Henbane. The stalks of this seldom rise more than three feet high; the leaves are placed alternately on the stalks, standing upon short foot-stalks; they are oval and smooth. The flowers grow in small loose bunches on the top of the stalks; they have short tubes, which spread open at the top, and are cut into five obtuse segments. They are of an herbaceous yellow colour, appearing in *July*, and are succeeded by roundish capsules filled with small seeds, which ripen in the autumn.

The eighth sort rises with a strong stalk near four feet high; the leaves of this are shaped like those of the former, but are greatly furrowed on their surface, and near twice the size of the former, of a darker green, and have longer foot-stalks. The flowers are larger than those of the former, and of the same shape. This is undoubtedly a distinct plant from the former, for I have sown the seeds more than thirty years, and have never found any of the plants vary.

The ninth sort was found growing naturally in the valley of *Lima*, by *Pere Feuille*, in the year 1710; and of late years the seeds of it were sent from *Peru*, by the younger *de Jussieu*, to *Paris*. The stalk of this sort rises more than three feet high, dividing upward into many smaller branches, which are rounder and a little hairy; the leaves are heart shaped, about four inches long, and three broad, standing upon pretty long foot-stalks. The flowers are produced in loose panicles at the end of the branches; these have tubes about an inch long, shaped like a club; the brim is slightly cut into nine obtuse segments, which are reflexed; they are of a yellowish green colour, and are succeeded by roundish capsules, filled with very small seeds. It flowers about the same time with the other sorts.

The seeds of the tenth sort were sent from *Peru* with those of the former, by the younger *de Jussieu*; the stalk of this is round, and rises near four feet high, sending out

two or three branches from the lower part; the leaves are large, heart-shaped, and a little waved; they are very clammy, standing upon long foot-stalks. The flowers grow in long loose spikes at the top of the stalk, having short open tubes, which are curved almost like the lip flowers; they are of a dull purple colour; the empalement is unequally cut, one of the segments being twice the size of the other.

The eleventh sort was discovered by the late Dr. *Houssour* at *La Vera Cruz*, who sent the seeds to *England*. This hath a pretty thick taper root, which strikes deep in the ground; at the top comes out six or seven oval spear-shaped leaves, which spread on the ground; they are about the size of those of the common *Primrose*, but of a deeper green; the stalk rises about a foot high, branching into three or four divisions, at each of these is placed one small leaf; the branches are terminated by a loose spike of flowers, which are small, tubulous, of a yellowish green colour, having very short empalements, which are cut at the brim into five acute segments. The seed-vessel is small, oval, and divided into two cells, which are full of small seeds.

All the sorts except the seventh and eighth, require the same culture, and are too tender to grow from seeds sown in the full ground, to any degree of perfection in this country, so require to be raised in a hot-bed, after the following manner:

The seeds must be sown upon a moderate hot-bed in *March*, and when the plants are come up fit to remove, they should be transplanted into a new hot-bed of a moderate warmth, about four inches asunder each way, observing to water and shade them until they have taken root; after which you must let them have air in proportion to the warmth of the season, otherwise they will draw up very weak, and be thereby less capable of enduring the open air: you must also observe to water them frequently, but while they are very young, it should not be given to them in too great quantities; though when they are pretty strong, they will require to have it often, and in plenty.

In this bed the plants should remain until the beginning of *May*, by which time (if they have succeeded well) they will touch each other, therefore they should be inured to bear the open air gradually; after which they must be taken up carefully, preserving a large ball of earth to each root, and planted into a rich light soil, in rows four feet asunder, and the plants three feet distance in the rows, observing to water them until they have taken root; after which they will require no farther care (but only to keep them clear from weeds) until the plants begin to shew their flower-stems; at which time you should cut off the tops of them, that their leaves may be better nourished, whereby they will be rendered larger, and of a thicker substance. In *August* they will be full grown, when they should be cut for use; for if they are permitted to stand longer, their under leaves will begin to decay. This is to be understood for such plants as are propagated for use, but those plants which are designed for ornament, should be planted in the borders of the pleasure-garden, and permitted to grow their full height, where they will continue flowering from *July*, till the frost puts a stop to them.

The two smaller sorts of *Tobacco* are preserved in botanick gardens for variety, but are seldom propagated for use. The first sort is found growing upon dunghills, in divers parts of *England*. These are both very hardy, and may be propagated by sowing their seeds in *March*, upon a bed of light earth, where they will come up, and may be transplanted into any part of the garden, where they will thrive without farther care.

The last sort being somewhat tenderer than the other, should be sown early in the spring on a hot-bed; and when

e plants come up, they should be transplanted on another moderate hot-bed, where they must be duly watered, and should have a large share of free air in warm weather; and when the plants have obtained a good share of strength, they should be transplanted into separate pots, and plunged into a moderate hot-bed to bring them forward. About the middle of *June* some of the plants may be shaken out of the pots, and planted into beds of rich earth; but it will be proper to keep some plants in pots, which may be placed in the stove (in case the season should prove bad), that they may ripen their seeds, so that the species may be preserved.

NIGELLA. *Tourn. Inst. R. H. 258. tab. 134.* Fennel Flower, or Devil in a Bush.

The Characters are,

The flower has no empalement, but a leafy perianthium. It hath five oval, obtuse, plain petals, which spread open, and are contracted at their base, and eight very short nectariums situated in a circle, each having two lips, the exterior being larger, the inferior bifid, plain, and convex. It hath a great number of awl-shaped stamina, which are shorter than the petals, terminated by obtuse, compressed, erect summits; and in some five, in others ten, oblong, convex, erect germen. The germen afterward become so many oblong compressed capsules, divided by a furrow, but connected within, filled with rough angular seeds.

The Species are,

1. **NIGELLA** *pisillis quinis, petalis integris, capsulis turbinatis.* *Lin. Sp. Plant. 534.* Fennel Flower having five pointals, entire petals, and turbinated seed-vessels.

2. **NIGELLA** *floribus involucro folioso cinctis.* *Hort. Cliff. 215.* Fennel Flower whose flowers are encompassed with a leafy involucre.

3. **NIGELLA** *petalis subtricuspidatis, foliis subpilosis.* *Hort. Upsal. 154.* Fennel Flower with petals which are almost three-pointed, and leaves somewhat hairy.

4. **NIGELLA** *pisillis quinis corollâ longioribus, petalis integris.* Fennel Flower with five pointals longer than the petals, which are entire.

5. **NIGELLA** *pisillis denis corollâ brevioribus.* Fennel Flower with ten pointals, which are shorter than the petals.

6. **NIGELLA** *pisillis denis corollam æquantibus.* *Hort. Upsal. 154.* Fennel Flower with ten pointals of equal length with the petals.

7. **NIGELLA** *pisillis denis corollâ longioribus.* *Hort. Cliff. 215.* Fennel Flower with ten pointals which are longer than the petals.

The first sort grows naturally among the Corn, in *France, Italy, and Germany*, so is seldom propagated in gardens.

The second sort grows naturally in *Spain and Italy*, among the Corn; this rises with an upright branching stalk, a foot and a half high, garnished with leaves much longer, and finer than those of the first. The flowers are large, of a pale blue, and have a long leafy involucre under each; these are succeeded by larger swelling seed-vessels, with horns at the top; of this there is one with single white flowers, and another with double flowers, which is sown in gardens for ornament.

The third sort grows naturally in *Crete*; this rises about the same height as the former. The leaves are not so finely cut as those of the second, and are a little hairy. At the top of each stalk is one flower, composed of five white petals, which are slightly cut at their end into three points; these are succeeded by oblong swelling seed-vessels, with five horns at the top, filled with small pale-coloured seeds.

The fourth sort also grows naturally in *Crete*; this rises with branching stalks about a foot high, garnished with shorter and broader leaves than either of the other species. At the top of each branch is one flower, having no involucre; they are composed of five petals, and have five

pointals longer than the petals; the seed-vessel is not much swollen, and has five slender horns at the top; the seeds are of a light yellowish brown colour.

The fifth sort is also a native of *Crete*; this rises with a branching stalk a foot high, garnished with leaves like those of *Larkspur*. The flowers have five large oval petals which are entire, and ten pointals which are shorter than the petals, and a great number of green stamina with blue chives; the seed-vessels are like those of the last sort.

The sixth sort rises a foot and a half high; the lower leaves are finely cut, but those on the stalk are cut into broader segments. The flowers are larger than those of the other species, they are of a fine blue colour: the pointals of this are of equal length with the petals; the seed-vessel has five horns, and is of a firmer texture than any of the other. This grows naturally in the south of *France and Spain*; there is a variety of this with double flowers.

The seventh sort grows naturally in the Corn-fields about *Aleppo*; this rises with a branching stalk a foot and a half high, garnished with pretty long leaves, which are finely divided. The flowers are produced at the end of the branches, they are composed of five yellowish leaves or petals; at the base of these are placed eight nectariums, between which arise a great number of stamina, with an unequal number of germen, some having but five, others having eight or nine; they are oblong and compressed; these afterward become so many oblong compressed seed-vessels, joined together on their inner side, terminating with horns, and open longitudinally, containing many thin compressed seeds, having borders round them.

The varieties of these with double flowers, are chiefly propagated in gardens for ornament; but those with single flowers are rarely admitted into any but botanick gardens, where they are preserved for the sake of variety.

All these plants may be propagated by sowing their seeds upon a bed of light earth, where they are to remain (for they seldom succeed well if transplanted); therefore, in order to have them intermixed amongst other annual flowers in the borders of the flower-garden, the seeds should be sown in patches at proper distances; and when the plants come up, they must be thinned where they grow too close, leaving but three or four of them in each patch, observing also to keep them clear from weeds, which is all the culture they require. In *July* they will produce their flowers, and their seeds will ripen in *August*, when they should be gathered and dried; then rub out each sort separately, and preserve them in a dry place.

The season for sowing these seeds is in *March*; but if you sow some of them in *August*, soon after they are ripe, upon a dry soil and in a warm situation, they will abide through the winter, and flower strong the succeeding year; so by sowing of the seeds at different times, they may be continued in beauty most part of the summer.

They are all annual plants, which perish soon after they have perfected their seeds; which, if permitted to scatter upon the borders, will come up without any farther care.

NONSUCH, or FLOWER of BRISTOL. See *Lychnis*.

NORTHERN ASPECT is the least favourable of any in *England*, as having very little benefit from the sun, even in the height of summer, therefore can be of little use, whatever may have been advanced to the contrary; for although many sorts of fruit trees will thrive and produce fruit in such positions, yet such fruit can be of little worth,

since

since they are deprived of the kindly warmth of the sun to correct their crude juices, and render them well tasted and wholesome; therefore it is to little purpose to plant fruit trees against such walls, except it be to those which are intended for baking, &c. where the fire will ripen, and render those juices wholesome, which, for want of sun, could not be performed while growing.

You may also plant Morello Cherries, for preserving; and white and red Currants, to come late, after those which are exposed to the sun are gone; and if the soil be warm and dry, some sorts of summer Pears will do tolerably well on such an exposure, and will continue longer in eating, than if they were more exposed to the sun. But you should by no means plant winter Pears in such an aspect, as hath been practised by many ignorant persons, since we find, that the best south walls, in some bad years, are barely warm enough to ripen those fruits.

Duke Cherries planted against walls exposed to the north, will ripen much later in the season, and if the soil is warm, they will be well flavoured, so that hereby this fruit may be continued a month later than is usual.

NURSERY, or nursery-garden, is a piece of land set apart for the raising and propagating of all sorts of trees and plants to supply the garden, and other plantations. Of this sort there are a great number in the different parts of this kingdom, but particularly in the neighbourhood of London, which are occupied by the gardeners, whose business it is to raise trees, plants, and flowers for sale; and in many of these there is at present a much greater variety of trees and plants cultivated, than can be found in any other part of Europe. In France, their nurseries (which are but few, when compared with those in England) are chiefly confined to the propagation of fruit trees, from whence they have the appellation of Pepinier. For there is scarce any of those gardens, where a person can be supplied either with ever-greens, flowering shrubs, or forest trees. And in Holland, their nurseries are principally for flowers; some few of them, indeed, propagate tender exotic plants. But those nurseries in the neighbourhood of London do, several of them, include all these, and from hence most of the curious persons abroad, are supplied with furniture for their gardens; therefore every planter should begin by making of a nursery upon the ground which is intended for planting, where a sufficient number of the trees may be left standing, after the others have been drawn out, to plant in other places; which, for all large growing trees, but particularly such as are cultivated for timber, will be found by much the most advantageous method; for all those trees which come up from the seed, or which are transplanted very young into the places where they are designed to remain, will make a much greater progress, and become larger trees, than any of those which are transplanted at a greater age, and hereby the expence and trouble of staking, watering, &c. will be saved, and the trees will succeed much better. These should be thinned gradually, as the trees advance; for, by taking away too many at first, the cold will check the growth of the remaining trees. But then those trees which are taken out from these nurseries, after a certain age, should not be depended on for planting; and it will be prudence rather to consign them for fuel, than by attempting to remove them large, whereby, in endeavouring to get them up with good roots, the roots of the standing trees will be often much injured.

What has been here proposed, must be understood for all large plantations in parks, woods, &c. but those nurseries which are only intended for the raising of ever-greens, flowering shrubs, or plants which are designed to embellish gardens, may be confined to one spot, because a small compass of ground will be sufficient for this purpose. Two or

three acres of land employed this way, will be sufficient for the most extensive designs, and one acre will be full enough for those of moderate extent.

Such a nursery as this should be conveniently situated for water; for where that is wanting, there must be an expence attending the carriage of water in dry weather. It should also be as near the house as it can with conveniency be admitted, in order to render it easy to visit at all times of the year, because it is absolutely necessary, that it should be under the inspection of the master, for unless he delights in it, there will be little hopes of success.

The many advantages which attend the having such a nursery, are so obvious to every person who has turned his thoughts the least to the subject, that it is needless for me to mention them here; and therefore I shall only beg leave to repeat here what I have so frequently recommended, which is the carefully keeping the ground always clean from weeds; for if these are permitted to grow, they will rob the young trees of their nourishment. Another principal business is, to dig the ground between the young plants at least once every year, to loosen it for the roots to strike out; but if the ground is stiff, it will be better to be repeated twice a year, viz. in October and March, which will greatly promote the growth of the plants, and prepare their roots for transplanting.

NUX AVELLANA. See Corylus.

NUX JUGLANS. See Juglans.

NUX VESICARIA. See Staphylo dendron.

NYCTANTHES. Lin. Gen. Plant. 16. Arabian Jasmine.

The Characters are,

The empalement of the flower is cylindrical, of one leaf, cut into eight acute segments. The flower is of the sakver shape, of one leaf, with a cylindrical tube longer than the empalement, cut into eight segments at the top. It hath two small awl-shaped stamina, situated in the bottom of the tube, and one roundish depressed germen, supporting a single style the length of the tube, crowned by a bifid erect stigma. The germen afterward becomes a roundish berry with two cells, each containing a large roundish seed.

The Species are,

1. NYCTANTHES caule volubili, foliis subovatis acutis. Hort. Upsal 4. Nyctanthes with a winding stalk, and oval acute leaves; or the Arabian Jasmine.

2. NYCTANTHES petiolis pedunculisque villosis. Lin. Sp. Plant. 6. Nyctanthes with the foot-stalks of the leaves and flowers hairy.

The first sort grows naturally in India, from whence it has been formerly brought to the islands in America, where the plants are cultivated for ornament; this rises with a winding stalk, to the height of ten or twelve feet, sending out many small branches, garnished with oval smooth leaves, of a light green, standing opposite, on short foot-stalks, which are hairy, ending in acute points. The flowers are produced at the end of the branches, upon short foot-stalks, each generally sustain three flowers, the two lower being opposite, and the middle one is longer; these have cylindrical empalements, which are short, and cut almost to the bottom into eight narrow segments. The tube of the flower is narrow, and is cut at the top into eight obtuse segments, which expand horizontally; they are of a pure white, and have a most agreeable odour, somewhat like the Orange flower, but sweeter; these flowers, when fully blown, drop out of their cups upon being shaken, and frequently fall in the night, so that when the plants are in full flower, the place under them is often covered with flowers in the morning, which soon change to a purplish colour. The plants continue flowering great part of the year, when they are kept in a proper temperature of warmth.

The second grows naturally in *India*, where it rises to the height of a tree, dividing into many branches, garnished with large, oval, smooth leaves, of a lucid green, with hairy foot-stalks; these come out on every side the branches, without order. The flowers are produced on the side of the branches, from the wings of the leaves, upon long hairy foot-stalks, each sustaining seven or eight flowers, which are of a pure white, and very fragrant, but have longer tubes than those of the former sort. The flowers of this plant open in the evening, and drop off in the morning, which has occasioned some to give it the title of *Arbor Tristis*, or the Sorrowful Tree, from its casting the flowers in the morning; this is very rare in *Europe* at present.

The plants of the first sort are frequently brought from *Italy*, by the *Italian* gardeners, who bring Orange trees here for sale; but those plants are always grafted upon stocks of the common *Jasmine*, which do not keep pace in their growth with the graft, so become very unfighly, when the plants are grown to any size; besides, the stocks are very subject to shoot from the bottom, and if these shoots are not constantly rubbed off, they will draw the nourishment from the graft, and starve it; therefore the best method to obtain the plants, is to propagate them by layers, or cuttings; the former is the surest method, for unless the cuttings are very carefully managed, they will not take root; and as the stalks of this sort are pliable, they may be easily brought down, and laid in pots filled with soft loamy soil, which should be plunged into a hot-bed of tan; if the branches are laid down in the spring and carefully watered, they will put out roots by autumn, when they may be cut from the old plants, and each transplanted into a separate small pot, and then plunged into the tan-bed, where they should be shaded from the sun till they have taken new root.

If these plants are propagated by cuttings, they should be planted in *April*, into pots filled with the before-mentioned earth, and plunged into a moderate hot-bed of tanners bark. The pots should be pretty large, and there may be ten or twelve cuttings planted in each; if these pots are closely covered with bell or hand-glasses, to exclude the air, it will greatly promote their taking root; they must also be shaded from the sun in the heat of the day, and gently refreshed with water when the earth is dry; with this management the cuttings will have taken root by *August*, when they may be transplanted into separate pots, and treated in the same way as the layers.

These plants may be preserved in a moderate degree of warmth, but if they are plunged in the tan-bed of the bark-stove, they will thrive much better, and produce a greater quantity of flowers; and as the leaves continue all the year, the plants will make a fine appearance in the stove at all seasons, and produce flowers great part of the year.

The second sort requires the same treatment but is much more difficult to propagate, so is very rarely found in the *European* gardens; there was two or three of these plants brought from *Florence* a few years since, but they were put into the hands of unskilful persons, so were lost.

NYMPHÆA. *Tourn. Inst. R. H.* 260. tab. 137, 138. The Water Lily.

The Characters are,

The empalement of the flower is composed of four or five coloured leaves. The flower hath many petals, sitting on the side of the germen, for the most part in a single series. It hath a great number of short, plain, incurved stamina, with oblong summits. It hath a large oval germen, but no style, with an orbicular, plain, target-shaped stigma. The germen afterward becomes a hard, oval, fleshy fruit, with a narrow neck, crowned at the top, and divided into ten or fifteen cells full of pulp, with many roundish seeds.

The Species are,

1. NYMPHÆA calyce magno pentaphyllo. *Flor. Lap.* 218. Water Lily with a large five-leaved empalement; or greater yellow Water Lily.

2. NYMPHÆA foliis cordatis integerrimis, calyce quadrifido. *Lin. Sp. Plant.* 510. Water Lily with heart-shaped entire leaves, and a four-pointed empalement; or greater white Water Lily.

There are some other species of this genus, which are natives of warm countries, but as they cannot, without great difficulty, be cultivated here, so I shall not enumerate them; for unless there is a contrivance for standing water in the stove, in which the plants may be planted, they will not grow; and such a place would be injurious to most other plants in the stove, by occasioning damps, so that unless a stove was contrived on purpose for some of these aquatick plants, it would be imprudent to attempt their cultivation.

The two sorts here mentioned, grow naturally in standing waters in many parts of *England*; they have large roots, which are fastened in the ground, from which arise the stalks to the surface of the water, where the leaves expand and float; they are large and roundish, those of the second sort are heart shaped. The flowers arise between the leaves, and swim upon the surface of the water. The white sort has a faint sweet scent; these appear in *July*, and are succeeded by large roundish seed-vessels, filled with shining black seeds, which ripen toward the end of *August*, when they sink to the bottom of the water.

The best method to propagate these plants is, to procure some of their seed-vessels just as they are ripe, and ready to open; these should be thrown into canals, or large ditches of standing water, where the seeds will sink to the bottom, and the following spring the plants will appear floating upon the surface of the water, and in *June* or *July* will produce their beautiful large flowers. When they are once fixed to the place, they will multiply exceedingly, so as to cover the whole surface of the water in a few years.

In some small gardens I have seen these plants cultivated in large troughs of water, where they have flourished very well, and have annually produced great quantities of flowers; but as the expence of these troughs is pretty great (their insides requiring to be lined with lead, to preserve them), there are few people who care to be at that charge.

NYSSA. *Flor. Virg.* 121. The Tupelo tree.

The Characters are,

It has hermaphrodite and male flowers on the same plant. It has no petal, but has ten awl shaped stamina, with twin summits as long as the stamina. The oval germen, situated under the flower, supports an awl-shaped incurved style crowned by an acute stigma. The germen afterward becomes an oval berry of one cell, inclosing an oval acute-pointed nut, with rough, angular, irregular furrows.

The Species are,

1. NYSSA foliis integerrimis. *Hort. Cliff.* 142. Tupelo tree with entire leaves.

2. NYSSA foliis acutè dentatis. Tupelo, with leaves acutely indented; commonly called Water Tupelo.

The first sort grows naturally in *Virginia* and several other parts of *North America*, where it rises with a pretty strong upright stalk, near twenty feet high, dividing at the top into several branches, garnished with pretty thick, soft, spear-shaped leaves, placed alternately. The flowers come out from the wings of the stalk, upon long foot stalks; they have a green empalement without petals. Some of them are male, which have ten stamina, and are barren; others are hermaphrodite, having five stamina, and a longer style arising from the germen, which is situated under the flower; these are succeeded by oval berries about

about the size of small Olives, inclosing a nut of the same form.

The second sort grows naturally in *Carolina*, in the shallow parts of rivers and swamps: it has a pretty large trunk, from which come out many branches toward the top, garnished with oblong, acute-pointed leaves, of a light green colour, standing upon long foot-stalks without order. The flowers come out from the wings of the stalk upon very long foot-stalks; they have no petals, but have a green empalement, and are some male, and others hermaphrodite, as in the first. The hermaphrodite flowers are succeeded by oblong oval berries, about the size and shape of *French Olives*, but are compressed, inclosing a rough hard-shelled nut of the same form.

Some of these plants have been introduced of late years into the *English* gardens, but there are few places where they have made much progress; they may be propagated by seeds, but these must be procured from places where they grow naturally, and should be put into the ground as soon as they arrive, for they always lie a year before the plants come up. The best way is to sow them in pots filled with light loamy earth, placing them where they may have only the morning sun; during the first summer the pots must be kept clean from weeds, and in dry weather duly watered. In autumn the pots should be plunged

into the ground, and if the winter should prove severe, they should be covered with old tan, Pease haulm, or other light covering, to prevent the frost from penetrating of the ground. The following spring the pots should be plunged into a moderate hot-bed which may be hooped over, and covered with mats, observing constantly to keep the earth moist. This will bring up the plants by the beginning of *May*; these must be gradually hardened to bear the open air, and during the following summer, the pots should be again plunged into an east border, and in dry weather duly watered. In autumn they should be removed into a frame where they may be screened from the frost, but in mild weather exposed to the open air. The spring following, before the plants begin to shoot, they should be parted carefully, and each planted in a separate small pot filled with loamy earth, and if they are plunged into a moderate hot-bed, it will forward their putting out new roots; then they may be plunged in an east border, and treated in the same way as in the former summer, and in winter sheltered again under a frame. The spring following such of the plants as have made the greatest progress, may be turned out of the pots, and planted in a loamy moist soil, in a sheltered situation, where they will endure the cold of this climate; but unless the ground is moist, they make very little progress.

O C Y

O C Y

OAK. See *Quercus*.
OBELISCOOTHECA. See *Rudbeckia*.
OCHRUS. See *Pisum*.
OCULUS CHRISTI. See *Horminum sylvestre*.
OCYMUM. *Tourn. Inst. R. H. 203. tab. 96.* Basil.

The Characters are,

The empalement of the flower is short, permanent, of one leaf, divided into two lips. The flower is of the lip kind, of one petal inverted; the rising lip is broad, and cut into four obtuse equal parts; the reflexed lip is long, narrow, and sawed. It hath four stamina in the lower lip, which are reflexed, two of which are a little longer than the other, terminated by half-moon-shaped summits. The germen is divided into four parts, which afterward becomes four naked seeds inclosed in the empalement.

The Species are,

1. *O*CYMUM *foliis ovatis glabris, calycibus ciliatis.* Hort. Cliff. 315. Basil with oval smooth leaves, and hairy empalements.

2. *O*CYMUM *foliis ovatis integerrimis.* Hort. Upsal. 169. Basil with oval entire leaves; commonly called Bush Basil.

3. *O*CYMUM *hirsutum, foliis ovato-lanceolatis acuminatis dentatis.* Hairy Basil with oval spear-shaped leaves, which are indented, and end in acute points.

4. *O*CYMUM *foliis ovato-oblongis serratis, bracteis cordatis reflexis concavis.* Lin Sp. Plant. 597. Basil with oval, oblong, sawed leaves, and heart-shaped, concave, reflexed bractæ.

5. *O*CYMUM *foliis lanceolatis subtus incanis, petiolis longissi-*

mis villosis floribus pedunculatis. Basil with spear-shaped leaves, which are hoary on their under side, and very long hairy foot-stalks to the flowers.

6. *O*CYMUM *foliis lineari lanceolatis serratis.* Flor. Zeyl. 229. Basil with linear spear-shaped leaves, which are sawed.

7. *O*CYMUM *racemis secundis lateralibus, caule erecto.* Lin. Sp. Plant. 597. Basil with fruitful spikes of flowers on the side of the stalk, which are erect.

The three first sorts grow naturally in *India* and *Persia*. Of these there is a great variety, which differ in the size, shape, and colour of their leaves, as also in their odour; but as these differences are accidental, so I have not enumerated them, being convinced from repeated experiments, that the seeds of one plant will produce many varieties.

The first sort rises with a branching stalk a foot and a half high; the leaves are large, oval, and smooth; the stalk is hairy, and four-cornered; the leaves are placed by pairs opposite, and the branches also come out in the same manner; the stalk is terminated by a whorled spike of flowers, which is five or six inches long, and the branches are also terminated by short spikes of flowers of the same sort; the whole plant has a strong scent of Cloves.

Of this there are the following Varieties:

1. The fringed-leaved Basil with purple leaves.
2. The green fringed-leaved Basil.
3. The green Basil with studded leaves.
4. The large-leaved Basil.

The second sort is a low bushy plant, which seldom rises more than six feet high, spreading out into branches from the bottom, forming an orbicular head; the leaves are small, oval, and smooth, standing opposite on short foot-stalks. The flowers are produced in whorls toward the top of the branches; they are smaller than those of the former sort, and are seldom succeeded by ripe seeds in *England*.

Of this there are some *Varieties*, as

1. The smallest Basil with black purple leaves.
2. The smallest Basil with variable leaves.

The third sort is the common Basil which is used in medicine, and also in the kitchen, particularly by the *French* cooks, who make great use of it in their soups and sauces. This rises about ten inches high, sending out branches by pairs opposite, from the bottom; the stalks and branches are four-cornered; the leaves are oval, spear-shaped, ending in acute points, and are indented on their edges; the whole plant is hairy, and has a strong scent of Cloves, too powerful for most persons, but to some it is very agreeable: the whole plant is an ingredient in the compound Briony water.

There are some *Varieties* of this *Species*, viz.

1. Common Basil with very dark green leaves, and a Violet-coloured flower.
2. Curled-leaved Basil with short spikes of flowers.
3. Narrow-leaved Basil smelling like Fennel.
4. Middle Basil with a scent of Citron.
5. Basil with studded leaves.
6. Basil with leaves of three colours.

The fourth sort grows naturally in *India*. This rises with a branching stalk a foot and a half high, which is taper, and of a purplish colour; the leaves are short and hairy; they are of an oval oblong figure, ending in obtuse points; they are sawed on their edges, and stand upon pretty long foot-stalks. The stalks are terminated by three spikes of flowers, that in the middle being longer than the other two; the spikes are long and narrow, and the flowers have short foot-stalks; under each whorl of flowers are two small leaves (or bractæ) placed opposite, which are heart-shaped, concave, and reflexed. The flowers are small, and in some plants are of a purplish colour, but in general they are white; their empalements are smooth, and cut into five parts at the top; the style of the flower is longer than the petal, and the whole plant has a strong, sweet, aromatick odour.

The fifth sort rises with an upright stalk near two feet high, sending out sometimes two, and at others four branches toward the top, opposite, garnished with spear-shaped leaves; their foot-stalks are two inches long, and are hairy. The flowers grow in whorled spikes at the top of the stalks, standing upon foot-stalks, each sustaining three flowers; these are about the size of those of the common Basil, and are white; the whole plant has a strong aromatick odour.

The sixth sort grows naturally in the island of *Ceylon*. This rises with a branching stalk about a foot high, garnished with linear spear-shaped leaves, which are sawed. The flowers grow in whorled spikes at the top of the stalks, which are like those of the common Basil; the whole plant has an odour like Anise seeds.

The seventh sort grows naturally in the island of *Ceylon*. This rises with a square stalk two feet high, which is hairy, and divides into three branches at the top; the lower leaves are roundish, ending in points; they are hairy, and crenated on their edges, standing upon slender foot-stalks; the leaves on the stalks are narrower, shorter, and have foot-stalks an inch long; the stalks are terminated by three spikes of flowers in whorls, that in the middle being the longest. The flowers are reflexed and hang downward;

they are white, and larger than those of the common sort. This plant has less odour than the other sorts.

These plants, being most of them annual, are propagated from seeds, which should be sown in *March*, upon a moderate hot-bed; and when the plants are come up, they should be transplanted into another moderate hot-bed, observing to water and shade them until they have taken root; after which they should have plenty of air in mild weather, otherwise they will draw up very weak. In *May* they should be taken up with a ball of earth to their roots, and transplanted either into pots or borders, observing to shade them until they have taken root; after which they will require no farther care, but to clear them from weeds, and refresh them with water in dry weather. Though these plants are only propagated from seeds, yet if you have any particular sort which may arise from seeds, which you are desirous to increase, you may take off cuttings any time in *May* or *June*, and plant them on a moderate hot-bed, observing to water and shade them for about ten days; in which time they will take root, and in three weeks time be fit to remove, either into pots or borders, with the seedling plants. In *September* these plants will perfect their seeds, when those sorts which appear the most distinct should have their seeds preserved separate; for sowing the following spring.

The seeds of these plants are usually brought from the south of *France* or *Italy* every spring, because they seldom ripen their seeds in this country in the open air. But whoever is curious to preserve the seeds of any of the varieties, should place them in an airy glass-case or stove in the autumn, when the weather begins to be cold or wet; and by supplying them with water, and letting them have free air every day in mild weather, they will perfect their seeds very well in this country.

The sixth sort is more tender than any of the other. It was discovered growing wild at *Campeachy*, by the late *Dr. William Houfoun*. This should be sown on a hot-bed early in the spring, and when the plants are come up, they should be transplanted on another very temperate hot-bed, to bring them forward; and when they have obtained strength, they should be each transplanted into a separate pot, and placed either in the stove, or on a moderate hot-bed, where they may have a large share of air in warm weather; but by being sheltered from the cold and wet, the plants will perfect their seeds very well in *England*.

The seventh sort grows to be shrubby, and if placed in a moderate warmth in winter, may be preserved two years; but as this will ripen its seeds the first year, if the plants are brought forward in the spring, so it is rarely allowed a place in the stove; but if they should fail, the plants may be placed in the stove, where they may be kept through the winter, and the following season they will perfect their seeds. In the summer the plants should be placed in the open air in a sheltered situation, and in warm weather they should have plenty of water.

CENANTHE. *Tourn. Inst. R. H.* 312. tab. 166. Water Dropwort.

The Characters are,

It is a plant with an umbelliferous flower; the principal umbel has but few rays, but the particular umbels have many short ones; the rays of the principal umbel are difform. Those flowers in the disk are hermaphrodite, and are composed of five heart-shaped inflexed petals, which are almost equal. The germen is situated under the flower, supporting two awl-shaped permanent styles, crowned by obtuse segments. The germen afterward becomes an oval fruit, divided in two parts, containing two almost oval seeds, convex on one side and plain on the other.

The Species are,

1. CENANTHE foliis omnibus multifidis obtusis subæqualibus. *Hort. Cliff.* 99. Water Dropwort, whose leaves all end in many obtuse points, and are almost equal.

2. *CENANTHE stolonifera, foliis caulinis pinnatis filiformibus fistulosis. Lin. Sp. Plant. 254.* Water Dropwort with slender, fistular, winged leaves growing on the stalks.

3. *CENANTHE foliolis radicalibus ovatis incisus, caulinis integris linearibus longissimis simplicioribus. Hort. Cliff. 99.* Water Dropwort, whose lower leaves are oval and cut, but those on the stalks entire, single, narrow, and very long.

4. *CENANTHE umbellularum pedunculis marginalibus longioribus ramosis masculis. Hort. Upsal. 63.* Water Dropwort, whose foot-stalks on the borders of the umbels are longer, branching, and bear male flowers.

5. *CENANTHE fructibus globosis. Hort. Cliff. 99.* Water Dropwort with globular fruit.

The first of those here mentioned, is very common by the sides of the *Thames* on each side *London*, as also by the sides of large ditches and rivers in divers parts of *England*: this plant commonly grows four or five feet high with strong jointed stalks, which, being broken, emit a yellowish fetid juice; the leaves are somewhat like those of the common Hemlock, but are of a lighter green colour: the roots divide into four or five large taper ones, which, when separated, have some resemblance to Parsneps; for which some ignorant persons have boiled them, whereby themselves and family have been poisoned.

This plant is one of the most poisonous we know; the juice, which is at first like milk, turns afterward to a Saffron colour: if a person should swallow ever so little of this juice, it will so contract every part it touches, that there will immediately follow a terrible inflammation and gangrene; and, which is worse, there has not yet been found any antidote against it; for which reason we ought to be very careful to know this plant, in order to avoid it, for fear we should take it for any other like it, which would certainly prove fatal.

The poisonous quality of this plant hath led some persons to believe it to be the *Cicuta* of the ancients; but according to *Wepfer*, the *Sium alterum olusatrici facie* of *Lobel*, is what the ancients called *Cicuta*, as may be seen at large in *Wepfer's* book *de Cicuta*.

The second sort is very common in moist soils, and by the sides of rivers in divers parts of *England*: this is not supposed to be near so strong as the first, but is of a poisonous quality.

All the sorts of these plants naturally grow in moist places, so that whoever hath a mind to cultivate them, should sow their seeds soon after they are ripe in autumn, upon a moist soil, where they will come up, and thrive exceedingly the following summer, and require no farther care but to clear them from weeds.

CENOTHERA. Lin. Gen. Plant. 424. Tree, or Night Primrose.

The Characters are,

The empalement of the flower is of one leaf, cut into four acute segments at the brim, which turn backward. The flower has four heart-shaped petals, which are lengthways inserted in the divisions of the empalement. It hath eight awl-shaped incurved stamina, which are inserted in the tube of the empalement. The cylindrical germen is situated under the tube of the empalement, supporting a slender style crowned by a thick, quadrifid, obtuse, reflexed stigma. The germen afterward becomes a four-cornered cylindrical capsule, having four cells, which are filled with small angular seeds.

The Species are,

1. *CENOTHERA foliis ovato-lanceolatis. Vir. Cliff. 33.* Tree Primrose with plain, oval, spear-shaped leaves.

2. *CENOTHERA foliis lanceolatis dentatis, caule hispido.* Tree Primrose with spear-shaped indented leaves, and a prickly stalk.

3. *CENOTHERA foliis lanceolatis planis, caule glabro.* Tree Primrose with plain spear-shaped leaves, and a smooth stalk.

4. *CENOTHERA foliis lanceolatis undulatis. Vir. Cliff. 33.* Tree Primrose with waved spear-shaped leaves.

5. *CENOTHERA foliis radicalibus ovatis, caulinis lanceolatis obtusis, capsulis ovatis sulcatis. Tab. 188.* Tree Primrose with oval leaves at the root, those on the stalks spear-shaped and blunt-pointed, and oval furrowed seed vessels.

The other species which have been formerly placed in this genus, are now under *JUSSIÆ* and *LUDWIGIA*, to which the reader is desired to turn.

The three first sorts grow naturally in *Virginia*, and in other parts of *North America*, from whence their seeds were brought to *Europe* in the beginning of the sixteenth century; but they are now become so common in many parts of *Europe*, as to be taken for natives. The first hath a long, thick, taper root, which runs deep into the ground, from which arise many oblong leaves which spread flat on the surface of the ground; between these the stalk comes out, which rises between three and four feet high; the stalk is of a pale green colour, a little hairy, and about the thickness of a finger, full of pith; this is garnished with long narrow leaves set close to the stalk without order. The flowers are produced all along the stalk from the wings of the leaves, the germen sitting close to the stalk, from the top of which arises the tube of the flower, which is narrow; at the top is the empalement, which is cut into four acute segments, reflexed downward. The petal of the flower is cut into four large obtuse segments, which in the evening are expanded quite flat, but are shut in the day; these are of a bright yellow colour. From the flower opening in the evening, many persons call it the Night Primrose. The plants begin to flower about *Midsummer*, and as the stalks advance in height, so other flowers are produced, whereby there is a succession of flowers on the same plant till autumn.

The second sort hath red stalks, which are set with rough protuberances; it does not rise so high as the first, the leaves are narrower, and the flowers are smaller.

The third sort differs from the first, in having shorter stalks, narrower leaves, and smaller flowers; and from the second, in having smooth stalks, which are of a pale green colour. These differences are permanent, so they are undoubtedly different species.

The fourth sort grows naturally at *Buenos Ayres*. This hath a shrubby stalk more than two feet high, garnished with narrow, hairy, spear-shaped leaves, ending in acute points, a little waved on their edges. The flowers come out from the wings of the leaves along the stalks, like the other sorts; they are first of a pale yellow, but as they decay change to an Orange colour; they are smaller than those of either of the former sorts, and expand only in the evening; the seed vessels are slender, taper, and hairy. This flowers at the same time with the former.

The fifth sort grows naturally in *Canada*, from whence the seeds were brought to *Paris* a few years past. This is a perennial plant, the root is fibrous; the lower leaves are oval and small, sitting close to the ground; the stalk is slender, near a foot high, and is garnished with small spear-shaped leaves, of a light green, ending in blunt points, sitting close to the stalks. The flowers come out from the wings of the leaves like the other species; these are small, of a bright yellow colour, and appear at the same time as the former, and are succeeded by short, oval, furrowed seed-vessels, filled with small seeds.

The three first sorts are very hardy plants, which if once brought into a garden, and the seeds permitted to scatter, there will be a supply of plants without any care. They are biennial, and perish after they have perfected their seeds. The seeds of these plants should be sown in the autumn, for those which are sown in the spring seldom rise the same year; when the plants come up, they should be thinned.

and kept clean from weeds, which is all the care they require till the autumn, when they should be transplanted to the places where they are designed to flower; but as the roots of these plants strike deep in the ground, so there should be care taken not to cut or break them in removing. The plants will thrive in almost any soil or situation, and will flower in London in small gardens, better than most other plants.

The fourth sort is now become pretty common in the English gardens, for if the seeds of this are permitted to scatter, the plants will come up the following spring, and require no other care but to keep them clean from weeds, and thin them where they grow too close. If these plants are kept in pots, and placed in a green-house in the autumn, they will live through the winter; but as they produce flowers and seeds in the open air, the plants are seldom preserved longer.

The fifth sort is perennial, and may be propagated either by parting of the roots or by seeds; if it is by the former, the best time for doing it is in the spring, but if they are propagated by seeds, these should be sown in the autumn; and the surest way is to sow the seeds in pots, and place them under a hot-bed frame in winter; in the spring the plants will appear, and when they are fit to remove, a few of them may be planted in small pots, to be sheltered under a common frame in the winter; and the others may be planted in a sheltered border, where they will endure the cold of our ordinary winters very well, and the following summer they will produce flowers and seeds in plenty, so there will be little occasion for parting of their roots, because the seedling plants will be much stronger and flower better than those propagated by offsets.

OLDENLANDIA. Plum. Nov. Gen. 42. tab. 36.

The Characters are,

The empalement of the flower is permanent, sitting upon the germen. The flower has four oval petals, which spread open, and four stamina terminated by small summits. It hath a roundish germen situated under the flower, crowned by an indented stigma. The germen after-ward turns to a globular capsule with two cells, filled with small seeds.

We have but one Species of this plant in the English gardens, viz.

OLDENLANDIA pedunculis multifloris, foliis linearilanceolatis: Lin. Sp. Plant. 119. Oldenlandia with many flowers on a foot-stalk, and linear spear-shaped leaves.

The seeds of this plant were sent into England by Mr. Robert Millar, who gathered them in Jamaica. It is a low annual plant, which divides into many branches, spreading upon the ground. These branches are garnished with long narrow leaves, placed opposite. From the wings of the leaves arises the flower-stalk, which grows about an inch, or a little more in length, and divides into three or four smaller foot-stalks; on the top of each of these stands one small white flower.

The seeds of this plant should be sown early in the spring on a hot-bed, and when the plants are come up, they should be transplanted on another hot-bed, or into small pots, and plunged into a moderate hot-bed of tanners-bark, observing to water and shade them until they have taken root; after which time they must have a large share of free air in warm weather, and must be frequently refreshed with water. With this management the plants will flower in June, and their seeds will ripen soon after, so that the seeds must be gathered from time to time as they ripen; for as the branches grow larger, so there will be fresh flowers produced until autumn, when the plants will perish; but if the seeds are permitted to scatter in the pots, the plants will soon after appear, which will live through the winter, provided they are placed in the stove, and will flower early the following spring.

OLEA: Tourn. Inst. R. H. 593. tab. 370. The Olive.

The Characters are,

It has a small tubulous empalement of one leaf, cut into four segments at the top. The flower consists of one petal, which is tubulous, cut at the brim into four segments. It has two short stamina terminated by erect summits, and a roundish germen supporting a short single style, crowned by a thick bifid stigma. The germen after-ward turns to an oval smooth fruit (or berry) with one cell, inclosing an oblong oval nut.

The Species are,

1. OLEA foliis linearilanceolatis subtus incanis. Olive with linear spear-shaped leaves, which are hoary on their under side; commonly called Provence Olive.

2. OLEA foliis lanceolatis, fructu ovato. Olive with spear-shaped leaves, and an egg-shaped fruit; called the Spanish Olive.

3. OLEA foliis lanceolatis obtusis rigidis, subtus incanis. Olive with spear-shaped, obtuse, rigid leaves, which are hoary on their under side; or the Wild Olive.

4. OLEA foliis lanceolatis lucidis, ramis teretibus. Olive with spear-shaped shining leaves, and taper branches; called African Olive.

5. OLEA foliis ovatis rigidis sessilibus. Olive with oval stiff leaves, sitting close to the branches; commonly called Box-leaved Olive.

The first sort is what the inhabitants of the south of France chiefly cultivate, because from this species the best Oil is made, which is a great branch of trade in Provence and Languedoc; and it is the fruit of this sort, which is most esteemed when pickled: of this there are some varieties; the first is called Olive Picholine; there is another with dark green fruit, one with white fruit, and another with smaller and rounder fruit; but as these are supposed to be only accidental varieties, which have risen from the same seeds, I have not enumerated them.

The Olive seldom rises to be a large tree, and is rarely seen with a single stem, but frequently two or three stems rise from the same root; these grow from twenty to thirty feet high, putting out branches from their sides almost their whole length, which are covered with a gray bark, and garnished with stiff leaves, of a lively green on their upper side, and hoary on their under, standing opposite. The flowers are produced in small bunches from the wings of the leaves; they are small, white, and have short tubes, spreading open at the top; these are succeeded by oval fruit, which, in warm countries, ripen in the autumn.

The second sort is chiefly cultivated in Spain, where the trees grow to a much larger size than the former sort; the leaves are much larger, and not so white on their under side; and the fruit is near twice the size of those of the Provence Olive, but are of a strong rank flavour, and the oil made from these is too strong for most English palates.

The third sort is the Wild Olive, which grows naturally in woods, in the south of France, Spain, and Italy, so is never cultivated; the leaves of this sort are much shorter and stiffer than those of the other; the branches are frequently armed with thorns, and the fruit is small and of no value.

The fourth and fifth sorts grow naturally at the Cape of Good Hope; the fourth rises to the height of the first, to which it bears some resemblance, but the bark is rougher; the leaves are not so long, and are of a lucid green on their upper side; but as this does not produce fruit in Europe, I can give no account of it.

The fifth sort is of humbler growth, seldom rising more than four or five feet high, sending out branches from the root upward, forming a bushy shrub; the branches are taper, and covered with a gray bark; the leaves are oval, very stiff, and smaller than those of the other species. This has not produced any fruit in England.

All these sorts are preserved in the gardens of the curious, but they are rather too tender to thrive in the open air, in the neighbourhood of *London*, where they are sometimes planted against walls, and with a little protection in very severe frost, they are maintained pretty well; but in *Devonshire* there are some of these trees, which have grown in the open air many years, and are seldom injured by the frost, but the summers are not warm enough to bring the fruit to maturity. There were several of these trees planted against a warm wall at *Cambden-house*, near *Kensington*, which succeeded very well, till their tops were advanced above the wall; after which they were generally killed in winter, so far down as to the top of the wall. These in 1719 produced a good number of fruit, which grew so large as to be fit for pickling; but since that time, their fruit has seldom grown to any size.

In *Languedoc* and *Provence*, where the Olive tree is greatly cultivated, they propagate it by truncheons split from the roots of the trees; for as these trees are frequently hurt by hard frosts in winter, so when the tops are killed, they send up several stalks from the root; and when these are grown pretty strong, they separate them with an ax from the root, in the doing of which they are careful to preserve a few roots to the truncheons; these are cut off in the spring, after the danger of frost is over, and planted about two feet deep in the ground, covering the surface with litter or mulch, to prevent the sun and wind from penetrating and drying of the ground; when the plants have taken new root, they are careful to stir the ground, and destroy the weeds.

This tree will grow in almost any soil, but when it is planted in rich moist ground, they grow larger and make a finer appearance, than in poor land; but the fruit is of less esteem, because the oil made from it, is not so good as that which is produced in a leaner soil. The chalky ground is esteemed the best for these trees, and the oil which is made from the trees growing in that sort of land is much finer, and will keep longer than the other.

In the countries where the inhabitants are curious in the making of their oil, they are frequently obliged to get truncheons of the ordinary sorts of Olives to plant; but after they have taken good root, they graft them with that sort of Olive which they prefer to the others. In *Languedoc* they chiefly propagate the *Cormeau*, the *Ampoulan*, and *Moureau*, which are three varieties of the first species: but in *Spain* the second sort is generally cultivated, where they have more regard to the size of the fruit, and the quantity of oil they will produce, than to their quality.

In *England* the plants are only preserved by way of curiosity, and are placed in winter in the green-house for variety, so I shall next give an account of the method by which they are here propagated, with their manner of treatment.

These plants may be propagated by laying down their tender branches (in the manner practised for other trees), which should remain undisturbed two years; in which time they will have taken root, and may then be taken off from the old plants, and transplanted either into pots filled with fresh light earth, or into the open ground in a warm situation. The best season for transplanting them is the beginning of *April*, when you should, if possible, take the opportunity of a moist season; and those which are planted in pots, should be placed in a shady part of the green-house until they have taken root; but those planted in the ground should have mulch laid about their roots, to prevent the earth from drying too fast, and now and then refreshed with water; but you must by no means let them have too much moisture, which will rot the tender fibres of their roots, and destroy the trees. When the plants have taken

fresh root, those in the pots may be exposed to the open air, with other hardy exoticks, with which they should be housed in winter, and treated as *Myrtles*, and other less tender trees and shrubs; but those in the open air will require no farther care until the winter following, when you should mulch the ground about their roots, to prevent the frost from penetrating deep into it; and if the frost should prove very severe, you should cover them with mats, which will defend them from being injured thereby; but you must be cautious not to let the mats continue over them after the frost is past, lest by keeping them too close, their leaves and tender branches should turn mouldy for want of free air, which will be of as bad consequence to the trees, as if they had been exposed to the frost, and many times worse; for it seldom happens, if they have taken much of this mould, or have been long covered, so that it has entered the bark, that they are ever recoverable again; whereas it often happens, that the frost only destroys the tender shoots; but the body and larger branches remain unhurt, and put out again the succeeding spring.

These trees are generally brought over from *Italy* every spring, by the persons who bring over *Oranges*, *Jasmines*, &c. from whom they may be procured pretty reasonable; which is a better method than to raise them from layers in this country, that being too tedious; and those which are thus brought over, have many times very large stems, to which size young plants in this country would not arrive in ten or twelve years growth. When you first procure these stems, you should (after having soaked their roots twenty-four hours in water, and cleaned them from the filth they have contracted in their passage) plant them in pots filled with fresh light earth, and plunge them into a moderate hot-bed, observing to screen them from the violence of the sun in the heat of the day, and also to refresh them with water, as you shall find the earth in the pots dry. In this situation they will begin to shoot in a month or six weeks after, when you should let them have air in proportion to the warmth of the season; and after they have made pretty good shoots, you should inure them to the open air by degrees, into which they should be removed, placing them in a situation where they may be defended from strong winds; in this place they should remain till *October* following, when they must be removed into the green-house, as was before directed. Having thus managed these plants until they have acquired strong roots, and made tolerable good heads, you may draw them out of the pots, preserving the earth to their roots, and plant them in the open air in a warm situation, where you must manage them as was before directed for the young ones, and these will in two or three years produce flowers, and in very warm seasons some fruit, provided they do well. The *Lucca* and *Box-leaved Olives* are the hardiest, for which reason they should be preferred to plant in the open air, but the first sort will grow to be the largest trees.

OMPHALODES. See *Cynoglossum*.

ONAGRA. See *Oenothera*.

ONIONS. See *Cepa*.

ONOBRYCHIS. *Tourn. Inst. R. H. 390. tab. 211.* Cock's Head, or Saintfoin.

The Characters are,

The empalement of the flower is permanent, cut into five parts at the top. The flower is of the butterfly kind. The standard is oblong, reflexed, and indented at the top. The wings are oblong and erect. The keel is compressed, broad at the end, and bifid at the base. It has ten angular stamina, nine joined, and one separate, and a narrow compressed germen, supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes a compressed roundish pod, which opens with two valves, inclosing one kidney-shaped seed.

The *Species* are,

1. *ONOBRYCHIS foliis pinnatis, leguminibus aculeatis, corollarum alis calyce brevioribus.* Cocks Head with winged leaves, prickly pods, and the wings of the flowers shorter than the empalment; or common Saintfoin.

2. *ONOBRYCHIS foliis pinnatis, leguminibus aculeatis, petalis æqualibus.* Cocks Head, or Saintfoin with winged leaves, prickly pods, and equal petals to the flowers.

3. *ONOBRYCHIS foliis pinnatis, leguminibus rugosis, petalis æqualibus, calycibus brevissimis.* Cocks Head with winged leaves, rough pods, equal petals to the flowers, and very short empalements.

4. *ONOBRYCHIS foliis pinnatis, foliolis obtusis, leguminibus aculeatis, petalis subæqualibus.* Cocks Head with winged leaves, having obtuse lobes, prickly pods, and the petals of the flowers almost equal.

The first sort is commonly cultivated in the fields for fodder for cattle, and is a great improvement to chalky lands, where there would be very little natural grass produced, if it was encouraged; so that many estates have been improved since this, and other plants have been introduced to double their rent.

The roots of this plant are large, stringy, and run deep in the ground, from which come out several winged leaves, composed of eight or ten pair of oval lobes, placed opposite along the midrib, terminated by an odd one. The stalks rise near two feet high; these are garnished toward the bottom, with the like winged leaves, but the upper part of the stalk is naked to about six inches of the top, where they are terminated by spikes of soft red flowers, shaped like those of the *French Honey-suckle*, but smaller; these are succeeded by roundish, compressed, prickly pods, each having one kidney-shaped seed. It flowers in *June*, and the seeds are ripe in *September*, but the roots will continue many years; there are two or three varieties of this, which differ only in the colour of their flowers.

The second sort grows naturally in *Sicily* and *Spain*; this is an annual plant, which perishes soon after it has perfected seeds. It has a jointed stalk, a foot and a half high; from each joint comes out one winged leaf, composed of six or eight small oval lobes, terminated by an odd one, and close to the base of the leaf, arises a naked foot-stalk, four or five inches long, sustaining at the top a few small purplish flowers, shaped like those of the former sort, but the petals are of equal length; they are succeeded by larger pods than those of the first, which are crested, and armed with stronger prickles. It flowers the latter end of *June*, and the seeds ripen in autumn.

The third sort grows naturally in *Italy*; this hath a perennial root, which runs deep in the ground, from which arise several slender branching stalks, a foot and a half high, garnished with winged leaves, composed of nine or ten pair of narrow lobes, terminated by an odd one. The stalks are terminated by long loose spikes of pale red flowers, which are much smaller than those of the first sort, whose petals are almost equal in length; these are succeeded by small, rough, crested pods, which are not armed with prickles. It flowers and ripens seeds about the same time as the first.

The fourth sort grows naturally in the island of *Crete*; this has a perennial root like the first. The stalks are stronger, and rise near two feet high; they are garnished with winged leaves, composed of nine or ten pair of lobes, terminated by an odd one. The lobes of this sort are broader than those of the first sort, and end in obtuse points; they are of a deep green, and stand more erect. The flowers are produced in pretty long spikes; they are of a pale red colour, and as large as those of the first, their petals are almost of equal length; these are succeeded by

larger, compressed, crested pods than those of the first, which are strongly armed with prickles. It flowers in *July*, and the seeds ripen in autumn.

The first is an abiding plant, which, if sown upon a dry, gravelly, or chalky soil, will continue eighteen or twenty years, without renewing; but if it be sown upon a deep, light, moist soil, the roots will run down into the ground, and in the winter season the moisture will rot them, so that it seldom lasts above two years in such places.

This is esteemed one of the best sorts of fodder for most cattle, and is a great improvement to chalky hills, upon which it succeeds better than in any other soil, and will continue many years, provided there is a surface of six or eight inches upon the chalk.

The season for sowing of this seed is in the beginning, or middle of *April*, according as the season is early or late, observing always to do it in dry weather, otherwise the seed will be apt to burst with moisture, and never come up. These seeds being large, there will require a greater quantity in measure to sow an acre, than of many other sorts; the common allowance is four bushels to an acre, but I would not advise above three at most; and if the seeds were sown in rows, in the manner directed for the *Medica*, it would be a great improvement to the plants, for when they have room enough, they are very subject to branch out on every side, and become very strong; so that where they are in rows, that the ground between them can be stirred with a hoe plough, it will cause them to shoot much stronger than when they grow so close, that there can be no culture bestowed on them; and by hoeing between the plants, the natural grass will be kept down, which, if permitted to grow, will rob the Saintfoin of its nourishment, and in time destroy it.

I have taken up roots of this kind, where they have grown singly, and been kept clear from weeds, whose shoots have spread near two feet wide, and were much stronger than those which grew nearer together upon the same soil.

There are some persons who recommend the sowing Oats or Barley with this seed; but that is a very bad method, for what is gained from the crop of Corn, will be doubly lost in the Saintfoin; and this generally holds true in most sorts of Grass seeds, for the Corn growing over it doth so weaken the crop beneath, that it scarcely recovers its strength in a years time after.

The ground in which this seed is sown, should be well ploughed, and made very fine; and if you sow it in rows, the drills should be made eighteen inches asunder, and about an inch deep, in which the seeds should be sown indifferently thick; for if the plants come up too close, it will be very easy to hoe them out, so as to leave the remaining ones six or eight inches asunder, for the ground should be hoed after the plants are come up, to destroy the weeds, which, if suffered to grow, would soon overbear the young plants, and destroy them; but when the plants have obtained strength, they will prevent the weeds from growing up amongst them.

The first year after sowing, you should by no means feed it down, for the crown of the roots being then young and tender, the cattle would eat it so low, as to entirely destroy the roots; and if large cattle were let in upon it, they would trample it down so much as to prevent its shooting again; therefore the first year it should be mowed, which should be done when it is in flower.

The sooner this is carried off the ground, when cut, it will be the better for the plants, so that if it were carried on a neighbouring ground to be made, the second crop would come up sooner and stronger; this doth not require to be so often turned as other Hay, for as the stalks are larger

larger, they will not lie so close in the cocks as to ferment; therefore in catching weather, the cocks may be made large, and if they are turned and spread every other day, or once in three days, there will be little danger of its heating, so as to receive damage; but if it is spread, and much exposed to rain and dews, the goodness of the Hay will be exhausted.

The time when this crop will be fit to cut the first year, is toward the latter end of *July*, or the beginning of *August*. After this is cleared off, the roots will soon shoot again, and by the end of *September*, provided the season be favourable, there will be a fine crop fit for feeding; at which time, or soon after, you may turn in sheep, which will, in eating down the grass, enrich the ground with their dung, whereby the roots will be greatly strengthened; but you should not suffer them to remain too long upon it, as I before observed, lest they should eat it down too low, which would destroy the roots; nor should they ever be suffered to remain upon it longer than the middle of *November* the first year; and the succeeding years, when the crop is early cut, it should not be fed longer than the middle of *September*.

There are some who cut two crops of this Hay in a year, but the latter crop is seldom of much value, and this weakens the roots, for which reason it should not be practised. When the seeds of Saintfoin are to be saved, the crop should not be fed too low the foregoing autumn, for that will occasion the stalks to be weak, therefore the best husbandry is not to feed it the season before, for I have made trial of two rows of plants standing by each other, one of which I cut down in *September*, with care, so as not to cut any buds for the future shoots; the other row I left untouched, and the following spring I found those plants which were not cut, put out earlier and stronger, and the stalks grew taller than those which were cut, and the plants produced a greater quantity of seeds, which were ripe a fortnight sooner.

The Hay which is made from the plants saved for seed, is of but little value, being no better fodder than chopped Straw, or chaff, so that those who are desirous to have the Hay in perfection, should cut it just before it begins to flower, when it abounds more with juice, and will nourish cattle much more than that which stands to be full in flower.

This sort of Hay is exceeding good for horses, and is esteemed one of the best sorts of food for most cattle, especially in the spring, there being no danger attending it, as there is in Clover, and some other sorts of fodder; it breeds abundance of milk, and the butter that is made of it is very good.

Since this plant has been introduced into *England*, there have been many dairy farms set up, in such places where it was formerly thought impracticable; and if this plant, and the Lucern, were properly cultivated, there might be yet much greater improvements made; for hereby not only a much greater quantity of milch cows might be maintained, but also a greater number of black cattle might be fattened, and more sheep and hogs, which would be a great improvement to many estates in the hilly countries, for by increasing of the live stock, there will be an addition of manure for dressing the arable land.

The other sorts of this plant are preserved in botanick gardens for variety, but as they have little beauty or use, they are rarely admitted into other gardens. The second sort being an annual plant, the seeds must be sown on an open border every spring, where the plants are to remain for good, and will require no other care, but to thin the plants, and keep them clean from weeds; the other sorts require no other culture than the first, as their roots last many years.

ONONIS. *Lin. Gen. Plant.* 772. Rest-harrow, Cammock, Petty-whin.

The Characters are,

The empalement of the flower is cut into five narrow segments, the upper being a little raised and arched, the lower bending under the keel. The flower is of the butterfly kind. The standard is heart-shaped, and larger than the wings. The wings are oval and short; the keel is pointed, and longer than the wings. It hath ten stamina joined together, and an oblong hairy germen, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes a turgid pod with one cell, inclosing kidney-shaped seeds.

The Species are,

1. ONONIS floribus subsessilibus solitariis lateralibus, caule spinoso. *Hort. Cliff.* 359. Rest-harrow with single flowers sitting close to the sides of the branches, and a prickly stalk; called Cammock, or Petty-whin.

2. ONONIS floribus subsessilibus solitariis lateralibus, ramis inermibus. *Hort. Cliff.* 359. Rest-harrow with single flowers sitting close to the stalks, and branches without spines.

3. ONONIS caulibus procumbentibus, floribus subsessilibus solitariis, foliis hirsutis. Rest-harrow with trailing stalks, single flowers sitting close to the branches; and hairy leaves.

4. ONONIS foliis ternatis carnosis sublinearibus tridentatis. *Lin. Sp. Plant.* 718. Rest-harrow with trifoliate fleshy leaves, which are narrow, and have three indentures.

5. ONONIS floribus paniculatis, pedunculis subtrifloris, stipulis vaginalibus, foliis ternatis. *Hort. Cliff.* 358. Rest-harrow with paniculated flowers, generally growing three upon a foot-stalk sheath-like stipulæ, and trifoliate leaves; or purple shrubby Rest-harrow.

6. ONONIS pedunculis unifloris filo terminatis foliis ternatis. *Hort. Cliff.* 358. Rest-harrow with one flower on a foot-stalk, which is terminated by a thread and trifoliate leaves.

7. ONONIS pedunculis unifloris, filo terminatis, caule ramoso villoso, foliis ternatis serratis. Rest-harrow with one flower on each foot-stalk, which are terminated by a thread, a branching hairy stalk, and trifoliate sawed leaves; or broad-leaved erect Rest-harrow of *Portugal*.

8. ONONIS floribus sessilibus lateralibus, foliis omnibus ternatis petiolatisque, stipulis setaceis. *Lin. Sp. Plant.* 717. Rest-harrow with flowers sitting close to the sides of the stalks, all the leaves trifoliate, growing upon foot-stalks, and bristly stipulæ.

9. ONONIS pedunculis bifloris, filo terminatis. *Prod. Leyd.* 376. Rest-harrow with two flowers on a foot-stalk, which are terminated by a thread.

10. ONONIS pedunculis axillaribus trifloris nudis, foliis ternatis. *Hort. Cliff.* 358. Rest-harrow with naked foot-stalks proceeding from the sides of the branches, and sustaining three flowers, and trifoliate leaves.

11. ONONIS pedunculis quinquefloris axillaribus, caulibus diffusis procumbentibus, foliis ternatis, leguminibus lunulatis. Rest-harrow with five flowers on a foot-stalk, proceeding from the sides of the branches, diffused trailing stalks, trifoliate leaves, and moon-shaped pods.

12. ONONIS stipulis floralibus ovatis membranaceis integerrimis. *Prod. Leyd.* 376. Rest-harrow with oval, entire, membranaceous stipulæ to the flowers.

13. ONONIS foliis ternatis lanceolato-ovatis integerrimis, caule erecto herbaceo, racemo terminali. Rest-harrow with trifoliate, spear-shaped, oval, entire leaves, and an erect herbaceous stalk, terminated by a loose spike of flowers; called *Carolina* Rest-harrow.

14. ONONIS spicis foliosis simplicibus obtusis. *Lin. Sp. Plant.* 717. Rest-harrow with leafy spikes, and single obtuse leaves.

15. ONONIS foliis ternatis ovatis, petiolis longissimis, leguminibus hirsutis. Rest-harrow with oval trifoliate leaves, growing on very long foot-stalks, and hairy pods.

The first sort is a common weed in most parts of *England*, so is rarely admitted into gardens. It has a strong creeping root,

root, which spreads far in the ground, and is with great difficulty eradicated; the stalks rise two feet and a half high, they are slender, reddish, and hairy, sending out small branches on their side, which are armed with sharp prickles. The flowers come out single from the side of the branches, they are of the butterfly kind, of a purple colour, which are succeeded by small pods, containing one or two kidney-shaped seeds. It flowers great part of summer, and the seeds ripen in the autumn. The root of this is one of the five opening roots; the cortical part of it is esteemed a good medicine for stoppage of urine, and to open the obstructions of the liver and spleen; there is a variety of this with white flowers.

The second fort grows naturally in many parts of *England*, and has been by some supposed to be only a variety of the first; but I have cultivated both by seeds, and have always found the plants retain their difference; the stalks of this fort are hairy, and more diffused than those of the first; the leaves are broader, and sit closer on the branches; the stalks grow more upright, and have no spines; the flowers and pods are like those of the first. There is also a variety of this with white flowers.

The third fort grows naturally on the borders of the sea in several parts of *England*; this hath a creeping root, from which arise many hairy stalks, which are near two feet long, spreading on every side upon the ground, garnished with trifoliate hairy leaves, those on the lower part of the stalks being pretty large and oval, but the upper are smaller and narrower. The flowers are like those of the first in shape, coming out singly from the side of the stalks, but are of a brighter purple colour; the pods are short, containing two or three seeds in each. It flowers in *July*, and the seeds ripen in autumn.

The fourth fort grows naturally in *Spain* and *Portugal*; this rises with shrubby stalks two feet and a half high, dividing into slender branches, very full of joints, garnished with narrow, trifoliate, thick, fleshy leaves, standing upon short foot-stalks. The flowers are produced at the end of the branches in loose panicles, some of the foot-stalks sustaining two, and others but one flower; they are of a fine purple colour, and appear in *June*; the seeds ripen in *September*.

The fifth fort grows naturally on the *Alps*, this is a very beautiful low shrub; it rises with slender shrubby stalks about three feet high, dividing into many branches, which are garnished with narrow trifoliate leaves sawed on their edges, sitting close to the branches. The flowers come out in panicles at the end of the branches upon long foot-stalks, which for the most part sustain three large purple flowers; the stipula is a kind of sheath, embracing the foot stalk of the flower. It flowers in *May*, and the flowers are succeeded by turgid pods about an inch long, which are hairy, inclosing three or four kidney-shaped seeds, which ripen in *August*.

The sixth fort grows naturally in the south of *France* and in *Spain*; this hath a perennial root and an annual stalk, which rises near two feet high, sending out short branches from the side of the lower part; these are garnished with trifoliate oblong leaves, which are hairy and clammy. The flowers grow in loose spikes at the end of the stalks, they are large, and of a bright yellow colour, standing upon pretty long foot-stalks, which are extended beyond the flowers, the flowers hanging downward from the middle of the foot-stalk. The flowers appear the latter end of *June*, which are succeeded by turgid pods an inch long, containing three or four brown kidney-shaped seeds, which ripen in *September*.

The seventh fort grows naturally in *Portugal*, from whence the seeds were sent to me. This is an annual plant,

with a strong, herbaceous, hairy stalk, rising a foot and a half high, sending out branches the whole length, closely garnished with trifoliate leaves; the middle lobe being large and oval, the two side lobes long and narrow, rounded at their points and indented on their edges; they are very clammy. The foot-stalks of the flowers come out from the wings of the stalks singly, each sustaining one pale yellow flower, standing erect in the middle of the foot-stalk, which is extended beyond the flower. This plant flowers in *July*, and the seeds ripen in the autumn.

The eighth fort grows naturally in the south of *France* and *Italy*; this is an annual plant, the stalks rise about nine inches high, sending out one or two side branches toward the bottom; the leaves are small, trifoliate, and oval, standing upon pretty long foot-stalks, and are indented on their edges. The flowers come out singly at the wings of the stalk, they are small, yellow, and sit very close to the stalk, having a sharp bristly stipula under the empalement; the pods are very short and turgid, containing two or three kidney-shaped seeds. It flowers in *July*, and the seeds ripen in the autumn.

The ninth fort grows naturally in *Sicily*, and is an annual plant; the stalks rise about nine inches high, sending out one or two branches toward the bottom; these are garnished with small trifoliate leaves, which stand on short foot-stalks. The flowers come out from the side of the branches upon short foot-stalks, each sustaining two small yellow flowers, which are succeeded by jointed compressed pots, like those of Bird's-foot, having four or five kidney-shaped seeds in each. This fort flowers in *July*, and the seeds ripen in the autumn.

The tenth fort grows naturally on the *Alps* and *Helvetian* mountains; this rises with a single jointed stalk a foot and a half high, garnished with oval, indented, trifoliate leaves, standing on pretty long foot-stalks. The foot-stalks of the flowers come out from the wings of the leaves, they are long, slender, each sustains three pale yellow flowers, which are succeeded by short turgid pods, containing two or three seeds in each. It flowers in *June*, and the seeds ripen in *September*.

The eleventh fort grows naturally in *Virginia*, from whence I received the seeds. This is a biennial plant, from the root comes out many diffused stalks which trail upon the ground, garnished with roundish trifoliate leaves indented on their edges, having short foot-stalks, they are of a light green and smooth. The flowers come out toward the end of the branches upon very slender foot-stalks, which arise from the wings of the leaves, each sustaining five small yellow flowers; these are succeeded by compressed pods shaped like a half-moon, or Medick Trefoil. This flowers in *July*, and the seeds ripen in autumn.

The twelfth fort came up in earth which was brought from *Barbados*, but it does not seem to be a native of that country, for it rises easily from seeds in the open air here, and perfects its seeds in the autumn, nor will it thrive in greater warmth. This hath an upright stalk a foot and a half high, sending out small side branches, which are garnished with roundish trifoliate leaves sawed on their edges, standing upon short foot-stalks. The flowers grow in short leafy spikes at the end of the branches, they are small, and of a pale purple colour, appearing in *July*, and are succeeded by short turgid pods, containing two or three kidney-shaped seeds which ripen in autumn.

The thirteenth fort grows naturally in *Carolina*, from whence Mr. *Catesby* sent the seeds to *England*. This hath a perennial root and an annual stalk; from the root arises three, four, or five stalks, in proportion to the size of the root, which grow from two to three feet high; they are smooth, herbaceous, and each divides toward the top into two or three

three branches, garnished with trifoliate leaves, whose lobes are oval, spear shaped, and entire. The stalks are terminated by loose spikes of white flowers near a foot long, which are ranged alternately, and stand upon short foot-stalks; these are succeeded by smooth turgid pods an inch and a half long, inclosing four or five large kidney-shaped seeds. This flowers in *June*, and the seeds ripen in *September*. There is a variety of this with blue flowers.

The fourteenth sort grows naturally in *Portugal, Spain, and Italy*. This is an annual plant, rising with upright branching stalks a foot high, garnished with single leaves sitting close to the stalks; the larger leaves are oval, about one inch long, and three quarters of an inch broad; the upper leaves are narrow, ending in obtuse points, and are slightly indented at their ends. The flowers grow in leafy spikes at the end of the stalks set close together, having hairy empalements; they are pretty large, of a purple colour, and appear in *July*; these are succeeded by taper pods about an inch long, inclosing four or five kidney-shaped seeds. This plant has several titles, in the different books of botany.

The fifteenth sort grows naturally in the *American* islands. This is an annual plant, rising with a branching stalk two feet high, garnished with trifoliate leaves, whose lobes are oval, standing upon very long foot-stalks, which are hairy. The flowers grow in loose spikes at the end of the branches; they are large, of a purplish yellow colour, and are succeeded by very turgid hairy pods, each containing five or six large kidney-shaped seeds. This sort flowers in *July* and *August*, and the seeds ripen in the autumn. From this plant indigo was formerly made, which, I suppose, was of less value than that which is made of Anil, so has not been for many years past cultivated in any of the islands.

The three first sorts are never cultivated in gardens; these are very troublesome weeds whenever they get into the fields, for the roots spread and multiply greatly in the ground, and are so tough and strong, that the plough will scarcely cut through them, so are with great difficulty eradicated when they have once gotten possession.

The fourth and fifth sorts are low shrubby plants, which are propagated by seeds. The fourth is too tender to thrive in the open air in *England*, unless it is planted in a warm situation, and in very severe frost covered to protect it. If the seeds of both sorts are sown upon a bed of light earth in *April*, the plants will come up in *May*, when they must be kept clean from weeds; and if they are too close, some of them should be carefully drawn up in moist weather, and transplanted at four or five inches distance; those of the fourth sort upon a warm sheltered border, but the fifth may be planted in a shady border, where they will thrive very well; after these have taken root, they will require no other care but to keep them clean from weeds till the following autumn, when they may be transplanted to the places where they are to remain; those plants which were left growing in the bed where they were sown, must also be treated in the same way. These plants will not thrive in pots, therefore should always be planted in the full ground, where the fifth sort will flourish greatly, and frequently send up many plants from their roots, but the other is more impatient of cold. These plants will flower the second year, and make a fine appearance during the continuance of their flowers, and the fifth sort will produce seeds in plenty.

The sixth sort is propagated by seeds, which should be sown thin in drills, upon a bed of light earth, and when the plants come up, they must be kept clean from weeds till the autumn, when they should be carefully taken up, and transplanted into the borders of the pleasure-garden, where they are to remain; the second year they will flower and produce ripe seeds, but the roots will continue some years, and are very hardy.

The seventh, ninth, and fourteenth sorts, are annual hardy plants; these are propagated by seeds, which should be sown in the places where the plants are to remain, and will require no other care but to thin them where they are too close, and keep them clean from weeds.

The eleventh sort is a biennial plant. The seeds of this should be sown on a bed of fresh earth, where the plants are to remain, and when they come up, if they are thinned where they grow too close, and are kept clean from weeds, they will require no other culture.

The thirteenth sort is propagated by seeds, which should be sown either on a moderate hot-bed or a warm border in the spring; and when the plants are fit to remove, they should be each transplanted into a separate small pot, plunging them into a gentle hot-bed, observing to shade them till they have taken new root, then they should be gradually inured to the open air; the latter end of *May*, or the beginning of *June*, they may be fully exposed to the open air, but in autumn they should be placed under a common hot-bed frame, to screen them from frost in winter. The spring following they may be shaken out of the pots, and planted in the full ground, where they are to remain. As these plants have long tap-roots, they will not thrive long in pots, and if they are planted in wet ground, their roots will rot in winter, but in a dry soil they are never hurt by cold, and their roots will abide many years.

The fourteenth sort is an annual plant; the seeds of this must be sown upon a moderate hot-bed in the spring, and, when the plants are fit to remove, they should be transplanted on another hot-bed, to bring the plants forward, treating them in the same way as the *African* and *French* Marigold. In *June* they should be taken up with balls of earth to their roots, and transplanted into the open borders, where, if they are shaded till they have taken root, they will thrive and flower the following month, and perfect their seeds in autumn.

ONOPORDUM. *Lin. Gen. Plant.* 834. Woolly Thistle.

The Characters are,

The common empalement is roundish, bellied, and imbricated. The flower is composed of many hermaphrodite florets, which are funnel-shaped, equal, and uniform, having narrow tubes swelling at the brim, cut into five points; they have five short hairy stamina, terminated by cylindrical summits, and an oval germen crowned with down, supporting a slender style, terminated by a crowned stigma. The germen becomes a single seed crowned with down, sitting in the empalement.

The Species are,

1. ONOPORDUM *calycibus squarrosis, foliis ovato-oblongis sinuatis.* *Lin. Sp. Plant.* 827. Woolly Thistle with rough empalements, and oblong, oval, sinuated leaves; or common Woolly Thistle.

2. ONOPORDUM *calycibus squarrosis, foliis linearibus pinnatifidis.* *Lin. Sp. Plant.* 827. Woolly Thistle with rough empalements, and narrow leaves ending in many points.

3. ONOPORDUM *calycibus imbricatis.* *Hort. Upsal.* 249. Woolly Thistle with imbricated empalements.

4. ONOPORDUM *calycibus squarrosis, foliis oblongis, pinnatifidis decurrentibus, capite magno.* Woolly Thistle with rough empalements, oblong, sinuated, wing-pointed leaves running along the stalk, and a large head.

5. ONOPORDUM *foliis oblongo ovatis dentato-aculeatis capite sessili.* Woolly Thistle with oblong oval leaves, having prickly indentures, and a head sitting close to the ground.

The first sort grows naturally on uncultivated places in most parts of *England*. It is a biennial plant; the first year it puts out many large downy leaves, which are sinuated on their edges, and are prickly; these spread on the ground, and continue the following winter, and in the spring arifes the

the stalk in the middle of the leaves, which upon dunghills, or good ground, grows five or six feet high, dividing upward into many branches, which have leafy borders running along them; these are indented, and each indenture is terminated by a spine. The stalks are terminated by scaly heads of purple flowers, which appear in *June*; and to these succeed oblong angular seeds, crowned with a hairy down, which assist their spreading about to a great distance by the wind, so that where the plants are permitted to ripen their seeds, they often become troublesome weeds.

The second sort grows naturally in *Spain, Portugal, and the Levant*. This rises with a taller stalk than the former, the leaves are much longer and narrower, and the indentures on their sides are regular, ending in sharp spines. The heads of flowers are larger, and the spines of the empalement are longer than those of the first sort.

The third sort grows to the height of nine or ten feet; the stalks divide into many branches; the leaves are longer than of any other species; the heads of flowers are large and of a purple colour; the empalement hath the scales lying over each other like those of fish. This grows naturally in *Spain and Portugal*.

The fourth sort grows naturally about *Aleppo*. This rises with an upright branching stalk seven or eight feet high, the leaves are long, and regularly sinuated on their borders, like wing-pointed leaves. The heads of flowers are very large, and the empalement is very rough and prickly.

The fifth sort hath several oblong, oval, woolly leaves, which spread on the ground; between these comes out the head of flowers sitting close to the ground; these heads are smaller than any of the other, and the flowers are white. Some of these plants have been formerly cultivated for the table, but it was before the *English* gardens were well supplied with other esculent plants, for at present they are rarely eaten here. They require no culture, for if the seeds are permitted to fall, the plants will come up fast enough.

OPHIOGLOSSUM, Adders-Tongue.

This plant grows naturally in moist meadows, and is not easy to be made to thrive in gardens, so is rarely attempted.

OPHRYS. *Tourn. Inst. R. H. 437. tab. 250. Lin. Gen. Plant. 902.* Twyblade.

The Characters are,

It has a single stalk with a vague spatha. The flower hath no empalement; it consists of five oblong petals, which join so as to form a helmet, the under one is bifid. The nectarium is dependent, and keel-shaped behind; it hath two short stamina sitting on the pointal. It hath an oblong contorted germen situated under the flower, with a style adhering to the inner border of the nectarium. The germen afterward turns to an oval, three-cornered, obtuse capsule, with one cell opening with three valves, filled with small seeds like dust.

The Species are,

1. OPHRYS *bulbo fibroso, caule bifolio, foliis ovatis, nectarii labio bifido. Lin. Sp. Plant. 546.* Twyblade with a fibrous root, two oval leaves on the stalk, and a bifid lip to the nectarium; common Twyblade, or Twayblade.

2. OPHRYS *bulbo fibroso, caule bifolio, foliis cordatis. Lin. Sp. Plant. 946.* Twyblade with a fibrous root, and two heart shaped leaves on the stalk; or Smallest Twyblade.

3. OPHRYS *bulbis fibroso fasciculatis, caule vaginato, nectarii labio bifido. Lin. Sp. Plant. 945.* Twyblade with bulbous bunched roots, a sheath-like stalk, and a trifid lip to the nectarium; Birds Nest, or mis-shapen Orchis.

4. OPHRYS *bulbis aggregatis oblongis, caule subfolioso, floribus secundis, nectarii labio indiviso. Act. Upsal. 1740.* Twyblade with oblong clustered bulbs, a leafy stalk, fruitful flowers, and an undivided lip to the nectarium; white, sweet-scented, spiral Orchis, called Tripple Ladies Traces.

5. OPHRYS *bulbo globofo, caule nudo, nectarii labio trifido.*

Act. Upsal. 1740. Twyblade with a globular bulb, a naked stalk, and a trifid lip to the nectarium; yellow, sweet, or Musk Orchis.

6. OPHRYS *bulbis subrotundis, caule folioso, nectarii labio lineari tripartito, medio elongato bifido. Lin. Sp. Plant. 948.* Twyblade with roundish bulbs, a leafy stalk, and a narrow three-pointed lip to the nectarium, the middle segment of which is stretched out and bifid; or Man Orchis.

7. OPHRYS *bulbis subrotundis, caule folioso, nectarii labio subquincelobo. Lin. Sp. Plant. 948.* Twyblade with roundish bulbs, a leafy stalk, and the lip of the nectarium divided almost into five lobes; Greater Fly Orchis.

8. OPHRYS *bulbis subrotundis, caule folioso, nectarii labio trifido.* Twyblade with roundish bulbs, a leafy stalk, and a trifid lip to the nectarium; the common Humble Bee Orchis.

9. OPHRYS *bulbis subrotundis, caule subfolioso, nectarii labio trifido hirsuto.* Twyblade with roundish bulbs, a leafy stalk, and a hairy trifid lip to the nectarium; Humble Bee Satyrion with green wings.

The first sort grows naturally in woods, and sometimes in moist pastures, in several parts of *England*. The root is composed of many strong fibres, from which arise two oval veined leaves; between these arises a naked stalk about eight inches high, terminated by a loose spike of herbaceous flowers, resembling knats, composed of five petals, with a long bifid lip to the nectarium, with a crest or standard above, and two wings on the side. The flowers sit upon an angular germen, which afterward swells to a capsule, opening when ripe in six parts, and filled with small dusty seeds. This plant refuses culture, but may be transplanted, from the places where it grows naturally, into a shady part of the garden, where, if the roots are not disturbed, they will continue several years, and flower in *May*, but they do not increase in gardens. The best time to remove the roots is in *July or August*, when the leaves are decaying, for it will be difficult to find the roots after the leaves are gone.

The second sort is found in some of the northern counties in *England*, but is seldom seen growing in the south. This hath a small bulb with many strong fibres to the root, and sends out two small, ribbed, heart-shaped leaves at bottom. The stalk rises about four inches high, and is terminated by a spike of small herbaceous flowers shaped like those of the first sort.

The third sort grows naturally in shady woods in *Kent and Suffex*. This has sometimes a single bulbous root, and at others several joined together, from which arises a single stalk near a foot high, embraced the whole length with leaves like sheaths; the top of the stalk is garnished with a loose spike of flowers shaped like those of the Orchis, and of the colour of decayed leaves. It flowers in *June*.

The fourth sort grows upon chalky hills in several parts of *England*. This hath a globular bulbous root, from which arises a single stalk six inches high, having two oblong leaves at bottom, and rarely any above; the flowers are small, of a yellowish green colour, growing in a loose spike on the top of the stalk; they have a musky scent. This flowers in *August*.

The fifth sort grows naturally in moist pastures in the northern parts of *England*; I have also found it in great plenty on *Enfield Chace*, not far from the town. This hath many oblong bulbs joined together at the top, from which arise three or four oblong leaves; and between these comes out a slender stalk about six inches high, having a few narrow leaves, which embrace it like a sheath. The flowers grow in a close spike at the top; they are white, and have an agreeable scent. This flowers in *August and September*.

The sixth sort grows upon the chalk-hills near *Northfleet* in *Kent*, and also upon *Causbam* hills near *Reading*. This hath a roundish bulbous root, from which come out a few oblong leaves; the stalks rise a foot and a half high, garnished with a few narrower leaves; the flowers grow in a loose spike on the top of the stalk, they are of a rusty iron colour, sometimes inclinable to green. The lip of the nectarium is divided into three parts, the middle segment being stretched out much longer than the other, and is divided into two; the upper part of the flower being hooded, the whole bears some resemblance to a naked man. This flowers in *June*.

The seventh sort is commonly called the Fly Orchis. This grows naturally in *England*, but not in great plenty. Mr. *Ray* found it growing on the banks of the *Devil's* ditch in *Cambridgeshire*. I gathered it near *Northfleet* in *Kent*. It hath a roundish bulbous root, from which arise four or five oblong leaves, and a stalk about a foot high, having a few narrow acute-pointed leaves, embracing it like sheaths. The flowers are ranged on the upper part of the stalk at a distance from each other; they have no spur, the crest and wings are of an herbaceous colour, but the nectarium is very like the body of a fly. It flowers the end of *May*.

The eighth sort grows naturally in dry pastures in several parts of *England*, and is commonly called the Humble Bee Orchis; of this there are two or three varieties found wild in *England*, and several more in *Spain* and *Portugal*. This hath a roundish bulbous root, the leaves are like those of the narrow-leaved Plantain. The stalk rises six or seven inches high, having two or three sheath-shaped leaves embracing it, which are erect; at the top of the stalk come out two or three flowers without spurs, having purplish crests and wings. The nectarium is large, shaped like the body of a humble bee, of a dark sooty colour, with two or three lines running cross it, of a darker or lighter colour, which appear brighter or duller according to the position of the flower to the sun. It flowers early in *June*.

The ninth sort grows naturally on the chalk-hills near *Northfleet* in *Kent*, and in several other places. This is called the green-winged Humble Bee Orchis. The roots of this are roundish, like those of the former sort; the leaves are narrower and fewer; the stalks are shorter, the flowers a little smaller; the wings are green, and the nectarium of a dark sooty colour, and hairy. This flowers the end of *April*.

All these sorts may be preserved in gardens, though not propagated there. The best time to remove the roots from the places where they naturally grow, is just before the stalks fall, for at that time the roots may be easily discovered, and then they are beginning to rest, so that the bulb will be fully formed for flowering the following year, and will not shrink; but when they are removed at a time of the year when they are in action, the bulb designed for flowering the following year, not being fully ripened, will shrink, and frequently perish; or if they survive their removal do not recover their former strength in less time than two years.

When these are removed into a garden, the soil should be adapted to the sorts. Such of them as grow naturally in moist pastures, should be planted in shady moist borders; those which are inhabitants of woods may be planted under trees in wildernesses, but such as grow upon chalk-hills should have a bed of chalk prepared for them in an open situation; and when the plants are fixed in their several places, they should not be disturbed after, for if they are kept clean from weeds, the less the ground is disturbed, the better the plants will thrive, and the longer they will continue.

OPUNTIA. *Tourn. Inst. R. H.* 239. *tab.* 122. The Indian Fig, or prickly Pear.

The Characters are,

The flower is composed of several petals, which are obtuse, concave, and placed in a circular order, sitting upon the germen. It has a great number of awl-shaped stamina, which are inserted in the germen. The germen, which is situated under the flower, supports a cylindrical style the length of the stamina, crowned by a multifid stigma. The germen after-ward turns to a fleshy umbilicated fruit with one cell, inclosing many roundish seeds.

The Species are,

1. OPUNTIA *articulis ovatis compressis, spinis setaceis.* Indian Fig with oval compressed joints, and bristly spines; the common Indian Fig.

2. OPUNTIA *articulis ovato-oblongis, spinis setaceis.* Indian Fig with oblong oval joints, and bristly spines.

3. OPUNTIA *articulis ovato-oblongis, spinis subulatis.* Indian Fig with oblong oval joints, and awl-shaped spines.

4. OPUNTIA *articulis ovato-oblongis, spinis longissimis nigricantibus.* Indian Fig with oblong oval joints, and very long black spines.

5. OPUNTIA *articulis ovato-oblongis crassissimis, spinis inæqualibus.* Indian Fig with oblong, oval, thick joints, and unequal spines.

6. OPUNTIA *articulis ovato-oblongis subinermibus.* Indian Fig with oblong oval joints, almost without spines; commonly called the Cochineal Fig.

7. OPUNTIA *articulis cylindrico-ventricosis compressis, spinis setaceis.* Indian Fig with compressed, cylindrical, bellied joints, and bristly spines; Pinpillow.

8. OPUNTIA *articulis longissimis tenuibus compressis, spinis longissimis confertissimis, gracilibus albicantibus armatis.* *Houst. Mss.* Stalky Indian Fig with large, narrow, compressed leaves, armed with the longest, narrowest, white spines, growing in clusters; this is by the gardeners called *Robinson Crusoe's* Coat.

9. OPUNTIA *prolifer ensiformi-compressus serrato-repandus.* Indian Fig with compressed sword-shaped joints, whose indentures turn backward; Torch Thistle with a branching Spleenwort leaf.

These plants are all of them natives of *America*, though the first sort is found growing wild on the sides of the roads about *Naples*, in *Sicily*, and *Spain*, but it is probable that the plants may have been brought from *America* thither, at first. This has been long in the *English* gardens; the joints or branches are oval or roundish, compressed on their two sides flat, and have small leaves coming out in knots on their surface, as also on their upper edges, which fall off in a short time; and at the same knots there are three or four short bristly spines, which do not appear, unless they are close viewed; but on being handled they enter the flesh, and separate from the plant, so are troublesome, and often very difficult to get out. The branches of this sort spread near the ground, and frequently trail upon it, putting out new roots, so are extended to a considerable distance, and never rise in height; these are fleshy and herbaceous while they are young, but as they grow old become drier, of a tough contexture, and have ligneous fibres. The flowers come out on the upper edges of the branches, generally, though sometimes they are produced on their sides; these fit upon the embryo of the fruit, and are composed of several roundish concave petals, which spread open; they are of a pale yellow colour, and within arise a great number of stamina, fastened to the embryo of the fruit, which are terminated by oblong summits; and in the center is situated the style, crowned by a many-pointed stigma; after the flowers are past, the embryo swells to an oblong fruit, whose skin or cover is set with small spines in clusters, and the inside is fleshy, of a purple or red colour, in which are lodged many black seeds. This plant flowers here in *July* and

and *August*, but unless the season is very warm, the fruit will not ripen in *England*.

The second sort hath oblong, oval, compressed branches, which grow more erect than those of the first, armed with longer bristly spines, which come out in clusters from a point on each of the compressed sides, spreading open like the rays of a star. The flowers grow upon the embryo of the fruit, which come out from the upper edges of the leaves like the first, but are larger, and of a brighter yellow colour. The fruit is also larger, and of a deeper purple; the outer skin is also armed with longer spines: this is the most common sort in *Jamaica*, and upon the fruit of this the wild sort of *Cochineal* feeds, which is called *Sylvester*.

The third sort hath stronger branches than the second, which are armed with larger thorns, of an awl-shape; they are whitish, and come out in clusters like those of the other sort. The flowers are large, of a bright yellow colour, and the fruit is shaped like the second sort.

The fourth sort grows taller than either of the former; the branches are larger, thicker, and of a deeper green; they are armed with strong black spines, which come out in clusters like those of the other sorts, but the clusters are farther asunder. The flowers are produced from the upper edges of the branches; they are smaller than those of the other sorts, and are of a purplish colour, as are also the stamina; the fruit is of the same form as those of the first, but do not ripen here.

The fifth sort is the largest of all yet known. The joints of these are more than a foot long, and eight inches broad; they are very thick, of a deep green colour, and armed with a few short bristly spines; the older branches of this often become almost taper, and are very strong. The flowers of this sort I have never yet seen; for although I have had many of the plants more than ten feet high, none of them has produced any flowers.

The sixth sort has been always supposed to be the plant, upon which the *Cochineal* insects feed; this hath oblong, smooth, green branches, which grow erect, and rise to the height of eight or ten feet, having scarce any spines on them, and those few which are can scarce be discerned at a distance, and are so soft as not to be troublesome when handled. The flowers of this sort are small, and of a purple colour, standing upon the embryo of the fruit, in the same manner as those of the other sort, but do not expand open like them. The flowers of this appear late in the autumn, and the fruit drops off in winter, without coming to any perfection here; this is cultivated in the fields of *New Spain*, for the increase of the insects, but it grows naturally in *Jamaica*, where it is probable the true *Cochineal* might be discovered, if persons of skill were to search after the insects.

The seventh sort is said to grow naturally at *Curacoa*. This hath cylindrical swelling joints, which are closely armed with slender white spines. The branches spread out on every side, and where they have no support fall to the ground, very often separating at the joints from the plants, and, as they lie upon the ground, put out roots, so form new plants; this sort very rarely produces flowers in *England*. In the *West-Indies* it is called *Pinpillow*, from the appearance which the branches have to a pin-cushion stuck full of pins.

The eighth sort was sent me from *Jamaica*, by the late Dr. *Houfoun*, who found it growing naturally there in great plenty, but could never observe either fruit or flower upon any of the plants, nor have any of them produced either in *England*. The branches of this sort have much longer joints than any of the other; they are narrower, and more compressed. The spines of this are very long, slender, and of a yellowish brown colour, coming out in clusters all over

the surface of the branches, crossing each other, so as to render it dangerous to handle; for upon being touched the spines adhere to the hand, and quit the branches, and penetrate into the flesh, so become very troublesome.

The ninth sort grows naturally in the *Brazils*. This hath very thin branches, which are indented regularly on their edges like *Spleenwort*; they are of a light green, and shaped like a broad sword; these are smooth, having no spines. The flowers come out from the side, and at the end of the branches, sitting on the embryos in the same way as the other sorts; they are of a pale yellow colour. The fruit is shaped like those of the first sort, but rarely ripens in *England*.

All these sorts (except the first) are too tender to thrive in the open air in *England*, nor can many of them be preserved through the winter here, unless they have artificial heat; for when they are placed in a green-house, they turn to a pale yellow colour, their branches shrink, and frequently rot on the first approach of warm weather in the spring.

These plants may all be propagated by cutting off their branches at the joints, during any of the summer months, which should be laid in a warm dry place for a fortnight, that the wounded part may be healed over, otherwise they will rot with the moisture which they imbibe at that part, as is the case with most other succulent plants. The soil in which these plants must be planted, should be composed after the following manner, *viz.* one third of light fresh earth from a pasture, a third part sea sand, and the other part should be one half rotten tan, and the other half lime rubbish; these should be well mixed, and laid in a heap three or four months before it is used, observing to turn it over at least once a month, that the several parts may be well united; then you should pass it through a rough screen, in order to separate the largest stones and clods, but by no means sift it too fine, which is a very common fault; then you should reserve some of the smaller stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off, which is what must be observed for all succulent plants, for if the moisture be detained in the pots, it will rot their roots, and destroy the plants.

When you plant any of the branches of these plants (except the first sort) you should plunge the pots into a moderate hot-bed, which will greatly facilitate their taking root; you should also refresh them now and then with a little water, but be very careful not to let them have too much, or be too often watered, especially before they are rooted. When the plants begin to shoot, you must give them a large share of air, by raising the glasses, otherwise their shoots will draw up so weak, as not to be able to support themselves; and after they have taken strong root, you should inure them to the air by degrees, and then remove them into the stove where they should remain, placing them near the glasses, which should always be opened in warm weather, so that they may have the advantage of a free air, and yet be protected from wet and cold.

During the summer season these plants will require to be often refreshed with water, but it must not be given to them in large quantities, lest it rot them; and in winter this should be proportioned to the warmth of the stove, for if the air be kept very warm, they will require to be often refreshed, otherwise their branches will shrink; but if the house be kept in a moderate degree of warmth, they should have but little, for moisture at that season will rot them very soon.

The heat in which these plants thrive best, is the temperate point, as marked on botanical thermometers, for if they are kept too warm in winter, it causes their shoots to be very tender, weak, and unsightly. Those sorts which

are inclinable to grow upright, should have their branches supported with stakes, otherwise their weight is so great, as to break them down.

ORANGE. See *Aurantium*.

ORCHARD. In planting of an orchard, great care should be had to the nature of the soil, and such sorts of fruits only should be chosen, as are best adapted to the ground designed for planting, otherwise there can be little hopes of their succeeding; and it is for want of rightly observing this method, that we see in many countries orchards planted, which never arrive to any tolerable degree of perfection, the trees starving, and their bodies are either covered with moss, or the bark cracks and divides, both which are evident signs of the weakness of the trees; whereas, if instead of Apples the orchard had been planted with Pears, Cherries, or any other sort of fruit better adapted to the soil, the trees might have grown very well, and produced great quantities of fruit.

As to the position of the orchard, (if you are at full liberty to choose) a rising ground, open to the south-east, is to be preferred; but I would by no means advise planting upon the side of a hill, where the declivity is very great, for in such places the great rains commonly wash down the better part of the ground, whereby the trees would be deprived of proper nourishment; but where the rise is gentle, it is of great advantage to the trees, by admitting the sun and air between them, better than it can upon an entire level; which is an exceeding benefit to the fruit, by dissipating fogs and drying up the damps, which, when detained amongst the trees, mix with the air, and render it rancid; if it be defended from the west, north, and east winds, it will also render the situation still more advantageous, for it is chiefly from those quarters that fruit trees receive the greatest injury; therefore, if the place be not naturally defended from these by rising hills (which is always to be preferred), then you should plant large growing timber trees at some distance from the orchard, to answer this purpose.

You should also have a great regard to the distance of planting the trees, which is what few people have rightly considered, for if you plant them too close, they will be liable to blights; the air being hereby pent in amongst them, will also cause the fruit to be ill tasted, having a great quantity of damp vapours from the perspiration of the trees, and the exhalations from the earth mixed with it, which will be imbibed by the fruit, and render their juices crude and unwholesome.

Wherefore I cannot but recommend the method which has been lately practised by some particular gentlemen with very good success, that is, to plant the trees fourscore feet asunder, but not in regular rows. The ground between the trees they plough and sow with Wheat and other crops, in the same manner as if it were clear from trees; and they observe their crops to be full as good as those quite exposed, except just under each tree, when they are grown large, and afford a great shade; and by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, scarcely ever having any moss, or other marks of poverty, and will abide much longer and produce better fruit.

If the ground, in which you intend to plant an orchard, has been pasture for some years, then you should plough in the green sward the spring before you plant the trees; and if you will permit it to lie a summer fallow, it will greatly mend it, provided you stir it two or three times, to rot the sward of Grass, and prevent weeds growing thereon:

At *Michaelmas* you should plough it pretty deep, in order to make it loose for the roots of the trees, which should be planted thereon in *October*, provided the soil be dry; but if it be moist, the beginning of *March* will be a better season. The distance, if designed for a close orchard, must not be

less than forty feet, but the trees planted twice that distance will succeed better.

When you have finished planting the trees, you should provide some stakes to support them, otherwise the wind will blow them out of the ground, which will do them much injury, especially after they have been planted some time, for the ground in the autumn being warm, and for the most part moist, the trees will very soon push out a great number of young fibres, which, if broken off by their being displaced, will greatly retard the growth of the trees.

In the spring following, if the season should prove dry, you should cut a quantity of green sward, which must be laid upon the surface of the ground about their roots, turning the Grass downward, which will prevent the sun and wind from drying the ground, whereby a great expence of watering will be saved; and after the first year they will be out of danger, provided they have taken well.

Whenever you plough the ground betwixt these trees, you must be careful not to go too deep amongst their roots, lest you should cut them off, which would greatly damage the trees; but if you do it cautiously, the stirring the surface of the ground will be of great benefit to them, though you should observe never to sow too near the trees, nor suffer any great rooting weeds to grow about them, which would exhaust the goodness of the soil, and starve them.

If after the turf, which was laid round the trees, be rotted, you dig it in gently about the roots, it will greatly encourage them.

There are some persons who plant many sorts of fruit together in the same orchard, mixing the trees alternately; but this is a method which should always be avoided, for hereby there will be a great difference in the growth of the trees, which will not only render them unsightly, but also the fruit upon the lower trees ill tasted, by the tall ones overshadowing them; so that if you are determined to plant several sorts of fruit on the same spot, you should observe to place the largest growing trees backward, and so proceed to those of less growth, continuing the same method quite through the whole plantation; whereby it will appear at a distance in a regular slope, and the sun and air will more equally pass throughout the whole orchard, that every tree may have an equal benefit therefrom; but this can only be practised upon good ground, in which most sorts of fruit trees will thrive.

The soil of your orchard should also be mended once in two or three years with dung, or other manure, which will also be absolutely necessary for the crops sown between; so that where persons are not inclinable to help their orchards, where the expence of manure is pretty great, yet, as there is a crop expected from the ground besides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an orchard, you should always observe to procure them from a soil nearly akin to that where they are to be planted, or rather poorer; for if you have them from a very rich soil, and that wherein you plant them is but indifferent, they will not thrive well, especially for four or five years after planting; so that it is a very wrong practice to make the nursery, where young trees are raised, very rich, when the trees are designed for a middling or poor soil. The trees should also be young and thriving, for whatever some persons may advise to the contrary, yet it has always been observed, that though large trees may grow and produce fruit after being removed, they never make so good trees, nor are so long lived, as those which are planted while young.

These trees, after they are planted out, will require no other pruning, but only to cut out dead branches, or such as cross each other, which render their heads confused and unsightly: the pruning them too often, or shortening their branches,

branches, is very injurious, especially to Cherries and stone fruit, which will gum prodigiously, and decay in such places where they are cut; and the Apples and Pears, which are not of so nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak shoots, whenever their branches are thus shortened; and many times the fruit is hereby cut off, which, on many sorts of fruit trees, is first produced at the extremity of their shoots.

It may, perhaps, seem strange to some persons, that I should recommend the allowing so much distance to the trees in an orchard, because a small piece of ground will admit of very few trees when planted in this method; but they will please to observe, that when the trees are grown up, they will produce a great deal more fruit, than twice the number when planted close, and will be vastly better tasted; the trees when placed at a large distance, being never so much in danger of blighting as in close plantations, as hath been observed in *Herefordshire*, the great county for orchards, where they find, that when orchards are so planted or situated, that the air is pent up amongst the trees, the vapours which arise from the damp of the ground, and the perspiration of the trees, collect the heat of the sun, and reflect it in streams so as to cause what they call a fire blast, which is the most hurtful to their fruits; and this is most frequent where the orchards are open to the south sun.

But as orchards should never be planted, unless where large quantities of fruit are desired, so it will be the same thing to allow twice or three times the quantity of ground, since there may be a crop of grain of any sort upon the same place (as was before said), so that there is no loss of ground; and for a family only, it is hardly worth while to plant an orchard, since a kitchen-garden well planted with espaliers will afford more fruit than can be eaten while good, especially if the kitchen-garden be proportioned to the largeness of the family; and if cyder be required, there may be a large avenue of Apple trees extended cross a neighbouring field, which will render it pleasant, and produce a great quantity of fruit, or there may be some single rows of trees planted to surround fields, &c. which will fully answer the same purpose, and be less liable to the fire blasts before-mentioned.

ORCHIS. *Tourn. Inst. R. H.* 431. *tab.* 248 & 249. *Satyrium*, or Fool-stones.

The Characters are,

It hath a single stalk with a vague sheath. The flower hath five petals, three without and two within. The nectarium is of one leaf, fixed to the side of the receptacle, between the division of the petals. The upper lip is short and erect, the under large, broad, and spreading; the tube is pendulous, horn-shaped, and prominent behind. It hath two short slender stamina sitting upon the pointal, with oval erect summits, fixed to the upper lip of the nectarium. It hath an oblong contorted germen under the flower, with a short style fastened to the upper lip of the nectarium. The germen afterward turns to an oblong capsule with one cell, having three keel-shaped valves, opening on the three sides, but joined at top and bottom, filled with small seeds like dust.

The Species are,

1. ORCHIS *bulbis indivisis, nectarii labio quadrifido crenulato, cornu obtuso. Aët. Upsal.* 1740. Orchis with undivided bulbs, the lip of the nectarium cut into four points, which are slightly indented, and an obtuse horn; or common female Orchis.

2. ORCHIS *bulbis indivisis, nectarii labio æquali, cornu integro, galeæ alis reflexis acutis.* Orchis with undivided bulbs, the lip of the nectarium equal, an entire horn, and the wings of the standard acute and reflexed; the male Orchis.

3. ORCHIS *bulbis indivisis, nectarii labio lanceolato integerrimo, cornu longissimo, petalis patentibus. Aët. Upsal.* 1740.

Orchis with undivided bulbs, the lip of the nectarium entire and spear-shaped, a very long horn, and petals spreading very wide; or Butterfly Orchis.

4. ORCHIS *bulbis indivisis, nectarii labio quinquesido punctis scabro, cornu obtuso, petalis consuentibus. Aët. Upsal.* 1740. Orchis with undivided bulbs, a five-pointed lip to the nectarium, having rough spots, an obtuse horn, and petals running together; or the Man Orchis.

5. ORCHIS *bulbis indivisis, nectarii labio trifido antice bidentato, cornu longo, petalis acuminatis. Aët. Upsal.* 1740. Orchis with undivided bulbs, a trifid lip to the nectarium, indented with two teeth behind, a long horn, and acute-pointed petals; Mountain military Orchis, with a reddish conglomerated spike.

6. ORCHIS *bulbis indivisis, nectarii labio quadrifido punctis scabro, cornu obtuso, petalis distinctis. Aët. Upsal.* 1740. Orchis with undivided bulbs, the lip of the nectarium quadrifid, having rough spots, an obtuse horn, and distinct petals.

7. ORCHIS *bulbis subpalmatis rectis, nectarii cornu conico, labio trilobo, lateribus reflexo, bracteis flore longioribus. Aët. Upsal.* 1740. Orchis with straight, palmated, bulbous roots, a conical horn to the nectarium, the lip cut into three lobes, which are reflexed on the sides, and bractæ longer than the flowers.

8. ORCHIS *bulbis palmatis patentibus, nectarii cornu germinibus brevior, labio plano petalis dorsalis erectis. Aët. Upsal.* 1740. Orchis with handed spreading bulbs, the horn of the nectarium shorter than the germen, a plain lip, and the hinder part of the petals erect.

9. ORCHIS *bulbis palmatis, nectarii cornu setaceo germinibus longiore, labio crenato. Aët. Upsal.* 1740. Orchis with palmated bulbs, a bristly horn to the nectarium, which is longer than the germen, and a crenated lip.

10. ORCHIS *bulbis fasciculatis filiformibus, nectarii labio ovato integerrimo. Aët. Upsal.* 1740. Orchis with thread-like bulbs growing in bunches, and the lip of the nectarium oval and entire; or Purple Bird's Nest.

The first sort grows naturally in pastures, in most parts of *England*. This hath a double bulbous root, with some fibres coming out from the top; it has four or six oblong leaves lying on the ground, which are reflexed. The stalk rises nine or ten inches high, having four or six leaves which embrace it: this is terminated by a short loose spike of flowers, having a four-pointed indented lip to the nectarium, and an obtuse horn. The flowers are of a pale purple colour, marked with deeper purple spots. It flowers in *May*.

The second sort grows naturally in woods and shady places in many parts of *England*. This hath a double bulbous root, which is about the size and shape of middling Olives; it hath six or seven long broad leaves, shaped like those of Lillies, which have several black spots on their upper side; the stalk is round, and a foot high, having one or two smaller leaves embracing it. The flowers are disposed in a long spike on the top of the stalk; they are of a purple colour, marked with deep purple spots, and have an agreeable scent. It flowers the latter end of *April*.

The third sort grows naturally under bushes by the side of pastures in many parts of *England*. This hath a root composed of two oblong Pear-shaped bulbs, from which come out three or four Lilly-shaped leaves, of a pale green, with a few faint spots; the stalk rises near a foot high; it is slender, furrowed, and has a few very small leaves which embrace it: this is terminated by a loose spike of white flowers smelling sweet, which resemble a butterfly with expanded wings. This flowers in *June*.

The fourth sort is found growing naturally on *Carvsham* hills, and in other places where the soil is chalk. The roots of this sort are composed of two bulbs, from which come

out four or five oblong leaves; the stalk is about nine inches high, sustaining a loose spike of sweet smelling flowers, each hanging on a pretty long foot-stalk; they have a short obtuse horn, a crest and wings of an Ash colour without, reddish within, and striped with deeper lines; the lip is oblong, divided into five parts, having rough spots. This flowers in *June*.

The fifth sort grows naturally on chalk-hills in several parts of *England*. The root of this is composed of two oblong bulbs, from which arise three or four narrow oblong leaves; the stalk rises a foot high, having three or four narrow erect leaves, which embrace it. The flowers are produced in a thick roundish spike at the top; they are of a reddish colour, having long spurs, and the wings are acute-pointed. It flowers in *June*.

The sixth sort grows naturally on dry pastures in many parts of *England*. This hath a double bulbous root; the leaves are oblong and narrow; the stalk rises six or seven inches high, having two or three leaves, which embrace it like sheaths. The flowers grow in close short spikes at the top; they are of a purple colour; the lip of the nectarium is divided into four parts, having rough spots; the spur is obtuse, and the petals are distinct. There is a variety of this with a white nectarium. It flowers in *June*.

The seventh sort grows naturally in moist meadows in many parts of *England*. The root of this is composed of two fleshy bulbs, which are divided into four or five fingers, so as to resemble an open hand; the stalk rises from nine inches to a foot high, garnished with leaves the whole length, which are three or four inches long and one broad, embracing the stalk with their base; these are not spotted, and end in acute points. The flowers are disposed in a spike on the top of the stalk, with small narrow leaves (called bractæ) between them, which are longer than the flowers. The spur is half an inch long, extended backward; the lip of the nectarium is broad, divided into three lobes, two side ones being reflexed; the flowers and bractæ are of a purplish colour, having deep purple spots. It flowers in *May*. There are two varieties of this, differing in the colour of their flowers, and one with a narrow leaf.

The eighth sort grows naturally in meadows in several parts of *England*. The root of this is composed of two broad fleshy bulbs, both of which are divided into four fingers, which spread asunder. The stalk rises a foot and a half high, and is very strong, inclining to a purple colour; it is garnished with leaves the whole length. The flowers are collected in a close spike at the top of the stalk; they are of a pale purple colour; the spur is about a third part of an inch long; the beard of the nectarium is plain, and divided into three parts, which is marked with deep purple spots; under each foot-stalk is placed a narrow leaf (or bractæ) of a purplish colour. The leaves and stalks of the plant have many dark spots. It flowers in *June*. There are two or three varieties of this, which differ in the colour of their flowers.

The ninth sort grows naturally in moist meadows in several parts of *England*. This hath a double handed root, that which sustains the stalk being wasting and decaying, but the other is full, succulent, and plump; the fingers which compose the root are long, and spread asunder; the lower leaves are six or seven inches long; they are narrow, of a pale green, and have no spots. The stalk rises a foot high; it is garnished with a few narrow short leaves, which embrace it like sheaths. It is terminated by a beautiful spike of red flowers six inches long; the flowers are not marked with any spots; they have long slender bristly spurs like birds claws, being crooked; the lip of the nectarium is indented on the edge. It flowers in *June*.

The tenth sort grows naturally in shady woods in several

parts of *England*, but particularly in *Suffex* and *Hampshire*, in both which counties I have several times found it. The root of this plant is composed of many thick, oblique, long fibres, which are fleshy; the stalk rises near two feet high, wrapped round with leaves like sheaths; these are of a purple colour. The flowers are disposed in a loose thyrse at the top of the stalk; they are of a purple colour, having an oval entire lip to the nectarium, the crest terminating in a horn. It flowers in *June*.

All these sorts of *Orchis* grow wild in several parts of *England*, but, for the extreme oddness and beauty of their flowers, deserve a place in every good garden; and the reason for their not being cultivated in gardens, proceeds from their difficulty to be transplanted; though this, I believe, may be easily overcome, where a person has an opportunity of marking their roots in their time of flowering, and letting them remain until their leaves are decayed, when they may be transplanted with safety; for it is the same with most sorts of bulbous or fleshy rooted plants, which, if transplanted before their leaves decay, seldom live, notwithstanding you preserve a large ball of earth about them; for the extreme parts of their fibres extend to a great depth in the ground, from whence they receive their nourishment, which, if broken or damaged by taking up their roots, seldom thrive after; for though they may sometimes remain alive a year or two, yet they grow weaker until they quite decay; which is also the case with *Tulips*, *Fritillarias*, and other bulbous roots, when removed, after they have made shoots; so that whoever would cultivate them, should search them out in their season of flowering, and mark them; and when their leaves are decayed, or just as they are going off, the roots should be taken up, and planted in a soil and situation as nearly resembling that wherein they naturally grow, as possible, otherwise they will not thrive, so that they cannot be placed all in the same bed; for some are only found upon chalky hills, others in moist meadows, and some in shady woods, or under trees; but if their soil and situation be adapted to their various sorts, they will thrive and continue several years, and, during their season of flowering, will afford as great varieties as any flowers which are at present cultivated.

OREOSELINUM. See *Athamanta*.

ORIGANUM. *Lin. Gen. Plant.* 645. *Origany*, or *Pot Marjoram*.

The Characters are,

The flower is of the lip kind; the upper lip is plain, erect, obtuse, and indented; the under lip is trifid, the segments being nearly equal. The flowers have four slender stamina, two being as long as the petal, the other two are longer, terminated by simple summits; they have a four-cornered germen, supporting a slender style inclining to the upper lip, crowned by a bifid stigma. The germen afterward turns to four seeds shut up in the empalement of the flower.

The Species are,

1. ORIGANUM *spicis subrotundis paniculatis conglomeratis, bracteis calyce longioribus ovatis. Lin. Sp. Plant.* 590. *Pot Marjoram* with roundish paniculated spikes gathered in clusters, and oval bractæ which are longer than the empalement; or common wild *Origany*.

2. ORIGANUM *spicis longis pedunculis aggregatis, bracteis longitudine calycum. Lin. Ger. Plant.* 589. *Origany* with long spikes growing in bunches, and bractæ as long as the empalement; or winter sweet *Marjoram*.

3. ORIGANUM *spicis oblongis paniculatis conglomeratis, foliis ovatis glabris. Origany* with oblong spikes of flowers growing in clustered panicles, and oval smooth leaves; or broad-leaved smooth *Origany*.

4. ORIGANUM *caule repente, spicis oblongis conglomeratis, bracteis florum longioribus. Origany* with a creeping stalk, and

and oblong spikes of flowers growing in clusters, with bractæ longer than the flower; low wild Origany.

5. *ORIGANUM caule erecto ramoso, foliis ovatis rugosis, spicis subrotundis conglomeratis, bracteis calycum brevioribus.* Origany with an erect branching stalk, oval rough leaves, roundish spikes of flowers growing in clusters, with bractæ shorter than the empalement.

6. *ORIGANUM spicis aggregatis longis prismaticis rectis bracteis, membranaceis, calyce duplo longioribus.* *Lin. Sp. Plant.* 589. Origany with long, upright, prismatical spikes growing in clusters, and membranaceous bractæ twice the length of the empalement; Origany of *Crete*.

7. *ORIGANUM foliis ovalibus obtusis, spicis subrotundis compactis pubescentibus.* *Hort. Cliff.* 304. Origany with oval obtuse leaves, and roundish, compact, hairy spikes; common, or sweet Marjoram.

8. *ORIGANUM foliis carnosis tomentosis.* *Lin. Sp. Plant.* 588. Origany with fleshy woolly leaves.

9. *ORIGANUM foliis ovatis acutè serratis, spicis congestis umbellatim fastigiatis.* *Hort. Cliff.* 304. Origany with oval leaves acutely sawed, and spikes of flowers disposed in umbellated bunches.

10. *ORIGANUM foliis omnibus tomentosis, spicis nutantibus.* Origany with all the leaves woolly, and nodding spikes of flowers; or Dittany of *Crete*.

11. *ORIGANUM foliis omnibus glabris, spicis nutantibus.* *Hort. Cliff.* 304. Origany with all the leaves smooth, and nodding spikes of flowers; Dittany of mount *Sipylyus*.

12. *ORIGANUM foliis inferioribus tomentosis, spicis nutantibus.* *Hort. Cliff.* 304. Origany with the under leaves hoary, and nodding spikes of flowers.

13. *ORIGANUM spicis oblongis aggregatis hirsutis, foliis cordatis tomentosis.* *Lin. Sp. Plant.* 590. Origany with oblong hairy spikes growing in bunches, and heart-shaped woolly leaves.

The first grows naturally in thickets, and among bushes in several parts of *England*; the root is perennial, composed of many small ligneous fibres. The stalks are square, and rise near two feet high; they are ligneous, and garnished with oval leaves placed by pairs at each joint; from the wings of these come out three or four smaller leaves on each side, which resemble those of Marjoram, sitting close to the stalk; they have an aromattick scent; the flowers are produced in roundish spikes growing in panicles at the top of the stalks, many of the spikes being gathered together; they are of a flesh colour, and peep out of their scaly covering. Their upper lip is cut into two, standing erect, and the lower lip or beard is divided into three; the stamina stand out a little beyond the petals, and are of a purplish colour. It flowers in *June* and *July*, and the seeds ripen in the autumn. This sort is sometimes cultivated in gardens, and is by some called Pot Marjoram, as it is generally used in soups.

It will rise plentifully from scattered seeds, or it may be propagated by parting of the roots; the best time for doing this is in autumn, and may be planted in any soil not overmoist, and will thrive in any situation, so require no other care, but to keep it clear from weeds. There is a variety of this with white flowers and light green stalks, and another with variegated leaves.

The second sort is now commonly known by the title of winter sweet Marjoram, though this was formerly stiled Pot Marjoram. This hath a perennial root, from which arise many branching four-cornered stalks a foot and a half high, inclining to a purplish colour, garnished with oval, obtuse, hairy leaves, resembling greatly those of sweet Marjoram, standing opposite; the flowers are disposed in spikes about two inches long, several arising together from the divisions of the stalk. They are small, white, and

peep out of their scaly covers; these appear in *July*, and the seeds ripen in autumn. It grows naturally in *Greece* and the warm parts of *Europe*, but is hardy enough to thrive in the open air in *England*, and is chiefly cultivated for nose-gays, as it comes sooner to flower than sweet Marjoram, so it is used for the same purposes, till the other comes to maturity. There is a variety of this with variegated leaves. This is generally propagated by parting of the roots in autumn, and should have a dry soil, where it will thrive, requiring no other culture than the first sort.

The third sort grows naturally in *France* and *Italy*; this hath a perennial root, from which arise several slender bending stalks near a foot high, garnished with oval smooth leaves, standing on pretty long foot-stalks. The flowers are produced in oblong spikes, which grow in clustered panicles; they are small, of a purplish colour, peeping out of their scaly covering. It flowers in *June*, and may be propagated by parting of the roots in the same way as the former.

The fourth sort grows plentifully about *Orleans*; this hath a perennial root, from which arise several four-cornered stalks about six inches high, which frequently bend to the ground, and put out roots; they are garnished with oblong hairy leaves, sitting close to the stalk. The flowers grow in oblong clustered spikes at the top of the stalks, having long coloured bractæ between each; the flowers are some whitish, others purple in the same spikes; they are small, and peep out of their scaly covers. This flowers in *June*, and may be propagated in the same way as the former.

The fifth sort grows naturally in the *Levant*; it is a perennial plant. The stalks rise near two feet high, and branch out their whole length; they are purple, garnished with oval rough leaves, somewhat like those of Self-heal, but smaller. The flowers grow in roundish clustered spikes, having short bractæ; they are purple, and appear in *June*, but are not succeeded by seeds here. It is propagated by parting of the heads in the same way as the former, and must have a dry soil.

The sixth sort is the Origany of *Crete*, which is directed to be used in medicine, but there has been great confusion among botanists in distinguishing the species. This rises with four-cornered stalks a foot high, garnished with thick, hoary, oval leaves, of a strong aromattick scent. The flowers grow in long, erect, bunched spikes at the top of the stalks, having membranous bractæ between, which are twice the length of the empalement; the flowers are small and white like those of the common Origany. It flowers in *July*, but seldom perfects seeds in *England*. It is propagated by parting of the roots as the former, but must have a dry soil and a warm situation, otherwise it will not live through the winter here.

The seventh sort is the common sweet Marjoram, which is so well known as to need no description. With us in *England* it is esteemed an annual plant, though the roots often live through the winter in mild seasons, or if they are sheltered in a green-house; but in warm countries, I believe, it is only biennial.

This is propagated by seeds, which are generally imported from the south of *France* or *Italy*, for they seldom ripen in *England*. These are sown on a warm border toward the end of *March*, and when the plants are come up about an inch high, they should be transplanted into beds of rich earth, at six inches distance every way, observing to water them duly till they have taken new root, after which they will require no other care, but to keep them clean from weeds. The plants will spread and cover the ground, in *July* they will begin to flower, at which time it is cut for use, and is then called knotted Marjoram, from the heads

of flowers being collected into roundish close heads like knots.

The eighth sort grows naturally in *Africa*; this is a perennial plant with a low shrubby stalk, seldom rising more than a foot and a half high, dividing into branches, which are garnished with roundish, thick, woolly leaves, hollowed like a ladle; they are like those of the common Marjoram, but are of a thicker substance and woolly, and have much the same scent. The flowers are produced in roundish spikes closely joined together at the top of the stalks, and, at the end of the small side branches, they are of a pale flesh colour, peeping out of their scaly coverings. This sort flowers in *July* and *August*, but does not ripen seeds in *England*.

It is propagated by slips or cuttings, which if planted in a border of good earth during any of the summer months, and shaded from the sun and duly watered, will take root freely, and afterward the plants may be taken up, and planted in small pots filled with light kitchen-garden earth, and placed in the shade till they have taken new root; then they may be removed into an open situation, where they may remain till the end of *October*, when they must be placed under shelter, for they will not live through the winter in the open air here; but if they are put under a hot-bed frame, where they may be protected from hard frost, and have as much free air as possible in mild weather, they will thrive better than if they are more tenderly treated.

The tenth sort is the Dittany of *Crete*, which is used in medicine; this grows naturally upon mount *Ida*, in *Candia*; it is a perennial plant. The stalks are hairy, and rise about nine inches high, of a purplish colour, and send out small branches from their sides by pairs opposite; they are garnished with round, thick, woolly leaves, which are very white; the whole plant has a piercing aromatick scent, and biting taste; the flowers are collected in loose leafy heads of a purple colour, which nod downward. They are small, and of a purple colour; the stamina stands out beyond the petal, two of them being much longer than the other. It flowers in *June* and *July*, and in warm seasons the seeds ripen in autumn.

This is propagated easily by planting cuttings or slips, during any of the summer months. These should be planted either in pots or a shady border, covering them close with a bell or hand-glass to exclude the air, and now and then refreshing them with water, but they must not have too much wet. When these have taken root, they should be carefully taken up, and each planted into a separate small pot, filled with light earth, and placed in the shade till they have taken new root, when they should be removed into an open situation, where they may continue till autumn, and then placed under a hot-bed frame, to screen them from the frost, but they should enjoy the free air at all times in mild weather. The following spring some of the plants may be shaken out of the pots, and planted in a warm border near a good aspect wall, and in a dry soil, where the plants will live through the common winters without any other shelter; but as they are liable to be killed by severe frost, so it will be proper to keep a few plants in pots, to be sheltered in winter to preserve the kind.

The eleventh sort grows naturally on mount *Sipylos* near *Magnesia*, where it was discovered by Sir *George Wheeler*, who sent the seeds to the *Oxford* garden, where the plants were raised: this hath a perennial root, but an annual stalk. The root is composed of many slender ligneous fibres; the leaves are oval, smooth, and of a grayish colour; the stalks are slender, of a purplish colour, four-cornered and smooth; they rise near two feet high, sending out slender branches on each side opposite, which are terminated by slender oblong

spikes of purplish flowers, which peep out of their scaly covers; the flowers are small, but shaped like those of the tenth sort; their stamina are extended out of the petal a considerable length. The leaves on the lower part of the stalk, are almost as large as the common *Origany*, but those on the upper part of the stalk and branches are very small, and sit close to the stalk. It flowers in *June* and *July*, and in warm seasons the seeds ripen here in autumn. It is propagated by cuttings or slips, in the same way as the *Cretan* Dittany, and the plants require the same treatment.

The twelfth sort is undoubtedly a variety, which has been produced from the intermixing of the farina of the *Cretan* Dittany with that of mount *Sipylos*; for the plants now in the *Chelsea* garden, were accidentally produced from the seeds of one species, where both sorts stood near each other, in the garden of *John Browning*, Esq; of *Lincoln's-Inn*; the seeds were dropped from the plant into the border between the two sorts, so that it is uncertain from which species; but as the stalks and heads of flowers bear a greater resemblance to the Dittany of mount *Sipylos*, we may suppose it arose from the seeds of that, which had been impregnated by the farina of the *Cretan* Dittany, which grew near it; for the under leaves of this are round, of a thick texture and woolly, so nearly resembling those of the *Cretan* Dittany, as not to be distinguished from it; but the stalks rise full as high as those of the Dittany of mount *Sipylos*, but branch out more their whole length, they are of a purple colour and hairy. The lower leaves on the stalks are much larger than those of mount *Sipylos*, and are a little hairy, approaching to those of the *Cretan* Dittany, but are not so thick or woolly; the upper leaves are smooth, and approach to those of the other sort, but are larger, as are also the spikes of flowers, and the scaly leaves which cover the flowers are larger and of a deeper purple colour.

I have also dried samples of another variety, which arose from seeds in the *Leyden* garden; the seeds were sent from *Paris*, by the title which *Tournefort* gave to that which he found in the *Levant*, which I have joined to the variety before-mentioned. The leaves of this are as large as those of the Dittany of *Crete*, but are not so thick or woolly; the stalks rise more like those of the Dittany of mount *Sipylos*, but branch out wider at the top; the flowers grow in closer clusters, and do not nod downward; they are small, and shaped like those of the former sort, flowering at the same time.

By the title which *Dr. Linnæus* has given to the *Cretan* Dittany, it may be supposed he has not seen the true sort, for his title better suits the variety to which I have applied it; for all the leaves of the true Dittany are very thick and woolly, even those which are situated immediately below the flowers, whereas the lower leaves only are so in his title.

The thirteenth sort grows at *Syracuse*; this hath perennial ligneous stalks, which rise a foot and a half high, dividing into many small branches, which are garnished with small heart-shaped leaves, a little larger than those of *Marjoram*, which are woolly. The flowers grow in oblong tufted spikes which are hairy, they are small, white, and peep out of their scaly covers; they appear in *July*, but seldom perfect seeds in *England*. This is propagated by cuttings or slips, in the same way as the tenth sort, and the plants require the same treatment.

The first and sixth sorts are used in medicine, but the first being a native of this country, is frequently substituted for the other, which is pretty rare in *England*, and is now seldom imported here. When the first sort is used, those plants which grow upon dry barren ground are to be preferred, as they are much stronger and have greater virtue, than those which grow on good land, or are cultivated in gardens.

The Dittany of *Crete* is also used in medicine, but the dried herb is generally imported into *England*, which, by being closely packed, and the voyage being long, it loses much of its virtue; so that if the plants of *English* growth were used, they would be found much better.

ORNITHOGALUM. *Tourn. Inst. R. H.* 378. tab. 203. Star of *Bethlehem*.

The Characters are,

The flower has no empalement. It is composed of six petals, whose under parts are erect, but spread open above. It hath six erect stamina, about half the length of the petals, crowned by single summits, with an angular germen, supporting an awl-shaped style, terminated by an obtuse stigma. The germen afterward turns to a roundish angular capsule with three cells, filled with roundish seeds.

The Species are,

1. ORNITHOGALUM *racemo longissimo, filamentis lanceolatis, pedunculis floriferis patentibus æqualibus, fructiferis scapo approximatis. Lin. Sp. Plant.* 307. Star-flower with a very long spike of flowers, spear-shaped filaments, and foot-stalks to the flowers equal and spreading, and those of the fruit approaching to the stalk; or Star-flower, with whitish green flowers.

2. ORNITHOGALUM *racemo conico, floribus numerosis ascendentibus. Prod. Leyd.* 32. Star-flower with a conical spike, having numerous flowers rising above each other.

3. ORNITHOGALUM *racemo longissimo, foliis lanceolato-oviformibus. Lin. Sp. Plant.* 307. Star-flower with the longest spike, and spear-shaped leaves.

4. ORNITHOGALUM *racemo longissimo, pedunculis alternis brevioribus, petalis exterioribus angustioribus.* Star-flower with a very long spike, the foot-stalks of the flowers alternately shorter, and the outer petals narrow.

5. ORNITHOGALUM *floribus secundis pendulis, nectario lamineo campaniformi. Lin. Sp. Plant.* 308. Star-flower with fruitful hanging flowers, and a bell-shaped nectarium.

6. ORNITHOGALUM *petalis alternis patentibus, interioribus erectis. Lin. Sp. Plant.* 308. Star-flower with spreading alternate petals, and the lower ones erect.

7. ORNITHOGALUM *scapo anguloso diphylo, pedunculis umbellatis simplicibus. Flor. Suec.* 270. Star-flower with an angular stalk having two leaves, and single umbellated foot-stalks; yellow Star-flower.

8. ORNITHOGALUM *scapo angulato diphylo, pedunculis umbellatis ramosis. Flor. Suec.* 271. Star-flower with an angular stalk bearing two leaves, and branching foot-stalks having umbels.

9. ORNITHOGALUM *floribus corymbosis, pedunculis scapo altioribus, filamentis emarginatis. Hort. Cliff.* 124. Star-flower with flowers growing in a corymbus, whose foot-stalks are taller than the stalk, and indented filaments.

10. ORNITHOGALUM *floribus corymbosis, pedunculis scapo humilioribus, filamentis emarginatis. Prod. Leyd.* 32. Star-flower with flowers growing in a corymbus, foot-stalks lower than the stalk, and indented filaments.

11. ORNITHOGALUM *racemo conico laxo, pedunculis longissimis, floribus erectis. Plat.* 192. Star-flower with a loose conical spike of flowers, very long foot-stalks, and flowers standing erect.

12. ORNITHOGALUM *foliis cordatis ovatis. Prod. Leyd.* 31. Star-flower with oval heart-shaped leaves.

13. ORNITHOGALUM *racemo longissimo, foliis teretibus fistulosis.* Star-flower with a very long spike, and taper fistular leaves.

The first sort grows naturally near *Bristol*, and also near *Chichester* in *Suffex*, and some other parts of *England*. This hath a pretty large bulbous root, from which come out several long keel-shaped leaves, which spread on the ground; between these comes out a single naked stalk about two feet

long, sustaining a long loose spike of flowers of a yellowish green colour, standing upon pretty long foot-stalks, which spread wide from the principal stalk; the petals of the flowers are narrow, making but little appearance. The flowers have an agreeable scent; they appear in *May*, and when the seed-vessels are formed, the foot-stalks which sustain them become erect, and approach near the stalk. The seeds ripen in *August*.

The second sort grows naturally upon the hills in *Portugal* and *Spain*, but has been long cultivated in the *English* gardens, by the title of *Star of Bethlehem*. This hath a very large, oval, bulbous root, from which arise several long keel-shaped leaves of a dark green colour, and in the middle comes out a naked stalk which rises near three feet high, terminated by a long conical spike of white flowers, standing upon pretty long foot-stalks, which rise one above another, inclining to an upright. These appear in *June*, and are succeeded by roundish seed-vessels, having three cells filled with roundish seeds, which ripen in *August*.

The third sort grows naturally in *Arabia*; this hath a very large bulbous root, from which come out several broad keel-shaped leaves; the stalk is thick and strong, rising between two and three feet high, bearing a long spike of large white flowers, standing upon long foot stalks. They are composed of six petals, which spread open in form of a star, and appear in *June*, but do not ripen their seeds in *England*.

The fourth sort grows naturally in the *Levant*. I had this brought me from the island of *Zant*, by *Mr. Moore*, who was consul there; this hath a pretty large bulbous root, from which arise five or six long narrow leaves. The stalk rises about a foot and a half high, and is terminated by a long loose spike of white flowers, composed of six petals; the inner ones are broad, and the outer which stand alternate, are narrow. It flowers in *June*, but does not perfect seeds here.

The fifth sort grows in great abundance naturally in the kingdom of *Naples*, and is now become almost as common in *England*, for the roots propagate so fast by offsets and seeds, as to become troublesome weeds in gardens; and in many places where the roots have been thrown out of gardens, they have grown upon dunghills and in waste places as plentifully as weeds. This hath a pretty large compressed bulbous root, from which come out many long, narrow keel-shaped leaves, of a dark green colour. The stalks are very thick and succulent, rising about a foot high, sustaining ten or twelve flowers in a loose spike, each hanging on a foot-stalk an inch long; they are composed of six petals, which are white within, but of a grayish green on their outside, having no scent; within the petals is situated the bell-shaped nectarium, composed of six leaves, out of which arise the six stamina, terminated by yellow summits. The flowers appear in *April*, and are succeeded by large, roundish, three-cornered capsules, which are filled with roundish seeds; as the capsules grow large, they are so heavy as to weigh the stalk to the ground.

The sixth sort grows naturally in *Africa*, as also in the island of *Zant*, from whence I received it; this hath a bulbous root, much smaller than either of the former. The leaves are long, narrow, keel-shaped, and flaccid. The stalks rise about a foot high; they are slender, and sustain six or seven flowers hanging on long slender foot-stalks, placed at a distance from each other; they are composed of six petals, of a yellowish green colour, the three inner standing erect, and the three outer spread open wide. This flowers in *July*, but does not produce seeds here.

The seventh sort grows naturally in *Yorkshire*, and some of the other northern counties in *England*; this hath a large bulbous root, from which come out four or five keel-shaped

leaves about six inches long, and in the middle arises an angular stalk having two narrow leaves, which grow about six inches high, sustaining at the top six or eight yellow flowers in form of an umbel, standing upon slender long foot-stalks. These appear in *April*, and are succeeded by triangular capsules having three cells, which are filled with roundish seeds.

The eighth sort hath small bulbous roots not larger than Peas, from which arise one or two narrow keel-shaped leaves about five inches long, of a grayish colour; the stalk is angular, and rises about four inches high, having two narrow keel-shaped leaves just below the flowers, which are disposed in an umbel upon branching foot-stalks; these are yellow within, but of a purplish green on their outside. They appear in *May*, and are succeeded by small triangular capsules, filled with reddish uneven seeds. It grows on the borders of cultivated fields in *France* and *Germany*.

The ninth sort grows naturally in most parts of *Europe*, and is supposed to do so in *England*, though it is seldom found here, unless in orchards or grounds, where the roots may have been planted, or thrown out of gardens with rubbish. This hath a bulb as large as a small Onion, to which adhere many small offsets; the leaves are long, narrow, and keel-shaped, spreading on the ground, and have a longitudinal white line through the hollow. The stalk rises about six inches high, sustaining an umbel of flowers which are white within, but have broad green stripes on the outside of the petals; these stand upon long foot-stalks, which rise above the principal stalk. It flowers in *April* and *May*, and is succeeded by roundish three-cornered capsules, filled with angular seeds, which ripen in *July*.

The tenth sort grows naturally in *Arabia*; this hath a large bulbous root, from which arise many long keel-shaped leaves, which embrace each other with their base; they are of a deep green, and stand erect. The flowers of this kind I have never yet seen, though I have tried many ways to procure them: the roots multiply exceedingly, and are never injured by frost, although the leaves are put out before winter. These roots are frequently brought over from *Italy* for sale, but I have not heard of any having flowered; and *Clusius* says, he never saw but one root flower, and that came from *Constantinople*.

The eleventh sort grows naturally at the *Cape of Good Hope*; this hath a round bulbous root, covered with a white skin, from which come out four or five keel-shaped leaves, embracing each other at their base; they are of a deep green, eight or nine inches long; in the middle of these arises the stalk, which is naked and about a foot high; just under the flowers come out two or three short leaves, which end in acute points. The flowers stand upon very long foot-stalks, they are formed in a conical spike, and are composed of six oval petals of a pure white; within these are situated six stamina, which are about half the length of the petals, terminated by roundish summits. The flowers are in beauty in *May*, and are succeeded by roundish three-cornered capsules with three cells, filled with roundish seeds, which some years ripen here in *July*.

The twelfth sort grows naturally at the *Cape of Good Hope*; this hath an irregular tuberous root, varying greatly in form and size, covered with a dark brown bark, from which arise several oval heart-shaped leaves, upon pretty long foot-stalks; they have several longitudinal veins, like Ribwort Plantain. The flower-stalks are slender, naked, and rise about a foot high, sustaining several small, greenish, white flowers, formed in a loose spike, standing upon long slender foot-stalks. They come out in *November*, making but little appearance, and are not succeeded by seeds in *England*.

The thirteenth sort grows naturally on the dry rocks at

the *Cape of Good Hope*; this hath a large, depressed, bulbous root, as big as a man's fist, covered with an uneven brown skin, putting out several taper hollow leaves, nine or ten inches long, between which comes forth a naked stalk near a foot high, terminated by a loose spike of yellow flowers, of an agreeable sweet scent. It flowers in *May*, but does not produce seeds in *England*.

The four sorts first mentioned, are cultivated for ornament in the *English* gardens. These are propagated by offsets, which their roots commonly produce in great plenty. The best time to transplant their roots is in *July* or *August*, when their leaves are decayed; for if they are removed late in autumn, their fibres will be shot out, when they will be very apt to suffer, if disturbed. They should have a light sandy soil, but it must not be over dunged. They may be intermixed with other bulbous-rooted flowers in the borders of the pleasure-garden, where they will afford an agreeable variety, and continue in flower a long time. Their roots need not be transplanted oftener than every other year, for if they are taken up every year, they will not increase so fast; but when they are suffered to remain too long unrecovered, they will have so many offsets about them as to weaken their blowing roots. These may also be propagated from seeds, which should be sown and managed as most other bulbous rooted flowers, and will produce their flowers in three or four years after sowing.

The fifth sort is scarce worthy of a place in gardens, but as it will thrive in any situation or under trees, so a few plants may be admitted for the sake of variety.

The sixth sort has not much beauty, therefore a few roots of it will be enough for variety, as also of the seventh and eighth sorts; the two last will thrive in shade, but the sixth should have an open situation.

The ninth and tenth sorts multiply so fast by offsets from the roots, as to become troublesome weeds in a garden; for every small root will grow, and in two years produce twenty or thirty more, so that unless the large roots are taken up every year, and divested of their offsets, the borders will be over-run with them.

The eleventh sort is too tender to thrive in the open air in *England*, so the roots of this should be planted in pots filled with light earth, and in the autumn placed under a hot-bed frame, where they may be screened from frost, and in mild weather enjoy the free air. The leaves of this appear in the autumn, and continue growing all the winter, so must not be exposed to frost; nor should be drawn up weak, for then the flowers will be few on a stalk, and not large. If the pots do now and then receive a gentle shower of rain in winter, it will be sufficient, for they should not have much wet during that season. Toward the beginning of *July* the leaves and stalks decay, and then the roots may be taken up, laying them in a dry cool place till the end of *August*, when they must be planted again.

The twelfth and thirteenth sorts, were formerly more common in the *English* gardens than at present. These kinds are more tender than either of the former, so should be planted in pots filled with fresh light earth; and in winter must be placed in an airy glass-case, amongst Sedums, Ficoideſes, and such other pretty hardy succulent plants, which require a large share of air in mild weather, and but little wet. In summer they may be removed out of the house, and placed in a warm sheltered situation, observing never to give these plants much water when they are not in a growing state, lest it rot their roots; but when they are growing freely, they must be frequently but gently refreshed with water. These roots should be transplanted every year; the best time to perform this work is soon after the flower-stems are decayed, when the roots will be in the most inactive state. When this is done, the offsets should be carefully

carefully taken off, and each transplanted into a separate small pot, filled with light fresh earth, and may be treated as the old roots.

The other species, which were included in this genus, are now removed to *Scilla*.

ORNITHOPUS. *Lin. Gen. Plant.* 790. Birds-foot.

The Characters are,

The empalement of the flower is permanent, of one leaf, tubulous, and indented in five equal segments at the brim. The flower is of the butterfly kind; the standard is heart-shaped and entire; the wings are oval, erect, and almost as large as the standard; the keel is small and compressed. It hath ten stamina, nine of which are joined, and one stands separate, terminated by single summits. The germen is narrow, supporting a bristly ascending style, terminated by a punctured stigma. The germen afterward becomes a taper incurved pod, having many joints connected together, but when ripe separate, each containing one oblong seed.

The Species are,

1. *ORNITHOPUS foliis pinnatis, leguminibus compressis subarcuatis.* Birds-foot with winged leaves, and compressed pods a little arched.

2. *ORNITHOPUS foliis pinnatis, leguminibus confertis pedunculatis.* Birds-foot with winged leaves, and pods growing in clusters upon foot-stalks.

3. *ORNITHOPUS foliis pinnatis, pinnis linearibus, leguminibus binis compressis arcuatis.* Birds-foot with linear winged leaves, and compressed arched pods growing in pairs.

4. *ORNITHOPUS foliis pinnatis, leguminibus compressis villosis recurvis.* Birds-foot with winged leaves, and compressed woolly pods, which are recurved.

5. *ORNITHOPUS foliis ternatis subsessilibus appendiculatis, impari maximo.* *Hort. Cliff.* 364. Birds-foot with trifoliate leaves sitting close to the stalk, having appendages, and the middle lobe very large.

The first sort grows naturally in the south of France, in Spain and Italy. It is an annual plant, having many trailing stalks a foot and a half long, from which come out a few side branches; these are garnished with long winged leaves, composed of about eighteen pair of small oval lobes, terminated by an odd one; these lobes stand sometimes opposite, and at others they are alternate and hairy. The flowers are produced in small clusters at the top of foot-stalks, which arise from the wings of the stalks, and are near three inches long, having a small winged leaf, part of which is below, and the other part above the flowers, so that they seem to come from the midrib of the leaf; the flowers are of a deep gold colour, shaped like a butterfly. These appear in July, and are succeeded by flat narrow pods about three inches long, which turn inward at the top like a bird's claw. These are jointed, and a little hairy, containing a single seed in each joint, which ripens in autumn, when the joints separate and fall asunder.

The second sort grows naturally on dry commons and heaths in most parts of England. The root of this sort is composed of two or three strong fibres, to which hang several small tubercles or knobs like grains. There are many slender stalks come out from the root, which spread on the ground, and are from four to eight inches long; these are garnished with small, winged, hairy leaves, composed of six or seven pair of narrow lobes, terminated by an odd one. The flowers stand upon slender foot-stalks, which come out at every joint of the stalk; they are small, of a yellow colour, and are succeeded by clusters of short pods, which are a little incurved at the top. It flowers and feeds about the same time as the former.

The third sort grows plentifully about Messina and Naples. The root of this sort runs deep into the ground, sending out a few small fibres on the side; the stalks are about six inches long, and do not lie flat on the ground like the other; the

leaves are hairy, and are composed of ten or twelve pair of narrow lobes placed along the midrib, terminated by an odd one. The flowers grow in small bunches on the top of the branches; they are yellow, and these are generally succeeded by two flat pods not much more than an inch long, turned inward like a bird's claw. This flowers and seeds about the same time with the former.

The fourth sort was sent me from the Pisa garden by Dr. Tilli, the professor of botany, who informed me he had received the seeds from Africa. This approaches near to the first sort, but the stalks are much longer and smooth; the leaves are not so long; the lobes are larger, and not more than five pair to each leaf; the pods are longer and broader, and but little arched at the point. This is annual, and flowers at the same time with the former.

The fifth sort grows naturally among the Corn in Spain and Italy. This hath many smooth branching stalks, which rise near two feet high, garnished toward their top with trifoliate oval leaves sitting close, having two small appendages. The lower leaves are often single, and of a grayish colour, the middle lobe being twice the size of the two side ones. The flowers stand upon slender foot-stalks, are yellow, and succeeded by taper pods, which are two inches long, shaped like a bird's claw. This flowers and seeds about the same time with the former.

These plants are propagated by sowing their seeds in the spring upon a bed of light fresh earth, where they are to remain (for they seldom do well when they are transplanted); and, when the plants come up, they must be carefully cleared from weeds, and where they are too close, some of the plants should be pulled out, so as to leave the remaining ones about ten inches asunder. In June these plants will flower, and the seeds will ripen in August. There is no great beauty in these plants, but, for the variety of their jointed pods, they are preserved by some curious persons in their pleasure-gardens; where, if their seeds are sown in patches in the borders, each sort distinctly by itself, and the plants thinned, leaving only two at each patch, they will require no farther care, and will add to the variety, especially where the snail and caterpillar plants are preserved, which are very proper to intermix with them. They are all annual plants, which perish soon after the seeds are ripe.

OROBUS. *Tourn. Inst. R. H.* 393. tab. 214. Bitter Vetch.

The Characters are,

The empalement of the flower is tubulous, of one leaf; the brim is oblique and indented in five parts. The flower is of the butterfly kind; the standard is heart-shaped; the two wings are almost as long as the standard, and join together; the keel is bifid, acute-pointed, rising upwards; the borders are compressed, and the body swollen. It hath ten stamina, nine are joined, and one separate. It hath a cylindrical compressed germen, supporting a crooked rising style, crowned by a narrow downy stigma. The germen afterward becomes a long taper pod, ending in an acute point, having one cell, containing several roundish seeds.

The Species are,

1. *OROBUS foliis pinnatis ovatis, stipulis semisagittatis integerrimis, caule simplici.* *Lin. Sp. Plant.* 728. Bitter Vetch with oval winged leaves, entire stipulæ, half arrow-pointed, and a single stalk.

2. *OROBUS foliis pinnatis lanceolatis, stipulis semisagittatis, caule simplici.* *Lin. Sp. Plant.* 728. Bitter Vetch with spear-shaped winged leaves, entire half arrow-pointed stipulæ, and a single stalk.

3. *OROBUS foliis pinnatis oblongo-ovatis obtusis, stipulis semisagittatis integerrimis, caule hirsuto.* Bitter Vetch with oblong, oval, obtuse, winged leaves, entire stipulæ half arrow-pointed, and a hairy stalk.

4. *OROBUS caule ramoso, foliis sexjugis ovato-oblongis.* Hort. Cliff. 366. Bitter Vetch with a branching stalk, and leaves composed of six pair of oblong oval lobes.

5. *OROBUS foliis pinnatis lineari-lanceolatis decurrentibus, stipulis semisagittatis, caule simplici.* Bitter Vetch with linear, spear-shaped, winged-leaves, running along the stalk, half arrow-shaped stipulæ, and a single stalk.

6. *OROBUS caule ramoso, foliis quadrijugatis lanceolatis nervosis.* Bitter Vetch with a branching stalk, and leaves composed of four pair of nervous spear-shaped lobes.

7. *OROBUS foliis conjugatis subsessilibus, stipulis dentatis.* Hort. Upsal. 220. Bitter Vetch with leaves placed by couples close to the stalks, and indented stipulæ.

8. *OROBUS foliis pinnatis ovato-oblongis, stipulis rotundato-lunatis dentatis, caule simplici.* Lin. Sp. Plant. 728. Bitter Vetch with oval, oblong, winged leaves, roundish, moon-shaped, indented stipulæ, and a single stalk.

9. *OROBUS foliis pinnatis ovatis acutis, quatuor-jugatis, caule simplici.* Tab. 193. fol. 2. Bitter Vetch with oval, acute-pointed, winged leaves, having four pair of lobes and a single stalk.

10. *OROBUS foliis pinnatis lineari-lanceolatis infernè tomentosiss, caule ramosissimo frutescente.* Bitter Vetch with linear, spear-shaped, winged leaves, which are woolly on their under side, and a very branching shrubby stalk.

11. *OROBUS foliis pinnatis oblongo-ovatis infernè sericeis, caule erecto tomentoso, floribus spicatis terminalibus.* Bitter Vetch with oblong, oval, winged leaves, which are silky on their under side, and have an upright woolly stalk, terminated by a spike of flowers.

12. *OROBUS foliis pinnatis, foliis exterioribus majoribus tomentosiss, caule procumbente.* Bitter Vetch with winged leaves, whole outer lobes are woolly, and the largest trailing stalk.

13. *OROBUS foliis pinnatis, foliis linearibus villosiss, caule procumbente floribus alaribus & terminalibus.* Bitter Vetch with winged leaves, having hairy linear lobes, a trailing stalk, and flowers growing on the sides at the ends of the branches.

The first sort grows naturally in the forests of *Germany* and *Switzerland*. The root of this is perennial, composed of many strong fibres; the stalks rise a foot high, and are garnished with winged leaves, composed of two pair of oval acute-pointed lobes, and at the base of the foot-stalk is situated a stipula, (or small leaf) shaped like the point of an arrow cut through the middle. This embraces the stalk. The flowers stand upon foot-stalks, which arise from the wings of the stalk; they are about three inches long, sustaining six or seven flowers ranged in a spike, which are of the butterfly kind. These are at first of a purple colour, but afterward change blue; they appear early in the spring, and are succeeded by slender taper pods an inch and a half long, having one cell, in which are lodged four or five oblong bitter seeds, which ripen in *June*. There is a variety with pale flowers, which is preserved in some gardens.

The second sort grows naturally in woods and shady places in most parts of *England*. This hath a perennial creeping root, from which arise angular stalks nine or ten inches long, garnished at each joint by one winged leaf, composed of four pair of smooth spear-shaped lobes, and at the base of each is situated a stipula like that of the first sort; from the wings of the stalks arise the foot-stalks of the flowers, which are about four inches long, each sustaining two or three purplish red flowers, which turn to a deep purple before they fade. These appear in *April*, and are succeeded by long taper pods, containing six or seven roundish seeds, which ripen the beginning of *June*.

The third sort grows naturally in *Cumberland* and *Wales*. The root is perennial and ligneous, from which arise several hairy stalks a foot and a half high, garnished at each

joint with one winged leaf, composed of ten or eleven pair of narrow lobes ranged close together along the midrib, at the base of which is situated an acute stipula embracing the stalk. The flowers are disposed in a close spike standing upon foot-stalks, which arise from the wings of the leaves; they are of a purple colour, and are succeeded by short flat pods, containing two or three seeds. It flowers the beginning of *June*, and the seeds ripen in *July*.

The fourth sort grows naturally on the mountains in *Germany* and *Switzerland*. This hath a strong, ligneous, perennial root, from which arise many branching stalks two feet high, garnished at each joint by one winged leaf; composed of five or six small, oblong, oval lobes, ranged along the midrib. The flowers stand upon very long foot-stalks, which arise from the wings of the stalk; these sustain at their top four, five, or six purple flowers, which appear in *May*, and are succeeded by compressed pods, containing four or five oblong seeds, which ripen the beginning of *July*. The stalks decay in autumn, and new ones arise in the spring.

The fifth sort grows naturally about *Bologna*, and in other parts of *Italy*; this hath a perennial root, composed of many thick fleshy tubers. The stalks are cornered, and rise a foot and a half high, garnished with winged leaves, composed of four pair of linear spear-shaped lobes placed along the midrib, which is bordered by the running of the lobes from one to another; at the base of each leaf is situated a stipula shaped like that of the first, and out of this arises the foot-stalk of the flower, sustaining seven or eight flowers ranged in a loose spike. They are variegated with purple, blue and red, appear in *May*, and are succeeded by pods, containing two or three seeds, which ripen in *July*.

The sixth sort grows naturally on the *Pyrenean* mountains. This hath a perennial root, from which arise several smooth branching stalks a foot and a half high, garnished with winged leaves, composed of four pair of spear-shaped lobes, which have three longitudinal veins; at the base of the leaves is situated a stipula, embracing the stalk in the same manner as the first. The flowers stand upon long foot-stalks, arising from the wings of the leaves; toward the upper part of the stalk they are ranged in a loose spike; are of a purple colour, appearing in *May*, and are succeeded by compressed pods about two inches long, containing three or four seeds, which ripen in *July*.

The seventh sort grows naturally in *Siberia*. This hath a perennial root, from which arise three or four branching stalks about a foot high. The leaves stand opposite along the stalks, to which they fit close, having an indented stipula at their base; they are smooth, stiff, and of a lucid green. The flowers grow in close spikes upon short foot-stalks, which rise from the wings of the leaves at the top of the stalks, where are generally three or four of these spikes standing together. The flowers are of a fine blue colour, so make a pretty appearance. These appear in *June*, and are succeeded by short flattish pods, containing two or three seeds in each, which ripen in *August*.

The eighth sort grows naturally in *Siberia*. This hath a perennial root, from which arise several herbaceous stalks a foot and a half high, garnished with winged leaves, composed of four or five pair of oval oblong lobes, having at their base a roundish moon-shaped stipula embracing the stalk. The flowers come out from the wings of the leaves upon short foot-stalks; they are large, and of a purple colour, appearing in *April*, and are succeeded by swelling pods, containing four or five seeds, which ripen in *June*.

The ninth sort grows naturally in *India*. This hath a perennial root, from which arise two or three single stalks about a foot high, garnished with winged leaves, composed of four pair of oval lobes, ending in acute points; they

are smooth, and of a pale green colour, placed pretty far distant on the midrib. The flowers come out upon slender foot-stalks, which arise from the wings of the leaves, four or five standing at the top; they are of a purple colour, and appear in *February*. These are succeeded by swelling pods, each containing three or four roundish seeds, which ripen in *May*.

The tenth sort grows naturally in *Jamaica*, from whence the late Dr. *Houfoun* sent the seeds. This rises with a very branching stalk about three feet high, which is ligneous; the branches are garnished with winged leaves, composed of five or six pair of narrow spear-shaped lobes, which are woolly on their under side. The flowers grow in loose spikes at the end of the branches, are of a pale purple colour, and are succeeded by smooth compressed pods, each containing five or six roundish seeds.

The eleventh sort was discovered by the late Dr. *Houfoun* at *La Vera Cruz*, from whence he sent the seeds to *England*. This rises with a shrubby stalk five or six feet high, dividing into many slender branches, which are covered with a brown woolly bark, garnished with soft, fatteny, winged leaves; those on the young branches are composed of four pair of oval obtuse lobes, of a brownish green colour, hairy on their upper side, but of a silvery silky hue on their under. The leaves on the upper branches are composed of seven or eight pair of oblong oval lobes, of the same colour and consistence as the lower. The flowers are produced in long erect spikes, at the end of the branches; they are of a deep purple colour, and are succeeded by long, woolly, compressed pods, each containing four or five seeds.

The twelfth sort was discovered by Dr. *Houfoun* at *La Vera Cruz*. This is a low plant, whose stalks bend to the ground, and are seldom more than six or eight inches long, from which come out a few short side branches; they are garnished with winged leaves, composed of four or five pair of small, oblong, oval, woolly lobes, terminated by an odd one, the upper lobes being much larger than the lower. The flowers come out in small bunches, standing upon short foot-stalks, which arise from the wings of the stalk; they are small, of a bright purple colour; these are succeeded by compressed pods, each having six or seven roundish compressed seeds.

The thirteenth sort was discovered at the same time, growing naturally in the same country as the former, by the same gentleman. This hath a pretty thick ligneous root, which sends out many slender stalks a foot and a half long, trailing upon the ground, garnished with winged leaves, composed of three or four pair of narrow hoary lobes, about half an inch long. The flowers come out from the side and at the end of the stalks, three or four standing upon a short foot-stalk; they are small, and of a scarlet colour, and are succeeded by short taper pods, each containing three or four small roundish seeds.

The nine sorts which are first mentioned have perennial roots, but annual stalks; several of these may be propagated by parting their roots; the best time for doing this is in the autumn, that the plants may be well established before the spring; for as several of them begin to put out their stalks very early in the spring, so if they are then disturbed, it will either prevent their flowering, or cause their flowers to be very weak. Most of these plants delight in a shady situation, and love a loamy soil.

They are also propagated by seeds, but these should be sown in the autumn, for if they are kept out of the ground till spring, some of the sorts will never grow, and those which do, seldom vegetate the same year; and the fourth sort I could never raise from seeds sown in the spring, though I have made the trial in different situations many times; but the seeds which have scattered in the summer, have

come up well the following spring, as have also those which were sown in *September*. When the plants come up, they must be kept clean from weeds, and where they are too close together they should be thinned, so as they may have room to grow till the autumn, when they should be transplanted into the places where they are designed to remain. If the roots are strong, they will flower very well the following spring, but those which are weak will not flower till the second year; therefore such may be planted in a shady border at four or five inches distance, where they may grow one year to get strength, and then may be removed to the places where they are to remain. The farther care of them is only to dig the ground between them in winter; and in summer to keep them clean from weeds.

The first, fourth, fifth, seventh, eighth, and ninth sorts, are ornamental plants; and as they are very hardy, requiring little culture, and will thrive in the shade, they deserve a place in every good garden.

The three last mentioned sorts being natives of warm countries, are tender, so must be preserved in stoves, otherwise they will not live in *England*. These are propagated by seeds, which should be sown early in the spring, in small pots filled with light rich earth, and plunged into a hot-bed of tanners bark, observing frequently to moisten the earth, otherwise the seeds will not grow. When the plants come up, they should be carefully taken out of the pots, and each transplanted into separate small pots filled with rich earth, and then plunged again into the tan-bed, observing to shade them until they have taken root; after which time they should have fresh air admitted to them every day in warm weather, and must be frequently watered. With this management the plants will make a great progress. When any of the plants are grown too tall to remain in the hot-bed, they should be taken out, and plunged into the bark-bed in the stove, where they may have room to grow, especially the tenth and eleventh sorts; but the other being of humbler growth, may be kept in the hot-bed until *Michaelmas*, when the nights begin to be cold; at which time they should be removed into the stove, and plunged into the bark-bed, where they must be treated as other tender exotic plants; by which method they may be preserved through the winter, and the following summer they will produce flowers. These plants are perennial, so that if they should not perfect their seeds, the plants may be maintained for several years.

ORYZA. *Tourn. Inst. R. H.* 513. tab. 296. Rice.

The Characters are,

The chaff is small, acute-pointed, having two valves nearly equal, inclosing a single flower. The petal has two valves, which are boat-shaped, ending in a beard or awn. It has a two-leaved nectarium, and six hairy stamina the length of the petal, terminated by summits, whose base are bifid, and a turbinate germen, supporting two reflexed hairy styles, crowned by feathered stigmas. The germen afterward becomes one large, oblong, compressed seed, having two channels on each side, sitting on the petal of the flower.

There is but one Species of this plant, viz.

ORYZA. *Matth.* 403. Rice.

This grain is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into *England* and other *European* countries every year, where it is in great esteem for puddings, &c. it being too tender to be produced in these northern countries, without the assistance of artificial heat; but from some seeds which were formerly sent to *South Carolina*, there have been great quantities produced; and it is found to succeed as well there as in its native country, which is a very great improvement to our *American* settlements.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up; so that whoever would cultivate it in *England* for curiosity, should sow the seeds upon a hot-bed; and when the plants are come up, they should be transplanted into pots filled with rich light earth, and placed into pans of water, which should be plunged into a hot bed; and as the water wastes, so it must, from time to time, be renewed again. In *July* these plants may be set abroad in a warm situation, still preserving the water in the pans, otherwise they will not thrive; and toward the later end of *August* they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable.

OSIER. See *Salix*.

OSMUNDA, the Osmond Royal, or flowering Fern.

This is one of the kinds of Fern which is distinguished from the other sorts, by its producing flowers on the top of the leaves, whereas the others, for the most part, produce them on the back of their leaves.

There is but one kind of this plant, which grows wild in *England*, but there are several sorts of them which grow in *America*; but as they are seldom kept in gardens, I shall not enumerate their species.

The common sort grows on bogs in several parts of *England*, therefore whoever hath an inclination to transplant it into gardens, should place it in a moist shady situation, otherwise it will not thrive.

OSTEOSPERMUM. *Lin. Gen. Plant.* 887. Hard-seeded Chrysanthemum.

The Characters are,

The flower hath an hemispherical empalement, and is composed of several hermaphrodite flowers in the disk, which are tubulous, cut at the brim into five parts. These are surrounded by several female flowers, which are radiated, each having a long narrow tongue, which is cut into three parts at the top. The hermaphrodite flowers have each five slender short stamina, terminated by cylindrical summits, with a small germen supporting a slender style, crowned by an obsolete stigma; these are barren. The female flowers have each a globular germen supporting a slender style, crowned by an indented stigma; the germen afterward becomes one single hard seed.

The Species are,

1. OSTEOSPERMUM *foliis oppositis palmatis*. *Hort. Cliff.* 424. Hard-seeded Chrysanthemum, with palmated leaves growing opposite.

2. OSTEOSPERMUM *foliis ovalibus obsolete serratis*. *Lin. Hort. Cliff.* 424. Hard-seeded Chrysanthemum, with oval leaves which are slightly sawed.

3. OSTEOSPERMUM *foliis lanceolatis acutè dentatis, caule fruticoso*. *Tab.* 194. *fig.* 1. Hard-seeded Chrysanthemum, with spear-shaped leaves which are acutely indented, and a shrubby stalk.

4. OSTEOSPERMUM *spinis ramosis*. *Lin. Hort. Cliff.* 424. Hard-seeded Chrysanthemum, with branching spines.

5. OSTEOSPERMUM *foliis lanceolatis imbricatis sessilibus*. *Flor. Leyd. Prod.* 179. Hard-seeded Chrysanthemum with spear-shaped leaves sitting close to the stalks, and lying over each other like the scales of a fish.

The first sort is a native of *America*, growing in *Virginia* and *New England*, in low moist ground. This sort dies to the root every autumn, and rises again the following spring; and when growing on a moist rich soil, the shoots will rise to the height of five or six feet, and are garnished with very large, angular, divided leaves, placed opposite, which are shaped somewhat like those of the Plane-tree. The flowers are produced at the extremity of the shoots, which are shaped like those of the Sun-flower, but small, so do not make much appearance. This sort never produces any seeds in *England*, so can only be propagated by

parting of the roots, but this should not be done oftener than every third or fourth year. The best season for this, and for transplanting of the roots is in *October*, soon after the shoots decay. These roots should be planted in light rich earth, and should have a moist situation, where they will thrive extremely well; but in dry ground, if they are not duly watered in dry weather, they will make no progress, and frequently decay in hot weather. It will endure the winter's cold very well in the open air.

If the seeds of this plant are procured from *America*, they should be sown on a bed of rich earth, and in dry weather they should be watered. These seeds generally remain in the ground a whole year, before the plants appear. When the plants come up, they should be treated in the same manner as hath been directed for the old plants.

The second sort grows naturally at the *Cape of Good Hope*, but has been several years an inhabitant in the *English* gardens. This rises with a shrubby stalk seven or eight feet high, covered with a smooth gray bark, and divides into several branches, which are garnished with oval leaves, which are unequally indented on their edges; they are placed alternately, and are of a thick consistence, covered with a hoary down, which goes off from the older leaves. The flowers are produced in clusters at the end of the branches, six or eight coming out together; these are yellow, and shaped like those of Ragwort. The border or rays are composed of about ten half florets, which spread open; the disk or middle is composed of tubulous florets, which are cut into five parts at the brim; these are barren, but the half florets round the border have one hard seed, succeeding each of them. This plant flowers but seldom here; the time of its flowering is in *July* or *August*.

The third sort grows like the second, but the leaves are more pointed, of a green colour, and acutely sawed on the edges; the foot-stalks of the leaves are bordered, and the leaves are deeply veined. This produces tufts of yellow flowers at the extremity of the shoots from spring to autumn, and frequently ripens seeds.

The fourth sort is a low shrubby plant, which seldom rises above three feet high, and divides into many branches; the ends of the shoots are beset with green branching spines; the leaves are very clammy, especially in warm weather; these are long and narrow, and set on without any order. The flowers are produced singly at the ends of the shoots, which are yellow, and appear in *July* and *August*.

These three sorts are too tender to live in the open air in *England*, so are placed in the green-house in *October*, and may be treated in the same manner as Myrtles, and other hardy green-house plants, which require a large share of air in mild weather; and in the beginning of *May* the plants may be removed into the open air, and placed in a sheltered situation during the summer season. The second and third sorts must have plenty of water, being very thirsty plants, but the fourth sort must have it given but moderately, especially in winter.

These plants are propagated by cuttings, which may be planted in any of the summer months, upon a bed of light earth, and should be watered and shaded until they have taken root, which they will in five or six weeks, when they must be taken up, and planted in pots; for if they are suffered to stand long, they will make strong vigorous shoots, and will be difficult to transplant afterward, especially the second and third sorts; but there is not so much danger of the fourth, which is not so vigorous, nor so easy in taking root as the other. During the summer season the pots should be frequently removed, to prevent the plants from rooting through the holes in the bottom of the pots into the ground, which they are very apt to do when they continue long undisturbed, and then they shoot very luxuriantly; and,

and, on their being removed, these shoots, and sometimes the whole plants, will decay.

The fifth sort grows naturally at the *Cape of Good Hope*. This hath a shrubby stalk about four feet high, which divides into many small branches, garnished with small oblong leaves, which sit close to them, and in some of the upper branches they lie over each other like the scales of fish. The flowers come out at the end of the branches, standing singly upon foot-stalks, which are about an inch long; the half florets, which compose the border or rays, are acute-pointed and spread open; the disk is composed of florets, which are barren. This sort is propagated by cuttings, in the same manner as the other sorts, and must be treated in the same way.

OSYRIS. *Lin. Gen. Plant.* 978. Poets Casia.

The Characters are,

It is male and female in different plants; the empalement of the flower is of one leaf, which is divided into three acute segments. The flower hath no petals, but those on the male plants have three short stamina; the female have a germen, which afterward changes to a globular berry, having a single seed.

We have but one Species of this plant, viz.

OSYRIS frutescens baccifera. C. B. P. Shrubby Berry-bearing Poets Casia; and by some Red-berried shrubby Casia.

This is a very low shrub, seldom rising above two feet high, having ligneous branches, which are garnished with long narrow leaves, of a bright colour. The flowers appear in June, which are of a yellowish colour, and are succeeded by berries, which at first are green, and afterward turn to a bright red colour, somewhat like those of Asparagus.

This plant grows wild in the south of France, in Spain, and some parts of Italy, by the side of roads, as also between the rocks, but is with great difficulty transplanted into gardens, nor does it thrive after being removed; so that the only method to obtain this plant is, to sow the berries where they are to remain. These berries commonly remain a year in the ground before the plants appear, and sometimes they will lie two or three years, so that the ground should not be disturbed under three years, if the plants do not come up sooner. These seeds must be procured from the places where the plants naturally grow, for those which have been brought into gardens never produce any, and it is with great difficulty they are preserved alive.

OTHONNA. *Lin. Gen. Plant.* 888. Ragwort.

The Characters are,

It hath a radiated flower, composed of hermaphrodite florets, which form the disk, and female half florets, which form the rays or border; these are included in one common single empalement of one leaf. The hermaphrodite flowers are tubulous, indented at the top in five parts; the female half florets are stretched out like a tongue, and the point has three indentures, which are reflexed. The hermaphrodite florets have short hairy stamina, terminated by cylindrical summits, and an oblong germen supporting a slender style, crowned by a single stigma. The female half florets have oblong germen with a slender style, crowned by a large, bifid, reflexed stigma. The hermaphrodite florets are seldom fruitful, but the female half florets have an oblong seed, which is sometimes naked, and at others crowned with down; these sit in the permanent empalement.

The Species are,

1. OTHONNA foliis pinnatifidis tomentosis, laciniis sinuatis, caule fruticoso. *Hort. Upsal.* 273. Othonna with woolly wing-pointed leaves, sinuated jags, and a shrubby stalk; Sea Ragwort.

2. OTHONNA foliis oblongo-ovatis, pinnato-sinuatis, superne viridi-nigris, inferne tomentosis, caule fruticoso. Othonna with oblong, oval, wing, sinuated leaves, of a dark green on their upper side, woolly on their under, and a shrubby stalk broad-leaved Sea Ragwort,

3. OTHONNA foliis reniformibus suborbiculatis denticulatis petiolatis. *Lin. Sp. Plant.* 924. Othonna with kidney-shaped, orbicular, indented leaves, having foot-stalks.

4. OTHONNA foliis infimis lanceolatis integerrimis, superioribus sinuato-dentatis. *Hort. Cliff.* 419. Othonna with spear-shaped lower leaves, which are entire, and the upper ones indented in sinuses.

5. OTHONNA foliis lanceolatis integerrimis. *Hort. Cliff.* 419. Othonna with spear-shaped entire leaves.

6. OTHONNA foliis cuneiformibus integerrimis sessilibus, caule fruticoso procumbente, pedunculis longissimis. Othonna with entire wedge-shaped leaves sitting close, a shrubby trailing stalk, and very long foot-stalks to the flowers.

7. OTHONNA foliis pinnatifidis, laciniis linearibus parallelis. *Hort. Cliff.* 419. Othonna with wing-pointed leaves, whose segments are narrow and parallel.

8. OTHONNA foliis multifido-pinnatis linearibus. *Flor. Leyd. Prod.* 380. Othonna with very narrow leaves, ending in many winged points.

9. OTHONNA foliis ovato-cuneiformibus dentatis. *Lin. Sp. Plant.* 926. Othonna with oval, wedge-shaped, indented leaves.

10. OTHONNA foliis ovato-lanceolatis denticulatis subtus tomentosis, floribus corymbosis. Othonna with oval, spear-shaped, indented leaves, which are woolly on their under side, and flowers growing in a corymbus.

There are some other species of this genus, some of which grow naturally in England, and being troublesome weeds, are not admitted into gardens, so I have not enumerated them here.

The first sort is the common Sea Ragwort, which has been supposed to grow naturally near the sea in some parts of England; but I have never yet met with it wild in any part where I have been, nor have I heard that any other person has seen it growing naturally here. It grows in great plenty on the sea coast in France and Italy. This sends out many shrubby stalks, which rise from two to three feet high; they are hoary, and are garnished with woolly leaves six or eight inches long, jagged to the midrib in five or six parts; the jags are opposite, narrowest at their base, and at their points are divided into three or four obtuse segments; the stalks have a few leaves toward the bottom of the same shape, and are terminated with yellow flowers growing in a corymbus; these are succeeded by downy seeds, which ripen in the autumn.

The seeds of the second sort I received from the Mediterranean, where it grows naturally. This hath shrubby stalks, which rise three or four feet high, covered with a hoary down, and garnished with leaves from two to three inches long, and an inch and a half broad, standing on very long foot-stalks; they are regularly sinuated on their edges, in form of winged leaves; the under side of the leaves are hoary, but their upper side are of a blackish green colour. The flowers grow in small clusters at the end of the branches; they are of a deep yellow colour, and are succeeded by downy seeds like the first. This is a very different plant from the first, and always retains its difference from seeds. There are two varieties of the first sort, mentioned by Tournefort, which he found growing naturally in the Levant; but these I have frequently propagated by seeds, and have always found them vary; sometimes the leaves became green on both sides, and at others only on their upper side, so that these are not worthy of being noticed.

The third sort grows naturally at the *Cape of Good Hope*, from whence the seeds were brought to Holland in 1697, where the plants were raised, and have since been communicated to most of the curious gardens in Europe. This hath a root composed of many small fibres; the stalks are round, branching, and weak; they are herbaceous, hairy, and

and trail upon the ground, if they are not supported, dividing into a great number of branches, garnished with roundish indented leaves, not unlike those of Ground-ivy, hollowed at their base; the flowers are produced at the end of the stalks in loose umbels; they are radiated; the rays are yellow, like those of common Ragwort; the disk is composed of hermaphrodite flowers of a dark colour; the seeds have a down on their top.

The fourth sort grows naturally in *Æthiopia*. This rises with a shrubby stalk four or five feet high, dividing into several branches, which are garnished with grayish leaves placed without order; those on their lower part being narrow and entire, but the others are indented on the edges after the manner of Hartshorn. The flowers are produced in loose umbels at the end of the branches; they are yellow, and are succeeded by downy seeds.

The fifth sort grows naturally at the *Cape of Good Hope*. This rises with a round stalk, which at first is herbaceous, but afterward becomes ligneous, dividing into many branches, which rise from three to four feet high, garnished with thick, succulent, grayish leaves, placed without order; these are narrow at their base, and broad toward their points, entire, and sit close to the branches. The flowers are produced on branching foot-stalks at the end of the larger branches, each flower standing upon a separate foot-stalk; they have broad yellow rays, with a large disk in the middle, and are succeeded by downy seeds.

The sixth sort was discovered by the late Dr. *Shaw*, growing naturally near *Tunis* in *Africa*, from whence he brought the seeds. This sends out many ligneous stalks from the root, which spread out on every side, declining toward the ground, and are garnished with grayish leaves, which are narrow at their base, enlarging upward, and are broad at their points, where they are rounded; these sit close to the stalks. The flowers are produced upon long, thick, succulent foot-stalks at the end of the branches; they are yellow; the rays are sharp-pointed, and not much longer than the empalement; the disk is large, and the florets are as long as the empalement; the seeds are crowned with a long down.

The seventh sort grows naturally at the *Cape of Good Hope*, from whence the seeds were brought to *Holland*, and the plants were raised in the *Amsterdam* garden in 1699. This rises with a shrubby stalk about the thickness of a man's finger two feet high, which divide into many branches; these are covered with a hoary down, and are garnished with hoary leaves about three inches long and one broad, cut into many narrow segments almost to the midrib; these segments are equal and parallel, and are indented at their ends into two or three points. The flowers are produced on long foot-stalks, which arise from the wings of the stalks; toward the end of the branches they have large yellow rays or borders, with a disk of florets, and are succeeded by oblong purple seeds crowned with down.

The eighth sort grows naturally on the hills near the *Cape of Good Hope*, and was raised from seed in the *Amsterdam* garden. This hath a low, shrubby, branching stalk; the leaves are thick, like those of Samphire, and are cut into many narrow segments. The flowers are produced on short foot-stalks at the end of the branches; they are yellow, and shaped like the other species of this genus, and are succeeded by brown seeds crowned with soft down.

The ninth sort grows naturally at the *Cape of Good Hope*. This hath a thick shrubby stalk, dividing into several branches, which rise five or six feet high; the leaves come out in clusters from one point, spread on every side; they are smooth, narrow at their base, enlarging gradually to their points, which are rounded; their edges are acutely indented like those of the Holly. From the center of the

leaves arise the foot-stalks of the flowers, which are five or six inches long, branching out into several smaller, each sustaining one yellow radiated flower, shaped like the former; these are succeeded by slender seeds crowned with down.

The tenth sort grows naturally in *Jamaica*, from whence the late Dr. *Houfoun* sent the seeds to *England*. This rises with a shrubby stalk seven or eight feet high, which is covered with a hoary down, and garnished with oval, spear-shaped, smooth leaves, of a dark green on their upper side, but very white and woolly on their under, standing alternately on short woolly foot-stalks. The upper part of the stalk is naked, and at the top divides into five or six foot-stalks, each sustaining a roundish bunch of yellow radiated flowers, which are succeeded by slender seeds crowned with down.

The first sort was formerly preserved in green-houses, and was supposed too tender to live abroad in the open air; but later experience has taught us that the cold will not destroy it, provided it is planted on a lean dry soil; but in rich moist ground the plants grow too vigorous in the summer, so their branches being replete with moisture, are sometimes killed in very severe winters. This is easily propagated by slips or cuttings during any of the summer months, which may be planted in a shady border, and now and then refreshed with water; in about six weeks or two months they will have good roots: then they may be transplanted to the places where they are to remain, shading them from the sun, and supplying them with water until they have taken new root; after which they will require no other care, but to keep them clean from weeds. This sort flowers most part of summer, but they have little beauty; however the plants are preserved more for the variety of their hoary divided leaves.

The second sort is not quite so hardy as the first; but if it is planted in a warm situation, and on a dry soil, it will live abroad through our ordinary winters very well, but in severe frosts they are sometimes killed. This may be propagated by slips or cuttings, in the same way as the first.

The third sort is too tender to live in the open air through the winter, but may be preserved, with a little protection, in hard frost, and requires as much free air as possible in mild weather; so if it is sheltered under a common frame in winter, it will thrive better than in a green-house. It is easily propagated by cuttings, in the same way as the first.

The third, fourth, fifth, seventh, eighth, and ninth sorts, are preserved in green-houses through the winter, but require no artificial warmth; if these are protected from the frost it is sufficient, and in mild weather they must have a large share of free air. In the summer they must be placed abroad in a sheltered situation, among other hardy exotick plants, where they will add to the variety, and flower great part of the summer. These may be all propagated by cuttings during any of the summer months, which may be planted upon an old hot-bed, and covered with glasses, shading them from the sun in the heat of the day. When these have taken root, they should be planted each into a separate pot, filled with soft loamy earth, placing them in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain till autumn, treating them in the same way as the old plants.

The sixth sort will live in the open air, if it is planted in a warm situation and a dry soil. Some of these plants have endured the open air for more than twenty years in the *Chelsea* garden, without protection. It is easily propagated by cuttings, in the same way as the former.

The tenth sort is too tender to live through the winter in *England* without artificial warmth, therefore the plants should be placed in a stove kept to a moderate temperature of warmth, for the plants are apt to draw up weak when they

are in too great heat; these require to be frequently refreshed with water in winter, but it must not be given them in too great quantity during that season. In the latter end of *June* the plants should be removed into the open air, placing them in a warm sheltered situation; and in warm dry weather they will require a greater quantity of water. This sort will grow by cuttings, which should be planted on a moderate hot-bed the beginning of *July*, and shaded till they have taken root; then they may be each planted in a separate small pot, filled with loamy earth, placing them under a frame till they have taken new root, after which they must be gradually inured to the open air, and treated as the old plants.

OXALIS. *Lin. Gen. Plant.* 515. Wood Sorrel.

The Characters are,

The empalement of the flower is permanent, and cut into five acute parts. The flower is of one petal, cut into five obtuse indented segments; it hath ten erect hairy stamina, and a germen with five angles, supporting five slender styles. The germen afterward becomes a five-cornered capsule with five cells, which open longitudinally at the angles, containing roundish seeds, which are thrown out with an elasticity on the touch when ripe.

The Species are,

1. OXALIS *scapo uniflora, foliis ternatis, radice squamoso-articulata.* *Hort. Cliff.* 175. Common Wood Sorrel with one flower on a foot-stalk, trifoliate leaves, and a scaly-jointed root.

2. OXALIS *caule ramoso diffuso, pedunculis umbelliferis.* *Hort. Cliff.* 175. Wood Sorrel with a branching diffused stalk, and umbellated foot-stalks.

3. OXALIS *caule ramoso erecto, pedunculis umbelliferis.* *Flor. Virg.* 161. Wood Sorrel with a branching upright stalk, and umbellated foot-stalks.

4. OXALIS *pedunculis unifloris, caule dichotomo.* *Lin. Sp. Plant.* 443. Wood Sorrel with one flower on a foot-stalk, and spreading stalks.

5. OXALIS *scapo uniflora, foliis ternatis, radice bulbosa.* *Hort. Cliff.* 175. Wood Sorrel with a foot-stalk supporting one flower, trifoliate leaves, and a bulbous root, with large purple flowers.

6. OXALIS *scapo umbellifero, foliis ternatis bipartitis.* *Lin. Sp. Plant.* 434. Wood Sorrel with an umbelliferous stalk, and trifoliate leaves divided in two parts.

7. OXALIS *caule erecto fruticoso, foliis ternatis, impari maximo.* Wood Sorrel with an upright shrubby stalk, and trifoliate leaves, the middle one being very large.

The first sort grows naturally in moist shady woods, and close to hedges in many parts of *England*, so is but seldom admitted into gardens; though whoever is fond of acid herbs in salads, can scarce find a more grateful acid in any other plant. The roots of this sort are composed of many scaly joints, which propagate in great plenty. The leaves arise immediately from the roots upon single long foot-stalks, are composed of three heart-shaped lobes, which meet in a center where they join the foot-stalk; they are of a pale green, and hairy; between these come out the flowers upon pretty long foot-stalks, each sustaining one large white flower of the open bell shape. They appear in *April* and *May*, and are succeeded by five-cornered oblong seed-vessels, having five cells inclosing small brownish seeds; when these are ripe, the seed-vessels burst open on the least touch, and cast out the seeds to a considerable distance. This is the sort which is directed for medicinal use in the dispensaries, but those people who supply the market with herbs, generally bring the third sort, which is now become common in the gardens; but this hath no acid, so is unfit for the purpose; but as it rises with an upright branching stalk, so it is soon gathered and tied up in bunches; whereas the leaves of the first grow singly from the root, and require more

time in gathering. There is a variety of the first sort with a purplish flower, which grows naturally in the north of *England*, but as it does not differ from it in any other respect, I have not enumerated it.

The second sort is an annual plant, which grows naturally in woods and shady places in *Italy* and *Sicily*. The root of this is long, slender, and fibrous; the stalks trail upon the ground, spreading out eight or nine inches wide on every side, dividing into small branches; the leaves stand upon pretty long foot-stalks, and are composed of three heart-shaped lobes, which have deeper indentures at their points, than those of the first sort. The flowers are yellow, growing in form of an umbel upon pretty long slender foot-stalks, arising from the side of the branches. These appear in *June* and *July*, and are succeeded by seed-vessels near an inch long, which open with an elasticity, and cast out the seeds.

The third sort grows naturally in *Virginia* and other parts of *North America*, from whence the seeds were formerly brought to *Europe*; but wherever this plant has been once introduced and suffered to ripen seeds, it has become a common weed. This is an annual plant, rising with a branching herbaceous stalk eight or nine inches high; the leaves stand upon very long foot-stalks, and are shaped like those of the second sort. The flowers are yellow, standing in a sort of umbel, upon long, slender, erect foot-stalks; the seed-vessels and seeds are like those of the second sort.

These three sorts require no particular culture; if the roots of the first sort are taken up and transplanted in a shady moist border, they will thrive and multiply exceedingly; and, if they are kept clean from weeds, will require no other care. If the seeds of the other two sorts are sown in an open border, the plants will rise freely, and require no care; for if they are permitted to scatter their seeds, there will be a plentiful supply of the plants.

The fourth sort hath a roundish bulbous root, from which come out slender stalks about six inches high, which divide into branches by pairs, and from the divisions come out the foot-stalks of the leaves; these are long, slender, and sustain a trifoliate leaf, composed of three small, roundish, heart-shaped lobes. The foot-stalks of the flowers are long, slender, and arise from the division of the stalks, each sustaining one purplish flower about the same size and shape as those of the first sort. This flowers in *May*, *June*, and *July*, and sometimes produces ripe seeds in *England*. It grows naturally at the *Cape of Good Hope*, so is too tender to live through the winter in the open air in *England*; but if it is sheltered from hard frost, under a common frame in winter, it will require no other protection. It propagates in plenty by offsets from the root, as also by bulbs, which come out from the side of the stalks.

The fifth sort grows naturally at the *Cape of Good Hope* in such plenty, that the earth which came from thence, in which some plants were brought to *England*, was full of it. This hath a roundish bulbous root, covered with a brown skin sending out strong fibres, which strike deep into the ground; the leaves are trifoliate, composed of three roundish, large, hairy lobes, which are but little indented at the top; these stand upon long slender foot-stalks, which arise from a thick short stalk, which adheres to the root. The foot-stalks of the flowers arise between the leaves, each supporting one large purple flower; these appear in *January* and *February*, but are rarely succeeded by seeds here, but the roots put out offsets in great plenty, whereby it is propagated. This will not thrive in winter in the open air here, so the roots should be planted in pots, which may be sheltered under a common frame in winter, where it may have as much free air as possible in mild weather, otherwise

the leaves will draw up weak; for the leaves of this plant come out in *October*, and continue growing till *May*, when they begin to wither and decay. The roots may be transplanted any time after the leaves decay, till they begin to push out again.

The sixth sort is a native of the same country as the fifth; the roots of this are bulbous; the leaves stand upon long slender foot-stalks, which arise from a head; they are composed of three lobes, which are for the most part divided into two parts almost to their base. The foot-stalks of the flowers are five or six inches long, sustaining several large yellow flowers ranged in form of an umbel. These appear in *March*, and are sometimes succeeded by seeds here. This requires the same treatment as the fifth.

The seventh sort was discovered by *Plumier* in some of the *French colonies in America*, and was since found growing plentifully at *La Vera Cruz* by the late *Dr. Houstoun*. It rises with a shrubby stalk a foot and half high, sending out several slender branches, which are garnished with trifoliate small leaves, composed of three oval lobes, the middle one being twice as large as the side ones. They are

placed opposite, and sometimes by threes round the stalk, standing upon short foot-stalks. The foot-stalks of the flowers arise from the wings of the stalks, which are near two inches long, each sustaining four or five yellow flowers, whose petals are not much longer than the empalement; each of these have a smaller foot-stalk which is crooked, so that the flowers hang downward.

This is much tenderer than either of the former, so requires to be placed in a stove kept to a moderate degree of warmth in winter. It is propagated by seeds, which must be sown in pots, and plunged into a moderate hot-bed, and when the plants come up, they should be each planted in a separate pot filled with light sandy earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root; after which they must be treated in the same manner as other tender plants from the same country.

OX-EYE. See *Buphthalmum*.

OXYACANTHA. See *Berberis*.

OXYS. See *Oxalis*

P.

P A D

PADUS. *Lin. Gen. Edit. prior.* 476. The Bird Cherry, or Cherry Laurel.

The Characters are,

The empalement of the flower is bell-shaped. The flower hath five large roundish petals, which spread open, and are inserted in the empalement. It hath from twenty to thirty awl-shaped stamina, which are inserted in the empalement, and a roundish germen supporting a slender style. The germen afterward becomes a roundish fruit, inclosing an oval-pointed nut having rough furrows.

The Species are,

1. PADUS glandulis duobus, basi foliorum subjectis. *Hort. Cliff.* 185. Bird Cherry with two glands at the base of the leaves.

2. PADUS foliis lanceolato-ovatis deciduus, petiolis biglandulosis. *Tab.* 196. fol. 2. Bird Cherry with spear-shaped, oval, deciduous leaves, whose foot stalks have two glands; commonly called by the gardeners *Cornish Cherry*.

3. PADUS foliis oblongo-ovatis serratis acuminatis deciduus, basi antice glandulosis. Bird Cherry with oblong, oval, sawed, acute-pointed, deciduous leaves, and glands on the fore part of the foot-stalk; *American Bird Cherry*.

4. PADUS foliis sempervirentibus lanceolato-ovatis. *Hort. Cliff.* 42. Bird Cherry with ever-green, spear-shaped, oval leaves; or common Laurel.

5. PADUS foliis oblongo-ovatis sempervirentibus eglandulosis. Bird Cherry with oblong, oval, ever-green leaves having glands; smaller *Portugal Laurel*, called *Asarero* by the *Portuguese*.

6. PADUS foliis lanceolatis acutè denticulatis sempervirentibus. Ever-green Bird Cherry with spear-shaped leaves, having small acute indentures; called in *America* *Bastard Mahogany*.

The first sort grows naturally in the hedges in *Yorkshire*,

P A D

and many of the northern counties in *England*, as also in some few places near *London*, but is propagated as a flowering shrub in the nursery-gardens for sale. This rises with several woody stalks to the height of ten or twelve feet. The branches, which grow wide and scattering, are covered with a purplish bark, and garnished with oval spear-shaped leaves placed alternate, and have two small protuberances or glands, at their base. The flowers are produced in long loose bunches from the side of the branches; they have five roundish petals, which are much smaller than those of the Cherry, and are inserted in the border of the empalement; and within these are a great number of stamina, which also are inserted in the empalement; they have a strong scent, which is very disagreeable to most persons. These flowers appear in *May*, and are succeeded by small roundish fruit, which are first green, afterward turn red, and when ripe, are black, inclosing a roundish furrowed stone or nut, which ripens in *August*.

The second sort grows naturally in *Armenia*, from whence I have received the seeds, but has been many years propagated in the nursery-gardens about *London*, where it is generally called *Cornish Cherry*. This sort has been often confounded with the first, many of the late writers in botany having supposed it was the same species; but I have raised both sorts from seeds, and have always found the young plants to retain their difference. This rises with a strait upright stem more than twenty feet high; the branches are shorter and broader than those of the other, and are not so rough; the flowers grow in closer shorter spikes, which stand more erect; the fruit is larger, and red when ripe. This flowers a little after the first sort.

The third sort grows naturally in *Virginia*, and other parts of *North America*. It rises with a thick stem from ten to thirty feet high, dividing into many branches, which have a dark

a dark purple bark, and are garnished with oval leaves, placed alternately on short foot-stalks, of a lucid green, and slightly sawed on their edges, continuing in verdure as late in the autumn as any of the deciduous trees. The flowers come out in bunches like those of the second sort, and are succeeded by larger fruit, which is black when ripe, and is soon devoured by the birds. The wood of this tree is beautifully veined with black and white, and will polish very smooth, so is frequently used for cabinet work; as is also the wood of the first sort, which is much used in *France*, where it is called, *Bois de Sainte-Lucie*.

The fourth sort is the common Laurel, which is now so well known as to need no description. This grows naturally about *Trebisond*, near the *Black Sea*, and was brought to *Europe* 1576, and is now become very common, especially in the warmer parts of *Europe*.

The fifth sort was brought to *England* from *Portugal*, but whether it is a native of that country, or was introduced there from some other, is hard to determine. The *Portuguese* call it *Asarero*, or *Azerero*. This was supposed to have been but a low ever-green shrub, but by experience we find, that when it is in a proper soil, it will grow to a large size. There are at present some of these trees whose trunks are more than a foot diameter, and ten or twelve feet high, which are not of many years standing, and are well furnished with branches, which when young have a reddish bark; the leaves are shorter than those of the common Laurel, approaching near to an oval form; they are of the same consistence, and of a lucid green, which mixing with the red branches, make a beautiful appearance. The flowers are produced in long loose spikes from the side of the branches; they are white, and shaped like those of the common Laurel, appearing in *June*, and are succeeded by oval berries smaller than those of the common Laurel; they are first green, afterward red, and when ripe are black, inclosing a stone like the *Cherry*.

The seeds of the sixth sort were sent from *Carolina*, by the title of Bastard Mahogany, from the colour of the wood, which is somewhat like Mahogany. This seems to be little more than a shrub, if we may judge from its growth here; the stalk does not rise in height, but sends out lateral branches, which spread on every side, covered with a brown bark, and garnished with spear-shaped leaves near two inches long, and three quarters of an inch broad, with small acute indentures on the edges; they stand alternately upon very short foot-stalks, and are of a lucid green, continuing their verdure all the year. This has not as yet flowered in *England*, so I can give no account of it; but by the seeds and description which I received of its flowers, it belongs to this genus.

This plant will live in the open air, if it is planted in a warm situation, and sheltered in severe frost, especially while the plants are young; but when they have acquired strength, there is no doubt of their thriving very well in the open ground. It may be propagated in the same manner as the *Portugal* Laurel from the berries, and if the branches are laid down they will take root.

The three first sorts are easily propagated, either by the seeds or layers; when they are propagated by the seeds they should be sown in autumn, for if they are kept out of the ground till spring, they seldom grow till the second year. They may be sown upon a bed or border of good ground, in the same way as *Cherry* stones, which are designed for stocks; and the young plants may be treated in the same manner, planting them out in a nursery, where they may stand two years to get strength, and then they may be transplanted to the places where they are to remain. They are usually intermixed with other flowering shrubs, in wilderness work, where they add to the variety.

If they are propagated by layers, the young shoots should be laid down in the autumn, which will have good roots by that time twelvemonth, when they may be separated from the old plants, and transplanted into a nursery for a year or two, to get strength, and may then be removed to the places where they are to grow.

The third sort will grow to be a very large tree, when it is planted in a moist soil, but in dry ground it rarely rises more than twenty feet high. There have been some plants of late years raised from seeds which came from *Carolina*, which have all the appearance of the third sort, but are of much humbler growth; whether this may proceed from their being brought from a warmer climate, so do not agree with the cold of our winters, or whether they are a different species from that I cannot yet determine, as they have not produced fruit here.

The Laurel may be easily propagated by planting of cuttings; the best time for doing this in *September*, as soon as the autumnal rains fall to moisten the ground; the cuttings must be the same year's shoots, and if they have a small part of the former year's wood to their bottom, they will more certainly succeed, and form better roots. These should be planted in a soft loamy soil about six inches deep, pressing the earth close to them. If they are properly planted, and the ground is good, there will be few of the cuttings fail; and if they are kept clean from weeds the following summer, they will make good shoots by the following autumn, when they may be transplanted into a nursery, where they may grow two years to get strength, and then should be removed to the places where they are to remain. These plants were formerly kept in pots and tubs, and preserved in green houses in winter; but afterward they were planted against warm walls, to preserve them, being frequently injured by severe frost. After this the plants were trained into pyramids and globes, and constantly kept sheered; by which the broad leaves were generally cut in the middle, which rendered the plants very unsightly. Of late years they have been more properly disposed in gardens, by planting them to border woods, and the sides of wilderness quarters, for which purpose we have but few plants so well adapted; for it will grow under the drip of trees, in shade or sun; and the branches will spread to the ground, so as to form a thicket; and the leaves being large, and having a fine glossy green colour, set off the woods and other plantations in winter, when the other trees have cast their leaves; and in summer they make a good contrast with the green of the other trees. These trees are sometimes injured in very severe winters, especially where they stand single, and are much exposed; but where they grow in thickets, and are screened by other trees, they are seldom much hurt; for in those places it is only the young tender shoots which are injured, and there will be new shoots produced immediately below these from the larger branches, to supply their place, so that in one year the damage will be repaired. But whenever such severe winters happen, these trees should not be cut or pruned till after the following *Midsummer*; by which time it will appear what branches are dead, which may then be cut away, to the places where the new shoots are produced; for by hastily cutting these trees in the spring, the drying winds have free ingress to the branches; whereby the shoots suffer as much, if not more, than they had done by the frost.

In warmer countries this tree will grow to a large size, so that in some parts of *Italy* there are large woods of them, but we cannot hope to have them grow to so large stems in *England*; for should these trees be pruned up, in order to form them into stems, the frost would then become much more hurtful to them, than in the manner they usually grow, with their branches to the ground: however, if these

trees are planted pretty close together in large thickets, and permitted to grow rude, they will defend each other from the frost, and they will grow to a considerable height: an instance of which is now in that noble plantation of ever-green trees, made by his Grace the Duke of Bedford, at *Wooburn-Abbey*; where there is a considerable hill, covered entirely with Laurels; and in the other parts of the same plantation, there are great numbers of these intermixed with the other ever-green trees, where they are already grown to a considerable size, and make a noble appearance.

The best season for transplanting the plants is in the autumn, as soon as the rain has prepared the ground for planting; for although they often grow when removed in the spring, yet those do not take so well, nor make so good progress, as those which are removed in the autumn, especially if the plants are taken from a light soil, which generally falls away from their roots; but if they are taken up with balls of earth to their roots, and removed but a small distance, there will be no danger of transplanting them in the spring, provided it is done before they begin to shoot; for as these plants will shoot very early in the spring, so if they are removed after they have shot, the shoots will decay, and many time the plants entirely fail.

There are some persons who, of late have banished these plants from their gardens, as supposing them possessed of a poisonous quality, because the distilled water has proved so in many instances; but however the distilled water may have been found destructive to animals, yet from numberless experiments, which hath been made both of the leaves and fruit, it hath not appeared that there is the least hurtful quality in either; so that the whole must be owing to the oil, which may be carried over in distillation.

The berries have been long used to put into brandy, to make a sort of ratafia, and the leaves have also been put into custards, to give them an agreeable flavour; and although these have been for many years much used, yet there have been no instance of their having done the least injury; and as to the berries, I have known them eaten in great quantities without prejudice.

There are some persons who have grafted the Laurel upon Cherry stocks, with design to enlarge the trees; but although they will take very well upon each other, yet they seldom make much progress, when either the Laurel is grafted on the Cherry, or the Cherry upon the Laurel; so that is only a matter of curiosity, attended with no real use: and I would recommend to persons who have this curiosity, to graft the Laurel upon the *Cornish* Cherry, rather than any other sort of stock, because the graft will unite better with this; and as it is a regular tree and grows large, so it will better answer the purpose of producing large trees.

The *Portugal* Laurel may be propagated in the same way as the common Laurel, either by cuttings, layers, or seeds. If the cuttings are planted at the same season, and in the same way as hath been directed for the common Laurel, they will take root very freely; or if the young branches are laid in the autumn, they will take root in one year, and may then be removed into a nursery, where they may grow a year or two to get strength, and then transplanted where they are to remain.

But although both these methods are very expeditious for the propagating these plants, yet I would recommend the raising them from the berries, especially where they are designed for tall standards; for the plants which are propagated by cuttings and layers, put out more lateral branches and become bushy, but are not so well inclined to grow upright, as those which come from seeds; and as there are

now many trees in the *English* gardens which produce plenty of berries every year, so if they are guarded from birds till they are ripe, there may be a supply of them sufficient to raise plants enough, without propagating them any other way. These berries must be sown in the autumn, and treated in the same way as the common Laurel.

This tree is much hardier than the common Laurel, for in the severe frost of the year 1740, when great numbers of Laurels were entirely killed, and most of them lost their young shoots, this remained unhurt in perfect verdure, which renders it more valuable; and as by the appearance of some trees now growing in the gardens, they seem as if they will grow to a large size, so it is likely to be one of the most ornamental ever-greens we have.

PÆONIA. *Tourn. Inst. R. H.* 275. tab. 146. The Peony.

The Characters are,

The flower has a permanent empalement, composed of five concave reflexed leaves. The flower hath five large, roundish, concave petals which spread open, and a great number of short-hairy stamina, with two, three, or four, oval, erect, hairy germen in the center, having no styles. The germen afterward become so many oval, oblong, reflexed, hairy capsules, having one cell, opening longitudinally, containing several oval, shining, coloured seeds, fixed to the furrow.

The Species are,

1. PÆONIA *foliis lobatis ex ovato-lanceolatis*. Haller. *Helv.* 311. Peony with lobated leaves which are oval, and spear shaped; or Male Peony.

2. PÆONIA *foliis difformiter lobatis*. Haller. *Helvet.* 311. Peony with difformed lobated leaves; common or Female Peony.

3. PÆONIA *foliis difformiter lobatis, lobis incisis, petalis florum rotundioribus*. Peony with difformed lobated leaves, which are cut, and rounder petals to the flower; Foreign Peony, with a deep red flower.

4. PÆONIA *foliis lobatis, lobis lanceolatis integerrimis*. Peony with lobated leaves, whose lobes are spear-shaped and entire.

5. PÆONIA *foliis difformiter lobatis pubescentibus*. Tab. 199. Peony with difformed lobated leaves, which are downy.

6. PÆONIA *foliis lobatis, lobis ovatis infernè incanis*. Peony with lobated leaves, whose lobes are oval and hoary on their under side; or *Portugal* Peony, with a single sweet flower.

The first sort here enumerated, is the common Male Peony, which grows naturally in the woods on the *Helvetian* mountains. The root of this is composed of several oblong knobs, shaped like the dugs of a cow, which hang by strings fastened to the main head; the stalks rise about two feet and a half high, which are garnished with leaves composed of several oval lobes, some of which are cut into two or three segments; they are of a lucid green on their upper side, but are hoary on their under. The stalks are terminated by large single flowers, composed by five or six large roundish red petals, inclosing a great number of stamina, terminated by oblong yellow summits. In the center is situated two, three, or sometimes five germen, which join together at their base; they are covered with a whitish hairy down; these afterward spread asunder, and open longitudinally, exposing the roundish seeds, which are first red, then purple, and when perfectly ripe turn black. The flowers appear in *May*, and the seeds ripen in the autumn.

There is one variety of this with pale, and another with white flowers, as also one whose leaves have larger lobes; but as these are generally supposed to be only seminal variations, so I have not enumerated them here.

The second sort is called the Female Peony; the roots of this are composed of several roundish thick knobs or tubers, which hang below each other, fastened with strings; the stalks are green, and rise about the same height as the former; these are garnished with leaves, composed of several unequal lobes, which are variously cut into many segments; they are of a paler green than those of the first, and are hairy on their under side; the flowers are smaller, and of a deeper purple colour. It flowers at the same time as the first.

There are several varieties of this sort with double flowers, which are cultivated in the *English* gardens; these differ in the size and colour of their flowers, but are supposed to have been accidentally obtained from seeds.

The third sort grows naturally in the *Levant*; the roots of this are composed of roundish knobs like those of the second sort, as are also the leaves, but are of a thicker substance; the stalks do not rise so high, the flowers have a greater number of petals. This flowers a little after the other. The large double purple Peony, I suspect is a variety of this sort.

The fourth sort hath roots like the second; the stalks are taller, and of a purplish colour; the leaves are much longer, the lobes are spear-shaped and entire; the flowers are large, and of a deep red colour. This flowers at the same time as the two first sorts.

The seeds of the fifth sort were brought from the *Levant*, and from them there were plants raised, which produced single, and others with double flowers, of the same shape, size, and colour. The roots of these are composed of oblong fleshy tubers or knobs; they are of a pale colour, and hang by strings like the other species. The stalks rise about two feet high, which are of a pale green, and are garnished with leaves composed of several lobes, which are irregular in shape and size, some of them having but six, and others have eight or ten spear-shaped lobes; these are some cut into two, some three segments, and others are entire; they are of a pale green, and are downy on their under side. The stalks are terminated by one flower of a bright red colour, a little less than that of the Female Peony, and has fewer petals; they have a great number of stamina, and sometimes two, at others three germen, like those of the Female Peony, but shorter and whiter. This flowers a little later than the common Peony.

The seeds of the sixth sort were sent to the *Chelsea* garden by Dr. de *Jussieu*, who brought them from *Portugal*, where the plants grow naturally. The root of this sort is not composed of roundish tubers or knobs, but hath two or three long, taper, forked fangs like fingers. The stalk rises little more than a foot high, and is garnished with leaves composed of three or four oval lobes, of a pale colour on their upper side, and hoary on their under; the stalk is terminated by a single flower, which is of a bright red colour, smaller than either of the former, and of an agreeable sweet scent. This flowers about the same time with the common sort.

The first of these sorts is chiefly propagated for the roots, which are used in medicine; for the flowers being single, do not afford near so much pleasure as those with double flowers, nor will they abide near so long in beauty.

All the sorts with double flowers are preserved in curious gardens for the beauty of their flowers, which, when intermixed with other large growing plants in the borders of large gardens, will add to the variety; and the flowers are very ornamental in basons or flower-pots, when placed in rooms.

They are all extremely hardy, and will grow in almost any soil or situation, which renders them more valuable; for they will thrive under the shade of trees, and in such places they will continue much longer in beauty.

They are propagated by parting their roots, which multiply very fast. The best season for transplanting them is toward the latter end of *August*, or the beginning of *September*; for if they are removed after their roots have shot out new fibres, they seldom flower strong the succeeding summer.

In parting of these roots you should always observe to preserve a bud upon the crown of each offset, otherwise they will come to nothing; nor should you divide the roots too small (especially if you have regard to their blowing the following year); for when their offsets are weak, they many times do not flower the succeeding summer, or at least produce but one flower upon each root: but where you would multiply them in quantities, you may divide them as small as you please, provided there be a bud to each offset; but then they should be planted in a nursery-bed for a season or two, to get strength, before they are placed in the flower-garden.

The single sorts may be propagated from seeds (which they generally produce in large quantities, where the flowers are permitted to remain); which should be sown soon after they are ripe upon a bed of light fresh earth, covering them over about half an inch thick with the same light earth. The spring following the plants will come up, when they should be carefully cleared from weeds, and in very dry weather refreshed with water, which will greatly forward their growth. In this bed they should remain two years before they are transplanted, observing in autumn, when the leaves are decayed, to spread some fresh rich earth over the beds about an inch thick, and constantly to keep them clear from weeds.

The *Portugal* Peony may also be propagated either by seeds, or parting of the roots, in the same manner as the other sorts, but should have a lighter soil and a warmer situation. The flowers of this kind are single, but smell very sweet, which renders it worthy of a place in every good garden.

PALIURUS. *Tourn. Inst. R. H.* 616. *tab.* 387. *Christ's Thorn.*

The Characters are,

The flower has no empalement. It hath five petals which are ranged circularly. It hath five stamina, which are inserted in the scales under the petals, terminated by small summits, and a roundish trisid germen, supporting three short styles, crowned by obtuse stigmas. The germen afterward becomes a buckler-shaped nut divided into three cells, each containing one seed.

We know but one Species of this genus, *viz.*

PALIURUS. *Dod. Pempt.* 848. *Christ's Thorn.*

This plant grows naturally in the hedges near *Palestine*; it rises with a pliant shrubby stalk to the height of eight or ten feet, sending out many weak slender branches, garnished with oval leaves placed alternately; they have three longitudinal veins, and are of a pale green. The flowers come out at the wings of the stalk in clusters, almost the length of the young branches; they are of a greenish-yellow colour, and appear in *June*, and are succeeded by broad, roundish, buckler-shaped seed-vessels, which have borders like the brims of a hat, the foot-stalks being fastened to the middle, and have three cells, each containing one seed.

This is by many persons supposed to be the plant from which the crown of thorns, which was put upon the head of our Saviour, was composed; the truth of which is supported by many travellers of credit, who affirm that this is one of the most common shrubs in the country of *Judæa*; and from the pliability of its branches, which may be easily wrought into any figure, it may afford a probability.

This shrub grows wild in most parts of the *Levant*, as also in *Italy*, *Spain*, *Portugal*, and the south of *France*, especially near *Montpelier*, from whence their seeds may be procured, for they do not ripen in *England*. These seeds should be sown as soon as possible, after they arrive, in a bed of light earth, and the plants will come up the following spring; but when the seeds are kept out of the ground till spring, they will not come up till the next year, and very often fail; therefore it is much the best way to sow them in autumn. These seedling plants may be transplanted the following season into a nursery to get strength, before they are planted out for good.

It may also be propagated by laying down its tender branches in the spring of the year, which, if carefully supplied with water in dry weather, will take root in a year's time, and may then be taken off from the old plant, and transplanted where they are to remain.

The best time for transplanting this plant is in autumn, soon after the leaves decay, or the beginning of *April*, just before it begins to shoot, observing to lay some mulch upon the ground about their roots to prevent them from drying, as also to refresh them now and then with a little water until they have taken fresh root; after which they will require but very little care. They are very hardy, and will grow to be ten or twelve feet high, if planted in a dry soil and a warm situation. There is little beauty in this plant, but it is kept in gardens as a curiosity.

PALMA. *Plum. Gen.* 1. The Palm-tree.

The Characters are,

It hath male and female flowers; in some species on the same plant, and in others on different plants; the empalement of the male flowers are divided into three parts. The flowers have three petals, and six stamina terminated by oblong summits, with an obsolete germen, supporting three short styles, crowned by acute stigmas; these are barren. The female flowers have a common sheath, but no empalement; they have six short petals, and an oval germen sitting upon an awl-shaped style, crowned by a trifid stigma. The germen afterward becomes a fruit of various forms and sizes in different species.

The Species are,

1. PALMA *frondibus pinnatis, foliolis angustioribus aculeis terminalibus*. Palm-tree with winged leaves, whose lobes are narrow, and terminated by spines; or Date-tree.

2. PALMA *frondibus pinnatis, foliolis replicatis, spadiceis alaribus, fructu maximo anguloso*. Palm-tree with winged leaves, whose lobes are folded back, foot-stalks proceeding from the sides of the branches, and a large angular fruit; commonly called Cocoa nut.

3. PALMA *frondibus pinnatis, ubique aculeatis, aculeis nigricantibus fructu majore*. Palm-tree with winged leaves, which are every where armed with black spines, bearing a larger fruit; commonly called great Macaw-tree.

4. PALMA *frondibus pinnatis, foliolis replicatis, ramis aculeatis, aculeis sepius geminatis nigricantibus*. Palm-tree with winged leaves, whose lobes are folded back, and prickly branches, whose thorns often come by pairs, and are black.

5. PALMA *frondibus pinnatis, caudice æquali, fructu minore*. Palm-tree with winged leaves, an equal trunk, and a smaller fruit; commonly called the Cabbage-tree.

6. PALMA *frondibus pinnatis, caudice tereti aculeato, fructu minore*. Palm-tree with winged leaves, a taper prickly stalk, and a smaller fruit; called Prickly Pole.

7. PALMA *frondibus pinnatis, foliolis linearibus planis, stipitibus spinosis*. Palm-tree with winged leaves, having narrow plain lobes, and prickly midribs; commonly called oily Palm-tree.

8. PALMA *frondibus pinnato-palmatis plicatis, caudice squamato*. Palm tree with hand-shaped winged leaves, which are plaited, and a scaly stalk; called Palmetto, or Thatch.

9. PALMA *frondibus pinnatis, foliolis linearibus lanceolatis, petiolis spinosis*. *Hort. Cliff.* 482. Palm-tree with winged leaves, whose lobes are linearly spear-shaped, and prickly foot-stalks.

10. PALMA *frondibus pinnatis, foliolis rigidis, alternis, aculeis terminalibus*. Palm-tree with winged branches, whose lobes are rigid, alternate, and terminated by prickles.

11. PALMA *frondibus pinnato-palmatis, foliolis replicatis, inferuè incanis*. Palm-tree with hand shaped winged leaves, whose lobes are folded backward, and are hoary on their under side.

12. PALMA *fructu clavato polyphyreno*. *Trew. Dec. tab.* 7. Palm tree with a club-shaped fruit containing many seeds.
